SEMI E1-0697
SPECIFICATION FOR 3 inch, 100 mm, 125 mm, AND 150 mm PLASTIC AND METAL WAFER CARRIERS

1 Scope

1.1 This specification covers the dimensional requirements for plastic and metal wafer carriers used for the processing and handling of 3 inch, 100 mm, 125 mm, and 150 mm diameter wafers. The specification has two classifications: General Usage and Auto Transport Usage. General Usage is a basic guideline that covers 3 inch, 100 mm, 125 mm, and 150 mm wafer sizes. Auto Transport Usage is intended to meet the in-use requirements for the interface of wafer carriers with automated wafer processing equipment. Auto Transport Usage covers the 125 mm and 150 mm sizes.

1.2 To meet these specifications, carriers must be manufactured within the dimensional limits and be dimensionally stable within the specification when used in accordance with manufacturers' recommendations.

NOTE: Recommended usage should be agreed to between user and supplier, since wafer carriers are manufactured from a number of different materials by several manufacturing methods.

2 Selected Definitions

For a pictorial explanation of most of the selected definitions, see Figure 1. Figure 1 symbols are defined in Table 1.

bar — (See "crossbar.")

bar end — The end surface of the carrier that has only one crossbar.

bar radius — The radius nearest the bar end of the carrier on the crossbar. (See Figure 1, D5b, Type II.)

bar web — The mass of material for structural support which may or may not be present on the crossbar. (See Figure 1, D5a, Type II.)

bar width — The distance or thickness of the bar when measured perpendicular to the top face. (See Figure 1, D5b.)

cassette — (See "wafer carrier.")

crossbar — The mass of material connecting the two sides of the carrier at the bar end of the carrier.

edge perimeter distance — The distance from the edge of the wafer to the top face of the carrier. (See Figure 1, D7.)

end wall — The wall of the carrier opposite the bar end of the carrier.

flange — Mass of material on the exterior and perpendicular to the side walls.

hole — The area for the pin on another carrier to enter for transferring wafers. (See Figure 1, C8.)

lot — (See "hole.")

parallelism tolerance — The minimum and maximum dimension allowance for the opposite pockets to vary in relation to their distance from the crossbar end of the carrier. (See Figure 1, D1.)

pin — The mass of material which enters the hole or slot of another carrier for transferring wafer. (See Figure 1, C7.)

pin and hole center distance from pocket centerline — The distance from centerline of either the pin or hole to the closest pocket centerline. (See Figure 1, C9.)

pocket — The area in which the wafer is located in the carrier.

pocket centerline — The imaginary line which bisects each pocket.

pocket depth — The distance from the pocket flat to its own pocket nose, not to the opposite pocket. (See Figure 1, C2.)

pocket flat — The width of the pocket along the vertical walls at its narrowest distance. (See Figure 1, C3.)

pocket nose — The top of the mass of material between adjacent pockets.

pocket nose radius — The radius on the pocket nose.

pocket size — The distance between opposite pocket flats. (See Figure 1, C4.)

pocket spacing — The distance between pocket centerlines. (See Figure 1, B2.)

pocket width — The width of the pocket at its widest distance. (See Figure 1, C1.)

top face — The plane or surface of the carrier from which side wafers enter into or out of the carrier.

track clearance — The unobstructed area between the two carrier sides on the bar end. (See Figure 1, D6; Figure 1a, D6a, D6b, D6c.)

wafer carrier — A device for the holding of wafers for various processing steps in semiconductor manufacturing.

wafer tilt — The possible unparallel position of the wafer in relation to the bar end of the carrier when the carrier is resting on the bar end. (Not shown in Figure 1.)

wafer transfer — The act of relocating wafers from one carrier into another. This can be accomplished by several methods.

Table 1 Symbols Outline General Usage

C3	Pocket flat
C4	Pocket size
C5	Center of pin to center of hole

Figure 1A Reference	*Description*
C6	Center pin to pin and hole to hole
C7	Diameter of pin (2×) times height of pin
C8	Diameter of hole
C9	Center of pin/hole to center of first pocket
	Machine Fit Specifications
D1a	From the outside plane of the bar end to the center line of the 1st pocket opening
D1b	Slot parallelism-coincident tolerance for center line of slots
D2a	From the center line of the 1st pocket to the closest point on the crossbar or web
D2b	From the center of the 25th pocket to the closest point on the endwall
D3a	The step from the bar end of the carrier to the crossbar (the tolerance indicates allowable bow)
D3b	The step from the bar end of the carrier to the crossbar (the tolerance indicates the allowable deviation measured at a maximum distance of 1/2" from the crossbar/sidewall junction)
D4a	From the bottom of the carrier to the center of the crossbar, measured at the bar end of the carrier
D4b	From the bottom of the carrier to the center of a nominal 125 mm wafer, measured with wafer in place and carrier sitting on bottom
D5a	Bar web width which is the mass of material which may be present on the crossbar and is measured perpendicular to the top surface
D5b	Bar width measured perpendicular to the top surface
D5c	From the bar end of the carrier to the surface of the bar web (the tolerance indicates allowable bow)
D6a	Track clearance which is the unobstructed area between the two carrier sides on the bar end and the distance between the two sides at the bottom of the carrier for the entire length of the carrier
D6b	On the bar end surface, the distance between the two struts perpendicular to the crossbar
D6c	On the bar end surface, the thickness of each of the two struts perpendicular to the crossbar
D6d	On the bar end surface, the length of each of the two struts perpendicular to and extending above the crossbar
D6e	On the bar end surface, the length of each of the two struts perpendicular to and extending below the crossbar
D6f	Radius allowed on the crossbar
D6g	The overall width at the bottom of the carrier measured within 3/8 inch from the bottom
Wafer Tilt	The allowable deviation of the wafer from a parallel position in relation to the plane of the bar end of the carrier, when said wafer properly positioned and carrier is resting on the bar end. Wafer is said to be properly positioned when it is fully inserted in pocket and is centered.
Wafer Center	The allowable deviation of the center point of the wafer from the center line to the carrier (see Section A.A. Figure 5) when carrier is resting on bottom and wafer is fully inserted.
	Detailed Dimensions
	Handling Slots
D7 Dimensions	The handle slots are located on the bar end and the opposite endwall of the carrier. There are two slots on each end. These slots are intended to be used as points for engaging the carrier and picking it up. Currently, these slots are used in both manual and automated systems. Dimensions D7a through D7d detail this feature.
	Pickup Flanges
D8 Dimensions	The pickup flanges are located on the endwall of the carrier only. They are not present on the bar end. There are two flanges on the endwall. These flanges are intended to be used for engaging the carrier and picking it up. Currently, these flanges are used in both manual and automated systems. Dimensions D8a through D8e detail this feature.
	Center Alignment Features
D9 Dimensions	This feature is located on the bottom sidewalls of the carrier. The center alignment feature is used to find the location of the first pocket. It is intended to be used while the carrier is resting on its bottom. This feature is used in conjunction with wafer transfer machines and pick and place equipment. Dimensions D9a through D9k detail this feature.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E1.4-0697
STANDARD FOR 125 mm PLASTIC AND METAL WAFER CARRIERS, AUTO TRANSPORT USAGE

This standard is intended to meet the in use requirements necessary for the interface of wafer carriers with automated wafer processing equipment. Specifications for carriers intended for general use are outlined in SEMI E1.3. The complete specification for this product includes all general requirements of SEMI E1.

SEMI E1.9-0701
MECHANICAL SPECIFICATION FOR CASSETTES USED TO TRANSPORT AND STORE 300 mm WAFERS

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on March 22 and April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001. Originally published in 1994; previously published June 1999.

1 Purpose

1.1 This standard specifies the cassettes used to transport and store 300 mm wafers in an IC manufacturing facility. This includes both manual and auto-transport use as well as high-speed extraction of the wafers in processing equipment.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Most of the requirements given in this specification are in the form of maximum or minimum dimensions wit very few required surfaces. Only the mechanical interfaces for cassettes are specified; no materials requirements or micro-contamination limits are given. However, this standard has been written so that both metal and injection-molded plastic cassettes can be manufactured in conformance with it.

2.2 The cassette has the following components and sub-components, and other features. A "†" symbol indicates components or features that include dimensions required for boxes with non-removable cassettes.

Key:

- • Required feature
- ◊ Optional feature

- • 1 top domain
- • 2 optical wafer sensing paths
  - ◊ 4 robotic handling flanges (optional)
  - ◊ 1 top cassette identification tag area (optional)
- • 2 or 4 side domains (2 in front and 2 in rear, if needed)
- • supports (for 13 or 25 wafers) with correct wafer pitch (10 mm) †
- • 1 optical cassette sensing hole on each front side domain
  - ◊ 1 side cassette identification tag area on front right side domain only (optional)
  - ◊ features that prevent wafer creep-out (optional)
  - ◊ 2 pentagonal side grip pits on each front side domain (optional)
- • 1 bottom domain
- • 2 optical wafer sensing paths
- • 5 carrier sensing pads †
- • 4 info pads †
- • 1 pod latch-pin hole
- • 2 conveyor rails
- • 2 fork-lift pick-up areas
- • 2 fork-lift pin holes
- • 3 features that mate with kinematic coupling pins and provide a 10 mm lead in †
  - ◊ 3 features that mate with kinematic coupling pins and provide a 15 mm lead in (optional)
  - ◊ 1 bottom cassette identification tag area (optional)
- • Other features
- • multiple horizontal wafer sensing paths
- • 2 end-effector exclusion zones †

3.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E19 — Standard Mechanical Interface (SMIF)

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

SEMI E57 — Provisional Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

4 Terminology

4.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

4.2 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.3 *carrier capacity* — the number of substrates that a carrier holds.

4.4 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

4.5 *cassette bottom domain* — volume (below *z*6 above the horizontal datum plane) that contains the bottom of the cassette.

4.6 *cassette sensing pads* — surfaces on the bottom of the cassette for triggering optical or mechanical sensors.

4.7 *cassette side domains* — volumes (from *z*6 above the horizontal datum plane to *z*15 above the top nominal wafer seating plane) that contain the mizo teeth or slots that support the wafer and the supporting columns on the sides and rear of the cassette.

4.8 *cassette top domain* — volume (higher than *z*15 above the top wafer) that contains the top of the cassette.

4.9 *conveyor rails* — parallel edges on the bottom of the cassette for supporting the cassette on roller conveyors.

4.10 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

4.11 *fork-lift slots* — rectangular holes (open to the front and rear) in the bottom of the cassette for picking up the cassette with a fork.

4.12 *front-opening unified pod (FOUP)* — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a FIMS port that complies with SEMI E62) (as defined in SEMI E47.1).

4.13 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

4.14 *nominal wafer center line* — the line that is defined by the intersection of the two vertical datum planes (facial and bilateral) and that passes through the nominal centers of the seated wafers (which must be horizontal when the carrier is placed on the coupling) (as defined in SEMI E57).

4.15 *nominal wafer seating plane* — horizontal plane that bisects the wafer pick-up volume.

4.16 *optical wafer sensing paths* — lines of sight for optically sensing the positions of the wafers. Several horizontal optical wafer sensing paths are present in between the cassette side domains. In addition, two vertical optical wafer sensing paths are created by rectangular exclusion zones in the front of the cassette top and bottom.

4.17 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

4.18 *process batch* — a set of substrates that are processed simultaneously in a process chamber.

4.19 *robotic handling flanges* — four horizontal projections on top of the cassette for lifting and rotating the cassette.

4.20 *sensor hole* — an indentation on the bottom of the cassette for inserting optical sensors.

4.21 *side grip pits* — two rectangular indentations on each side of the cassette for lifting and rotating the cassette.

4.22 *transport group* — a set of substrates that are transported together between tools.

4.23 *virtual tracking unit* — an entity (which could be a number of substrates or an individual die or mask group) that the factory floor control system treats as a single unit for tracking purposes.

4.24 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

4.25 *wafer extraction volume* — the open space for extracting a wafer from the cassette.

4.26 *wafer pick-up volume* — the space that contains entire bottom of a wafer if the wafer has been pushed to the rear of the cassette.

4.27 *wafer set-down volume* — the open space for inserting and setting down a wafer in the cassette.

5 Ordering Information

5.1 *Intended Use* — This standard is intended to specify 300 mm cassettes over a reasonable lifetime of use, not just those in new condition. For this reason, the purchaser needs to specify a time period and the number and type of uses to which the cassettes will be put. It is under these conditions that the cassettes must remain in compliance with the requirements listed in Section 6.

5.2 *Temperature Ranges* — The purchaser of 300 mm cassettes needs to specify two sets of temperatures to which the cassettes might be exposed. An operating temperature range is the set of environmental temperatures in which the cassettes will remain in compliance with the requirements listed in Section 6. A temporary temperature range is the set of environmental temperatures to which the cassettes can be exposed such that when the cassettes return to the operating temperature range, the cassettes will be in compliance with the requirements listed in Section 6. Limits on exposure times to elevated temperatures should be specified. Also, the purchaser needs to specify a range of temperatures for the wafers that might be inserted in the cassettes.

5.3 *Info Pad Configurations* — The purchaser of 300 mm carriers needs to specify the desired info pad configuration (up or down). See Appendix 1 (Application Notes).

6 Requirements

6.1 *Kinematic Couplings* — The physical alignment interface on the bottom of the cassette consists of features (not specified in this standard) that mate with six pins underneath as defined in SEMI E57. Most of the dimensions of the cassette are determined with respect to the three orthogonal datum planes defined in that standard: the horizontal datum plane, the facial datum plane, and the bilateral datum plane. All of the dimensions for the cassette are bilaterally symmetric about the bilateral datum plane. The three features that mate with the pins must provide a lead-in capability that corrects a cassette misalignment no greater than *r*19 in any horizontal direction. However, it is recommended that robots placing cassettes on kinematic couplings use as little of this lead-in capability as possible to avoid wear.

6.2 *Wafer Orientation and Numbering* — The wafers must be horizontal when the carrier is placed on the coupling, and the wafers are numbered in increasing order from bottom to top (so the bottom wafer is wafer number 1, the next wafer up is wafer number 2, etc.). After processing at a tool, each wafer should be returned to the same slot from which it was taken.

6.3 *Cassette Sides* — Figure 1 shows a cross-section of the horizontal boundaries of the cassette side domains (which contain the parts of the cassette higher than *z*6 above the horizontal datum plane and lower than *z*15 above the top wafer). In this and following figures, the most heavy lines are used for surfaces that have tolerances (not surfaces that have only maximum or minimum dimensions). Table 1 defines the dimensions shown in this and following figures. The maximum protrusions of any part of the cassette from the nominal wafer center line and from the bilateral datum plane is *r*5 and *x*9, respectively. There are two optional side grip pits on each side. For optically sensing whether a cassette is properly in place, from left to right under the bottom wafer is an optical cassette sensing hole. The radius of this hole is given with both upper and lower tolerances, but the upper tolerance is only to define a minimum aperture that must be met at only one section on each side. Other than through the optical cassette sensing holes, the cassette bottom and side domains must block any line of sight passing through both of the two rectangles at *x*10 on each side bounded by *z*4, *z*20, *y*2, and *y*3.

6.4 *Cassette Top* — Figure 2 shows a top view of the horizontal boundaries of the cassette top domain which contains any part of the cassette higher than *z*15 above the top nominal wafer plane. The top robotic handling flanges (optional), the side grip pits (optional), and optical cassette sensing hole on the side can be seen in Figure 3, which is an oblique view of the maximum cassette dimensions (see Figure 14 to see how cassettes need not take up all of that volume). The maximum radial protrusions of the cassette top in the front and rear are *r*6 and *r*12, respectively. Dimensions *x*6, *x*12 (shown in Figure 4), and *y*15 define a vertical path for optically sensing wafers through the top and bottom domains.

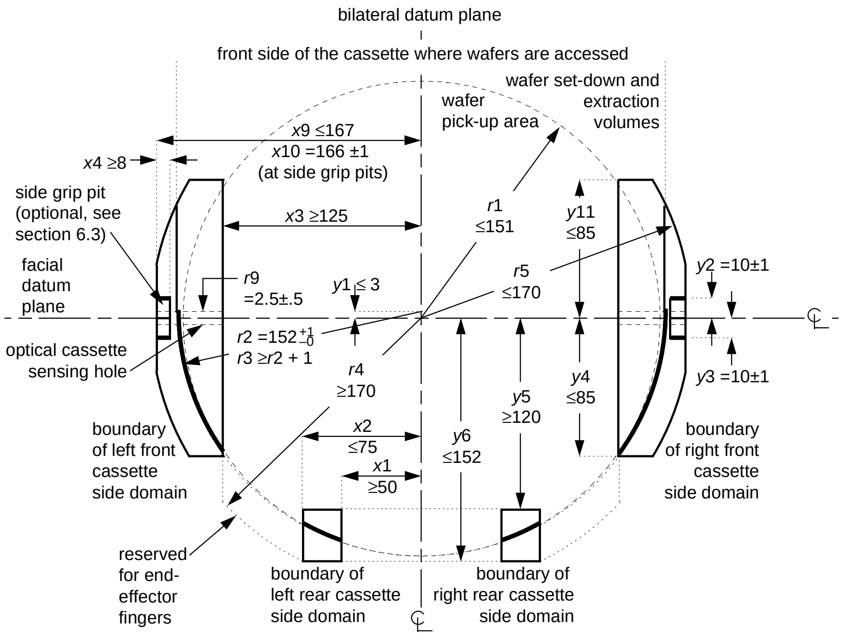

Figure 1
Cassette Side Domains

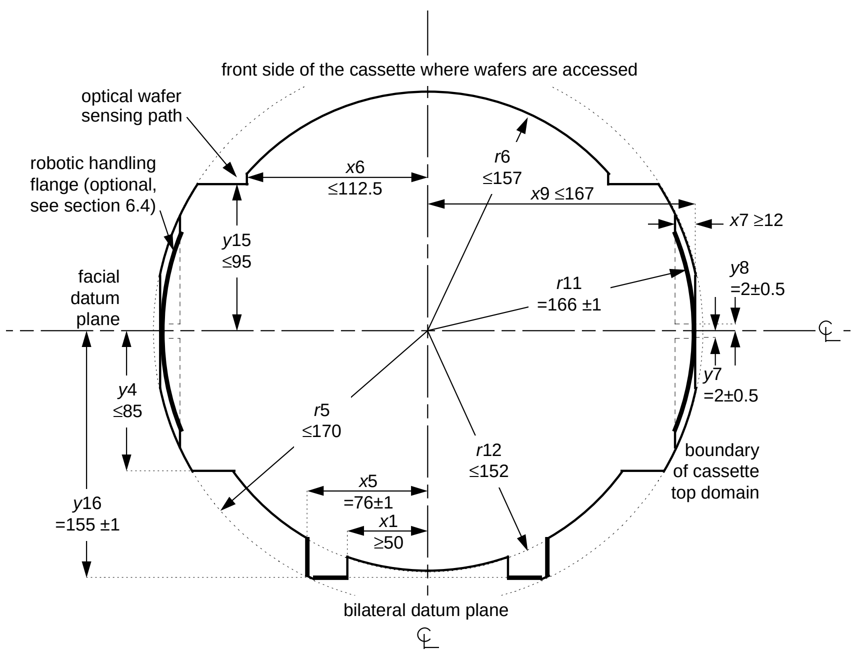

Figure 2
Cassette Top Domain

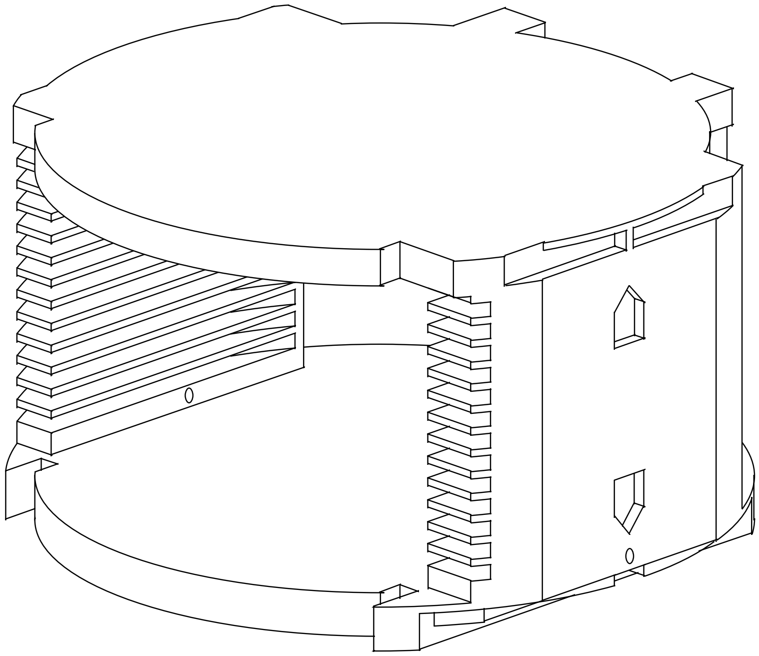

Figure 3
Oblique View of Maximum Cassette Dimensions

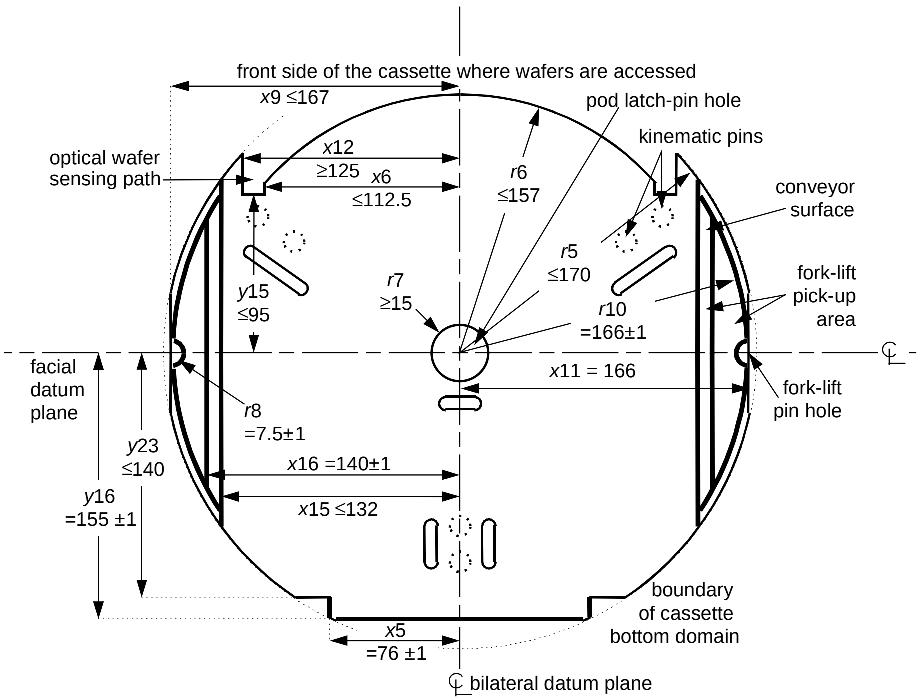

Figure 4
Cassette Bottom Domain

6.5 *Cassette Bottom* — Figure 4 shows a bottom view of the horizontal boundaries of the cassette bottom domain (which contains any part of the cassette lower than *z*6 above the horizontal datum plane). At the nominal wafer center line, a circular hole with a radius of *r*7 must be present (up to a height of *z*5) in the cassette bottom to avoid interfering with pod latch pins. For moving the cassette on roller conveyors and for picking up the cassette with a fork lift, the cassette must have surfaces on the left and right open to the bottom and outside bounded by *x*15, *x*16, *r*10, *z*3 and *z*4. A cylindrical section of radius *r*8 and axis at *x*11 on the facial datum plane must be clear up to a height of *z*22 to hold the cassette firmly on the lifting forks by the use of a cylindrical pin.

6.6 *Carrier Sensing Pads and Info Pads* — When the cassette is fully down, the carrier sensing pads (shown in Figure 5) must be *z*2 above the horizontal datum plane. It is recommended that the areas surrounding all of the carrier sensing pads be designed in conjunction with the features that mate with kinematic coupling pins so that a mechanical sensor pin cannot interfere with the lead-in function of the kinematic couplings. Other sensing pads (called info pads and given letter names) communicate information about the carrier. Carrier types that might need differentiation include the open cassette, the front-opening unified pod (FOUP), the single-wafer interface (SWIF), and the front-opening shipping box (FOSB) in both 13-wafer and 25-wafer capacities (and possibly other capacities if reduced-pitch versions are later standardized). Note that since this is a bottom view, the positions of sensors on a load port will be switched, with the sensor for info pad A on the right and the sensor for info pad B on the left as one faces the tool from the front.

6.7 *Vertical Dimensions* — Figures 6 through 13 show the vertical dimensions of the cassette. Note that *z*8 (the height of the bottom nominal wafer seating plane above the horizontal datum plane) and *z*12 (the distance between adjacent nominal wafer seating planes) are given as absolute distances with no tolerance. This means that the sum of actual height variations in the cassette from the kinematic coupling to the supporting features holding each wafer must be contained within the tolerance of *z*10 with no further stack-up at each higher wafer. The method for meeting this requirement is left up to the cassette supplier.

6.7.1 The open space for the wafer set-down volume consists of a cylindrical section with radius *r*2 and a main axis parallel to and *y*1 in front of the nominal wafer center line. The top of this cylindrical section is *z*11 above the nominal wafer seating plane and its bottom is *z*10 above the nominal wafer seating plane. The implications for wafer positioning of the tolerance on *r*2 are as follows. The wafers should be placed in the cassette within a circle of radius corresponding to the smaller bound on *r*2 to avoid touching the edge of the wafer to the side of the cassette. Once the wafer has been placed, the cassette must not allow a wafer to move outside of a circle of radius corresponding to the larger bound on *r*2. There are two exceptions to this limit on wafer movement. When the wafer is pushed toward the rear of the cassette, the location of the wafer is defined by the wafer pick-up volume (see Section 6.7.3). When the cassette is gently tilted forward up to 45°, the wafers may slide forward, but it is recommended that they not extend further than *y*20 from the facial datum plane. This may be accomplished by designing the teeth supporting the wafers to include a "wafer stopper" at the front (as shown in Figure 11) that is outside of *r*2 and under *z*29. Note that use of this feature will reduce the height of the wafer extraction volume.

6.7.2 The open space for the wafer extraction volume includes a cylindrical section with radius *r*3 and a main axis parallel to and *y*1 in front of the nominal wafer center line. The top of this cylindrical section is *z*11 above the nominal wafer seating plane and its bottom is *z*23 above the nominal wafer seating plane. The wafer extraction volume also includes the extrusion out the front of the cassette of this cylindrical section and the portion of the wafer set-down volume above *z*29. The implications for wafer extraction of the definition of dimension *r*3 ($r3 \geq r2 + 1$) are as follows. The cassette must give an extra 1 mm (0.04 in.) of horizontal clearance once the wafer is picked up from wherever it ends up (within the bounds of *r*2) after transport in the cassette.

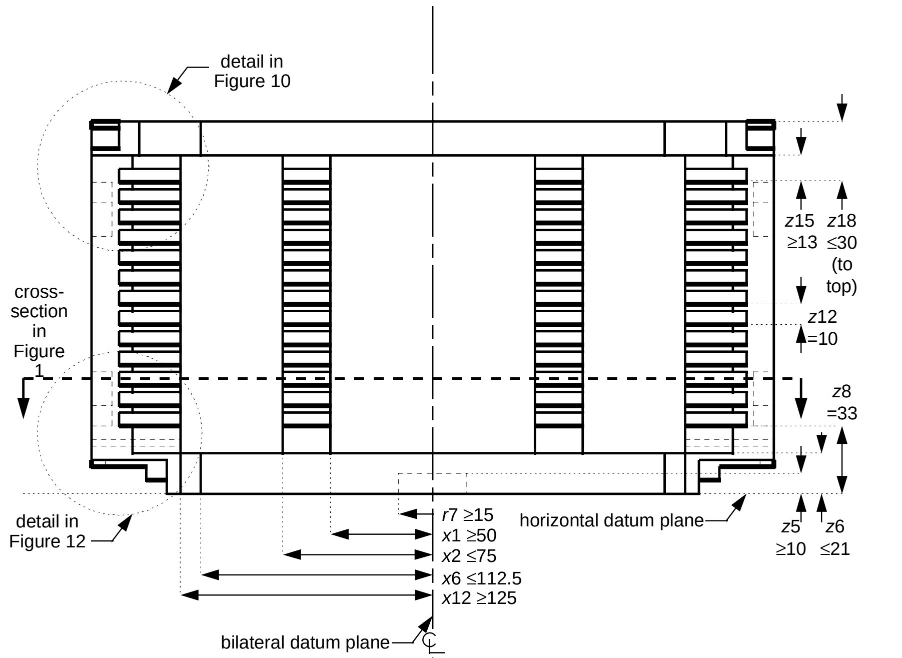

Figure 9
Front View of Cassette

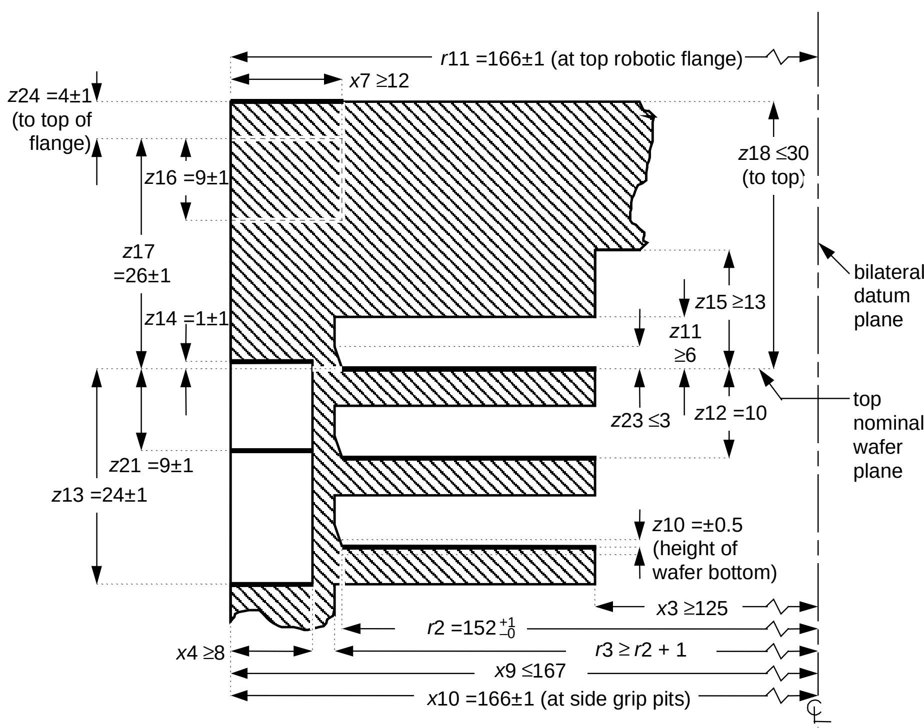

Figure 10
Upper Cross-Section at Facial Datum Plane

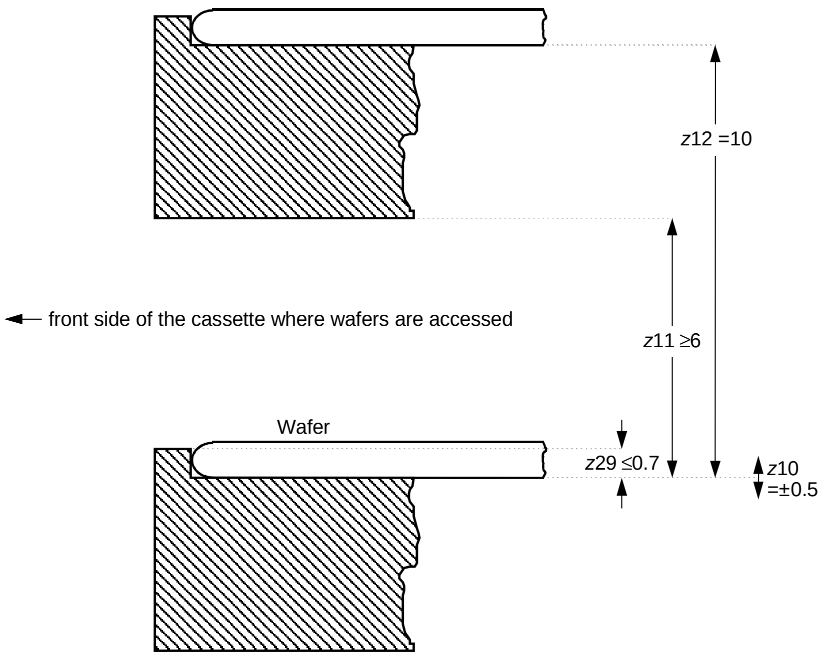

Figure 11
Optional Feature to Prevent Wafer Creep-Out

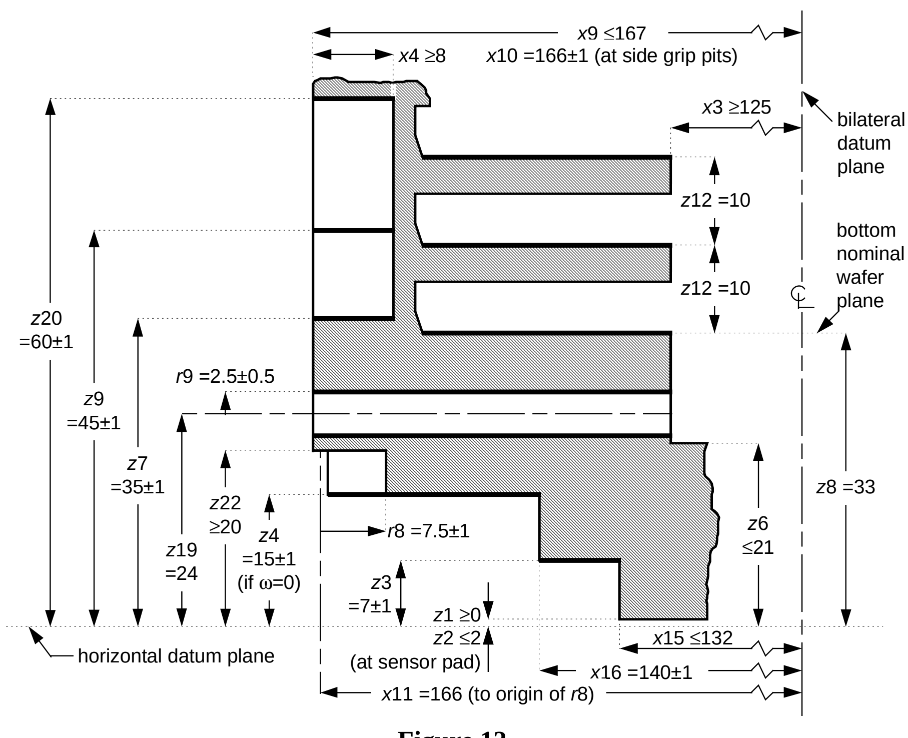

Figure 12
Lower Cross-Section at Facial Datum Plane

6.7.3 If a wafer is placed in the wafer set-down volume and is then pushed toward the rear of the cassette, then the entire bottom of the wafer must be contained in the wafer pick-up volume. However, if the wafer is not pushed toward the rear of the cassette (or the cassette is not tilted back during transport), then the wafer may only be somewhere within the wafer extraction volume. The wafer pick-up volume is defined by a cylindrical section with radius *r*1 and a main axis at the nominal wafer center line. Its top and bottom are the upper and lower tolerance of *z*10 around the nominal wafer seating plane.

6.7.4 To prevent wafers from creeping out of the cassette during transport, the fork-lift area may be slanted so that the front of the cassette is higher than the rear. Specifically, the surface defined by *z*4 may be rotated by an angle ω about the line where *z*4 intersects *y*29 (as shown in Figure 13). Only the surface behind y29 may be rotated. Thus, the height of *z*4 shown in Figure 12 might only be defined at *y*29, and *z*4 can be greater than 15 ± 1 behind *y*29. However, the flatness of the resulting tilted surface must still fall within the tolerance given for *z*4.

6.8 *Cassette Identification Tag Area* — The following areas are provided for putting identification tags on the cassette. Examples of such tags include thin electronic modules and printed labels designed to be read by either humans or machines. It is recommended that such tags be contained within the 18 mm by 60 mm (0.71 in. by 2.36 in.) region defined when the bounds are tight. It is also recommended that if such tags are smaller than the minimum bounds of the tag area, they should be centered within those bounds.

6.8.1 An optional place for an identification tag on the top of the cassette is shown in Figure 14. Although the height of this surface is not specified, the surface must be completely visible from above. The parallelism of the top identification tag with respect to the horizontal datum plane is given by *z*25. It is recommended that the identification tag should be centered on the bilateral datum plane at a point *y*21 behind the facial datum plane.

6.8.2 An optional place for an identification tag on the right-hand side of the cassette is shown in Figure 15 (where "right-hand" is defined as the right side of the cassette when it is oriented correctly and it is viewed from the rear). Although the left-right location of this surface is not specified, the surface must be completely visible from the right of the cassette. The parallelism of the side identification tag with respect to the bilateral datum plane is given by *x*27. It is recommended that the identification tag should be centered on the facial datum plane at a point *z*99 above the horizontal datum plane.

6.8.3 An optional place for an identification tag on the bottom of the cassette is shown in Figure 16. Although the height of this surface is not specified, the surface must be completely visible from below. The parallelism of the bottom identification tag with respect to the horizontal datum plane is given by *z*25. It is recommended that the identification tag should be centered on the bilateral datum plane at a point *y*22 behind the facial datum plane.

Optional Top Cassette Identification Tag Area

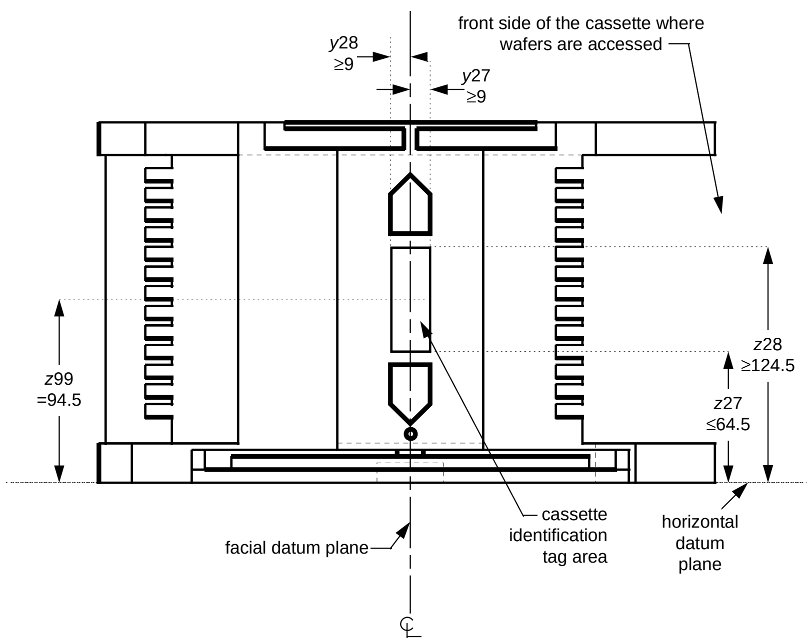

Figure 15
Optional Side Cassette Identification Tag Area

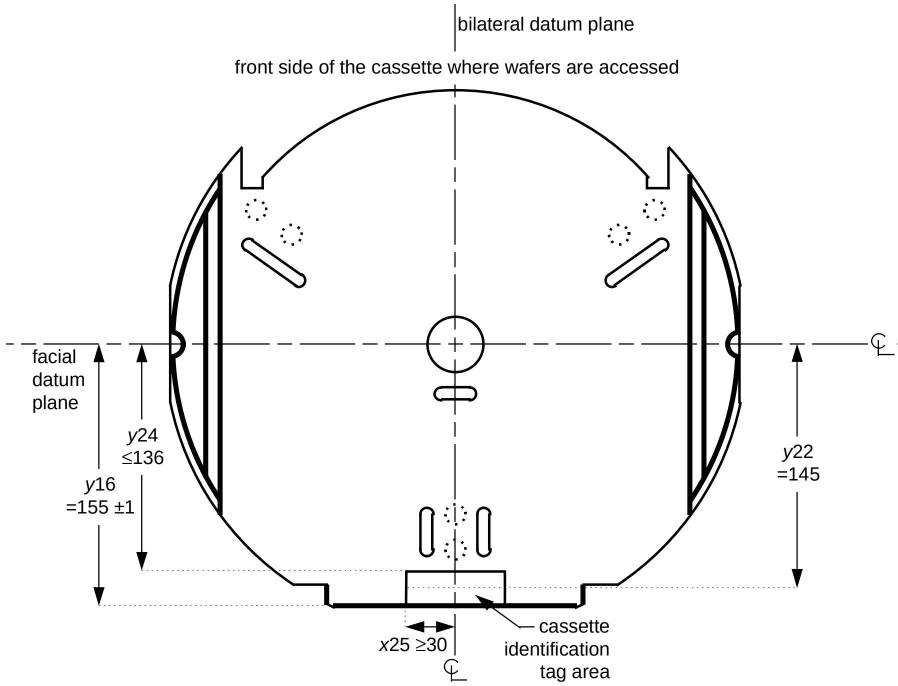

Figure 16
Optional Bottom Cassette Identification Tag Area

6.9 *Pitch and Capacity* — Table 2 shows the different options with regard to the wafer pitch (spacing) and the cassette capacity. Again, no tolerance is given on the wafer pitch (*z*12), for reasons given in Section 6.7.

6.10 *Inner and Outer Radii* — All concave features may have a radius no greater than *r*15 to allow cleaning and to prevent contaminant build-up. All required convex features must also have a radius of *r*16 to prevent small contact patches with large stresses that might cause wear and particles. Here a required feature is an area on the surface of the carrier specified by a dimension (or intersections of dimensions) that has a tolerance and not just a maximum or minimum (such as the rim of the fork-lift pin hole, the edges of the robotic handling flanges, and the corners at the rear of the cassette top and bottom domains).

6.11 *Vertical Wafer Access* — This standard does not cover accessing wafers in a vertical orientation.

APPENDIX 1
APPLICATION NOTES

NOTE: The material in this appendix is an official part of SEMI E1.9 and was approved by full letter ballot procedures on December 18, 1998. The recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 The cassette capacity is intended to include one test wafer. It is recommended that process equipment be designed for 12 or 24 product wafers, but tool robotics should reach all slots.

NOTE: The carrier capacity need not be the same as the transport group size, the process batch size, or the virtual tracking unit size.

A1-2 The shape of the features holding the wafers is not specified in this standard. However, a mizo tooth shape (an exaggerated version of which is shown in Figure A1-1) is recommended. It is also recommended that the surface that touches the wafer have a large radius to minimize stress on the wafer and the supporting feature. It is recommended that the supporting feature touch the wafer only on the back side and far enough away from the edge to avoid contact with the wafer notch (if any) in any radial orientation.

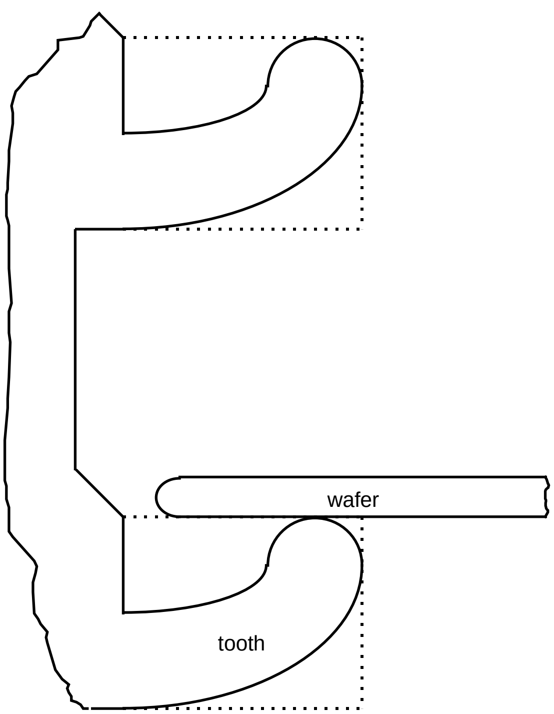

Figure A1-1
Mizo Tooth

A1-3 In general, it is recommended that the wafer notch and/or its fiducial identification marks be kept toward the front of the cassette and the front of the cassette top extend no farther than *y*14 from the facial datum plane, so that the identification marks on the top wafer can be read without removing the wafer.

A1-4 Extra clearance (larger than the pitch) has been added below the bottom wafer (for non-random sequential access to the wafers with a faster or less precise robot) and above the top wafer (for accessing the wafers in a vertical orientation), see Section 6.11.

A1-5 If wear at the kinematic couplings is a concern with plastic cassettes, ceramic or metal inserts can be used for the mating features.

A1-6 Skewness, warp, rock, and stiffness are implicitly defined in the geometric tolerances.

A1-7 To increase the stability of the cassette on the kinematic couplings, the points on the cassette bottom that are the most distant from the lines connecting each pair of coupling pins can be made as close as practical to the horizontal datum plane so that the cassette cannot tip very far off of the kinematic coupling pins.

A1-8 Figure A1-2 shows several paths for optically sensing the presence and planarity of wafers in the cassette. Also shown are the two vertical paths for sensing how far the wafers protrude.

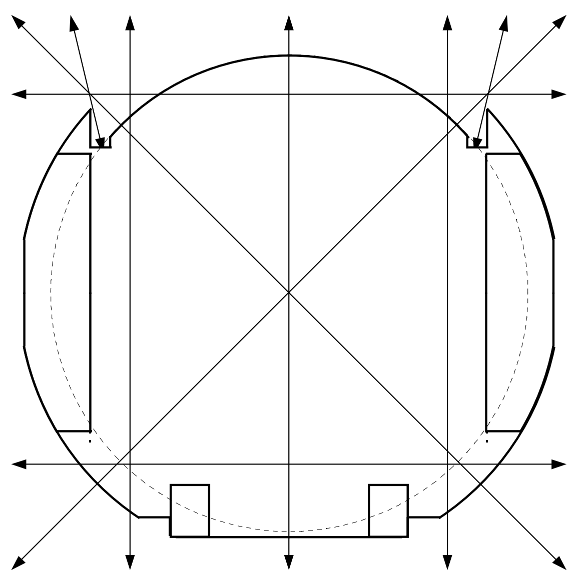

Figure A1-2
Optical Sensing Paths

A1-9 Figure A1-3 shows a small-footprint cassette that conforms to the requirements of this specification. In order to prevent such a small cassette from being set on the kinematic couplings in the wrong orientation, a frame such as shown in Figure A1-4 can be placed around the couplings. In order to not interfere with the kinematic couplings alignment function, the frame can extend no further than *r*19 from the maximum boundaries of a cassette.

NOTE: If the bottom of the cassette does not extend below the bottom conveyor rail, the conveyor rail may become contaminated and may distribute particles.

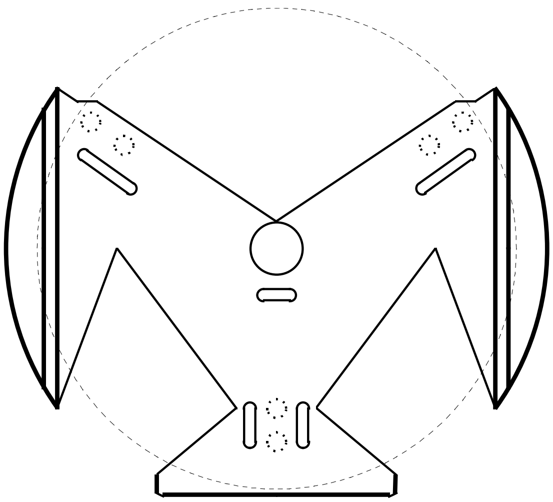

Figure A1-3
Small-Footprint Cassette

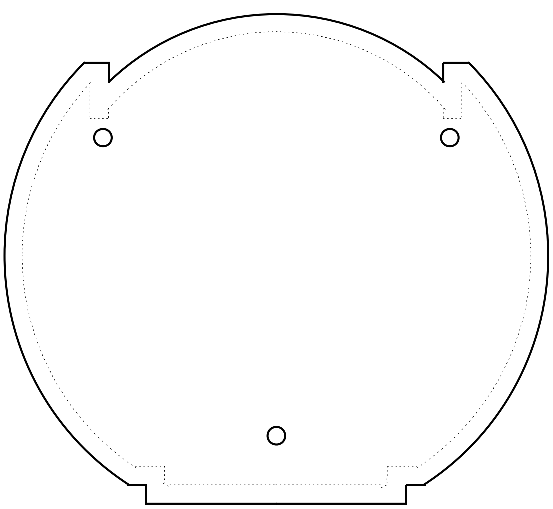

Figure A1-4
Frame to Prevent Misalignment

A1-10 Conveyor rail edges need to be well defined for smooth guidance and to avoid vibration. Thus, the minimum radius on the edge that does not create particles is recommended. For similar reasons, the tolerance on conveyor rail parallelism and on dimension *x*16 should be kept as small as possible for the materials used.

A1-11 Table A1-1 can be used for communicating which optional features are present on cassettes that comply with this specification.

A1-12 In general, info pad A (on the lower left in Figure 5) was intended to indicates the carrier capacity (the number of wafers). For example, info pad A was previously defined to be in the down position (at *z*2 above horizontal datum plane) if the carrier holds 13 wafers and was previously defined to be in the up position (at *z*26 above horizontal datum plane) if the carrier holds 25 wafers. Info pad A is intended to be read with a mechanical switch or optical sensor.

A1-13 In general, info pad B (on the lower right in Figure 5) was intended to indicates the carrier type (cassette or box, etc.). For example, info pad B was previously defined to be in the down position (at *z*2 above horizontal datum plane) if the carrier is a cassette and was previously defined to be in the up position (at *z*26 above horizontal datum plane) if the carrier is a box. Info pad B is intended to be read with a mechanical switch or optical sensor.

A1-14 Info pads C and D (slightly forward and to the outside of info pads A and B) are intended to show whether the carrier is dedicated to the front-end-of-line (FEOL) part of the fabrication process (before any metal layers have been deposited on the wafer) or to the back-end-of-line (BEOL) part of the fabrication process (during which metal contamination may be present). If such carrier differentiation is required by the user, info pads C and D are recommended to be down and up (respectively) for a front-end-of-line carrier and the opposite for a back-end-of-line carrier. Info pads C and D are intended to interact with a mechanical pin. See application note R1-2 in SEMI 15.1 for a discussion of how to use pins to differentiate FEOL and BEOL carriers.

Table A1-1 Open Cassette Optional Features Checklist

Section	*Optional Feature*	*Choice*
6.9	carrier capacity (c)	☐ 13 wafers or ☐ 25 wafers
6.7.4	slant on 2 required fork-lift pick-up areas	angle ω = ____ (0° ≤ ω ≤ 2°)
6.4	4 robotic handling flanges	☐ yes or ☐ no
6.3	4 pentagonal side grip pits	☐ yes or ☐ no
6.7.1	features that prevent wafer creep-out	☐ yes or ☐ no
6.1	full 15 mm lead in provided by 3 features that mate with kinematic coupling pins	primary kinematic coupling pins ☐ yes or ☐ no and secondary kinematic coupling pins ☐ yes or ☐ no
6.8.1	top cassette identification tag area	☐ yes or ☐ no
6.8.3	bottom cassette identification tag area	☐ yes or ☐ no
6.8.2	side cassette identification tag area (on front right side domain)	☐ yes or ☐ no

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E1.9, and it is not intended to modify or supersede the standard in any way. This information was inserted by the North America Physical Interfaces and Carriers Committee to alert the readers to potential changes to this provisional standard.

R1-1 A revision ballot will be submitted to insert a statement that application of info pads C and D are reserved to be defined by the user (for example, distinguishing between FEOL and BEOL carriers).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights are entirely their own responsibility.

SEMI

SEMI E2-93 (Reapproved 0299)
SPECIFICATIONS FOR QUARTZ AND HIGH TEMPERATURE WAFER CARRIERS

These specifications were technically reapproved by the Physical Interfaces & Carriers Committee and are the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1986; previous published revision in 1996.

1 Scope

1.1 These specifications cover the dimensional requirements for quartz and high temperature wafer carriers used in processing wafers. These general requirements assist in the compatibility of wafer carriers and most automated wafer processing equipment. Wafer pre-orientation is recommended before transferring wafers into quartz carriers to avoid interference between the flat fiducial(s) and carrier slots. These standards are intended to promote the interchangeability of wafer carriers and encourage the production of equipment suitable to a greater percentage of the market.

1.2 The design definitions of SEMI Wafer Carrier Specifications assume compliance to wafer dimensions defined in SEMI M1, M3, or M9. For a wafer carrier to be said to “meet the SEMI specifications,” it must be manufactured within the dimensional limits of the given specification, and in addition be dimensionally stable within specification when used in accordance with manufacturer's recommendations. Since wafer carriers are manufactured from a number of different raw materials and several different manufacturing methods, it is up to each manufacturer to determine the recommended usage for each wafer carrier type. The specifications were not established nor do they represent or suggest a means to obtain any ideal efficiencies in wafer processing results or quality of end product.

1.3 For referee purposes, SI (System International, commonly called metric) units shall be used for 80 mm and larger diameter wafers.

2 Selected Definitions

2.1 For illustrations of terms, see Figure 1 for Carrier Style 1, and Figure 2 for Carrier Style 2. Dimensions and tolerances are given in Table 1 of the standards for carriers of the appropriate wafer diameter.

2.1.1 *base* — the material at the bottom of the carrier that the carrier rests on when placed on a flat reference surface.

2.1.2 *bottom plane* — a horizontal plane tangent to the base.

2.1.3 *end* — either end of carrier parallel to wafer plane.

2.1.4 *lift access* — the clearance space used to insert an implement to pick up a wafer carrier.

2.1.5 *side* — either one of the sides perpendicular to the wafer plane.

3 Dimension Definitions

Symbol

A	Wafer Height — distance from the horizontal center line of the wafer to the bottom plane
B	Base Width — the outside dimension of the base from side to side
C	Base Length — length of the base from end to end
D	Lift Access Height — distance from horizontal centerline of lift access opening to bottom plane
E	Lift Access Spacing — distance from center line to center line of lift access opening
F	Lift Access Opening — size of opening for the insertion of an implement to pick up the carrier
G	Base End to First Slot — the distance from either end of the carrier to the first slot on same end
H	Slot Spacing — the distance from the center line of one slot to the center line of the adjacent slot
I	End Slot to other End Slot — the center line of the first slot on either end to the center line of the slot on the other end
J	Pocket Size — the diameter of a circle coincident to the bottom of all wafer slots in a wafer position
K	Base Side to Wafer Center line — horizontal distance from the vertical wafer center line to either side of the base
L	Carrier Region — region enclosed by the greatest included angle between a line drawn from the center point of the wafer and the outermost member of the carrier on one side and a similar line on the other side
P	Separation — separation of wafers when placed in slots

APPLICATION NOTE

NOTE: The material contained in these application notes is not an official part of SEMI E2 and is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard, as such, they are to be considered as reference material only. The standard should be referred to in all cases.

Table A1-1 lists the dimensions in linear, versus angular, measurements for ease of dimensional verification. The dimensions fall within SEMI specification; however, they correspond closer to an "L" angular dimension of 140 degrees versus the 150 degrees. The figures A1-1 and A1-2 illustrate these dimensions for non-contiguous and contiguous style quartz carriers.

A1-1 *Carrier — Dimension L*

Automated mass transfer of silicon wafers requires edge contact below the centerline of the wafer according to Table 1. These dimensions have been determined as the minimum distance below the wafer center line allowing the gripping mechanism to overlap the vertical tangent of the wafer edge below the centerline. This overlap allows the wafers to be passively crattled. Contacting the wafer any higher toward the centerline will require clamping force on the wafers.

Table A1-1

Wafer Size	*100 mm*	*125 mm*	*150 mm*	*200 mm*

SEMI

SEMI E2.3-93 (Reapproved 0299)
STANDARD FOR 100 mm QUARTZ AND HIGH TEMPERATURE WAFER CARRIERS

This standard was technically reapproved by the Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1993; previous published revision in 1996.

NOTE: Terms and Dimensions used in this specification are defined in SEMI E2.

	Description	*Style 1 — Non-Contiguous (Figure 1)*	*Style 2 — Contiguous (Figure 2)*
Symbol			
A	Wafer Height	57.0 mm ± 0.5 mm (2.25 in. ± 0.020 in.)	57.0 mm ± 0.5 mm (2.25 in. ± 0.020 in.)
B	Base Width	39.1 mm ± 0.25 mm (1.54 in. ± 0.010 in.)	39.1 mm ± 0.25 mm (1.54 in. ± 00.010 in.)
D	Lift Access Height	17.8 mm (0.70 in.) min.	17.8 mm (0.70 in.) min.
E	Lift Access Spacing	134.5 ± 0.50 mm (5.296 in. ± 0.02 in.)	109.2 mm ± 0.5 mm (4.30 in. ± 0.02 in.)
F	Lift Access Opening	8 mm I.D. (3.15 in. I.D.) min.	8 mm I.D. (3.15 in. I.D.) min.
J	Pocket Size (DIA)	101.6 mm ± 0.5 mm (4.00 in. ± 0.020 in.)	101.6 mm ± 0.5 mm (4.00 in. ± 0.020 in.)
K	Base Side to Wafer Centerline	1/2 B ± 0.25 mm (0.01 in.)	1/2 B ± 0.25 mm (0.01 in.)
L	Carrier Region	150° max.	125° max.
P	Separation — Wafer to Wafer	≥ 10% H	≥ 10% H
25 Capacity			
C	Base Length	145.7 mm ± 0.076 mm (5.736 in. ± 0.003 in.)	119.00 ± 0.076 mm (4.688 in. ± 0.003 in.)
G	Base End to 1st Slot	15.7 mm ± 0.076 mm (0.618 in. ± 0.003 in.)	2.390 mm ± 0.076 mm (0.094 in. ± 0.003 in.)
H	Slot Spacing (non-accumulative)	4.76 mm ± 0.051 mm (0.1875 in. ± 0.002 in.)	4.76 mm ± 0.051 mm (0.1875 in. ± 0.002 in.)
I	End Slot to End Slot	114.3 mm ± 0.076 mm (4.500 in. ± 0.003 in.)	114.3 mm ± 0.076 mm (4.500 in. ± 0.003 in.)
50 Capacity			
C	Base Length	145.7 mm ± 0.076 mm (5.736 in. ± 0.003 in.)	121.46 mm ± 0.076 mm (4.782 in. ± 0.003 in.)
G	Base End to 1st Slot	14.50 mm ± 0.076 mm (0.571 in. ± 0.003 in.)	2.390 mm ± 0.076 mm (0.094 in. ± 0.003 in.)
H	Slot Spacing (non-accumulative)	2.381 mm ± 0.051 mm (0.09375 in. ± 0.002 in.)	2.381 mm ± 0.051 mm (0.09375 in. ± 0.002 in.)
I	End Slot to End Slot	116.69 ± 0.076 mm (4.594 in. ± 0.003 in.)	116.69 mm ± 0.076 mm (4.594 in. ± 0.003 in.)

NOTE 1: 25 capacity slot spacing is derived from SEMI E1.2.

NOTE 2: 50 capacity slot spacing is SEMI E1.2 divided by 2; to insure compatibility for wafer transfer between Plastic & High Temperature Carriers, the U.S. customary dimension is carried out to 5 decimals to eliminate accumulation in rounding error when multiplying times 49 spaces to achieve I.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI

SEMI E2.4-93 (Reapproved 0299)
STANDARD FOR 125 mm QUARTZ AND HIGH TEMPERATURE WAFER CARRIERS

This standard was technically reapproved by the Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1993; previous published revision in 1996.

NOTE: Terms and Dimensions used in this specification are defined in SEMI E2.

	Description	*Style 1 — Non-Contiguous (Figure 1)*	*Style 2 — Contiguous (Figure 2)*
Symbol			
A	Wafer Height	69.1 mm + 0.5 mm (2.72 in. + 0.02 in.)	69.1 mm + 0.5 mm (2.72 in. + 0.02 in.)
B	Base Width	46.0 mm + 0.25 mm (1.80 in. + 0.01 in.)	46.0 mm + 0.25 mm (1.80 in. + 0.01 in.)
D	Lift Access Height	17.8 mm (0.70 in.) min.	17.8 mm (0.70 in.) min.
E	Lift Access Spacing	134.5 mm + 0.50 mm (5.296 in. + 0.02 in.)	109.2 mm + 0.5 mm (4.30 in. ± 0.02 in.)
F	Lift Access Opening	8 mm I.D. (0.315 in. I.D.) min.	8 mm I.D. (0.315 in. I.D.) min.
J	Pocket Size (DIA)	4.935 in. min.	same
K	Base Side to Wafer Centerline	1/2 B ± 0.25 mm (0.01 in.)	same
L	Carrier Region	150° max.	125° max.
P	Separation — Wafer to Wafer	≥ 10% H	≥ 10% H
25 Capacity			
C	Base Length	145.7 mm ± 0.076 mm (5.736 in. ± 0.003 in.)	119.00 mm ± 0.076 mm (4.688 in. ± 0.003 in.)
G	Base End to 1st Slot	15.7 mm ±0.076 mm (0.618 in. ±0.003 in.)	2.390 mm ± 0.076 mm (0.094 in. ± 0.003 in.)
H (See NOTE 1.)	Slot Spacing (non-accumulative)	4.76 mm ± 0.51 mm (0.1875 in. ±0.002 in.)	4.76 mm ± 0.51 mm (0.1875 in. ± 0.002 in.)
I	End Slot to End Slot	114.3 mm ± + 0.076 (4.500 in. ± 0.003 in.)	114.3 mm ± + 0.076 mm (4.500 in. ± 0.003 in.)
50 Capacity			
C	Base Length	145.7 mm ± 0.076 mm (5.736 in. ± 0.003 in.)	121.46 mm ± 0.076 mm (4.782 in. ± 0.003 in.)
G	Base End to 1st Slot	14.50 mm ± 0.076 mm (0.571 in. ± 0.003 in.)	2.390 mm ± 0.076 mm (0.094 in. ± 0.003 in.)
H (See NOTE 2.)	Slot Spacing (non-accumulative)	2.381 mm ± 0.051 mm (0.09375 in. ± 0.002 in.)	2.381 mm ± 0.051 mm (0.09375 in. ± 0.002 in.)
I	End Slot to End Slot	116.69 ± 0.076 mm (4.594 in. ± 0.003 in.)	116.69 mm ± 0.076 mm (4.594 in. ± 0.003 in.)

NOTE 1: 25 capacity slot spacing is derived from SEMI E1.3 and E1.4.

NOTE 2: 50 capacity slot spacing is SEMI E1.3 divided by 2 or E1.4 divided by 2; to insure compatability for wafer transfer between Plastic & High Temperature Carriers, the U.S. customary dimension is carried out to 5 decimals to eliminate accumulation in rounding error when multiplying by 49 spaces to achieve I.

SEMI E2.5-93 (Reapproved 0299)
STANDARD FOR 150 mm QUARTZ AND HIGH TEMPERATURE WAFER CARRIERS

This standard was technically reapproved by the Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1993; previous published revision in 1996.

NOTE: Terms and Dimensions used in this specification are defined in SEMI E2.

K	Base Side to Wafer Centerline	½ B ± 0.25 mm (.01 in.)	same
L	Carrier Region	150° max.	125° max.
P	Separation — Wafer to Wafer	≥ 10% H	≥ 10% H
25 Capacity			
C	Base Length	145.7 mm ± 0.076 mm (5.736 in. ± 0.003 in.)	119.00 mm ± 0.076 mm (4.688 in. ± 0.003 in.)
G	Base End to 1st Slot	15.7 mm ± 0.076 mm (0.618 in. ± 0.003 in.)	2.390 mm ± 0.076 mm (0.094 in. ± 0.003 in.)
H (See NOTE 1.)	Slot Spacing (non-accumulative)	4.76 mm ± 0.051 mm (0.1875 in. ± 0.002 in.)	4.76 mm ± 0.051 mm (0.1875 in. ± 0.002 in.)
I	End Slot to End Slot	114.3 mm ± 0.076 mm (4.500 in. ± 0.003 in.)	114.3 mm ± 0.076 mm (4.500 in. ± 0.003 in.)
50 Capacity			
C	Base Length	145.7 mm ± 0.076 mm (5.736 in. ± 0.003 in.)	121.46 mm ± 0.76 mm (4.782 in. ± 0.003 in.)
G	Base End to 1st Slot	14.50 mm ± 0.076 mm (0.571 in. ± 0.003 in.)	2.390 mm ± 0.076 mm (0.094 in. ± 0.003 in.)
H (See NOTE 2.)	Slot Spacing (non-accumulative)	2.381 mm ± 0.051 mm (0.09375 in. ± 0.002 in.)	2.381 mm ± 0.051 mm (0.09375 in. ± 0.002 in.)
I	End Slot to End Slot	116.69 mm ± 0.076 mm (4.594 in. ± 0.003 in.)	116.69 mm ± 0.076 mm (4.594 in. ± 0.003 in.)

NOTE 1: 25 capacity slot spacing is derived from SEMI E1.5.

NOTE 2: 50 capacity slot spacing is SEMI E1.5 divided by 2; to insure compatibility for wafer transfer between Plastic & High Temperature Carriers, the U.S. customary dimension is carried out to 5 decimals to eliminate accumulation in rounding error when multiplying by 49 spaces to achieve I.

SEMI E6-1296
FACILITIES INTERFACE SPECIFICATIONS GUIDELINE AND FORMAT

1 Purpose

This guideline is intended to assist suppliers with the communication of information about the facilities needs of their equipment to those who are responsible for the facilities design and the equipment installation.

The successful installation and operation of semiconductor equipment is the mutual objective of the owner of the equipment, the operator, the installer, and the supplier. Within the semiconductor industry, the diversity and complexity of equipment have created significant problems for those who design the facilities and install the equipment. It is very difficult to stay current with the ever-changing requirements necessary for individual pieces of equipment. As a result, it is difficult to guarantee that the facilities will meet the needs of each piece of equipment.

2 Scope

Design and installation requirements vary with each owner and project. Therefore, this guideline is designed to cover all activities that may be included with equipment installation.

3 Impact

Any supplier who uses this format is expected to include within the document all requirements for the site facilities, equipment shipping, installation, startup, acceptance test, and training. This is a guiding document for those who design the facility and install the equipment. The format is to be used for all types of equipment. Therefore, it will be necessary for each supplier to make modifications as required to suit the complexity of the equipment. The intent is to have a simple, but complete, format for all equipment.

4 Referenced Documents

None.

6.3 *facilitization* — The provision of facilities or services.

7 Instructions and Sample

Following is a sample for equipment interface specifications. The sample below includes a table of contents and sample forms. Address each of the items in the table of contents with a comment, even if the item does not apply. Those responsible for the installation need to be sure every aspect has been considered and addressed. In the following sections, the instructions for each element of the table of contents is followed by a sample.

- Table of contents (sample)
- Introduction
- Administrative interface
- Safety
  - — Non-physical conditions
  - — Monitoring communications
  - — Clearances
- Facilities installation requirements
  - — Environment
  - — Schematic (single line) diagram and equipment data sheets
  - — Equipment facilitization drawings
- Shipping and receiving requirements
- Installation requirements
  - — Transport and positioning equipment tools
  - — Assembly and hookup tools and equipment
- Startup requirements
  - — Equipment
  - — Material
  - — Personnel
- Acceptance test
- Training
- Addenda (list by topic)

7.1 *Introduction*

7.1.1 *Instructions for Introduction* — The introduction should include general information about the scope of the document and any other introductory statements.

7.1.2 *Sample for Introduction* — This document contains the facilities design and equipment installation requirements for (indicate equipment name). It conforms to SEMI E6 (Facilities Interface Specifications Guideline and Format).

7.2 *Administrative Interface*

7.2.1 *Instructions for Administrative Interface* — The administrative interface should include the contacts for commercial questions and technical questions.

The equipment description should include:

- Functionality and intended use
- Wafer or material handling method
- Interface with other equipment (especially cluster tools)
- Special process requirements
- Number of pieces included as part of this equipment

Suppliers are encouraged to make the specifications document as specific as possible to the delivered equipment.

Include here information about the availability of facilities data in electronic formats. Specify the software format name and revision level, and indicate the names of data files contained in it.

Options Included:		

7.3 *Safety*

7.3.1 *Instructions for Safety* — Any special safety concerns relating to the facilities design or equipment installation, startup, or testing should be addressed here.

7.3.1.1 *Non-Physical Conditions* — Information should be provided by the supplier on all non-physical equipment emissions including radio frequencies, temperature, humidity, vibrations, noise, odors, and ionizing and non-ionizing radiation. This information should be formatted to show emissions during normal operation and potential emission or releases in the event of malfunction or abnormal conditions.

Information should be provided on any non-physical conditions that could exist in the user's facility that would adversely affect the operation of the equipment being supplied.

7.3.1.2 *Monitoring Communications* — The supplier should provide information on the protocol, number, type, and location of the data/communication connectors for external monitoring that are provided or desirable.

Examples of conditions that are typically monitored are: chemicals that could present a health hazard, flammable chemicals and other fire hazard conditions, equipment temperature, exhaust systems, radiation sources, and power supplies.

7.3.1.3 *Clearances* — Drawings required under Section 7.4.3, Equipment Facilitization Drawings, should include clearances required for operator access and equipment maintenance and the operation of doors, drawers, and panels integrated into the equipment. Notations should be given if the clearances shown are in compliance with standards or codes.

7.3.2 *Sample for Safety* — Safety-related checks should be performed to supplier specification prior to system acceptance. These safety checks at point of installation should be accepted by:

- Supplier(s) safety representative
- Customer safety representative

Installation site acceptance test should be signed off by a supplier and a customer. The following test should be performed prior to acceptance to verify that the system meets requirements:

- Statement of conformance to SEMI S2 (Safety Guidelines for Semiconductor Manufacturing Equipment)
- Safety interlocks function and shut-down correct hazards
- Ventilation flow test at specifications and location where this can be verified by measurement
- Preventive maintenance and operating procedures are clearly documented, and personnel are trained
- Chemical spill containment is adequate for 110% of the quantity of fluids in the system
- UPS output(s) are isolated when emergency shutdown occurs
- Manual operation of the tool is documented, and personnel are trained
- EMO circuit functions
- Ability to lock out hazardous energy sources prior to maintenance
- Onboard gas detection system is functional
- Onboard fire detection system is functional
- Auxiliary equipment tie-ins function as intended and do not increase level of risk (scrubbers, purging systems, alarms)
- Site-specific installation does not degrade tool's ergonomic design factors
- Interface to building systems functions as intended
-

7.4 *Facilities Installation Requirements*

7.4.1 *Environment*

7.4.1.1 *Instructions for Environment* — These requirements must address the temperature and humidity requirements of equipment when it is facilitized for operation. Any other requirements, such as vibration, may be addressed in the body of the specifications or in the addenda with backup information provided in the addenda.

7.4.1.2 *Sample for Temperature*

Tool Area		to		
Support Equipment Area		to		

7.4.1.4 *Sample for Special Lighting* — Provide Table for Special Equipment Requirements.

7.4.1.5 *Sample for Vibration Requirements*

___________This equipment gives forth vibration that may impact sensitive equipment installed nearby. (If yes, indicate worst-case criterion here:___________.)

___________This equipment is sensitive to vibration. (If the facility needs to meet Criteria A or better, indicate here:___________.) If the tool requirement is more stringent than Criteria A, provide the information required in the Addendum Section.

7.4.1.6 *Sample for Noise Requirements*

___________This equipment gives forth electromagnetic radiation that may impact sensitive equipment installed nearby.

___________This equipment is sensitive to or produces electromagnetic radiation, electromagnetic interference, radio frequency, acoustical vibrations, or electrostatic discharge. (If yes, provide data.)

7.4.1.7 *Sample for Seismic Requirements*

___________This equipment has brackets or other mechanisms to secure for earthquake protection. (If yes, provide data.)

7.4.1.8 *Sample for Environment Cleanliness*

___________This equipment requires a clean room to meet operational specifications. (If yes, provide minimum cleanliness data.) Different areas of a tool or subassemblies may need different minimums. If so, the supplier should state this information.

7.4.2 *Schematic (Single Line) Diagram and Equipment Data Sheet*

7.4.2.1 *Instructions for Schematic (Single Line) Diagrams* — The diagram(s) is required. It may be included in the body of the specification or in an addendum at the option of the supplier. Included in the application notes are samples of possible formats. These also serve as a checklist of information needed by the facilities design and installation people.

A schematic (single line) diagram and equipment data sheet are to be developed for the various facilities requirements. The diagram should be designed to give the facilities designer or equipment installer a detailed overview of the facility requirement being covered. The equipment data sheet should be designed to give the facilities designer or equipment installer the following specific information about the facility items covered in the diagram:

- A description
- Whether the customer or supplier provides the item
- The "to" and "from" connection points, with connections named
- The length or other applicable physical characteristics
- A reference designation to the interface diagram

For equipment with simple facilities requirements, the supplier may combine requirements to reduce the number of diagrams and diagram data sheets. The facilities interface diagrams will be contained in the body of the document.

It is also recommended that equipment data sheets be included for all equipment, especially those with multiple stand-alone components. The equipment data sheet should give the facilities designer or equipment installer detailed information on all facilities required for a given assembly. This should include, but is not limited to:

- A description
- All physical characteristics of the assembly
- Environmental requirements
- Detailed facility requirements for items listed
- A reference designation to the interface diagram
- Applicable notes to guide the designer or installer when installing the equipment

As with the facilities interface specifications format, it is recommended that the diagrams and data sheets list items "not needed" so the facilities provider will know that these subjects were considered by the equipment supplier.

7.4.2.2 *Sample for Schematic (Single Line) Diagram*

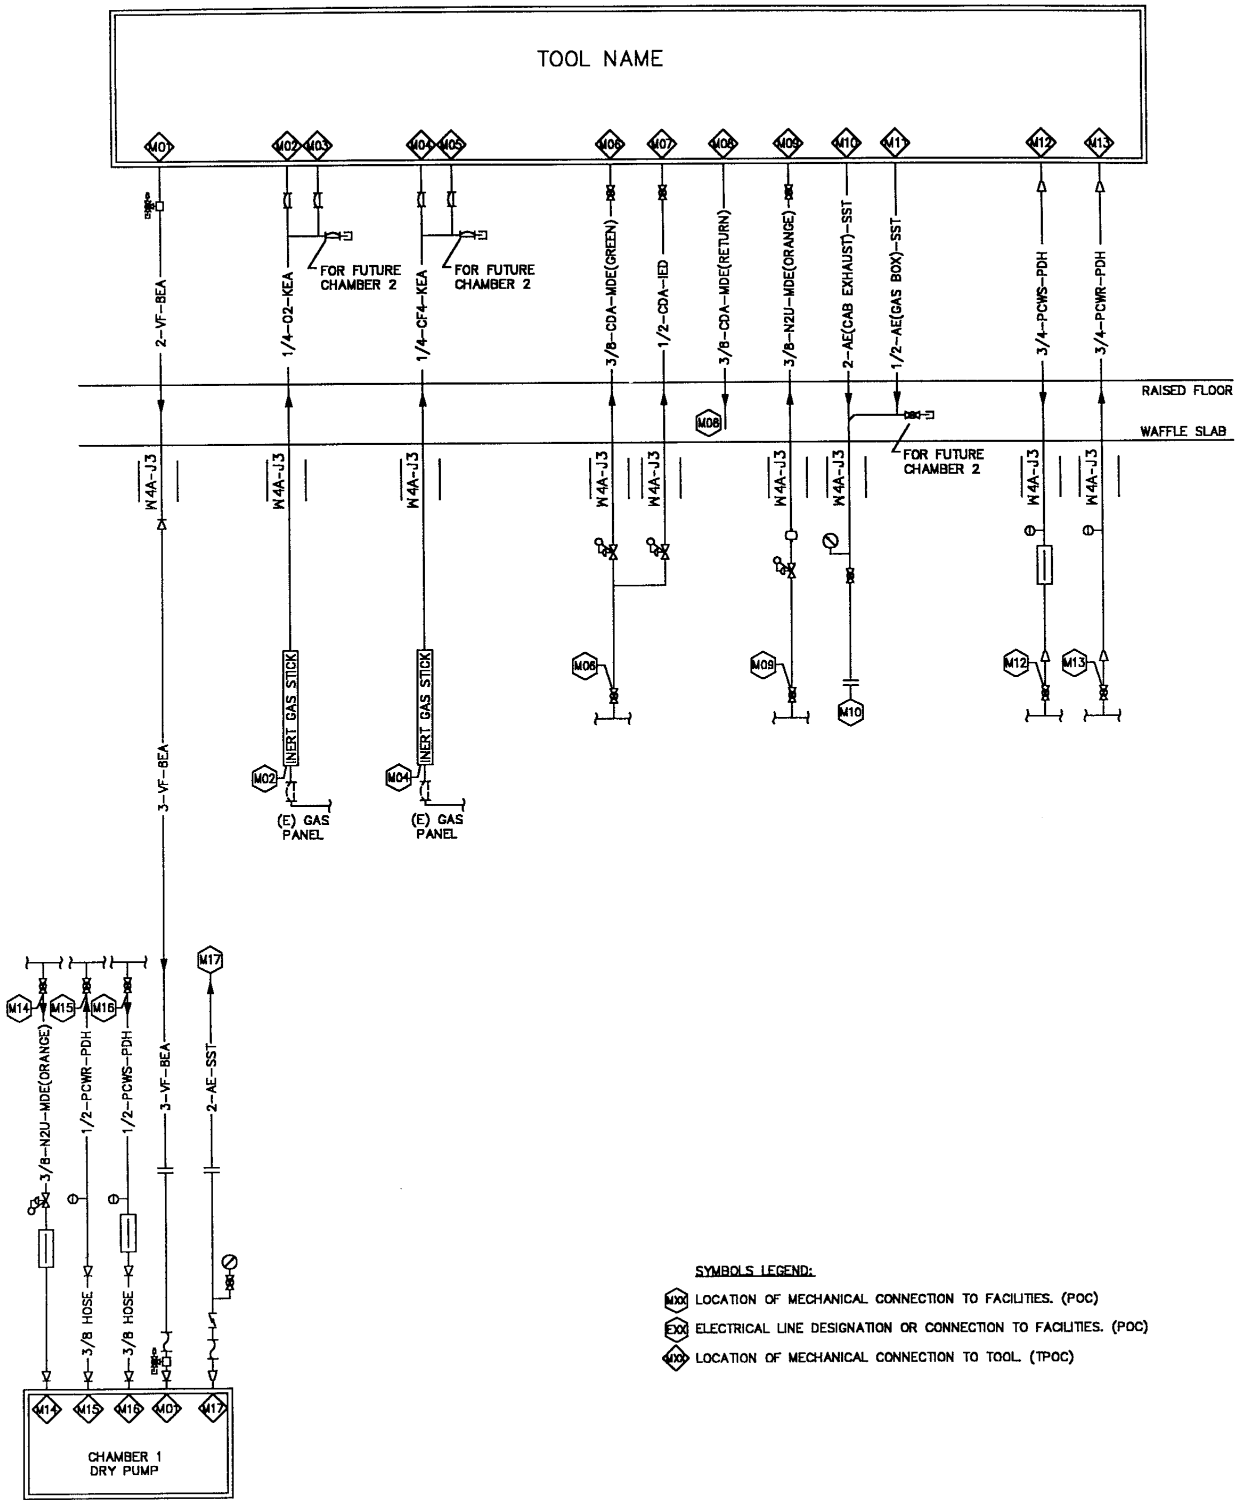

Figure 1
Schematic (Single Line) Diagram

7.4.2.3 *Notes on Equipment Data Sheet* — The equipment data sheet contains bold numbers in parentheses which refer to the key located at the end of the data sheet.

If more than one connection of a given utility exists for an equipment item, each should be indicated separately.

Flows, temperatures, etc. are for normal operating conditions. If there is a variation because of startup or emergency, those additional conditions should be indicated.

1. If there is a difference between normal operating current and peak current, it is necessary to know the duration of the peak to size the equipment circuit breaker. The equipment supplier may supply the peak duration or the size of the breaker.
2. Power connection should indicate the type of plug used or, if hard wired, indicate the number of wires with the minimum and maximum wire size that can be connected to the equipment lugs. Also, indicate the conduit connection opening size.

Please indicate if a drain trap is needed. If a drain trap is provided with the equipment, please indicate its height.

7.4.3 *Equipment Facilitization Drawings*

7.4.3.1 *Instructions for Equipment Facilitization Drawings* — As a minimum, the overall dimensions and clearances of equipment are to be provided. These should include: plan and elevation drawings that show connection locations, and minimum, maximum, and typical interconnect distances.

Table-mounted equipment must indicate the minimum table size and structural requirement.

A system interconnect schematic is required for any equipment that consists of more than one item.

A facilities interface matrix should be included, following the format in this guideline. For complex equipment, it is recommended that a summary matrix be included first, followed by an extended matrix for each component. As with other sections of this document, it is recommended that the extended matrix list items “not applicable” (N/A) so the facilities provider will know that these subjects were considered by the equipment supplier.

Information should be provided on all minimum/maximum distance limitations of the equipment to other equipment, sources of chemicals, and auxiliary equipment. Insert equipment drawings here and provide table of distance parameters.

Table 7 Drawing Checklist

Hard Copy	*Soft Copy and Format*	*Included Drawings*
		Legends and symbols
		Plan views with maintenance and electrical clearances and operator access
		Plan and elevation views, including: Front, side, and top views Height, width, and depth dimensions Centerline dimensions for all facilities connections Isometric view(s)
		Captioned photos
		Floor-loading diagram showing: Weight load on each contact point to the floor Dimensions of support mechanism that contacts floor Center of gravity location
		Receptacle or terminal strip connections (to be included when user is required to make connections)
		Through-the-wall mounting drawings: Dimensions for cutout size Cross-sectional top view Assembly drawings when applicable
		External piping and instrument drawings (P&ID) included? If yes, see Table 4.
		Internal P&ID included? If yes, see Table 4.

7.5 *Shipping and Receiving Requirements*

7.5.1 *Instructions for Shipping and Receiving Requirements* — Suppliers should include information about the type and number of containers in which this equipment is shipped and how they are to be handled and stored. This should include clearances for oversize equipment, special staging and uncrating or preparation areas, etc. In addition, any special receiving information should be noted. This is especially important for sensitive equipment or if supplier involvement is required. If containers cannot be unloaded by hand, please state the equipment needed.

7.5.2 *Sample for Shipping and Receiving Requirements*

Number of Containers:___________

Table 8 Shipping and Receiving Requirements

Container #	*Dimensions (L x W x H) (units)*	*Weight (units)*	*Impact Monitor*	*Tilt Monitor*

Impact monitors, if included, will have a maximum of ___________G's.

The following equipment will be required to unload:

Equipment can/must be stored as follows:

___________Outside

___________In a store room

___________Out of weather in a dry location

___________Moved to a cleanroom on arrival

Temperature range ___________to___________°C (___________to___________°F) Temperature

Humidity range ___________to___________%

Dimension of largest piece to move:________________________________

Weight of largest piece to move into the cleanroom________________________________

Special receiving instructions:________________________________

7.6 *Installation Requirements*

7.6.1 *Instructions for Installation Requirements* — Consider every step from receiving to final hookup. The installation process usually includes the need for tools, transportation equipment, and personnel (quantity, duration, and skills). All requirements should be indicated so their availability will be assured.

During the assembly and installation, the following provisions will be required:

7.6.2 *Sample for Transport and Locating Equipment*

____

____

7.6.3 *Sample for Assembly and Hookup Tools and Equipment*

____

____

7.7 *Start-Up Requirements*

7.7.1 *Instructions for Start-Up Requirements* — Consider every step from initial powerup to release for acceptance test. The startup process usually includes the need for tools, measurement equipment, and personnel (quantity, skills, and expected duration). All requirements should be indicated so their availability will be assured. In addition, for some equipment, it may be necessary to use materials (such as wafers) and supplies during startup. The supplier should indicate the type, quantity, and specifications of any materials needed.

It may also be necessary to use special measurement or analytical instruments to test performance of equipment or sample product produced. Requirements for these should also be stated.

If the supplier supplies separate start-up documentation, or if the supplier is responsible for start-up, this should be referenced.

7.7.2 *Sample for Equipment*

____

____

7.7.3 *Sample for Material*

____

____

7.7.4 *Sample for Personnel*

____

____

7.8 *Acceptance Test*

7.8.1 *Instructions for Acceptance Test* — Suppliers should indicate if acceptance testing will be required, what tests will be required and provide an estimate of the duration of the acceptance tests. It is especially important to indicate if any tests or inspection of the facility will be required prior to the installation or start-up of the equipment.

7.8.2 *Sample for Acceptance Test* — Tests will be performed to demonstrate that the facilities meet requirements.

__________Yes___________No

The following tests will be required:

____

____

Tests will be performed to demonstrate that the equipment meets requirements.

__________Yes___________No

The following tests will be required:

____

____

7.9 *Training*

7.9.1 *Instructions for Training* — Please indicate if any special training is required to install or operate the machine. It is especially important to indicate if any training is required for the installation process. If required, indicate whether this is part of the system deliverables, or is the responsibility of the customer.

If the supplier supplies separate training documentation, or if the supplier is responsible for training, this should be referenced.

7.9.2 *Sample for Training*

Special training will be required.

__________Yes___________No

User's personnel are required to be trained in the following as a prerequisite to supplier-supplied training and prior to operation, use, or maintenance of the equipment:

____

____

Supplier will provide the following training at:

__________Supplier's site:

__________User's site:

7.10 *Addenda*

7.10.1 *Instructions for Addenda* — The addenda is to contain all additional information requested by customer or deemed necessary by supplier. It is necessary to convey the facilities interface needs of the equipment. List and cover only the items necessary. It is the responsibility of the equipment supplier to determine the requirements to be covered. The application notes to this guideline contain an initial checklist of addendum topics and, for selected topics, examples of how information may be presented.

8 Addendum Topics

Following is a checklist of topics that should be considered for inclusion in the addenda. The equipment supplier may add addenda as necessary.

8.1 *Topics without Examples Provided in this Document*

- Process gas purity (refer to SEMI C3 and related standards)
- Supplier-supplied interconnecting cables and lines
- Special utilities requirements (water, compressed air, other support liquids, waste drains — traps, trap liquid height)
- Electromagnetic requirements (safety, shielding)
- Ionizing radiation requirements (safety, shielding)

8.2 *Topics with Examples* — For selected addendum topics, the following samples and information are provided.

8.2.1 *Addendum A, Computer Interface* — If the equipment has provision and capability for communication with a host computer, provide the information and applicable documentation requested below.

Communication Interface

___________Serial interface

___________This equipment complies with SEMI E4 (SEMI Equipment Communications Standard 1 Message Transfer (SECS I)). Attach the documentation requested in Section 9 of SEMI E4.

___________This equipment complies with SEMI E37 and E37.1, High-Speed SECS Message Services, Single Session (HSMS-SS). Specify the physical network (e.g. Ethernet) and required cabling (e.g. 10-Base-T) in the following Network section.

___________Network. Specify by reference to a published standard. Include physical link and protocol.

___________Other. Specify by reference to a published standard. Include the physical link and protocol.

Message Content

___________This equipment complies with SEMI E5 (SEMI Equipment Communications Standard 2 Message Content (SECS II)).

___________Message sequences conform to the recommendations of SEMI E30

The following capabilities scenarios are implemented on this equipment:

___________establish communications

___________data collection

___________alarm management

___________remote control

___________process program management

___________material movement

___________equipment terminal services

___________error messages

___________clock

___________spooling

___________log file

___________Additional, or other, messages are implemented. Attach message documentation requested in Section 8 of SEMI E5. If process programs are unformatted (per the definition of SEMI E5), attach documentation defining the format of the program.

8.2.2 *Addendum B, Vacuum Requirements* — This equipment requires installation of a vacuum pump at some distance from the system. The equipment is designed to achieve its required performance with a pump and vacuum line capable of the following flow(s) and pressure levels at the connection port to the equipment:

These levels can be achieved with the following specified pump and line sizing (specify number of elbows and other restrictions):

____

____

Because the vacuum pump and its installation are critical elements in the proper performance of this equipment, any deviation from the above should be designed in consultation with the supplier.

The vacuum pump must be prepared for chemical service as follows:

____

____

An interlock or alarm signal indicating pump failure is required at the equipment. Details on contact rating and connector are provided:

____

____

8.2.3 *Addendum C, Electrical Requirements*

__________This equipment complies with SEMI E7 (Specification for Electrical Interfaces for the U.S. Only).

__________This equipment requires special electrical connectors. List the special plug and/or receptacle requirements.

__________This equipment requires AC power line conditioning. List the power purity requirements and wattage.

__________This equipment requires UPS. List the required capacity (watts and time) and response specifications. List any suggested supplier whose equipment will meet the specifications.

__________This equipment has other special electrical requirements. List and specify.

8.2.4 *Addendum D, Vibration Requirements*

Vibration Criterion Checklist

This checklist summarizes the information needed for a sensitive equipment vibration criterion to be properly defined.

I. Analysis methodology

A. If time domain analysis is to be used, use:

1. Frequency range __________Hz to__________Hz

[ ] acceleration, [ ] velocity

[ ] displacement

2. Allowable amplitude

[ ] peak-to-peak, [ ] 0-peak,

[ ] RMS value.

B. If frequency domain analysis is to be used, use:

1. [ ] 1/3 octave analysis, with second filter time constant

2. [ ] constant bandwidth analysis with a frequency resolution of __________Hz

3. [ ] linear averaging

[ ] exponential averaging

[ ] peak hold averaging

4. Allowable amplitudes

Provide a plot of allowable amplitude as a function of frequency. Amplitude is given in terms of:

[ ] peak-to-peak

[ ] 0-peak

[ ] RMS value

Equipment manufacturer:____

Equipment model number:____

Equipment use (e.g., microscope, stepper, etc.):____

Person to contact for questions:____

Phone number: (_____)______-_______

II. Plot of vibration criteria

The following plot of generic vibration criteria for sensitive equipment in buildings shows velocity vs. frequency, using 1/3 octave analysis.

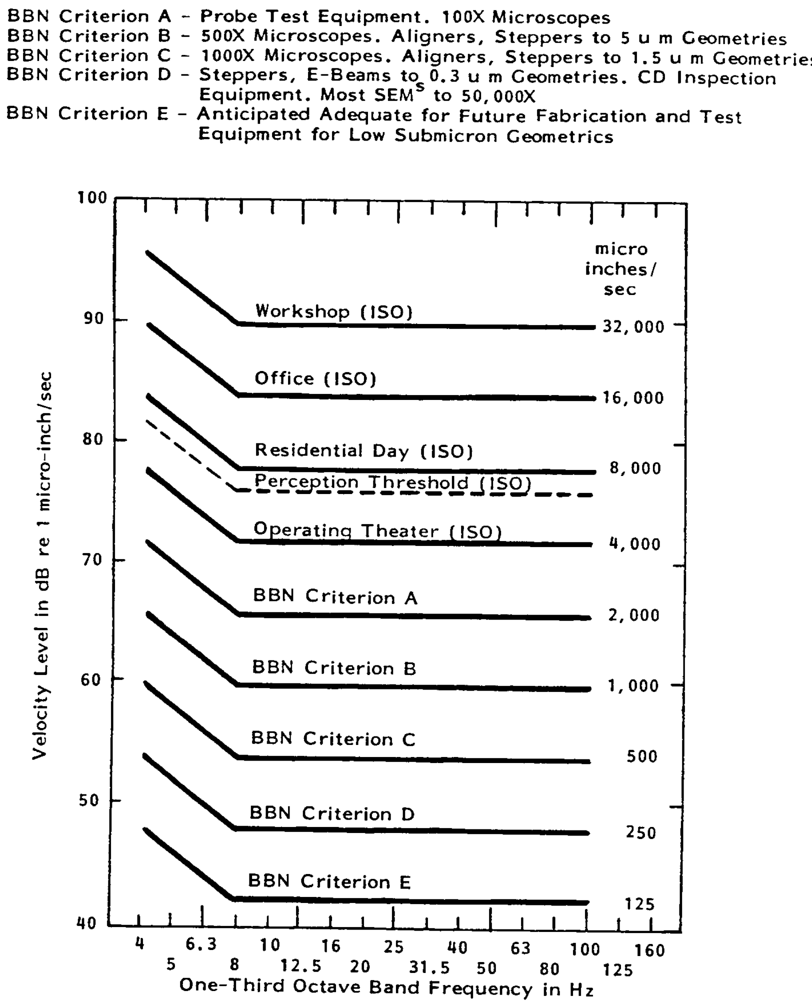

Figure 2
Floor Vibration Criterion for Equipment Used in the Production of Integrated Circuits
(Other Curves Represent Criteria Recommended by International Standards Organization)

8.2.5 *Addendum E, Floor Loading*

No.	Type	No. Places	Weight Each	Remarks
1	2" ϕ Foot	5	310 LBS	
2	6" ϕ Foot	2	1120 LBS	
3	18" × 24" Pad	1	2100 LBS	
Total Weight			5890 LBS	

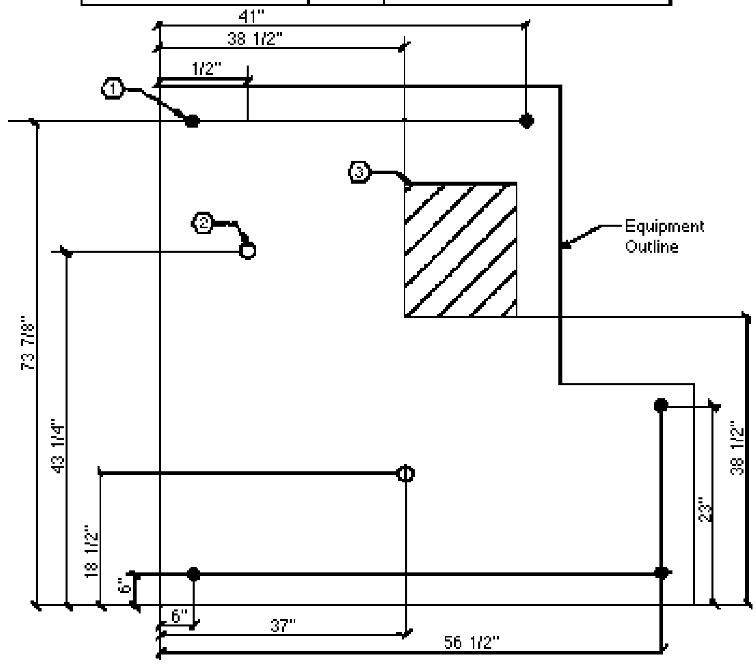

Figure 3
Sample Floor Loading Diagram

8.2.6 *Addendum F, Wafer Handling*

Wafer Size

This equipment, as delivered, is configured to handle_______mm wafers. It is capable of processing wafers of other sizes as follows:

Table 9 Wafer Size

Wafer Size	*As Delivered*	*By Adjusting Installed Parts*	*By Replacing Installed Parts*	*Supplier Must Modify*
3 inch				
100 mm				
125 mm				
150 mm				
200 mm				
___mm				

Wafer Interface

________________Wafers are inserted manually, one at a time, into this equipment.

________________This equipment is provided with a single-wafer transport mechanism and port in compliance with SEMI E8 (Specification for Wafer Transport Systems: Interface Coordinates). Show datum point and locations of input and output port centerlines on the equipment facilitization drawings. See Section 7.4.3.

________________Wafers are inserted into this equipment in wafer carriers (cassettes). Provide the information requested in the sections below.

Wafer Carriers Accommodated

________________This equipment, as delivered, is capable of accepting wafers delivered in SEMI standard carriers (cassettes) conforming to the following:

Table 10 Wafer Carriers

Wafer Size	*As Delivered*	*By Adjusting Installed Parts*	*By Replacing Supplied Parts*	*Supplier Must Modify*
3 inch/SEMI E1.1				
100 mm/SEMI E1.2				
125 mm/SEMI E1.3				
125 mm/SEMI E1.4				
150 mm/SEMI E1.5				
200 mm/SEMI E1.7				
___mm				

________________This equipment requires special wafer carriers:

______________________supplied with the equipment

______________________other — provide name of supplier and specification

Wafer Carrier Interface

Carriers are placed on the receiving platform in the following orientation:

________________wafers horizontal ________________degrees tilt

________________wafers vertical ________________degrees tilt

Wafer Alignment

Wafer flat/notch alignment__________is/_________is not required.

Inter-Equipment Material Transport

________________This equipment complies with SEMI E15 (Specification for Inter-Equipment Material Transport Interface), with the following parameters and exceptions:

________________equipment has an enclosed interface (e.g., load lock)

________________equipment allows use of cassettes only

________________equipment allows use of a box conforming to:

______________________SEMI E19 (Standard Mechanical Interface (SMIF))

______________________other — attach specification

________________vertical clearance, C3, is:

_____________________mm (________________inches)

_____________________unrestricted

____________________other exception — describe in detail

8.2.7 *Addendum H, Contractual Language* — Since facility performance and equipment performance-to-specifications are inter-related, a contractual section may be used to ensure that proper performance is achieved.

8.2.7.1 *Equipment Performance* — Performance of the equipment to specifications is based upon its installation in a facility which meets or exceeds the requirements of Exhibit X (the SEMI E6 furnished by the supplier). Accordingly, customer agrees to provide supplier with:

8.2.7.2 A monthly report which details the status of the facility design, construction, and materials in relation to schedule milestones;

8.2.7.3 Certified complete facility drawings, specifications and calculations at least _________days before the start of acceptance testing;

8.2.7.4 Facility supplier materials list, test procedures, and certifications at least _________days before the start of acceptance testing.

8.2.8 *Supplier Inspection* — Customer shall make its facility available for supplier's inspection __________days before the start of acceptance testing. At that time, supplier will verify that the facility meets or exceeds specifications. If the facility fails to meet specifications, supplier may recommend modifications that customer may choose to accept or reject. If customer chooses to reject supplier's recommendations, then customer must waive that portion of the specifications or acceptance criteria that may be affected by the lack of proper facilities as designated by supplier.

8.2.8.1 The determination that customer's facility is deficient will be a joint decision made by supplier and customer. Any re-audit of customer's facility by supplier will be at customer's expense.

8.2.8.2 If customer's facility is determined to be deficient, then the final system progress payment shall be due at supplier's scheduled shipment date for the system. If customer requests installation of the system without re-audit of the facility, customer shall be responsible for supplier's costs associated with failure of the facility to meet specifications.

.

SEMI E7-91 (Reapproved 0699)
SPECIFICATION FOR ELECTRICAL INTERFACES FOR THE U.S. ONLY

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org April 1999; to be published June 1999. Originally published 1984, previously published 1991.

For Japan electrical interface requirements, see SEMI E31.

1 Introduction

1.1 *Intent* — The purpose of this standard is to simplify the design and implementation of future semiconductor facilities where both equipment suppliers and users can be assured of the exact electrical interfaces required.

1.2 *Overview* — This standard presents recommendations for the selection of specific electrical power interfaces:

- Service categories by voltage, current and phase for systems, motors, and other electrical loads
- Electrical connectors
- Cordage

1.3 *Applicable Documents and References*

NEMA — National Electrical Manufacturer's Association[1]

NFPA 70-1981 — National Electrical Code, (NEC) National Fire Protection Association[2]

1.4 *Service Categories*

1.4.1 Voltage, current, and phase for motors and other electrical/electronic loads:

1.4.2 *Motors* — (From Article 430-148, 150 of National Electrical Code)

Power	*Recommended Phase & Voltage*	*Recommended Current Range*
Motors 1/6 to 3/4 HP	120V 1Ø 208V 1Ø 230V 1Ø	4.4 to 13.8 AMPs 2.4 to 7.6 AMPs 2.2 to 6.9 AMPs
Motors 3/4 to 5 HP	208V 3Ø 230V 3Ø	3.1 to 16.7 AMPs 2.8 to 15.2 AMPs
Motors 5 HP and Larger	480V 3Ø	7.6 AMPs and up

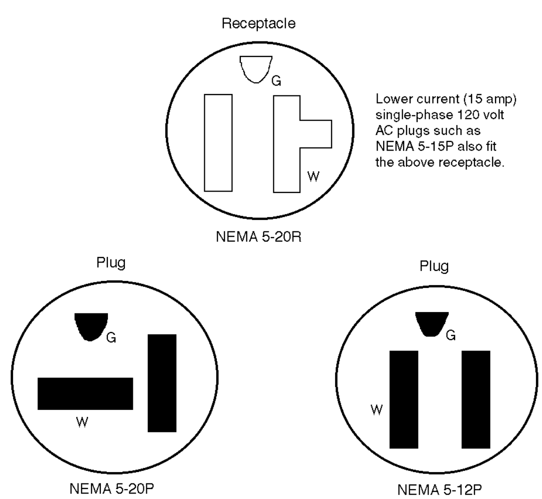
1.4.3 *Other Loads* — (By Calculation)

	Ampere Range for Recommended Volts & Phases			
Power	120V 1Ø	208V 1Ø	208V 3Ø	480V 3Ø
0-3000 Watts	0 to 25 A.	0 to 14 A.	0 to 8 A.	
3000-5000 Watts		14 to 24 A.	8 to 14 A.	
5000-30,000 Watts			13 to 83 A.	
30,000 and Above				36 A. and up

2 Electrical Connectors

2.1 The NEMA types listed below are available in many forms from many manufacturers. For example, the "receptacle" configurations shown also apply to connectors and flanged outlets.

2.1.1 125 Volt, 1Ø, 20 AMPs max., straight blade

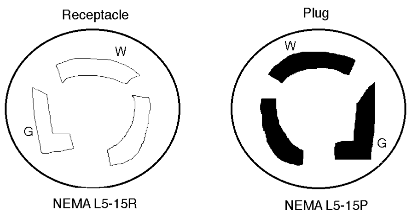


[1] *National Electrical Manufacturer's Association, 2101 "L" Street, N.W., Washington, D.C. 20037*

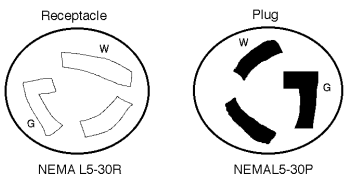
[2] *National Fire Protection Association, 470 Atlantic Avenue, Boston, MA 02210*

Dead front plugs are preferred.

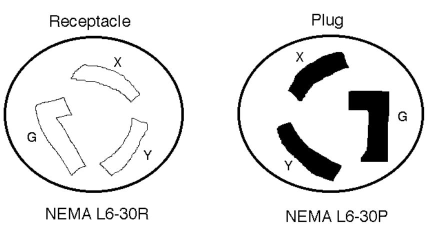
2.1.2 120 Volt, Ø, 30 AMPs max., locking type.



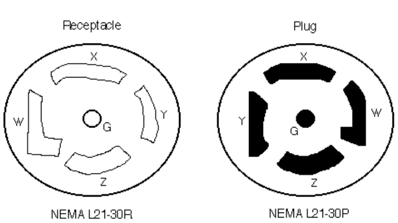
2.1.3 120 Volt, 1Ø, 30 AMPs max., locking blade type.



2.1.4 250 Volt, 1Ø, 30 AMPs max., locking type



2.1.5 120/208 Volt, 3ØY, 30 AMPs max., locking type (4 pole, 5-wire grounding)



2.1.6 Above 10,000 watts, use of connectors is discouraged. Wherever possible, such loads should be wired into junction boxes using appropriate crimped or pressure terminations.

3 Cordage and Cables

3.1 The flexible cord and cable types shown are examples; for more detail see the National Electrical Code.

3.2 The following table gives the allowable ampacity for the specified number of current-carrying copper conductors in a cord.

3.3 Type SO-ST-STO preferred with 600 Volt insulation.

AWG	*#18*	*#16*	*#14*	*#12*	*#10*	*#8*	*#6*	*#4*
2 cond.	10	13	18	25	30	40	55	70
3 cond.	7	10	15	20	25	35	45	60
4 cond.	5.6	8	12	16	20	28	36	48
5 cond.	5.6	8	12	16	20	28	36	48

Flexible Cord and Cable Conductor Color Code

1	4	208/480	Blk	Red		Wht[a]	Green[b]
3	4	208/480	Blk	Red	Orange		Green[b]
3	5	208/480	Blk	Red	Orange	Wht[a]	Green[b]

Notes

a. Natural Grey or Light Blue may be used. Under no circumstances may White, Natural Grey or Light Blue be used for any purpose other than to identify neutral or rounded conductors.

b. Green/Yellow may be used. Green/Yellow will be Green with one or more Yellow stripes (Green = 50 to 70%; Yellow = 50 to 30%). Green/Yellow is the only color internationally accepted for use as an equipment grounding conductor. Under no circumstances may Green/Yellow, Green or Yellow be used for any purpose other than to identify grounding conductors.

c. For double insulated machines only.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E10-0701
SPECIFICATION FOR DEFINITION AND MEASUREMENT OF EQUIPMENT RELIABILITY, AVAILABILITY, AND MAINTAINABILITY (RAM)

This standard was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001. Originally published in 1986; previously published March 2001.

1 Purpose

1.1 This document establishes a common basis for communication between users and suppliers of semiconductor manufacturing equipment by providing standards for measuring RAM performance of that equipment in a manufacturing environment.

2 Scope

2.1 The document defines six basic equipment states into which all equipment conditions and periods of time must fall. The equipment states are determined by functional issues, independent of who performs the function. The measurement of equipment reliability in this specification concentrates on the relationship of equipment failures to equipment usage, rather than the relationship of failures to total elapsed time.

2.2 Section 5 (Equipment States) defines how equipment time is categorized. Section 6 (RAM Measurement) defines formulas for measurement of equipment performance. Section 7 (Uncertainty Measurement) gives additional methods for evaluating the statistical significance of calculated performance metrics.

2.3 Effective application of this specification requires that equipment performance (RAM) be tracked with regard to time and/or equipment cycles. Automated tracking of equipment states is not within the scope of this specification, but is covered by SEMI E58. Clear and effective communication among users and suppliers promotes continuous improvement in equipment performance.

2.4 The RAM indices in this specification may be applied directly to non-cluster tools at the whole equipment and sub-system levels. The RAM indices may be applied at the sub-system level (e.g., process module) for multi-path cluster tools.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E58 — Automated Reliability, Availability, and Maintainability Standard (ARAMS)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *availability* — the probability that the equipment will be in a condition to perform its intended function when required.

4.2 *cluster tool* — a manufacturing system made up of integrated processing modules mechanically linked together (the modules may or may not come from the same supplier).

4.2.1 *single path cluster tool* — a cluster tool with only one process flow path (as used).

4.2.2 *multi-path cluster tool* — a cluster tool with more than one independent process flow path (e.g., multiple load ports/load-locks, multiple process chambers of the same type) and used as such.

4.3 *cycle* — one complete operational sequence (including unit load and unload) of processing, manufacturing, or testing steps for an equipment system or subsystem. In single unit processing systems, the number of cycles equals the number of units processed. In batch systems, the number of cycles equals the number of batches processed.

4.4 *downtime (DT)* — the time when the equipment is not in a condition, or is not available, to perform its intended function. It does not include any portion of non-scheduled time.

4.5 *downtime event* — a detectable occurrence significant to the equipment that causes the equipment to go from an uptime state to either a scheduled or an unscheduled downtime state.

4.6 *failure* — any unscheduled downtime event that changes the equipment to a condition where it cannot perform its intended function. Any part failure, software or process recipe problem, facility or utility supply malfunction, or human error could cause the failure.

NOTE 2: It is important to categorize and qualify failures in ways that facilitate the resolution of problems and improve overall equipment performance. Use of this specification requires agreement between supplier and user on categorizing failures.

4.6.1 *equipment-related failure* — any unplanned event that changes the equipment to a condition where it cannot perform its intended function solely caused by the equipment.

4.7 *host* — the intelligent system that communicates with the equipment, acts as a supervisory agent, and represents the factory and the user to the equipment.

4.8 *intended function* — a manufacturing function that the equipment was built to perform. This includes transport functions for transport equipment and measurement functions for metrology equipment, as well as process functions such as physical vapor deposition and wire bonding. Complex equipment may have more than one intended function.

4.9 *maintainability* — the probability that the equipment will be retained in, or restored to, a condition where it can perform its intended function within a specified period of time.

4.10 *maintenance* — the act of sustaining equipment in or restoring it to a condition to perform its intended function. In this document, maintenance refers to function, not organization; it includes adjustments, change of consumables, software upgrades, repair, preventive maintenance, etc., no matter who performs the task.

4.11 *manufacturing time* — the sum of productive time and standby time.

4.12 *non-scheduled time* — the time when the equipment is not scheduled to be utilized in production.

4.13 *operations time (oper-time)* — total time minus non-scheduled time.

4.14 *operator* — any person who communicates locally with the equipment through the equipment's control panel.

4.15 *product* — units produced during productive time (see unit).

4.16 *ramp-down* — the portion of a maintenance procedure required to prepare the equipment for hands-on work. It includes purging, cool-down, warm-up, software backup, storing dynamic values (e.g., parameters, recipes), etc. Ramp-down is only included in scheduled and unscheduled downtime.

4.17 *ramp-up* — the portion of a maintenance procedure required, after the hands-on work is completed, to return the equipment to a condition where it can perform its intended function. It includes pump down, warm-up, stabilization periods, initialization routines, software load, restoring dynamic values (e.g., parameters, recipes), control system reboot, etc. It does not include equipment or process test time. Ramp-up is only included in scheduled and unscheduled downtime.

4.18 *reliability* — the probability that the equipment will perform its intended function, within stated conditions, for a specified period of time

4.19 *shutdown* — the time required to put the equipment in a safe condition when entering a non-scheduled state. It includes any procedures necessary to reach a safe condition. Shutdown is only included in non-scheduled time.

4.20 *specification (equipment operation)* — the documented set of intended functions within stated conditions for equipment operation as agreed upon between user and supplier.

4.21 *start-up* — the time required for equipment to achieve a condition where it can perform its intended function, when leaving a non-scheduled state. It includes pump down, warm-up, cool-down, stabilization periods, initialization routines, software load, restoring dynamic values (e.g., parameters, recipes), control system reboot, etc. Start-up is only included in non-scheduled time.

4.22 *support tool* — a tool that, although not part of a piece of equipment, is required by and becomes integral with it during the course of normal operation (e.g., cassettes, wafer carriers, probe cards, computerized controllers/monitors).

4.23 *total time* — all time (at the rate of 24 hrs/day, 7 days/week) during the period being measured. In order to have a valid representation of total time, all six basic equipment states must be accounted for and tracked accurately.

4.24 *training (off-line)* — the instruction of personnel in the operation and/or maintenance of equipment done outside of operations time. Off-line training is only included in non-scheduled time.

4.25 *training (on-the-job)* — the instruction of personnel in the operation and/or maintenance of equipment done during the course of normal work functions. On-the-job training typically does not interrupt operation or maintenance activities and can therefore be included in any equipment state (except standby and non-scheduled) without special categorization.

4.26 *unit* — any wafer, substrate, die, packaged die, or piece part thereof.

4.27 *uptime* — the time when the equipment is in a condition to perform its intended function. It includes productive, standby, and engineering time, and does not include any portion of non-scheduled time.

4.28 *user* — any entity interacting with the equipment, either locally as an operator or remotely via the host. From the equipment's view point, both the operator and the host represent the user.

4.29 *utilization* — the percent of time the equipment is performing its intended function during a specified time period.

4.30 *verification run* — a single cycle of the equipment (using units or no units) used to establish that it is performing its intended function within specifications.

5 Equipment States

5.1 To clearly measure equipment performance (RAM), this document defines six basic equipment states into which all equipment conditions and periods of time must fall.

5.2 The equipment states are determined by function, not by organization. Any given maintenance procedure, for example, is classified the same way no matter who performs it, an operator, a production technician, a maintenance technician, or a process engineer.

5.3 Figure 1 is a stack chart of the six basic equipment states. These basic equipment states can be divided into as many sub-states as are required to achieve the equipment tracking resolution that a manufacturing operation desires. SEMI E10 makes no attempt to list all possible sub-states, but does give some examples for guidance.

5.4 Key blocks of time associated with the basic states and example substates are given in Figure 2. These blocks of time are used in the RAM equations given later in this document. The blocks of time associated with the basic states and example substates are described in the following sections.

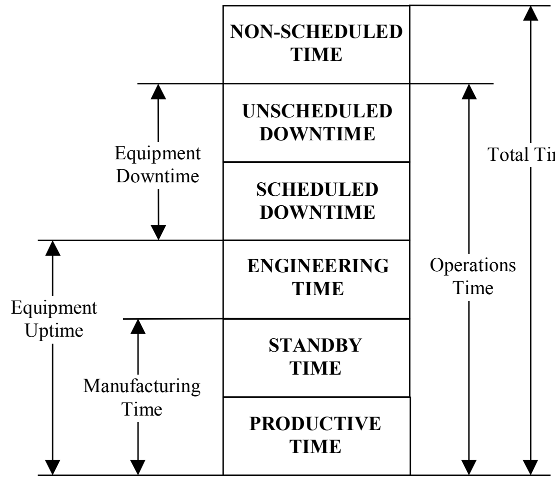

Figure 1
Equipment States Stack Chart

5.5 *PRODUCTIVE STATE* — The time (productive time) when the equipment is performing its intended function. The productive state includes:

- Regular production (including loading and unloading of units)
- Work for third parties
- Rework
- Engineering runs done in conjunction with production units (e.g., split lots and new applications)

5.6 *STANDBY STATE* — The time (standby time), other than non-scheduled time, when the equipment is in a condition to perform its intended function, chemicals and facilities are available, but it is not operated. The standby state includes:

- No operator available (including breaks, lunches, and meetings)
- No units available (including no units due to lack of available support equipment, such as metrology tools)
- No support tools (e.g., cassettes, wafer carriers, probe cards)
- No input from external automation systems (i.e., host)

5.7 *ENGINEERING STATE* — The time (engineering time) when the equipment is in a condition to perform its intended function (no equipment or process problems exist), but is operated to conduct engineering experiments. The engineering state includes:

- Process engineering (e.g., process characterization)
- Equipment engineering (e.g., equipment evaluation)
- Software engineering (e.g., software qualification)

5.8 *SCHEDULED DOWNTIME STATE* — The time (scheduled downtime) when the equipment is not available to perform its intended function due to planned downtime events. The scheduled downtime state includes:

- Maintenance delay (maint-delay)
- Production test
- Preventive maintenance
- Change of consumables/chemicals
- Setup
- Facilities related (fac-rel)

5.8.1 *Maintenance Delay* — The time (maint-delay downtime) during which the equipment cannot perform its intended function because it is waiting for either user or supplier personnel or parts (including consumables/chemicals) associated with maintenance. Maintenance delay may also be due to an administrative decision to leave the equipment down and postpone maintenance.

5.8.1.1 Maintenance delays may occur at any point in the maintenance process. These maintenance delay downtimes must be tracked separately from maintenance time. Delay downtime is included in time off-line, but not in time to repair (see Sections 6.3 and 6.4 Equipment Availability and Maintainability).

5.8.2 *Production Test* — The time (production test downtime) for the planned interruption of equipment availability for evaluation of units, as defined in the specifications of equipment operation, to confirm that the equipment is performing its intended function within specifications. It does not include testing that can be done in parallel with, or transparent to, the running of production, nor does it include any testing done following a preventive maintenance, setup, or repair procedure.

5.8.3 *Preventive Maintenance* — The sum of the times (preventive maintenance downtimes) for:

- Preventive action: A predefined maintenance procedure (including equipment ramp-down and ramp-up), at scheduled intervals, designed to reduce the likelihood of equipment failure during operation. Scheduled intervals may be based upon time, equipment cycles, or equipment conditions.
- Equipment test: The operation of equipment to demonstrate equipment functionality; (e.g., system reaches base pressure, wafers transfer without problem, gas flow is correct, plasma ignites, source reaches specified power).
- Verification run: The processing and evaluation of units after preventive action to establish that the equipment is performing its intended function within specifications.

NOTE 3: Equipment suppliers are responsible for specifying a preventive maintenance program to achieve a predetermined equipment performance level. Users are obligated to identify any deviation from the recommended program if they expect the supplier to meet or improve that performance level.

5.8.4 *Change of Consumables/Chemicals* — The time (change of consumables/chemicals downtime) for the scheduled interruption of operation to replenish the raw materials of semiconductor processing. It includes changes of gas bottles, acids, targets, sources, etc., and any purging, cleaning, or flushing normally associated with those changes. It does not include delays in obtaining those consumables/chemicals.

5.8.5 *Setup* — The sum of the times (setup downtimes) for:

- Conversion: The time required to complete an equipment alteration necessary to accommodate a change in process, unit, package configuration, etc. (excluding modifications, rebuilds, and upgrades).
- Equipment test: The operation of equipment to demonstrate equipment functionality; (e.g., system reaches base pressure, wafers transfer without problem, gas flow is correct, plasma ignites, source reaches specified power).
- Verification run: The processing and evaluation of units after conversion to establish that equipment is performing its intended function within specifications.

NOTE 4: Equipment suppliers are responsible for providing procedures which achieve setup conversion and testing within predetermined specifications. Users are obligated to identify any deviation from the procedures if they expect the supplier to make setups fall within those specifications.

5.8.6 *Facilities Related* — The time (facilities-related downtime) when the equipment cannot perform its intended function solely as a result of out of specification facilities. Those facilities include:

- Environmental (e.g., temperature, humidity, vibration, particle count)
- House hookups (e.g., power, cooling water, house gases, exhaust, LN2)

- Communications links with other equipment or host computers

5.8.6.1 Any downtime created by the items listed above shall be included in facilities-related downtime. For example, if, as a result of a scheduled 15-minute power outage an otherwise unnecessary cryo pump regeneration is needed, all time required to return the equipment to a condition where it can perform its intended function is included in facilities-related downtime.

5.9 *UNSCHEDULED DOWNTIME STATE* — The time (unscheduled downtime) when the equipment is not in a condition to perform its intended function due to unplanned downtime events:

- Maintenance delay (maint-delay)
- Repair
- Change of consumables/chemicals
- Out-of-spec input
- Facilities related (fac-rel)

5.9.1 *Maintenance Delay* — The time (maint-delay downtime) during which the equipment cannot perform its intended function because it is waiting for either user or supplier personnel or parts (including consumables/chemicals) associated with maintenance. Maintenance delay may also be due to an administrative decision to leave the equipment down and postpone maintenance.

5.9.1.1 Maintenance delays may occur at any point in the maintenance process. These maintenance delay downtimes should be tracked separately from maintenance time. Delay downtime is included in time off-line, but not in maintenance time (see Sections 6.3 and 6.4 Equipment Availability and Maintainability).

5.9.2 *Repair* — The sum of the times (repair downtimes) for:

- Diagnosis: The procedure of identifying the source of an equipment problem or failure.
- Corrective action: The maintenance procedure (including equipment ramp-down and ramp-up, re-booting, resetting, recycling, restarting, reverting to a previous software version, etc.) employed to address an equipment failure and return the equipment to a condition where it can perform its intended function.
- Equipment test: The operation of equipment to demonstrate equipment functionality (e.g., system reaches base pressure, wafers transfer without problem, gas flow is correct, plasma ignites, source reaches specified power).
- Verification run: The processing and evaluation of units after corrective action to establish that the equipment is performing its intended function within specifications.

5.9.3 *Change of Consumables/Chemicals* — The time (change of consumables/chemicals downtime) for the unscheduled interruption of operation to replenish the raw materials of semiconductor processing. It includes changes of gas bottles, acids, targets, sources, etc., and any purging, cleaning, or flushing normally associated with those changes. It does not include delays in obtaining these consumables/chemicals.

5.9.4 *Out-of-Spec Input* — The time (out-of-spec input downtime) when the equipment cannot perform its intended function solely as a result of problems created by out-of-specification or faulty inputs. Those inputs include:

- Support tools (e.g., warped cassettes or wafer carriers, faulty probe cards, reticles)
- Unit (e.g., upstream process problems, warped wafers, contaminated wafers, warped lead frames)
- Test data (e.g., metrology tool out of calibration, misread charts, erroneous data interpretation/entry)
- Consumables/chemicals (e.g., contaminated acid, leaky target bond, degraded photo resist, degraded mold compound)

5.9.4.1 Any downtime created by the items listed above shall be included in out-of-specification input downtime. For example, if, as a result of an intermittent probe card short, a prober/tester system is put down for repair, all downtime incurred prior to identifying the problem is re-categorized as out-of-specification input downtime.

5.9.5 *Facilities Related* — The time (facilities-related downtime) when the equipment cannot perform its intended function solely as a result of out-of-specification facilities. Those facilities include:

- Environmental (e.g., temperature, humidity, vibration, particle count)
- House hookups (e.g., power, cooling water, house gases, exhaust, LN2)
- Communications links with other equipment or host computers

5.9.5.1 Any downtime created by the items listed above shall be included in facilities-related downtime. For example, if, as a result of an unscheduled 15-minute power outage, an otherwise unnecessary cryo pump regeneration is needed, all time required to return the equipment to a condition where it can perform its intended function is included in facilities-related downtime.

5.10 *NON-SCHEDULED STATE* — The time (non-scheduled time) when the equipment is not scheduled to be utilized in production, such as unworked shifts, weekends, and holidays (including shutdown and start-up).

5.10.1 If equipment is out of the production plan due to off-line training or an installation, modification, rebuild, or upgrade (hardware or software) that cannot be accommodated by the regular preventive maintenance schedule, its status is the non-scheduled state. This includes any qualification time required to bring the equipment to a condition where it can perform its intended function from one of these states.

5.10.2 Any maintenance done to equipment during these periods cannot be counted in the non-scheduled state, since all maintenance must fall into either scheduled or unscheduled downtime (this includes automatic maintenance routines such as a programmed cryo pump regeneration).

5.10.3 By the same convention, any production or engineering work done during these periods must fall into either productive or engineering time (this includes an unattended operation that may shut itself off "after hours").

6 RAM Measurement

6.1 Reliability, availability, and maintainability are measures of equipment performance which have been used widely in industry for decades. This section defines them for the semiconductor industry in a manner that is consistent with existing industrial standards. Along with the definitions for RAM are given indicators by which these measures can be quantified.

6.2 *EQUIPMENT RELIABILITY* — The probability that the equipment will perform its intended function, within stated conditions, for a specified period of time.

NOTE 5: Two different methods of measuring this are presented, productive time (Sections 6.2.1 and 6.2.2) and equipment cycles (Sections 6.2.3 and 6.2.4):

- Productive time only considers what happens while making units (useful for manufacturing operation purposes).
- Equipment cycles take into account the wear and tear created by every machine cycle during all equipment states (useful for equipment reliability purposes).

6.2.1 $MTBF_p$ — Mean (productive) time between failures; the average time the equipment performed its intended function between failures; productive time divided by the number of failures during that time. Only productive time is included in this calculation. Failures that occur when an attempt is made to change from any state to a productive state are included in this calculation. Using $MTBF_p$, therefore, requires that the user not only have the capability of capturing failure information, but also tracking and categorizing total time accurately.

$$MTBF_p = \frac{\textit{productive time}}{\textit{\# of failures that occur during productive time}}$$

6.2.2 $E\text{-}MTBF_p$ — Mean (productive) time between equipment-related failures; the average time the equipment performed its intended function between these equipment-related failures; productive time divided by the number of equipment-related failures during that time. Only productive time is included in this calculation. Equipment-related failures that occur when an attempt is made to change from any state to a productive state are included in this calculation. Using $E\text{-}MTBF_p$, therefore, requires that the user not only have the capability of capturing failure information, but also tracking and categorizing total time and the root causes of failures accurately.

$$E\text{–}MTBF_p = \frac{\textit{productive time}}{\textit{\# of equipment-related failures that occur during productive time}}$$

6.2.3 *MCBF* — Mean cycles between failures; the average number of equipment cycles between failures; total equipment cycles divided by the number of failures during those cycles. This calculation transcends equipment states to include all cycles that the system, or subsystem, being considered experiences. It does not require tracking equipment states, only equipment cycles and equipment failures.

$$MCBF = \frac{\textit{total equipment cycles}}{\textit{\# of failures}}$$

6.2.4 *E-MCBF* — Mean cycles between equipment-related failures; the average number of equipment cycles between these equipment-related failures; total equipment cycles divided by the number of equipment-related failures during those cycles. This calculation transcends equipment states to include all cycles that the system, or subsystem, being considered experiences. It does not require tracking equipment states, only equipment cycles and equipment-related failures and their root causes.

$$E\text{–}MCBF = \frac{\textit{total equipment cycles}}{\textit{\# of equipment-related failures}}$$

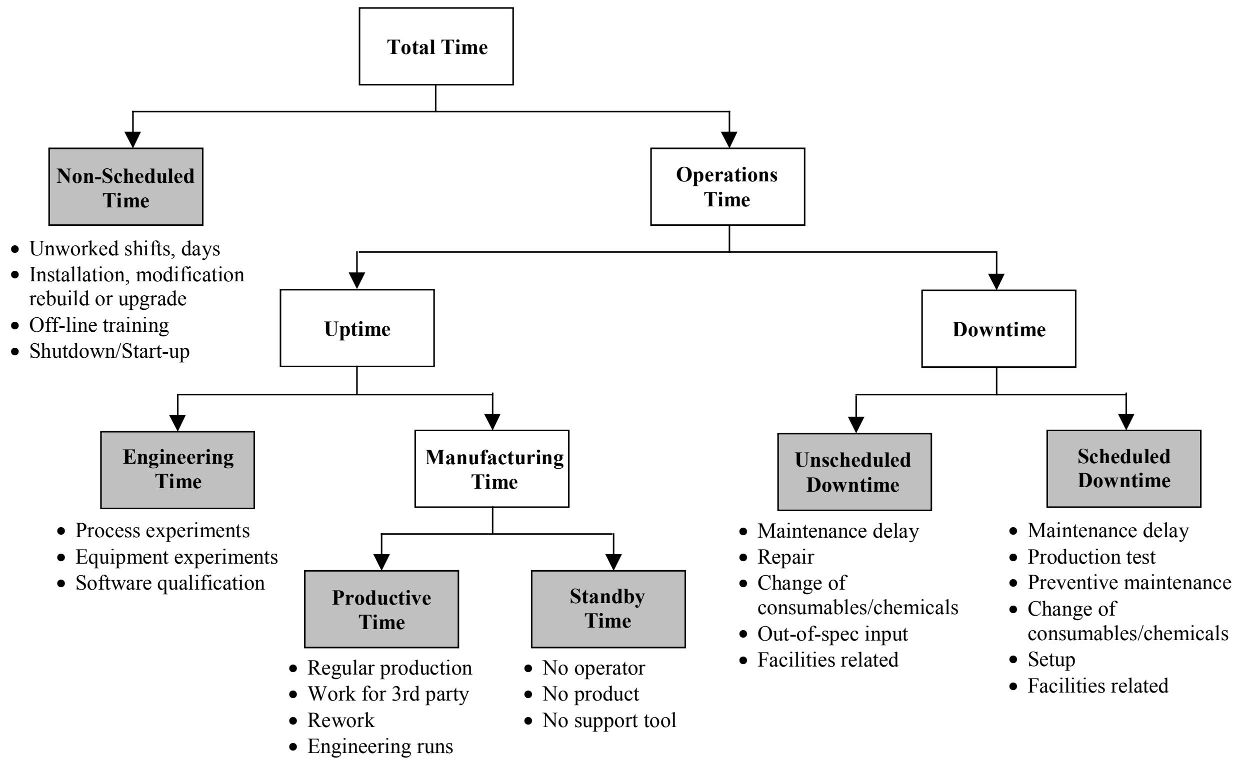

Figure 2
SEMI E10 Summary of Time

6.3 *EQUIPMENT AVAILABILITY* — The probability that the equipment will be in a condition to perform its intended function when required.

6.3.1 *Equipment Dependent Uptime* — The percent of time the equipment is in a condition to perform its intended function during the period of operations time minus the sum of all maintenance delay downtime, out-of-spec input downtime, and facilities-related downtime. This calculation is intended to reflect equipment reliability and maintainability based solely on equipment merit.

$$\textit{equipment dependent uptime (\%)} = \frac{\textit{equipment uptime} \times 100}{\textit{(oper-time – (all maint-delay DT + out-of-spec input DT + fac-rel DT))}}$$

6.3.2 *Supplier Dependent Uptime* — The percent of time the equipment is in a condition to perform its intended function during the period of operations time minus the sum of user maintenance delay downtime, out-of-spec input downtime, and facilities-related downtime. This calculation subtracts only user maintenance delay downtime from the period, thereby taking into account supplier delays for parts and service. The intention is to provide an effective performance measurement for use in supplier service contracts.

$$\textit{supplier dependent uptime (\%)} = \frac{\textit{equipment uptime} \times 100}{\textit{(oper-time – (user maint-delay DT + out-of-spec input DT + fac-rel DT))}}$$

6.3.3 *Operational Uptime* — The percent of time the equipment is in a condition to perform its intended function during the period of operations time. This calculation is intended to reflect overall operational performance for a piece of equipment.

$$\textit{operational uptime}\ (\%) = \frac{\textit{equipment uptime} \times 100}{\textit{operations time}}$$

6.4 *EQUIPMENT MAINTAINABILITY* — The probability that the equipment will be retained in, or restored to, a condition where it can perform its intended function within a specified period of time.

6.4.1 *MTTR* — Mean time to repair; the average time to correct a failure and return the equipment to a condition where it can perform its intended function; the sum of all repair time (elapsed time not necessarily total man hours) incurred during a specified time period (including equipment and process test time, but not including maintenance delay downtime), divided by the number of failures during that period.

$$MTTR = \frac{total\ repair\ time}{\#\,of\ \ failures}$$

6.4.2 *E-MTTR* — Mean time to repair equipment-related failures; the average time to correct an equipment-related failure and return the equipment to a condition where it can perform its intended function; the sum of all equipment-related failure repair time (elapsed time, not necessarily total man hours) incurred during a specified time period (including equipment and process test time, but not including maintenance delay downtime), divided by the number of equipment-related failures during that period.

$$E\text{–}MTTR = \frac{total\ repair\ time\ for\ equipment\text{-}related\ failures}{\#\ of\ equipment\text{-}related\ failures}$$

6.4.3 *MTOL* — Mean time off-line; the average time to maintain the equipment in or return the equipment to a condition where it can perform its intended function when downtime is incurred; the sum of all downtime (scheduled and unscheduled) during a specified time period, divided by the number of downtime events during that period.

$$MTOL = \frac{total\ equipment\ downtime}{\#\ \ of\ DT\ events}$$

6.4.4 *Equipment Dependent Scheduled Downtime* — The percent of time the equipment is not available to perform its intended function due to scheduled downtime events such as preventive maintenance. This time period does not include any maintenance delay downtime caused either by supplier or user. This calculation is intended to reflect the need for preventive maintenance based solely on equipment design.

$$equipment\ dependent\ scheduled\ downtime\ (\%) = \frac{equipment\ scheduled\ downtime \times 100}{(oper\text{-}time - (all\ maint\text{-}delay\ DT + out\text{-}of\text{-}spec\ input\ DT + fac\text{-}rel\ DT))}$$

6.4.5 *Supplier Dependent Scheduled Downtime* — The percent of time the equipment is not available to perform its intended function due to scheduled downtime events, such as preventive maintenance. This time period does not include any maintenance delay downtime caused by the user. This calculation is intended to reflect the need for preventive maintenance based solely on equipment design and supplier response to service.

$$supplier\ dependent\ scheduled\ downtime\ (\%) = \frac{equipment\ scheduled\ downtime \times 100}{(oper\text{-}time - (user\ maint\text{-}delay\ DT + out\text{-}of\text{-}spec\ input\ DT + fac\text{-}rel\ DT))}$$

6.5 *EQUIPMENT UTILIZATION* — The percent of time the equipment is performing its intended function during a specified time period.

6.5.1 *Operational Utilization* — The percent of productive time during operations time. This calculation is intended to be used for equipment utilization comparisons between operations with different work shift configurations, since it does not include non-scheduled time.

$$operational\ utilization\ (\%) = \frac{productive\ time \times 100}{operations\ time}$$

6.5.2 *Total Utilization* — The percent of productive time during total time. This calculation is intended to reflect bottom-line equipment utilization.

$$total\ utilization\ (\%) = \frac{productive\ time \times 100}{total\ time}$$

Table 1 RAM Measurement Metric Summary

EQUIPMENT RELIABILITY		
Metric	*How It Is Measured*	*Ref #*
$MTBF_p$: Mean (productive) time between failures	productive time/ # of failures that occur during productive time	6.2.1
E-$MTBF_p$: Mean (productive) time between equipment-related failures	productive time/ # of equipment-related failures that occur during productive time	6.2.2
MCBF: Mean cycles between failures	total equipment cycles/ # of failures	6.2.3
E-MCBF: Mean cycles between equipment-related failures	total equipment cycles/ # of equipment-related failures	6.2.4
EQUIPMENT AVAILABILITY		
Metric	*How It Is Measured*	*Ref #*
equipment dependent uptime (%)	equipment uptime × 100/(oper-time – (all maint-delay DT + out-of-spec input DT + fac-rel DT))	6.3.1
supplier dependent uptime (%)	equipment uptime × 100/(oper-time – (users maint-delay DT + out-of-spec input DT + fac-rel DT))	6.3.2
operational uptime (%)	equipment uptime × 100/ operations time	6.3.3
EQUIPMENT MAINTAINABILITY		
Metric	*How It Is Measured*	*Ref #*
MTTR: Mean time to repair	total repair time/ # of failures	6.4.1
E-MTTR: Mean time to repair for equipment-related failures	total repair time for equipment-related failures/ # of equipment-related failures	6.4.2
MTOL: Mean time off-line	total equipment downtime/ # of DT events	6.4.3
equipment dependent scheduled downtime (%)	equipment scheduled downtime × 100/(oper-time – (all maint-delay DT + out-of-spec input DT + fac-rel DT))	6.4.4
supplier dependent scheduled downtime (%)	equipment scheduled downtime × 100/(oper-time – (user maint-delay DT + out-of-spec input DT + fac-rel DT))	6.4.5
EQUIPMENT UTILIZATION		
Metric	*How It Is Measured*	*Ref #*
operational utilization (%)	productive time × 100/ operations time	6.5.1
total utilization (%)	productive time × 100/ operations time	6.5.2

NOTE: oper-time = operational time, DT = Downtime, fac-rel = facilities related, maint-delay = maintenance delay

7 Uncertainty Measurement

7.1 The measures of equipment reliability, availability, and maintainability defined in Section 6 are single value estimates. They do not indicate the uncertainty or precision of the estimate. Precision varies depending upon the number of failures observed and the amount of productive time contained within the observation period.

7.2 Precision is described by calculating a lower and upper confidence limit for the $MTBF_p$ and presenting this interval along with the $MTBF_p$ point estimate.

7.3 These procedures assume that the failure rate is constant and the times between failures are independently distributed according to the exponential distribution. Therefore, there are no improvement or degradation trends and it is meaningful to calculate $MTBF_p$. Section 8 applies when the failure times indicate that a non-constant failure rate is present (for example, when there is reliability growth or degradation). Section 8 would typically apply during prototype reliability improvement testing.

7.4 Since MTTR distributions are unlikely to follow an exponential distribution assumption, applying these procedures to put confidence limits on MTTR would be inappropriate.

7.5 Note that all procedures and tables referred to in this section apply equally well to measuring the precision of estimates for similar metrics, where hours are replaced by cycles or units, for example. These procedures apply to E-$MTBF_p$ or E-MCBF in the same way. It is also appropriate to combine data from identical tools being used the same way, in order to improve the precision of $MTBF_p$ estimates.

7.6 *Calculation of Lower and Upper Confidence Limits* — To obtain lower and upper $MTBF_p$ limits, multiply the $MTBF_p$ estimate by factors obtained by table look-up (Tables A1-1 and A1-2 in Appendix 1). For the case when there are zero failures during the measurement period, lower confidence limit factors for the $MTBF_p$ are given in the first row of Table A1-1 (they multiply the amount of productive time that had no failures to obtain the desired $MTBF_p$ lower limit). There is no upper limit estimate for performance when there are zero failures.

7.6.1 *Calculation of the $MTBF_p$ Lower Limit* — Use Table A1-1 in Appendix 1 to obtain a $k_{r;conf}$ factor, where r is the number of failures observed during the measurement period and *conf* is the confidence level desired. The rows of Table A1-1 correspond to different values of r and the columns correspond to different values of *conf*. Confidence levels ranging from 80 percent to 95 percent are typical choices.

7.6.1.1 Since the equipment being measured has demonstrated (at a given confidence level) that it is at least as good as the $MTBF_p$ lower limit, this lower limit is an important and useful performance statistic, and is often used contractually.

7.6.1.2 Note that the factors in Table A1-1 for 90% confidence are less than 0.5 until the number of failures equals or exceeds 4. This means that when the number of failures is under 4, the $MTBF_P$ lower limit will be less than half the $MTBF_p$ estimate, and confidence intervals will be wide. From the point of view of precision, it is advantageous to have had 4 or more failures.

7.6.1.3 *Example*: During a given calendar quarter, a tool was productive for 1200 hours and had 6 failures. The $MTBF_p$ estimate is 1200/6 = 200 hours. A 90 percent lower limit factor from Table A1-1 (corresponding to r = 6 failures) is 0.570. That means that 200 × 0.570 = 114.0 hours is a 90 percent lower confidence limit for the true tool $MTBF_p$.

7.6.2 *Calculation of the $MTBF_p$ Upper Limit* — Use Table A1-2 in Appendix 1 to obtain a $k_{r;conf}$ factor, where r is the number of failures observed during the measurement period and *conf* is the confidence level desired. The rows of Table A1-2 correspond to different values of r and the columns correspond to different values of *conf*. Confidence levels ranging from 80 percent to 95 percent are typical choices.

7.6.2.1 *Example*: During a given calendar quarter, a tool was productive for 1200 hours and had 6 failures. The $MTBF_p$ estimate is 1200/6 = 200 hours. A 90 percent upper limit factor from Table A1-2 (corresponding to r = 6 failures) is 1.904. That means that 200 × 1.904 = 380.8 hours is a 90 percent upper confidence limit for the true tool $MTBF_p$.

7.6.3 *Calculation of a Confidence Interval for the $MTBF_p$* — Lower and upper $100 \times (1 - \alpha/2)$ confidence limits for the $MTBF_p$ can be combined to give a $100 \times (1 - \alpha)$ confidence interval. Here $\alpha/2$ is the chance of missing on either end of the interval. A 90 percent lower limit has an $\alpha/2 = 0.1$ chance of not being low enough to capture the true $MTBF_p$, and the same is true for a 90 percent upper limit. Therefore, a 90 percent lower limit and a 90 percent upper limit combine to give an 80 percent confidence interval. Similarly, a 95 percent lower limit and a 95 percent upper limit would combine to give a 90 percent confidence interval.

7.6.3.1 *Example*: During a calendar quarter, a tool was productive for 1200 hours and had 6 failures. The $MTBF_p$ estimate is 1200/6 = 200 hours. The 90 percent lower and upper limits are 114 and 380.8 respectively (see Sections 7.6.1 and 7.6.2). The interval (114, 380.8) is then an 80 percent confidence interval for the true tool $MTBF_p$.

7.6.4 *Calculation of the $MTBF_p$ Lower Bound when there are Zero Failures* — Use the first row of Table A1-1 (corresponding to $r = 0$) to obtain a $k_{0;conf}$ factor corresponding to the desired confidence level. Multiply the length of the measurement period by this factor to obtain the lower limit estimate.

7.6.4.1 *Example*: During a calendar quarter, a tool was productive for 1200 hours and had zero failures. From Table A1-1, the 90% confidence level lower limit factor is 0.434. That means that 1200 × 0.434 = 520.8 hours, is a 90% lower confidence limit estimate for the true tool $MTBF_p$.

7.6.5 Choosing a test length in order to be able to demonstrate a required $MTBF_p$ at a given confidence, we first must pick a maximum number of failures, *r*, that can occur during the test period and still allow us to confirm a required $MTBF_p$ objective at a given confidence level. Next, the length of test time needed can be calculated using the factors in Table A1-4 in Appendix 1. The required $MTBF_p$ is multiplied by a factor based on *r* and the desired confidence level to obtain the total test time needed.

7.6.5.1 Note that minimum test times are obtained by allowing no failures. The cost, however, of using a minimum test length is to increase the possibility of an acceptable tool failing the test by chance. As mentioned in the discussion in Section 6.2.1, it is advantageous to design a test that allows up to 4 failures, whenever possible.

7.6.5.2 *Example*: We would like to confirm a tool $MTBF_p$ of 400 hours at an 80% confidence level. We want to be able to pass a qualification test with 4 or less failures. We look up the appropriate factor from Table A1-4 and find 6.72. That means the length of test time required is 400 × 6.72 = 2688 hours. We can do this on one tool or split the test time across several tools. When we have accumulated 2688 hours and if 4 or less failures have occurred, the $MTBF_p$ objective of 400 hours will have been confirmed at (at least) the 80% confidence level.

8 Reliability Growth or Degradation Measurement

8.1 The previous calculations are meaningful only when the $MTBF_p$ (or MCBF) and E-$MTBF_p$ (or E-MCBF) are constant over the measurement period. If reliability is improving (typical during design verification and debug and also early life run-in) or if reliability is degrading (typical near the end of life for the piece of equipment, or if certain sub-assemblies have been over-stressed and are wearing out) then an overall $MTBF_p$ calculation is inappropriate and misleading and other methods must be used. Exact time of failure recording is required in order to detect reliability improvement or reliability degradation trends, and to fit appropriate models.

8.2 *Exact Time of Failure Recording* — Clock times of failure must be converted to durations of cumulative productive time as measured from the initial productive use of the tool (set as time 0). This is easily accomplished if total time is continuously monitored by duration within each of the six equipment states.

8.2.1 *Example*: A machine is intended for use during first shift operation five days a week. For simplicity, assume 100% productive utilization. After the first three weeks of use, it fails half-way through the day, and is not repaired until the start of the next day's operation. No more failures occur before the end of the first four weeks of operation. The exact time of failure is 124 hours (three weeks of 5 × 8 = 40 hours per week plus half of an 8 hour day). If a second failure occurred two hours into the third day of the fifth week, the exact time of failure would be 174 hours.

8.3 *Reliability Growth (Degradation) Models* — A useful family of reliability growth (degradation) models was developed by the U.S. Army Materials Systems Analysis Activity. These AMSAA models are described in Appendix 2, along with a general test for reliability growth (degradation) trends. Exact time of failure data is needed to test for trends, fit an AMSAA model, and test the fit for adequacy. The failures used to fit the model must occur during productive time (other failures can occur, but these are not used to fit reliability models).

APPENDIX 1
CONFIDENCE BOUND FACTORS

NOTE: This appendix was approved as an official part of SEMI E10 by full letter ballot procedure. It offers detailed information related to Section 7.

A1-1 *Introduction*

A1-1.1 E-MTBF$_p$ may be substituted for MTBF$_p$ in all calculations in this section.

A1-1.2 Tables A1-1 and A1-2 contain factors that multiply an MTBF$_p$ point estimate to obtain upper and lower confidence limits. Table A1-1 applies in the common case where the equipment is observed for a fixed period of time and the number of failures that will occur is unknown in advance (time censored data). The alternative is failure censored data, where the number of failures is specified in advance and the equipment is observed until that many failures occur. Table A1-3 contains lower limit factors for failure censored data. Since failure censored data rarely occurs in tool or equipment reliability measurement, Table A1-3 is only included for completeness. The upper limit factors given in Table A1-2 apply to both kinds of censored data.

A1-1.3 Table A1-4 can be used to plan equipment assessment or qualification tests in order to be able to demonstrate a desired MTBF$_p$ at a given confidence level. In order to use Table A1-4, you must first choose a maximum number of failures, *r*, you might observe during the test period and still be able to meet the required MTBF$_p$ objective.

A1-1.4 For reference, here are the formulas for the lower and upper confidence limit factors for time censored data found in Tables A1-1 and A1-2:

$$MTBF_{LOWER} = \frac{2r}{X^2_{2r+2;1-\alpha}} \times MTBF_p$$

$$\text{where } r = \# \text{ of failures}$$

$$MTBF_{UPPER} = \frac{2r}{X^2_{2r;\alpha}} \times MTBF_p$$

A1-1.5 In both cases, the confidence level is 100 × (1 – α) that the true MTBF$_p$ is above MTBF$_{LOWER}$ and below MTBF$_{UPPER}$ and chi square distribution tables are used.

A1-1.6 For 0 fails, use:

$$MTBF_{LOWER} = \frac{\text{productive time}}{-\log_e \alpha}$$

A1-1.7 Factors to use when there are 0 failures based on this formula are given in the first row of Table A1-1.

A1-1.8 For failure censored data, MTBF$_{UPPER}$ is the same, but the lower limit factor in Table A1-3 is:

$$MTBF_{LOWER} = \frac{2r}{X^2_{2r;1-\alpha}} \times MTBF_p$$

Table A1-1 1-Sided Lower Confidence Bound Factors for the $MTBF_p$ (Time or Cycle Censored Data or Fixed Length Test)

Use for time or cycle censored data to multiply the $MTBF_p$ or MCBF estimate to obtain a lower bound at the given confidence level.
For 0 failures, multiply the operating hours or cycles by the factor corresponding to the desired confidence level.

APPENDIX 2
RELIABILITY GROWTH OR DEGRADATION MODELS

NOTE: This appendix was approved as an official part of SEMI E10 by full letter ballot procedure. It offers detailed information related to Section 8.

A2-1 *Introduction*

A2-1.1 E-MTBF$_p$ may be substituted for MTBF$_p$ in all calculations in this section.

A2-1.2 If the times between failures (known as "interarrival times") of a repairable system or piece of equipment are independent random times sampled from the same exponential distribution, then the (theoretical) *rate of occurrence of failures* ("ROCOF") is a constant λ and the MTBF$_p$ is just $1/\lambda$. This situation is known in the reliability literature as a *homogeneous poisson process* (HPP). An HPP assumption underlies the definition of MTBF$_p$ given in Section 6, and the confidence limit factors described in Section 7 and Appendix 1. These concepts are described in detail in Ascher and Feingold [1] and Tobias and Trindade [2].

A2-1.3 If reliability is either improving or degrading with time, then the ROCOF is no longer a constant and a MTBF$_p$ calculation will be misleading.

A2-1.4 This appendix contains a simple test for trend that may be applied if a time-varying ROCOF is suspected, as well as a description of a well known and powerful model that may be used when reliability improvement trends are evident in the equipment failure time data.

A2-2 *Testing for Trends*

A2-2.1 A non-parametric *reverse arrangement test* (RAT) devised by Kendall [3] and further developed into a table by Mann [4] will be described. Begin by writing the interarrival times in the order they occurred. For a period with r failures, these might be X_1, X_2, …, X_r. Starting from left to right, define a reversal as any instance in which a lesser value occurs before any subsequent greater value in the sequence. In other words, any time we have $X_i < X_j$ and $i < j$, we count it as a reversal. For example, suppose a piece of equipment has $r = 4$ failures at 30, 160, 220, and 360 hours of productive time. The interarrival times are 30, 130, 60, and 140. The total number of reversals is 3 + 1 + 1 = 5.

A2-2.2 A larger than expected number of reversals indicates an improving trend; a smaller number of reversals than expected indicates a degradation trend.

A2-2.3 For r up to 12, use Table A2-1 below (adapted from [2]) to determine whether a given number of reversals, R, is statistically significant at the $100 \times (1 - \alpha)$ confidence level.

A2-2.4 For r greater than 12, approximate critical values for the number of reversals (based on Kendall's normal approximation) can be calculated from:

$$R_{(r;\,1\text{-}\alpha)} = z_{critical}\sqrt{\frac{(2r+5)(r-1)r}{72}} + \frac{r(r-1)}{4} - \frac{1}{2}$$

Table A2-1 Critical Values $R_{r;1-\alpha}$ the Number of Reversals for the Reverse Arrangement Test at a Given Confidence Level

Sample Size	*Single-Sided Lower Critical Value (Too Few Reversals Provide Evidence of Degradation)*			*Single-Sided Upper Critical Value (Too Many Reversals Provide Evidence of Improvement)*		
r	99%	95%	90%	90%	95%	99%
4		0	0	6	6	
5	0	1	1	9	9	10
6	1	2	3	12	13	14
7	2	4	5	16	17	19
8	4	6	8	20	22	24
9	6	9	11	25	27	30
10	9	12	14	31	33	36
11	12	16	18	37	39	43
12	16	20	23	43	46	50

A2-2.5 In this equation $z_{critical}$ comes from the critical values of the standard normal distribution (for 90% significance, $z_{critical}$ = 1.282, for 95% significance, $z_{critical}$ = 1.645, and for 99% significance, $z_{critical}$ = 2.33). The formula calculates the critical value for detecting an improvement trend. For degradation trends (a small number of reversals) use $(r)(r - 1)/2$ minus $R_{r;1-\alpha}$ as the critical value. Note that $(r)(r - 1)/2$ just the total possible number of reversals when there are r failures.

A2-2.6 For example, with 17 failures, the formula for $R_{r;1-\alpha,}$ using 95% significance, gives a critical number of reversals of $R_{17,95}$ = 88. The maximum number of reversals is 17 × 16/2 = 136. That means that observing 88 or more reversals signals a likely improvement trend, while observing 136 − 88 = 48 or less reversals signals a likely degradation trend.

A2-2.7 The example given in the next section shows an application for the reverse arrangement test using Table A2-1.

A2-2.8 The *AMSAA Reliability Growth Model*: Assume the sequence of interarrival time indicates an improvement trend. This will typically be the case during reliability improvement testing, where failures are analyzed down to root causes and actions are taken to improve the equipment's reliability. Duane [5] observed that a plot of t_k/k versus t_k, where t_k is the system age at the time of kth failure, typically appears linear on log versus log graph paper. The slope β of this line measures the rate of reliability growth. Typical empirical values of β lie between 0.3 and 0.6. Crow [6] developed this empirical observation into the power relationship model used by the U.S. Army Materials Systems Analysis Activity (AMSAA model). This model has proved successful in a wide range of applications.

A2-2.9 The AMSAA model assumes that during reliability improvement testing the $MTBF_p$ is improving with time and has an instantaneous value denoted by $MTBF_I$ (t). When the test ends at time T, the $MTBF_p$ becomes a constant with the value $MTBF_I$ (T). An estimate of the $MTBF_p$ after a test of T hours with r failures is given by:

$$MTBF_I(T) = \frac{T}{r \times (1 - \beta)} \quad (1)$$

A2-2.10 In this equation, β is the reliability improvement (Duane) slope, β is estimated by

$$\beta = 1 - \frac{r - 1}{\sum_{i=1}^{r} \ln \frac{T}{t_i}} \quad (2)$$

using the *modified maximum likelihood estimates* given by Crow [6]. Crow developed confidence limits for $MTBF_I$ (T) that are described in [2] and [6].

A2-2.11 *Example*: During a calendar quarter a tool has 550 hours of productive time. Eleven failures were recorded at the following points of productive time: 18, 20, 35, 41, 67, 180, 252, 287, 390, 410, and 511 hours. Determine whether there appears to be an improvement trend and use the AMSAA model to estimate the achieved $MTBF_I$ at the end of the quarter.

A2-2.12 *Solution:* The interarrival times are: 18, 2, 15, 6, 26, 113, 72, 35, 103, 20, and 101. The number of reversals is 7 + 9 + 7 + 7 + 5 + 0 + 2 + 2 + 0 + 1 = 40. Using Table A2-1, this is significant at greater than the 95% confidence level, indicating an improvement trend is likely. Figure A2-1 shows the Duane plot, which appears to show a linear improvement trend on log-log paper. The AMSAA model equations give an improvement slope estimate of 0.43 and an instantaneous $MTBF_P$ estimate at 550 hours of 87.2. Note that a standard calculation ignoring the improvement trend would yield an $MTBF_P$ estimate of 550/11 = 50, which is a 43% underestimate.

A2-2.13 Figure A2-2 summarizes the recommended procedure to follow when analyzing system or equipment reliability data, with appropriate references to SEMI E10 sections or appendices.

RELATED INFORMATION 1
MULTI-PATH CLUSTER TOOL RAM METRICS

NOTE: This related information is not an official part of SEMI E10 and was derived from the work of the SEMI Cluster Tool RAM Metrics Task Force. This related information was approved for publication by vote of the NA Metrics Technical Committee on March 21, 2001.

R1-1 Introduction

R1-1.1 Multi-path cluster tools (also called flexible-sequence cluster tools in E79-0200 "Standard For Definition And Measurement Of Equipment Productivity") have become as much a part of the fab as HEPA filters over the past decade, but we still cannot apply uniform RAM metrics to them to determine their performance. A new approach that evaluates the tool as a series of systems will provide us with the ability to measure the conventional E10 RAM metrics with relative ease. In this new approach we look at each intended process path (IPP) as a separate entity, and the overall performance of the multi-path cluster tool is derived from the performance of the individual IPPs.

R1-2 Limitations of Existing E10 Metrics

R1-2.1 Within E10 it is specifically stated that the metrics that exist presently cannot handle multi-path cluster tools at an overall level, however they can be applied to the individual process modules. This allows us to measure reliability (e.g., $MTBF_p$), availability (e.g., operational uptime), and maintainability (e.g., MTTR) for the modules, but does not give us those measurements for the multi-path cluster tool as an entity itself.

R1-2.2 With this approach a multi-path cluster tool with multiple process chambers could have at least one chamber incapable of processing wafers all month, and still be considered up all month. After all, it was producing product. However, at the same time that it was making product it still had significant problems, which required equipment maintenance personnel to fix them. The present E10 definition of uptime would apply (i.e., the time when the equipment is in a condition to perform its intended function). In fact, it would even be possible to consider the system to be in the productive state (i.e., the time (productive time) when the equipment is performing its intended function).

R1-3 Intended Process Paths

R1-3.1 A process path is the sequential module-to-module flow that a given process follows from load to processing to unload. A cluster tool configuration may allow multiple process paths within the cluster tool. Users would determine the intended process paths (IPPs) for their multi-path cluster tools based on configuration and processes. It is important to differentiate between possible process paths and those that are actually intended for operational use. Figure R1-1 illustrates the process path concept. This example is a simplified generic multi-path cluster tool configuration that represents some of the potential module-to-module relationships. Automated module-level state change data collection is required to effectively calculate multi-path cluster tool RAM metrics.

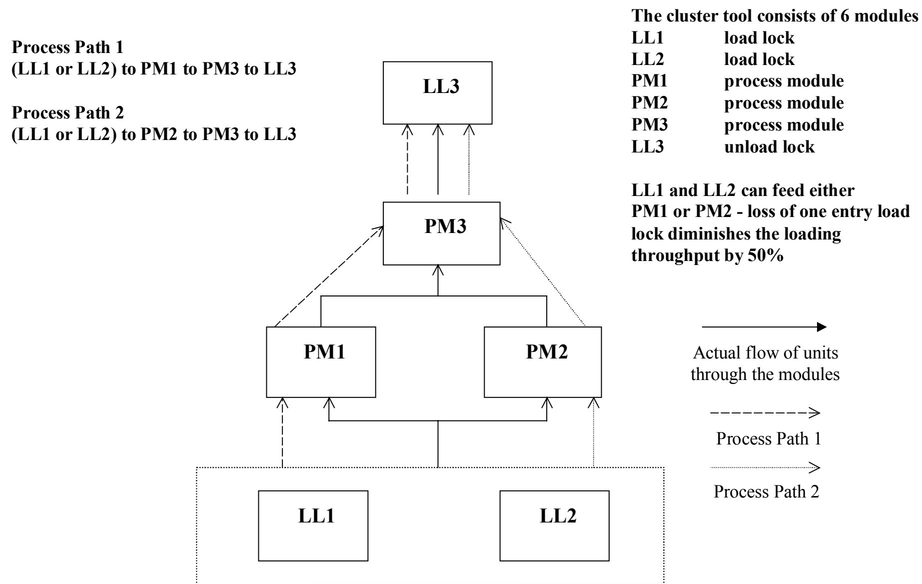

Figure R1-1
Multi-Path Cluster Tool Process Path Concept

R1-4 Determining What Makes up a Process Path

R1-4.1 A process path is comprised of a transport system and one or more process modules.

R1-4.2 The transport system in this scenario is considered to be a "non-processing module," as it is used in SEMI E79. It includes all other non-processing modules of the cluster tool besides the process modules and the hardware and software directly associated with them. A definition of a non-processing module is given below.

> Non-processing module — an equipment entity that supports the movement or conditioning of units through the system, such as,
>
> - robotic handler
> - load/unload lock
> - pre-aligner

R1-4.3 The processing modules are defined in SEMI E79 as:

> Processing module — an indivisible production entity within an equipment system, e.g., a processing chamber or station within a cluster tool.

R1-4.4 The intended process path is defined as the combination of one or more processing modules that are identified in the recipe per SEMI E79.

> Recipe — the pre-planned and reusable portion of the set of instructions, settings, and parameters under control of a processing agent, that determines the processing environment seen by the material. Recipes may be subject to change between runs or processing cycles (SEMI E38, SEMI E40, SEMI E42).

R1-4.5 For the example in Figure 1, the simplified process paths are shown below in Figure R1-2.

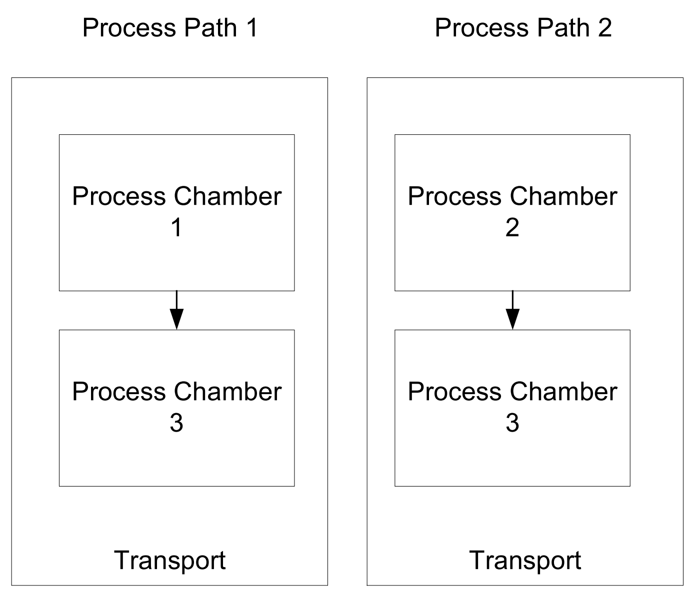

Figure R1-2
Simplified Process Paths

R1-5 Proposed New E10 Metrics

R1-5.1 By looking at the whole multi-path cluster tool as the sum of its intended process paths, we can produce valuable metrics that more accurately reflect the performance of the entire platform as a whole. The basis for this approach is in SEMI E79, where the concept of the multi-path cluster tool as an aggregate of its "virtual tools," is first described. By extending that concept to the E10 metrics as well, we can view the RAM performance similarly.

R1-5.2 Availability (e.g., operational uptime) is measured at the process path level. A process path is "Up" when its defined modules are in a state that allow the process path to execute its intended function.

R1-5.3 Operational uptime for the multi-path cluster tool would be defined as follows.

Operational Uptime (multi-path cluster tool) =

(Σ Uptime for All Intended Process Paths) ÷ [(# of Process Paths) × (Operations Time (as defined in E10) for the Multi-Path Cluster Tool)] × 100

NOTE: In cases where the loss of a module diminishes the throughput of a process path (e.g., the loss of one load lock which reduces throughput by 50%), the productivity loss is reflected in the overall equipment efficiency (OEE) rather than the availability.

R1-5.4 To determine the Process Path availability, a simple truth table could be used. Table R1-1 demonstrates availability determination for the multi-path cluster tool configuration noted in Figure R1-1.

Table R1-1 Simple Truth Table for Process Path Availability for Tool Configuration in Figure 1

LL1	LL2	PM1	PM2	PM3	LL3	IPP 1	IPP 2
Up	Up	Up	Up	Up	Up	Up	Up
Down	Up	Up	Up	Up	Up	Up	Up
Down	Down	Up	Up	Up	Up	Down	Down
Up	Up	Down	Up	Up	Up	Down	Up
Up	Up	Up	Down	Up	Up	Up	Down
Up	Up	Up	Up	Down	Up	Down	Down
Up	Up	Up	Up	Up	Down	Down	Down

R1-5.5 To determine the transport system availability, a simple truth table could be used. Table R1-2 demonstrates availability determination for the multi-path cluster tool configuration noted in Figure R1-1.

Table 2 Simple Truth Table for Transport System Availability for Tool Configuration in Figure 1

LL1	LL2	LL3	Transport
Up	Up	Up	Up
Down	Up	Up	Up
Up	Down	Up	Up
Down	Down	Up	Down
Up	Up	Down	Down

R1-5.6 To determine the process path availability, a simple truth table could be used. Table R1-3 demonstrates availability determination for the multi-path cluster tool configuration noted in Figure R1-1 by combining Tables R1-1 and R1-2.

Table 3 Simple Truth Table for Transport System Availability for Tool Configuration in Figure 1

PM1	PM2	PM3	Transport	IPP 1	IPP 2
Up	Up	Up	Up	Up	Up
Up	Up	Up	Up	Up	Up
Up	Up	Up	Down	Down	Down
Down	Up	Up	Up	Down	Up
Down	Down	Up	Up	Down	Down
Up	Down	Up	Up	Up	Down
Up	Up	Down	Up	Down	Down
Up	Up	Up	Down	Down	Down

R1-5.7 The following example shows how Table R1-3 can be used to determine operational uptime. Other availability metrics in E10 could be calculated in a similar fashion.

Given:

Uptime IPP 1 = 100 hours

Uptime IPP 2 = 140 hours

Operations Time = 168 hours

Operational Uptime (multi-path cluster tool) =

(Σ Uptime for All Intended Process Paths) ÷ [(# of Process Paths) × (Operations Time (as defined in E10) for the Multi-path Cluster Tool)] × 100

= (100 hours + 140 hours) / [(2 IPPs × 168 hours)] × 100 = 240/336 × 100 = 0.714 × 100 = 71.4%

R1-5.8 $MTBF_p$ is measured at the module level and can be aggregated for the multi-path cluster tool.

$MTBF_p$ (multi-path cluster tool) =

(Σ Productive Time for All Process Modules) ÷ (Σ Failures during Productive Time for All Modules)

R1-5.9 The following example shows how Table R1-4 can be used to determine $MTBF_p$. Other reliability metrics in E10 can be calculated in a similar fashion.

Table R1-4 Example Performance Data for Tool Configuration in Figure 1

Item	*Productive Hours*	*# Failures*	*$MTBF_p$*
Process Module 1	100	1	100
Process Module 2	140	1	140
Process Module 3	140	2	70
Transport	—	1	140
Multi-path cluster tool (total)	380	5	76

$MTBF_p$ (multi-path cluster tool) =

(Σ Productive Time for All Process Modules) ÷ (Σ Failures during Productive Time for All Modules)

= (100 hours + 140 hours + 140 hours) ÷ (1 + 1 + 2 + 1) = 380/5 = 76 hours

R1-5.10 A new metric suggested for multi-path cluster tools is total failures (multi-path cluster tool) per month (TFM).

TFM = Σ Total Failures for All Modules (Process and Transport) During the Month

For the above example, TFM = 5.

TFM provides a trending metric for equipment engineers and managers to monitor the effectiveness of equipment continuous improvement activity. When combined with MTTR data calculated for multi-path cluster tools per formulas in E10, this new metric provides maintenance planning capability to the equipment manager as well.

R1-5.11 In the special case of a single intended path (i.e., single-path cluster tool), these multi-path cluster tool RAM metrics should, and do, reduce to the standard E10 RAM metrics.

R1-6 Summary

R1-6.1 By using the E79 concept of virtual tools to develop the "intended process path" approach for multi-path cluster tool metrics in E10, we can demonstrate system-level RAM metrics for multi-path cluster tools. The operational uptime (multi-path cluster tool) metric can be used to provide input to capacity planning systems and allow modeling of multi-path cluster tool availability. $MTBF_p$ can now be calculated at the whole equipment level for multi-path cluster tools, based on existing sub-sytem level metrics. The new metric of total failures per month (TFM) provides a trending metric for the multi-path cluster tool at the whole tool level.

SEMI E11-0697
GUIDELINE FOR 125 mm, 150 mm, AND 200 mm PLASTIC AND METAL WAFER CARRIER APPLICATION

1 Scope

This guideline identifies the wafer carrier details required to properly register the carrier on semiconductor process and transport tools. Specific registration coordinates for both horizontal and vertical carrier orientation are defined to improve wafer and carrier transport operations.

Automated wafer and carrier transport applications require precision placement of carriers within the various types of semiconductor process, inspection and logistic equipment. In some applications it is necessary to adequately support the carrier to avoid deformation. Operations requiring adequate wafer handling must reference the carrier to the datums defined in the SEMI Carrier Specifications.

2 Applicable Documents

2.1 *SEMI Documents*

SEMI E1 — Specification for 3 inch, 100 mm, 125 mm, and 150 mm Plastic and Metal Wafer Carriers

SEMI E1.4 — Standard for 125 mm Plastic and Metal Wafer Carriers, Auto Transport Usage

SEMI E1.7 — Standard for 200 mm Plastic and Metal Wafer Carriers, General Usage (Proposed)

3 Selected Definitions

horizontal orientation — Carrier position when wafers are in the horizontal plane.

vertical orientation — Carrier position when wafers are in the vertical plane.

Symbols Description:

S1 — Draft angle of both side walls of carrier for length defined by S4.

S2 — Draft angle of both carrier legs on outside surfaces only.

S3 — Height from bottom of carrier legs (Datum B) to start of side walls.

S4 — Minimum length of unobstructed side walls.

S5 — Height of carrier legs.

S6 — Angle from carrier leg to side wall.

V1 — Height from base of carrier legs (Datum B) to center of vertical alignment pin. Vertical alignment pin is a locating pin which is an equipment feature, not attached to the wafer carrier.

V2 — Diameter of vertical alignment pin.

4 Application Guides

4.1 *Centrifuge Equipment* — Wafer carriers require support during the centrifugal process operations. The following symbols represent the carrier coordinates that must be supported by the centrifuge tools to ensure adequate support: S1 through S6, A2b, D6a, D6g.

4.2 *Horizontal Carrier Registration* — Wafer carriers positioned with the "H-Bar" down on a stationary or elevator platform should reference the carrier at stable locations shown in Figure 2 to ensure dependable placement. D5b, D5c, and D6b are the recommended final detect points within the D6d and D6e envelope (including provision for D6f).

NOTE: Other features may be employed as prealignment guides, but only for coarse placement.

4.3 *Vertical Carrier Registration* — Wafer carriers positioned with the wafers in the vertical orientation should employ the "center alignment" feature shown in Figure 3. The D6a, D6g, and D9a through D9d details would be the final registration coordinates.

NOTE: Dimensions A1 and A2b may be used to guide the carrier to final placement.

Table 1 Carrier Dimensions for Centrifuge Equipment

Carrier Size	*125 mm*	*150 mm*	*200 mm*
S1	1/4°	1/4°	1/2°
S2	2°	2°	2°
S3	53.4 mm ± 1.0 mm (2.10 in. ± 0.040 in.)	60.5 mm ± 1.5 mm (2.38 in. ± 0.059 in.)	114.3 mm ± .51 mm (4.5 in. ± 0.020 in.)
S4	66.0 mm minimum (2.60 in.)	76.2 mm minimum (3.00 in.)	76.2 mm minimum (3.00 in.)
S5	25.4 mm ± 1.0 mm (1.00 in. ± 0.040 in.)	30.2 mm ± 1.27 mm (1.20 in. ± 0.050 in.)	30.0 mm ± 1 mm (1.18 in. ± 0.039 in.)
S6	45°	45°	Not Applicable
A2b	see Section 2	see Section 2	see Section 2
D6a	see Section 2	see Section 2	see Section 2
D6g	see Section 2	see Section 2	see Section 2

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E12-96
STANDARD FOR STANDARD PRESSURE, TEMPERATURE, DENSITY, AND FLOW UNITS USED IN MASS FLOW METERS AND MASS FLOW CONTROLLERS

NOTE: This entire document was revised in 1995.

1 Purpose

1.1 In the past, confusion has existed in the values of standard temperature and standard pressure when gas flow is expressed in “standard” volumetric units. To eliminate this confusion, the Mass Flow Controllers Committee has established this standard.

2 Referenced Documents

2.1 *ASTM Standard*[1]

E 380-89a — Standard Practice for Use of the International System of Units (the Modernized Metric System)

3 Terminology

None.

4 Standard Temperature

4.1 Standard temperature is defined as 273.15 K (0.0°C).

5 Standard Pressure

5.1 Standard pressure is defined as 101,325 pascals (1 atm, 760 Torr).

6 Standard Density

6.1 The standard density is defined as Mw/22,413.6 grams per standard cubic centimeter (g/scc), where Mw is the molecular weight of the gas in grams per mole (g/mol), and 22,413.6 is the standard molar volume in cubic centimeters (scc/mol) (i.e., the volume of one mole of a perfect gas at standard temperature and standard pressure).

7 Standard Flow Rate

7.1 Standard flow rate is the volumetric flow rate of the gas at the standard density defined in Paragraph 6.1.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

8 Units

8.1 Units for standard flow rate may be expressed as standard cubic centimeters per minute (sccm), standard liters per minute (slm), standard cubic decimeters per minute (scdm), or as standard cubic meters per minute (scmm).

$$1 \text{ sccm} = 1 \times 10^{-3} * \text{slm}$$

$$= 1 \times 10^{-3} * \text{scdm}$$

$$= 1 \times 10^{-6} * \text{scmm}$$

NOTE: Units in this document have been editorially changed to sccm, slm, scdm, and scmm in line with international standards which require all units to be expressed in SI terms. While neither “minute” nor “liter” is a primary SI unit, each is acceptable under the system, and eliminating the use of these units in this standard would seriously diminish its acceptability.

9 Background

9.1 In the absence of this specification, there has been confusion in the definition of standard conditions. “Standard” temperature in particular has been variously defined as 59°F, 68°F, 70°F, 20°C, 22°C, etc. to reflect “normal” test conditions. The scientific community has generally accepted 0°C, as has the semiconductor industry, in its definition of sccm. Standard pressure has almost universally been accepted as one atmosphere, except for rounding errors in different units.

9.2 Further confusion has existed in the definition of standard density when extended to vapors. For perfect gases (most light gases are nearly perfect), the standard density can be defined as the density of the gas at standard temperature and pressure. Since one gram mole of a perfect gas occupies 22,414 cubic centimeters at standard pressure and standard temperature, it follows that a flow rate of 22,414 sccm of any perfect gas is one mole per minute.

9.3 By defining standard density as in Section 6.1, the correlation between sccm and moles/minute is retained, even for vapors. If standard density were defined as the actual density of the vapor at standard temperature and pressure, then the correlation with moles per minute would differ by the vapor's compressibility factor (Z). This is not an acceptable alternative because the compressibility of many vapors is not accurately known, and, in fact, does not exist for those materials that are liquid at standard temperature and pressure.

10 Implications for Calibration

10.1 Since the standard flow units are defined at a standard density, they represent units of mass flow rather than volumetric flow.

10.2 Gravimetric calibration readings in grams per minute (g/min) can be converted to standard cubic centimeters per minute (sccm) by dividing by the standard density (g/scc) as defined in Section 6.1.

10.3 Rate-of-rise (ROR) data will generally have negligible compressibility error when operated over a low absolute pressure range. If compressibility errors are significant, they will cause the rate of pressure rise to be reduced and become pressure-dependent as the pressure increases. In this case, the pressure range must be reduced, or correction made, for compressibility.

10.4 Volumetric flow data must be corrected from actual density of the real gas at the test conditions to the standard density. The actual density can be approximated for near-perfect gases by ratios of absolute pressure and temperature to the standard density. For vapors, the actual density at the test conditions must be known from other data.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E14-93
MEASUREMENT OF PARTICLE CONTAMINATION CONTRIBUTED TO THE PRODUCT FROM THE PROCESS OR SUPPORT TOOL

CONTENTS

NOTES

This page intentionally left blank.

SEMI E14-93
MEASUREMENT OF PARTICLE CONTAMINATION CONTRIBUTED TO THE PRODUCT FROM THE PROCESS OR SUPPORT TOOL

1 Introduction

This document describes the methods, procedures, and application of a technique for determining the average number of particles added to a wafer as a result of the wafer being passed through a semiconductor process tool.

1.1 *Purpose* — The purpose of this document is to provide a standardized methodology and detailed procedure for measuring the contamination performance of a particular process or tool in terms of the number and size distribution of particles added to a silicon wafer as a result of having been passed through that process tool. This standardized procedure is primarily intended to be used for the qualification of new or repaired processing equipment, but may be extended to new processes or methods, continuous process or tool monitoring, and qualification of new materials. As a result, this document contains supporting information; however, one may not need to read all of the information to determine the particles per wafer pass (PWP) of the process tool.

The measurement of surface particulate contamination on a wafer as it passes through the tool requires an understanding of the overall environment as well as the equipment in question. A flow chart summarizing the decision–making process at each phase of the evaluation is found in Figure 1. Each of the subsections begins with a brief description of the methodology for carrying out the measurement, followed by the step–by–step data collection and statistical evaluation procedure. More extensive background information and detailed explanations for the procedures are given in the appendices.

The working portion of this document follows a workbook format; each section may be used as a stand-alone method. Definitions should be reviewed and understood before applying a method (or section).

1.2 *Scope and Application* — The methodology and procedures provided in this document are applicable for evaluating the PWP for virtually any semiconductor processing equipment located in a cleanroom that is used to transport, inspect, measure, or process silicon wafers. The complexity of the process to be evaluated by this methodology is determined by the user. It ranges from a relatively simple process of moving wafers into and out of an ellipsometer to the full simulation of a CVD process including transport of a wafer into quartzware, pushing quartzware into a reactor chamber, multiple purge/vent cycles, process simulation with inert gas flow including establishment of process pressure, temperature ramping and soak, venting, cooldown, and transport back to the cassette. Although this procedure may be extended to actual fabrication processes, it is primarily intended to be used to quantify contamination added by a process tool and not by the actual process.

The measurement of PWP performance is in terms of particles located on the front surface of the wafer; it does not apply to particles on the back surface of the wafer. It is important that both the customer and supplier follow the same test method. This will help to ensure that communication takes place on the same level and that actual performance of the equipment is discussed.

1.3 *Protocols* — Figure 1 shows the sections included in the applications portion of this document. The section of most importance is Section 6. This section details how to measure PWP during process tool characterization. Section 4 explains how to calibrate the measurement instrument. If the calibration of the measuring instrument has been validated, then skip to Section 6. However, be sure to also perform the routine monitoring of the measurement instrument as described in Section 5. Section 7 explains how to perform routine monitoring of the process tool once it is characterized and incorporated in the process.

1.4 *Impact* — This document supersedes SEMI E14-90 in its entirety.

1.5 *Limitations* — The application of the procedures and methodologies provided in this document is limited by the following constraints:

1.5.1 The measurement vehicle is an unpatterned wafer. Where appropriate and practical, the unpatterned wafer shall represent the physical state of a patterned wafer at a similar stage of the process. Due to the variety of processes and tools in use at each site, it is recommended that the user or supplier define the exact process recipe to be used, keeping in mind the impact that the process may have on the PWP measurement results.

1.5.2 The detection of particles added is limited by the performance capability of the particle detection instrument being used.

1.5.3 The identification of the source and composition of particles measured is outside the scope of this procedure.

2.4 SEMI M10 — Standard Nomenclature for Identification of Structures and Features on Gallium Arsenide Wafers

2.5 Western Electric Co., *Statistical Quality Control Handbook,* 1956.

3 Terminology

3.1 *Abbreviations*

3.1.1 *CI* — confidence interval

3.1.2 *LCL* — lower confidence limit

3.1.3 *PSL* — polystyrene latex sphere

3.1.4 *PWP* — particles per wafer pass

3.1.5 *s* — standard deviation

3.1.6 *SL* — specification limit

3.1.7 *S/N* — signal to noise (ratio)

3.1.8 *UCL* — upper confidence limit

3.2 *Definitions*

3.2.1 *confidence interval (CI)* — Upper and lower bounds around an estimated value that will, within a certain percentage of confidence, include that estimated value.

3.2.2 *contaminant* — A broad category of foreign matter visible to the unaided eye on the wafer surface which is, in most cases, removable by gas blow-off, detergent wash, or chemical action. [ASTM 1241-90]

3.2.3 *control chart* — A graphic representation of a characteristic of a process, showing plotted values of some statistic gathered about that characteristic, and one or two control limits. [EIA 557] [Note: A control chart has two basic uses—as a judgment to determine if a process is in control, and as an aid in achieving and maintaining statistical control.]

3.2.4 *control limits* — A line (or lines) on a control chart used as a basis for process control. Variation beyond a control limit is evidence that special causes are affecting the process. Control limits are calculated from process data and are not to be confused with engineering specifications. [EIA 557]

3.2.5 *counting accuracy* — A percent of total known countable features on a wafer. Counting accuracy is determined by scanning a wafer with a known pattern of individual scattering centers.

3.2.6 *false negative* — A measurement that indicates the failure to count a particle that is present.

3.2.7 *false positive* — A measurement that indicates the presence of particles when no particles are present.

3.2.8 *in–line measurement* — A measurement made on a silicon wafer while the wafer resides in any portion of a processing tool or work cell except the processing chamber.

3.2.9 *in situ measurement* — A measurement made while a silicon wafer resides in the processing chamber of a processing tool.

3.2.10 *out–of–control actions* — A list of steps to be taken when the process is flagged as out–of–control. The desired outcome of executing the steps in the specified order is that the process comes back into control.

3.2.11 *particulate* — A discrete particle of dirt or other matter. [Reference ASTM 1241-90]

3.2.12 *polystyrene latex sphere* — Consistently sized and characterized spheres that represent particles on the wafer surface, but may not be indicative of actual particles encountered in the fab environment. These spheres are used to calibrate the particle counter response curve.

3.2.13 *process characterization* — Cycling a single wafer or batch of wafers through the tool with process or chemical changes. The purpose is to determine particle contributions from the mechanical and process aspects of the process tool.

3.2.14 *particles per wafer pass (PWP)* — The average number of particles added to a wafer as it passes through a tool, expressed in particles per wafer pass or in particles/cm^2/pass.

3.2.15 *scratch* — A long, narrow, shallow groove or cut below the established plane of the wafer surface. The ratio of the length of the groove to the width of the groove is typically greater than 5:1. [SEMI M10, ASTM 1241-90]

3.2.16 *signal-to-noise ratio* — The ratio of signal voltage at a given threshold to the background noise voltage.

3.2.17 *standard deviation* — A measure of the variation among the members of a statistical sample.

Equation : $$s = \sqrt{\frac{\sum_{i=1}^{n}\left(\overline{x} - x_i\right)^2}{n-1}}$$

3.2.18 *threshold* — A level set within the control software of a measurement instrument such that a signal which exceeds this level is recorded as an event and a signal below this level is ignored.

3.2.19 *U-chart* — An attributes chart used to track the number of nonconformities with varying sample size (for example, to track the particle density per wafer).

3.2.20 *wafer* — A thin slice with parallel faces cut from a semiconductor crystal. Also called *slice* and *substrate*. [ASTM1241-90]

3.2.21 *wafer, control* — A wafer that is allowed to pass entirely through a tool, being subject to a mechanical characterization without being subject to the actual process conditions.

3.2.22 *wafer, dummy* — A noncritical wafer added to a load–sensitive operation or run to complete a load of the equipment or process. Dummy wafers are never measured.

3.2.23 *wafer, test* — A wafer that is exposed to all of the conditions of process characterization, including, but not limited to, actual etch conditions or actual film deposition conditions.

3.2.24 *$\overline{X}$ -MR (mean-moving range) control chart* — A chart that tracks the difference between a current measurement and the value of the previous measurement.

3.3 *Descriptions of Terms*

3.3.1 *area defect (related to particle detection)* — A large single particle (≥ 10 µm in size) or a cluster of smaller particles that cannot be distinguished from each other.

3.3.2 *attributes* — Qualitative data that can be counted. For purposes of this document, examples include the number of particles per wafer, number of failed die per wafer, and particle density per wafer. Attributes are measured on a discrete scale.

3.3.3 *bin (of particle measurement instruments)* — A subset of the total range of particles counted, based on size. [Note: Many particle counting instruments measure the size of a particle while counting and then sort the total number of counts into bins. Some instruments have the size ranges of the bins set at the factory, while some designs allow the user to set the ranges of the bins. Also called *channel*.]

3.3.4 *C-chart* — An attributes chart used to track the number of nonconformities with a constant sample size. In this method, a C-chart can be used to track the total number of particles per wafer, assuming the underlying particle distribution is a Poisson distribution.

3.3.5 *calibration size* — The median size within the monodispersed size distribution that is produced for a deposit of PSL spheres on a calibration wafer. By definition, the count efficiency at the first threshold of minimum calibration particle size is 50%.

3.3.6 *interquartile range* — The range within which 50% of the data points fall.

3.3.7 *mechanical characterization* — When a single wafer or batch of wafers is cycled through the tool with no intentional process or chemical changes. The purpose is to determine particle contributions from the mechanical wafer movement throughout the process tool.

3.3.8 *particle* — A minute quantity of solid or liquid matter. For purposes of this document, particles are typically considered to be between 0.02 µm and 10.0 µm.

3.3.9 *repeatability* — The ability of a surface particle counter to repeat the total particle count on the wafer surface under the same conditions on the same wafer. [Note: For purposes of this method, at least 20 consecutive inspections are made.]

3.3.10 *size resolution* — The capability of a surface measurement instrument to differentiate between particles of nearly the same size.

3.3.11 *upper adjacent value* — Upper quartile range multiplied by 1.5 times the interquartile range.

3.3.12 *variables* — Those characteristics of a part or process which can be measured. Examples are thickness in Å, step height in ⌠m, and haze in parts per million. Variables are measured on a continuous scale.

3.3.13 *wafer, calibration* — A wafer with a known distribution of simulated particles to be used for sizing (e.g., PSL spheres) in terms of diameter in µm or a known number of simulated particles to be used for counting accuracy and location information (e.g., etch pits) on the wafer surface.

3.4 Control and Test Wafer Statistics and Definition of Variables

C_{ai} — Average "after"' count for each control wafer scanned five times.

C_{bi} — Average "before" count for each control wafer scanned five times.

$CI_{PWPtool}$ — Confidence interval of the average "particles added" contributed by the process tool.

n_c — Number of control wafers.

n_t — Number of test wafers.

P — Number of passes through the process tool.

PWP_{tool} — Average number of "particles added" contributed by the process tool ($X_{test}X_{control}$).

$S^{adj}_{control}$ — Standard deviation of the control wafers adjusted for the measurement error of the particle counter.

S^{adj}_{test} — Standard deviation of the test wafers adjusted for the measurement error of the particle counter.

$S_{calibration}$ — Standard deviation of the particle counter.

$S_{control}$ — Standard deviation of the control wafers.

SL (specification limit) — Total number of "particles added" allowed by the process tool.

S_{test} — Standard deviation of the test wafers.

T_{ai} — Average "after" count for each test wafer scanned five times.

T_{bi} — Average "before" count for each test wafer scanned five times.

$X_{control}$ — Average particles contributed by handling.

X_{test} — Average particles contributed by the test wafers.

4 Measurement Instrument Evaluation

4.1 *Methodology for Instrument Acceptance*

4.1.1 The purpose of evaluating the surface measurement instrument is to verify that the size accuracy, size resolution, PWP, repeatability, false negative test, false positive test, S/N ratio, and counting accuracy of the instrument are acceptable to evaluate the PWP performance of process and support tools.

4.1.2 This portion of the evaluation is to be completed upon user acceptance of the measuring instrument from the instrument manufacturer or upon a major preventive maintenance action to the instrument, such as a laser tube replacement.

4.1.3 It may not be practical to schedule this evaluation on a regular basis because of its complexity. Figure 2 details the steps in the calibration acceptance process. If the measurement instrument is shown to be in calibration using normal criteria, go to Section 5 for process tool PWP acceptance.

4.1.4 The methodology to measure noise on the measuring instrument may be restricted by the design of the instrument and the quality of the wafers. It is imperative to ensure that noise does not contribute false positive counts at the specified particle sensitivity of the instrument. Refer to Appendix A2, Section A2.1.3 for details on this procedure.

4.1.5 *Calibration Wafers* — To obtain representative results of the customer's operation, the calibration wafers must be produced on clean, bare silicon product wafers from that customer. Calibration wafers should be dedicated for instrument calibration only and should be stored in a clean cassette at all times until needed.

Calibration wafers with full or half deposition of PSL calibration monospheres of nominal diameter, which represent the first and subsequent thresholds, are indicated below. Also included is an etched pit wafer. The etched pit wafer can be either a four distribution or a single distribution wafer. Different PSL diameters are noted for HeNe and argon laser systems. Refer to Appendix A1 for application notes to produce PSL calibration wafers. Additional PSL calibration wafers may be used.

CAL	*PSL Diameter (nominal)*	
Wafer Count	*HeNe*	*Argon*
A appx 2000	see note*	see note*
B " 600	0.30 µm	0.20 µm
C " 600	0.50 µm	0.40 µm
D " 600	1.00 µm	1.10 µm

E Etched pit count accuracy wafer

* Specified sensitivity of the instrument.

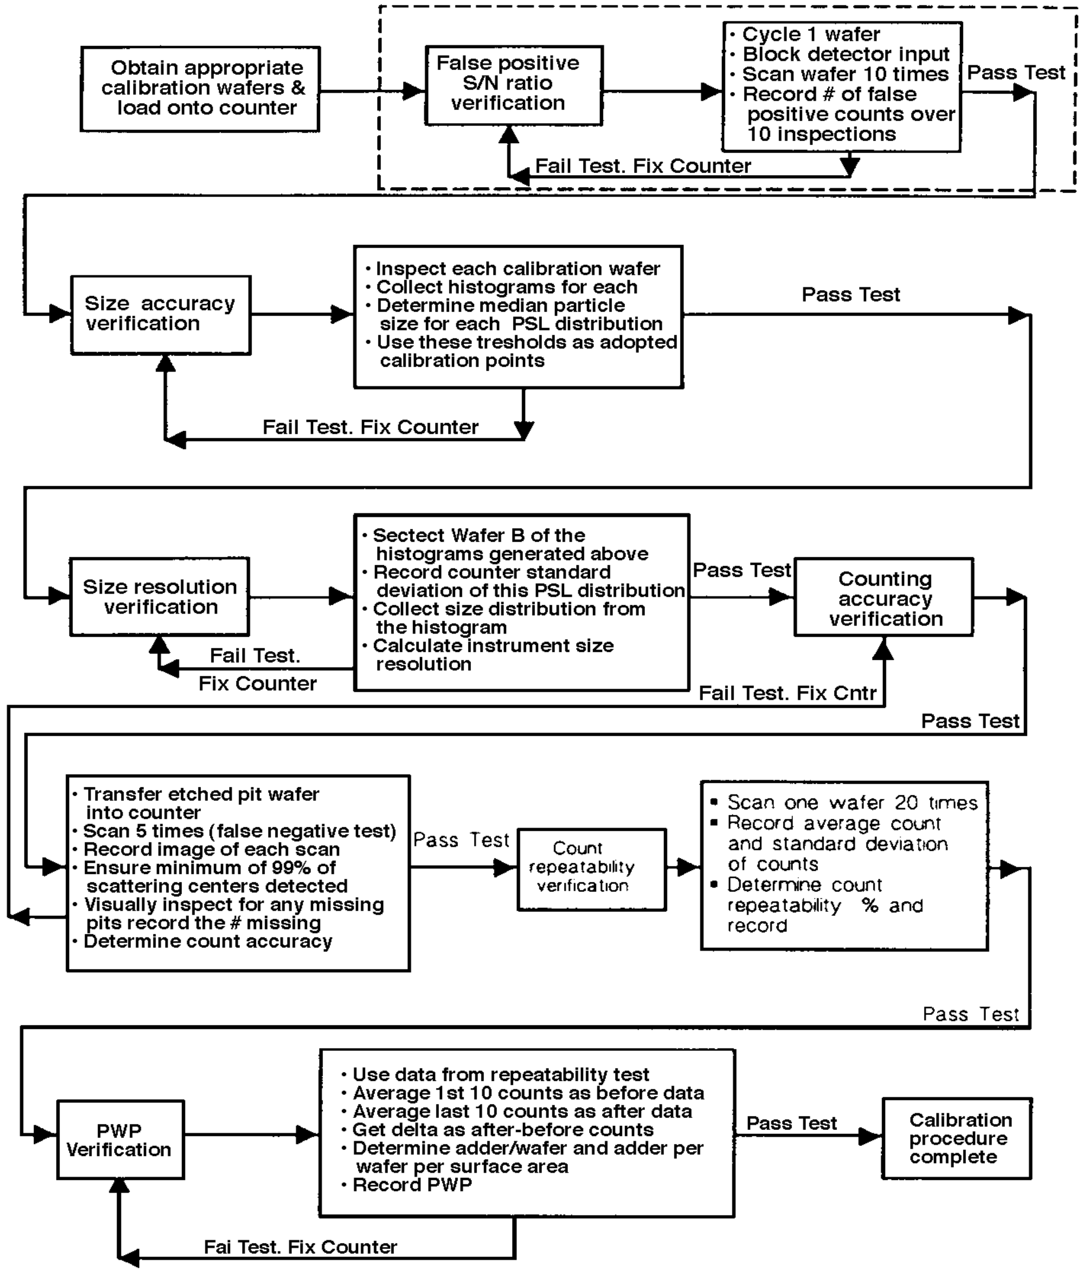

Figure 2
Instrument Calibration Acceptance Process

4.2 *Procedure for Instrument Calibration acceptance*

4.2.1 Load the calibration wafers onto the instrument load station (with the wafer flat/notch oriented to the back of the cassette) ensuring that Class 10 vertical laminar flow is extended beyond the load station at all times.

Additional calibration wafers can be used other than those noted above. Intersperse the calibration wafers in a clean cassette with several empty slots between each wafer.

4.2.2 Verify Noise

See Application Note, Appendix A2.

4.2.3 Verify Size Accuracy

4.2.3.1 Determine if the instrument has adequate dynamic range to collect full sphere distribution peaks for all four size PSL calibration wafers A, B, C, and D.

- Set the instrument program parameters (e.g., gain, threshold, maximum size) to collect a full peak for PSL calibration Wafer A. Record the settings.

Program parameters for Wafer A:

____

____

____

____

____

- Scan PSL calibration Wafers B, C, and D using the program parameters used to scan PSL Wafer A and determine if the sphere distribution peaks are fully resolved.
- If all four peaks are fully resolved, proceed to paragraph 4.2.3.2.
- If all four peaks were not fully resolved, determine the program setting needed to fully resolve the sphere peaks for each PSL wafer and record the results. [Note: In some cases, four different programs may be required; in some cases, two or three may be sufficient.]

Attach copies of each distribution. (See Appendix A2, Application Notes for discussion.)

Program parameters for Wafer B:

____

____

____

____

Program parameters for Wafer C:

____

____

____

____

Program parameters for Wafer D:

____

____

____

____

4.2.3.2 Set up the instrument with the setting needed to scan Wafer A.

4.2.3.3 Scan Wafer A.

4.2.3.4 Isolate the PSL sphere peak. [Note: The distribution is isolated by either manually moving the cursors to the left and right of the distribution and redisplaying the histogram or by letting the system isolate the distribution automatically, depending on the type of measurement instrument in use.] Record the median of the distribution in µm. (These numbers are displayed on the screen.)

Median of distribution___________________

[Note: If the median is displayed in units other than µm, use a manufacturer-supplied calibration curve to convert the units to µm.]

4.2.3.5 Scan Wafer A four additional times. Isolate the distribution and record the median as above.

Median of distribution___________________

Median of distribution___________________

Median of distribution___________________

Median of distribution___________________

4.2.3.6 Calculate the average median of the distribution. Record the results.

Average median________________________

4.2.3.7 Determine if the median is within 5% of the specified PSL calibration size. If not, resolve the problem or contact the instrument manufacturer for recalibration. Restart the calibration procedure.

Specified sphere diameter________________

4.2.3.8 If necessary, modify program parameters to scan Wafer B at a different level of sensitivity.

4.2.3.9 Scan Wafer B.

4.2.3.10 Isolate the PSL sphere distribution. Record the median and standard deviation of the distribution in µm.

Attach histogram for future use.

Median of distribution___________________

s of distribution________________________

4.2.3.11 Scan Wafer B four additional times. Isolate the distribution and record the median and standard deviation as above.

Median of distribution___________________

Median of distribution___________________

4.2.3.18 Calculate the average median of the distribution median. Record the results.

Average mean__________________________

Average s______________________________

4.2.3.19 Determine if the median is within 5% of the specified PSL calibration size. If not, resolve the problem or contact the instrument manufacturer for recalibration. Restart the calibration procedure.

Specified sphere diameter________________

4.2.3.20 If necessary, modify program parameters to scan Wafer D at a different level of sensitivity.

4.2.3.21 Scan Wafer D.

4.2.3.22 Isolate the PSL sphere distribution. Record the median of the distribution in µm.

Median of distribution___________________

4.2.3.23 Scan Wafer D four additional times. Isolate the distribution and record the median as above.

Median of distribution___________________

Median of distribution___________________

Median of distribution___________________

Median of distribution___________________

4.2.3.24 Calculate the average median of the distribution. Record the results.

Average median________________________

4.2.3.25 Determine if the mean is within 5% of the specified PSL calibration size. If not, resolve the problem or contact the instrument manufacturer for recalibration. Restart the calibration procedure.

Average s______________________________

Specified sphere diameter________________

4.2.4 Verify Size Resolution

Determine size resolution using the calibration histogram of Wafer B.

4.2.4.1 Collect the PSL size distribution from the instrument in µm or extrapolate the size resolution from the manufacturer's primary calibration data and record the response.

Attach size resolution response and retain for reference.

4.2.4.2 Collect from the instrument, or record from Section 4.2.3.12, the standard deviation of this PSL sphere size.

Record the instrument standard deviation of the size distribution_________. If the instrument reports a coefficient of variance (CV) in percent (s%), multiply the CV times the mean diameter to acquire s.

Record the reported PSL standard deviation from the PSL bottle or from the certificate________. If the PSL bottle reports the coefficient of variance (CV), multiply CV times the mean deviation to acquire s.

4.2.4.3 Calculate the instrument size resolution in % as follows:

$$\frac{\sqrt{\text{Instrument } s^2 - \text{Reported PSL } s^2}}{\text{Particle Mean Diameter, } \mu\text{m}} \times 100$$

Record the calculated resolution___%___.

4.2.4.4 To minimize inter-instrument data variability, the percent resolution should not exceed 15%. If the variability is > 15% for the selected particle size, resolve problems and rerun 4.2.4. If resolution is ≤ 5%, go to 4.2.5.1.

4.2.5 Verify Counting Accuracy

4.2.5.1 Transfer Wafer E (etched pit wafer) into the instrument. Set the min and max display sensitivity to see only the etched pit distributions. Adjust the edge exclusion to see just the image of the etched pit pattern. Inspect the wafer five times. Use a 150-mm wafer if 200 mm is not available.

4.2.5.2 Print each image and attach the printouts. Specify the actual number of scattering centers on the wafer.

Attach count accuracy images as a reference. Record the actual number of scattering sights on the count accuracy wafer ____.

4.2.5.3 Using the patterned description provided by the producer of the count accuracy wafer, ensure that a minimum of 99% of the scattering centers are detected on each scan. Furthermore, ensure that there are no patterns of double counting of the scattering centers in any quadrant or on the XY axis.

4.2.5.4 Visually inspect each image for missing scattering centers within the defined pattern. Disregard any disparate particles outside or within the etched pit zone; these particles are not a part of the defined etched pit pattern. Average the missing pits over the 5 images and record to one decimal point.

Record the actual number of missing pits within the pattern. Do not confuse particles within the pattern as pits.

#1 image_____

#2 image_____

#3 image_____

#4 image_____

#5 image_____

Average missed sites to one decimal point = ___.

4.2.5.5 Determine count accuracy % as follows:

$$1 - \frac{\text{average number of missed or added pits}}{\text{actual number of pits}} \times 100$$

If the count accuracy is < 99%, resolve problems on the instrument and rerun 4.2.4. If count accuracy is 99 to 100% go to 4.2.5.1.

The acceptance calibration of the particle counter is complete.

Count accuracy = ___%.

4.2.6 *Verify Count Repeatability* — The purpose of this test is to verify the counting repeatability of the particle counter. Typically, count repeatability is determined with a PSL distribution on the wafer, but it can also be accomplished on a bare silicon wafer.

The equipment user and supplier must mutually agree on which wafer type will be used.

4.2.6.1 Inspect calibration Wafer B a minimum of 20 cycles while noting the total defect count from each inspection.

Record the total number of particles from each inspection (1–20).

4.2.6.2 Determine the average total particle count and the standard deviation of the count.

Average detected particles **X** = ___.

Standard deviation = ___.

4.2.6.3 Determine count repeatability at n.

$$\frac{n \times \sigma}{\overline{X}} \times 100 = \text{\% repeatability}$$

Select the value of n ______, which correlates to the confidence interval required.

4.2.6.4 Record the percentage of repeatability. If count repeatability is not ≤ that specified by the particle counter manufacturer's specification, resolve problems and rerun this test. If successful, go to 4.2.7.1.

Count repeatability = ___%, at n sigma.

4.2.7 Verify PWP of the Instrument

The purpose of this test is to measure the level of particle contributions from the particle counter to a wafer. PWP values of less than zero should be set to zero.

4.2.7.1 Using the data collected from the count repeatability test, determine PWP as follows:

- Average the first 10 total particle counts ("before count").

Average of first 10 counts = ___.

- Average the last 10 total particle counts ("after count").

Average of last 10 counts = ___.

- Delta = "after count" – "before count"

Delta = ___.

- Delta/10 = particles added per pass.

Delta/10 = ___.

PWP/cm^2 =

$$\frac{\left(\left[\frac{\text{wafer diameter mm}}{2}\right] - \text{edge exclusion mm}\right)^2 \times \pi}{100}$$

Particles added/included surface area = ___.

PWP =_______particles/cm^2 of a size ≥__µm.

- If PWP is not ≤ the equipment supplier's specification, verify cleanliness of the system and rerun 4.2.7.

5 Measurement Instrument Monitoring

5.1 *Methodology for Instrument Monitoring* — This procedure is included for completeness. Many fabs have existing SPC methodology for particle tool monitoring. Monitor the particle counter on a routine, regular basis (e.g., per day or per shift), regardless of the particle methodology chosen.

The purpose of monitoring the particle measurement instrument is to verify that the instrument is in calibration. Routinely verify the performance of the measurement instrument so that the results of process tool particle testing can be trusted. The instrument calibration is tested using an etched pit standard. The etched pit standard provides information about instrument count accuracy and size trend monitoring. Etched pit wafers are the standard of choice for routine monitoring because they can be cleaned and recertified when contaminated. PSL wafers should be replaced when contaminated.

The calibration wafer should be run regularly (e.g., once per shift, once per day, or once per week) for 25 tests, and the data should be recorded on control charts. When 25 points have been collected, control limits can be defined. $\overline{X}$ -MR control charts are used to track the collected information by measuring an identical sample repeatedly. $\overline{X}$ -MR charts track the difference between a current measurement and the value of the measurement the last several times the sample was run, which is the desired measured performance. For more information on $\overline{X}$ -MR charts, see Appendix A3.

Figure 3 details the steps outlined in this section.

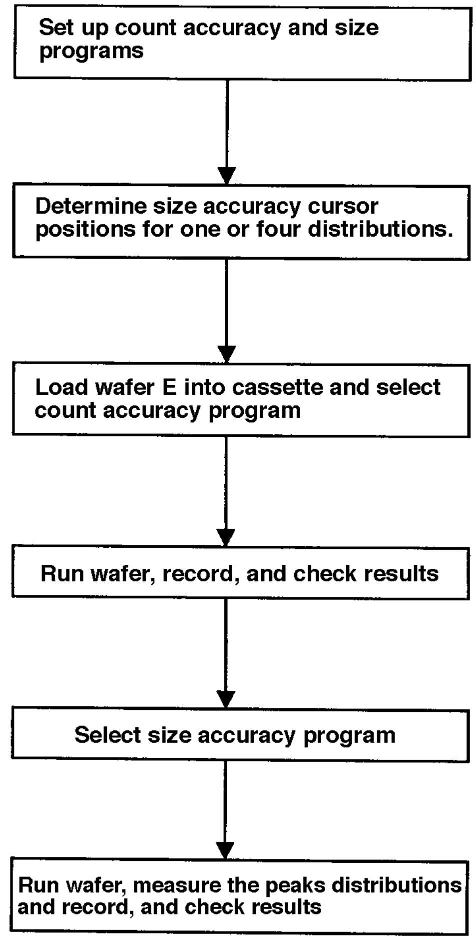

Figure 3
Procedure for Instrument Monitoring

5.2.1.4 Calculate and plot the average median of the distributions on the control chart.

$\overline{X}$ = ________µm____Average count

5.2.1.5 Determine whether the monitored size is in or out of specification of the control chart.

5.2.1.6 Determine if the averaged etched pits not detected or added from each of the 25 scans is > 99% and < 100%.

5.3 *Out-of-Control Actions* — If any of the distributions are out of control, recalibrate the instrument.

In control_________ Out of control_________

Count accuracy =

$$1 - \frac{\text{average number of missed or added pits}}{\text{actual number of pits}} \times 100$$

If count accuracy is < 99% or > 100%, recalibrate the instrument or contact the manufacturer for repairs.

6 Measuring PWP for Process Tool Acceptance

6.1 *Methodology for Process Tool Acceptance*

6.1.1 The purpose of performing process tool acceptance is to assure the customer and supplier that the tool meets all the criteria as agreed upon by the user and supplier. The acceptance process characterizes the tool so that its performance level can be documented. The purpose of this section is to determine the particles per wafer pass (PWP) of the process tool. This number is usually reported in particles/cm^2/pass. This section is intended to document a standard method of arriving at the PWP of the process tool. There are five areas that require the understanding of the customer and supplier. (See Figure 4.)

6.1.2 *Explanation of Steps in Methodology for Acceptance (see Figure 4)*

6.1.2.1 The first step is intended to ensure that both the customer and the supplier agree on a set of control and test parameters for the process tool. Some of the issues are the specification limit (SL) for the allowable number of particles added by the process tool (for example, 0.05 particles/cm^2/pass 0.1 µm); the number and timing of conditional cycles, whether or not to use dummy wafers in the cassette; and the recipes to be used for the process tool. The issues and parameters should be agreed upon before the start of data gathering and should replicate actual wafer processing as closely as possible.

6.1.2.2 The second step concerns the cleanliness of the control and test wafers. By obtaining the most consistently clean wafers available, the experiment will provide much higher confidence for a given number of replications. The end result is fewer replications for a chosen confidence interval and, therefore, a potential savings of experiment cost in time and money.

6.1.2.3 The third and fourth steps deal with the control and test wafers. The control wafers are used to determine the effect of handling on the PWP added. Minimize the amount of particles added by the handling so that it is clear which particles can be attributed to the process tool. Once the number of particles added by the handling is determined, this number can be subtracted from the test wafer total. For convenience, the number of control and test wafers is the same.

6.1.2.4 After determining the PWP of the process tool, the customer and supplier should discuss the results. This is the fifth step. The customer and supplier must agree with the results. If the process tool fails to meet specification limit, the customer and supplier should determine the next step.

Note: This document assumes a Class 10 or better cleanroom per FED-STD-209.

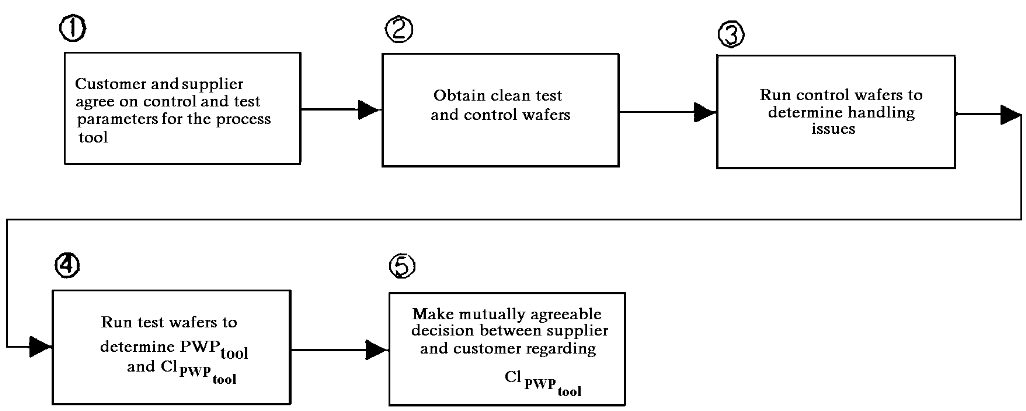

Figure 4
Steps in Methodology for Process Tool Acceptance

Figure 5 shows the basic steps necessary to complete the process tool characterization. It is intended to pictorially show the user of the document the derivation of each of the numbers determined in Sections 6.1 and 6.2.

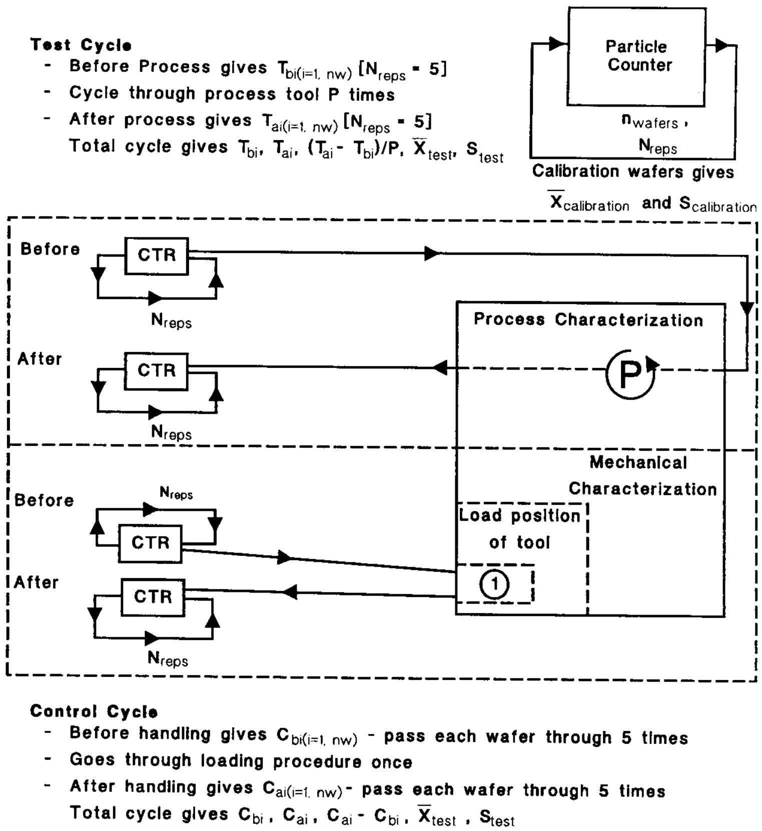

Figure 5
Basic Steps for Process Tool Characterization

6.2 *Procedure for Process Tool Acceptance*

6.2.1 *Step 1* — Determine control and test parameters as agreed upon by the user and supplier. These should include the following:

6.2.1.1 The specification limit (SL) shall be < ___ PWP, particles/cm^2 per wafer pass, of a size ≥___ µm.

6.2.1.2 The number of dummy wafers to be used in the test and/or control cassette is ____.

6.2.1.3 The number of conditioning run cycles to be used is ____.

6.2.1.4 Type and mechanical characteristics of the cassettes to be used, such as antistatic, supplier, and material (specify).

6.2.1.5 Surface preparation of the test and control wafers (for example, hydrophilic, hydrophobic, acid or base, and affinity for attracting particles) (specify).

6.2.1.6 Specifications for incoming material gases, liquids, etc. to be supplied to the process tool shall be agreed upon before the installation.

6.2.1.7 Installation requirements to be met.

6.2.1.8 Recipes to be used during this evaluation (specify).

6.2.1.9 Number of passes, P, through the process tool is ____.

6.2.2 *Step 2* — Ensure that the initial particle counts for the set of 25 wafers have a narrow spread. This is to ensure that little or no variability can be tied to wafer variation.

When deciding on the acceptable initial particle count, determine the expected number of particles added for the process tool.

Under ideal conditions, the ratio of the before-count of the control and test wafers to the PWP specification (the number of anticipated counts added by the process tool) should be 1:4; i.e., if the PWP specification is ≤ 20 particles larger than 0.3 µm, the before-count of the control and test wafer should be ≤ 5 particles larger than 0.3 µm. The upper limit of this ratio should not be less than 1:1. For example, the set of wafers may have pre-counts in the range of 20 ± 5 (at ± 0.3 µm) if the PWP specification of the process tool ≤ 80 particles added.

6.2.3 *Steps 3 and 4* — Figure 6 graphically depicts steps 3 and 4 of the process tool characterization. The procedure is presented in Section 6.2.4.

6.2.4 The numbers in parentheses (n) preceding paragraphs in this section correspond to the numbered blocks in the flow chart for steps 3 and 4. (See Figure 6.)

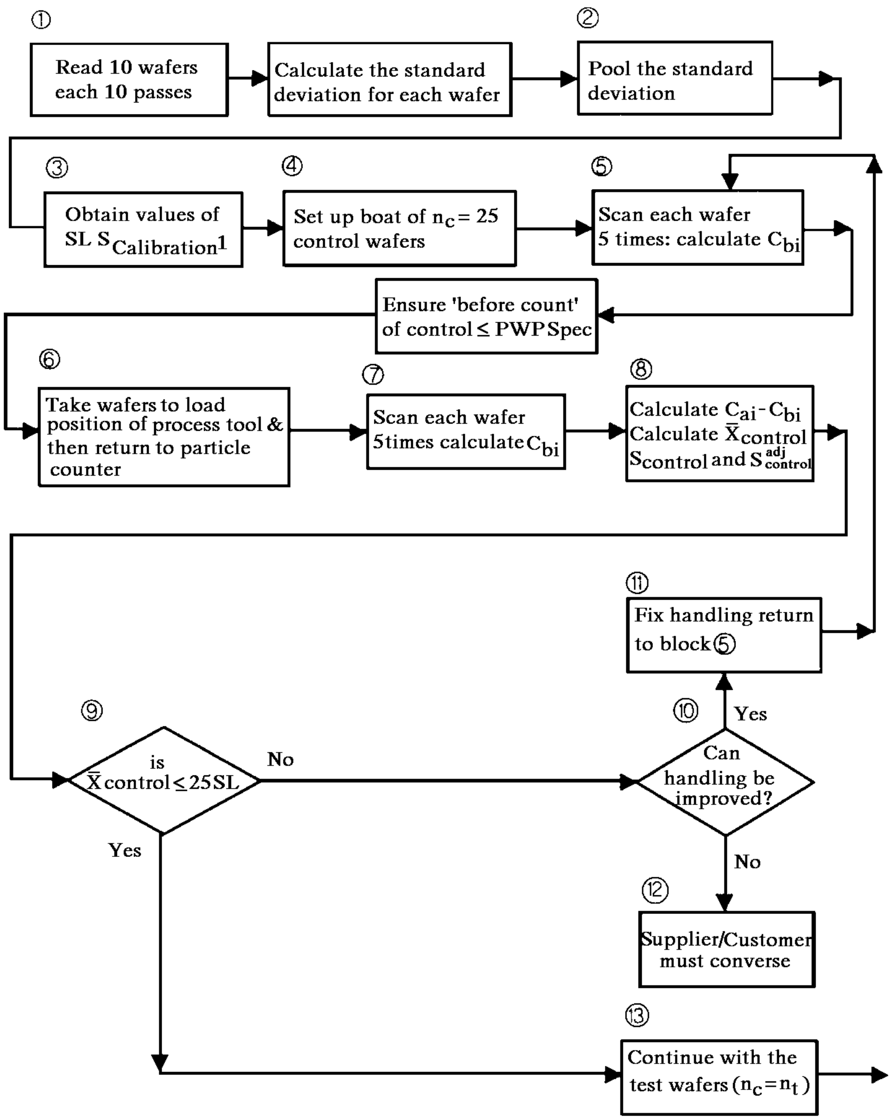

Figure 6
Detail of Steps 3 and 4

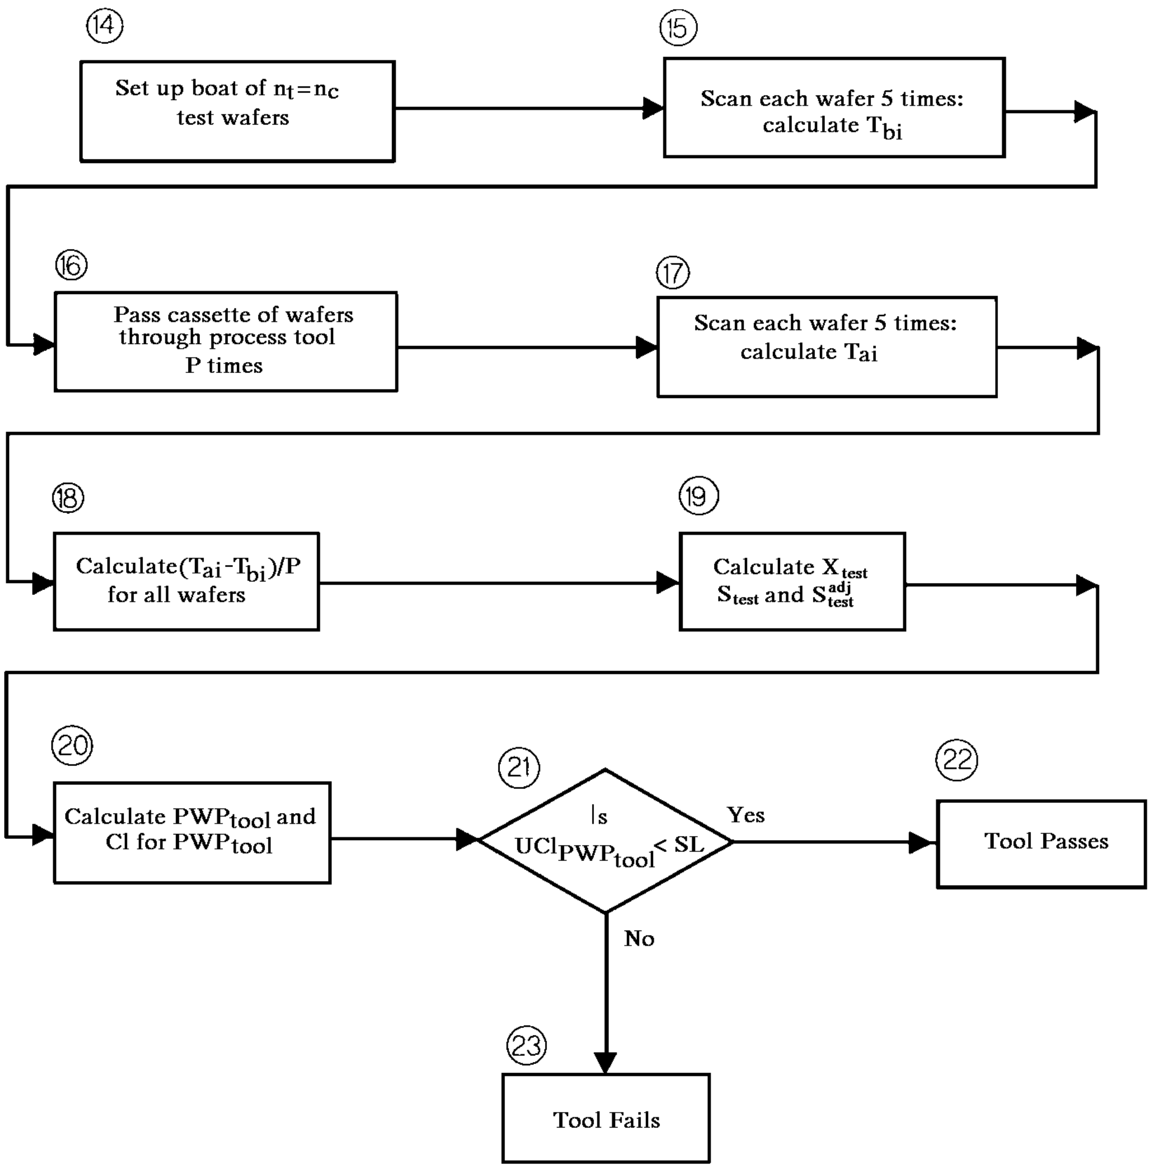

Figure 6
Detail of Steps 3 and 4

6.2.4.1 (1) To determine the value for **$S_{calibration}$**, begin by reading 10 wafers 10 times each, and record the standard deviation for each wafer. To ensure that the pre-counts of wafers are acceptable, reference paragraph 6.2.2.

6.2.4.2 (2) Calculate **$S_{calibration}$** by pooling the standard deviations for each wafer.

6.2.4.3 (3) Note the value of **SL** from 6.2.1.

6.2.4.4 (4) Set up a cassette of control wafers. **n_c** = 25 wafers.

6.2.4.5 (5) Scan each wafer five times and calculate **C_{bi}**(i=1->25).

j = # of reps for j=1->5

C_{b15} =______

(1) Standard deviations:

6.2.4.19 (19) Calculate X_{test}, S_{test} and S_{text}^{adj} of the test wafers.

(19)

$$\overline{X}_{test} = \frac{\sum_{i=1}^{n_t} (T_{ai} - T_{bi})/P}{n_t}$$

$\overline{X}_{test} =$ ____

$$S_{test} = \sqrt{\frac{\sum_{i=1}^{n_t} \left[\left((T_{ai} - T_{bi})/P\right) - \overline{X}_{te}\right]^2}{n_{t-1}}}$$

$S_{test} =$ ____

$$S_{test}^{adj} = \sqrt{s_{test}^2 - \frac{(2)s_{calibration}^2}{N_{reps}}}$$

$S_{test}^{adj} =$ ____

6.2.4.20 (20) Calculate the average number of "particles added" contributed by the process tool, **PWP_{tool}**, **S_{tool}**, and the respective **UCL**.

υ is the degrees of freedom (in this case it is n – 2); α is the confidence level chosen (for example, α gives a 95% confidence for the value).

(20)

$$S_{tool} = \sqrt{\frac{S_{test}^{adj^2}}{n_t} + \frac{S_{control}^{adj^2}}{n_c}} =$$

$$PWP_{tool} = \overline{X}_{tool} = \overline{X}_{test} - \overline{X}_{control}$$

$$UCL_{pwp_{tool}} = \left(\overline{X}_{test}\ \overline{X}_{control}\right) + t_{(\alpha,\upsilon)} S_{tool}$$

Select the desired confidence level and appropriate t value.

Examples:

for α = 0.05, υ = 23, t(α, υ) = 1.714

for α = 0.01, υ = 23, t(α, υ) = 1.319

Refer to a Student t table in any statistics handbook for additional values.

6.2.4.21 (21) Check to see if $\mathbf{UCL_{PWPtool}} \leq \mathbf{SL}$.

(21) $UCL_{PWPtool} \leq SL$?

6.2.4.22 (22) If (21) is true, the tool meets the PWP specification limit.

6.2.4.23 (23) If (21) is false, the tool does not meet the PWP specification limit.

6.2.4.24 Record the final values in the following Summary Table.

Summary Table	*Process Tool*
$\overline{X}_{control}$	
$S^{adj}_{control}$	
$\overline{X}_{test}$	
S^{adj}_{test}	
PWP_{tool}	
# wafers used	
pass/fail	

7 Process Tool Monitoring

7.1 *SPC Methodology* — Routine monitoring of the process tool is important to ensure that the tool is stable. There are many methods for statistical process control (SPC) in use. Be aware of the nature of the data before choosing an SPC methodology. Two major areas of importance are the distribution of the data (i.e., normal, Poisson, or log-normal) and the correlation of the data. The following methodology is relatively insensitive to non-normality of the distribution; however, it does not take correlated data into account.

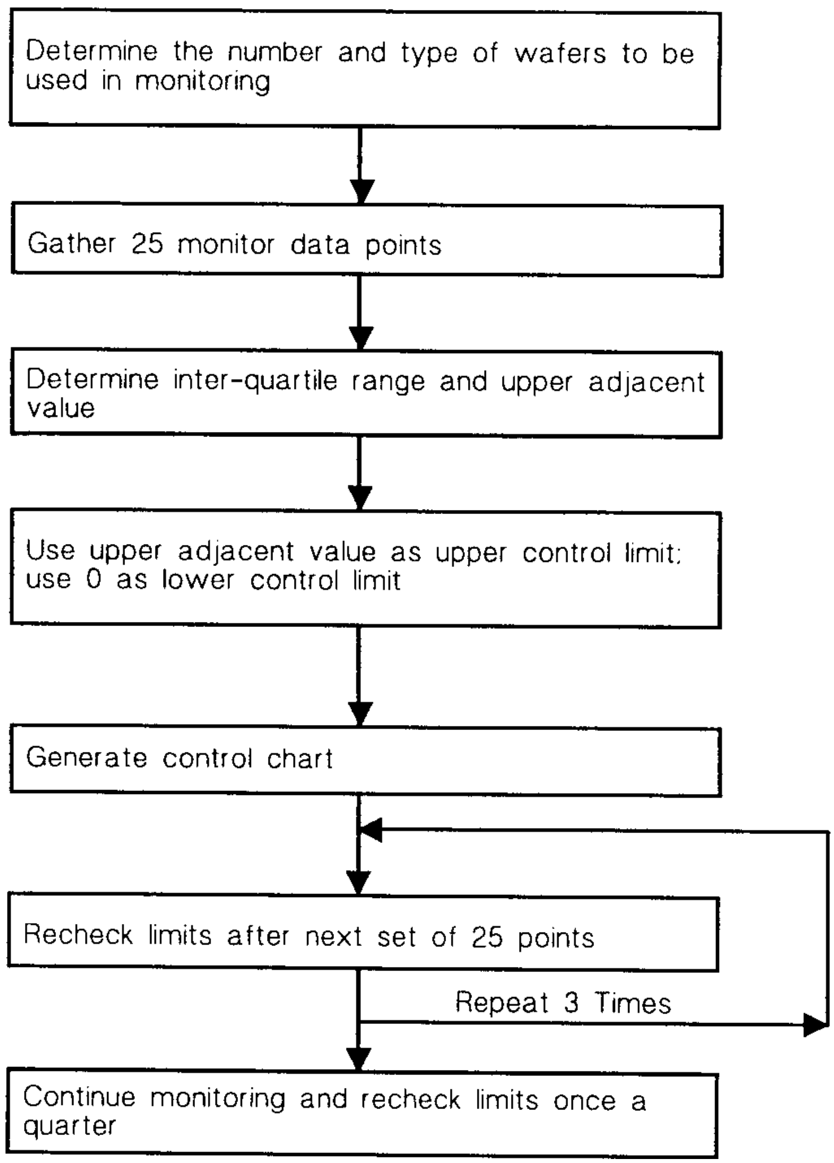

Figure 7
Methodology for Process Tool Particle Monitoring

7.2 Suggested Procedure for Process Tool Particle Monitoring

7.2.1 Determine the number of wafers to be used for monitoring. Read one wafer for 25 monitoring cycles, i.e., for 25 days or 25 shifts.

7.2.2 Gather 25 monitor points.

7.2.3 If using n = 1 wafers, then $D_i = post_i - pre_i$ for i = 1 to 25

where:

D = difference of particle counts before and after test.

7.2.4 If using n > 1 wafers, then

$$D_i = \sum_{i=1}^{n} \frac{post_i - pre_i}{n}$$

where n = # of wafers

n =_____

for n = 1:

$D_i = post_i - pre_i$

D_1 =______

D_2 =______

D_3 =______

D_4 =______

D_5 =______

D_6 =______

D_7 =______

D_{17} =___
D_{18} =___
D_{19} =___
D_{20} =___
D_{21} =___
D_{22} =___
D_{23} =___
D_{24} =___
D_{25} =___

7.2.5 Sort from lowest to highest.

7.2.6 Compute the upper adjacent value and median as follows:

Note:

UAV = upper adjacent value

UQR = upper quartile range

LQR = lower quartile range

IQR = interquartile range

Int = integer

If the number of passes or wafers is even:

median = average of value @ n/2 + value @ n/2 + 1
value @ n/2 + value @ n/2 + 1

UQR = average of value @ 3(n/4)
+ value @ 3(n/4 + 1)

LQR = average of value @ n/4
+ value @ n/4 + 1

IQR = UQR - LQR

UAV = UQR + 1.5 (IQR)

If the number of passes or wafers is odd:

median = Int(value @ n/2) + 1
LQR = (value @ n/4)Int + 1
UQR = (value @ 3n/4)Int + 1
IQR = UQR - LQR
UAV = UQR + 1.5(IQR)

7.2.7 Recheck limits after the next set of 25 data points (to make a total of 50 data points) is taken and validate data. Occasionally (every quarter) recheck limits using the above parameters.

APPENDIX 1

Note: The material contained in this appendix is not an official part of SEMI E14, and is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such they are to be considered as reference material only. The standard should be referred to in all cases.

A1 Notes on Preparing PSL Calibration Wafers

Light scattering from a particle is a major technique for counting and sizing particles in air, water, vacuum systems, or wherever they exist, including on surfaces. Although the theory of light scattering is well understood for a single particle suspended in a homogeneous medium, the addition of a reflecting plane next to the particle introduces enough additional complexities that the scattering problem cannot be solved analytically and requires considerable machine capacity for numerical solutions. Refer to A.1.2, Wojcik, Vaughan, and Galbraith, 1987; and Liu, 1990 for information on solutions to a few specific problems.

The primary calibration of specific instruments is empirical, correlating the instrument response to monodisperse particles (usually polystyrene latex spheres) of known size on surfaces of known optical properties. These measurements generate curves relating instrument (Figure A1) response to the diameter of the monodisperse PSL spheres. These curves vary with instrument design and also with surface type, typically necessitating a new empirical calibration for each type of surface examined. Coating composition and thickness can make significant differences. (See Figure A2 and, for example, Allen and Duty, 1991, Reference A.1.2). In addition, over at least a narrow range of sphere diameters, the calibration curves are not monotonic.

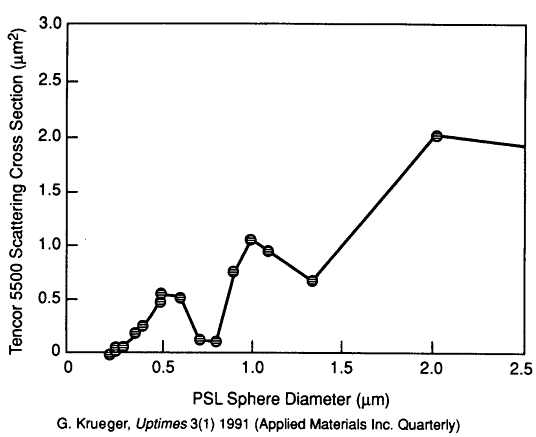

Figure A1
Substrate Dependence of Light Scattering by PSL Spheres

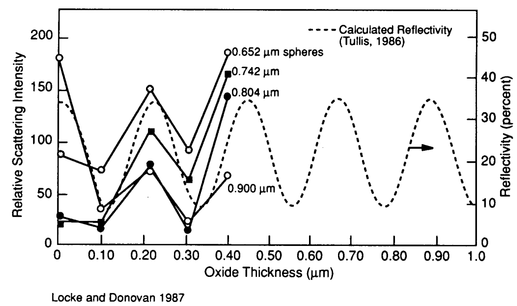

Figure A2
The Effect of Wafer Surface Reflectivity upon Surface Particle Light Scattering

Calibration is in terms of PSL sphere size, a convenient test particle of known optical properties but not a common contaminating particle in production environments. Thus, although a particle is considered a 0.2 μm particle if it generates a signal similar to that of a 0.2 μm PSL sphere, it is highly likely that the unknown particle is not spherical and has no specific dimension that is actually 0.2 μm.

A1.1 *PSL Deposition Procedures* — Procedures for counting surface particles using a commercial light scattering instrument depend on the specific equipment used. For all instruments, calibration curves corresponding to the surface being counted should be used. If not available, the instruments should be prepared to define the lower size detection limits and regions of multivalued response.

Construction of a calibration curve requires a set of 5-10 surfaces identical to that surface from which particle counts are desired. Each of these surfaces should have its own specific diameter of polystyrene latex (PSL) spheres spanning the diameter range from about 0.1 μm to 1-2 μm in increments defined by the size regions of highest interest. Typically, calibration curves exhibit the highest variation in size within the vicinity of wavelength of the incident light. Size increments should be the smallest over the size region. While some surfaces, such as bare silicon wafers, can be purchased with appropriately sized spheres already deposited, most surfaces of interest need to be prepared by the user. Three procedures for doing so follow.

The first procedure uses an aerosol generator, dryer, and neutralizer to feed aerosol through an electrostatic classifier and into a deposition chamber; it requires aerosol instrumentation for monitoring and control of the deposition. While less elaborate procedures are often satisfactory for depositing particles of diameters greater than 0.2 µm, this procedure minimizes extraneous particle deposition arising from contaminants in the deionized water supply, the PSL sphere supply, or other sources. These contaminants are probably more objectionable in the preparation of calibration wafers with PSL sphere diameters less than 0.1 µm.

The second procedure consists of the aerosol generator, dryer, and neutralizer. This simpler procedure sacrifices control over particle concentration and uniformity in return for simplicity of materials required and operation.

The third procedure is nonaerosol-based, using only a spinner similar to that typically used in films of liquid photoresist. The major advantage of this simplest procedure is that it requires no apparatus or materials beyond a source of PSL spheres and a high-speed spinner. Purity and uniformity of deposits by this third procedure are generally inferior to those of the other methods but may be adequate for inexpensively producing contaminated wafers dominated by a known PSL sphere size.

A1.1.1 Method 1: PSL Deposition from an Aerosol (Highly Controlled Procedure) — Materials:

PSL calibration spheres

PSL atomizer

Aerosol dryer

Aerosol neutralizer

Electrostatic classifier — A device for selecting particle populations according to electrical mobility.

Deposition chamber — An enclosure into which aerosol can be injected and deposited on the calibration surfaces also placed in the chamber. The chamber design should be such that it can be made particle-free by HEPA (or better) filtration prior to injecting the PSL aerosol and exposing the surfaces. To meet this requirement, the chamber may be located in a cleanroom. If the chamber is not located in a cleanroom, the surfaces must be loaded into the chamber in protective housings and not uncovered until the chamber atmosphere is particle-free.

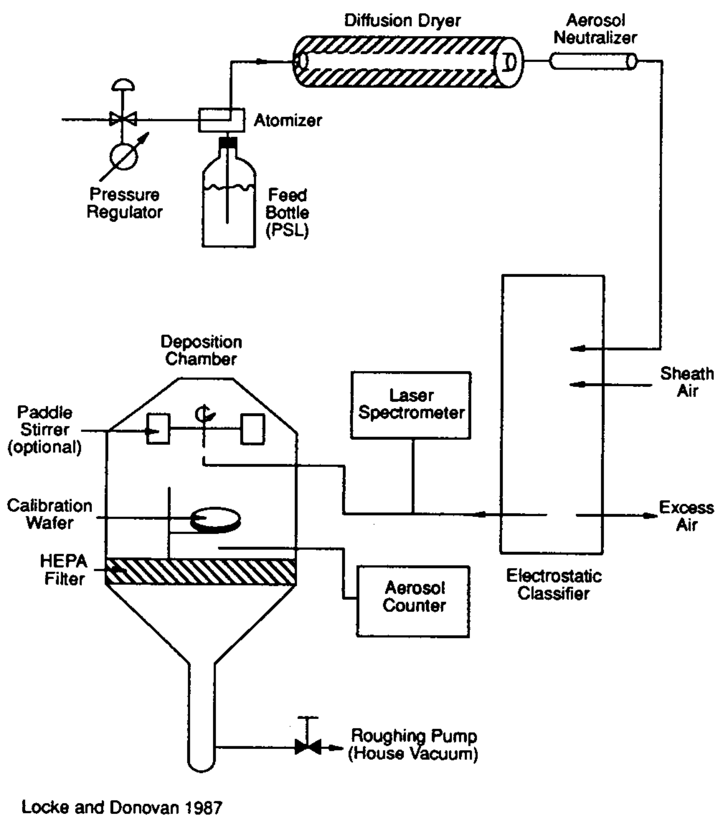

Figure A.3
Method 1 Aerosol Deposition System

Instrumentation and Components:

The chamber interior must remain isolated from all particle sources except the PSL aerosol both before and during surface exposure. The chamber design must be such that the wafer surfaces can be sealed in protective housing before unloading.

Particle-free source of compressed air (clean, dry air) or nitrogen

Regulators and tubing as needed

Aerosol particle spectrometer — A high-resolution spectrometer

Blank calibration wafer — Bare silicon or a silicon surface covered with a uniform film; this wafer should be as particle free as possible (particle concentration less than 10% of the anticipated PSL sphere population).

Steps

(1) Assemble components in the configuration of Figure A3. Connecting tubing should be as short as possible; inductive tubing should be used downstream of the atomizer.

(2) Charge the feed bottle with appropriately sized PSL spheres — 1 to 2 drops from the sphere manufacturer's solution into 800–1000 ml of deionized water is a good starting concentration.

(3) Initiate gas flow.

(4) Adjust electrostatic classifier voltage and flow rates for maximum particle concentration (calibration of the classifier may not agree with the PSL sphere diameter specified by the manufacturer); note PSL particle diameter measured by the laser spectrometer.

(5) Measure particle concentration, C_0, inside the deposition chamber.

(6) Insert clean calibration wafer into deposition chamber (or uncover a preloaded wafer).

(7) Expose wafer to the aerosol for a time period determined by:

$$t = \frac{DN}{AC_o V_D}$$

where:

t = time of wafer exposure

DN/A = desired area density of PSL particles on the calibration wafer

C_o = measured PSL aerosol concentration in the deposition chamber

VD = deposition velocity of the PSL spheres (estimate from Figure A4)

Deposition velocity depends on a number of variables. The curve calculated for a Boltzmann distribution in Figure A4 is a reasonable initial estimate.

A1.1.2 *Method 2: PSL Deposition from an Aerosol (Abbreviated Procedure)* — This method, though not as tightly controlled as Method 1, provides good calibration wafers with half depositions or partial wafer depositions as defined by the nozzle motion.

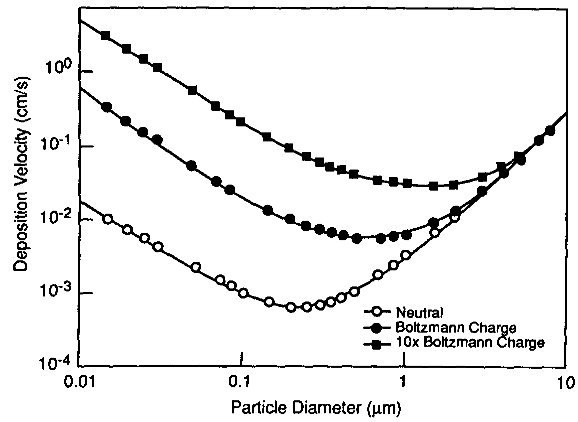

Figure A4
Calculated Deposition Velocity Including Effects of Diffusion, Setting, and Electric Field
Figure A3 — Method 1

Materials

This procedure omits the classifier and the deposition chamber used in Method 1. The configuration is the same as shown in Figure A3 until after the aerosol neutralizer. All apparatus downstream of the neutralizer can be omitted; or an arrangement such as shown in Figure A5 can be used, which includes an aerosol spectrometer. The items within the boxed area in Figure A5 can be purchased in an integrated package.

Steps

(1) Assemble components in the configuration of Figure A3. Connecting tubing should be as short as possible; inductive tubing should be used downstream of the atomizer.

(2) Charge the feed bottle with appropriately sized PSL spheres — 1 to 2 drops from the sphere manufacturer’s solution into 800–1000 ml of deionized water is a good starting concentration.

(3) Initiate gas flow.

(4) If an aerosol spectrometer is used, adjust the gas flow rate so that the spectrometer reads the most

monodispersed distribution in the proper size range. (Without the spectrometer the PSL sphere diameter is assumed to be that listed on the vial label by the manufacturer.)

(5) Using a backside vacuum pick, hold a blank calibration wafer vertically in front of the nozzle. This step should be in a particle-free space, such as in the vertical laminar flow downstream of a HEPA (or better) filter.

(6) Pass the nozzle several times across that portion of the wafer on which spheres are to be deposited.

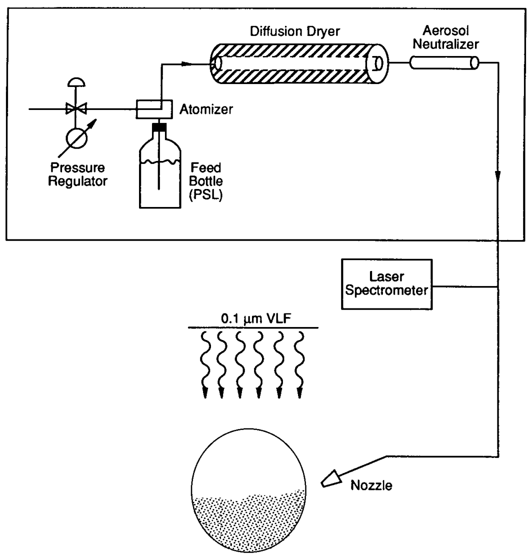

Figure A5
Method 2 Deposition Schematic

A1.1.3 Method 3: PSL Deposition from a Hydrosol — Materials:

Method 3 is a nonaerosol deposition procedure and requires only PSL calibration spheres, a blank calibration wafer, and a variable speed spinner with a vacuum hold down chuck.

Steps
(1) Prepare a dilute aqueous solution of PSL spheres of the desired size — 1 to 2 drops from the sphere manufacturer's solution into 800–1000 ml of deionized wafer is a good starting concentration.

(2) Place the blank calibration wafer on the vacuum chuck of the spinner.

(3) Start the spinner and add several drops of dilute PSL solution to the center of the wafer when the spinner is up to speed (dynamic dispense).

The strength of the PSL solution, the quantity of solution placed on the wafer, and the spinner speed should be optimized by trial and error.

A2 Notes on Measurement Instrument Calibration

A2.1 The particle measuring instrument should have the following minimum performance requirements:

Although this document is designed for 0.1 µm particle counting instruments, the minimum measurable particle size for consistent performance should be no greater than 0.3 µm. At its first threshold, the instrument should not generate an average background internal noise level > 1 false particle count per ten (10) wafer (review) cycles. A primary signal-to-size calibration curve should be available from the instrument manufacturer, covering a minimum size range of 0.3 µm–1.0 µm. The instrument must have a dynamic range of particle size sufficient to span below 0.3 µm and above 1.0 µm PSL (polystyrene latex) calibrating spheres without sensitivity or gain adjustments. The instrument should not add more than .003 particles/cm/pass > 0.1 µm in size per measurement cycle per wafer.

A2.2 *Acceptance Calibration*

A2.2.1 *Loading Wafers* — Some instruments may have the propensity to detect a different number of particles on the wafer surface as the wafer is changed in orientation from inspection to inspection. Loading the calibration wafers at a constant orientation ensures a minimal amount of count orientation effects. This will help minimize count variations from instrument to instrument and site to site.

Slot separation minimizes effects of particle migration from the back of one wafer to the front of the next wafer.

A2.2.2 *Electrical False Positive Test* — The instruments used must provide false positive test capability.

The purpose of the false positive test is to determine that, when the instrument's optical detector is blocked from light input, the electronic output at the specified sensitivity equals less than or equal to one false positive count over ten scans.

If the first threshold, specified sensitivity, is adjusted too close to the background noise band, particle counts will be noted when no count should be present.

Electrical False Positive Test Procedure:

(1) Adjust the gain or display for specified sensitivity of the instrument.

(2) Scan a wafer with the specified distribution to observe sensitivity.

(3) Block the optical detector input.

(4) Scan the same wafer 10 times while observing each count output.

(5) If the total number of counts is > 1, the particle counter cannot be used at the present gain setting or display sensitivity.

If the count is ≤ 1, continue to A2.2.3.

A2.2.3 *First Threshold Signal-to-Noise Ratio Test* — This test is designed to show that the instrument's first threshold can be sufficiently detected to verify normal operation of wafer inspections.

If the instrument's first threshold is too close to the scatter band, count repeatability and accuracy can be affected. The noise that affects counts at maximum sensitivity is due to molecular scatter from the laser, shot noise from detector dark (leakage) current, and surface roughness generated noise. It is necessary to design the laser and shot noise out of the instrument, it is also necessary to discriminate between the particle signal and the surface roughness signal; when this is done, the surface roughness signals should not be counted as particles.

Gainsetting____

Scan 1 ___,2 ___,3 ___,4 ___,5 ___,

6 ___,7 ___,8 ___,9 ___,10 ___.

Readjust gain or display and restart this procedure at step 3. If the test continues to fail, readjust gain until test is successful and note the noise-free display sensitivity.

First Threshold Signal-to-Noise Ratio Test Procedure:

(1) Scan a very clean, bare silicon wafer of typical surface roughness. The displayed output should approximate the first figure below.

Under normal conditions, the total particle count should be relatively low, and the counts should increase as 0.1-µm sensitivity is approached.

For 0.1-µm instruments, the far left side of the particle distribution should not move toward zero. If this occurs, the electronic software may be partially forcing the display to zero.

(2) Nebulize onto the wafer a 1/2 deposition of PSL spheres representing the specified sensitivity of the instrument.

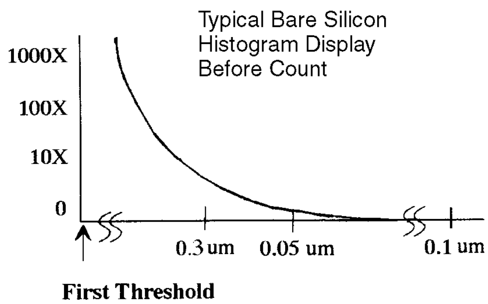
(3) Review the displayed output to calculate the S/N ratio. Use the second figure below for calculations. The figure represents a 0.1-µm instrument. Instruments with less sensitivity can use the same calculation.

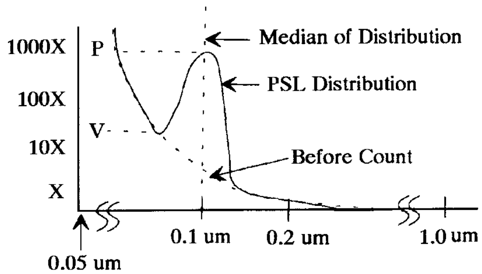
(4) Determine the median of the distribution, which is the same point as the first threshold of the instrument. Determine the particle count at the median of the peak.

Determine the particle count at the valley on the left side of the distribution.

$S/N = P/V \geq 2.0$

Be aware that if the S/N ratio > 2.0 and the distribution is clearly separate from the far left noise region, the instrument has a potential to provide excellent separation between particle counts introduced as a result of surface scatter.

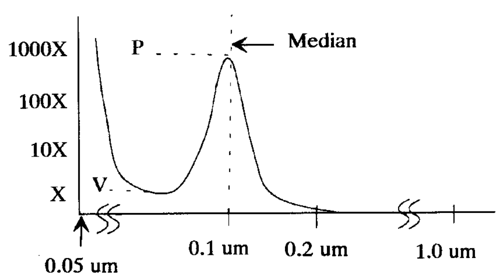




Peak count =____________.

Valley count =__________.

S/N ratio =_____________.



If the first threshold does not meet specifications, determine whether there is an instrument electrical problem. If the instrument is operating properly, verify that a new threshold is required and adjust the first threshold slightly above its present setting (away from the noise band) and rerun this test until the specification is met.

A2.2.3.1 *Surface Roughness* — Surface roughness is a term which describes the effects of the bare silicon polish (or a metal/film deposition) to the scattered light. The design of the particle counter also determines how the surface roughness data is collected. Surface roughness is also known as surface texture scatter or haze. Surface roughness is a noise produced by an ensemble of microimperfections in the surface and not attributable to a single point. Even in the case of highly-polished wafers, the roughness is measurable, and the relative scattering generated is a continuum. The noise thus arises from the variations and nonuniformity of the surface texture. A typical value of texture–generated scatter from a typical polished wafer is 1 ppm ("ppm" refers to parts per million; i.e., the ratio of incident light intensity to scattered light intensity as measured when the incident light illuminates a clean wafer surface—whether the surface is bare silicon or deposited with a metal or film process).

In some particle counters, the light source is mechanically manipulated by mirrors or optics to scan the surface. If the optics are not totally uniform in reflectivity or transmission, the beam steering process effectively modulates the source of illumination. It is difficult to prevent such modulation from increasing the noise by several percent.

All of these noise components are of an AC nature and are all that need to be considered when analyzing for particles on the wafer surface. Texture or roughness–generated scatter is optically unresolvable and pervasive over the entire surface. It is thus a DC term and can be quite large.

If 100% of the scattered light is collected, the texture–related scatter is related to the rms roughness according to:

$$\Delta \text{rms} = \frac{\lambda}{4\pi}\sqrt{s}$$

where Δrms = root mean square roughness height

λ = wavelength of illumination

s = fractional texture - related scatter

If the wafer surface were perfectly smooth, 100% of the light illuminating the surface would be reflected with no texture-generated scatter captured by the optical detector. However, as the roughness worsens, texture-generated scatter increases, causing the DC term to increase and the sensitivity of the particle counter to decrease. As the DC term increases above the threshold of display sensitivity, the wafer image will appear to have many thousands of particles. The gain, therefore, must be adjusted up or down accordingly to optimize the particle counter's ability to detect particles, but not texture-generated noise. In the case of some films and metal depositions, the amount of surface roughness can be as high as 25,000 ppm, requiring the gain to be adjusted quite high (2 µm to 5 µm sensitivity).

Other sources of noise, which combine with texture-related scatter, are molecular noise from the light source and stray light. Molecular noise is generated from the light source prior to illuminating the wafer surface. This provides an unwanted DC term to the optical detector. Consider whether or not the optical detector is protected from this unwanted noise.

A2.2.4 *Size Accuracy* — Calibration wafers with polystyrene latex (PSL) calibration monospheres can be prepared by test personnel on-site or purchased from a qualified source. Additional calibration wafers can be used. If on-site personnel are using aerosol nebulizers, care should be taken to minimize agglomerates and the lack of cogenerated residue particles sufficient in size to contribute significant particle background.

The operator should set the calibration points as close to the median of each PSL distribution as possible. The setting may be slightly below or above the actual median according to the histogram. If one is trying to compare two different process tools for particle contributions, it is best to use the same calibration wafers for particle counter instrument calibration at both locations. However, this methodology is not a guarantee of absolute correlation between instruments.

As a result of calibrating the instrument response at the median of each PSL distribution, by definition the first threshold has a count efficiency of 50% at the first threshold. It is much simpler and more accurate to identify the median of a monodispersed distribution for a calibration point. It is also advantageous to know the point on the response curve above the first threshold where 100% of the particles are being detected, as this is the point from which count repeatability is determined.

If the particle counting instrument has the ability to discriminate between particles and surface roughness at the first threshold, this issue poses no problem. If an instrument has difficulty in discriminating between surface roughness and particles, the particle count can be misrepresented. One will need to determine the minimum sensitivity at which particle counts are not affected by surface roughness of the wafer.

A2.2.5 *Size Resolution* — Size resolution of an instrument defines how accurately the instrument can differentiate between two particles of nearly the same size. As the percentage of resolution increases, the instrument begins to lose its ability to differentiate between particle sizes. This effect is greatest at the first threshold where particle counts are usually highest. Ideally, it is good to know the size resolution of the instrument at all calibration points. If determining size resolution at only one calibration point is required, it should be at the minimum particle size affecting the process.

Resolution is quantified by measuring the increase in standard deviation (s) caused by the instrument to the true standard deviation of a deposit of monosized particles as reported by the particle producer. (See 4.2.4.3.)

Instrument Size Resolution(in %):

$$\frac{\sqrt{\text{Instrument s}^2 \text{ - Reported PSL s}^2}}{\text{Particle Mean Diameter } \mu\text{m}}$$

A2.2.6 *Count Accuracy* — Count accuracy is critical to define as it signifies an instrument's ability to provide an accurate particle count. Although the etched pit wafers in use today have anywhere from 300 to 800 scattering sites, it would be ideal to have an etched pit wafer with only 20 scattering sites on the surface in the pattern of a plus sign. In addition, it would be ideal to have 5 scattering sites in each quadrant, each of which forms a plus (+) sign across the X and Y axis of the wafer. If this type of standard is not available, use existing etched pit standards. The count accuracy wafer is to be used to evaluate the ability of the instrument to detect a known number of scattering centers at discrete positions on the surface of the wafer.

The edge exclusion should be set to include only the desired pattern of scattering sites. The lower and upper size display should be set to display only the distributions of the peaks. Some etched pit wafers have only one size of scattering site while others have 4 sizes. Count accuracy is determined with these parameters. Particles related to the etched pit pattern are to be disregarded from the count accuracy test. One should review each image of the inspected etched pit wafer to discern if particular scattering sites are repeatedly not detected. This does not necessarily mean that the particle counter is at fault.

For example, if the scattering site in question has residue at the bottom of the site, it is possible for the particle counter to incorrectly size the scattering sites repeatedly or not to detect them. Steps should be taken to resolve any uncertainty.

The exact number of the features on the etched pit wafer is either a function of which of four sizes (if a 4 distribution etched pit wafer is used) is displayed on the scanner or a function of the amount of edge exclusion used. For example, if only one of four sizes is displayed to the screen, the maximum total count (excluding non-planned features) will be one-fourth the total feature count. If a single-sized etched pit wafer is used, it is possible to vary the measurement tool by varying the edge exclusion.

Consistently use the same etched pit wafer exactly (not just the same model number) on a given machine to do trend monitoring or to construct control charts.

If there is a significant amount of background particle contamination or surface scratches on the etched pit wafer, the standard should be cleaned properly or discarded. Contact the etched pit manufacturer for cleaning instructions.

A2.2.7 *Count Repeatability* — Repeatability is often determined with a PSL distribution of a known size on the wafer surface, but can also be determined on bare silicon with far fewer particle counts. Significant differences in instrument response may be noted between the two approaches. The number of counts and wafer orientation may contribute to this problem. Hence, the equipment user and equipment manufacturer must mutually agree as to whether bare silicon or PSL spheres on the wafer are to be used.

Count repeatability is determined from a particle sensitivity greater than or equal to the threshold at which 100% count efficiency is specified. If there are any noise problems in the instrument's response, count repeatability is immediately affected. If the PWP performance of the instrument itself is poor, the count repeatability is unacceptable.

If the wafer orientation is permitted to change, each particle on the wafer will present a different surface area to the illuminated light. If this circumstance is permitted by the instrument or the operator, particle sizing and particle counts may vary, possibly affecting count repeatability. It is recommended that wafer orientation remain the same on all wafers.

The three basic designs that are currently in use by the various instrument suppliers illuminate the wafer surface by raster scan, telecentric scan, and orthogonal scan. Raster scanning the wafer surface with a laser provides a changing angle of illumination to the particle. If the wafer orientation is not held constant (i.e., no wafer prealignment), the effect of a changing angle of illumination and a varying orientation may cause the particle sizing and count to vary.

If the operator were to scan a wafer one time with the wafer at 0° orientation (wafer flat or notch down in the cassette) a certain number of particles would be noted in each size bin. By changing the wafer orientation over a number of scans, the operator may note a deviation in each bin-i.e., varying size. The solution to the orientation problem is to prealign the wafer flat or notch to a constant orientation before each scan. It should not be assumed that one particular orientation is more correct than another. Prealignment of the wafer simply minimizes the effects of a changing wafer orientation.

Telecentric scanning instruments provide a constant angle of illumination. However, if the wafers are not prealigned to a common reference every time, wafer orientation may cause the same problem as with a raster scanning system.

Orthogonally scanning instruments provides a constant angle of illumination while spinning the wafer. The wafer flat can be at any orientation at the beginning of the scan, but the particle will always be illuminated at the same angle of orientation. Hence, the effects of wafer orientation are greatly reduced.

A2.2.8 *PWP* — Collecting 20 or more inspections of a wafer serves two purposes. Not only does it provide a good check for count repeatability, but it also provides the data to develop the PWP profile of the particle counting instrument. If the slope of the count repeatability is too high, both repeatability and PWP will fail. By averaging the first ten (before) and last ten (after) data points of the 20 inspections, a line having a specific slope can be ascertained. While the deviation from the mean of all the individual points reflects the count repeatability, the slope of the line determines the PWP performance. The delta is divided by 10 to determine average contributions per pass. The number of particles added is divided by the inspected surface area to determine the instrument PWP/cm^2.

A3 Notes on Measurement Instrument Monitoring

The following routine may be used to implement instrument monitoring or to complement a current implementation.

The purpose of monitoring the particle measurement instrument is to verify that the instrument is in calibration. Routinely verify the performance of the measurement instrument so that results can be trusted. The instrument calibration is tested using an etched pit standard, which provides information about instrument count accuracy and sizing accuracy. Etched pit wafers are the standard of choice for routine monitoring because they may be cleaned and recertified when they get contaminated. PSL wafers, on the other hand, need to be replaced when they become contaminated.

Count accuracy is verified by recording the total number of particles counted by the system. Simply recording the total number of particles is valid if care is taken in handling the wafer, so as to minimize extraneous contamination. The program used to run the standard should be similar to the program used during instrument acceptance. That is, the edge exclusion should be maximized to isolate the scattering centers, and care should be taken in regard to wafer orientation.

Sizing accuracy is verified by recording the location of the median of the Gaussian distribution corresponding to each of the four different size scattering centers. The absolute sizing is not as important as the day-to-day position of the distributions. Programs should be set up which enable the four different distributions to be collected. If the instrument has sufficient dynamic range, one program may be sufficient. If the instrument has limited dynamic range, two or more programs may be required. The instrument manufacturer may supply the necessary measurement program parameters.

The calibration wafer should be run regularly (for example, once per shift, once per day, or once per week) for 25 tests, and the data should be recorded on $\overline{X}$-MR control charts. Once 25 points have been collected, control limits can be defined. $\overline{X}$-MR control charts are used to track information collected by measuring an identical sample over and over again. $\overline{X}$-MR charts track the difference between a current measurement and the value of the measurement the last time the sample was run.

$\overline{X}$-MR charts are constructed by recording the mean of the variable being tracked, perhaps the total number of particles for count accuracy or the mean diameter or scattering cross-section for sizing accuracy. The moving range can be calculated, once two data points have been recorded, by taking the absolute value of the difference between today's measurement and the previous measurement. For example,

	Sept 15		Sept 16		Sept 17		Sept 18		Sept 19
$\overline{X}$	425		430		428		424		425
MR		5		2		4		1	

Note that there will always be one less MR value than there are $\overline{X}$ values. The $\overline{X}$ and MR values should be plotted on separate charts.

Once 20 points have been collected, control limits can be calculated as follows:

1. Calculate the mean of the Xs, $\overline{X}$.
2. Calculate the mean of the MRs, $\overline{MR}$.
3. Calculate the upper and lower control limits for the X chart.

$$UCL = \overline{X} + 1.88 \bullet \overline{MR}$$

$$LCL = \overline{X} - 1.88 \bullet \overline{MR}$$

4. Calculate the upper and lower control limits for the MR chart.

$$UCL = 3.27 \bullet \overline{MR}$$

$$LCL = 0.00$$

These upper and lower control limits represent three sigma limits. One sigma and two sigma levels can be indicated on the charts. Reference these levels during testing for out-of-control points.

The area between the center line and the three sigma level is Zone A. The area between the center line and the two sigma level is Zone B. The area between the center line and the one sigma level is Zone C. Subsequent measurements are "out-of-control" if they violate any one of the following rules:

1. One point beyond Zone A.
2. Two out of three consecutive points in Zone B.
3. Four out of five consecutive points in Zone C.
4. Five rising or five falling consecutive points.
5. Seven points on one side of the center line.
6. Six consecutive up and down pairs (applies only during setup).
7. Thirteen consecutive points in Zone C (applies only during setup).
8. Five consecutive points outside of Zone C (applies only during setup).

In-house monitoring should be used. If no SPC methodology exists, the above method is appropriate.

A4 Notes on Process Tool Monitoring

Particle Test Definition — Particle test definition requires prioritizing of the process tools, identification of the number and type of wafers to be used to test each tool, definition of the procedure to be followed when the test is run, and definition of ultimate uses for the data.

Process tools should be prioritized so that fab personnel are not overwhelmed and so that the testing can be implemented in a controlled and systematic manner. An example of tool prioritization follows:

Type A: Equipment used to process critical levels, Equipment known to generate high-particle counts

Type B: Equipment known to generate low-particle counts, Baths and spin dryers

Type C: Metrology equipment, Noncritical processing equipment

Identify the number and type of wafers to be used to test each tool to ensure that the test is statistically significant and that all key subprocess steps are tested. These steps are generally best accomplished when the contamination control engineer works directly with the process engineer responsible for each tool. The two engineers should analyze the wafer flow for each processing step. For example:

Metal Etch

hard bake
load into etcher
pump down
flow gases for metal etch
start plasma
stop plasma
flow gases for passivation
start plasma
stop plasma
vent
unload from etcher
inspect
wet strip
dry strip

With these breakdowns the two engineers should identify the key subprocessing steps to be tested for particles. For example,

From these key subprocessing steps particle test wafers should be identified. For example,

Metal etch:

load/unload	1 wafer
load/pump/vent/unload	1 wafer
load/p/flow gases/v/unload	1 wafer

After the particle test steps have been identified, the type of wafers and sampling plan should be defined. For example,

1. The number of acceptable wafers before particle counts
2. The number of passes per wafer (to ensure reasonable statistics for low particle contributions)
3. Use of control wafers

One wafer should be run per subprocessing step. The use of control wafers should be limited to cases where day-to-day environmental conditions may vary widely and seriously compromise the test outcome (for example, when the processing tool is located near a door that people could open during particle testing). Running only one wafer per subprocessing step is valid during tool monitoring because these tests are run frequently enough to generate valid statistics. In addition, the tests may be cost and time prohibitive if rigorous multiple wafer testing were employed.

Once the tests have been defined, the test procedure can be defined. The test procedure should include the following information: when the tests should be run; who is responsible for running each part of the test; what test protocol is used (for example, how the wafer should be transferred from the measurement instrument to the processing tool and back or how the wafer should be transferred from cassette to cassette); what instrument and tool measurement programs are used; and what should be done with the data once it is collected.

A4.2 *Tool Baselining* — Tool baselining is the systematic collection of the data needed to construct a control chart and define statistically significant control limits. Tool baselining quantifies the variations in particle counts due to random fluctuations. For this reason, collect baselining data in a controlled and systematic manner. This allows variations in particle counts to be attributed first only to variation in the process tool and second as variations with different people at different shifts.

As many factors as possible should be held constant during the tool baselining timeframe. People and shift variations must be isolated from the process tool baseline. For example,

1. The tests should be run at the same time each shift or each day.
2. The tests should be run by the same people. The process tool should be operated by the process engineer or technician responsible for the tool, and the particle measurement instrument should be operated by the contamination control engineer or technician responsible for the instrument.
3. Calibration of the measurement instrument should be verified.
4. Wafer before particle counts should be approximately the same.

Plot the data on baseline charts while it is being collected. The pattern of points should be tested for a pattern of six consecutive up-down pairs (see Figures A7, A8, A9). This pattern indicates that a nonrandom special cause is influencing the test, and the test procedure should be reevaluated. This baseline chart establishes optimal tool performance with no variation associated with people or shift changes. For defining control limits based on actual operating conditions, see Section A.3.

A4.3 *Routine Tool Monitoring* — Routine tool monitoring has two purposes. First, routine tool monitoring provides the periodic testing needed to ensure that the tool remains in control. Second, routine tool monitoring provides a means of improving microcontamination awareness and operating protocol.

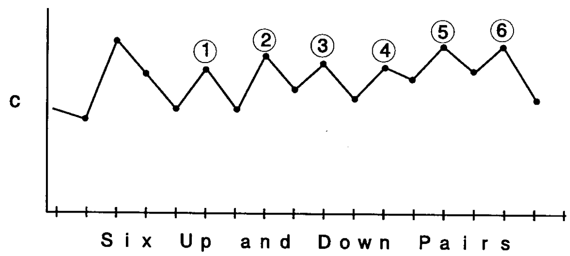


Figure A7
Six Up-Down Pairs

Both of these tasks are accomplished simultaneously because, as routine tool monitoring begins, the rigorous systematic and controlled test conditions applied in the tool baselining phase tend to be relaxed. As a result, routine particle monitoring begins to more closely approximate normal processing conditions.

For example,

1. The tests are not necessarily to be run at the same time each shift or each day.
2. Responsibility for running the particle tests is transferred to the processing engineers and technicians.
3. A range of acceptable before particle counts (usually “not greater than some number”) is to be defined.

To define control limits, collect 25 data points, vary people and shifts on a routine basis (e.g., daily, per shift change). Plot this data on a control chart while it is being collected.

In addition to training processing engineers and technicians in particle testing procedures, this transfer-of-responsibility stage is a good time for contamination control engineers to review protocol practices. In the initial stages, contamination control engineers should be highly visible so that out-of-control conditions are dealt with in a controlled manner. For example, if a processing technician logs an out-of-control datapoint, the contamination control engineer should be available to ensure that the source of the problem is the processing tool and not the test procedure.

Out-of-control conditions are identified by testing the C-chart patterns against the Western Electric rules (see Referenced Documents, Section 2). The Western Electric rules define conditions where the probability of a pattern of points on a control chart occurring by chance alone is less than 1%. Because C-charts represent Poisson (asymmetric) distributions, only the following Western Electric rules apply:

1. one point outside control limits
2. five rising or five falling segments (see Figure A8).

Due to the nature of particle counts, rule one above is usually applied as one point above the upper control limit; particle counts below the lower control limit are advantageous and, therefore, not considered out-of-control. Other Western Electric rules are not applied to C-charts because they assume normal distributions.

When routine tool monitoring begins, the charts for the key subprocessing steps should be reviewed to determine if additional information is gleaned by monitoring the different steps independently. For example:

1. Did deviations in particle levels track together, implying that running the different wafers was redundant?
2. Were deviations independent, implying different particle sources and requiring that all subprocesses needed to be monitored?
3. Did one subprocess capture all the deviations while other subprocesses were constant, implying that just monitoring that one subprocess was sufficient?

The routine monitoring phase is also the time to define out-of-control actions. Out-of-control actions are a list of procedures that should be followed if the particle level of a processing tool goes out-of-control. For example:

Etcher Out-of-Control Actions:

1. Retest

If still out-of-control:

2. Put tool “down”
3. Run 5 conditioning runs
4. Retest

If still out-of-control:

5. Call maintenance technician
6. Wipe down chamber
7. Run 5 conditioning runs
8. Retest

If still out-of-control:

9. Call responsible engineer

This list of actions enables particle problems to be addressed in a rapid and systematic manner.

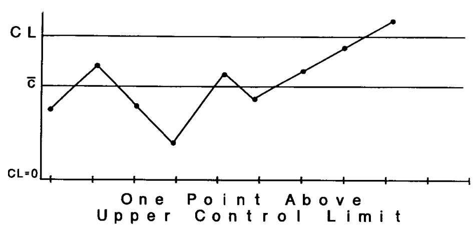

Figure A8
One Point Above Upper Control Limit

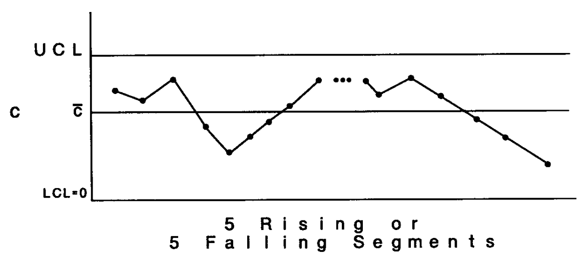

Figure A9
5 Rising or Five Falling Segments

Due to the nature of particle counts, rule one above is usually applied as one point above the upper control limit; particle counts below the lower control limit are advantageous and therefore not considered out-of-control. Other Western Electric rules are not applied to C-charts because they assume normal distributions.

SEMI E15-0698
SPECIFICATION FOR TOOL LOAD PORT

1 Purpose

This standard is intended to unify the interface between process/inspection tools and automated wafer carrier transport systems while maintaining compatibility with human transport.

2 Scope

This specification deals with the mechanical interface (load port) for wafer carrier transfer between wafer carrier material transport systems, including humans, and wafer fabrication/inspection equipment (tools). The concept defines the placement and orientation of a wafer carrier on a tool to allow reasonable interfacing with mechanized material movement systems without compromising human access to perform the material exchange function.

3 Impact

Compliance with this specification requires the placement of load ports on tools to specific heights, orientations, and load depths. Restrictions are also placed on clearances to obstructions which may be adjacent to such ports.

4 Referenced Documents

4.1 *SEMI Documents*

SEMI E1 — Specification for 3 inch, 100 mm, 125 mm, and 150 mm Plastic and Metal Wafer Carriers

SEMI E1.7 — Standard for 200 mm Plastic and Metal Wafer Carriers, General Usage (Proposed)

SEMI E19 — Standard Mechanical Interface (SMIF)

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

5 Terminology

5.1 *Selected Definitions*

5.1.1 *box* — A protective portable carrier for a cassette and/or substrate(s) per SEMI E44.

5.1.2 *cassette* — An open structure that holds one or more substrates per SEMI E44.

5.1.3 *cassette centroid* — A datum representing the theoretical center of a stack of wafers in a cassette formed by the pocket centerline and the "center" pocket as defined by the location associated with dividing dimension B3 by two (see SEMI E1, Figure 1).

5.1.4 *cassette envelope* — A rectangular volume with vertical sides which completely contains a cassette, even if the cassette is tilted (see Figure 1).

5.1.5 *enclosed load port* — A load port with overhead clearance obstructed by the tool.

5.1.6 *global orientation* — The general orientation of a wafer carrier in a tool; may be vertical or horizontal.

5.1.7 *load depth* — The horizontal distance from the load face plane to cassette centroid or carrier centroid (see Figures 2 and 3 (D)).

5.1.8 *load face plane* — The furthest physical vertical boundary plane from cassette centroid or carrier centroid on the side (or sides) of the tool where loading of the tool is intended (see Figures 2 and 3).

5.1.9 *load height* — The distance from the bottom of the cassette or carrier to the floor at the load face plane (see Figure 3 (H)).

5.1.10 *load port* — The interface location on a tool where wafer carriers are delivered. It is possible that wafers are not removed from, or inserted into, the carrier at this location.

5.1.11 *open load port* — A load port with overhead clearance unobstructed by the tool.

5.1.12 *pod* — A box having a Standard Mechanical Interface (SMIF) per SEMI E19 and SEMI E44.

5.1.13 *spacing* — The minimum spacing between centroids (see Figure 2, S).

5.1.14 *tool* — Any piece of semiconductor fabrication or inspection equipment designed to process wafers delivered in wafer carriers.

5.1.15 *tilt* — A small angle of offset from the normal horizontal or vertical orientation of a cassette or wafer carrier designed to preferentially align or keep wafers in their intended place within the carrier/cassette (see Figure 1, T).

5.1.16 *wafer carrier* — Any cassette, box, pod, or boat that contains wafers.

5.1.17 *wafer carrier centroid* — A datum representing the theoretical location of the center of a stack of wafers in the carrier.

5.1.18 *wafer carrier envelope* — A rectangular volume with vertical sides which completely contains a carrier, even if the carrier is tilted (see Figure 1).

5.2 *Description of Terms Specific to this Standard*

5.2.1 *carrier* — Wafer carrier.

6 Ordering Information

6.1 The following items require communication between the tool supplier and user and shall be included in any request for quotation, quotation, or purchase order:

6.1.1 If the tool has multiple load ports, provide the spacing, S, between carrier centroids (see Section 7.8).

6.1.2 Specify what carrier (e.g., SEMI standard cassette, pod) is to be accommodated by the load port.

6.1.3 Specify whether the load port is open or enclosed.

6.1.4 Specify whether the wafer orientation is horizontal (per Section 6.3.1) or vertical (per Section 6.3.2).

7 Requirements

7.1 The dimensions for the placement of a wafer carrier on the load port of a tool are given in Table 1.

7.2 The standard is based upon the concept that any wafer carrier can be used. Dimensions are usually specified as clearances to wafer carrier envelopes (see envelope concept in Figure 1).

7.3 The global orientation of the cassette or wafer carrier is constrained to be parallel or perpendicular to the load face plane. Allowable cassette orientations are:

7.3.1 For wafers horizontal, the opening of the cassette must be opposite the load face plane, and the front surface of the wafer must face up (see Figure 4a);

7.3.2 For wafers vertical, the opening of the cassette must face up, and the front surface of the wafer must face the load face plane (see Figure 4b).

7.3.3 This requirement also applies to cassettes in pods.

7.4 The maximum tilt is 10 degrees.

7.5 The load height is specified as follows (see Figure 3):

7.5.1 Dimension H is 900 mm (~35.4 in.), fully adjustable over ± 10 mm (~0.4 in.).

7.6 The maximum height above H of an obstruction between the load face plane and the carrier envelope (such as for an alignment device or identification tag reader) is 50 mm (~2 in.) (see Dimension H1 in Figure 3).

7.7 Clearances (C1, C2, and C3) are defined with respect to the largest carrier envelope required. For cassettes, envelopes are defined using cassette dimensions from SEMI E1 or SEMI E1.7. For pods or other wafer carriers, envelopes are defined using the carrier standard (if any) or the carrier manufacturer's specifications (see Figure 1 for concept and Figures 2 and 3 for use).

7.8 Dimension S specifies the recommended minimum spacing between cassette/wafer carrier centroids. In any case, if S violates clearance C1 in any application, then C1 prevails (see Figure 2).

7.9 Tools with enclosed load ports shall have a minimum vertical clearance, C3, above the cassette or carrier at the load port. Open load ports shall have a vertical clearance above the load port which is unrestricted by the tool.

Table 1 Dimension Requirements, mm (inches)

Dimension	*Application*	*Value, mm (in.)*	*Notes*
C1	minimum	75 (3)	
C2	minimum	30 (1.2)	
C3	minimum	225 (9)	See Note 1
D	maximum	250 (0)	
H	range	900 (35.4) ± 10 (.4)	See Note 2
H1	maximum	50 (2.0)	
S	≤ 150 mm carriers 200 mm carriers	350 (13.8) 400 (15.7)	See Section 7.8
T	maximum	10 degrees	

NOTE 1: Applies to tools with enclosed port; otherwise, clearance above the port must be unrestricted by the tool (see Section 5.8).

NOTE 2: Fully adjustable over ± 10 mm (~0.4 in.) range.

Dimension Definitions

C1 — Minimum side clearance between one carrier envelope and another, or to vertical obstruction.

C2 — Minimum rear clearance from carrier envelope to vertical obstruction.

C3 — Minimum clearance above carrier envelope to horizontal obstruction on the tool.

D — Maximum load depth to carrier centroid.

H — Allowable load height to bottom of carrier envelope.

H1 — Maximum height of horizontal obstruction above load height between load face plane and carrier envelope.

S — Recommended minimum spacing between carrier centroids.

T — Maximum cassette or wafer carrier tilt.

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was approved as an official part of SEMI E15 by full letter ballot procedure.

Material transport automation can come in a number of forms, including AGV's (automated guided vehicles) and tracks (conveyers), which operate anywhere from tool loading level to ceiling level. Wafers may be transported in cassettes or in carriers (such as cassettes in pods). Automation provides flexibility with regard to the range of interface coordinates it can accommodate. On the other hand, it is clear that humans will continue to load carriers on tools in many fabs. SEMI E15 is an attempt to satisfy all of these needs, including continued human compatibility. In fact, compatibility of automation and human ergonomics has been considered of primary importance in the rewrite of this standard.

The increased value for C1, of 75 mm, over the previous value in this standard is determined by the ergonomic requirement to accommodate a 95th percentile human male hand carrying a pod by its handles. Limitation of the load port height to 900 mm was, again, driven by ergonomic considerations, as the previously allowed value of up to 1300 mm was clearly "user unfriendly."

Equipment suppliers must consider the dimension, S, in order to ensure that their tool will be compatible with automation systems and pods. This fact applies to tools with more than one load port per tool. In order to enable space for two pods on side-by-side load ports, the dimension, S, must be greater than or equal to 350 mm for tools processing 150 mm or smaller wafers, and 400 mm for 200 mm wafer tools. The dimension, S, is defined as the distance between wafer carrier centroids. Driving factors for S are that the size of a pod is larger than a cassette and that ergonomic guidelines suggest a clearance of at least 75 mm between the box and an adjacent object in order to provide space for the human hands to grasp and pick up the box by its handles.

A global horizontal placement tolerance of 15 mm of the carrier centroid should be allowed by the alignment means of the load port. (That is, a misalignment by up to ± 7.5 mm in both the x and y directions of the carrier centroid will still allow the alignment means to guide the carrier to its correct final location on the load port). The misplacement dimension is made large to be consistent with the tactile/visual capabilities of humans and the placement accuracy of AGV's. This requires that the load port provide some alignment aid to bring the carrier centroid to within the final registration tolerance (generally 0.5 mm) required by the automated wafer handling of the tool. Standards for this registration tolerance will generally be found in the SMIF documents.

The standard purposely does not address vacuum load locks. Since minimization of volume is usually a design requirement for a vacuum load lock, the minimum clearances (C1 – C3) of this standard are not compatible with optimum load lock design. It is not intended that vacuum load locks would be the load port of a tool in which vacuum processing is performed. Simple solutions exist today for transportation of a cassette, or of individual wafers, from a SEMI E15-compatible load port to a vacuum load lock. Open load ports are intended to be specified for use with overhead transport systems for automation.

It is not easy to formulate a standard which allows compatibility with such a wide range of requirements. Nor is it easy to design equipment compatible with a number of different standards affecting the same hardware. SEMI E15 covers a wide range of applications without causing undue compromise in any particular implementation, while remembering that most of our fabs will continue to use human transport in the immediate future. We hope this short discussion of key issues aids in your understanding of the intent and details of the standard.

SEMI E15.1-0600
SPECIFICATION FOR 300 mm TOOL LOAD PORT

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org April 2000; to be published June 2000. Originally published in 1996; previously published February 2000.

1 Purpose

1.1 This specification defines dimensional requirements for the load ports of 300 mm wafer process and inspection equipment. It is intended to promote a uniform physical interface between equipment and the factory, to facilitate the use of automated wafer carrier transport systems, and/or to meet ergonomic requirements for manually loaded equipment.

2 Scope

2.1 This standard covers 300 mm equipment only. Similar requirements covering equipment for 200 mm wafers and smaller are covered in SEMI E15.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard is not met by direct loading/ unloading of vacuum load locks. Requirements of such interfaces may differ from those in this document.

5 Terminology

See SEMI E15.

6 Ordering Information

6.1 Per Section 6 of SEMI E15, except for Sections 6.1.3 and 6.1.4. Also, the user must specify which of the three options (defined in Section 7.5) is required for each load port, and whether a cover is needed over the exclusion volume for photo-coupled I/O interfaces (defined in Section 7.8).

7 Requirements

7.1 The dimensional requirements for the load port of a tool are given in Table 1 with reference to the figures in this document. Although the carrier transport systems shown in these figures appear similar to overhead monorails, they are intended to represent any type of transport system (AGV, PGV, conveyor, overhead track, etc.).

7.2 The dimensional requirements for the placement of a wafer carrier on the load port are given in Table 1 with reference to the figures of this document. The carriers shown in these figures are intended to represent any type of carrier (cassette or box).

7.3 The wafers are to be oriented horizontally face up with zero nominal tilt at the time they are placed on the load port. The tolerance in the horizontal plane is determined by the registration and alignment feature between the carrier and the load port, as specified in SEMI E57.

7.3.1 The carrier shall be loaded and unloaded with its front parallel to and away from the load face plane (see Figure 1).

7.4 Dimension H is nominally 900 mm, fully adjustable at installation over the range of 890 to 910 mm. The precision with which the load port height must be maintained is dictated by the needs of the carrier delivery system.

7.5 As shown in Figure 3, the maximum allowable height of an obstruction on the load port over which the carrier must be lifted (before being set down on the kinematic couplings) is H1. Examples of such obstructions include alignment devices and identification tag readers as well as the kinematic couplings themselves. Below H1 above the horizontal datum plane, clearances C1 and C2 no longer apply.

7.5.1 Two exclusion volumes on the left and right side of the load port must also be kept clear so that fork-lifts or conveyors may be used. Each exclusion volume extends from the load face plane to D0 beyond the facial datum plane and extends H0 below the horizontal datum plane between W1 and W2 from the bilateral datum plane. Although the carrier shown in Figure 3 is an open cassette, these exclusion volumes are also required on load ports that are configured with a FIMS interface (conforming to SEMI E62) for front-opening boxes. However, these exclusion volumes are not required on load ports that are configured for bottom-opening (SMIF) pods, because SEMI E19.5 already defines that part of the load port.

7.5.2 A load port that advances the carrier from the undocked position (where the carrier is initially delivered to the load port) to the docked position (where the carrier is ready for wafer extraction or insertion) must reserve an exclusion volume that is intended for (but not limited to) containing automated units that read or write to an ID tag on the rear of a carrier in the *undocked* position (where the carrier is initially delivered to the load port). This exclusion volume extends W4 to either side of the bilateral datum plane and between D3 and D4 from the facial datum plane. When the load port is in the correct position to read or write to the ID tag, the exclusion volume must extend from the carrier down to H3 plus H4 below the horizontal datum plane. When the load port is in a different position, the volume from the carrier down to H3 below the horizontal datum plane may be occupied temporarily. The value of H3 is at the load port supplier's choice. As a result, reader/writer units (for this exclusion volume) must fit in a space no taller than H4, no wider than 2 times W4, and no deeper than D4 minus D3. If no reader/writer unit is installed, the exclusion volume may be covered by a panel. See Table 2 for dimensions of this exclusion volume.

7.5.3 Also, the load port must reserve another exclusion volume that is intended for (but not limited to) containing automated units that read or write to an ID tag on the rear of a carrier in the *docked* position (where the carrier is ready for wafer extraction or insertion). In this case, dimensions D3´, D4´, and W4´ are measured with respect to the datum planes defined by the kinematic couplings in the docked position (unlike all other use of datum planes in this standard). The distance between these two sets of datum planes (in the docked vs. undocked position) is not defined, and if the carrier is rotated during the advance motion, the two facial (or bilateral) datum planes will not be parallel. At the load port supplier's choice, the reader/writer unit in this exclusion volume may be mounted either on the advance mechanism of the load port (so it is very close to the carrier and it moves with the kinematic couplings) or below the advance mechanism (so it is farther from the carrier, is stationary, and may be covered temporarily by the advance mechanism). Again, this exclusion volume extends W4´ to either side of the bilateral datum plane and between D3´ and D4´ from the facial datum plane. When the load port is in the correct position to read or write to the ID tag, the exclusion volume must extend from the carrier down to H3 plus H4 below the horizontal datum plane. When the load port is in a different position, the volume from the carrier down to H3 below the horizontal datum plane may be occupied temporarily. The value of H3 is at the load port supplier's choice. As a result, reader/writer units (for this exclusion volume) must fit in a space no taller than H4, no wider than 2 times W4´, and no deeper than D4´ minus D3´. If no reader/writer unit is installed, the exclusion volume may be covered by a panel. See Table 2 for dimensions of this exclusion volume.

7.5.4 A load port that is configured for open cassettes (with bar-code ID tags on the bottom) or for FOUPs (with bar-code ID tags on the rear) must provide the appropriate exclusion volume a bar-code reader defined in Table 2.

7.6 As shown in Figure 2, tool load ports must conform to one of the following configuration options. If no option is specified, Option 1 is assumed.

7.6.1 In Option 1, the load port must nominally be at 900 mm, and it must be open from above to facilitate automatic carrier delivery from an overhead transport system. The open volume required for vertical delivery is defined by a projection of the tool load port area, including the area required for C1 and C2 clearances, projected upward to the top of the tool. Note that this condition need only be met when the tool is being loaded. For example, the load port may be formed by a surface that extends outward during loading to provide overhead access.

7.6.2 In Option 2 (which allows faster automatic carrier delivery from an overhead transport system), the horizontal datum plane of the load port may be at any height above H that leaves the top of the carrier under H2, but it must be open from above.

7.6.3 In Option 3 (which allows bulkhead mounting of tools with fan/filter units at C3), the load port must nominally be at 900 mm, and it must have a clearance C3 above the maximum height of the carrier.

7.7 Clearances C1, C2, and C3 are defined with respect to the maximum dimensions of the carrier (defined in SEMI E47.1 for a box or in SEMI E1.9 for an open cassette), not to the rectangular wafer carrier envelope (defined in SEMI E15). To prevent interference between transport systems on the same or adjacent load ports, it is recommended that floor-based transport vehicles not exceed clearances C2 and C3 and over-head hoist vehicles not exceed clearance C2 when picking up or placing a carrier on the load port.

7.8 Dimension S specifies the recommended minimum spacing between cassette/wafer carrier centroids. In any case, if S violates C1, then C1 prevails. As shown in Figure 1, below each load port must be an exclusion volume (defined by dimensions D7, D8, H7, H8, and W8) for photo-coupled I/O interfaces to floor-based transport vehicles. This exclusion volume is centered on the bilateral datum plane, but its distance behind the load face plane may vary between zero and the upper limit on D7. If no photo-coupled I/O interfaces unit is installed, the exclusion volume may be covered by a panel. If a photo-coupled I/O device is installed, the center of its horizontal beam line must be within W9 of the bilateral datum plane and within H9 of a point H7 above the floor. On each tool, load ports are numbered in increasing order (beginning with 1) from left to right (as seen by a person facing the load face plane) beginning with load ports that are nominally at 900 mm (Option 1 or Option 3) and then continuing (from left to right) with any load ports that are higher (Option 2).

7.9 To add clearance for overhead carrier transport, no part of the tool in front of the plane defined by C2 may be higher than H2 from the floor. The volume below H2 may contain carriers stored in an internal buffer by the tool.

7.10 If the tool occupies the space behind the load port and above any interface to the carrier, then the front of that upper part of the tool (shown as the equipment boundary in Figure 1) must be at a distance D1 from the facial datum plane. This equipment boundary is parallel to the load face plane, and carriers may be moved or rotated below this surface after loading.

7.11 If the load port provides the option to use roller conveyors for carrier loading, the conveying surface of the rollers must be H5 above the horizontal datum plane (as shown in Figure 3) at the time of carrier loading or unloading. When not in use, the conveyors must be lowered below H0 under the horizontal datum plane.

7.12 *Dimension Definitions* — See SEMI E15 for applicable definitions.

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E15.1 and is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such, they are to be considered as reference material only. The standard should be referred to in all cases.

R1-1.1 This standard is meant to address both bottom-opening and front-opening boxes, as well as open cassettes. The C2 dimension applies to the initial placement of the carrier on the load port. Front-opening boxes, as defined in SEMI E47.1, and SEMI E62, would subsequently move forward to dock against a vertical surface. Consideration of reduction of C2 is deferred pending approval of the standards for wafer transport carriers.

R1-1.2 It is the device makers' expectation that process equipment suppliers are ultimately responsible for ensuring that their equipment (as installed in the device makers' facility) complies with SEMI E15.1. This expectation is the same whether the equipment load port is developed internally by the process equipment supplier or is purchased from a third party source. In either case, the process equipment supplier is responsible for understanding all of the requirements contained in this standard. Compliance with SEMI E15.1 can only be determined after the load port is integrated with the process equipment and is directly affected by process equipment design features (such as user interfaces and light towers).

R1-1.3 In the case of a front-opening-box, dimension C2 is a required clearance between the box and the tool's front-opening interface when the box is placed on the load port. After the box is placed on the load port, the kinematic couplings will move the box forward to engage with the tool's front-opening interface. The possibility of human fingers being pinched between the box and the tool's front-opening interface may be a safety concern for tool designers. The possibility of human fingers being pinched between the carrier and a carrier ID reader/writer unit may also be a safety concern for tool designers.

R1-1.4 There is some interest in roll-in transport of front-opening carriers to the load port. The implementation of such a scheme will require dealing with a number of issues related to registration mechanisms, tag readers and guide-in. Resolution of these issues may make it desirable to reduce the minimum value of H1.

R1-1.5 A tool load port may need to accommodate a device or system that is capable of automatically storing and retrieving additional carriers. Such a storage device is alternately referred to as a local buffer, a micro-stocker, tool-based storage, and other names. When defining the load port as in SEMI E15, the exact definition may become blurred. The transfer station or drop off location for a local buffer becomes the tool load port and must comply with SEMI E15. In this case, it may not be essential that the tool-buffer port also comply.

R1-1.6 Another case is in factories that employ overhead delivery of carriers onto tool load ports. In this case, it is possible that the transfer station or drop-off location where the intra-bay transport system delivers carriers may actually be located 8 or 10 feet above the floor. We assume that in these cases there would also need to be a transfer station that would be suitable for human loading. The ergonomic-driven requirements of SEMI E15 (height, clearances) would apply to the human-based transfer station.

R1-1.7 To avoid interfering with the lead-in capability (misalignment correction) function of the kinematic couplings, it is recommended that no part of the tool (other than the kinematic couplings) come horizontally closer than 10 mm (0.39 in.) to the carrier between the horizontal datum plane and H1 above it.

R1-1.8 It is recommended that the systems that deliver carriers to tool load ports have a mechanism to correct for misalignment of tools and load ports.

R1-1.9 A revision ballot will be submitted to allow projections in front of the OHT zone.

R1-1.10 Equipment can be configured with a variety of load ports chosen from the three options defined in Section 7.6. Figure R1-1 (a) shows a tool with two Option 1 load ports, which may work with any carrier. Although the tool is shown occupying the space on either side of the load ports, it is recommended that tool designers reserve this volume for installation of carrier buffers. Figure R1-1 (b) shows a tool with one Option 2 load port and one Option 3 load port, which may work with boxes delivered by an overhead transport system with manual back-up. Figure R1-1 (c) shows a tool with two Option 3 load ports, which may work with open cassettes and bulk head-mounted tools with AGV or manual delivery.

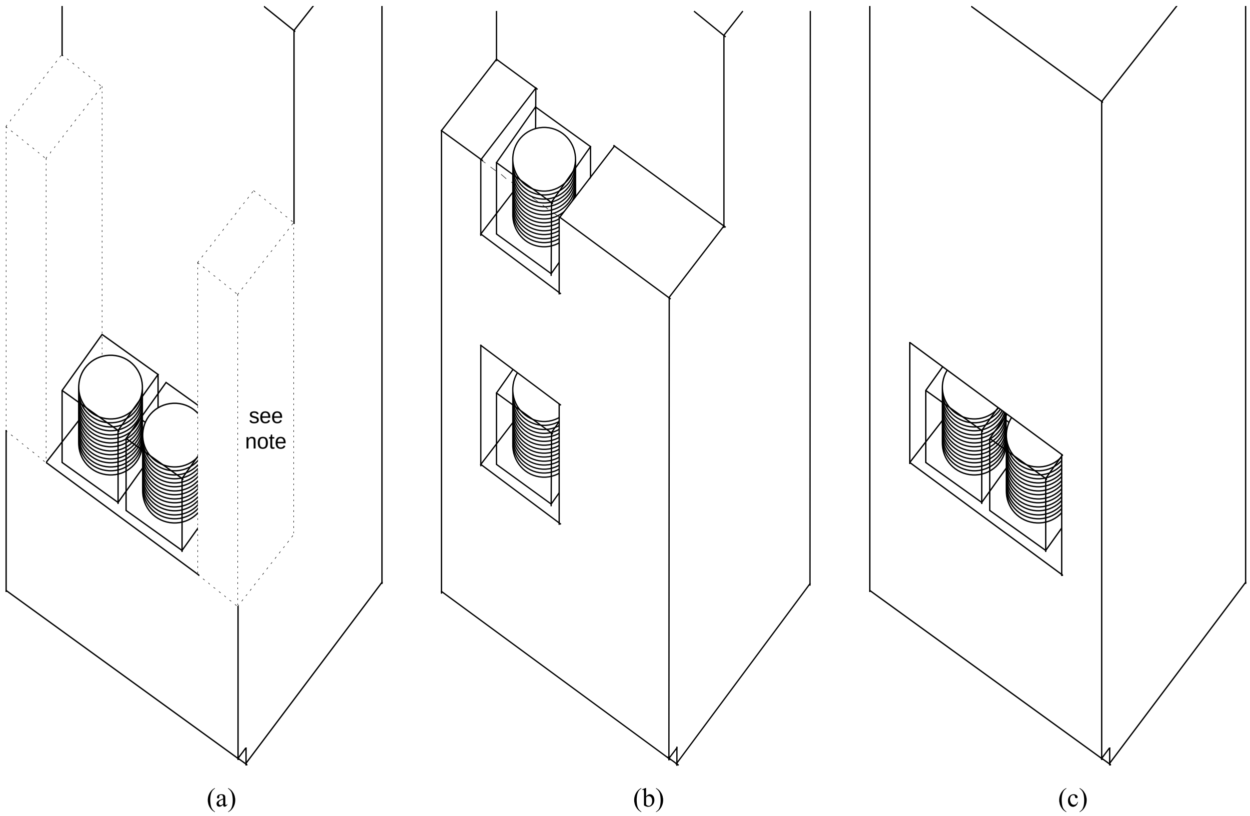

Figure R1-1
Example Combinations of Load Port Options

R1-1.11 Safety and process contamination issues can arise when using SEMI E15.1-compliant load ports in conjunction with SEMI E47.1-compliant FOUPs, and the corresponding FIMS ports. An empty FOUP, when mounted to a load port and retained only by the mandatory front clamping/retaining feature described in Section 6.10 of SEMI E47.1, can potentially be removed with no more effort than an operator would exert in trying to remove a full FOUP (perhaps 70 N of 16lbf. Lifting force can accomplish this). Therefore, the potential exists that an operator may mistake an empty FOUP for a full one, lift it off, and create both a mechanical safety hazard (an unguarded FIMS opening into the wafer handling robotics area) and a process contamination risk.

R1-2 Mechanical Interference Lockout Pins for FEOL and BEOL Load Ports

R1-2.1 *Background* — Many device manufacturers are planning to use process options for 300 mm wafers that pose significant risk of cross-contamination of wafers and production (process and metrology) equipment. In such a case, equipment load ports and carriers may be dedicated to front-end-of-line (FEOL) processing or back-end-of-line (BEOL) processing only. To eliminate the possibility of cross-contamination, device manufacturers want to ensure that FEOL carriers cannot be processed on production equipment with BEOL load ports and vice versa.

R1-2.1.1 In addition to traditional lockout methods (software, electronic, and visual approaches) to eliminate mis-processing, device manufacturers also want a “hard” mechanical lockout that makes it physically impossible for a carrier to register correctly on the kinematic coupling on a wrong load port. This application note describes one possible procedure for achieving a hard mechanical interference lockout (MIL) using pins located on FEOL and BEOL 300 mm load ports. Corresponding pads on FEOL and BEOL carriers are also discussed.

R1-2.2 *Info Pads C and D on Carriers* — FEOL carriers must have info pad C low and info pad D high. BEOL carriers must have info pad D low and info pad C high. Locations and dimensions for pads C and D are defined in SEMI E1.9 for 300 mm carriers and shown in Figure R1-2.

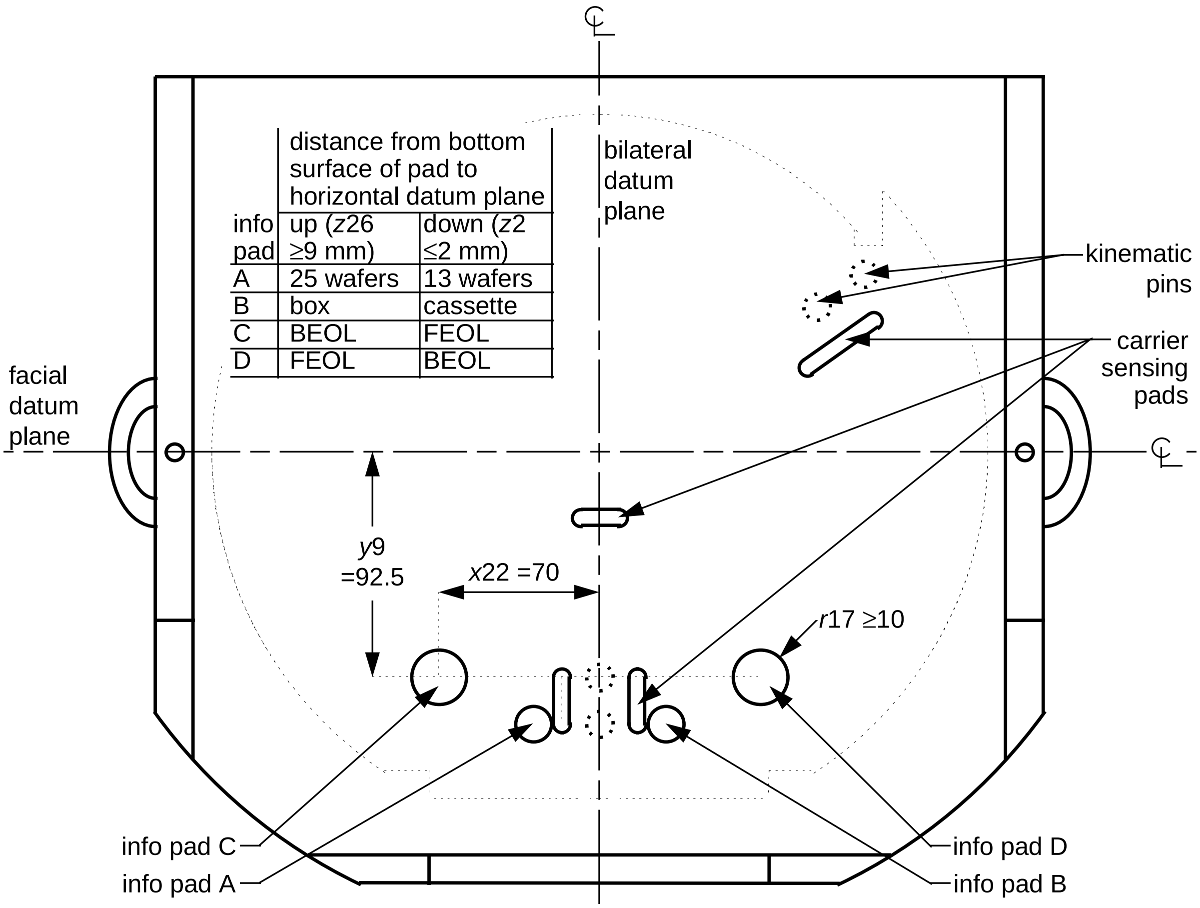

Figure R1-2
Carrier Bottom View Showing Info Pads C and D

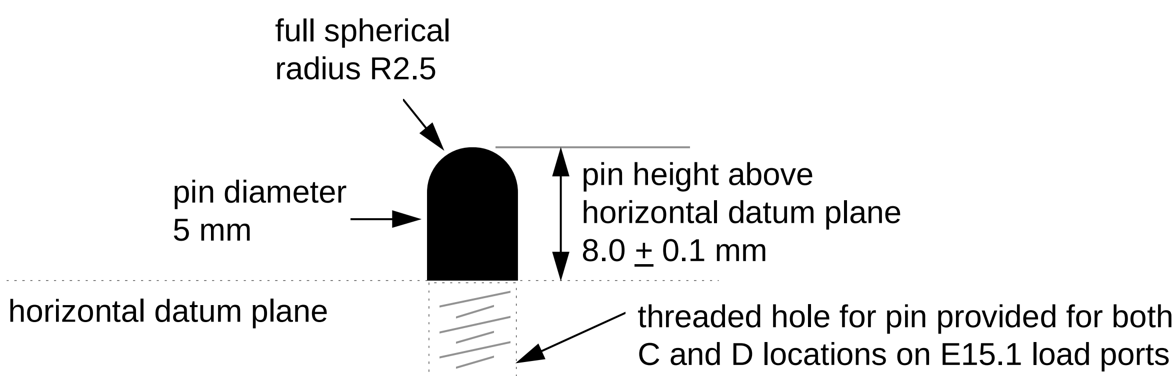

Figure R1-3
Detail of Pin C or D on the Load Port

R1-2.3 *Mechanical Interference Lockout Pins* — FEOL load ports must have a lockout pin D centered under info pad D, and BEOL carriers load ports must have a lockout pin C centered under info pad C. The dimensions for pins C or D are shown in Figure R1-3. When a carrier is placed on the wrong load port, the info pad and lockout pin will interfere with each other, preventing the carrier from being seated correctly on the kinematic coupling pins. As a result, the carrier placement OK sensor (or nested OK sensor) does not get triggered. Manual operator intervention may be required when this happens.

R1-2.4 *Lockout Pin Installation in the Fab* — Since it will be impossible for device manufacturers to specify in every case whether production equipment will be a FEOL equipment or an BEOL equipment at the time of ordering (when placing a purchase order), it is their expectation that the production equipment is delivered to the fab with the lockout pins, but without the pins installed on any load port. During tool install in the cleanroom, device manufacturers will decide whether the equipment is dedicated as an FEOL or BEOL equipment. At that time, equipment must be capable of having lockout pins C or D installed on the load ports in the fab. To meet this requirement, each load port must have pre-drilled holes at both C and D positions prior to shipment to the customer factory. The production equipment supplier must provide and install the lockout pins in the field. Table R1-1 summarizes the lockout requirements and corresponding sensor actions when different types of carriers are placed on different types of load ports during fab processing. Note that the carrier Placement OK Sensor and the carrier Presence Sensors are identified as requirements in the I300I/J300 CIM Global Joint Guidance document published in December, 1997.

R1-2.5 *Operation* — During normal operation, the pins and pads don't interfere with each other as shown in Figure R1-4. Normal operation is when a FEOL carrier is placed on a FEOL load port or when a BEOL carrier is placed on a BEOL load port, as shown below. Both the carrier placement OK sensor and the carrier presence sensors are triggered OK and wafer processing is allowed to continue.

R1-2.5.1 When a FEOL carrier is placed on a BEOL load port or vice versa, the pads and pins interfere with each other as shown in Figure R1-5, and the carrier does not nest correctly on the kinematic coupling of the load port. Note that the extent of interference is highly exaggerated in Figure R1-5, and is so depicted only for clarity. When interference occurs, the carrier rests in a secure manner on the front two kinematic coupling pins and the mechanical interference pin. As a result, the Carrier Placement OK sensor is not triggered OK, although the Carrier Presence sensor detects the presence of the carrier. Wafer processing does not start, thereby eliminating any wafer and equipment cross-contamination opportunity. When such a condition occurs, a production operator may be required to correct the problem.

R1-2.5.2 Some device manufacturers may identify certain type of fab equipment as not being sensitive to FEOL and BEOL contamination issues. In such a situation, the device manufacturer end user has the option to not install either FEOL or BEOL pin. In this case, FEOL and BEOL carriers will work on these load ports without any interference.

Table R1-1 Operational Summary

Carrier Type	*Load Port Type*	*Pad and Pin Interference Requirement*	*Carrier Placement OK Sensor State*	*Carrier Presence Sensor State*
FEOL	FEOL	No interference.	Sensor is triggered OK since carrier is nested correctly.	Sensor detects carrier presence.
FEOL	BEOL	Pad C and pin D interfere with each other.	Sensor is not triggered since carrier does not nest correctly.	Sensor detects carrier presence.
BEOL	BEOL	No interference.	Sensor is triggered OK since carrier is nested correctly.	Sensor detects carrier presence.
BEOL	FEOL	Pad D and pin C interfere with each other.	Sensor is not triggered since carrier does not nest correctly.	Sensor detects carrier presence.

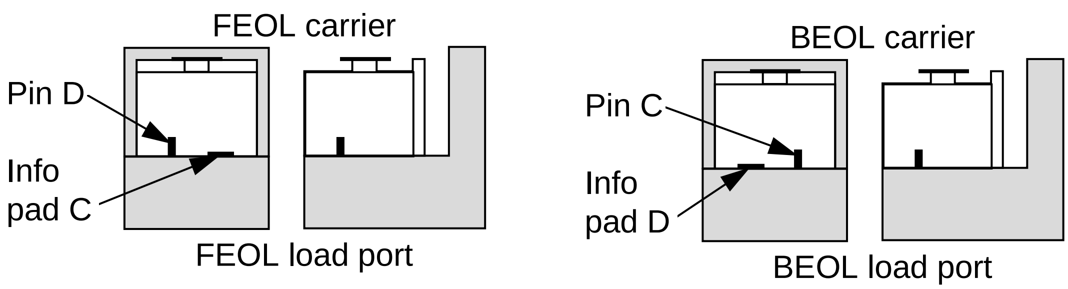

Figure R1-4
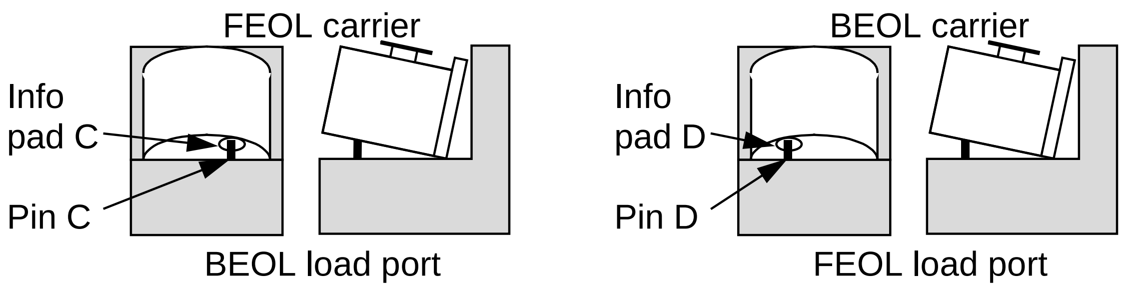
Pad and Pin Non-Interference with Each Other During Normal Operation



NOTE: Pads and pins interfere with each other. The carrier does not nest correctly on the kinematic coupling.

Pin and Pad Interference When a Carrier Is Placed on a Wrong Load Port

SEMI E16-90 (Reapproved 0699)
GUIDELINE FOR DETERMINING AND DESCRIBING MASS FLOW CONTROLLER LEAK RATES

This Guideline was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org February 1999; to be published June 1999. Originally published in 1990.

Editorial changes were made to Sections 4.2.2, 4.3.1, and 4.3.2.

1 Purpose

1.1 The purpose of this guideline is to establish a uniform, worldwide means for describing and measuring leak rates of mass flow controllers. The leak integrity of a gas delivery system is important to maintaining product quality and performance. This guideline is intended to prevent confusion and misunderstanding between manufacturers and users. In particular, it distinguishes between mechanical and diffusion leak rates.

2 Scope

2.1 This guideline contains definitions of terms and procedures for determining the Leak Rates of mass flow controllers as used in the semiconductor industry.

3 Definitions

3.1 *Leak* — A path or paths in a sealed system which will pass helium when a partial pressure differential exists. A partial pressure differential can exist for helium even though a total gas pressure differential may not exist. There are two major leak mechanisms, a mechanical passage or a material through which gas can diffuse or permeate. In a real system, a leak may have both mechanisms operating in parallel.

3.1.1 A mechanical leak may be a physical crack, pit, scratch or other imperfection in a sealing surface, or contamination or debris on the seals. A diffusion or permeation leak is caused by the movement of helium through gaskets, O-rings, polymers, or other materials through which helium can diffuse.

3.2 *Standard Leak Rate* — The quantity of helium at 25°C and 101.3 kPa (760 Torr) flowing through a leak when the high pressure side is at 101.32 kPa and the low pressure side is below 100 Pa (approximately 1 Torr). Standard Leak Rate shall be expressed in the following units:

Pa-m^3/s (He) = "Pascal cubic meters per second, helium"

or, alternatively,

atm-cc/s (He) = "atmospheric cubic centimeters per second, helium"

NOTE 1: The Pascal (1Pa = 1 N/m^2) is defined as the pressure unit of the international unit system SI. Therefore, the SI units above are preferred. Atm-cc/s is acceptable, as it is widely used in the semiconductor industry.

3.2.1 The "mass spectrometer helium leak detector" is generally used for leak rate testing of high and medium level vacuum apparatus. Units of sccs, Torr-L/s, and m bar-L/s, have been used in the past but are not encouraged. Reference materials include MIL STD-202E, C-1.

3.3 *Measured Leak Rate* — The leak rate of a given system measured under specified conditions and employing a specified test gas (helium). For the purposes of comparison with rates determined by other methods of testing, measured leak rates must be converted to equivalent standard leak rates.

3.4 *Sensitivity (Minimum Detectable Leak Rate)* — The smallest standard leak rate that an instrument, method or system is capable of measuring under specified conditions.

3.5 For the purposes of this document, the Measured Leak Rate shall be corrected to Standard Leak Rate by multiplying by the ratio of 101.32 kPa to the absolute value of the pressurizing helium unless otherwise called for by the MFC specifications.

$$\frac{\text{Measure Leak Rate} \times 101.32 \text{ kPa}}{\text{He Actual Pressure}} = \text{Standard Leak Rate}$$

4 Testing

4.1 *General Requirements*

4.1.1 *Leak Detector* — The leak detector shall be of the helium mass spectrometer type. It shall have a sensitivity at least equal to or smaller than the specified leak rating of the mass flow controller to be tested. If the actual leak rate is to be reported, the sensitivity shall be five times smaller than the leak to be measured. If the sensitivity is not five times smaller, the actual leak rate may be reported if the sensitivity of the detector is also reported.

4.1.2 Helium must have access to all primary seals.

4.1.3 Connections between the MFC and the leak detector must be leak-tight.

4.1.4 The ambient temperature of the MFC should be 25° ± 5°C unless otherwise specified. If another test temperature is used, it must be recorded during the test.

4.2 *Test Procedures* — There are two basic setups which may be used to measure the leak rate from the external environment to the internal gas passages of the MFC or from the internal passages to the external environment. Results for either test method may be reported. The method used must be reported as well. A third test, the through-the-valve setup, is intended to measure the quality of the valve seat shutoff.

4.2.1 *Internally-Pressurized Leak Test* — The purpose of this test set-up is to simulate operation of the MFC under conditions where the internal pressure is above ambient. The recommended internal pressure is 300 kPa absolute (30 psig) of helium. (See Figure 1.)

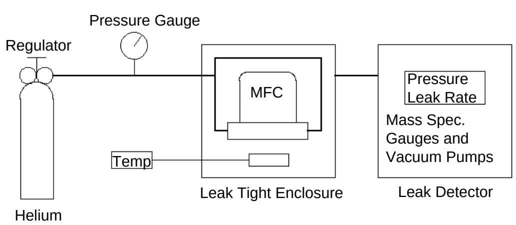

Figure 1

Internally-Pressurized Leak Test

4.2.2 *Externally-Pressurized Leak Test* — The purpose of this test is to simulate operation of the MFC under conditions where the internal pressure is at vacuum. The external pressure should be equal to atmospheric pressure. The internal pressure should be less than 100 kPa. (See Figure 2.)

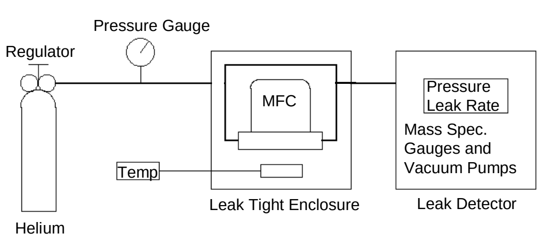

Figure 2

Externally-Pressurized Leak Test

4.2.3 *Control Valve Seat Leak Test* — The purpose of this test is to determine the leakage through the control valve under simulated operation in the closed control mode. The MFC should be electrically energized for normal operation and placed in the closed position as specified for the operation of the MFC. The input pressure to the MFC should be 100 kPa ± 20%. The outlet should be connected directly to the helium leak detector, and pressure should be as low as possible using good leak detector practice. (See Figure 3

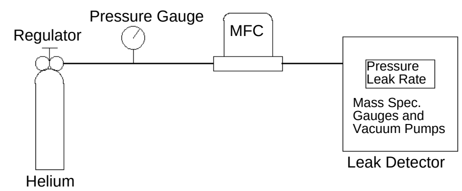

Figure 3

Control Valve Seat Leak Test

4.2.3.1 In the case of MFCs which are not designed for positive shutoff at the control valve, alternative methods may be employed if documented and reported.

4.3 *Reporting Results* — The example shown in Figure 4 is a plot of leak detector output value vs. time for a representative elastomer-sealed MFC. This curve is the sum of mechanical and permeation leak components.

NOTE 2: All times are from application of helium, starting with a leak detection system pumped down to base reading.

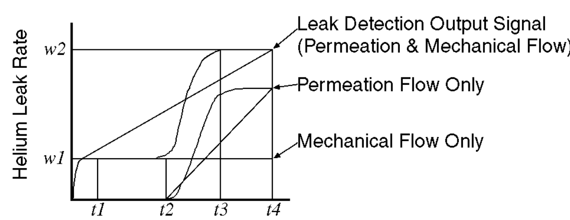

Figure 4

Leak Detector Output Value vs. Time

Interval	*Rate*	*Example*
t1 Initial System Response		Less than 10 seconds
t2 Leak Prior to Onset of Permeation	*w1*	10 seconds to 1 minute
t3 Increasing Permeation		1 minute to 30 minutes
t4 Total Saturation	*w2*	Beyond 30 minutes

4.3.1 The actual shape of these curves and time intervals is dependent on the design of the MFC under test, the elastomer used, if any, and the characteristics of the leak detection system. These time intervals must be determined using sound engineering judgment following qualification testing of the specific MFC model and test set-up. Once determined, it is recommended that receiving inspection consist of measuring for leak rate value *w1* at the end of interval *t2*.

4.3.2 Following qualification testing, report typical values for *t1* through *t4* and *w1* and *w2*. *w1* is primarily the mechanical portion of the leak, and *w2* is mechanical plus permeation. In the case where *w2* is significantly greater than *w1*, *w2* is primarily permeation. In the case of a gross mechanical leak, *w1* could greatly exceed, and thereby mask, *w2*.

NOTE 3: This test must be performed with elastomers that are devoid of helium. Such elastomers have either not been previously exposed to helium or have been degassed following exposure. Once this test has been performed, the elastomers must be purged of helium by the passage of time and/or baking.

4.3.3 In good leak testing practice, the background level should be verified before the application of helium to ensure that the elastomers are in a helium degassed state and that the leak detecting system is in proper operation.

SEMI E17-0600
GUIDELINE FOR MASS FLOW CONTROLLER TRANSIENT CHARACTERISTICS TESTS

This guideline was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on April 10, 2000. Initially available at www.semi.org April 2000; to be published June 2000. Originally published in 1991.

1 Scope

1.1 This guideline is intended to establish a common basis for communication between users and suppliers of semiconductor equipment. It provides terminology and methodology aimed at eliminating confusion regarding what previously has been referred to as MFC "response time." The conditions and procedures are given for determining and expressing the transient characteristics of a mass flow controller (MFC) to a step change in set point. This guideline applies to mass flow controllers for gases used in semiconductor fabrication equipment.

1.2 This guideline does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2 Definitions (Figures 1 and 2)

2.1 *Actual Flow* — For the purpose of this standard, the output value of the master reference standard.

2.2 *Dead Time* — The interval of time between the set point step change and the start of the resulting observable response.

2.3 *Final Steady State Value* — The average value of the actual flow, after the effects of the input transient have expired to a value equal to or below the intrinsic drift and noise.

2.4 *Settling Time* — The time between the set point step change and when the actual flow remains within the specified band.

2.5 *Step Response Time* — The time between the setpoint step change and when the actual flow first enters the specified band.

2.6 *Transient Overshoot* — The maximum change in actual flow minus the steady state change in actual flow, expressed as a percentage of the set point step change.

2.7 *Transient Undershoot* — The maximum amount that the actual flow passes the final steady state value, in the opposite direction of overshoot, expressed as a percentage of the set point step change.

2.8 *Set Point* — The electrical input signal to the MFC which sets the desired value of the controlled flow.

2.9 *Specified Band* — The region between ± 2% of the final steady state value or ± 0.5% of full scale, whichever is greater.

3 Test Setup

3.1 The purpose of the flow system is to furnish the mass flow controller under test with a constant pressure supply of suitable gas. It must also provide a means of determining the gas flow rate through the mass flow controller that responds to changes in gas flow significantly faster than the device under test. The recommended flow system for testing the speed of response of MFCs is shown in Figure 3a.

3.2 The flow system shall have straight tubing or pipe connecting the MFC to the master reference standard. The inside diameter of the interconnecting tubing or pipe shall be of sufficient size to preclude any pressure drop that would affect the performance of the MFC.

3.3 The pneumatic time constant, Tau, should be minimized. (See Section 3.7.)

Tau =	(V*DPm) / (Qm*Pa)

Where:

V =	Internal volume of the flow system between the MFC under test and the master reference standard, including tubing, fittings and the side of the master reference standard that is connected to the MFC under test.
Qm =	Maximum volumetric flow expected during the test.
DPm =	Pressure drop of the master reference standard at flow Qm.
Pa =	The absolute pressure present at the outlet of the master reference standard at final steady state value.

3.4 The source of the test gas shall be capable of delivering an essentially constant upstream pressure to the mass flow controller under test during the transient characterization. A maximum variation of ± 2% from the median absolute pressure is considered adequate for most mass flow controllers.

3.5 Nitrogen is the recommended gas for the standard test shown in Figure 3a. The inlet pressure is 25 psig (1.75 kg/cm^2G). Outlet pressure is the prevailing atmospheric pressure. The temperature of the gas entering the flow controller and the temperature surrounding the flow controller shall be the same. Neither shall vary during the test so as to have a significant effect.

3.5.1 The preceding conditions are recommendations. Deviations may be made to more accurately reproduce the conditions that the MFC will experience in use, such as the variation shown in Figure 3b. Any deviation from the above gas and pressure conditions and/or test setup must be noted with the test results.

3.6 The master reference standard is used to provide a representation of the instantaneous actual flow. It is customary to refer to the output of the master reference standard as the actual flow. It shall have an accuracy of ± 5% of reading (including linearity), or better, over the flow range for which results will be reported. The pressure drop across the master reference standard at the test flow shall be small enough to not effect the response of the MFC under test.

3.6.1 Typical master reference standards are Hot-Wire flow meters (or similar immersible thermal flow sensors), laminar flow elements with a differential pressure transducer, and Rate of Rise (RoR) systems.

3.7 The measuring system response time is the sum of the pneumatic time constant, master reference response time and the recording system response time. The measuring system response time shall be less than 1/5 of any reported transient characteristic. If the measuring system response time is greater than 1/5 of a specific transient characteristic, that characteristic may be reported if the measuring system response time is also reported.

3.8 The test setup shall provide a step change in the setpoint to the mass flow controller, along with a time-zero cue to the data acquisition system. The step change transient time shall be less than 1% of the step response time of the MFC under test.

3.9 The test setup is recommended for MFC full scale flow rates above 10 sccm. In those cases where the flow rate is below 10 sccm and the pneumatic time constant is not less than 1/5 of the step response time of the MFC the pneumatic time constant shall be reported.

3.10 The MFC shall be electrically energized for the supplier recommended “warm up” time prior to the start of the test.

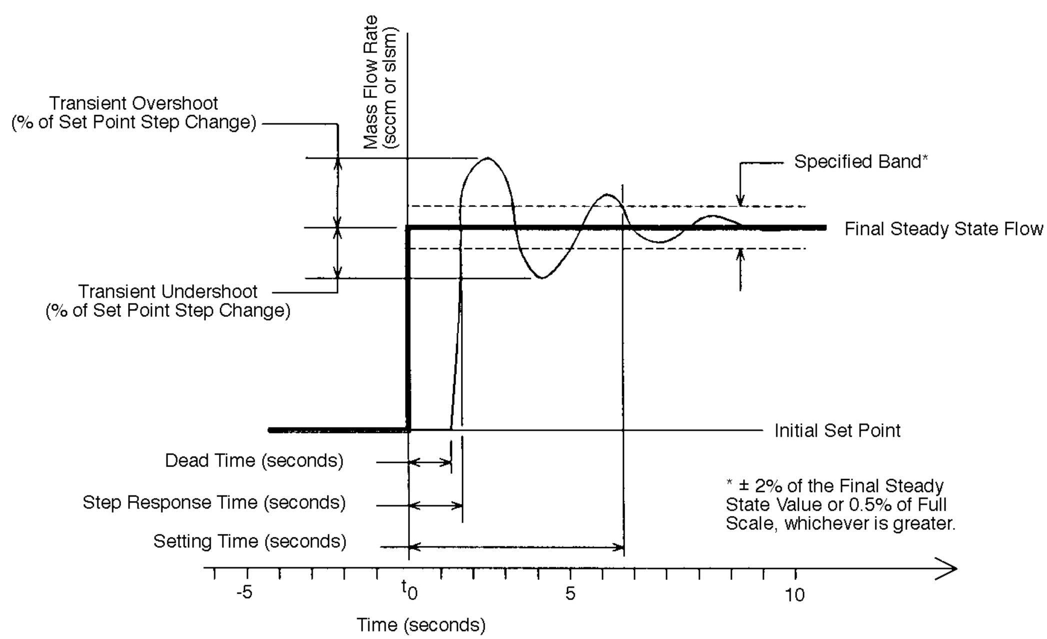

Figure 1
Definitions of MFC Transient Characteristics Terminology in the Case Where the Final Set Point Is Higher than the Initial Set Point

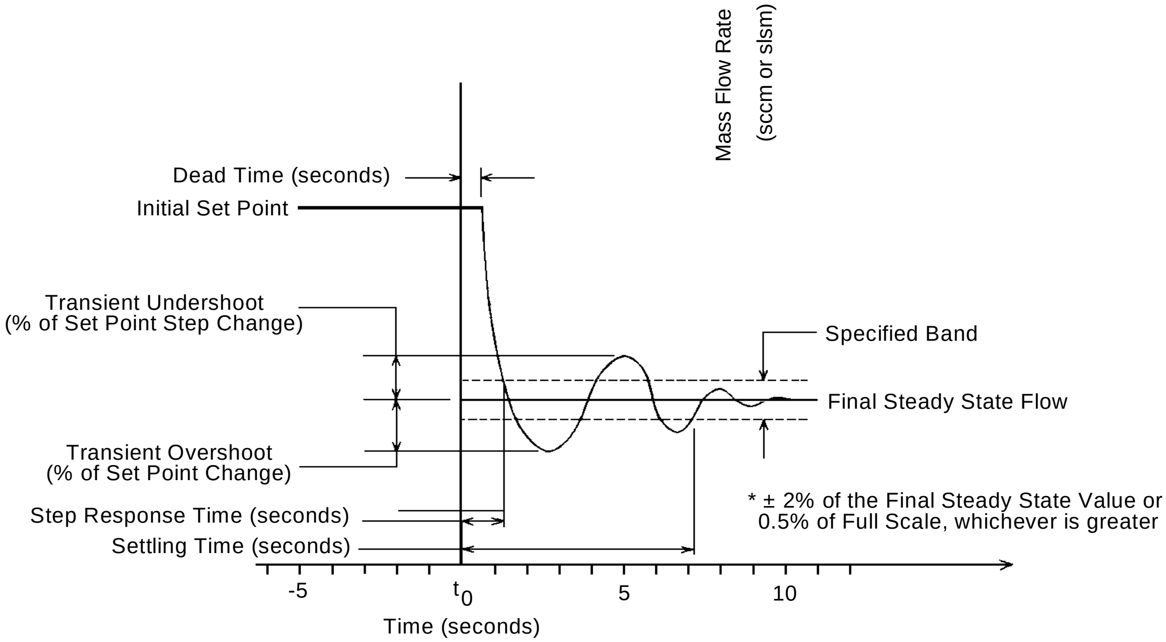

Figure 2
Definitions of MFC Transient Characteristics Terminology in the Case Where the Final Set Point Is Lower than the Initial Set Point

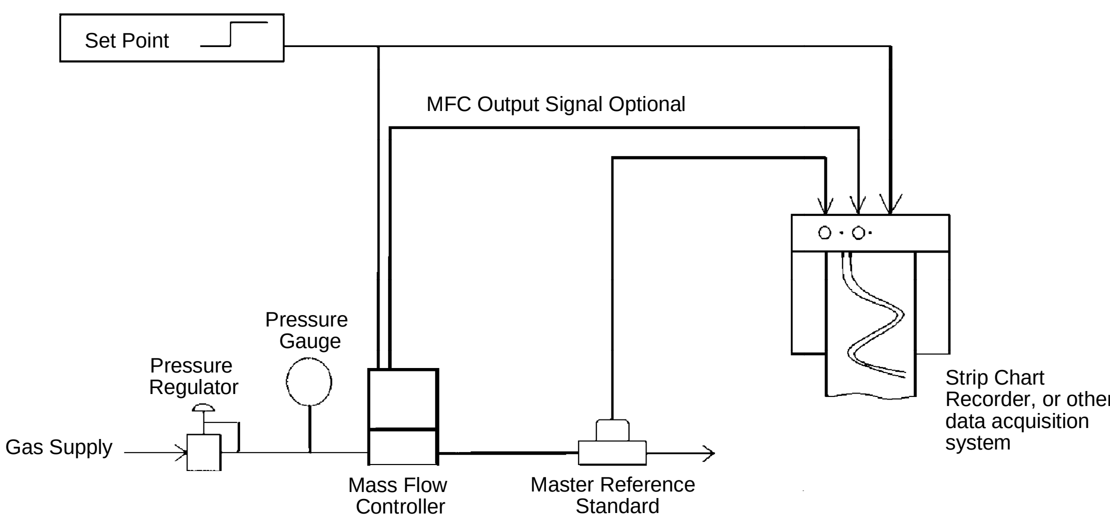

Figure 3a
MFC Transient Characteristics Test Setup with Outlet at Atmospheric Pressure

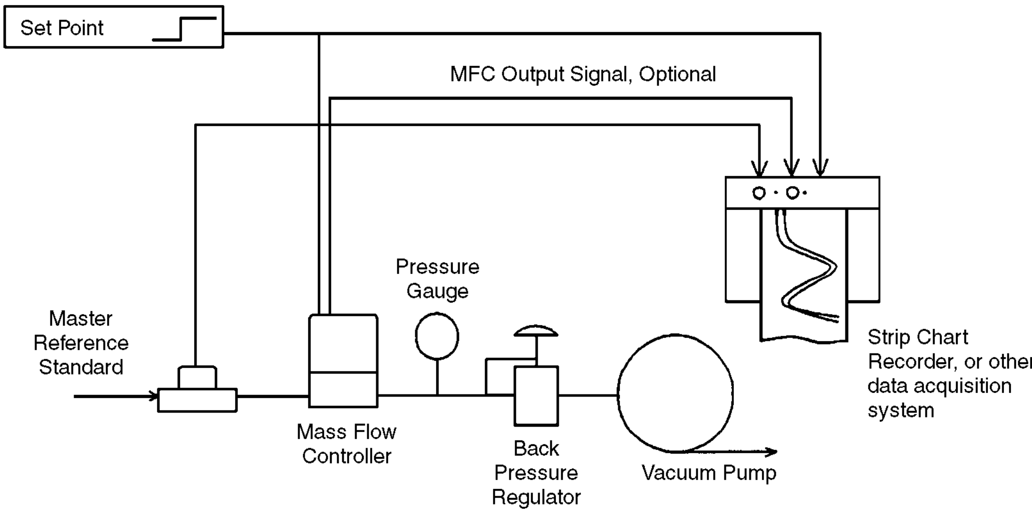

Figure 3b
MFC Transient Characteristics Test Setup with Outlet at Vacuum

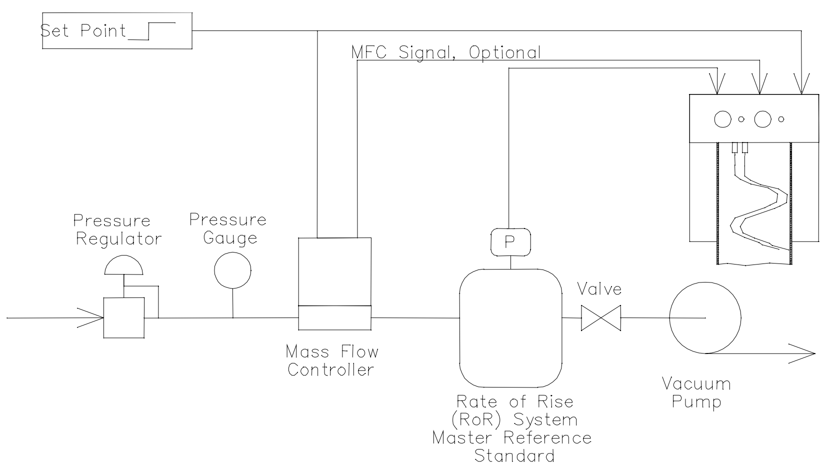

Figure 3c
VFC Transient Characteristics Test Setup with Rate of Rise (RoR) System

4 Test Procedure

4.1 Evaluate the transient characteristics from “OFF” to a flowing condition at final set point by a transition in set point voltage only.

4.1.1 Apply a set point voltage sufficient to close the control valve following the manufacturer’s recommendation. This may be a voltage other than zero, either positive or negative. Allow the output of the mass flow controller and the actual flow, if any, to stabilize.

4.1.2 Apply the final set point value as shown in Table 1.

4.2 Evaluate the transient characteristics from "OFF" to a flowing condition at final set point by using an auxiliary input to an MFC designed for the purpose.

4.2.1 Establish an "OFF" condition following the manufacturer's recommendation. The setpoint should be applied as shown in Table 1. Allow the output of the mass flow controller and the actual flow, if any, to stabilize.

4.2.2 Change the state of the auxiliary input to achieve control.

4.3 Evaluate the testing transient characteristics between two non-zero set point controlled flows.

4.3.1 Adjust the command to the "initial set point" in Table 1, and allow the actual flow (as measured by the master reference standard) to stabilize.

4.3.2 Apply final set point as shown in Table 1.

4.4 Refer to Figures 3 and 4 to determine the dead time, step response time, settling time, overshoot, and undershoot. Record the results in Table 1.

5 Test Results

5.1 Transient characteristics test results shall be presented as follows:

(1) "OFF" means the MFC set point is zero or the lowest value permitted.

(2) The control valve leak rate at shut-off shall be recorded.

(3) Other initial and final set points may be tested and reported.

(4) The transient characteristics of the MFC electrical output signal shall also be recorded during the above testing for purposes such as comparison with the actual flow.

Table 1

Initial Set Point (% of Full Scale)	**OFF (1)**	**OFF (1)**	25	75	**OTHER (3)**
Final Set Point (% of Full Scale)	100	25	75	25	**OTHER**(3)
Dead Time (Seconds)					
Step Response Time (Seconds)					
Settling Time (Seconds)					
Transient Overshoot (Percent of set point step change)					
Transient Undershoot (Percent of set point step change)					

NOTICE: SEMI makes no warranties or representations as to the suitability of the guideline set forth herein for any particular application. The determination of the suitability of the guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this guideline may require use of copyrighted material or of an invention covered by patent rights. By publication of this guideline, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this guideline. Users of this guideline are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E18-91 (Reapproved 0299)
GUIDELINE FOR TEMPERATURE SPECIFICATIONS OF THE MASS FLOW CONTROLLER

This guideline was technically reapproved by the Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1991; previously published in 1996.

1 Purpose

1.1 The purpose of this guideline is to establish a uniform, worldwide means to describe the temperature parameters which are characteristic of mass flow controllers. It is intended to prevent confusion and misunderstanding between manufacturers and users.

2 Scope

2.1 This guideline contains definitions of terms which describe the effects of temperature upon mass flow controllers as used in the semiconductor industry.

3 Definition of Terms (See Figure 1)

3.1 *Units* — Degrees Celsius (C) is used as the temperature unit.

3.2 *Ambient Temperature* — The temperature of the medium surrounding the device.

Note: The ambient temperature assumes that the instrument is not exposed to significant radiant energy sources.

3.3 *Gas Temperature* — The actual temperature of the flowing gas at the primary flow standard.

3.4 *Calibration Temperature* — The ambient temperature at which the mass flow controller was calibrated.

Description Form: ___°C

CAUTION — Calibration Temperature is not to be confused with Gas Temperature or Standard Temperature.

3.5 *Standard Temperature* — The temperature to which a volumetric flow rate (measured at the Gas Temperature) is referenced through the ideal gas law (PV = nRT). SEMI E12 defines Standard Temperature as 0.0°C.

CAUTION — Standard Temperature is not the same as the Gas Temperature or Calibration Temperature.

3.6 *Reference Operating Temperature* — The range within which accuracy statements apply without requiring correction for Temperature Effects (see 3.11).

Description Form: ___°C – ___°C

3.7 *Normal Operating Temperature* — The temperature range within which the influence of ambient temperature on the performance is stated.

Description Form: ___°C – ___°C

3.8 *Operating Temperature Limits* — Operation is permitted within this range but performance is not specified beyond the Normal Operating Temperature. If the instrument is operated outside these limits damage may occur.

Description Form: ___°C – ___°C

3.9 *Maximum Baking Temperature* — The highest temperature to which the Mass Flow Controller or its components in contact with the gas can be heated in accordance with a specified baking procedure. The specified baking process will not impair the performance characteristics per the manufacturers specifications. ("Baking" is a process whereby a device is heated to accelerate the removal of adsorbed gases and/or other volatile material.)

Description Form: MAX. ___°C

3.10 *Storage Temperature Limits* — The temperature limits to which the mass flow controller may be subjected in an unpowered condition. No permanent impairment shall take place, however minor adjustments may be needed to restore performance to normal.

Description form: ___°C – ___°C

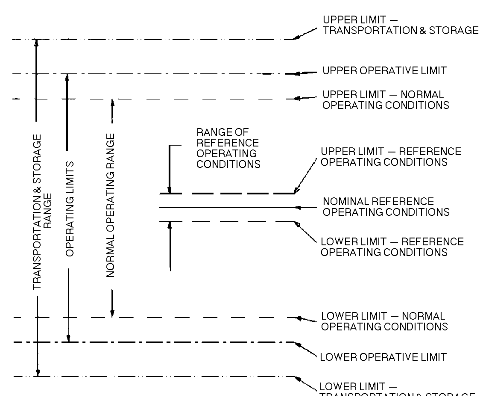

Figure 1

3.11 *Temperature Effects* — See Figure 2.

NOTE 1: This section requires that Gas Temperature be the same as Ambient Temperature.

3.11.1 *Total Effect* — The change in output, including zero and span, due to a change in Ambient Temperature from one normal operating temperature to a second normal operating temperature. All other conditions must be held within the limits of reference operating conditions.

3.11.2 *Zero Effect* — The change in zero due to a change in ambient temperature from one normal operating temperature to a second normal operating temperature. All other conditions must be held within the limits of reference operating conditions.

The effect of temperature change on zero may be expressed as a coefficient calculated as the ratio of full scale percent change in output to the corresponding change in temperature. The change in ambient temperature should be specified. This coefficient is defined as the "temperature coefficient of zero."

Example: Temperature coefficient of zero may be expressed as:

$$\frac{2\% \text{ of Full Scale}}{40°\text{C} - 20°\text{C}} = 0.1\% \text{ of Full Scale}/°\text{C}$$

NOTE 2: If the relation between temperature and change in output is linear, one coefficient will suffice.

If the temperature influence is non-linear a different method of expression may be used. Two examples:

1. The percent of full scale change in output will not exceed a specified value for any value of temperature within a specified temperature range.

Example: "± 1.5% of full scale maximum error over 10°C to 50°C"

2. It may be desirable to state a series of coefficients for successive increments of temperature within a specified temperature range.

3.11.3 *Span Effect* — The change in span due to a change in ambient temperature from one normal operating temperature to a second normal operating temperature. All other conditions must be held within the limits of reference operating conditions.

The effect of temperature change on span may be expressed as a coefficient calculated as the ratio of percent of reading change in output to the corresponding change in temperature. The change in ambient temperature should be specified. This coefficient is defined as the "temperature coefficient of span."

Example: Temperature coefficient of span may be expressed as:

$$\frac{1\% \text{ of reading}}{40°\text{C} - 20°\text{C}} = 0.05\% \text{ of reading}/°\text{C}$$

NOTE 3: If the relation between temperature and change in output is linear, one coefficient will suffice.

If the temperature influence is non-linear a different method of expression may be used. Two examples:

1. The percent of span change in output will not exceed a specified value for any value of temperature within a specified temperature range.

Example: "± 1.0% of reading maximum error over 10°C to 50°C"

2. It may be desirable to state a series of coefficients for successive increments of temperature within a specified temperature range.

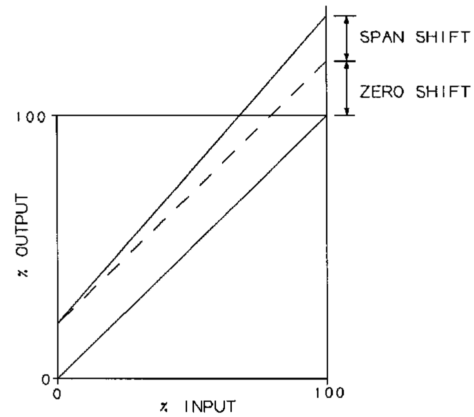

Figure 2
Span and Zero Shift

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E19-0697 (Reapproved 0702)
STANDARD MECHANICAL INTERFACE (SMIF)

This standard was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on March 17, 2002. Initially available at www.semi.org June 2002, to be published July 2002. Originally published in 1991; previously published June 1997.

NOTE: This standard has been purposely restricted to 100 mm (4 in.), 125 mm (5 in.), and 150 mm (6 in.) versions of the SMIF port. This has been done to establish a base for SMIF port standardization. Aspects of the 200 mm (8 in.) version have been negotiated by interested parties and published as SEMI E19.4.

1 Purpose

1.1 A standard interface is required for containers intended to control the transport environment of cassettes containing wafers or disks. The interface must address the proper container orientation for material transfer and maintain continuity between the container and equipment environment in order to control particulate matter.

2 Scope

2.1 This specification describes one approach to interfacing a clean cassette transport box to a clean environmental housing on a piece of semiconductor processing equipment or to other clean environments. The system concept involves mating a door on a cassette container to a door on an equipment canopy and transferring the cassette into, and out of, the equipment without exposing the cassette and wafers to outside contamination.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Impact

3.1 The incorporation of this standard requires equipment designers to include the features of the interface into the tool design. Spacing between open cassette ports is inadequate for incorporation of this interface. Designers are directed to the recommendations made in SEMI E15 in this regard.

4 Limitations

4.1 This standard is specific to the size of the designated wafer and references the appropriate SEMI cassette and wafer diameter. A single numerical suffix is assigned to this base standard number or each wafer diameter. This specification focuses on applications in which the interface port is positioned horizontally. The standard is focused exclusively on the box-to-canopy interface. Other considerations of box and equipment design are purposely excluded.

NOTE 1: Hewlett-Packard has stated that it is seeking patent coverage for this design and is offering non-exclusive licenses on an equal basis to any company. Companies intending to manufacture products to this standard should be aware of Hewlett-Packard's position.

NOTE 2: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position with respect to the validity of any patent rights asserted in connection with any item mentioned in this document. Users of this document are expressly advised that determination of any such patent rights and the risk of infringement of such rights are entirely their own responsibility.

5 Referenced Standards

5.1 *SEMI Standards*

SEMI E1 — Specification for 3 inch, 100 mm, 125 mm, and 150 mm Plastic and Metal Wafer Carriers

SEMI E15 — Specification for Tool Load Port

6 Terminology

(See Figure 1 for a pictorial depiction of most terms.)

6.1 *Definitions*

6.1.1 *box* — an environmentally controlled enclosure for a cassette containing wafers or disks. For purposes of this standard, a box has features that conform to the specified interface. A box includes a box door and box latches. (A box is also referred to as a *container*.)

6.1.2 *box door* — a removable bottom for the box that contains a means (such as registration holes) for properly positioning the wafer cassette.

6.1.3 *box latches* — mechanical latches that hold the box door in position until activated by the latch pins. Upon activation, a portion of each box latch engages a latch cavity and smaller, thereby locking the box to the port plate.

6.1.4 *guide rail* — a component of a port plate that provides coarse location for placing the box on the port assembly.

6.1.5 *latch cavities* — spaces located in the port assembly guide rails that accommodate the box latches in the open position of the box door.

6.1.6 *latch pins* — pins that engage the box latches and accomplish the lock/unlock functions. Latch pins are on the port plate.

6.1.7 *port* — a port assembly appropriately sized for the wafers or disks that are to be transferred. Three port sizes are specified for the purposes of this standard: 100 mm (4 in.) for 100 mm (4 in.) wafer cassettes, 125 mm (5 in.) for 125 mm (5 in.) wafer cassettes, and 150 mm (6 in.) for 150 mm (6 in.) wafer cassettes.

6.1.8 *port assembly* — an assembly of the port plate and port door that includes the guide rails, registration pins, latch pins, and latch cavities.

6.1.9 *port door* — a door for the port plate opening that provides a mating surface for the bottom of the box door when the box is in place on the port plate. The port door contains the registration pins.

6.1.10 *port plate* — a horizontal mating surface for the base of the box that provides a seal surface to the bottom surface of the box perimeter. The port plate contains the guide rails and the latch pins.

6.1.11 *registration holes* — holes in the bottom of the box door that fit over registration pins in the top of the port door when the box is placed on the port door.

6.1.12 *registration pins* — pins that provide fixed position and orientation between the port door and box door and assist in final positioning of the box on the port assembly. The registration pins fit into the registration holes in the bottom of the box door.

7 Requirements

7.1 *Cassette Sizes* — The requirements and dimensions for the design of mechanical interface standard ports and boxes are given in this section. All dimensions of the interface between box and port are specified in reference to the port. Different sets of port dimensions are standardized to accommodate the following three cassette sizes:

100 mm (4 in.)	per SEMI E1.2
125 mm (5 in.)	per SEMI E1.3 and E.4
150 mm (6 in.)	per SEMI E1.5

7.2 *Port Design Requirements* — The general design of the port is shown in Figures 2 and 3. Specific dimensions for the different cassette sizes are given in SEMI E19.1, SEMI E19.2, and SEMI E19.3. Design requirements for the interface components are provided in Sections 7.2.1 through 7.2.5. The general design of the port is shown in Figures 2 and 3. Specific dimensions for the different cassette sizes are given in SEMI E19.1, SEMI E19.2, and SEMI E19.3. Design requirements for the interface components are provided in Sections 7.2.1 through 7.2.5.

7.2.1 *Port Door* — Dimensions A1 through A3 specify the port door top view. The gap between port door and port plate is not specified, but should be kept to a minimum distance to restrict particle movement.

7.2.2 *Guide Rails* — The inside distance of the guide rails on the four sides of the port is specified (B1 and B2). The guide rail can be continuous or in sections. If connected at the corners, the inside radius shall not exceed B9. The maximum height of the rail is given by B5. The guide rails include cavities. Two cavities are provided for the 100 mm (4 in.) port size or four cavities for the the 125 mm (5 in.) and 150 mm (6 in.) port sizes.

7.2.3 *Latch Pins* — The 100 mm (4 in.) port requires two latch pins (C5), located on the port center line at a distance specified by C1 in the unactivated position. The 125 mm (5 in.) and 150 mm (6 in.) ports require four latch pins, positioned by C1 and C3. The displacement to move the latch pins from the unactivated (box door closed) to the activated (box door unlatched) position is specified by the linear dimension C2 . The minimum available force per pin to unlatch and latch the box door is specified by F1 and F2. The latch pins can move in a linear or circular motion as long as the position of the activated pins falls within the target area dimensioned by C8.

7.2.4 *Registration Pins* — The three registration pins on the port door are located asymmetrically, and spaced by dimensions D1 through D4. The size of the pins is specified by D5 through D7.

7.2.5 *The Box* — The bottom surfaces of the box body and box door shall conform to the specified port dimensions. The upper part of the box body and top surface of the box door must fit and hold in place the wafer cassette specified by SEMI E1, for 100 mm (4 in.), 125 mm (5 in.), and 150 mm (6 in.) cassettes. Although the box dimensions are not explicitly specified by this standard, the following requirements apply:

7.2.5.1 The bottom surface of the box door at its perimeter shall match the dimensions of the port door top (A1 through A3). The tolerances shall be chosen so that the box door does not extend over the port door in any instance, even when the port door is built to its minimal acceptable dimensions and potential variance between registration pins and holes is considered. This is to ensure interference free passage of the box door through the port opening.

7.2.5.2 The base of the box body shall fit freely but with close tolerance between the guide rails (B1, B2, and B9), which not only hold the box in place while the port is open, but also provide proper alignment for the closure of the box at the end of the open/shut cycle.

7.2.5.3 The bottom surface of the box requires three registration holes to engage with the registration pins on the port. The registration pins shall be positioned in the door bottom so that the registration pins prevent seating of the box with the port in the event that the box is improperly rotated by 180 degrees from the correct orientation. The correct orientation is illustrated in Figure 2.

7.2.5.4 The perimeter of the bottom surface of the box body shall be continuous (except possibly at the latch locations) and shall be positioned against the port surface. This positioning assures the activation of an optional limit switch placed in an unspecified location along the port perimeter for the sensing of proper box placement.

7.2.5.5 Each box door latch requires a hole to engage its corresponding port latch pin. The hole shall be elongated to provide a target area for the activated pin (box door open) as shown by dimension C8. A protrusion from each latch shall engage with its corresponding cavity in the guide rail to prevent the removal of the box while the port is open.

7.2.5.6 The center of the cassette crossbar shall coincide with the center of the box door, with the cassette orientated as shown in Figure 2. The top surface of the box door requires registration bars that hold the cassette in place. The horizontal cassette movement is limited by the tolerances G2. The vertical position of the cassette while located on the box door is specified by the distance G1 between the top of the port surface and the bottom surface of the cassette.

7.2.5.7 The external top of the box shall not exceed the top of the cassette by more than two inches. This is to prevent possible interference between the box and the equipment.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels,

product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E19.4-0998
200 mm STANDARD MECHANICAL INTERFACE (SMIF)

NOTE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position with respect to the validity of any patent rights asserted in connection with any item mentioned in this document. Users of this document are expressly advised that determination of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

1 Purpose

1.1 A standard interface is required for containers intended to control the transport environment of cassettes containing substrates. The interface must address the proper container orientation for material transfer and maintain continuity between the container and equipment environment in order to control particulate matter.

2 Scope

2.1 This specification describes one approach to interfacing a clean cassette transport box to a clean environmental housing on a piece of semiconductor processing equipment or to other clean environments. The system concept involves mating a door on a cassette container to a door on an equipment enclosure and transferring the cassette into, and out of, the equipment without exposing the cassette and substrates to outside contamination.

2.2 The incorporation of this standard may require equipment designers to include the features of the interface into the tool design. Spacing between open cassette ports must be considered when incorporating this interface. Designers are directed to the specifications and recommendations made in SEMI E15 in this regard.

3 Limitations

3.1 This standard is specific to 200 mm wafers. This specification focuses on applications in which the interface port is positioned horizontally. The standard is focused exclusively on the box-to-canopy interface. Other considerations of box and equipment design are purposely excluded.

NOTE: Hewlett Packard has patent coverage for this concept and is offering non-exclusive licenses on an equal basis to any company. Companies intending to manufacture products to this standard should be aware of Hewlett Packard's position.

4 Referenced Documents

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E19 — Standard Mechanical Interface (SMIF)

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

5 Terminology

(See Figure 1 for a pictorial depiction of most terms.)

5.1 *box* — A protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

5.2 *cassette* — An open structure that holds one or more substrates (wafers, masks, etc.) (as defined in SEMI E44).

5.3 *guide rail* — A component of a port plate that provides coarse location for placing the pod on the port assembly.

5.4 *hold-down latch* — A mechanism for locking the pod to the port plate.

5.5 *latch pins* — Pins that engage the pod door latch and accomplish the pod door lock/unlock functions. Latch pins are carried by the port door.

5.6 *pod* — A box having a Standard Mechanical Interface per SEMI E19 (as defined in SEMI E44).

5.7 *pod door* — A removable bottom for the pod that contains a means for properly positioning the cassette.

5.8 *pod latch* — A mechanical latch that holds the pod door to the pod until activated by the latch mechanism pins. Upon activation, the pod door is released from the pod.

5.9 *pod latch holes* — Holes near the center of the pod door bottom which accept the latch pins.

5.10 *port assembly* — An assembly of the port plate and port door that includes the guide rails, registration pins, latch pins, and pod hold-down latches.

5.11 *port door* — A door for the port plate opening that provides a mating surface for the bottom of the pod door when the pod is in place on the port plate. The port door contains the registration pins and the pod door latch pins.

5.12 *port plate* — A horizontal mating surface for the base of the pod that provides a seal surface for the bottom surface of the pod perimeter. The port plate contains the guide rails and the pod hold-down latches.

5.13 *registration holes* — Holes in the bottom of the pod door that fit over registration pins in the top of the port door when the pod is placed on the port door.

5.14 *registration pins* — Pins that provide fixed position and orientation between the port door and pod door and assist in the final positioning of the pod on the port assembly. The registration pins fit into the registration holes in the bottom of the pod door.

6 Requirements

NOTE: The requirements and dimensions for the design of mechanical interface standard ports and pods are given in this section. See Table 1 for 200 mm (8 inch) Port Dimensions.

6.1 *Cassette Sizes* — All specifications are related to 200 mm wafers held in an appropriate cassette. It is understood that smaller diameter wafers and other substrates may be contained in pods which are compatible with this standard.

6.2 *Port Design Requirements* — The general design of the port is shown in Figures 2 and 3. Design requirements for the interface components are provided in Sections 6.2.1 through 6.2.5.

6.2.1 *Port Door* — Dimensions A1 through A3 specify the port door top view. The gap between port door and port plate is not specified, but should be kept to a minimum distance to restrict particle movement.

6.2.2 *Pod Guide* — The inside distance of the corner guides of the port is specified by B1 and B2. The length of the corner is specified by B12. The corner guides may be connected by guide rails if desired.

6.2.3 *Latch Pins* — Two latch pins are located around the port door center. For location of the pins, see C1, C2, and C3.

6.2.4 *Registration Pins* — The three registration pins on the port door are located asymmetrically, and spaced by dimensions D1 through D4. The size of the pins is specified by D5 through D7.

6.2.5 *Pod* — The bottom surfaces of the pod body and pod door shall conform to the specified port dimensions. The upper part of the pod body and top surface of the pod door must fit and hold in place the cassette for 200 mm (8 inch) wafers. Although the pod dimensions are not explicitly specified by this standard, the following requirements apply:

6.2.5.1 The bottom surfaces of the pod door at its perimeter shall match the dimensions of the port door top (A1 through A3). The tolerances shall be chosen so that the pod door does not extend over the port door in any instance, even when the port door is built to its minimal acceptable dimensions and potential variance between registration pins and holes is considered. This is to ensure an interference-free passage of the pod door through the port opening.

6.2.5.2 The base of the pod body shall fit freely but with close tolerance between the guide rails (B1, B2, and B9), which not only hold the pod in place while the port is open, but also provide proper alignment for closure of the pod at the end of the open/shut cycle.

6.2.5.3 The bottom surface of the pod requires three registration holes to engage with the registration pins on the port. The registration pins shall be positioned in the door bottom so that the registration pins prevent seating of the pod with the port in the event that the pod is improperly rotated by 180 degrees from the correct orientation. The correct orientation is illustrated in Figure 2.

6.2.5.4 The perimeter of the bottom surface of the pod body shall be continuous and shall be positioned against the port surface. This positioning assures the activation of an optional limit switch, placed in an unspecified location along the port perimeter, for the sensing of proper pod placement.

6.2.5.5 The center of the cassette crossbar shall coincide with the center of the pod door, with the cassette oriented as shown in Figure 2. The top surface of the pod door requires the registration bars that hold the cassette in place. The horizontal cassette movement is limited by the tolerances G2. The vertical position of the cassette while located on the pod door is specified by the distance G1 between the top of the port surface and the bottom surface of the cassette.

6.2.5.6 A pod hold-down latch is required. The available latch area is specified by dimension B11 in Figure 2. Latch detail dimensions are specified in Figure 3.

6.2.5.7 The pod latch holes have a dimension of I1 perpendicular to the plane connecting both holes.

Positions for latches are identified in Figure 2 by positions 1, 2, 3, and 4. The following options for hold-down latch positions are defined by this specification:

Option A	Positions 1 and 2
Option B	Positions 3 and 4
Option C	Positions 1, 2, 3, and 4

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was approved as an official part of SEMI E19.4 by full letter ballot procedure, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 Notes

A1-1.1 Automated pod transfer between load port and automated material handling system (AMHS) might require a lead-in capability of more than 5 mm. This can be achieved by increasing the height of the guide rails (dimension B5). SEMI standard E15 limits this height to 50 mm (1.97 inches) maximum (see Figure 5). The capture range can be increased to more than 15 mm (.6 inches) if supplier and customer agree to increase the guide rail height without violating SEMI E15.

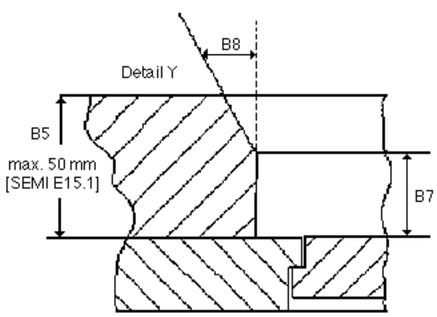

Figure 5
Optional Rail Dimensions

A1-1.2 The dimensions of the pod bottom are not specified in this standard (see Section 6.2.5.1). It is recommended that these dimensions should not exceed 282.0 mm (11.14 inches) in one direction and 292.6 mm (11.52 inches) in the other direction. These maximum outer dimensions ensure a sufficient gap around the pod and the guide rails in relation to B1 and B2 to allow a reliable motion of the pod onto the port plate.

A1-1.3 It is important that the external top of the pod does not exceed the top of the cassette by more than 50 mm (1.97 inches). This is to prevent possible interference between the pod and the equipment.

SEMI E19.5-0996
SPECIFICATION FOR 300-mm BOTTOM-OPENING STANDARD MECHANICAL INTERFACE (SMIF)

NOTICE: Hewlett-Packard has patent coverage for this concept and is offering non-exclusive licenses on an equal basis to any company. Companies intending to manufacture products to this standard should be aware of Hewlett-Packard's position.

The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position with respect to the validity of any patent rights asserted in connection with any item mentioned in this document. Users of this document are expressly advised that determination of any such patent rights, and the risk of infringement of such rights are entirely their own responsibility.

1 Purpose

This standard specifies a standard interface for containers intended to control the transport environment of contained wafers. The interface must address the proper container orientation for material transfer and maintain continuity between the container and equipment environment in order to control particulate and non-particulate contamination.

2 Scope

This specification describes an approach to interfacing a clean transport container (pod) to a clean environmental housing on a piece of semiconductor processing equipment or to other clean environments. The system concept involves mating a pod door to a port door in an equipment interface and transferring the wafers into, and out of, the equipment without exposing the wafers to outside contamination.

The incorporation of this standard may require equipment designers to include the features of the interface into the tool design. Spacing between equipment interface ports must be considered when incorporating this interface. Designers are directed to the recommendations made in SEMI E15.1 in this regard.

This standard is specific to the size of the designated wafer and references the appropriate Semiconductor Equipment and Materials International (SEMI) cassette and wafer diameter. This specification focuses on applications in which the interface port is positioned horizontally.

3.1 *SEMI Standard*

SEMI E15.1 — Provisional Specification for 300-mm Tool Load Port

4 Terminology

(See Figure 1 for a pictorial depiction of most terms.)

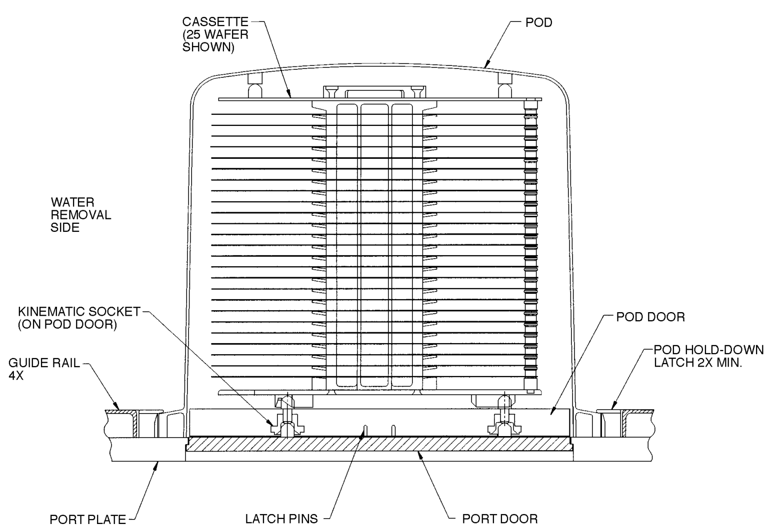

Figure 1
Port Terminology

4.1 *box* — A protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.2 *cassette* — An open structure that holds one or more substrates (as defined in SEMI E44).

4.3 *horizontal datum plane* — A plane that is parallel to the floor and coincides with the tool interface surface. A more detailed definition will be included in a companion document currently under development.

4.4 *guide rail* — A component of a port plate that provides coarse and final location for placing the pod on the port assembly.

4.5 *hold-down latch* — A mechanism for securing the pod to the port plate.

4.6 *kinematic socket (pod door)* — Grooves in the bottom of the pod door that fit over kinematic pins on the top of the port door when the pod is placed on the port door.

4.7 *kinematic pins (port door)* — Pins that provide fixed position and orientation between the port door and pod door. The kinematic pins fit into the kinematic sockets in the bottom of the pod door.

4.8 *latch pins* — Pins that engage the pod door latch and accomplish the pod door lock/unlock functions. Latch pins are carried by the port door.

4.9 *pod* — A box having a Standard Mechanical Interface (as defined in SEMI E19, SEMI E44).

4.10 *pod door* — A removable bottom for the pod that contains a means for properly positioning the wafer cassette.

4.11 *pod lock* — A mechanical latch that holds the pod door to the pod until activated by the latch mechanism pins. Upon activation, the pod door is released from the pod.

4.12 *port assembly* — An assembly of the port plate and port door.

4.13 *port door* — A door for the port plate opening that provides a mating surface for the bottom of the pod door when the pod is in place on the port plate. The port door contains the kinematic location pins and the pod door latch pins.

4.14 *port plate* — A horizontal mating surface for the base of the pod that provides a seal surface for the bottom surface of the pod perimeter. The port plate contains the guide rails and the pod hold-down latches.

5 Requirements

(See Table 1 for 300 mm (12-inch) port dimensions.)

Table 1 Port Dimensions for 300 mm (12-inch) Wafer Cassette

Port Door:	A1	185.00 mm rad. ± 0.13 mm	(7.283 in. rad. ± 0.005 in.)
Guide Rails:	B1	208.71 mm rad. ± 0.13 mm	(8.217 in. rad. ± 0.005 in.)
	B2	106.00 mm ± 0.13 mm	(4.190 in. ± 0.005 in.)
	B3	119.00 mm ± 0.13 mm	(4.690 in. ± 0.005 in.)
	B4	25.00 mm max.	(0.984 in. max.)
	B5	70.0 mm max.	(2.75 in. max.)
Latch Pins:	C1	16 deg. ± 0 deg. 30 min.	(16 deg. ± 0 deg. 30 min.)
	C2	86 deg. ± 0 deg. 30 min.	(86 deg. ± 0 deg. 30 min.)
	C3	26.72 mm dia. ± 0.05 mm	(1.052 in. dia. ± 0.002 in.)
	C4	3.175 mm dia. ± 0.025 mm	(0.125 in. dia. ± 0.001 in.)
	C5	-----------	----------
	C6	9.14 mm ± 0.25 mm	(0.360 in. ± 0.010 in.)
	C7	Full Spherical Radius	Full Spherical Radius
Pod Hold-Down Latches:	D1	22.10 mm ± 0.25 mm	(0.870 in. ± 0.010 in.)
	D2	10 deg. ± 0 deg. 30 min.	(10 deg. ± 0 deg. 30 min.)
Pod in Place Sensor:	E1	26.92 mm ± 0.25 mm	(1.060 in. ± 0.010 in.)
	E2	12.70 mm ± 0.25 mm	(0.500 in. ± 0.010 in.)
Activation Height:	E3	4.32 mm min.	(0.170 in. min.)
Latch Pin Force (Torque):	F1	8.08 kg cm min.	(7 lbs. in. min.)
		17.27 kg cm max.	(15 lbs. in. max.)

The requirements and dimensions for the design of 300 mm standard mechanical interface ports and pods are given in this section. All external dimensions of the interface between a pod and port are specified in SEMI E15.1.

5.1 *Port Design Requirements* — The general design of the port is shown in Figures 2 and 3. Design requirements for the interface components are provided in Sections 5.1.1 through 5.1.6.

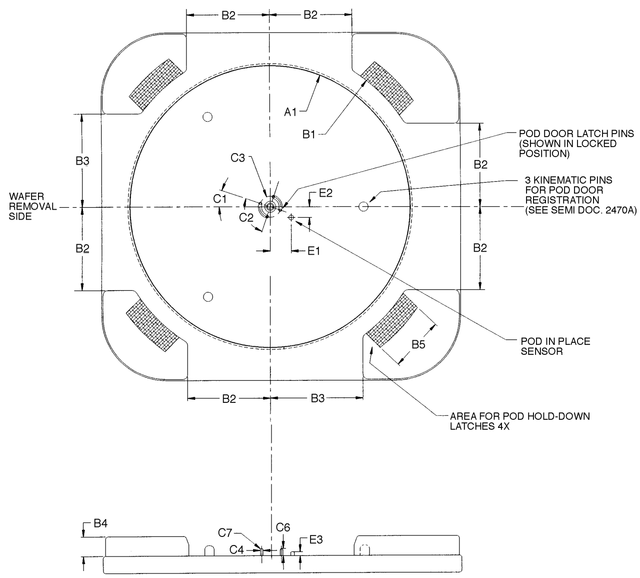

Figure 2
Port Dimensions

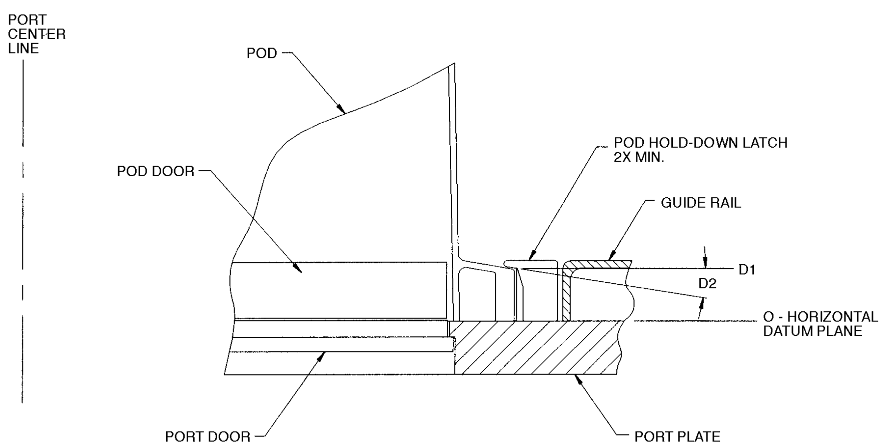

Figure 3
Port Detail

5.1.1 *Port Door* — Dimension Al specifies the port door radius. The gap between port door and port plate is not specified, but should be kept to a minimum distance to restrict particle transport.

5.1.2 *Pod Guide Rails* — The inside feature of the pod guides rails of the port are specified by B1, B2, and B3. The features provide alignment for the pod top.

5.1.3 *Pod Hold-Down Latches* — The available latch area is specified by dimensions B1, B4, and B5 in Figure 2. Latch detail dimensions are specified by D1 and D2 in Figure 3.

5.1.4 *Pod Door Latch Pins* — Two latch pins are located around the port door center and are specified by C1, C2, and C3.

5.1.5 *Kinematic Pins* — Three kinematic pins provide registration of the pod door to port plate. Details and locations of the kinematic pins are not specified in this standard. They are being addressed in a separate document currently under development.

5.1.6 *Pod in Place Sensor* — An optional sensor, for the sensing of proper pod placement shall be located on the port door as specified by E1 and E2. The sensor shall have a minimum activation height of E3 and full travel to the port plate.

5.2 *Pod* — The bottom surfaces of the pod body and pod door shall conform to the specified port dimensions. Although the pod dimensions are not explicitly specified by this standard, the following requirements apply. (Pod dimensions are being addressed in a separate document currently under development.)

5.2.1 The upper part of the pod body and the top surface of the pod door must fit and hold in place the wafer cassette, which will be specified in a separate document currently under development.

5.2.2 The center of the wafers and pod door shall coincide. The top surface of the pod door incorporates kinematic features that position the cassette on the pod door.

5.2.3 The bottom surface of the pod door at its perimeter shall match the radius of the port door top (dimension Al). The tolerances shall be chosen so that the pod door does not extend over the port door in any instance, even when the port door is built to its minimal acceptable dimensions and potential variance between kinematic pins and socket is considered. This is to ensure an interference-free passage of the pod door through the port opening.

5.2.4 The base of the pod body shall fit freely but with close tolerance between the pod guide rails, which not only hold the pod in place while the port is open, but also provide proper alignment for closure of the pod at the end of the open/close cycle.

SEMI E20-0697
CLUSTER TOOL MODULE INTERFACE: ELECTRICAL POWER AND EMERGENCY OFF STANDARD

1 Introduction

1.1 *Scope* — The standard deals with the delivery and emergency interruption of electrical power to the modules of a cluster tool.

1.2 *Purpose* — The purpose of the standard is to specify the Emergency Off capability to the modules of a cluster tool; to allow module Emergency Off disconnect and reconnect in a safe manner without removing power from the rest of the tool; and to prevent power from being applied to a module when its Emergency Off is non-functional.

1.3 *Impact* — The standard requires that power can be delivered to an individual module only if its Emergency Off is functional. This does not preclude removal of power from the module by non-emergency means.

The standard specifies the Emergency Off circuit functions that must be provided at the Emergency Off interfaces of a cluster tool, including the plug, momentary bypass switch and bypass jumper plug. Pinouts for the Emergency Off plug and bypass jumper plug are specified.

SEMI E21 — Cluster Tool Module Interface: Mechanical Interface and Wafer Transport Standard

2.2 *Military Standards*[1]

MIL-C-26500E — General Specification for Connectors — General Purpose, Electrical, Miniature, Circular, Environmental Resisting

3 Definitions

3.1 *daisy-chained* — Connected so that the removal of one component causes the interruption of the circuit to another component.

3.2 *emergency off (EMO)* — Fail-safe control switch or circuit which, when de-energized, will stop the operation of associated equipment and will shut off all potential hazards outside the main power enclosure.

3.3 *EMO interface* — The location at which a process or cassette module EMO cable is connected into the cluster tool circuit.

4 Requirements

4.1 *Power Distribution*

4.1.1 *Mains* — Each cluster tool (as defined in SEMI E21) shall have its power provided by one or more contactors enabled by the EMO. The power is to be delivered to one or more power distribution enclosures, where voltage transformation may take place before distribution to the module (as defined in SEMI E21).

4.1.2 *Module Power Distribution* — The power distribution to each module is provided through a dedicated circuit breaker in the power distribution enclosure. The rated current and voltage in each circuit is determined by the tool configuration. A discussion of how this standard may be implemented is given in Application Note A.1.

4.1.3 *Operation of the EMO* — Activation of the EMO shall not cause or allow an unsafe condition to exist (see Application Note A.2).

4.2 *EMO Circuit*

4.2.1 *Description* — Each module attached to the cluster tool is to have at least one EMO button operating an EMO switch (see Application Note A.3). The switches are daisy chained into a circuit, or circuits, that disconnect the main power and any backup power sources. The 24 VAC power to energize this circuit is provided from within a main power enclosure, so that the EMO circuit is independent of module power. Each module EMO is connected to the chain at its EMO interface. A momentary bypass switch, also located at each module EMO interface, allows separation of the module from the cluster tool without tripping the EMO, provided that electrical power is removed from the module by turning off the dedicated circuit breaker (see Application Note A.4). Jumpers in the bypass jumper plug connect the EMO circuit in series with contacts that open if the dedicated circuit breaker is turned on.

4.2.2 *Wiring* — Copper wire used in the EMO circuits shall be 0.82 mm^2 cross-section (#18 AWG) or larger.

4.2.3 *Labeling* — A label with the following legend is to be affixed to the power distribution enclosure near each module circuit breaker: Caution: Energizing this circuit with the associated EMO bypass jumper plug installed will interrupt power to the entire cluster tool.

1 Military Standards, Naval Publication and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120.

4.3 *Connection at EMO Interface*

4.3.1 *EMO Connector* — The connector at the EMO interface is reserved for EMO functions only. Metal shell bayonet-type connectors are specified per MIL-C-26500E as follows: MS24265R16B10SN on the panel, and MS24266R16B10PN on the cable and on the EMO bypass jumper plug. The receptacle is panel mounted at the EMO interface and the plug is mounted on the module EMO cable.

4.3.2 *Module EMO Connector Pinouts* — Pins 1 and 2 of the EMO cable plug connect across contacts in the module EMO switch. In the receptacle, pins 1 and 2 connect to the EMO circuit and pins 3 and 4 connect across the contacts specified in Section 4.2.1.

4.3.3 *EMO Bypass Jumper Plug* — Pin 1 is jumpered to pin 4 and pin 2 is jumpered to pin 3 in the plug. This will result in placing the contacts specified in Section 4.2.1 into the EMO circuit when the plug is installed.

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

APPLICATION NOTES

NOTE: The material contained in these application notes is not an official part of SEMI E20 and is not meant to modify or supersede it in anyway. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such, they are to be considered as reference material only. The standard should be referred to in all cases.

A.1 AC Power Distribution

One method of providing power and EMO functions to a cluster tool is shown in Figure F1 (see Section 4.1.2). A standby power supply (SPS) or uninterruptible power supply (UPS) is included to maintain EMO and selected cluster tool functions in the event of main power failure. It may be desirable to include additional circuit breakers in the main power enclosure if individual module disconnects are needed at level I in Figure F1. Disconnect at level II in Figure F1 is made possible by the module circuit breakers; SEMI E7, “Electrical Interfaces Specification,” should be used for loads up to 10 kW. Additional main power enclosures could be provided for modules with heavy AC loads, provided that each main contactor is operated by one common EMO circuit, however, some user’s safety codes may demand a single source of supply.

A.2 Operation of Remote Equipment

Activation of the EMO shall stop, by fail-safe means at the tool, the delivery of potentially hazardous energy (e.g., high voltage, laser) or hazardous material (e.g., toxic process gas, coolant) to the cluster tool (see Section 4.1.3).

A.3 EMO Switch Placement

The EMO switches on each module (see Section 4.2.1) need to be placed so that they are accessible to any person in the vicinity of the cluster tool. Local safety codes may take precedence in matters of EMO switch placement. The standard ensures that each module has at least one EMO switch and that its operation, when the module is attached, removes power from the entire cluster tool.

A.4 EMO Bypass

A.4.1 *Implementation* — The functions, specified in Section 4.2.1, to allow EMO bypass and to ensure that module power is off when the EMO is removed from the cluster tool EMO circuit, can be implemented as shown in Figure F2. A relay or switch, operated in parallel with the dedicated circuit breaker specified in Section 4.1.2 for the module, provides 24 VAC to the coil of a double pole relay when the circuit breaker is de-energized. An indicator light in parallel with the coil illuminates when the bypass is enabled and the power to the module is off. One set of contacts of this relay is used to enable the momentary EMO bypass switch. The other set is connected across pins 3 and 4 of the EMO receptacle at the EMO interface and is in the EMO circuit when the EMO bypass jumper plug is installed. Both sets of contacts are wired to open when voltage is removed from the relay coil, i.e., when the circuit breaker is closed.

A.4.2 *Module Disconnect* — The dedicated circuit breaker (see Section 4.2.1) to the module must be turned off prior to disconnect. This causes the contacts in series with the momentary EMO bypass switch to close, rendering it operational. At this point, the EMO switch on the module is still in the cluster tool EMO circuit. To disconnect, the operator holds in the EMO bypass switch while removing the module EMO plug from the EMO interface and then connecting the EMO bypass jumper plug. The momentary bypass switch can then be released.

A.4.3 *Module Connect* — To connect a module, the dedicated circuit breaker (see Section 4.2.1) must be off at the power distribution point to the module. The power cable may be attached to the module at this time. The operator holds in the momentary bypass switch while disconnecting the EMO bypass jumper plug from the EMO interface and connecting the module EMO Plug. The momentary bypass switch can then be released. Power cannot be applied to the module unless the EMO is connected (as shown in Figure F2).

SEMI E21-94 (Reapproved 0699)
CLUSTER TOOL MODULE INTERFACE: MECHANICAL INTERFACE AND WAFER TRANSPORT STANDARD

This standard was technically reapproved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition reapproved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1991; previously published in 1994.

Minor editorial changes were made to this document to conform to editorial guidelines.

1 Introduction

1.1 *Scope* — The standard defines the interface plane between modules in a cluster tool. It provides the mechanical specifications at the interface that allow modules from different suppliers to be connected together; no requirements are imposed on the module content.

1.1.1 The standard is limited to wafers which are 200 mm (~8 in.) in diameter or smaller and to the interface between cluster tool modules, with the following exception. The transport module operates across the interface plane; thus, a definition of the wafer transport plane within cassette and process modules is required.

1.2 *Purpose* — The purpose of the standard is to simplify cluster tool implementation in the fab. Equipment suppliers are required to provide modules that can be connected into any cluster tool using the specifications contained herein.

1.2.1 Process and cassette modules accept wafers at locations that may vary substantially from one module to another. This places a burden on the capabilities of transport modules to move wafers to and from various modules in a cluster tool. This specification defines wafer transport planes within cassette and process modules. This obviates the wafer transport problem to a large extent, but does not unduly restrict module content.

1.3 *Impact* — The adoption of the standard requires cluster tool equipment designers to limit the wafer transport height to a nominal value at the interface plane between two modules. It also requires equipment designers to assure that wafer transport planes within cassette and process modules be clear for wafer transport. The transport module requires the capability for a minimum reach outside the module across the interface plane. Modules may be connected using a quick connect/disconnect clamping system. Constraints are placed on sealing surfaces.

2 Referenced Documents

ISO 1609-1986 (E)[1] — "Vacuum Technology — Flange Dimensions," International Organization for Standardization (ISO).

3 Definitions

3.1 *cassette module* — a two-port module. One port accepts or presents a cassette of wafers or possibly, in an automated factory, an individual wafer for intertool transport; the second port accepts or presents a single wafer within the module for intratool transport.

3.2 *cluster tool* — an integrated, environmentally isolated manufacturing system consisting of process, transport, and cassette modules mechanically linked together. The modules may or may not come from the same supplier.

3.3 *environmental isolation* — separated from the ambient atmospheric environment.

3.4 *interface plane* — the vertical surface defined by the mating surfaces of two joined modules.

3.5 *interface seal zone* — an absolute surface or face reserved for establishing an environmental seal between modules.

3.6 *intertool transport* — wafer or cassette movement between independent tools.

3.7 *intratool transport* — wafer movement inside a cluster tool.

3.8 *module* — an independently-operable unit that is part of a tool or system.

3.9 *process module* — a module that accepts or presents a single wafer inside the module for intratool transport.

---

[1] *ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland, website: www.iso.ch*

3.10 *reach* — the distance measured from the interface plane to the wafer centroid within a process or cassette module.

3.11 *transport module* — a module that accepts or presents a single wafer outside the module across the interface plane for intratool transport.

3.12 *wafer transport plane* — the horizontal surface a wafer traverses between modules.

3.13 *wafer transport zone* — the area of the interface plane free of physical obstructions, reserved for wafer movement between modules.

4 Requirements

4.1 *Wafer Transport and Placement*

4.1.1 *Horizontal Transport Plane* — The dimensions for wafer placement during wafer transport are referenced from the interface plane in the plan view shown in Figure 1. The transport module is required to present or accept a horizontal wafer outside the module *anywhere* along an axis perpendicular to the center of the interface plane to a maximum 305 mm (12 in.) from the interface plane. Thus, a transport module is required to have the capability to reach 305 mm (12 in.) beyond its interface plane to a wafer centroid (see Section R1-1). However, location of the wafer at a distance less than 305 mm (12 in.) from the interface plane requires that the transport module be capable of addressing the intermediate location. Similarly, a cassette module or process module accepts a horizontal wafer inside the module *anywhere* along an axis perpendicular to the center of its interface plane up to a maximum 305 mm (12 in.) from the interface plane as required by the application.

4.1.1.1 *Placement Accuracy* — The requirements for placement accuracy of a wafer in the horizontal plane within a module are 1.0 mm (0.04 in.) true position, ± 0.5 mm (± 0.020 in.) radially, with less than one degree angular rotation for every module-to-transport-to-module wafer transport (B_n:A:B_n + 1as shown in Figure 1). If the wafer is displaced in the process module, it must be returned to the original position within the non-culmulative placement accuracy of 1.0 mm (0.04 in.) true position, ± 0.5 mm (± 0.020 in.) radially.

4.1.2 *Vertical Position of Transport Plane* — The elevation of the wafer transport plane is measured from the facility floor as shown in Figure 2. The transport module is required to present or accept a horizontal wafer outside the module at a nominal wafer transport height of 1100 mm (43.307 in.) from the facility floor (see Section R1-2).

4.1.2.1 *Vertical Motion* — The transport module is required to move the wafer to within ± 0.5 mm (0.020 in.) in the wafer transport plane. The transport module is also required to posess a vertical motion capability to a second plane 6.0 mm ± 0.5 mm (0.236 in. ± 0.020 in.) below the wafer transport plane in order to allow wafer handoff to or from passive cassette or process modules (see Figure 2 and Section R1-3).

4.1.2.2 *Reference Plane* — The interface plane alignment pins define a reference plane 9.5 mm (.374 in.) below the wafer transport plane (see Figure 2).

4.2 *Interface Plane* — The interface plane contains the interface seal zone and the wafer transport zone, which do not overlap, and the location of the interface plane alignment pins (see Figures 3 and 4).

4.2.1 *Interface Seal Zone* — The interface seal zone is rectangular and symmetrically referenced to the interface plane alignment pins. The inside boundary dimension of the interface seal zone is 46 mm (1.811 in.) by 236 mm (9.291 in.). The outside boundary is 76 mm (2.992 in.) by 266 mm (10.472 in.). A seal zone is either a seal surface or an O-ring face. All interface seal zones facing toward a transport module are seal surfaces polished to a surface finish less than or equal to 0.8 micrometer (32 microinches) parallel to the circumference (see Section R1-4). All interface seal zones facing toward a cassette or process module are O-ring faces equipped with the appropriate capture groove for the sealing method employed (see Figure 3 and Section R1-4.1).

4.2.2 *Wafer Transport Zone* — The wafer transport zone is the area within the interface seal zone reserved for moving the wafer between modules. The wafer transport zone which cannot be compromised by any module is defined as the area at least 16 mm (.630 in.) above and below the alignment pin centerlines, and 111 mm (4.370 in.) to the left and right of the centerline between the two alignment pins (see Figure 3 and Section R1-5).

4.2.3 *Interface Plane Alignment Pins* — Provisions are made for two 10 mm (.394 in.) diameter locating pins (see Figure 4) to be used as alignment aids between modules. Under no circumstances should the flanges at the interface plane and the alignment pins be subject to a total load exceeding 500N (112 lbf) in shear. The alignment pins have an absolute centerline separation of 300.0 mm (11.811 in.) in the horizontal plane. The pins reside in the seal surface side of the flange pair, opposite the O-ring, facing toward the transport module. Mild press fit holes are provided in the seal surface flange face. A clearance hole and a slot are provided in the O-ring flange face as shown in Figure 1 and specified in Figure 3. Alignment pin height above the flange face is 6 mm (.24 in.) minimum to 8 mm (.31 in.) maximum (see Section R1-6).

4.2.4 *Isolation Valves* — The transport module is always equipped with a valve for environmental isolation at each module interface plane. The intratool transport port on a process or cassette module may be equipped with an environmental isolation valve (see Section R1-7).

4.3 *Flange* — A flange is specified as 162 mm (6.378 in.) by 340 mm (13.386 in.). One horizontal edge is specified to be 50 mm (1.969 in.) from the alignment pins' centerline (see Figure 4).

4.3.1 *Clamping* — Clamping grooves as specified in the International Standards Organization document, Vacuum Technology, Flange Dimensions (ISO 1609-1986), Table 2, nominal bores 40 mm-250 mm (1.575 in.Ð9.843 in.) are located at the flange perimeter (see groove detail in Figure 4). Clamps for ISO flanges can be used to generate the force necessary to produce an environmental seal (see Section R1-8).

4.3.2 *Non-Flanged Surfaces* — A non-flanged surface may be used to join with a flanged surface. An attachment means to engage the flange must be provided. If a flanged adaptor piece is necessary to join two non-flanged surfaces, then the adaptor piece shall be located on the process or cassette side of the interface plane.

Flange Specification

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E21 but was reapproved for publication by full letter ballot procedures on February 28, 1999.

R1-1 Transport Module Reach

R1-1.1 The reach (see Section 4.1.1) permits a wafer of 200 mm (8 in.) diameter or smaller to be placed on a wafer support platform in a process chamber with allowance for the optional isolation valve on the process module and the chamber wall thickness. The substantial clearance between the wafer and the chamber wall is to allow freedom for process-specific design requirements.

R1-1.2 Individual process chamber designs may place the wafer closer to the interface plane than 305 mm (12 in.) and still conform to the standard.

R1-1.3 Wafers are transported individually in a horizontal attitude. Modules may contain any number of wafers. For example, batch processing is allowed.

R1-2 Vertical Position of Transport Plane

R1-2.1 The transport plane elevation of 1100 mm (43.307 in.) (see Section 4.1.2) is positioned within the constraints placed on the cluster tool by the Inter-Equipment Automation requirement for cassette placement (SEMI E15). SEMI E15 specifies the load height for cassettes to be 900 mm (35.46 in.) ± 10 mm (.394 in.) outside an environmental load-lock.

R1-2.2 The vertical position of the transport plane is derived from the following contributions:

— 910 mm (35.854 in.) is a worst-case cassette load height position.

— 12 mm (.473 in.) is a nominal pickup clearance to zero a wafer elevator indexer after the cassette is drawn into the environmental load-lock.

— 178 mm (7.01 in.) is the location of the top slot in a standard 200 mm (8 in.) wafer carrier (SEMI E1.7).

R1-2.3 These additive contributions assure that the transport plane elevation allows as much space as possible for location of support equipment such as pumps, electronics, and power supplies below the process chamber. The 1100 mm (43.307 in.) "nominal" dimension could be adjustable by the module(s) to within ± 25 mm (1 in.).

R1-3 Vertical Motion

R1-3.1 The standard (see Section 4.1.2.1) requires that the transport module be capable of moving in two planes. An ability to move in other planes is optional.

R1-3.2 The transport module moves the wafer in the horizontal wafer transport plane (see Definition 3.12). The transport module has a vertical motion capability for wafer handoff or pickup. It is assumed that the transport module moves in the lower plane after wafer handoff or prior to wafer pickup.

R1-4 Interface Seal Zone

R1-4.1 The interface seal zone (see Section 4.2.1) is sufficiently wide to permit double seals with intermediate pumping.

R1-4.2 *Blank-Off Plates* — The location of the seals on the transport module allows plain blank-off plates to be used for environmental sealing.

R1-5 Wafer Transport Zone

R1-5.1 The minimum specified height of 32 mm (1.184 in.) (see Section 4.2.2) provides sufficient clearance for passage of a knuckle joint or pivot point in the transport module end effector (see SEMI E22, "Cluster Tool Module Interface: Transport Module End Effector Exclusion Volume Standard") and for 6 mm (.238 in.) of vertical motion. The wafer transport zone may be expanded up to the boundary of the interface seal zone when a module requires a larger opening (see Section 4.2.1 and Figure 3).

R1-6 Interface Plane Alignment Pins

R1-6.1 The standard (see Section 4.2.3) implies the normal engineering practice of chamfering pin ends and countersinking pin locating holes. Actual dimensions for this have been specified or recommended by other authorities.

R1-6.2 Pins reside in the sealing surface to avoid accidental damage to the surface finish during assembly and disassembly. With centrally placed pins, valves may be mounted in either orientation if this simplifies servicing or accessibility.

R1-6.3 A clearance hole and slot arrangement allows use of dissimilar flange materials in a dynamic thermal environment.

R1-7 Isolation Valves

R1-7.1 The standard (see Section 4.2.4) allows the valves to be integral to the modules or discrete separable units.

R1-8 Clamping

R1-8.1 The standard (see Section 4.3.1) allows a universal clamping scheme to be employed. Claw clamps designed for use with ISO flanges are accommodated by the use of a perimeter groove around the flange.

R1-8.2 The clamping scheme provides several benefits:

— Independence from any hole pattern requirements.

— Flanges may be connected to flat plates or to other flanges.

— The number of clamps and the number of sides used to draw the flanges together may be varied as required by the compression forces necessary for the sealing method used. For example, clamps may be spaced on 30 mm (1.191 in.) centers for metal seals and on 150 mm (6 in.) centers for elastomeric seals.

— Any type of clamp may be used that accommodates the perimeter groove.

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

SEMI E21.1-1296
CLUSTER TOOL MODULE INTERFACE 300 mm: MECHANICAL INTERFACE AND WAFER TRANSPORT STANDARD

1 Introduction

The standard provides the requirements to extend the limits of SEMI E21 from 200 mm diameter wafers or smaller to 300 mm diameter wafers or smaller.

2 Applicable Documents

SEMI E21 — Cluster Tool Module Interface: Mechanical Interface and Wafer Transport Standard

3 Requirements

The standard is identical to E21 (see Application Note A.1) except for the requirements listed in Table 1 and Figures 1 and 2.

Table 1 Mechanical Interface Requirements for 300 mm Diameter Wafers

	E21 Requirements	*300 mm Wafer Requirements*
Transport Maximum Reach[1]	305.0 mm (12.01 in.)	380.0 mm (14.96 in.)
Inside Boundary Width-Interface Seal Zone[2]	236.0 mm (9.29 in.)	336.0 mm (13.23 in.)
Outside Boundary Width-Interface Seal Zone[2]	266.0 mm (10.47 in.)	366.0 mm (14.41 in.)
Wafer Transfer Zone Minimum Width[2]	222.0 mm (8.74 in.)	322.0 mm (12.68 in.)
Alignment Pins Centerline Separation[2]	300.0 mm (11.81 in.)	400.0 mm (15.75 in.)
Flange Width[2]	340.0 mm (13.39 in.)	440.0 mm (17.32 in.)
Vertical Slot Opening (Inner boundary of Seal Zone)	46 mm (1.811 in.) Maximum	50 mm (1.969 in.)
Distance of Wafer Transfer Plane above Alignment Pin Datum Line (see Figure 1)	9.5 ± 0.5 mm (0.37 ± 0.02 in.)	15.5 ± 0.5 mm (0.61 ± 0.02 in.)
Vertical Motion Capability (see Figure 1)	6 ± 0.5 mm (0.24 ± 0.02 in.)	10 ± 0.5 mm (0.39 ± 0.02 in.)
Minimum Distance of Slot Top above Alignment Pin Datum on Attached Modules	(13 mm)	23 mm (0.906 in.)
Minimum Distance of Slot Bottom below Alignment Pin Datum on Attached Modules	(13 mm)	13 mm (0.512 in.)

Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

APPENDIX 1
APPLICATION NOTES

NOTE: The material contained in these application notes is not an official part of SEMI E21.1, and is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such they are to be considered as reference material only. The standard should be referred to in all cases.

A.1 Vertical Requirements

Changes in vertical requirements are made because of the need to provide adequate transport arm stiffness (thickness) for the longer reach specified for 300 mm. However, for many processes, it is desirable to limit the slot size as far as possible. An option is now allowed to reduce the vertical slot opening on the Attached Modules side of the Interface Plane (see Figure 1, E21), but any such reduction will compromise the space otherwise available for transport arm vertical thickness and/or movement. Specification of the extent of this option will be needed in each case it is used.

A.2 Transport Maximum Reach

The maximum reach beyond the interface plane (see Table 1) is increased by 75 mm (from 305.0 mm to 380.0 mm); a 50 mm increase in wafer radius (from 100 mm to 150 mm) and a 25 mm increase in clearance between the wafer and the chamber walls.

A.3 Width Requirements

The increase in wafer diameter from 200 mm to 300 mm necessitates a 100 mm increase in all width values (see Table 1) specified in SEMI E21.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

SEMI E22-0697
CLUSTER TOOL MODULE INTERFACE: TRANSPORT MODULE END EFFECTOR EXCLUSION VOLUME STANDARD

1 Introduction

1.1 *Scope* — The standard describes the volume within any process or cassette module which shall be accessible to the transport module end effector in a cluster tool. The standard is limited to modules which accommodate wafer sizes from 100 mm up to and including 200 mm in diameter.

1.2 *Purpose* — The purpose of the standard is to provide sufficient detail to allow the transport module end effector to move wafers to and from process and cassette modules in a cluster tool without mechanical interference.

1.3 *Impact* — The adoption of the standard requires equipment designers to allow specific unobstructed volumes within process and cassette modules for wafer transport and places restrictions on the design of the transport module end effector. Some restrictions are dependent on the wafer size.

2 Applicable Documents

2.1 *SEMI Documents*

SEMI E1 — Specification for 3 inch, 100 mm, 125 mm, and 150 mm Plastic and Metal Wafer Carriers

SEMI E21 — Cluster Tool Module Interface: Mechanical Interface and Wafer Transport Standard

3 Definitions

3.1 *exclusion zone* — A restricted area within a process or cassette module reserved for access by the transport module end effector during wafer handling.

3.2 *fork* — A two-prong transport module end effector designed to hold the wafer around its periphery.

3.3 *paddle* — A blade transport module end effector designed to support the wafer.

3.4 *pedestal* — A support pillar axially symmetric to the wafer transport position in a process or cassette module.

3.5 *slot* — A two-sided support, for example as defined for a standard wafer carrier in SEMI E1 when the carrier is oriented with its axis in a vertical attitude.

3.6 *transport module end effector* — That part of the transport module that supports the wafer and can extend beyond the interface plane (defined in SEMI E21).

3.7 *wafer support platform* — A slot, pedestal, or set of pins used to hold a wafer in a horizontal attitude.

3.8 *wafer transport axis* — The centerline of transport module end effector motion. This centerline is symmetric with the wafer transport zone as described in SEMI E21.

3.9 *wafer transport position* — A location within a process or cassette module where the wafer is accepted or presented by the transport module end effector. This is also the location of the wafer centroid.

4 Requirements

4.1 *Wafer Transport* — The wafer is to be transported in a horizontal attitude (see Application Note A.1).

4.2 *Wafer Transport Plane Exclusion Zone* — The exclusion zone is illustrated in Figure 1, and the variables are defined in Table 1 and specified in Table 2 (see Application Note A.2). The clear areas between B and C and along the wafer transport axis are specified to allow the transport module end effector to be retracted after the wafer has been placed on the support platform in the process or cassette module. The right-hatched (////) area denotes the exclusion zone which could be occupied by a paddle. The left-hatched (\ \ \ \ ) area denotes the additional exclusion zone which could be occupied by a fork. The cross-hatched (XXXX) area denotes the reduction in the dimensions of the paddle exclusion zone to accommodate a pedestal and or pin(s) in a process or cassette module (referred to as a pedestal or pin exclusion zone).

4.3 *Maximum Pedestal Diameter* — The diameter is not to exceed dimension H given in Table 2.

4.4 *Pin Location* — Wafer support pins to be located relative to the wafer transport plane exclusion zone. The pins are to be located at radii dependent upon wafer diameter as specified in Table 2.

4.5 *Vertical Plane Exclusion Zone* — The extent of the exclusion zone in the vertical plane is indicated by the hatched area and the dashed outline in Figure 2. The maximum extent of the exclusion zone allows the transport module end effector to clear the minimum wafer transport zone at the interface plane (see Application Note A.3). The vertical plane exclusion zone is decreased in height in the vicinity of the wafer transport position to allow the presence of shields, electrodes, etc. in the process or cassette module.

4.6 *Transport Module End Effector Exclusion Volume* — The exclusion volume within a process or cassette module reserved for access by the transport module end effector is defined by the intersection of the two orthogonal exclusion zones described in Sections 4.2 and 4.5. This exclusion volume allows the transport module end effector to accept or present a wafer at the wafer transport position within a process or cassette module (see Application Note A.4).

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

APPLICATION NOTES

NOTE: The material contained in these application notes is not an official part of SEMI E22, and it is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such, they are to be considered as reference material only. The standard should be referred to in all cases.

A.1 Wafer Transport

The standard (see Section 4.1) does not require that the entire transport module end effector move in a horizontal attitude while the wafer does have this requirement. For example, the transport module end effector may have a component of motion in a plane other than the horizontal during wafer transport across the interface plane.

A.2 Variables — Definitions and Dimensions

The function of Table 2 (see Section 4.2) is to list the numerical values for the wafer dependent variables used in Figures 1 and 2. The values are wafer size dependent so as not to penalize the design of a transport module end effector when handling only small diameter wafers. For example, the physical size of a transport module end effector for a 100 mm diameter wafer may be smaller than that for a 200 mm diameter wafer.

A.3 Vertical Plane Exclusion Zone

The development of the numeric values specified in the standard (see Section 4.5) and given in Figure 2 are described below.

The 3 mm height above the wafer transport plane (defined in SEMI E21) allows for transport module end effectors which use contraints (e.g., a cupped device or pins) to ensure the wafer does not slide. Also, this may be necessary if the wafer is transported with the circuit side facing down.

The 7 mm value allows for a 4 mm thickness below the wafer transport plane to accommodate a structurally and thermally strong transport module end effector design.

The 12.5 mm thickness allows for process or cassette modules with a minimum slot opening value of less than 32 mm (see SEMI E21).

The 200 mm minimum length part of the exclusion zone allows for a transport module end effector of limited reach to pass into modules with slot openings smaller than the minimum value of 32 mm.

The 23 mm thickness allows for the presence of a “wrist” joint or for additional rigidity in the transport module end effector.

The 120 mm length is specified as a fixed number to ensure that multiple wafer sizes (and transport module end effectors) do not necessarily demand a change in geometry of the receiving module around the wafer transport position.

The minimum nominal clearance above and below the exclusion zone is 1.5 mm on both sides of the transport module end effector when it passes through the minimum slot opening. This takes into account the exclusion zone size due to the vertical travel the transport module end effector may experience.

A subset of the vertical plane exclusion zone (see Figure A.1) is required by a transport module end effector which must access wafers directly from SEMI standard or equivalent cassettes. The vertical plane exclusion zone described in the standard (see Figure 2) was not subject to these restrictions since a single generic transport module end effector design was found not to be practical.

A.4 Transport Module End Effector Exclusion Volume

This volume as described in Section 4.6 is intended to be the volume within which the transport module end effector has complete autonomy. Therefore, process and cassette modules are not allowed to violate this volume during wafer transport. This prevents mechanical interference between the transport module end effector and the process or cassette module.

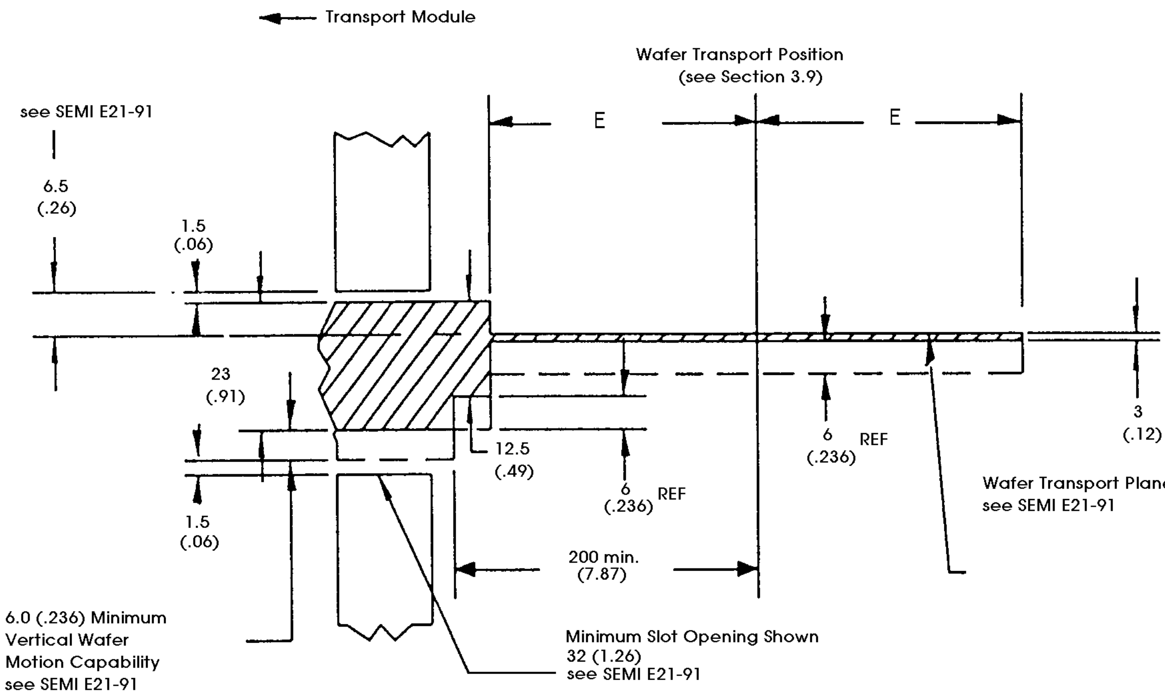

Figure A.1
Vertical Plane Exclusion Zone (Elevation View)
(Restricted Case for SEMI Standard Cassette Access)

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

SEMI E22.1-1296
CLUSTER TOOL MODULE INTERFACE 300 mm: TRANSPORT MODULE END EFFECTOR EXCLUSION VOLUME STANDARD

1 Introduction

The standard provides the requirements to change the limits of applicability of SEMI E22 from 100 mm to 200 mm diameter wafers to 300 mm diameter wafers.

2 Applicable Documents

2.1 *SEMI Standards*

SEMI E1.9 — Provisional Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

SEMI E22 — Cluster Tool Module Interface: Transport Module End Effector Exclusion Volume Standard

3 Requirements

3.1 *Wafer Transport Plane Exclusion Zone* — All fixed dimensions remain the same as for SEMI E22 with the following exception. The 25 mm and 10 mm dimenions for the rectangular space excluded from the front of the Paddle Exclusion Zone are expanded and defined by Variables I and H respectively. These variables are shown in Figure 1. Variables for 250 mm and 300 mm diameter wafers are specified in Table 1.

Table 1 Wafer Transport Plane Exclusion Zone Dimensions for 250 mm and 300 mm Diameter Wafers

Variables	*Wafer Size*	
	250 mm (10 in. nom.)	*300 mm (12 in. nom.)*
A	270 mm (10.63 in.)	320 mm (12.60 in.)
B	215 mm (8.46 in.)	250 mm (9.84 in.)
C	130 mm (5.12 in.)	225 mm (8.86 in.)
D	122 mm (4.80 in.)	147 mm (5.79 in.)
E	135 mm (5.31 in.)	160 mm (6.30 in.)
F	145 mm (5.71 in.)	170 mm (6.69 in.)
G	122 mm (4.80 in.)	147 mm (5.79 in.)
H	75 mm (2.95 in.)	154 mm (6.06 in.)
I		117 mm (4.61 in.)

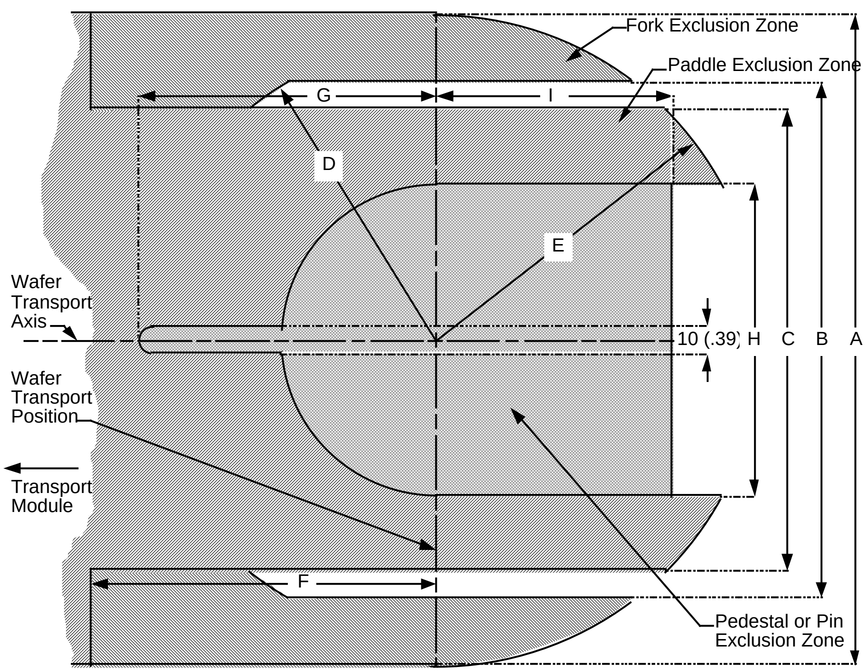

Figure 1
New Wafer Transport Plane Exclusion Zone Dimensions

3.2 *Vertical Plane Exclusion Zone* — This zone is illustrated in Figure 2, which defines dimensional values.

Proposed 300 mm Vertical Plane Exclusion Zone (Elevation View)

APPENDIX 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E22.1, and is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such they are to be considered as reference material only. The standard should be referred to in all cases.

The standard applies to both attached modules and wafer carriers; there is no special subset for carriers. The extreme end of the exclusion zone should allow adequate stiffness for end effectors and also permit insertion into carriers (with a 10 mm pitch).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

SEMI E23-96 (Reapproved 0702)
SPECIFICATION FOR CASSETTE TRANSFER PARALLEL I/O INTERFACE

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the North American Physical Interfaces and Carriers Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published in 1991; previously published in 1996.

1 Purpose

1.1 Cassette transfer between process equipment and transport equipment is performed by means of a mechanical operation in the interactive area and requires quick response and reliable interlock signals.

1.2 The purpose of this specification is to provide a cassette transfer parallel input/output (I/O) interface for control of the interface mechanism that supplements the SECS standard for material movement.

2 Scope

2.1 This specification deals with the parallel I/O interface for the cassette transfer between two pieces of equipment, such as a piece of process equipment and a piece of transport equipment.

2.2 This standard defines the wire-connected parallel I/O interface between two pieces of equipment and the photo-coupled parallel I/O interface between the process equipment and the transport equipment.

2.3 The application of the parallel I/O interface to the cassette transport is as follows.

2.4 Each piece of equipment is connected to the HOST at the SECS interface, and each of the two pieces of equipment between which the cassette transfer will be made is connected at the parallel I/O interface as shown in Figure 1.

2.5 The cassette transfer request, or load/unload command, is notified by the SECS-II message. The actual cassette transfer action is executed using the parallel I/O interface, interlocking each mechanism. (An example of a cassette transfer transaction using the parallel I/O interface is shown in Related Information 1.)

2.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

4 Terminology

4.1 *Definitions*

4.1.1 *active equipment* — Equipment that loads a cassette onto the cassette stage of another piece of equipment or unloads a cassette from the cassette stage of another piece of equipment.

4.1.2 *cassette* — A plastic or metal wafer carrier as defined in SEMI E1.

4.1.3 *cassette stage* — A stage on a piece of equipment on which a cassette is placed or from which it is removed that allows the cassette transfer.

4.1.4 *cassette transfer robot* — A robot that transfers cassettes (see Figure 2).

4.1.5 *load* — To place a cassette on the cassette stage of the equipment.

4.1.6 *passive equipment* — Equipment that is loaded or unloaded by the active equipment.

4.1.7 *photo-coupled interface* — A parallel I/O interface connected without contact by means of a photo-coupled device.

4.1.8 *process equipment* — Fabrication equipment, inspection equipment, and cassette stage equipment used in semiconductor manufacturing.

4.1.9 *robot vehicle* — A piece of equipment having a cassette transfer robot on the vehicle that moves to another piece of equipment and transfers cassettes (see Figure 2).

4.1.10 *transfer* — To either load or unload.

4.1.11 *transport equipment* — A piece of equipment (or system) which transports or transfers cassettes. It mainly consists of a transport vehicle, a robot vehicle, and a cassette transfer robot.

4.1.12 *transport vehicle (see Figure 2)* — A vehicle which transports cassettes but which has no mechanism for cassette transfer.

4.1.13 *unload* — To remove a cassette from the cassette stage of the equipment.

4.1.14 *wire-connected interface* — A parallel I/O interface connected by means of wire and a connector.

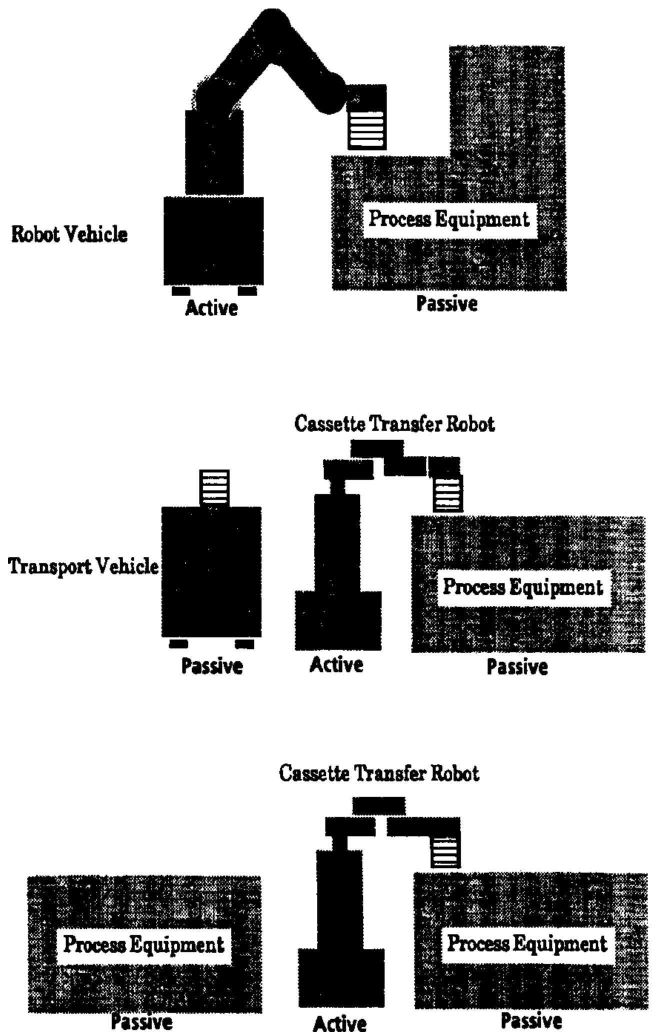

Figure 2
Cassette Transfer between Active Equipment and Passive Equipment

5 Parallel I/O Interface Specification

5.1 This standard refers only to the cassette transfer between active and passive equipment.

5.2 *Wire-Connected Parallel I/O Interface Specification* — The equipment is to have a parallel I/O interface for the passive mode when it becomes passive, and the parallel I/O interface for the active mode when it becomes active.

5.2.1 *Signals for Each Cassette Stage* — The cassette stage is to have the input/output signal lines listed in Table 1.

2 Japanese Industrial Standards, Available through the Japanese Standards Association, 1-24, Akasaka 4-Chome, Minato-ku, Tokyo 107-8440, Japan. Telephone: 81.3.3583.8005; Fax: 81.3.3586.2014 Website: www.jsa.or.jp

Table 1 Signals for Each Cassette Stage (Wire-Connected Interface)

Signal Type	*P/A*	*Description*
L_REQ (LOAD REQUEST)	P->A	This signal means that the CS can be loaded. The signal turns OFF when the cassette is detected on the CS. (The CS is a cassette stage.)
U_REQ (UNLOAD REQUEST)	P->A	This signal means that the CS can be unloaded. The signal turns OFF when it is detected that the cassette has been removed from the CS.
READY	P->A	This signal means that the CS is in a state where it can be accessed by the active equipment. It turns ON when the CS is in the READY state after the TR_REQ signal from the active turns ON. The signal turns OFF by handshakes with the COMPT signal.
TR_REQ (TRANSFER REQUEST)	A->P	This signal turns ON when the active equipment is going to start transferring the cassette. It turns OFF when the BUSY signal is OFF. (Active equipment starts transferring the cassette with the BUSY ON after recognizing the READY ON.)

5.2.2 *Common Signals* — The signals in Table 2 show the status of the cassette transfer action of the active equipment. The CS's are allowed to input these signals commonly from active equipment.

Table 2 Common Signals (Wire-Connected Interface)

Signal Type	*P/A*	*Description*
BUSY	A->P	This signal turns ON when the active equipment starts transferring the cassette to the CS while it is in READY and turns OFF after the robot has loaded or unloaded a cassette and has moved away from the interactive zone. The passive equipment does not perform any mechanical action in the interactive zone while this signal is ON.
COMPT (COMPLETE)	A->P	This signal means the active equipment has completed the transfer action. It turns OFF after handshaking with the READY signal.

It is recommended that the BUSY signal turn OFF after the active equipment has confirmed L_REQ (or U_REQ) is OFF.

5.2.3 *Cassette Transfer Sequence* — Time charts for the cassette transfer sequence are shown in Figures 3 (a) and (b).

5.2.3.1 The TR_REQ from the active equipment initiates the cassette transfer sequence. The active equipment starts carrying out the transfer action with the BUSY ON as soon as it recognizes that the READY signal of the passive equipment is ON. The handshake is finished after the cassette transfer action has been completed.

5.3 *Photo-Coupled Parallel I/O Interface Specification* — This interface is concerned only with the cassette transfer between the process equipment and the transport robot vehicle. The robot vehicle is active and the process equipment is passive.

5.3.1 This interface is defined between the robot and the cassette stages to which the robot can transfer a cassette at the same stopping position.

5.3.2 *Signals* — The signals for the photo-coupled parallel I/O interface are listed in Table 3. The CS_0, CS_1, and CS_2 signals specifying the CS to or from which the active equipment transfers and the VALID signal indicating effectiveness of the data of CS_0~ CS_2, are newly added to the signals defined in the wire-connected parallel I/O interface.

Table 3 Signals for the Photo-Coupled Parallel I/O Interface

Signal Type	*P/A*	*Description*
VALID	A->P	This signal remains high (ON) while the data of CS_0, CS_1, CS_2 is effective. (The data of CS_0, CS_1, CS_2 is not effective when VALID signal is OFF.)
CS_0 (LSB) CS_1 CS_2 (MSB)	A->P	The 3-bit signals specify the cassette stage number (0 ~ 7) of the passive equipment, to or from which the active equipment (robot vehicle) is going to transfer a cassette. They are set before the VALID signal turns ON. VALID and CS_0~ CS_2 signal.
TR_REQ	A->P	This is the same in the wire-connected parallel I/O specification and is valid for the specified CS.
L_REQ	P->A	This is the same in the wire-connected parallel I/O specification and is valid for the specified CS.
U_REQ	P->A	This is the same in the wire-connected parallel I/O specification and is valid for the specified CS.
READY	P->A	This is the same in the wire-connected parallel I/O specification and is valid for the specified CS.
BUSY	A->P	This is the same in the wire-connected parallel I/O specification.
COMPT	A->P	This is the same in the wire-connected parallel I/O specification.

5.3.3 *Cassette Transfer Sequence* — Time charts for the cassette transfer sequence in the case of the photo-coupled interface are shown in Figure 4 (a) and (b). After the active equipment (robot vehicle) reaches the process equipment, it sets the CS_0, CS_1, CS_2 3-bit-signals to specify the CS number of the passive equipment, to or from which the active equipment (robot vehicle) is going to transfer a cassette. Then the robot vehicle turns the VALID signal ON, which shows the date of the CS_0, CS_1, CS_2 signal is effective. After the cassette stage is specified, cassette transfer sequence is the same as in the wire-connected parallel I/O specification. TR_REQ, L_REQ,U_REQ, READY signals show the data for the specified CS while the VALID signal is ON, and the CS_0, CS_1, CS_2 signals are inhibited to change their data while the VALID signal is ON.

5.4 *Error Detection and Recovery* — The cassette transfer using this interface in the practical manufacturing lines will need handshake time interval control, cassette misalignment detection, and report of alarm or error to find an error or abnormal termination in the cassette transfer. An error recovery procedure with appropriate assist by human operators will be also required. This standard, however, does not define the specifications related to the error detection and recovery because of difference in process time, failure mode, and error recovery procedure of individual equipment and system.

5.4.1 The recommendation for basic error detection is that the active equipment should control handshake time intervals, and at least the interval time T between the beginning of the cassette transfer and the end of the transfer should be controlled — see the time chart of the cassette transfer sequence shown in Figures 3(a), 3(b), 4(a), and 4(b), describing the time chart of the cassette transfer sequence.

SEMI E24-92 (Reapproved 0699)
CLUSTER TOOL MODULE INTERFACE: ISOLATION VALVE INTERLOCKS STANDARD

This standard was technically reapproved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition reapproved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1992.

Minor editorial changes were made to this document to conform to editorial guidelines.

1 Introduction

1.1 *Scope* — This standard requires hardware interlocks that govern the opening and closing of the environmental isolation valve(s) at the interface planes of a cluster tool. This standard applies to all modules of a cluster tool (as defined in SEMI E21).

1.2 *Purpose* — The purpose of this standard is to prevent any opening or closing of the isolation valve(s) which would result in an unsafe condition or possible damage to material or equipment.

1.3 *Impact* — This standard requires cluster tool module suppliers to implement the interlock and to define the conditions that trip the interlock.

2 Referenced Documents

2.1 *SEMI Documents*

SEMI E21 — Cluster Tool Module Interface: Mechanical Interface and Wafer Transport Standard

2.2 *Other Documents*

MIL-C-26500E[1] — General Specification for Connectors — General Purpose, Electrical, Miniature, Circular, Environmental Resisting

3 Requirements

3.1 *Interlock Provision and Use* — Each module joined to another module, across a common interface plane (as defined in SEMI E21), must provide a fail-safe interlock that enables opening and closing of the isolation valve of the other mocule. Each module that has an isolation valve must use the interlock provided by the module it is joined to across their common interface plane.

3.2 *Interlock Trip* — Conditions that trip the interlock must be defined by the module supplier. (See Section R1-1.)

3.3 *Interlock Logic* — The interlock is to consist of two normally open relays and associated actuation circuitry in each module. (See Section R1-2.)

3.3.1 *First Relay* — One relay enables opening of the isolation valve of the attached module. Contact closure indicates a safe condition, enabling valve opening. Contact opening disables valve opening if the valve is closed. Contact opening does not cause the valve to close if the valve is open. (See Section R1-3.)

3.3.2 *Second Relay* — The other relay enables closure of the isolation valve of the attached module. Contact closure indicates a safe condition, enabling valve closure. Contact opening disables valve closure if the valve is open. Contact opening does not cause the valve to open if the valve is closed.

3.3.3 *Monitoring* — Situations can arise where the module A interlock inhibits an operation of the valve on module B, when that valve is already in the inhibited condition. This potential conflict must be detected and resolved within module B. (See Section R1-3.)

3.4 *Contact Rating* — The relay contacts shall be rated for a minimum of 1 A at 24 VDC.

3.5 *Wiring* — Copper wire used in the interlock circuit shall be 0.82 mm^2 cross section (18 AWG) or larger.

3.6 *Interlock Connectors* — Metal shell bayonet-type connectors are specified per MIL-C-26500E as follows: MS24265R18B11SN panel mounted receptacles on each of the modules and MS24266R18B11PN plugs terminating each end of the cable which interconnects the interlock receptacles of two connected modules.

3.7 *Interlock Connector Pinouts*

3.7.1 *Receptacle* — Pins 2 and 3 of the receptacle are connected across the contacts of the relay specified in Section 3.2.1. Pins 5 and 6 are connected to the circuit which enables opening of the module's isolation valve at that interface. Pins 7 and 8 are connected across the contacts of the relay specified in Section 3.2.2. Pins 9 and 10 are connected to the circuit which enables closure of the module's isolation valve at that interface.

---

[1] *Military Standards, Naval Publication and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120.*

3.7.2 *Cable and Plugs* — Pins 2 and 3 of each plug on the interlock cable are connected to pins 5 and 6 respectively of the other plug. Pins 7 and 8 of each plug on the interlock cable are connected to pins 9 and 10 respectively of the other plug. The resulting interlock cable is symmetric.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E24 but was reapproved for publication by full letter ballot procedures on February 28, 1999.

R1-1 Interlock Situations

R1-1.1 Examples are given below, for the different types of modules, of situations in which it might be considered hazardous for a connected module to operate its isolation valve. Note that some of these conditions prevent opening and others prevent closing of the valves. (See Section 3.1.). Module types are defined in SEMI E21. SEMI S2 provides guidance in defining potential safety hazards. It is common practice to detect valve positions and so verify operation, but this is not an interface matter.

R1-1.2 *Transport Module Examples* — The transport module end effector (see SEMI E22) is extended beyond the interface plane. The connected module should not close its isolation valve, as such an operation could damage the end effector.

R1-1.2.1 The transport module is not at an acceptable transfer pressure. Opening the isolation valve of the connected module could result in damage to the valve or wafer.

R1-1.3 *Process Module Examples* — The transport module end effector exclusion volume (see SEMI E22) is obstructed. The transport module should not open its isolation valve and attempt to extend its end effector.

R1-1.3.1 The process module is not at an acceptable transfer pressure. For instance, the module may be at atmospheric pressure for preventive maintenance. The transport module should not open its isolation valve.

R1-1.3.2 An unsafe partial pressure of a hazardous gas exists in the process module. The transport module should not attempt to open its isolation valve.

R1-1.4 *Cassette Module Example* — The cassette port (loading door) is open, indicating the possibility of a person's hand in the cassette module. The transport module should not operate its isolation valve to avoid the possibility of injury to personnel.

R1-2 Illustration of Logic

R1-2.1 The interlock logic is illustrated in Figure A1 and described in Section 3.2. In the figure, the contacts in module B are closed, enabling operation of the isolation valve controlled by module A, while one of the contacts in module A is open, preventing closure of the isolation valve controlled by module B.

R1-3 Interlock Example

R1-3.1 This example elucidates some of the interlock logic described in Section 3.2. In the case described here, the Transport Module (TM) end effector is extended into a Process Module (PM), which is equipped with an isolation valve. This valve is inhibited from closing by the interlock in the TM.

R1-3.2 A situation arises in the PM which results in its interlock inhibiting the opening of the isolation valve (which is already open) on the TM. As specified in Section 3.2.3, the TM detects the interlock change and immediately withdraws its end effector from the PM. The TM interlock enables the closure of the PM isolation valve (which the PM may do if that is the appropriate response to the situation) and the TM can close its isolation valve.

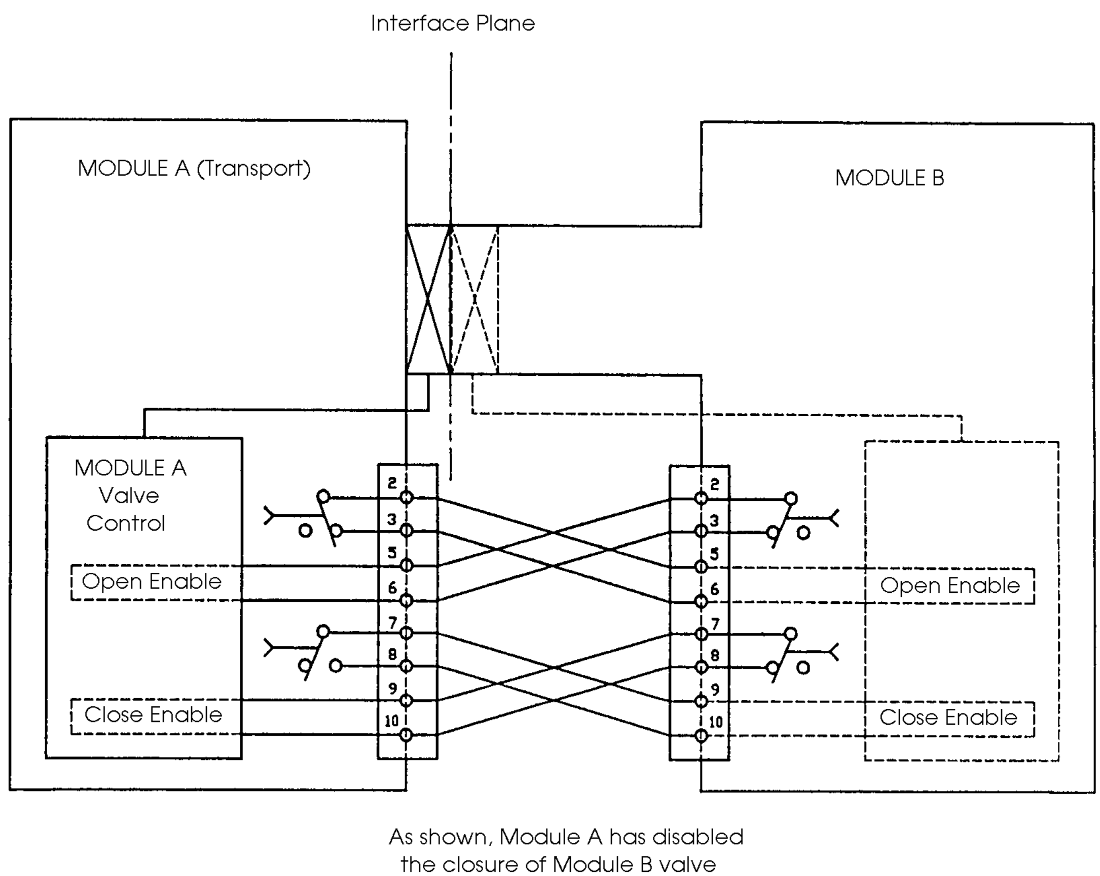

Figure R1-1

Illustration of Isolation Valve Interlock Standard

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

SEMI E25-92 (Reapproved 0699) CLUSTER TOOL MODULE INTERFACE: MODULE ACCESS GUIDELINE

This guideline was technically reapproved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition reapproved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1992.

Minor editorial changes were made to this document to conform to editorial guidelines.

1 Introduction

1.1 *Scope* — This guideline specifies an envelope within which a cluster tool module is situated. Entry and exit locations through the envelope and connection locations to the module for utilities and facility services are recommended.

1.2 *Purpose* — The purpose of the cluster tool module access guideline is to provide assistance in the placement of utilities and facility services to cluster tool modules in order to improve access for maintenance and service and to simplify cluster tool installation.

1.3 *Impact* — This guideline recommends that equipment designs limit the placement of utility lines and facility services to specific portions of the module envelope.

1.4 *Exceptions* — Local safety regulations must always take precedence over this guideline. Local conditions may justify exceptions to this guideline.

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

3 Module Envelope

3.1 For the purpose of this guideline, the module envelope is taken to be a set of six surfaces that completely encloses a module. Individual module envelopes may contact but not penetrate adjacent module envelopes. The six surfaces are the inboard and outboard planes, the two sides, the bottom and the top.

3.2 The inboard plane is the interface plane between a transport module and any other module as defined in SEMI E21; thus, a transport module possesses multiple inboard planes. The outboard surface is parallel to the interface plane and normally coincides with that part of the module which is farthest from the interface plane. Each side of the module envelope consists of several vertical planes. The bottom surface generally coincides with the floor, and the top is a horizontal plane that contains the highest point of the module.

3.3 In the sections that follow, the distinction between the physical module and the space reserved for the module within the envelope must be kept in mind. Section 4 refers to where utility lines penetrate the envelope, and Section 5 refers to constraints on where these lines connect to the physical module.

4 Allocation of Module Envelope Surfaces

4.1 The allocation of surfaces is subject to the need for access to the interface plane, module movement, maintenance access space, and protection of module components (particularly electrical components) from liquid leaks.

4.2 *Inboard Plane* — To allow access to the isolation valve(s), no utilities or facility services should be routed through the inboard surface close to the valve boundary. (See SEMI E21) The inboard surface is preferred for intra-tool communications, EMO (see SEMI E20) and the interlock interface between the transport module and the attached modules. (See SEMI E24.)

4.3 *Outboard Plane* — The outboard surface should be limited to non-rigid lines. To minimize potential mechanical damage, chemical utilities should not enter through the lower half of this surface.

4.4 *Sides* — In order to facilitate maintenance access, utilities and facility services should not penetrate the module envelope sides.

4.5 *Top Surface* — The top surface is preferred for power, exhaust, process gases and make-up air. Communications and electronic control harnesses could also enter through this surface.

4.6 *Bottom Surface* — The bottom surface is preferred for vacuum lines and all liquid supplies, returns and drains. The location of all lines should not restrict the removal of the module.

5 Module Considerations

5.1 The locations of utility and facility lines and connections to the module, which is located within the module envelope, are given below.

5.2 *Exhaust, Vacuum and Make-up Air* — The size of piping for exhaust, vacuum and make-up air suggests that the module sides are undesirable locations for connections.

5.3 *Maintenance Access* — Utility and facility lines and connections to the module sides should not compromise maintenance access to the module. Connections should be located above or below areas requiring periodic maintenance access.

5.4 *Liquids* — Liquid supply connections to the module sides should be as low as practical.

5.5 *Electrical Components* — Electrical components that need to be accessible for maintenance while energized should not be located at the sides of the module. (See SEMI S2.)

5.6 *Remote Equipment* — For ease of maintenance access, some pieces of equipment (for example, coolant chiller and RF power supplies) may be located outside the module envelope. In such cases, the lines and connections between the remote equipment and the module should follow this guideline.

6 Examples

6.1 The relationship between the location of specific utility and facility lines entering the module envelope and their subsequent routing and connection to the module within the module envelope is illustrated by the following examples.

6.2 *Liquid Connections* — Two suggested methods of providing liquid connections are shown in Figures 1 and 2. The liquid lines enter through the bottom of the module envelope (see Section 4.5) then connect to either the side of the module or the bottom of the module (see Section 5.3).

6.3 *Gas Connections* — Two suggested methods of providing gas connections are shown in Figure 2. The gas lines pass through the top of the module envelope (see Section 4.4), and then connect to the module either at the top or at the side.

6.4 *Exhaust and/or Make-Up Air* — Two suggested methods of providing exhaust and/or make-up air connections are shown in Figure 2. The exhaust line passes through the top of the module envelope (see Section 4.4) and then connects to the module at or near the top. Exhaust and make-up air connections are flanged in Figure 2.

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of an invention covered by patent rights. By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. In particular, users of the specification should be aware that Drytek, Inc., A Unit of General Signal, 16 Jonspin Road, Wilmington, MA 01887-1087, Phone: (508) 657-3933, has neither claimed nor disclaimed that compliance with this specification would require use of an invention covered by one or more of its patents. Users of this standard are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

SEMI E26-92 (Reapproved 0699)
RADIAL CLUSTER TOOL FOOTPRINT STANDARD

This standard was technically reapproved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition reapproved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1992.

Minor editorial changes were made to this document to conform to editorial guidelines.

1 Introduction

1.1 *Scope* — The standard specifies the footprints within which the modules of a radial cluster tool must be accommodated and the restricted areas between such footprints. The standard also applies to those portions of nonradial cluster tools that possess radial elements. The standard is limited to wafers 200 mm (8 in.) in diameter or smaller.

1.2 *Purpose* — The purpose of the standard is to ensure that modules from different suppliers can be integrated into a radial cluster tool. It provides design specifications to equipment manufacturers so that physical interference between adjacent modules in a radial cluster tool is avoided and access to all modules of the cluster tool is guaranteed.

1.3 *Impact* — The standard requires equipment designers to ensure that modules attached to a transport module be confined within a specific footprint and its vertical boundaries.

SEMI E21 — Cluster Tool Module Interface: Mechanical Interface and Wafer Transport Standard

SEMI E22 — Cluster Tool Module Interface: Transport Module End Effector Exclusion Volume Standard

SEMI E25 — Cluster Tool Module Interface: Module Access Guideline

3 Definitions

3.1 *radial cluster tool* — A cluster tool (as defined in SEMI E21) in which all wafer transport axes (as defined in SEMI E22) intersect at a common point within the transport module (as defined in SEMI E21).

4 Requirements

4.1 *Module Footprint Description* — The footprint within which modules (as defined in SEMI E21) attached to the transport module must be accommodated is illustrated in Figure 1. The variables are given in Table 1 and defined in Table 2 (see Sections R1-1 through R1-6).

4.2 *Restricted Areas* — Modules shall not intrude upon the shaded region between adjoining module footprints in Figure 1 (see Section R1-7). Furthermore, utilities are restricted from entering the module through the vertical planes bordering the module footprint (see SEMI E25).

4.3 *Restriction on Alpha* — The values of alpha (see Table 1) are restricted to $36° \leq \alpha \leq 90°$ (see Section R1-8).

4.4 *Module Connect and Disconnect* — Space for module connect to and disconnect from the transport module and for any related tools must be provided by the module manufacturer within the boundaries of the module footprint and the adjacent restricted areas. Access from any other module footprint, including that of the transport module, is not allowed (see Section R1-9).

LIST OF TABLES AND FIGURES

Table 1 Modular Footprint Variables

L	Transport module side length
α (alpha)	Angle subtended by a side of the transport module at the common point (see Section 3.1)
a_α	Half-minimum separation of adjacent module footprints
A_R	Half-width of reach area within the restricted area
A_M	Half-width of maintenance access area within the restricted area
W1	Module footprint primary width
W2	Module footprint secondary width
X1	Minimum distance to the interface plane for the module footprint primary width
X2	Maximum distance to the interface plane for the module footprint primary width
X3	Minimum distance to the interface plane for the module footprint secondary width
X4	Maximum distance to the interface plane for the module footprint secondary width

Table 2 Definition of Module Footprint Variables (Units are in mm)

$$L \geq 420.0$$

$$A_R = \frac{1}{2}\left[720.0 + (L - 420.0)\times \sin\left(90 - \frac{\alpha}{2}\right)\right] \quad \text{or} \quad 360.0 + \left(\frac{L}{2} - 210.0\right)\cos\frac{\alpha}{2}$$

$$A_M = A_R + \frac{195.0}{2} \quad \text{or} \quad 457.5 + \left(\frac{L}{2} - 210.0\right)\cos\frac{\alpha}{2}$$

$$a_\alpha = \frac{1}{2}(L - 400.0)\times \sin\left(90 - \frac{\alpha}{2}\right) \quad \text{or} \quad \left(\frac{L}{2} - 200.0\right)\cos\frac{\alpha}{2}$$

$$W1 = 2\times 320.0\times \cos\left(90 - \frac{\alpha}{2}\right) + 400.0 \quad \text{or} \quad 640.0\sin\frac{\alpha}{2} + 400.0$$

$$W2 = 2\times 270.0\times \cos\left(90 - \frac{\alpha}{2}\right) + W1 \quad \text{or} \quad 1180.0\sin\frac{\alpha}{2} + 400.0$$

$$X1 = 320.0\times \sin\left(90 - \frac{\alpha}{2}\right) \quad \text{or} \quad 320.0\cos\frac{\alpha}{2}$$

$$X2 = \left(\frac{720.0}{2} - a_\alpha\right)\times \sec\left(90 - \frac{\alpha}{2}\right) + X1 \quad \text{or} \quad 360.0\,\mathrm{cosec}\frac{\alpha}{2} - \left(\frac{L}{2} - 200.0\right)\cot\frac{\alpha}{2} + 590.0\cos\frac{\alpha}{2}$$

$$X3 = \frac{1}{2}(W2 - W1)\times \tan\left(90 - \frac{\alpha}{2}\right) + X2 \quad \text{or} \quad 360.0\,\mathrm{cosec}\frac{\alpha}{2} - \left(\frac{L}{2} - 200.0\right)\cot\frac{\alpha}{2} + 590.0\cos\frac{\alpha}{2}$$

$$X4 = \frac{1}{2}(915.0 - 720.0)\times \sec\left(90 - \frac{\alpha}{2}\right) + X5 \quad \text{or} \quad 457.5\,\mathrm{cosec}\frac{\alpha}{2} - \left(\frac{L}{2} - 200.0\right)\cot\frac{\alpha}{2} + 590.0\cos\frac{\alpha}{2}$$

Radial Cluster Tool Module Footprint

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E26 but was reapproved for publication by full letter ballot procedures on February 28, 1999.

R1-1 Alpha Values

R1-1.1 A transport module in the shape of an N-sided regular polygon possesses an alpha value of 360/N (see Section 4.1 and Figure 1).

R1-2 Transport Module Side Length

R1-2.1 The specified transport module side length (L) of 420 mm (16.54 in.) given in Table 2 is a minimum value that will ensure clearance at the interface plane valve (see SEMI E21), assuming a 340 mm (13.39 in.) flange width at the interface plane plus additional clearance for side-mounted clamps. The side length is specified as a minimum value since a single transport module could have various side lengths and/or alpha values. Longer side lengths may ease access to the transport module, but will have the negative impact of increasing the transport module handler extension, which is the distance from the common point (in Figure 1) to the wafer transport position (defined in SEMI E22). For a radial cluster tool with the transport module handler having the "home" position at the common point, the maximum extension in millimeters is related to the side length, alpha, and the transport maximum reach, which is specified as 305 mm (12 in.) in SEMI E21 by:

$$\left(\frac{L}{2}\right) \times \tan\left(90 - \frac{\alpha}{2}\right) + 305$$

R1-3 Evaluation of Footprint Shapes

R1-3.1 Access (see Section 4.1) for a variety of purposes is severely restricted in a radial cluster tool, because all modules converge toward one areR1-Achieving access to clamps at the interface plane and to the module (usually a process module) in proximity to the interface plane is especially difficult. Thus, several footprint shapes were modelled: A radial architecture comprising an N-sided regular polygon transport module with L = 420 mm (see Table 2 and Section R1-2) was used, and the dimensional effects on the module footprint were investigated for $4 \leq N \leq 10$. Anatomical data was used to evaluate access to various parts of the radial cluster tool. The configuration chosen provides a short, fat footprint. It allows maximum freedom for the module designer and accommodates modules near the interface plane without forcing the design of additional wafer transport mechanisms. Guidance in setting W1 and W2 values (see Figure 1) was provided by the need for a single wafer sputter module to be placed directly on an N = 8 regular polygon transport module and a batch processing module with an intermediate "buffer" station on the same transport module.

R1-4 Module Width at Interface Plane

R1-4.1 Although L can be longer than 420 mm (16.54 in.), the module attached to the transport module cannot possess a width greater than 400 mm (15.75 in.) at the interface plane in order to be interchangeable among all transport module interfaces (see Figure 1).

R1-5 Flexibility for Module Suppliers

R1-5.1 Module footprint dimensions (calculated from the expressions in Table 2) and transport module handler extensions (calculated from the expression in Section R1-2) for L = 420 mm and for selected values of alpha are given in Table A1 to provide guidance for weighing design targets. Alpha values corresponding to values of N for an N-sided regular polygon transport module are noted.

R1-5.2 Modules designed for an N = 8 (α = 45º) transport module will fit on any transport module with $N \leq 8$ ($\alpha \leq 45$º), providing for greater flexibility, but possessing a more restrictive footprint, than a module designed for an N = 6 (α = 60º) transport module.

R1-6 Nonradial Cluster Tool Applicability

R1-6.1 An example of a nonradial transport module is shown in Figure R1-1. Sides 1, 3, 4, and 5 of the transport module are equivalent to a radial cluster tool. The standard applies to these four sides (see Section 4.1).

R1-7 Restricted Areas

R1-7.1 Access (see Section 4.2) for maintenance activities that involve the lifting of heavy components or crouching, requires a minimum separation of 2 AM = 915 mm (36 in.) between integrated module hardware (see Table 2). When a width of 915 mm (36 in.) for the entire restricted area was used in the model (see Section R1-3), it became apparent that footprints would comprise narrow corridors. This would force the design of buffer chambers and additional wafer handling mechanisms for many applications. For practical purposes, the concept of a smaller reach area (the hatched region in Figure R1-2), where the module should be detached from the transport module for heavy lifting or crouching tasks, was considered acceptable.

R1-7.2 *Dependence on L* — A transport module side length (L) greater than the minimum value of 420.0 mm will result in a larger restricted area by increasing the half widths A_M, A_R, and a_α beyond their respective minimum values of 457.5 mm, 360.0 mm, and 10×cos[α/2] mm (see Table 2).

R1-7.3 *Restricted Area Temporary Residence* — Equipment such as roll-out drawers or swing-out equipment may temporarily reside in the restricted area (see Section 4.2).

R1-8 Restriction on Alpha

R1-8.1 The maximum value of alpha was based on an N = 4 (α = 90º) regular polygon transport module design (see Section 4.3).

R1-8.2 In order for a module manufacturer to adequately design for access, some knowledge of the adjacent modules must be available. This can be done by setting a minimum value for alpha, which then defines the adjacent footprint leading to the most stringent "half" access area. For the purposes of the standard, the minimum value of alpha was based on an N = 10 (α = 36º) regular polygon transport module (see Figure R1-2).

R1-9 Module Connect and Disconnect

R1-9.1 The number of components and the degree of complexity at the interfaces of a radial cluster tool are high. To ensure non-interference between modules, the concept of an impenetrable wall at the interface plane and adjacent module footprints should be used. Within this area, requirements for module connect and disconnect are the responsibility of the module manufacturer (see Section 4.4).

Table R1-1 Module Footprint Dimensions and Transport Module Handler Extensions*

α(degrees)	a_α*(mm)*	*W1(mm)*	*W2(mm)*	*X1(mm)*	*X2(mm)*	*X3(mm)*	*X4(mm)*	*TMHE**(mm)*

SEMI E26.1-92 (Reapproved 0699)
RADIAL CLUSTER TOOL FOOTPRINT 300 mm STANDARD

This standard was technically reapproved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition reapproved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1992.

Minor editorial changes were made to this document to conform to editorial guidelines.

1 Introduction

1.1 The standard provides the requirements to extend the limits of applicability of SEMI E26 from 200 mm diameter wafers or smaller to 300 mm diameter wafers or smaller.

2 Referenced Documents

2.1 *SEMI Documents*

SEMI E26 — Radial Cluster Tool Footprint Standard

3 Requirements

3.1 *Fixed Dimensions* — Two of the fixed dimensions given in SEMI E26 are changed (see Section R1-1): The fixed distance along the interface plane is increased from 400.0 mm (15.75 in.) to 500.0 mm (19.69 in.) and the slant distance separating X2 and X3 (see Section R1-2) is increased from 270.0 mm (10.63 in.) to 420.0 mm (16.54 in.).

3.2 *Variables* — The variables given in SEMI E26 are restated in Table 1 to reflect the increase in fixed dimensions (see Sections 3.1 and R1-3).

3.3 *Restriction on Alpha* — The values of alpha are restricted to 45° ≤ α ≤ 90° (see Section R1-4).

Table 1 Definitions of Module Footprint 300 mm Variable (Units are in mm)

$$L \geq 520.0$$

$$a_\alpha = \left(\frac{L}{2} - 250.0\right)\cos\frac{\alpha}{2}$$

$$A_R = 360.0 + \left(\frac{L}{2} - 260.0\right)\cos\frac{\alpha}{2}$$

$$A_M = 457.5 + \left(\frac{L}{2} - 260.0\right)\cos\frac{\alpha}{2}$$

$$W1 = 640.0\sin\frac{\alpha}{2} + 500.0$$

$$W2 = 1480.0\sin\frac{\alpha}{2} + 500.0$$

$$X1 = 320.0\cos\frac{\alpha}{2}$$

$$X2 = 360.0\cos ec\frac{\alpha}{2} - \left(\frac{L}{2} - 250.0\right)\cot\frac{\alpha}{2} + 320.0\cos\frac{\alpha}{2}$$

$$X3 = 360.0\cos ec\frac{\alpha}{2} - \left(\frac{L}{2} - 250.0\right)\cot\frac{\alpha}{2} + 740.0\cos\frac{\alpha}{2}$$

$$X4 = 457.5\cos ec\frac{\alpha}{2} - \left(\frac{L}{2} - 250.0\right)\cot\frac{\alpha}{2} + 740.0\cos\frac{\alpha}{2}$$

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E26.1 but was reapproved for publication by full letter ballot procedures on February 28, 1999.

R1-1 Interface Plane Reach Dimension

R1-1.1 The 320.0 mm slant distance adjacent to the interface plane (see Figure 1 in SEMI E26) accommodates the reach of the human arm and therefore applies to the 200 mm standard and to the 300 mm standard (see Section 3.1).

R1-2 Large Modules

R1-2.1 Large modules such as batch process modules can be accommodated in the region of the module footprint defined by the width W2 (see Figure 1 in SEMI E26). An increase in the slant distance between X2 and X3 from 270.0 mm to 420.0 mm leads to an increase in W2 sufficient to accommodate most large modules (see Section 3.1).

R1-3 Selected Design Data

R1-3.1 The transport module handler extension is the distance from the common point (see SEMI E26) to the wafer transport position (defined in SEMI E22, "Cluster Tool Module Interface: Transport Module End Effector Exclusion Volume Standard"). The maximum extension in millimeters is related to L, alpha, and the transport maximum reach (specified as 380.0 mm in SEMI E21.1, "Cluster Tool Module Interface 300 mm: Mechanical Interface and Wafer Transport Standard") by:

$$\frac{L}{2} \times \cot \frac{\alpha}{2} + 380.0$$

R1-3.2 Transport module handler extensions and module footprint dimensions (calculated from the expressions in Table 1) for selected values of alpha are given in Table R1-1. Alpha values corresponding to values of N for an N-sided regular polygon transport module are noted (see Section 3.2).

R1-4 Restriction on Alpha

R1-4.1 If $\alpha < 45^\circ$ ($N > 8$ for an N-sided regular polygon transport module), process modules must be reduced in size or located further from the interface plane than would be the case for $45^\circ \leq \alpha \leq 90^\circ$.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E27-92 (Reapproved 0299)
STANDARD FOR MASS FLOW CONTROLLER AND MASS FLOW METER LINEARITY

This standard was technically reapproved by the Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1992.

1 Purpose

The purpose of this standard is to establish a uniform, worldwide definition of linearity in order to prevent confusion and misunderstanding between manufacturers and users of mass flow devices. A linearity specification is used to allow prediction to a known level of uncertainty, the output of an MFC at points other than those at which its output is known.

2 Scope

The scope is to define the linearity of the mass flow controller (controller with integral flow transducer and control valve) and the mass flow meter (flow transducer only). Terminal-based linearity is used to describe the linearity of MFCs and MFMs.

3 Background

There are three commonly-used methods of describing linearity: independent, zero-referenced, and terminal-based linearity. Terminal-based linearity best describes the performance requirements for MFCs and MFMs because of its ease of application. In addition, it also yields the maximum expression of deviation. See reference documents regarding independent and zero-referenced linearity.

4 Referenced Documents

4.1 *International Electrotechnical Commission (IEC) Standard*[1]

TC-65 — Industrial Process Measurement and Control Terms and Definitions

4.2 *Instrument Society of America (ISA) Standard*[2]

S51.1 — Process Instrumentation Terminology

5 Definitions (See Figures 1 and 2)

5.1 *Actual Flow* — The gas flow as measured by an external standard, not the electrical output of a mass flow meter. (See Section 4.2.)

5.2 *Linearity* — The closeness to which a curve approximates a straight line. It is measured as a non-linearity and expressed as a linearity. (See Section 4.2.)

5.3 *Range* — The region between the limits within which a quantity is measured, expressed by stating the lower and upper range values. (See Section 4.2.)

5.4 *Span* — The algebraic difference between the upper and lower range values.

e.g.,

Range = 4% to 100%, Span = 96%

Range = 0% to 100%, Span = 100%

5.5 *Lower Range Input Value* — Lowest value of input at which the instrument is specified to operate. In mass flow controllers this is zero or the lowest set point at which the instrument is specified. In mass flow meters this is no flow or the lowest actual flow value at which the instrument is specified.

5.6 *Upper Range Input Value* — Highest value of input at which the instrument is specified to operate. In mass flow controllers this is full scale or the highest set point at which the instrument is specified. In mass flow meters this is full scale or the highest actual flow value at which the instrument is specified.

5.7 *Terminal-Based Linearity* — Maximum deviation of the calibration curve from a straight line which intercepts the calibration curve at upper and lower input range values.

6 Significance and Use

6.1 The linearity of a mass flow controller (MFC) is expressed in terms of its actual flow output as a function of the setpoint input (control voltage). (See Figure 2.)

6.2 The linearity of a mass flow meter (MFM) is expressed in terms of its electrical output as a function

1 International Electrotechnical Commission, 3 rue de Varembe, CH-1211 Geneva 20, Switzerland

2 Instrument Society of America, 67 Alexander Drive, P.O. Box 12277, Research Triangle Park, NC 27709

of the actual flow (input) through the device. (See Figure 1.)

6.3 Terminal-based linearity shall be used to describe the linearity of MFCs and MFMs. The maximum deviation is expressed as a percentage of the algebraic difference between the output at the upper range value and the output at the lower range value.

$$\text{Linearity} = \pm \frac{d_{MAX}}{O_U - O_L} \times 100$$

where O_U = output at the upper range value

O_L = output at the lower range value

d_{MAX} = maximum deviation

6.3.1 Terminal-based linearity may be expressed as a percentage of some other value (such as a percentage of reading) if it is so identified.

6.3.2 If results are reported using range values other than zero and full scale, the actual range values used in the calculation shall be reported.

SEMI E28-92 (Reapproved 0299)
GUIDELINE FOR PRESSURE SPECIFICATIONS OF THE MASS FLOW CONTROLLER

This guideline was technically reapproved by the Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1992.

1 Purpose

The purpose of this guideline is to establish a uniform, worldwide means to describe pressure parameters as they relate to mass flow controllers. It is intended to prevent confusion and misunderstanding between manufacturers and users.

2 Scope

This guideline contains definitions of terms which describe gas pressure in mass flow controllers as used in the semiconductor industry. SI units are the reference units for this document.

3 Applicable Documents

3.1 *SEMI Standard*

SEMI E12 — Standard for Standard Pressure and Standard Temperature for Flow Units Used in Mass Flow Meters and Mass Flow Controllers

4 Definition of Terms

4.1 *units of pressure* — Several units of pressure are commonly used in conjunction with MFC's. The Pascal is the preferred unit of pressure for use within the semiconductor industry. Units of pressure include the following:

— Pascal (Pa)
— Pounds per square inch (psi)
— Torr (T)
— Kilograms per square centimeter (kg/cm^2)
— Bar (B)

NOTE: Units of pressure are sometimes expressed as an equivalent height of a column of some liquid, such as millimeters of mercury or inches of water. These units require correction to some standard for liquid density and gravity. As these corrections are neither broadly standardized nor often even addressed, their use should be avoided.

4.2 *absolute pressure* — The pressure measured relative to zero pressure (perfect vacuum). (See Figure 1.)

NOTE: Absolute pressure is the pressure illustrated by the ideal gas law, PV = nRT. For example, when the number of moles, n, equals zero (no molecules), absolute pressure, P, equals zero. To indicate unambiguously that a pressure measurement is absolute, the following abbreviations should be used:

Pa — Pascal (absolute assumed)
psi (a) — Pounds per square inch, absolute
Torr — Torr (absolute assumed)
kg/cm^2(a) — Kilograms per square centimeter, absolute
B (a) — Bar, absolute

Units such as Pascal and Torr are customarily absolute units.

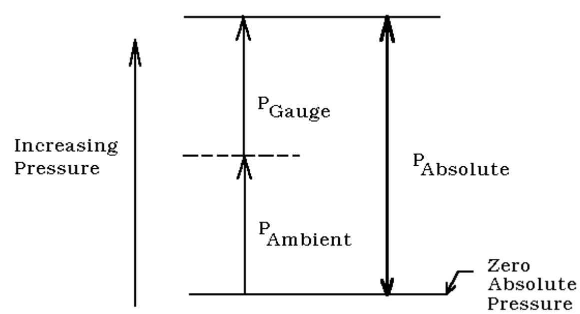

Figure 1
Relationship Between Absolute, Gauge, and Ambient Pressure

4.3 *differential pressure* — The difference in absolute pressure between two points of measurement in a system. (See Figure 2.)

NOTE — To indicate unambiguously that a pressure measurement is differential, the following abbreviations should be used:

Pa (d) — Pascal, differential
psi (d) — Pounds per square inch, differential
Torr (d) — Torr, differential
kg/cm^2(d) — Kilograms per square centimeter, differential
B (d) — Bar, differential

4.3.1 Gauge pressures may also be used in the differential pressure calculation if consistency is maintained. A common error would be to take the difference between an inlet gauge pressure and an outlet absolute pressure without first converting to common units.

4.3.2 As it applies to an MFC, differential pressure is usually the measured difference in pressures between the gas inlet and outlet fittings of the MFC.

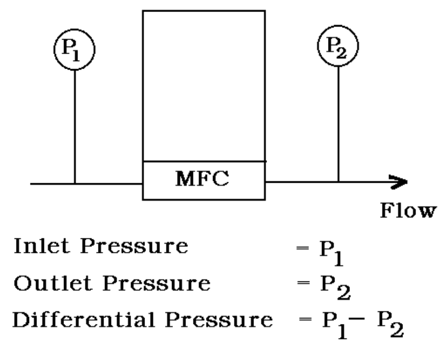

Figure 2
Definition of Differential Pressure for MFCs

4.4 *ambient pressure* — The absolute pressure of the medium surrounding the MFC. (See Figure 3.)

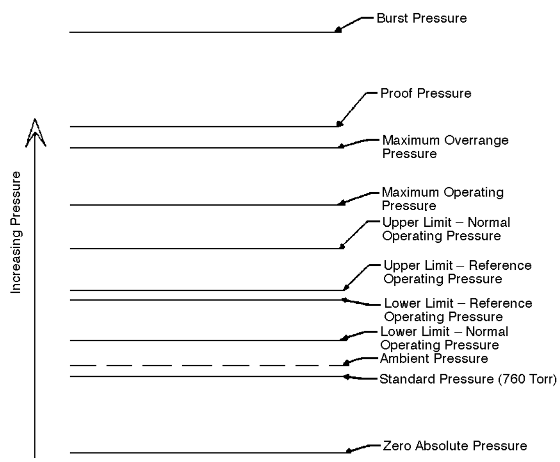

Figure 3
Pressure Definitions for MFCs

4.5 *reference ambient* — The composition and pressure range of the ambient medium surrounding the MFC within which performance specifications apply without requiring correction for changes in the ambient medium.

4.6 *gauge pressure* — The differential pressure measured relative to ambient pressure. For example, when the pressure within a system equals the prevailing ambient pressure, the gauge pressure equals zero. (See Figure 1.)

NOTE — To indicate unambiguously that a pressure measurement is gauge, the following abbreviations should be used:

Pa (g) — Pascal, gauge

psi (g) — Pounds per square inch, gauge

Torr (g) — Torr, gauge

kg/cm^2 — Kilograms per square centimeter, gauge

B (g) — Bar, gauge

NOTE : The performance of MFCs can vary significantly with gas density. Atmospheric pressure varies with the weather and altitude at various geographical locations. Gauge pressure units commonly reference atmospheric pressure. Therefore, the same gauge pressures measured at different geographical locations may correspond to different gas densities. For this reason, the use of gauge pressure units with MFCs can be imprecise and should be avoided.

4.7 *inlet pressure* — The pressure at the inlet fitting of the MFC. (See Figure 2.)

4.8 *outlet pressure* — The pressure at the outlet fitting of the MFC. (See Figure 2.)

NOTE: To completely specify the pressure operating environment for MFCs, at least two of the following three pressures must be listed: inlet, outlet, and differential.

4.9 *MFC calibration pressure, inlet and outlet* — The inlet and outlet pressure at which the MFC was calibrated. (See Figure 3.)

4.10 *reference operating pressure, inlet and outlet* — The range of gas pressures on the inlet of the MFC and across the MFC within which performance specifications apply without requiring correction for gas pressure effects. (See Figure 3.)

4.11 *normal operating pressure, inlet and outlet* — The pressure range within which the MFC meets its stated performance specifications. (See Figure 3.)

4.12 *normal operating differential pressure* — The range of differential pressure (see Section 4.3) required by the MFC to meet its stated performance specifications.

NOTE: The upper and lower limits are dependent upon the absolute inlet or outlet pressure. These limits are manufacturer-specific.

4.13 *maximum operating pressure* — Operation is permitted up to this inlet pressure, but performance is not specified above normal operating pressure. (See Figure 3.)

4.14 *maximum overrange pressure* — The maximum gas pressure to which the MFC may be subjected without degrading specified performance. When returned to normal operating pressure, the MFC must require no adjustment to return to specified performance. (See Figure 3.)

4.15 *proof pressure* — The maximum gas pressure the MFC may be subjected to without permanent damage. Some adjustment may be necessary to make it meet its specified performance when returning to normal operating pressure. (See Figure 3.)

4.16 *burst pressure* — The gas pressure at which the MFC may rupture.

4.17 *standard pressure* — SEMI E12 defines standard pressure as 760 Torr (101.32 kPa). (See Figure 3.)

5 Gas Pressure Effects

5.1 *Specified Gas* — Gas pressure effects may be gas species sensitive. The gas must be specified when stating gas pressure effects. Nitrogen is recommended as the standard gas.

5.2 *Pressure Measurement Point* — In this section, pressure is assumed to be measured at the fitting of the MFC, inlet or outlet, that is adjacent to the flow transducer.

5.3 *Total Calibration Effect* — The change in output, including zero and span, due to a change in gas pressure from one normal operating pressure to a second normal operating pressure. All other conditions must be held within the limits of reference operating conditions.

5.4 *Zero Calibration Effect* — The change in zero due to a change in gas pressure from one normal operating pressure to a second normal operating pressure. All other conditions must be held within the limits of reference operating conditions. (See Figure 4)

5.4.1 The effect of gas pressure change on zero may be expressed as a coefficient calculated as the ratio of full-scale percent change in output to the corresponding change in gas pressure. The change in gas pressure should be specified. This coefficient is defined as the "pressure coefficient of zero."

EXAMPLE — Pressure coefficient of zero may be expressed as:

$$\frac{0.2\% \text{ of full scale}}{240 \text{ kPa} - 220 \text{ kPa}} = 0.01\% \text{ of full scale/kPa with } N_2$$

NOTE: If the relation between gas pressure and change in output is linear, one coefficient will suffice.

5.4.2 If the gas pressure influence is non-linear, a different method of expression may be used. Two examples:

1) The percent of full-scale change in output will not exceed a specified value for any value of gas pressure within a specified gas pressure range.

EXAMPLE — "± 0.15% of full-scale maximum error over 200 kPa to 250 kPa with N_2"

2) It may be desirable to state a series of coefficients for successive increments of gas pressure within a specified gas pressure range.

5.5 *Span Calibration Effect* — The change in span due to a change in gas pressure from one normal operating pressure to a second normal operating pressure. All other conditions must be held within the limits of reference operating conditions. (See Figure 4.)

5.5.1 The effect of gas pressure change on span may be expressed as a coefficient calculated as the ratio of percent of reading change in output to the corresponding change in gas pressure. The change in gas pressure should be specified. This coefficient is defined as the "pressure coefficient of span."

EXAMPLE — Pressure coefficient of span may be expressed as:

$$\frac{0.1\% \text{ of reading}}{240 \text{ kPa} - 220 \text{ kPa}} = 0.005\% \text{ of reading/kPa with } N_2$$

NOTE: If the relation between gas pressure and change in output is linear, one coefficient will suffice.

5.5.2 If the gas pressure influence is non-linear, a different method of expression may be used. Two examples:

1) The percent of span change in output will not exceed a specified value for any value of gas pressure within a specified pressure range of a particular gas.

EXAMPLE — "± 0.1% of reading maximum error over 200 kPa to 250 kPa with Nitrogen"

2) It may be desirable to state a series of coefficients for successive increments of gas pressure within a specified pressure range.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. SEMI E29-93 (Reapproved 0299)
STANDARD TERMINOLOGY FOR THE CALIBRATION OF MASS FLOW CONTROLLERS AND MASS FLOW METERS

This standard was technically approved by the Global Faclities Committee and is the direct responsibility of the North American Facalities Committee. Current edition approved by the North American Regional Standards Committee on October 1998. Initially available at www.semi.org February 1999; to be published Febrauray 1999. Originally published 1993.

1 Purpose

This standard defines terms commonly used in the calibration of mass flow controllers (MFC) and mass flow meters (MFM). It is intended to provide for worldwide terminology to be used by manufacturers and users.

2 Scope

This standard defines terminology related to MFC/MFM calibration. At present, there are often several words used by the semiconductor industry to describe the same concept or device. This standard is intended to eliminate confusion and provide for a common language which users and manufacturers can employ to discuss MFC/MFM calibration.

3 Limitations

This standard attempts to provide basic definitions. In some instances, it may be impossible to provide definitions which thoroughly explain a concept. It is suggested, in such instances, that the user consult other sources or SEMI standards related to this topic.

4 Related Standards/Documents

SEMI E12 — Standard for Standard Pressure and Standard Temperature for Flow Units Used in Mass Flow Meters and Mass Flow Controllers

5 Referenced Documents

SEMI E18 — Guideline for Temperature Specifications of the Mass Flow Controller

SEMI E28 — Guideline for Pressure Specifications of the Mass Flow Controller

6 Terminology

6.1 *attitude* — For mass flow controllers and mass flow meters, the relationship between the base mounting plane of the MFC, the gas flow direction and the gravity vector. It may be stated as horizontal (base down), vertical (inlet up), vertical (inlet down), horizontal (upside down), or horizontal (either side down).

6.2 *calibration gas* — For mass flow controllers and mass flow meters, the gas which is flowed while the device is being calibrated.

6.3 *calibration temperature* — For mass flow controllers and mass flow meters, the ambient temperature at which the device is calibrated. (SEMI E18)

6.4 *mass flow controller (MFC)* — A self-contained device, consisting of a mass flow transducer, control valve, and control and signal-processing electronics, commonly used in the semiconductor industry to measure and regulate the mass flow of gas.

6.5 *mass flow meter (MFM)* — A self-contained device, consisting of a mass flow transducer and signal-processing electronics, commonly used in the semiconductor industry to measure the mass flow of gas.

6.6 *molar flow* — The number of moles per unit of time flowing in a closed channel.

6.7 *nameplate gas* — For mass flow controllers and mass flow meters, the gas, as labeled on the product, intended to be controlled or measured.

6.8 *primary flow standard* — A device or system which measures flow using a method based on some or all of the primary measurements of length, time, temperature, volume, pressure, or mass.

6.9 *process gas* — For mass flow controllers and mass flow meters, the principal gas which the user requires the device to control or measure.

6.10 *standard pressure* — The pressure in pascals specified as a reference for measurement and comparison. It is defined for use in the semiconductor industry as 101.32 kilo pascals (760 torr).

6.11 *standard temperature* — The temperature, in degrees Celsius, specified as a reference for measurement and comparison. It is defined for use in semiconductor industry as 0.0°C.

6.12 *standard volumetric flow* — For mass flow controllers and mass flow meters, the calculated volumetric flow, at standard temperature and pressure, of gas in a closed fluid channel. Volume at standard temperature and pressure assumes the ideal gas law, PV=nRT. Units of standard volumetric flow are commonly used to express mass flow in mass flow controllers and mass flow meters.

6.13 *surrogate gas* — For mass flow controllers and mass flow meters, a gas intended to simulate the calibration characteristics of another gas.

6.14 *transfer standard* — For mass flow controllers and mass flow meters, a device typically calibrated against a primary standard which can guarantee sufficient accuracy to, in turn, calibrate another device.

6.15 *warm-up time* — For mass flow controllers and mass flow meters, the time required, after going from an unpowered to a powered state, for the device to achieve sufficient electrical and thermal stability such that rated performance specifications can be met.

SEMI E31-93
SPECIFICATION FOR ELECTRICAL INTERFACE, JAPAN ONLY

NOTE: For U.S. electrical interface requirements, see SEMI E7.

1 Introduction

1.1 *Purpose* — The purpose of this standard is to ensure common electrical interfaces that fulfill the requirements of equipment suppliers and users in the Japan region and to ease the design and functionality of semiconductor equipment manufacturing facilities in the future.

1.2 *Scope* — This standard recommends electrical interfaces for selected power supplies as follows:

— Facilities-Systems Motors and electrical loads having various voltages, currents, and phases

— Electrical connectors

— Cords/cables

2 Referenced Documents

2.1 *JIS-C-8303* — Japanese Industrial Standard[1]

SEMI E33-94
SPECIFICATION FOR SEMICONDUCTOR MANUFACTURING FACILITY ELECTROMAGNETIC COMPATIBILITY

NOTICE: This standard does not purport to address safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to the use.

1 Introduction

1.1 *Purpose* — The purpose of this specification is to assure that semiconductor manufacturing facilities and the equipment used for manufacturing semiconductor devices will operate together reliably without failures caused by electromagnetic interference or electrostatic discharge. This goal is generally known as "electromagnetic compatibility" or EMC.

1.2 *Scope* — This specification applies to facilities and equipment constructed for the purpose of manufacturing semiconductor devices including all facilities alarm, safety, communications and control systems, processing equipment, metrology equipment, automation equipment, and information technology equipment.

1.3 *Limitations* — This specification does not apply to the equipment and facilities used for the assembly and functional testing of integrated circuits. This specification does not apply to process-specific charging that may occur to semiconductors under manufacture.

5 National Technical Information Service, U.S. Department of Commerce, Springfield, VA 22161.

3.4 *electrostatic discharge (ESD)* — The transfer of electrostatic charge between bodies at different electrostatic potentials.

3.5 *ELF* — Extremely low frequency (about 1 Hz to 1 kHz) magnetic fields generated by current flow (most commonly 60 Hz in the U.S. and 50 Hz in Europe) within equipment and facilities.

3.6 *ELF sensitive equipment* — Any equipment whose performance is adversely affected by ELF, such as a scanning electron microscope (SEM).

3.7 *EUT* — Equipment under test.

3.8 *port* — (For purposes of this specification), a particular interface of the specified equipment with the external electromagnetic environment, (see Figure 1).

3.9 *enclosure port* — (For purposes of this specification), the physical boundary of the apparatus through which electromagnetic fields may radiate or impinge.

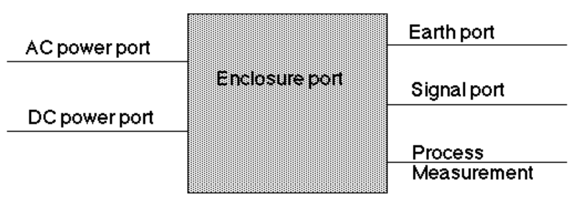

Figure 1

4 Requirements

4.1 *Performance Criteria* — The following are generic failure criteria for the various classes of equipment and electronic systems used in semiconductor manufacturing. However, any kind of failure or aberration during EMC testing shall be noted in the test report.

4.1.1 *Performance Criteria A* — The equipment operates as intended during and after the test. In the case of process equipment, all process results are within specifications. No safety hazards nor false alarms are present. In some cases, the performance level may be replaced by a documented permissible loss of performance if such loss is minor and agreeable to the concerned parties.

4.1.2 *Performance Criteria B* — The equipment operates as intended after the test, but experiences a loss of function or degradation of performance during the test to a level specified by the manufacturer. No change of operating state or loss of stored data is allowed. Restoration of performance or function does not require human intervention.

4.1.3 *Performance Criteria C* — Temporary loss of function is allowed, provided the loss of function is recoverable, either automatically or through operation of the controls. Any failure of control or alarm systems is in a fail-safe mode, such as a false alarm or equipment shutdown.

4.1.4 *Safety Criteria* — Equipment will automatically fail if testing results in an unsafe or potentially unsafe condition, such as threat to life or property. Examples would be failure of an emergency machine off (EMO) button to operate or faulty opening of a toxic gas valve.

4.1.5 *Conditions during Testing* — All EMC testing is to be done with the equipment installed and operational. As much as possible, the test installation should be identical to the final production installation. Substitutes may be used for hazardous gases and chemicals, and other modifications may be made as deemed reasonable to ensure testing can be performed in a completely safe and environmentally acceptable manner. Special EMC facilities are not required by this standard.

5 Test Methods

The tables below are organized by ports to which the tests apply, as defined above. The basic standards provide the test setup and procedures to be followed, except as noted. In all events, EMC testing is intended to prevent EMC problems when the equipment is installed and operating in a semiconductor manufacturing facility. Any modification or interpretation of the test setup and procedure should be judged by this overriding goal.

5.1 *Immunity Tests*

Table 1 Enclosure Ports

	Test Type	*Specification*	*Basic Standard*	*Remarks*	*Performance Criteria*
1.1	ESD immunity	4 kV Contact 8 kV Air discharge	IEC 801-2 (1991)	See Appendices A and B	A
1.2	Radiated immunity Amplitude modulated	10 V/m 450-520 MHz 800-950 mHz 80% AM (1 kHz)	IEC 801-3	See facilities requirements (See Section 5.1.1)	A
1.3	ELF immunity	Level A - E as required	ELF testing (See Section 5.1.2)	Required only of ELF-sensitive equipment	A
1.4	Radiated immunity Pulse modulated	3 V/m 1.89 GHz 50% Duty cycle 100 Hz rep freq.	TC 65 (Sec.) 136 Draft	Europe only Cellular phone band	A

5.1.1 *Facilities Requirements* — Due to the size and complexity of much semiconductor factory equipment, testing in a shielded enclosure, anechoic chamber, or other special facility is not required. If such facilities can be used, the results will be more reproducible and accurate.

Note that radiated immunity testing is required only at frequencies used for mobile communications. As shown in Table 1, Row 1.2. Testing should be conducted in conformance with national and local emission requirements at the frequencies specified (see Appendix D).

5.1.2 *ELF Testing* — The following sensitivity levels are defined:

Level A — ELF of less than 0.25 milliGauss rms
Level B — ELF of less than 0.50 milliGauss rms
Level C — ELF of less than 1.00 milliGauss rms
Level D — ELF of less than 2.00 milliGauss rms
Level E — ELF of 2.00 milliGauss rms and greater

ELF sensitivity is to be determined by applying ELF through a coil or set of coils designed to produce a uniform magnetic field at or near the power-line frequency at the position of maximum ELF sensitivity of the EUT. The direction of the applied field shall be set to produce the maximum disturbance to the EUT. The field level shall be determined using a calibrated ELF meter.

If allowable performance degradation is permitted at the higher ELF levels, the performance shall be specified at each level.

Table 2 Ports for Signal Lines and Short Distance (< 30 m) Data Buses Not Involved in Process Control

	Test Type	*Specification*	*Basic Standard*	*Remarks*	*Performance Criteria*
2.1	Fast transients common mode	1 kV (peak) 5/50 Tr/Th ns 5 kHz rep. frequency	IEC 801-4 Capacitive clamp	Applicable to cables whose length can exceed 3 m	B
2.2	Radio Frequency common mode 1 kHz 80% AM	0.15-100 MHz 3 V (rms) (unmod) 150 Ω source impedance	IEC TC 65 (Sec.) 144	Applicable to cables whose length can exceed 1 m	A

Table 3 Ports for Process, Measurement and Control Lines, and Long Bus and Control Lines

	Test Type	*Specification*	*Basic Standard*	*Remarks*	*Performance Criteria*
3.1	Fast transients common mode	2 kV (peak) 5/50 Tr/Th ns 5 kHz rep. frequency	IEC 801-4 Capacitive clamp		B
3.2	Radio Frequency common mode 1 kHz 80% AM	0.15-100 MHz 3 V (rms) (unmod) 150 Ω source impedance	IEC TC 65 (Sec.) 144	Applicable to cables whose length can exceed 1m	A

Table 4 Input and Output DC Power Ports

	Test Type	*Specification*	*Basic Standard*	*Remarks*	*Performance Criteria*
4.1	Fast transients common mode	2 KV (peak) 5/50 Tr/Th ns 2.5 kHz rep. frequency	IEC 801-4	4 kV (peak) when coupling with capacitive clamp	B
4.2	Radio Frequency common mode 1 kHz 80% AM	0.15-100 MHz 3 V (rms) (unmod) 150 Ω source impedance	IEC TC 65 (Sec.) 144	Applicable to cables whose length can exceed 1 m	A

Note: Direct injection method shall be used if current consumption is less than 100 A. This test is not applicable to input ports intended for connection to dedicated non-rechargeable power supplies.

Table 5 Input and Output AC Power Ports

	Test Type	*Specification*	*Basic Standard*	*Remarks*	*Performance Criteria*
5.1	Fast transients common mode	4 kV (Peak) 5/50 Tr/Th ns 5 kHz rep. frequency	IEC 801-4	4 kV (peak) when coupling with capacitive clamp	B
5.2	Radio Frequency common mode 1 kHz 80% AM	0.15-100 MHz 150 Ω source impedance	IEC TC 65 (Sec.) 144	Applicable to cables whose length can exceed1 m	A
5.3	Surge	4.0 kV	IEC TC 65 (Sec.) 137	Use combination wave test generator:1.2/50 µs open circuit, 8/20 µs short circuit wave form	C

5.2 *Emissions Test*

5.2.1 *EMI Testing Required* — Equipment shall be tested in accordance with CISPR 22 and EN 55 022. Test limits are Class A, which is generally limited to non-residential use.

As noted above for radiated immunity testing, the size and complexity of semiconductor factory equipment may rule out the use of special facilities. Thus, the tests in CISPR 22 may be adapted as required due to test site limitations. Again, use of such facilities will yield more reproducible and accurate data, and is recommended whenever possible.

In any event, emissions greater than 6 dB above the Class A limits are not allowed.

5.2.2 ELF Testing Required — ELF emission testing is required for all ELF-sensitive equipment, since such equipment is commonly grouped together. ELF emission testing for other types of equipment is required on request of a purchaser intending installation of ELF-sensitive equipment in the immediate vicinity.

ELF emissions shall be measured using a calibrated ELF meter. Equipment emissions shall be measured at a distance of 1.5 meters from the entire perimeter of the EUT at a height of 1 meter. Facility ELF shall be measured at a height of 1 meter in the region where ELF-sensitive equipment installation is intended. Measurement points shall be no greater than 0.5 meter apart in the regions specified above. Facilities electrical systems and adjacent equipment should be in normal operation to assure accurate measurement of the actual operating environment.

At each measurement point, the ELF sensor should be oriented to produce the maximum reading. The maximum from all the measurement points is then used to determine the level from the table below:

Level A — ELF of less than 0.25 milliGauss rms

Level B — ELF of less than 0.50 milliGauss rms

Level C — ELF of less than 1.00 milliGauss rms

Level D — ELF of less than 2.00 milliGauss rms

Level E — ELF of 2.00 milliGauss rms and greater

6 Equipment Installation and Grounding

Special installation, power, and grounding requirements necessary to meet this standard shall be thoroughly documented by the equipment supplier. FIPS Publication 94 and the IEEE Emerald Book are suggested sources of information for recommended practices in this area.

Removable shielded panels or doors that must be properly secured to meet this standard should be labeled "SECURE THIS PANEL TO REDUCE ELECTROMAGNETIC EMISSIONS." This labeling requirement is not applicable to interlocked panels that must be in place for the equipment to operate.

7 Documentation

Upon request of the purchaser a report of the test results against this standard shall be furnished. Similarly, the supplier may use this standard as a reference in specifying the environmental requirements of equipment.

8 Alternate Testing

Testing completed under a different, but substantially similar standard may be substituted for the basic standards specified herein if the performance criteria and test levels are similar to those above. Such substitution shall be noted in the test report, and must be agreed to by the concerned parties. Examples include substitution of ANSI C63.4-1991 testing for CISPR 22.

Similarly, equipment which satisfies the European EMC Directive and bears the CE mark meets this specification.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

APPENDICES

The appendices are not an official part of this standard. However, they contain relevant information for customizing the basic standards for testing of semiconductor equipment and facilities, and point out areas of concern for which no standard currently exists.

A.1 Appendix A: Charged Wafer Testing

Due to overriding microcontamination concerns, non-static-dissipative wafer carriers must be used during semiconductor fabrication. It is suggested that any equipment which handles wafers be tested with wafers charged to 18 kV/in. The charge generator used for 801-2 testing can be used to charge the wafer. Some experimentation will be required to determine the best means to carry out this test. Alternately, the handling mechanism may be challenged by air or contact discharge directed to the mechanism.

It is suggested that wafer handlers be designed to dissipate charge on incoming wafers in a controlled, non-sparking manner. A simple AM radio tuned between stations and placed near the handler has been found to be a good qualitative means to detect sparking. Sparking will result in pops and static being heard on the radio.

A.2 Appendix B: ESD Test Methods

Although the contact method of ESD testing has been found to be much more reproducible than the air discharge, the air discharge is a more realistic simulation of possible events that can occur in the semiconductor factory. Also, the air discharge method is the only realistic way to test objects that are primarily fabricated from insulators, such as wet stations and keyboards.

In addition to testing surfaces that come in contact with humans and wafers, it is important to test any area of the equipment that can be exposed to ESD. For instance, wet stations are composed of assemblies involving large masses of insulators in proximity to metallic sensors and controllers. It is possible for the insulating surfaces to build up charge, which then sparks to a sensor or controller — all internal to the equipment itself.

A.3 Appendix C: Future Directions

Items in this section are not requirements of this standard, but are included to indicate currently ill-defined goals for further improvements to semiconductor factory EMC.

A.3.1 *Static Charge* — Minimization of static charge promotes cleanliness, and avoids damage to material in process and reticles.

It is suggested that electrostatic fields be held to under 200 V/cm (500 V/in). This would be applicable to personnel, wafers, cassettes, cassette boxes, reticles, reticle boxes, and all equipment and facility surfaces in proximity to these items as well as all surfaces exposed to filtered airflow. Measurements shall be made using a properly-grounded electrostatic field meter in accordance with its manufacturer's instructions.

A.4 Appendix D: National Requirements

A.4.1 *U.S.* — Section 5.1.1 Table 1, row 1.2: Radiated immunity testing outside a shielded enclosure is legally accomplished by obtaining an experimental license from the FCC using FCC form 442. The FCC recommends using techniques such as scanning or hopping to avoid interference.

A.4.2 *Europe* — The earth port: Refer to Table 1.6 of the informative annex to EN 50 082-2 for test requirements applicable to the earth.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E34-95
GUIDELINE FOR MASS FLOW DEVICE RETURN

NOTICE: This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1 Purpose

Mass flow devices (mass flow controllers, mass flow meters and flow control valves) are used as an integral part of the chemical delivery system in semiconductor processing equipment. Many of the chemicals used in semiconductor processes can be hazardous to equipment and personnel. Once exposed to these chemicals, the contaminated mass flow devices can present a hazard to repair personnel and equipment if not handled properly.

Implementing the procedures outlined in this guideline provide a mechanism to reduce the risk associated with shipping and/or receiving any potentially hazardous mass flow device used to monitor or control gases or liquids.

2 Scope

This guideline is intended to:

Recommend and encourage the purging of devices used with hazardous materials prior to removal to reduce the risk of handling them.

Alert the recipient of possibly hazardous mass flow devices to the nature of the hazard.

Establish mechanism for properly identifying and documenting possibly hazardous mass flow devices by using an orange tag and a health and safety disclosure form.

3 Referenced Documents

49 CFR[1] — Title 49 of the Code of Federal Regulations (CFR)

NFPA 704[2] — Standard System for the Identification of Fire Hazards of Materials

1 United States Government Printing Office, Washington, D.C. 20402

2 National Fire Protection Association, Batterymarch Park, Quincy, MA 02269

4 Terminology

4.1 *hazardous materials* — Those chemicals or substances that are physical hazards or health hazards as defined and classified in NFPA 704 whether the materials are in use or in waste conditions.

4.2 *mass flow controller (mfc)* — A self-contained device, consisting of a mass flow transducer, control valve, and control- and signal-processing electronics, commonly used in the semiconductor industry to measure and regulate the mass flow of gas.

4.3 *mass flow meter (mfm)* — A self-contained device, consisting of a mass flow transducer and signal-processing electronics, commonly used in the semiconductor industry to measure the mass flow of gas.

4.4 *material safety data sheet (msds)* — Written or printed material concerning a hazardous material which is prepared in accordance with the provisions of 29 CFR 1910.1200.

4.5 *protective container* — A sealable plastic bag or other container which will keep hazardous material from the mass flow device from contaminating the outer package. The container should be transparent, if possible.

4.6 *purge* — To dilute potentially harmful material in the mass flow device by flowing an inert gas through the device. Purging a chemical delivery line containing a mass flow device with an inert substance is intended to dilute hazardous materials and reduce the level of the hazard. To be effective, the inert substance must be able to reach all points within the chemical delivery system in sufficient quantity to dilute the hazardous material to safe levels. The nature of the hazard and the physical configuration of the chemical delivery system must be considered when developing a purge procedure.

4.7 *safe* — Free of conditions that can cause occupational illness, injury, or death to personnel or damage to or loss of equipment or property or the environment.

5 Procedure

5.1 *Disclosure Form*

- Complete the disclosure form for mass flow device return.
- Send the completed form via Fax or other suitable method to the recipient of the mass flow device.

- Attach a copy of the form to the exterior of the shipping container.
- Enclose another copy inside the package attached to the protective plastic bag containing the mass flow device during shipment.
- Retain the original form for your records.

5.2 *Purging Prior to Removal* — Thoroughly purge the mass flow device following the applicable purge procedure. Purge procedures are usually unique to the equipment and installation. Obtain purging procedures from your facilities manager, corporate safety department, and/or the equipment manufacturer. If a formal purge procedure is available, note on the disclosure form the purge procedure document number and source.

5.3 *Equipment Removal* — WARNING: Do not remove the mass flow device until it has been properly purged.

5.3.1 The person removing the mass flow device should fill out an orange-colored device tag indicating the process gas(es) or chemicals used, possible exterior contamination and the purge procedure document number prior to removal of the device. A sample orange device tag is shown in Figure 1.

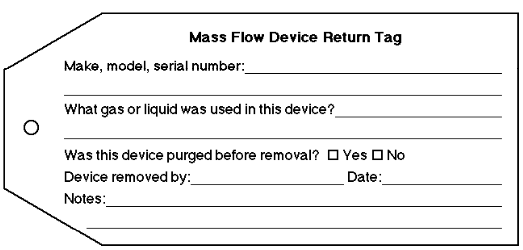

Figure 1

Sample Orange Device Tag

5.3.2 Carefully remove the mass flow device from the installation or system.

5.3.3 The inlet and outlet ports should be sealed to prevent any leakage into or out of the mass flow device.

5.3.4 The person removing the mass flow device should attach the orange tag to the device.

5.4 *Equipment Packaging* — Package all mass flow devices for shipment per government regulations including the following:

5.4.1 Seal the device in a protective container to prevent the contamination of the shipping package. If the orange tag is not visible through the container, an additional tag should be attached to the outside of the container.

5.4.2 Place the device in a shipping container with adequate packing to avoid damage to the device and the protective container during shipment.

5.5 *Shipping* — Ship the device so that it conforms to all applicable regulations of the countries of origin, trans-shipment, and destination governing the shipment of materials.

SEMI E35-0701
COST OF OWNERSHIP FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT METRICS

This guideline was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001. Originally published in 1995; previously published February 2000.

1 Purpose

1.1 The purpose of this guide is to provide standard metrics for evaluating unit production cost effectiveness of factory equipment subsystems in the semiconductor industry. The guideline is appropriate for application to any type of equipment processing semiconductor units, which may be wafers, devices, or other material.

1.2 The guideline establishes a well-defined practice to facilitate an understanding of equipment-related costs by providing definitions, classifications, algorithms, methods, and default values necessary to build a full or constrained cost of ownership (COO) calculator. A number of constraint types are defined. Related Information 1 provides some discussion of COO to expand upon the guideline presentation. Default values which can be used in a COO calculation are presented in Related Information 2 to provide representative data. Such default data are not meant to be a substitute for having actual data appropriate to the process being analyzed.

2 Scope

2.1 The definitions provide a metric which can be applied to any factory equipment system, but are specialized to silicon integrated circuit wafer and device production. The guideline is formulated in terms of units which are wafers or wafer equivalents of the devices produced and is thus appropriate to both front-end and back-end considerations. Application specific guidelines based upon this general guideline will be developed in the future and will address particular aspects of various types of equipment, materials, gases, etc.

2.2 Effective use of the metric to build a COO model requires identification of the constraints, parameter values, and data values within the adopted category classification. Default data is provided in Related Information 2 to this document and may be updated periodically through support documents. Where possible, use direct values for inputs rather than deriving them from secondary models or using default values.

2.3 Full calculation of COO often requires data held proprietary and is coupled to the overall factory through yield and the related cost of yield loss. It is envisioned that this guide will be used for internal factory and equipment optimization as well as investment evaluation by IC manufacturers.

2.4 The companion guide, "Guide for Cost of Equipment Ownership Comparison," is intended for competitive evaluation of equipment and is an alternative to the full analysis defined in this guideline. Both guidelines identify elements that are attributable to the equipment and to the operating decisions made by manufacturers in using the equipment.

2.5 Section 7 lists limitations of the guideline.

2.6 This guideline does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Documents*

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E35.1 — Guide for Cost of Equipment Ownership Comparison Metric

SEMI Compilation of Terms

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

NOTE 2: Additional definitions are contained in Sections 10 and 11, Classification Element Details.

4.1 *Abbreviations and Acronyms*

4.1.1 *CEO* — Cost of equipment ownership

4.1.2 *COO* — Cost of ownership

4.1.3 *CYL* — Cost of yeld loss

4.1.4 *DLY* — Defect limited yield

4.1.5 *EY* — Equipment yield

4.1.6 *GWE* — Good wafer equivalents

4.1.7 *P/T* — Precision tolerance ratio

4.1.8 *PLY* — Parametric limited yield

4.1.9 *PRY* — Product yield

4.1.10 *PU* — Production utilization

4.1.11 *SR* — Systems required - integer number

4.1.12 *TP* — Throughput

4.1.13 *α* — Type 1 test yield for false bad

4.1.14 *β* — Type 2 test yield for false good

4.2 *Definitions*

4.2.1 *baseline cost of ownership* — a constraint version of cost of ownership which only includes equipment yield, i.e., defect limited yield and parametric limited yield are not included.

4.2.2 *comprehensive cost of ownership* — cost of ownership calculated with no constraints.

4.2.3 *constraint version* — cost of ownership version with a set of defined restrictions to facilitate comparisons or to remove ambiguity. An example is baseline as defined in SEMI E35.1, which excludes defect limited yield and parametric limited yield.

4.2.4 *consumables* — cost of all parts of the equipment that are worn out by the process operation of equipment and require replacement after less than one (1) year of operation.

4.2.5 *cost footprint* — the area (A) of the smallest horizontal rectangle that contains all of the shadow footprint and half of the easement space around a tool. This is computed as:

$$A = \left[Wt + 1/2\left(Ws - Wt\right)\right] * \left[Dt + 1/2\left(Ds - Dt\right)\right]$$
$$= 1/4\left(Wt + Ws\right) * \left(Dt + Ds\right)$$

where:
Dt = Depth of tool
Ds = Combined depth of tool and easement space
Wt = Width of tool
Ws = Combined width of tool and easement space

4.2.6 *cost of equipment ownership (CEO)* — a factor in cost of ownership (see Sections 5.1.1 and 8.3).

4.2.7 *cost of ownership* — full cost of embedding, operating, and decommissioning in a factory environment a process system needed to accommodate the required volume of product material (see Section 5.1.1 for further description).

4.2.8 *cost of yield loss (CYL)* — a unit lost at the end of a given step represents the loss of the cost of manufacturing to that point. In addition, units leaving a step may be lost at some later step. Calculating cost of yield loss (CYL) therefore requires knowing the accumulated cost of manufacturing before the wafer is lost. Therefore, cost of yield loss should be tracked as a separate cost for factory optimization. CYL is given in Equation 4.

4.2.9 *default or default value* — value to be used if actual data are not available. In lieu of actual data, data should fall within the range specified by default values given in the Related Information section. Where possible, actual data should be used in COO calculations.

4.2.10 *defect limited yield (DYL)* — devices not lost from defects added by the equipment. For front-end process, defect yield is usually derived from a model.

4.2.11 *easement space* — the floor space that must remain clear to the rear and sides of the tool (but not in front of the load face plane). This includes safety aisles, ergonomic maintenance access space, component removal space, and room for doors to swing out.

4.2.12 *equipment availability* — equipment dependent uptime or the percent of time the equipment is in a condition to perform its intended function during the period of operations time minus the sum of all maintenance delay, out-of-spec input downtime, and facilities-related downtime. This calculation is intended to reflect equipment reliability and maintainability based solely on equipment merit see SEMI E10. (NOTE: Equipment availability is the responsibility of the equipment supplier and should reflect the need for unscheduled maintenance and any scheduled maintenance that cannot be accomplished within the semiconductor manufacturer's standard allotment.)

4.2.13 *equipment production lifetime* — the number of years a piece of equipment is used for manufacturing.

4.2.14 *equipment yield (EY)* — the percentage of units received by the equipment which can be passed to the next step based on any criteria such as damaged material, or material determined to be defective by inspection or test. Inclusion of equipment yield results in a decreasing population of units flowing through the factory. At later steps, equipment will process fewer units than the full factory wafer starts. For test equipment, validly rejected material is scrap, but not a component of equipment yield.

4.2.15 *factory utilization (FU)* — a measure of the allocation for operating hours, scheduled maintenance shifts, and other nonproduction hours as defined by SEMI E10. Expressed as hours and % of 365 × 24 =

8,760 hours per year. As defined, FU is determined by the semiconductor manufacturer.

4.2.16 *fixed costs* — costs incurred once and usually associated with the acquisition and incorporation of equipment into the factory.

4.2.17 *good wafer equivalents (GWE)* — derived from the number of good product die at wafer probe or devices at test and expressed as completely good product wafers.

4.2.18 *lifetime* — the time over which the fixed and recurring costs are spread for an annualized basis. Examples are: 1) tax lifetime - lifetime used for tax depreciation and 2) equipment production lifetime.

4.2.19 *materials* — bulk gases, specialty gases, general or specialty chemicals used in the process. Test and filler wafers consumed in the support of the equipment.

4.2.20 *monitor units* — test or filler units (wafers or devices) consumed in the support of the equipment. Also called test units.

4.2.21 *parametric limited yield (PLY)* — an estimate of devices that are not lost from device parameters being outside the required range.

4.2.22 *precision-tolerance ratio (P/T)* — characterization of test equipment being used to evaluate product quality for yield determination.

4.2.23 *production utilization (PU)* — a measure of factory utilization and equipment availability expressed as hours and % of 8,760 hrs per year.

PU = factory utilization * equipment availability

As defined, PU has a component attributable to the manufacturer and a component attributable to the equipment supplier.

4.2.24 *product yield (PRY)* — the percentage of units expressed as good unit equivalents which pass through the factory and result in good product. Product yield for wafers is the composite yield from Equation 2. The components are defined in this section. Since defect limited yield (DLY) is generally a wafer level phenomena, Equation 2 may be simplified for other types of units by setting DLY=1. Particle additions are a predictor of defect yield loss at a future step, but not a complete predictor of all the possible loss since there may be other defects or parametric problems.

(See Equation 2, Section 5.5.2).

4.2.25 *recurring costs* — costs that are incurred on an accrued basis.

4.2.26 *rework* — any units being reprocessed by the equipment because of a fault or defect.

4.2.27 *service contract* — an agreement for the supplier to provide equipment maintenance under specified terms and conditions.

4.2.28 *shadow footprint* — the area of the floor space directly under every part of the tool during its operation. This includes any temporary projections from the tool during loading or processing (such as carriers that stick out from the tool or tool load ports that protrude only when the tool is being loaded).

4.2.29 *spare parts* — pre-purchased inventory of components maintained to service the equipment. Repair parts are paid for at the time of repair.

4.2.30 *supplier* — provider of equipment or services to the semiconductor manufacturer, same as a vendor or equipment manufacturer.

4.2.31 *system throughput* — see throughput.

4.2.32 *systems required (SR)* — the integer number of systems required to obtain the throughput for the step.

4.2.33 *test wafers* — see monitor units.

4.2.34 *test yield* — incorrect test determination of a die being good or bad:

α or type 1 is percentage of false bad.

β or type 2 is percentage of false good.

4.2.35 *throughput (TP)* — the number of units (wafers or devices) per hour the process system delivers to the factory, including all input, output, and internal overhead operation. Throughput includes all test or monitor wafers processed, since the cost of these non-product wafers is accounted for directly.

4.2.36 *tool* — often used synonomously with equipment in the silicon wafer processing industry.

4.2.37 *unit* — any wafer, die, packaged device, or piece part thereof (includes product and non-product units) see SEMI E10. For the purposes of this guideline, units are converted to wafer equivalents so that cost of ownership is expressed on a per wafer basis.

4.2.38 *volume requirement* — the number of units required to be processed by the equipment in a specific time period, normally units per week.

4.2.39 *warranty contract or service contract* — an alternate method for handling maintenance beyond that which is supplied with the equipment.

4.2.40 *yield* — see product yield.

5 Cost of Ownership

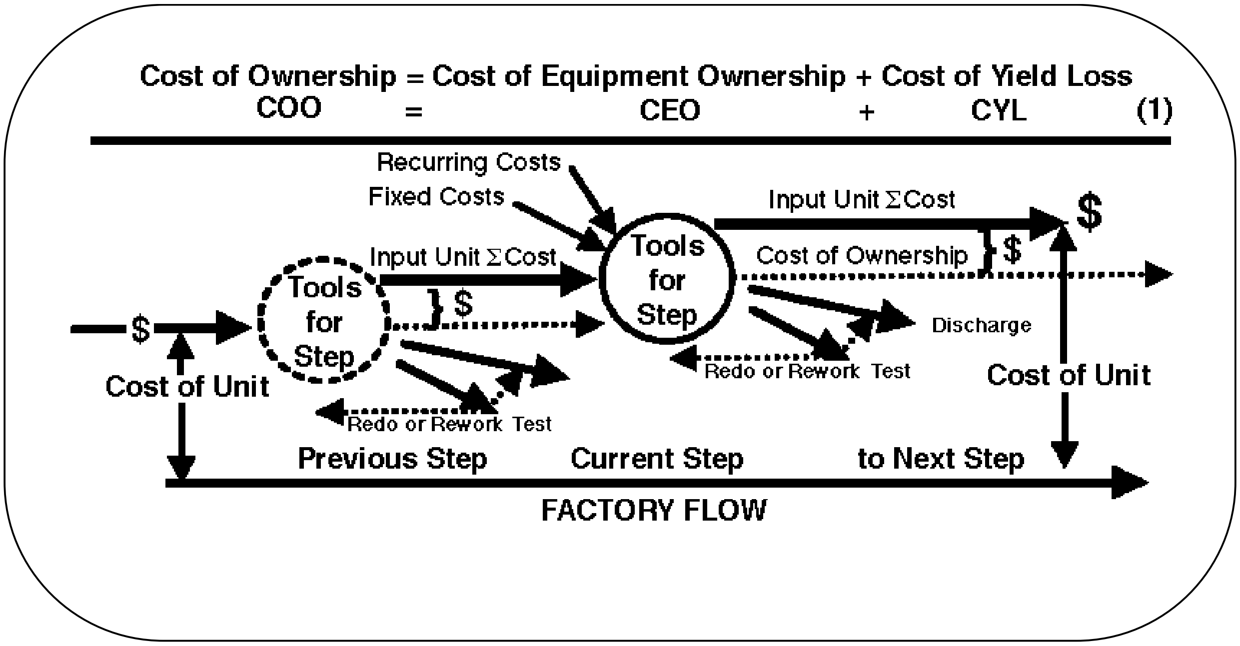

Figure 1
Factory Flow

5.1 *Description*

5.1.1 A cost of ownership metric is the incremental cost added to a unit of good product material flowing through a volume-sized process system embedded in a factory environment for a specified lifetime plus the cost of yield loss. COO is calculated on an annualized basis. The metric is expressed as cost per good wafer equivalents (GWE) for one pass through the system. GWE is determined from the good die yield at wafer probe or at a later stage if appropriate. Figure 1 depicts this accumulation of cost which can be factored into two components, cost of equipment ownership (CEO) and cost of yield loss (CYL).

5.1.2 COO is the full cost of embedding, operating, and decommissioning in a factory environment a process system needed to accommodate the required volume of product material.

5.2 *Constraint Version*

5.2.1 A constraint version of cost of ownership imposes a set of defined restrictions to facilitate comparisons or to remove ambiguity. An example is: baseline cost of ownership which only includes equipment yield, i.e., defect limited yield and parametric limited yield are not included. Cost of ownership calculated with no constraint is referred to as comprehensive.

5.2.2 The constraint type definition will also provide a unique description of the elements included in the classification system defined in Section 9 as well as other details. SEMI E35.1, "Guide for Cost of Equipment Ownership Comparison Metric," is a specific constraint version equivalent to a baseline cost of ownership.

5.3 *Lifetimes*

5.3.1 The time over which the fixed and recurring costs are spread for the annualized basis is the equipment production lifetime. Tax life-depreciation is customarily used in COO, based upon standard accounting practice.

5.3.2 The equipment usually remains in production much longer than the tax life, so it is often useful to consider the equipment production lifetime in evaluating the value of equipment.

COO Lifetimes

1. Tax life - depreciation

2. Equipment production lifetime

5.4 *CEO: Fixed and Recurring Costs*

5.4.1 Determining CEO requires enumerating all of the fixed and recurring costs that are incurred in the life cycle of the equipment. Fixed costs are those incurred once and are usually associated with the acquisition and incorporation of equipment into the factory. Recurring costs are those which arise on an annual basis from the operation and maintenance of the equipment. The calculation is shown in Section 8.

5.5 *Yield*

5.5.1 Yield is a metric of the percentage of the unit volume that results in good product. Yield affects the cost of ownership in a number of ways.

1. Volume of units that must be processed for the required product requirements.

2. Cost of units that do not produce good product.

5.5.2 Product yield (PRY) is the percentage of units expressed as good unit equivalents which pass through the factory and result in good product. Product yield for wafers is the composite yield from Equation 2. The components are defined in Section 4. Since defect limited yield (DLY) is generally a wafer-level phenomena, Equation 2 may be simplified for other types of units by setting DLY = 1. Particle additions are a predictor of defect yield loss at a future step, but not a complete predictor of all the possible loss since there may be other defects or parametric problems.

$$\mathrm{PRY} = \mathrm{EY} \times (1 - \alpha) \times (1 - \beta) \times \mathrm{DLY} \times \mathrm{PLY} \times (1 - \mathrm{Rework}) \quad (2)$$

5.6 *Cost of Yields*

5.6.1 A unit lost at the end of a given step represents the loss of the cost of manufacturing to that point. In addition, units leaving a step may be lost at some later step. Calculating cost of yield loss (CYL) therefore requires knowing the accumlated cost of manufacturing before the wafter is lost. Therefore, cost of yield loss should be tracked as a separate cost for factory optimization. CYL is given in Equation 4 in Section 8.1.

5.7 *Volume Requirement*

5.7.1 The volume requirement is the unit flow to be processed and can be derived from specification of the product units needed corrected for yield and the number of other units required to be processed by equipment in a specific time period such as those being redone. One complication in accurately dealing with the volume requirement is that the volume of units actually reaching the equipment will depend on the volume loss from equipment yield for all the prior steps. One common approach is to deal with volume parametrically.

5.8 *Good Wafer Equivalents (GWE)*

5.8.1 Good wafer equivalents (GWE) is derived from the number of good product units or good product die at wafer probe or at a later stage, if appropriate, and is expressed as completely good wafers.

5.9 *Systems Required*

5.9.1 Once the volume is specified, the number of systems required (SR) is obtained from the throughput (TP), and the production utilization (PU).

$$\mathrm{SR} = \mathrm{VOLUME\ REQUIRED}/(\mathrm{TP} \times \mathrm{PU}) \quad (3)$$

6 Reporting Results

6.1 Reports on cost of ownership should always show the following items. Other data items should be reported as required by clarity.

6.1.1 *Input Items*

1. Identification of standard conformance

2. Declarations

    1. Classification system: functional, cost center, or other
    2. Summed categories: all or enumerate
    3. Volume requirement
    4. Factory utilization
    5. Equipment availability
    6. Production utilization
    7. Equipment throughput
    8. Number of systems and chambers

6.1.2 *Output Items:*

1. Cost per unit

2. Classification summary cost distribution

3. Related statistics

7 Limitations

7.1 Certain factors are more difficult than others to accurately determine. Figure 2 depicts the relation-ship of some of the cost of ownership factors. Thus, the accuracy of a cost of ownership calculation may be prone to a variety of errors or omissions.

7.2 In addition, line balance considerations are not included in cost of ownership calculation. Line balance considerations are not included because an individual COO model does not have the capability to know what impact the process being modeled has on the rest of the fab.

7.3 A cost of ownership calculation may have more detail than presented explicitly in this guideline. The structure of the guideline, however, allows for the proper handling of these situations.

8 Procedures

8.1 *COO Calculation*

8.1.1 The COO algorithm requires the specification or calculation of the volume level, the determination of the number of systems required to process the volume, the enumeration of all fixed and recurring costs associated with processing the volume by the systems, and the yield related costs. The COO metric is a function defined by equation 1 to be:

$$COO = CEO + CYL$$

The cost of yield loss (CYL), is given by Equation 4, and is broken into two components. The CEO component is described in Equation 5 and is expressed in Equation 6 as the sum of a number of categories which constitute a classification system. The classification system is described in Section 9. Constrained versions of COO restrict certain elements included in calculation.

8.1.2 The algorithm for CEO is depicted in diagrams presented in Related Information 1. The CEO is expressed as a sum over the elements in the Category Table 1 as expressed in Equation 5. Each item in the classification system is defined, and a method for evaluating its expression given as described in Section 9. Default values or handling are specified in Related Information 2. All costs must be assigned through the defined classification system and calculated per system for the number of production hours.

8.1.3 Figure 2 depicts some of the elements in terms of the difficulty in establishing various costs.

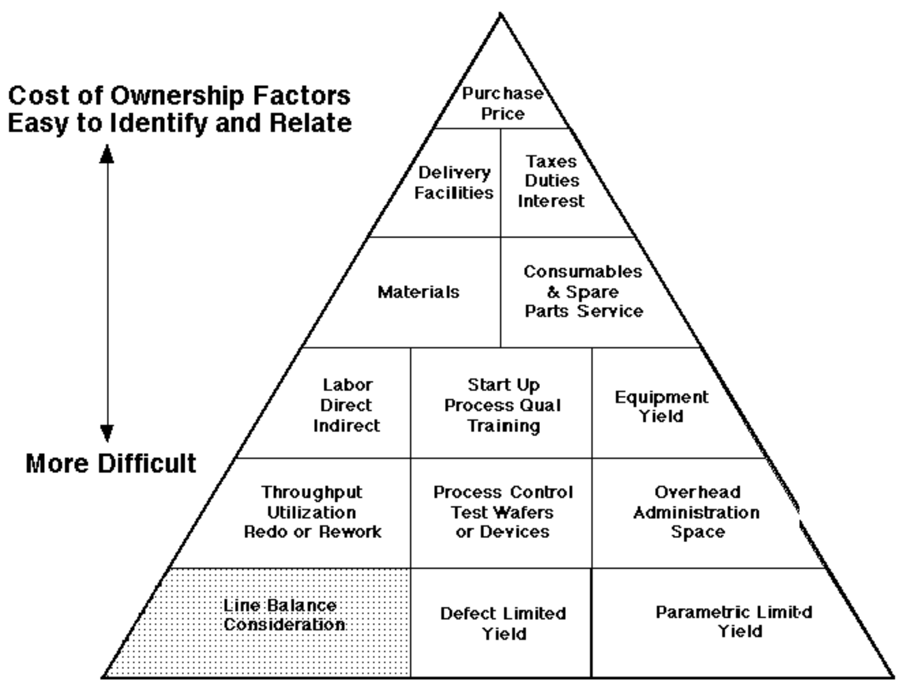

Figure 2

8.2 *Cost of Yield Loss*

$$\text{CYL} = \left(\begin{array}{c} \text{annualized} \\ \text{cost of} \\ \text{wafers lost to} \\ \text{equipment yield} \end{array} + \begin{array}{c} \text{annualized} \\ \text{attributed cost of} \\ \text{wafers lost to} \\ \text{die \& parametric yield} \end{array} \right) * \frac{1}{\begin{array}{c}\text{good units} \\ \text{per year}\end{array}} \quad (4)$$

8.3 *Cost of Equipment Ownership*

$$\text{CEO} = \left(\begin{array}{c} \text{annualized} \\ \text{fixed cost} \\ \text{per system} \end{array} + \begin{array}{c} \text{annualized} \\ \text{recurring cost} \\ \text{per system} \end{array} \right) * \frac{\begin{array}{c}\text{volume required} \\ \text{\# systems}\end{array}}{\begin{array}{c}\text{good units} \\ \text{per year}\end{array}} \quad (5)$$

$$= \left(\sum_{j} F_{j0} + \sum_{k} R_{k0} \right) * \left(\frac{\begin{array}{c}\text{volume required} \\ \text{\# systems}\end{array}}{\begin{array}{c}\text{good units} \\ \text{per year}\end{array}} \right) \quad (6)$$

$$= \left(\sum_{ij} F_{ij} + \sum_{kl} R_{kl} \right) * \left(\frac{\begin{array}{c}\text{volume required} \\ \text{\# systems}\end{array}}{\begin{array}{c}\text{good units} \\ \text{per year}\end{array}} \right) \quad (7)$$

Where j and k are the number of primary categories in Table 1, and ij and kl are the number of detailed elements in Sections 10 and 11.

8.3.1 Fj0 and Rk0 are the primary categories in Table 1 and in the expansions shown in Sections 10 and 11. Fij and Rkl are the detailed elements, each of which is defined.

9 Cost Classifications and Categories

9.1 Cost classifications may be defined as a tree starting with the superclass/class category structure shown in Table 1. The superclass structure starts from the fixed and recurring cost categories. Detailed element expansion is shown in Sections 10 and 11. Equation 5 shows the way the tables are used to represent the CEO calculation. The purpose of this format is to remove ambiguity that often results in trying to follow calculations done with spreadsheets.

Note that any class expansion should give the same results since they are just different views of the same fixed and recurring costs.

9.2 Subclass elements may be expanded into further items and then summed up to the next level if more detail is required. The cost center example in Table 1 is one view of the categories. Another view is given in section 11 for a functional view of the costs. Note that since both views are summing the same fixed and recurring costs, they give equivalent results. Category tables can be developed as required to expose particular details of the cost structure with the requirement that the table be reported in the documentation.

9.3 Constrained versions of the COO calculation are created by defining a modification of the calculation such as the way yield is included or in restricting the items in the classification tables that are used.

Table 1 Example Classification Structure for Expanding COO

VIEW	*SuperClass*		*Class*	*SubClass*
Cost Center	Fixed	1	Equipment

On the following pages are given the definitions of the items included in the classification and the methods for calculating the items if the values are not available. Default values are given in Related Information 2.

CF1.0 Equipment

Definition	Fixed cost categories associated with the purchase of equipment.
Method	Sum of all subcategories.

CF1.1 Equipment: Depreciation

Definition	Equipment purchase price divided by the appropriate depreciation schedule.
Method	Any accepted depreciation schedule (straight-line, double declining balance, etc.).

CF1.2 Equipment: System Qualification

Definition	The cost of qualifying for production.
Method	Expressed in person-hours of expended effort and material costs.

CF1.3 Equipment: Installation

Definition	The cost of installing a system for production.
Method	Expressed in terms of actual cost.

CF1.4 Equipment: Training

Definition	The initial training requirements for new equipment for operators, supervision, engineers, and maintenance personnel.
Method	The training person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Training course costs will be added if applicable.

CF1.5 Equipment: Moves & Rearrangements

Definition	The cost of displacing existing equipment in order to install the new equipment.
Method	Provided by semiconductor manufacturer.

CF1.6 Equipment: Floor Space

Definition	The cleanroom overhead allocated to the equipment.
Method	The cost footprint of the equipment is multiplied by the cost of cleanroom space for each class of cleanroom space utilized.

CR1.0 Material

Definition	Material cost categories associated with the operation of equipment.
Method	Sum of all subcategories.

CR1.1 Material: Test/Filler Wafers

Definition	Test and/or filler wafers consumed in the support of the equipment.
Method	Number of wafers consumed multiplied by the cost of the wafer.

CR1.2 Material: Utilities

Definition	Cost of electricity, city water, deionized water, and chilled water used by the equipment.
Method	Cost of electricity, city water, deionized water, and chilled water per system per year.

CR1.3 Material: Supplies

Definition	Cost of all supplies used by, or in support of, the equipment to produce water. This would include bulk gases, specialty gases, and specialty chemicals.
Method	Cost of supplies per system per year.

CR1.4 Material: Waste Disposal

Definition	Removing spent chemical or effluent. Gas exhaust charges.
Method	Cost per system per year.

CR2.0 Consumables

Definition	Cost of all parts of the equipment that are worn out by the process operation of equipment and require replacement after less than 1 year of operation.
Method	Consumable costs per system per year.

CR3.0 Maintenance

Definition	Maintenance cost categories associated with the operation of a manufacturing equipment.
Method	Sum of all subcategories.

CR3.1 Maintenance: Labor

Definition	IC manufacturer's internal repair and maintenance labor costs.
Method	Scheduled and unscheduled downtime are calculated by the COO model from E10 inputs and multiplied by the maintenance labor rate. Actual cost may be affected by warranty and service contract coverage.

CR3.2 Maintenance: Spare Parts

Definition	Spares Inventory Cost of IC manufacturer.
Method	Spare parts costs per system per year.

CR3.3 Maintenance: Repair Parts

Definition	Repair parts charged to the IC manufacturer.
Method	Repair parts costs per system per year.

CR3.4 Maintenance: Service Contracts

Definition	Service contracts charged to the IC manufacturer.
Method	Service contract costs per system per year.

CR3.5 Maintenance: Training

Definition	The ongoing training requirements for operators, supervision, engineers, and maintenance personnel.
Method	The training costs per system per year.

CR4.0 Labor

Definition	Labor cost categories associated with the operation of a manufacturing equipment.
Method	Sum of all subcategories.

CR4.1 Labor: Operation

Definition	The operator labor required to support the equipment set needed to meet the wafer start requirements of the IC manufacturer.
Method	Calculated by the COO model from equipment and tab specifications.

CR5.0 Support Personnel

Definition	Support personnel cost categories associated with the operation of a manufacturing equipment.
Method	Sum of all subcategories.

CR5.1 Support Personnel: Supervision

Definition	The supervisor labor required to support the equipment set needed to meet the wafer start requirements of the IC manufacturer.
Method	Supervision person-hours/week multiplied by the burdened salary rate.

CR5.2 Support Personnel: Engineering

Definition	The engineering labor required to support the equipment set needed to meet the wafer start requirements of the IC manufacturer.
Method	Engineering person-hours/week multiplied by the burdened salary rate.

CR6.0 Scrap

Definition	Scrap cost categories associated with the operation of a manufacturing equipment.
Method	Sum of all subcategories.

CR6.1 Scrap: Equipment Yield

Definition	The percent of units that are not broken or irreversibly misprocessed by the equipment.
Method	(1- Equipment Yield) multiplied by the value of the unit at that step in the process.

CR6.2 Scrap: Defect Yield

Definition	The percent of equivalent wafers that are not lost due to electrical malfunctions caused by particulate defects.
Method	(1- Defect Yield) multiplied by the value of the wafer at the end of the process. Defect yield is calulated by the COO model using a modified Seed’s formula. $$Y = \frac{1}{1 + (A_a \times D \times P)}$$ Where A_a is the active area of the device, D is the defect density, and P is the probability that a defect will be fatal.

CR6.3 Scrap: Parametric Yield

Definition	The percentage of equivalent wafers that are not lost due to electrical malfunction caused by device parameters being outside the required range.
Method	(1- Parametric Yield) multiplied by the value of the wafer at the end of the process.

CR7.0 Support Services

Definition	Support services cost categories associated with the support of a manufacturing equipment.
Method	Support service cost per system per year.

FF1.0 Acquisition

Definition	All cost categories associated with defining, evaluating, purchasing, and installing the equipment.
Method	Sum of all subcategories.

FF1.1 Acquisition: Price

Definition	The direct price to purchase the equipment.
Method	Actual price and accepted depreciation schedule (straight-line, double declining balance, etc.).

FF1.2 Acquisition: Purchasing

Definition	The cost of the process of initiating and completing the purchase of the equipment.
Method	Determine burdened person-hours cost.

FF1.3 Acquisition: Evaluation

Definition	The cost of qualifying a system for production.
Method	Expressed in person-hours of expended effort and consumable costs.

FF1.4 Acquisition: Installation

Definition	Cost to bring the equipment to an operational state.
Method	Expressed in dollars of actual cost.

FF1.5 Acquisition: Training

Definition	The initial training requirements for new equipment for operators, supervision, engineers, and maintenance personnel.
Method	The training person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Training course costs will be added if applicable.

FF2.0 Facilities

Definition	Facilities cost categories associated with requirements of equipment such as floor space and services.
Method	Sum of all subcategories.

FF2.1 Facilities: Space

Definition	The space overhead allocated to the equipment.
Method	The cost footprint of the equipment is multiplied by the cost of cleanroom space for each class of cleanroom space utilized.

FF2.2 Facilities: Infrastructure

Definition	Facilities Infrastructure cost categories associated with the cleanroom, other space, and service requirements of equipment.
Method	Sum of all subcategories.

FF2.2.1 Facilities: Infrastructure: Utilities

Definition	The costs allocated to the equipment for utilities connection.
Method	Provided by Semiconductor Manufacturer.

FF2.2.2 Facilities: Infrastructure: Services

Definition	The costs allocated to the equipment for miscellaneous services.
Method	Provided by Semiconductor Manufacturer.

FF3.0 Decommissioning

Definition	Cost categories associated with the disposition of spent equipment.
Method	Sum off all subcategories.

FF3.1 Decommissioning: Removal

Definition	The cost of removing existing equipment after it is no longer used for production.
Method	Provided by Semiconductor Manufacturer.

FF3.2 Decommissioning: Disposal

Definition	The cost of disposing of equipment after it is no longer used for production.
Method	Provided by Semiconductor Manufacturer.

FF3.3 Decommissioning: Cleanup

Definition	The cost of cleaning the fab after the equipment has been removed.
Method	Provided by Semiconductor Manufacturer.

Recurring Costs: FR1.0 Factory Interface

Definition	Factory cost categories associated with the interface of equipment to the factory systems.
Method	Sum of all subcategories.

FR1.1 Factory Interface: Labor

Definition	The labor requirements for interfacing equipment to the factory system.
Method	The person-hours for each personnel classification will be multiplied by their respective burdened wage or salary.

FR1.2 Factory Interface: Safety

Definition	The safety requirements for equipment run in producation.
Method	The safety person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Additional safety costs will be added if applicable.

FR1.3 Factory Interface: CIM

Definition	The computer integrated manufacturing (CIM) requirements for equipment run in production.
Method	The CIM person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Additional CIM costs will be added if applicable, such as port, communications, and server.

FR1.4 Factory Interface: Infrastructure

Definition	Period costs for overhead from factory infrastructure.
Method	Actual software and hardware costs.

FR2.0 Equipment Management

Definition	Equipment management cost categories associated with the operation of equipment in a production environment.
Method	Sum of all subcategories.

FR2.1 Equipment Management: Supervision

Definition	The supervisor labor required to support the equipment set needed to meet the wafer start requirements of the IC manufacturer.
Method	Supervision person-hours/week multiplied by the burdened salary rate.

FR2.2 Equipment Management: Support

Definition	The support required by the equipment to meet the wafer start requirements of the IC manufacturer.
Method	Provided by Semiconductor Manufacturer.

FR2.3 Equipment Management Administration

Definition	The administration costs allocated to the equipment to meet the wafer start requirements of the IC manufacturer.
Method	Provided by Semiconductor Manufacturer.

FR2.4 Equipment Management: Training-Other

Definition	The ongoing training requirements for operators, surpervision, engineers, and maintenance personnel.
Method	The training costs per system per year.

FR3.0 Maintenance

Definition	Maintenance cost categories associated with the operation of equipment.
Method	Sum of all subcategories.

FR3.1 Maintenance: Contracts

Definition	Service contracts charge to the IC manufacturer.
Method	Service contract costs per system per year.

FR3.2 Maintenance: Labor-Other

Definition	IC manufacturer's internal repair and maintenance labor costs.
Method	Scheduled and unscheduled downtime are calculated by the COO model from E10 inputs and multiplied by the maintenance labor rate.

FR3.3 Maintenance: Spare Parts

Definition	Spares Inventory Cost of IC manufacturer.
Method	Spare parts costs per system per year.

FR3.4 Maintenance: Repair Parts

Definition	Repair parts charged to the IC manufacturer.
Method	Repair parts costs per system per year.

FR4.0 Control

Definition	Equipment control cost categories.
Method	Sum of all subcategories.

FR4.1 Control: Software

Definition	The software purchase requirements for equipment run in production.
Method	Actual software costs.

FR4.2 Control: Training

Definition	The software training requirements for equipment run in production.
Method	The training person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Additional training costs will be added if applicable.

FR4.3 Control: Support

Definition	The software support requirements for equipment run in production.
Method	The support person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Additional support costs will be added if applicable.

FR4.4 Control: Backup

Definition	The software backup requirements for equipment run in production.
Method	The backup person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Additional backup costs will be added if applicable.

FR5.0 Inputs

Definition	Cost categories for items consumed in the manufacture of a wafer.
Method	Sum of all subcategories.

FR5.1 Inputs: Consumables

Definition	Cost of all parts of the equipment that are worn out by the process of operation of equipment and require replacement after less than 1 year of operation.
Method	Cost of supplies per system per year.

FR5.2 Inputs: Material

Definition	This includes bulk gases, specialty gases, and specialty chemicals. Test and/or filler wafers consumed in the support of the equipment.
Method	Number of wafers consumed multiplied by the cost of the wafer plus the cost of the process gas or chemicals used.

FR5.3 Inputs: Utilities

Definition	Cost of electricity, city water, deionized water, and chilled water or such used by the equipment.
Method	Determine from equipment usage or specification.

FR6.0 Operation Labor

Definition	The operator labor required to support the equipment set needed to meet the wafer start requirements of the IC manufacturer.
Method	Calculated by the COO model from equipment and fab specifications.

FR7.0 Quality/Performance

Definition	Quality/Performance cost categories associated with the operation of the equipment.
Method	Sum of all subcategories.

FR7.1 Quality/Performance: Metrology

Definition	The metrology requirements for supporting the equipment in production.
Method	Provided by Semiconductor Manufacturer.

FR7.2 Quality/Performance: Labor

Definition	The quality/performance labor requirements for equipment for operators, supervision, engineers, and maintenance personnel.
Method	Provided by Semiconductor Manufacturer. The quality/performance person-hours for each personnel classification will be multiplied by their respective burdened wage or salary. Additional quality/ performance costs will be added if applicable.

FR8.0 Non-Product Waste

Definition	Discharge cost categories associated with the equipment.
Method	Sum of all subcategories.

FR8.1 Non-Product Waste: Discharge

Definition	Cost of disposal of spent chemicals or effluent.
Method	Cost of disposal per system per year.

FR8.2 Non-Product Waste: Scrap

Definition	Scrap cost categories associated with the equipment.
Method	Sum of all costs.

FR9.0 Product Waste

Definition	Output product cost categories associated with the operation of equpment.
Method	Sum of all subcategories.

FR9.1 Product Waste: Breakage

Definition	The percent of wafers that are not broken or irreversibly misprocessed by the equipment.
Method	(1-Equipment Yield) multiplied by the value of the unit at that step in the process.

FR9.2 Defect Yield Loss

Definition	The percent of equivalent wafers that are not lost due to electrical malfunctions caused by particulate defects.
Method	(1-Defect Yield) multiplied by the value of the wafer at the end of the process. Defect yield is calculated by the COO model using a modified Seed's formula. $Y = \frac{1}{1 + (A_a \times D \times P)}$ Where A_a is the active area of the device, D is the defect density, and P is the probability that a defect will be fatal.

FR9.3 Product Waste: Parametric Yield

Definition	The percentage of equivalent wafers that are not lost due to electrical malfunction caused by device parameters being outside the required range.
Method	(1-Parametric Yield) multiplied by the value of the wafer at the end of the process.

APPENDIX 1
COST OF OWNERSHIP FOR GAS DELIVERY SYSTEMS

NOTE: This appendix is an official part of SEMI E35, but is not intended to modify or supersede the official standard. It was developed by a Task Force that was formed as a follow-on to a SEMI/SEMATECH project on modular surface mount gas boxes. Publication was by full ballot procedures on April 30, 2001. Determination of the suitability of the material is solely the responsibility of the user.

A1-1 Purpose

A1-1.1 The purpose of this information is to illustrate how to apply the cost of ownership (COO) metrics to gas delivery systems. Users should be able to calculate the COO for any piece of gas delivery equipment using this Related Information. A spreadsheet (Microsoft Excel) has been provided as an illustrative example.

A1-2 Description of Model

A1-2.1 The formula for computing COO is given in Equation 1.

$$\mathbf{COO = (F\$+R\$+Y\$)/(L*T*Y*U)} \quad (1)$$

where

$$\mathbf{U = 1 - (SM+USM+A+S+Q+E)/H} \quad (2)$$

A1-2.1.1 Definitions for each term are repeated here for convenience.

F$	=	annualized fixed costs, $
R$	=	annualized recurring costs, $
Y$	=	annualized yield costs, $
L	=	useful life of equipment, yrs
T	=	tool throughput, wafers/yr
Y	=	composite yield, dimensionless
U	=	equipment utilization, dimensionless
SM	=	scheduled maintenance, hrs/week
USM	=	unscheduled maintenance, hrs/week
A	=	assist time, hrs/week
S	=	standby time, hrs/week
Q	=	production qualification time, hrs/week
E	=	process engineering time, hrs/week
H	=	total number of production hours scheduled per week, hrs/week

A1-2.2 *F$* is computed by summing the fixed cost categories CF1.0–CF1.6 listed in E35. *R$* is computed by summing the recurring cost categories CR1.0–CR5.2 and CR7.0 listed in E35. *Y$* is computed by summing the recurring cost categories CR6.0–CR6.3 listed in E35. The parameters *L* and *T* are input directly into the model. The model computes *Y* from two user inputs. The model computes *U* from inputs for *SM*, *USM*, *A*, *S*, *Q*, *E*, and *H*.

A1-2.3 While the example uses specific currency units, any currency may be used as long as it is applied consistently throughout the document.

A1-3 Sample Input to Model

A1-3.1 To effectively illustrate use of the COO model, it was run with a hypothetical set of input data. This input data is listed in Table A1-1. When studying this example, the user should remember that parameter values are for the gas delivery equipment only, not the entire process tool.

A1-4 Sample Model Output

A1-4.1 The model computes each term in the numerator of Equation 1 and then sums these results and applies the denominator to get COO. To enhance the user’s understanding of the components of COO, this appendix and the spreadsheet show interim results. For the set of inputs listed in Table A1-1, *F$* are shown in Table A1-2, *R$* are shown in Table A1-3, and *Y$* are shown in Table A1-4. Each of these terms is computed from the cost factors listed in E35. The italicized rows in Tables A1-2, A1-3, and A1-4 correspond to these cost factors and show the subtotal for that cost factor. The breakdown for each cost factor is shown in the rows below it.

A1-4.2 Tables A1-2, A1-3, and A1-4 show costs for years 1 through 7. The last year is based on user input. It is the longest of useful life or depreciable life. In the example shown, depreciable life was set to 7 years and useful life was set to 5 years. The depreciable life was deliberately made longer than the useful life to illustrate the feature of the spreadsheet that allows these two parameter values to differ. This often occurs in practice since equipment is sometimes “obsoleted” before it is fully depreciated. The user can enter any value up to 10 for these two parameters.

A1-4.3 Table A1-5 shows the COO results.

Table A1-1 Input Data for COO Model

Row [1]	*Parameter*	*Units*	*Sample Value*
TA8	*This Section Contains Equipment Procurement Cost Data*		
TA9	**Equipment Cost Data**		
TA10	For Straight Line Depreciation, input SLN. For Fixed Declining Balance Depreciation, input DB. For Double Declining Balance Depreciation, input DDB.	not applicable	SLN
TA11	Floor Space Rental Rate	$\$/m^2/yr$	2691
TA12	Gas Box (or Stick or Component) Purchase Price	$	100,000

4 The row numbering convention is the Table number followed by the row in that table.

Table A1-5 COO for the Input Data Listed in Table I.

For the results shown in the table, Useful Life of Equipment = 5 yrs; Depreciable Life of Equipment = 7 yrs; Tool Throughput = 33 wafers/hr = 277,200 wafers/yr; Equipment Utilization = 0.9855.

Row		*Year 1*	*Year 2*	*Year 3*	*Year 4*	*Year 5*	*Year 6*	*Year 7*	*Formula*
TE1	Fixed Costs, $	96,800	15,718	15,718	15,718	15,718	14,843	14,843	For Year n, =IF(TA13>=1,TB36 value for year n,"Asset Fully Depreciated")
TE2	Recurring Costs, $	64,035	65,956	67,935	69,973	72,072	Asset Retired	Asset Retired	For Year n, =IF(TA15>=1,TC28 value for year n,"Asset Retired")
TE3	Yield Costs, $	0	0	0	0	0	Asset Retired	Asset Retired	For Year n, =IF(TA15>=1,TD5 value for year n,"Asset Retired")
TE4	Total Costs, $	160,836	81,674	83,653	85,691	87,790	14,843	14,843	=Σ(TE1:TE3)
TE5	Cumulative Fixed Costs, $	96,800	112,518	128,236	143,954	159,672	174,515	189,358	=Year n value in row TB37
TE6	Cumulative Recurring Costs, $	64,035	129,992	197,927	267,900	339,973	339,973	339,973	=Year n value in row TC29
TE7	Cumulative Yield Costs, $	0	0	0	0	0	Asset Retired	Asset Retired	=Year n value in row TD6
TE8	Cumulative Total Costs, $	160,836	242,510	326,163	411,854	499,644	514,487	529,330	=Σ(TE5:TE7)
TE9	Yearly Cost, $/wafer	0.5887	0.2990	0.3062	0.3137	0.3214	Asset Retired	Asset Retired	=IF(TA15>=1,TE4/TA15/(TA24*TA29)/(TA141*TA142),"Asset Retired")
TE10	Cumulative Cost, $/wafer	0.5887	0.4439	0.3980	0.3769	0.3658	0.3767	0.3875	=IF(TA15>=1,TE8/TA15/(TA24*TA29)/(TA141*TA142),TE8/TA15/TA15/(TA24*TA29)/(TA141*TA142))

Total Cost = $529,330

Total COO = $0.3875/wafer. (The Cumulative Cost in the last year equals the Total COO.)

NOTICE: SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of the guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this guideline may require use of copyrighted material or of an invention covered by patent rights. By publication of this guideline, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this guideline. Users of this guideline are expressly advised that determination of such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

RELATED INFORMATION 1
COST OF OWNERSHIP

NOTE: This related information is not an official part of SEMI E35 and is not intended to modify or supercede the official guideline. This related information has been derived the development of the guideline and was felt by the committee to be useful supplemental material. Publication was authorized by vote of the responsible committee. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 A discussion of cost of ownership is provided in this related information to suppliment the presentation within the guideline.

R1-2 The COO calculation is shown graphically in Figures R1-1 and R1-2. These figures are not a flow-chart, but rather meant to illustrate the elements of the calculation.

R1-3 The left side of the diagram shows various cost factors, while the rate side shows how they are incorporated in the calculation. The upper section is the determination of the number of systems required to process the specified value. In the middle section, the fixed costs are converted to an annual basis and combined with the recurring costs. The total cost is then divided by the number of good wafer equivalents.

R2-2 *Cost Center Default Values*

CF1.0 Equipment

Default	Sum of subcategories.
Comment	

CF1.1 Equipment: Depreciation

Default	5 year straightline depreciation.
Comment	

CF1.2 Equipment: System Qualifications

Default	Actual equipment specification, consumable costs, and fully burdened man-hour cost by personnel category. Labor rates: Operator \$25/hr; Maintenance: \$25/hr; Supervision: \$75,000/yr; Engineering: \$100,000/yr.
Comment	

CF1.3 Equipment: Installation

Default	Actual equipment specification and cost to semiconductor manufacturer.
Comment	

CF1.4 Equipment: Training

Default	Actual equipment specification, consumable costs, and fully burdened man-hour cost by personnel category. Labor rates: Operator \$25/hr; Maintenance: \$25/hr; Supervision: \$75,000/yr; Engineering: \$100,000/yr.
Comment	

CF1.5 Equipment: Moves & Rearrangements

Default	Actual cost to semiconductor manufacturer.
Comment	

CF1.6 Equipment: Floor Space

Default	Actual equipment specification and floor space including safety aisles by cleanroom class, including:
	Class 1: \$350/ft^2
	Class 10: \$250/ft^2
	Class 100: \$100/ft^2
	Class 100+: \$ 50/ft^2
Comment	

CR1.0 Material

Default	Sum of subcategories.
Comment	

CR1.1 Material: Test/Filler Wafer

Default	Actual equipment specification and cost of test/ filler wafers. Test Filler wafer: \$100.
Comment	

CR1.2 Material: Utilities

Default	Actual equipment specification and cost to semiconductor manufacturer.
Comment	

CR1.3 Material: Supplies

Default	Actual equipment specification and cost to semiconductor manufacturer.
Comment	

CR1.4 Material: Waste Disposal

Default	Actual equipment specification and cost to semiconductor manufacturer.
Comment	

CR2.0 Consumables

Default	Actual equipment specification and cost to semiconductor manufacturer.
Comment	

CR3.0 Maintenance

Default	Sum of subcategories.
Comment	

CR3.1 Maintenance: Labor

Default	Actual equipment specification and fully burdened man-hour cost of maintenance. Labor rates: Maintenance \$25/hr.
Comment	

CR3.2 Maintenance: Spare Parts

Default	Actual equipment specification and inventory carrying cost to semiconductor manufacturer.
Comment	

CR3.3 Maintenance: Repair Parts

Default	Actual equipment specification and cost to semiconductor manufacturer.
Comment	

CR3.4 Maintenance: Service Contracts

Default	Actual equipment specification.
Comment	

CR3.5 Maintenance: Training

Default	Actual equipment specification.
Comment	

CR4.0 Labor

Default	Sum of subcategories.
Comment	

CR4.1 Labor: Operation

Default	Actual equipment specification and fully burdened man-hour cost for operators. Labor rates: Operator $25/hr.
Comment	

CR5.0 Support Personnel

Default	Sum of subcategories.
Comment	

CR5.1 Support Personnel: Supervision

Default	
Comment	

CR5.2 Support Personnel: Engineering

Default	Actual equipment specification and fully burdened man-hour cost for engineering. Labor rates: Engineering $100,000/yr.
Comment	

CR6.0 Scrap

Default	Sum of subcategories.
Comment	

CR6.1 Scrap: Equipment Yield

Default	Actual equipment specifications and cost of wafer lost at that point in the process. Equipment Yield: 99.99%. Value of incoming wafer: $250.
Comment	

CR6.2 Scrap: Defect Yield

Default	Calculated from actual equipment specifications, device parameters, and cost of wafer lost at the end of the process. Fault probability: 0%. Value of completed wafer: $500.
Comment	

CR6.3 Scrap: Parametric Yield

Default	Actual equipment specifications, device parameters, and cost of wafer lost at the end of the process. Parametric Yield: 100%. Value of completed wafer: $500.
Comment	

CR7.0 Support Services

Default	Actual equipment specifications and cost to semiconductor manufacturer.
Comment	

Supplemental supporting values:

Production schedule: 168 hours/week

Operator/maintenance productivity: 80%

Wafer size: 150 mm

Water coverage: 80%

NOTE: These values represent a 150 mm wafer fab running standard products at 0.8 µm design rules. This was a state-of-the-art factory in 1990.

NOTE 1: Revised from 1995 version.

NOTICE: SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of the guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this guideline may require use of copyrighted material or of an invention covered by patent rights. By publication of this guideline, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this guideline. Users of this guideline are expressly advised that determination of such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E35.1-95
GUIDE FOR COST OF EQUIPMENT OWNERSHIP COMPARISON METRIC

1 Purpose

1.1 The purpose of this guide is to provide a standard constrained version of the Cost of Ownership for Semiconductor Manufacturing Equipment Metrics Guide to provide a baseline metric for comparing cost effectiveness of competitive factory equipment subsystems in the semiconductor industry. The major constraints are the inclusion of only Equipment Yield and the exclusion of the Cost of Yield Loss consisting of defect limited yield and parametric yield.

1.2 The guide establishes well-defined practice to facilitate cost comparisons of equipment by using definitions, classifications and methods necessary to build a useful cost of equipment ownership comparator as a constraint version of SEMI E35. The guide should facilitate communication about cost of ownership.

2 Scope

2.1 This guide is a subset of a full COO calculator as presented in SEMI E35 and constitutes a fully conforming standard constraint version. The baseline metric is meant to reflect those equipment aspects over which an equipment supplier has responsibility and seeks to minimize aspects which couple costs for individual equipment to the entire factory system. The use of the metric is for competitive evaluation of equipment sets to be used for a specific process step.

2.2 Effective use of the metric to build a COO model requires identification of the constraints, parameter values within the adopted category classification. The primary calculators should, where possible, use direct values for inputs rather than deriving them from secondary models or using the default values provided in Related Information 1 and 2 in SEMI E35. A COO model requires data for many parameters. Default data for the COO is provided within this document and may be updated periodically through support documents.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI E10 — Guideline for Definition and Measurement of Equipment Reliability, Availability, and Maintainability

SEMI E35 — Guideline for Cost of Ownership for Semiconductor Manufacturing Equipment Metrics

SEMI Compilation of Terms

4 Terminology

All terminology in this guideline is defined in SEMI E35.

5 Cost of Equipment Ownership Comparator

The Cost of Equipment Ownership Comparator (CEOC) metric is the incremental cost added to a good wafer or IC device flowing through a volume sized process system embedded in a factory environment for a specified lifetime. The metric is expressed as Cost per Good Wafer Equivalent for one pass through the system. CEOC should reflect the full cost of embedding and operating in a factory environment a process system needed to accommodate a specified number of wafers but does not include defect yield or parametric yield loss.

5.1 *CEOC: Fixed and Recurring Costs* — Determining the Cost of Ownership requires enumerating all of the Fixed and Recurring costs. Fixed costs are those incurred once and are usually associated with the acquisition and incorporation of equipment into the factory. Recurring costs are those which arise on an annual basis from the operation and maintenance of the equipment.

5.2 *Yield*

5.2.1 Production yield (PY) is often tied to a large number of factors which are principally the responsibility of the IC manufacturer and equipment comparisons for production yield should be done directly in the context of the production flow. Yield is a metric of the percentage of the wafer volume that results in good wafers and enters the picture in a number of ways which can complicate comparisons. Yield-related comparisons of equipment should be dealt with directly rather than lumping them into the CEO.

$$\text{CEO} = \overbrace{\left(\begin{array}{c}\text{annualized}\\ \text{Fixed Costs}\\ \text{per system}\end{array} + \begin{array}{c}\text{annualized}\\ \text{Recurring Costs}\\ \text{per system}\end{array}\right)}^{\substack{\text{COST of}\\ \text{Embedding + Operating}}} * \frac{\begin{array}{c}\text{Volume Required}\\ \text{\# Systems}\end{array}}{\begin{array}{c}\text{Good Units}\\ \text{Per Year}\end{array}}$$

5.2.2 Particles additions for example are often used as a predictor of yield loss. Equipment should be compared directly on the basis of particles or other direct metrics such as uniformity.

5.2.3 The Cost of Equipment Ownership should only reflect Equipment Yield. The percentage of wafers which can be passed to the next step can be based on any criteria, such as broken wafers or wafers determined to be defective by inspection or test.

5.3 *Life* — Time over which the fixed and recurring costs are spread for the annualized basis. Tax Life is customarily used in COO based upon standard accounting practice.

COO Lifetimes

1. Tax Lifetime - Depreciation
2. Equipment Production Lifetime

5.4 *System Throughput* — Wafers per hour capability for the process system.

5.5 *Volume Requirement*

5.5.1 The volume requirement is the wafer or IC (unit) flow to be processed. The volume requirement can be derived from specification of the product wafers or IC devices needed corrected for yield and the required number of other wafers which might be designated as test, dummy, or monitor wafers. One complication in accurately dealing with the volume requirement is that the volume of wafers actually reaching the equipment will depend on the volume loss from equipment yield for all the prior steps.

5.5.2 For CEOC, volume should be dealt with parametrically based upon factory wafer starts. For multi-chamber equipment, the impact of added chambers to increase capacity should be included as well as the impact of adding whole systems.

5.6 *Good Wafer Equivalents (GWE)* — GWE is derived from the number of good product die at wafer probe and is expressed as completely good wafers.

5.7 *Systems Required* — See SEMI E35.

6 Reporting Results

Conform to SEMI E35.

7 Limitations

7.1 Certain factors are more difficult than others to accurately determine. Thus, the accuracy of a COO calculation may be prone to a variety of errors or omissions. In addition, line balance considerations are not included in cost of ownership calculation.

7.2 A COO calculation may have more detail than presented explicitly in this guide. The structure of the guide however allows for the proper handling of these situations.

8 Procedures

8.1 The CEOC algorithm requires the specification of the volume level and the enumeration of appropriate fixed and recurring costs associated with processing that volume. The CEOC metric is a function expressed as the sum of a number of categories which constitute a classification system as given in SEMI E35. Each item in the classification system should be defined, a method for evaluating its expression given, and default values or handling specified. The cost of equipment ownership is a sum over the elements in the Category Table as expressed in Equation 2 and defined in SEMI E35.

8.2 Each item in the classification system is defined, a method for evaluating its expression given, and default values or handling specified. All costs must be assigned through the classification system and calculated per system for the number of production hours.

$$\text{CEOC} = \left| \sum_{j} F_{0j} + \sum_{k} R_{0k} \right| * \left(\frac{\text{Volume Required} \ \# \ \text{Systems}}{\# \ \text{Good Units per year}} \right) =$$

$$\left(\sum_{ij} F_{ij} + \sum_{kl} R_{kl} \right) * \left(\frac{\text{Volume Required} \ \# \ \text{Systems}}{\# \ \text{Good Units per year}} \right) \qquad (2)$$

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E43-0301
GUIDE FOR MEASURING STATIC CHARGE ON OBJECTS AND SURFACES

This guide was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org December 2000; to be published March 2001. Originally published in 1995.

This document was entirely rewritten in 2001.

1 Purpose

1.1 The purpose is to establish a guide for reproducible measurement of electrostatic charge(s) on any surface or object, consistent with the scope and limitations set forth below.

2 Scope

2.1 The measurement methods described herein can be applied to characterize the general electrostatic charge level(s) on objects and surfaces in all environments. Acceptable instrumentation, calibration, and measurement techniques are described in this document. Appendices include background information on the equipment specified and calibration procedure, as well as information and advice on performing a useful general static survey.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 Direct measurement of charge usually requires the use of a coulombmeter. Charges on an isolated conductor can be measured by transferring the charge into the coulombmeter by contacting the isolated conductor with the coulombmeter input probe. Charges on isolated conductors and insulators can be measured by transferring the charged object into a Faraday enclosure that is connected to the coulombmeter. These measurements can be relatively precise if care is taken in the transfer process to avoid changing the charge level when making the measurements.

3.2 Direct measurement of charge is often impractical. In these instances, charge is indirectly evaluated by detecting the electrostatic field from a charged surface using an electrostatic fieldmeter or an electrostatic voltmeter.

3.3 This guide does not describe instrumentation and techniques capable of making highly precise measurement of electrostatic charge. It is not suitable for measurement of electrostatic charge on small objects, such as packaged devices (i.e., reading(s) obtained are indicative/general area and not precise/minute). No methods of preconditioning the surface prior to measurements and no methods of characterizing the basic electrostatic performance of materials, such as tribocharging, resistance, and decay rate are a part of this document. Measurements made using this guide on the same surface or object may differ due to differences in the environment or history of the surface or object between the times any two measurements are made.

4 Referenced Standards

4.1 None.

5 Terminology

5.1 *electrostatic discharge (ESD)* — the rapid spontaneous transfer of electrostatic charge induced by a high electrostatic field.

5.2 *ground* — a conducting connection between an object, electrical equipment, and earth, such as the portion of an electrical circuit of the same electrical potential as earth.

5.3 *grounded* — connected to earth or some other conducting body that serves in the place of earth.

6 Safety

6.1 *Measurements of Very High Static Potentials (> 30,000 Volts)* — Measurements of very high static potentials (> 30,000 V) may need to be done at larger distances to avoid exceeding the measurement range of the meter and/or an ESD event to the meter.

6.2 *Measurements on Moving Objects or Surfaces* — Care should be taken, when attempting to read electrostatic charges on moving objects or surfaces, to maintain correct distance and avoid any contact; this is to assure “good” readings with no mechanical damage or personal injury.

6.3 *Measurements Using Electrostatic Voltmeters* — Avoid handling electrostatic voltmeter probes during operation as their surfaces may be at elevated potentials that represent a shock hazard to the operator.

7 Equipment and Performance Verification Methods

7.1 *Equipment*

7.1.1 *Electrostatic Locator/Field Sensor/Field Meter* — An electrostatic fieldmeter measures the value of the electrostatic field at its sensor. Electrostatic fieldmeters are calibrated and recommended for use at a particular distance from the charged object. Fieldmeters are best suited for making general surveys or audits, for making measurements of surfaces at very high potentials *(charge levels)*, and for making measurements when long-term stability is not important. They are not well suited for measurements of surfaces with very low potentials or when high spatial resolution of the surface potential is needed.

7.1.1.1 The electrostatic locator/field sensor/field meter will henceforth be referred to as “the fieldmeter.” Note that for measurements to be taken in the presence of air ionization, a chopper stabilized fieldmeter is required. The fieldmeter must be capable of making field measurements at a distance of 2.54 centimeters (cm) = 1 inch or less, from the field source to the sensor for this guide, as written. However, see Section 7.2.5 for fieldmeters that are operated at fixed distance(s), and adjust values in this document where applicable.

7.1.2 *Electrostatic Voltmeter* — An electrostatic voltmeter nulls the electrostatic field at its sensor (probe). An electrostatic voltmeter indicates the presence and approximate level of the charge(s) creating the electrostatic field. Under appropriate conditions, electrostatic voltmeters provide a better approximation of the charge level as compared to electrostatic fieldmeters. Electrostatic voltmeters are relatively free of drift and more environmentally stable as compared to fieldmeters.

7.1.2.1 Electrostatic voltmeters are well suited for fixed installation in equipment. Electrostatic voltmeters exhibit a high degree of accuracy that is independent of the distance from the charge. Thus, they are considered better suited for making more accurate and repeatable measurements as compared to fieldmeters. The probe can be located very close to a charged surface without arc-over, and, under appropriate conditions, can resolve a small spatial area on a surface.

7.1.2.2 Electrostatic voltmeters are best suited for making measurements of surfaces at potentials below 20kV, or when a calibrated or fixed distance from the probe to the surface cannot be maintained. They are also best suited for measuring low surface potentials, or when it is desired to resolve a small area on the surface. Electrostatic voltmeters are unsuitable for measuring surfaces at very high potentials, such as above 20kV.

7.1.2.3 The electrostatic voltmeter will henceforth be referred to as “the voltmeter.”

7.1.3 *Electrometer* — An electrometer is a contact voltmeter with a very high input impedance. Ideally, this input impedance would be infinite. In practice, it is limited by intrinsic physical materials properties of insulators and by stray leakage paths between the input terminals. Low voltage electrometers (below 200 Volt) have typical input resistances of 10^{14} ohms, accuracies better than 0.1%, and can resolve microVolt type potentials. High voltage electrometers (Kilovolts) usually rely on resistive voltage dividers and have typical input resistances in the 10^{11} ohms range with accuracies in the 1% range. It is important to evaluate and understand the burden that the input impedance of an electrometer represents when measuring voltage potentials on very small charged structures.

7.1.4 *Charged Plate Monitor* — A charged plate monitor is an instrument typically used to monitor the performance of air ionization equipment. Monitoring is done with an electrically isolated 15 cm × 15 cm (6 inches × 6 inches) metal plate, henceforth referred to as “the plate.” The instrument typically provides a means to charge the plate to a known voltage (1000 or 5000 volts of either polarity), a plate sensor to determine the voltage on the plate, and timing circuitry to determine the time required to discharge the plate to a percentage of its initial charge. For the purposes of this guide, the charged plate monitor, or a separate isolated plate assembly, can be used for performance verification purposes as explained in Section 7.2.

7.2 *Equipment Performance Verification (Confidence Test)*

7.2.1 *Performance Verification of a Coulombmeter* — Refer to Figure 1.

7.2.1.1 Zero the coulombmeter prior to each measurement.

7.2.1.2 Maintain a reference calibration capacitor. It should be a polystyrene or polypropylene 10 nF capacitor (Mallory SX-110 or equivalent). Measure the value of the capacitor to better than 1%. It is important to handle the reference calibration capacitor very carefully. Do not hold the capacitor by its body or discharge it by touching both leads with the fingers. Hold the capacitor by one lead only. Use a clip lead connected between ground and this lead of the capacitor to maneuver the other lead of the capacitor between the “hot” side of the charging source and the input terminal of the coulombmeter.

7.2.1.3 Charge the reference calibration capacitor to 1 volt with a charging source (power supply). Calculate the amount of charge on the capacitor by multiplying the voltage by the value of the capacitor. Example: 1V x 10 nF = 10 nC of charge.

7.2.1.4 Disconnect the charging source from the capacitor.

7.2.1.5 Connect the coulombmeter input probe to the capacitor and discharge the capacitor into the coulombmeter. The coulombmeter should indicate the calculated value.

7.2.2 *Performance Verification of Fieldmeters and Voltmeters* — Refer to Figure 2.

7.2.2.1 *Choosing Test Voltage(s)* — Choose one or more test voltage(s) from Table 1, based upon the electrostatic field level of concern:

Table 1 Test Voltages

Field of Concern	*Test Voltage*
Under 4,000 volts/meter or 100 volts/2.5 cm	100 volts
Under 40,000 volts/meter or 1000 volts/2.5 cm	1,000 volts
Over 200,000 volts/meter or 5,000 volts/2.5 cm (See NOTE 1.)	5,000 volts

NOTE 1: If fieldmeter or voltmeter performance verification is needed above 5,000 volts, it is left to the user to select values using the table as guide.

7.2.2.2 *Instrument Performance Verification* — Charge a conductive test plate to the desired verification voltage. Use of a suitable power supply or a charged plate monitor for test purposes is recommended.

7.2.2.3 *Assuring Meters and Operator Are Grounded* — Assure that the fieldmeter, voltmeter and operator are grounded. Turn on the meter and zero it as required according to manufacturer's instructions.

7.2.2.4 *Directing or Pointing the Sense Head* — Direct or point the sense head of the fieldmeter or voltmeter at the center and parallel to the surface of the plate at a distance at least twice the manufacturer's recommended measurement. Slowly move the sense head toward the center of the charged plate until a reading equal to the voltage applied to the plate in Section 7.2.2.1 above is displayed by the meter. Measure and record the distance from the sense head to the surface to the plate. Using the plate voltage from Section 7.2.2.1 above and the recorded distance, compute the field strength for the fieldmeter. See Figure 2, Fieldmeter and Voltmeter Verification Check.

7.2.2.5 *Alternative to Section 7.2.2.4* — Take measurements at a specified/fixed distance per manufacturer's instructions. Locate the sense head of the fieldmeter or voltmeter as in Section 7.2.2.4, but, at specified distance; reading displayed (on meter) should be within 5% of applied voltage to plate.

NOTE 1: Section 7.2.2.4 or 7.2.2.5 should be applicable to most meters. However, in every case, the electrostatic fieldmeter or voltmeter manufacturer's instructions should be read, understood, and followed.

7.2.2.6 *Other Desired Test Voltages* — Repeat Sections 7.2.2.4 and 7.2.2.5 for any other desired test voltages.

7.2.3 *Performance Verification of an Electrometer* — It is good practice to occasionally check the performance of the electrometer by connecting it to a known voltage source, and comparing its readings with readings taken by another reference voltmeter.

7.2.4 *Meter Stability* — All measurement devices should be turned on and pre-conditioned for as long a warm-up period as recommended by the manufacturer

7.2.4.1 Reset (zero) the coulombmeter prior to each measurement.

7.2.4.2 Check the zero on the fieldmeter or voltmeter as specified by the manufacturer. Usually this is done while the probe is positioned to view a grounded surface. If the zero of the meter has drifted by more than 5% of the test voltage for any range contained in Table 1, the meter is not suitable for use for measurements over that range. It may be suitable for use over other ranges contained in Table 1, using other test voltages. Reverify the meter's calibration at the selected test voltage.

7.2.4.3 *Zeroing an Electrometer* — Except on some older analog models, there are usually no provisions to zero an electrometer. Some electrometers with analog or digital read-outs do allow offsetting of a reading, as well as relative (delta) measurements. However, the electronic zero of the electrometer is usually set by the manufacturer, and should be part of the normal calibration. It is good practice to occasionally check the zero by shorting the input terminals together and verifying that the zero reading is within the manufacturer's specifications.

7.2.4.4 See Related Information 1 for notes on equipment accuracy and limitations.

8 Sampling

8.1 Sampling methods for this guide should be determined by the requirements of the user's application. Electrostatic surveys can be repeated at different times to make them more representative of actual static charge conditions in the surveyed area. The results will vary due to environment (e.g., humidity) and workstation setup/conditions. However, any measurement that is in excess of a (user) defined maximum or that is a benchmark value, should be repeated more than once, after performing a zero check of the measuring equipment. This is to validate previous reading(s) and/or establish a range/bounds in the case of varying-moving fields on previous reading(s).

9 Test Methods & Measurements

9.1 *Coulombmeter Measurements*

9.1.1 *Verifying the Coulombmeter* — Verify the performance of the coulombmeter as in Section 7 above. Check/reset the zero before each measurement and/or per manufacturer's instructions. Assure that the coulombmeter and operator are grounded.

9.1.2 *Equipment Selection* — Use a coulombmeter for direct measurement of charge. A feedback-type coulombmeter is recommended for charge measurements for the most complete transfer of charge. Shunt-type coulombmeters do not completely transfer charge and are not as straightforward to use as feedback-type coulombmeters. When using a Faraday enclosure, the Faraday enclosure must be large enough to hold the objects to be measured. The Faraday enclosure is used to measure charge on insulating materials as well as on conductors.

9.1.3 *Measurements* — Best results are achieved when all surfaces surrounding the measurement area are grounded (to minimize the effects of stray fields on the measurement) and when a consistent, systematic handling method is used during the measurement process. The operator should be grounded using a grounded wrist strap.

9.1.3.1 *Isolated Conductors* — To measure the charge on an isolated conductor, touch the lead from the coulombmeter to the isolated conductor.

9.1.3.2 *Faraday Enclosure Measurements* — Refer to Figure 3. To measure the charge on an object, carefully pick up the object with an insulated tool and place the charged object into the Faraday enclosure. Special handling considerations: Be careful not to add or subtract any charge in the process of moving the charged object into the Faraday enclosure. Don't let the charged object rub or slide against any other surface, as this may add or subtract charge from the object.

9.1.4 *Limitations* — Do not attempt to measure charges of magnitudes that are below the drift rate of the coulombmeter.

9.2 *Electrostatic Fieldmeter Measurements*

9.2.1 *Verifying the Fieldmeter* — Verify the performance of the fieldmeter as in Section 7 above. Check/reset the zero periodically and/or per manufacturer's instructions. Assure that the fieldmeter and operator are grounded.

9.2.2 *Measurements* — Measurements made to this guide should be taken/reported in units that conform to the customer specifications. Most common fieldmeters manufactured to date have operating instructions that reflect the user doing calibration and taking measurements in English units of volts/inch or volts at a fixed distance in inch(es) and in these cases, raw data are reported/listed directly. The international community specifies that units shall be in SI (Standard International) Metric units and the SI conversion factor in Section 7.1.1.1 will apply. However, by definition, electric field is expressed in volts per meter, and thus would be expressed according to Table 2.

9.2.2.1 For instance, when using a meter calibrated only at 100 volts, measurements under 4,000 volts/m would be expressed to the nearest 400 volts/m. Measurements over 4,000 volts/m would be expressed as > 4,000 volts/m. For a meter calibrated to all three voltages, measurements under 4,000 volts/m would be expressed to the nearest 400 volts/m, measurements between 4,000 and 40,000 volts/m would be expressed to the nearest 4,000 volts/m, and measurements over 40,000 volts/m would be expressed to the nearest 40,000 volts/m.

Table 2 Measurement Units

Test Voltage	*For Readings of*	*Express in Multiples of*	*For Readings of*	*Express as*
100 V	< 4,000 V/m	400 V/m	> 4,000 V/m	> 4,000 V/m
1,000 V	< 40,000 V/m	4,000 V/m	> 40,000 V/m	> 40,000 V/m
5,000 V	< 200,000 V/m	20,000 V/m	> 200,000 V/m	multiples of 200,000 V/m

Note: Measurements above 1000 volts/2.54 cm may be made based on verification of the meter at 1000 volts where less precision is acceptable due to safety concerns with verification equipment/setup or availability of such equipment.

9.2.3 *Measurement Limitations* — Measurements made to this guide are only valid for surfaces that are flat to a radius of 1.5 times the measurement distance from a point directly below the sensor head. For surfaces that are not flat, measurements should be made by moving the sensor over the surface such that the specified measurement distance is maintained as closely as possible. These measurements may only be stated as a range, with rounding as applicable to the meter's measurement range according to Section 9.2.2. See Figure 4, Example of a Survey of a Carrier of Semiconductor Wafers. See Related Information 2 for notes on test methods environment and measurements.

9.3 *Electrostatic Voltmeter Measurements* — Refer to Figure 4.

9.3.1 *Verifying the Voltmeter* — Verify the performance of the voltmeter as in Section 7 above. Check/reset the zero periodically per manufacturer's instructions. Assure that the voltmeter and operator are grounded.

9.3.2 *Selecting the Voltmeter* — Select an electrostatic voltmeter with a measurement range consistent with the anticipated levels of charge on the objects to be measured. The selection of too high a measurement range will sacrifice voltage resolution, while selection of too low a range will cause out-of-range operation (saturation).

9.3.2.1 To measure moving objects, select an electrostatic voltmeter with a response speed fast enough to detect the objects when they are moving past the electrostatic voltmeter probe at the highest anticipated velocity.

9.3.2.2 Select a side- or end-viewing probe for the electrostatic voltmeter as is best suited to view the target object or surface when the probe is installed in an apparatus.

9.3.3 *Measurements* — Position the probe in front of the surface to be measured. Best results are obtained when the probe is placed less than two (probe) aperture diameters from the object or surface to be measured. At these closer spacings, the effects of extraneous fields are minimized.

9.3.3.1 To resolve a small surface area, the distance between the probe and the surface-under-measurement must be less than $1/5^{th}$ of the diameter of the surface area to be measured. At wider spacings the surface area resolved by the probe will exceed the surface area of interest, and measurement accuracy may be reduced together with the possibility of introducing effects of extraneous fields to the measurement.

9.3.4 *Measurement Limitations* — Voltage levels on isolated conductors can be measured. Insulators do not have a uniform surface charge distribution. Therefore, it is considered that voltage levels measured on insulators indicate an electrostatic field strength in a particular area.

9.4 *Electrometer Measurements* — Measuring with an Electrometer is very similar to measuring with any other voltmeter or multimeter.

9.4.1 Connect the “common” terminal of the electrometer through a test lead to the reference plane or ground. Connect the “hot” or signal lead to the object or test point of interest. Some electrometer measurements will use a separate wire or shield connected to the electrical ground or a guard ring. Connect this as recommended by the manufacturer of the equipment.

9.4.2 The major difference between the ordinary voltmeter and the electrometer is the orders of magnitude higher input impedance of the electrometer. An electrometer will therefore pick up voltage signals produced by stray electric fields, potentials associated with noise currents, and artifacts caused by intentional or unintentional ionization of the ambient air when measuring high voltages. An electrometer can, for example, be used to measure the triboelectric and the piezoelectric properties of a piece of coaxial cable: connect the cable under test to the electrometer, and flex it or tap on it with a finger. The voltages induced on the center conductor can be measured by the electrometer.

10 Certification

10.1 Certification to survey areas to this guide is for the person doing the certification (certifier) to assure that the person being certified (certifyee) can calibrate the meter and make acceptable measurement of known static field(s) per Section 7 and applicable example(s) per Section 9. The certifier shall be someone qualified by education and/or training to calibrate and make measurements with the equipment called out in this guide or someone previously certified. The ESD Association conducts such training programs and the National Association of Radio and Television Engineers (NARTE) administers an ESD Engineer and ESD technician certification program.

10.2 *Demonstrating Ability to Verify the Performance of the Meter Against Known Source* — The certifyee shall charge the test plate, zero the meter, and perform the measurement a minimum of two times per Section 7; record values per Section 11. Readings obtained shall be within 5% of expected values.

10.3 *Demonstrating Ability to Measure Example Item(s) Acceptably* — The certifier will have charged/uncharged example(s) of items/objects for measurement of static field(s) by certifyee(s) a minimum of two times per Section 9; record values per Section 11.

10.4 *Certifying* — Readings obtained per Section 10.2 shall be within 12% of expected values and methodology of obtaining readings shall be acceptable per certifier observation(s). A permanent record of certification is realized by certifyee when certifier signs record sheet(s) for file in personnel records and/or when certifier issues a certificate. Refer to Section R1-3.

11 Documentation

11.1 Meter calibration check(s), benchmark or laboratory measurements, items/areas surveys, and/or any other electrostatic field measurements should be recorded in permanent records. Recorded are initial reading, second/validation reading, and any subsequent readings taken to acceptable range/bound levels observed. Record sheet(s) should show meter used, area (name), location, date, and items listed opposite readings, name of person who took readings, and space for comments.

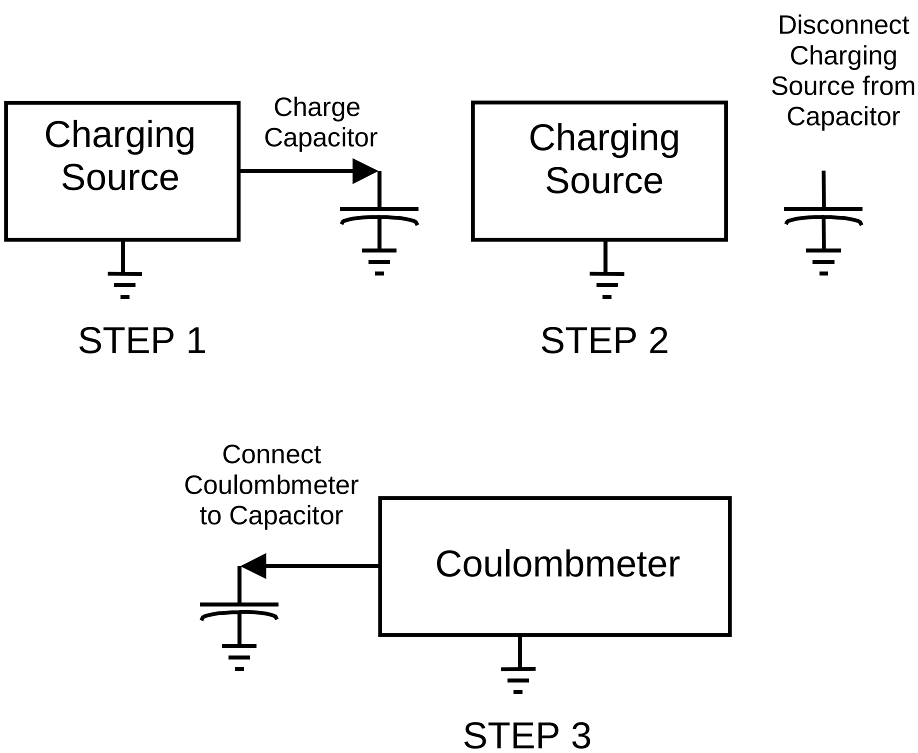

Figure 1
Verifying Performance of the Coulombmeter

A) Connect meter directly to charged plate ground reference.
B) Meter approximately 2.54 cm and parallel to charge plate.
C) Meter reading should be within 5% of voltage applied to plate.
D) Assure that both the meter and the operator are properly grounded.

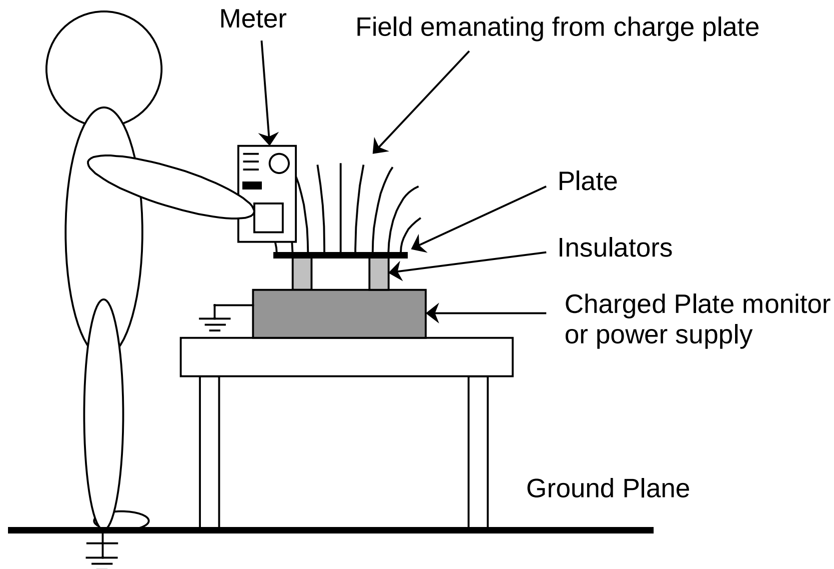

Figure 2
Fieldmeter and Voltmeter Verification Check

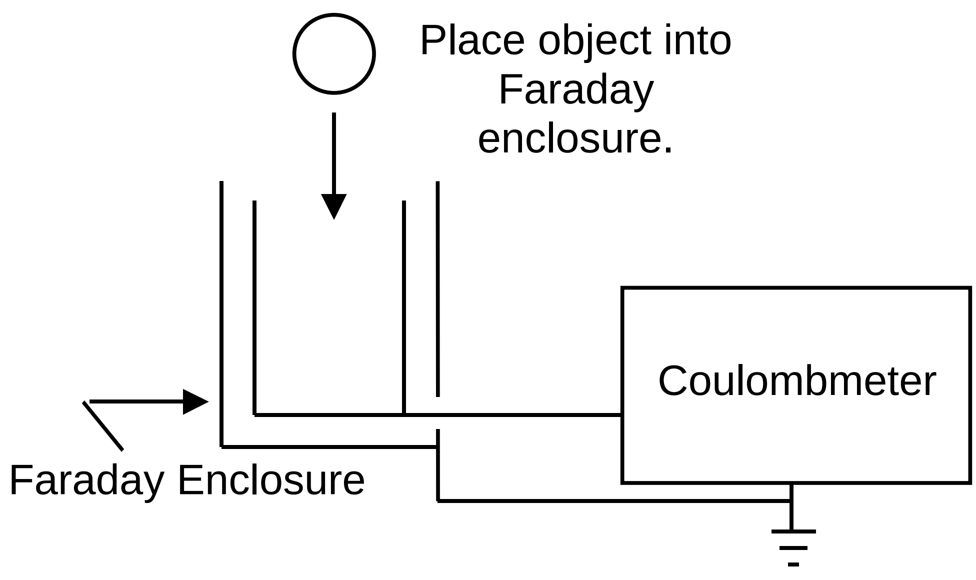

Figure 3
Measurement With a Coulombmeter and Faraday Enclosure

A) Make sure meter is properly grounded according to manufacturer's instructions.
B) Scan approximately 2.54 cm along both sides and ends of carrier.
C) Scan approximately 2.54 cm length of carrier and top-center of wafers with meter.
D) Note high-low values for B) & C).
E) Assure that the operator is properly grounded.

APPENDIX 1
MEASUREMENT SELECTION MATRIX

NOTE: This appendix offers information related to selecting the appropriate measurement methods from those contained in this document. It was approved as an official part of SEMI E43 by full letter ballot procedure.

A1-1 The matrix contained in Table A1-1 is intended to assist in the selection of an appropriate measurement method for static charge. Users should note that a variety of measurement methods is available for any given situation. Consult manufacturers of the equipment for additional information concerning its proper use and applicability.

Table A1-1 Measurement Method Recommendations

Object	*Electrostatic Fieldmeter*	*Charged Plate Monitor*	*Electrostatic Voltmeter*	*Electrometer*	*Coulombmeter*	*Oscilloscope*	*EMI Detector*

RELATED INFORMATION 1
NOTES ON EQUIPMENT

NOTE: This related information is not an official part of this standard. However, it contains relevant information for using the standard in situations commonly encountered with semiconductor manufacturing facilities and equipment. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 A charged conductive plate establishes a uniform electrostatic field as long as measurements are not made close to the edges and the measurement distance is small relative to the dimensions of the plate. This specification requires meters capable of making field measurements at a distance of 2.54 cm (1 inch) or less from a 15 cm (6 inch) square plate as a practical means to ensure performance verification to a known field.

R1-2 Charged plate monitors using 15 cm square plates with a 20 picofarad capacitance are commonly used to determine the performance of air ionization systems. Isolators are used to assure minimal leakage to ground. A 15 cm square plate of any metal approximately 1 mm thick and isolated from adjacent surfaces using insulative standoffs is a perfectly acceptable substitute.

R1-3 The verification procedure is intended to ensure that the meter used does not drift excessively (less than 5% in 5 minutes) and can repeatedly measure a known field to within 5%. When actually using the meter to do a field survey, maintaining the correct distance from the sensor head to the surface or object being measured becomes the greatest source of error. If the ability of the meter operator to maintain the correct distance is within 10%, then the total error of the measurement would be within about 12% using this calibration procedure (RMS of the 5% drift, 5% repeatability, and 10% distance errors).

R1-4 If two operators using two different meters follow the verification procedure, and they both are able to maintain the correct distance to within 10% as above, then they both would be within 12% of the true field strength when measuring the same surface or object. Taking the RMS of these errors, the two operators using two meters should be within 17% of each other.

R1-5 Many meters read out in volts/inch. 100 volts/inch is about 4,000 volts/m.

RELATED INFORMATION 2
NOTES ON TEST METHODS

NOTE: This related information is not an official part of this standard. However, it contains relevant information for using the standard in situations commonly encountered with semiconductor manufacturing facilities and equipment. Determination of the suitability of the material is solely the responsibility of the user.

R2-1 Prior handling and environmental conditions will significantly impact the field strength to be measured. Below are a number of these considerations:

- The presence of nearby grounded surface or object will tend to reduce the measured field strength. This phenomena is known as field suppression and is illustrated in Figure R2-1.
- Ionization of the surrounding air will tend to reduce the measured field strength by neutralizing the static charge on the surface of the object.
- Rubbing or contacting the surface being measured with another object or surface will tend to increase the measured field strength depending upon the tendency of the two materials in question to tribocharge.
- Increasing humidity will tend to reduce the field strength to be measured because it in turn will reduce the magnitude of the charge generated on objects and, over time, assist in the neutralization of charge on objects.
- Projections and sharp protrusions on the object being measured, or nearby objects, will increase the field strength.
- Insulating objects may have very irregular charge distributions.
- As a result of these considerations, a static measurement or survey made using this standard is only useful if these factors are taken into account in a realistic manner. For example:
    - If a surface is only used in a humidity or temperature controlled environment, field strength measurements made under these conditions are the main ones of interest. Measurements made at different humidities may be irrelevant.
    - An object may present close to zero field in an ionized environment, yet when contacted by another object may become highly charged. This charge may persist for a period of seconds or minutes while it is neutralized by the ionized environment. The time required to return the object to its original state may be a parameter of interest.
    - An object resting on a grounded metal surface may have very low external field strength. If the object is picked up and measured the field may be much higher.
    - Objects of irregular shape and size will give highly variable readings, depending on the position of the sensor relative to the object.
    - Dielectric objects may give highly variable readings, depending upon the position of the sensor relative to the charge distribution on the object.
    - The simple act of handling an object while performing a static survey can change the charge on the object. The best results will derive from making sure that objects and surfaces are treated and handled within the bounds of their actual use.
- During equipment verification, maintaining constant/steady voltage is important. If the plate is initially charged and allowed to float, its voltage will change as the meter is moved close to it.

Field Suppression

RELATED INFORMATION 3
ESD DAMAGE SIMULATORS

NOTE: This related information is not an official part of this standard. However, it contains relevant information for using the standard in situations commonly encountered with semiconductor manufacturing facilities and equipment. Determination of the suitability of the material is solely the responsibility of the user.

R3-1 ESD Damage Simulators

R3-1.1 ESD Simulators are used to replicate ESD events. Common types used to characterize semiconductor devices and equipment include:

- Component Level HBM ESD Simulator.
- Component Level MM ESD Simulator.
- Component Level CDM ESD Simulator
- System Level HBM/metal ESD Simulator

R3-1.2 The component level HBM ESD Simulator represents the parameters agreed upon for a standard, which represents the discharge from a typical human body. These parameters are 1500 ohms and 100 pF for the representative resistance and capacitance respectively of the human body.

R3-1.3 The component level MM ESD Simulator represents the parameters agreed upon for a standard, which represents the discharge from a charged metallic arm of a machine (automatic handler etc). These parameters are 200 pF and zero resistance for the representative capacitance and DC resistance respectively of the machine. We note here that the resulting waveform is dependent on the impedance of the circuity.

R3-1.4 The component level CDM ESD Simulator represents the parameters agreed upon for a standard, which represents the discharge from a charged device. These parameters are defined by the resulting waveform and depend almost exclusively on the capacitance, resistance and inductance of each device relative to ground. These parameters must not be confused with the equipment parameters, which affects the resulting waveform.

R3-1.5 The system level HBM/metal ESD Simulator represents the parameters agreed upon for a standard, which represents the discharge from a human holding a metallic instrument. These parameters are the lower resistance 350 ohms and 150 pF for the representative resistance and capacitance respectively of the human holding a metallic instrument. Note here that the waveform is greatly affected by the equipment parasitics.

R3.1.6 The above component level ESD simulators have also been used in simulating ESD damage to tooling, such as reticles and photomasks. This simulation is left to user discretion.

R3-2 Summary of procedures

R3-2.1 *HBM ESD Simulator-component level* — The procedure for using this simulator to stress test devices or wafers is based upon the standard requirements. ANSI and the ESD Association approved the HBM standard, ESD STM5.1, which contains a specific device pin combination sequence for stress testing. This test procedure is generally referred to as a Pin to Ground test since one pin is always grounded while the selected second pin is stressed. Calibration before use requires added equipment components like a current probe, high bandpass cable, a short wire, a 500 ohm resistor and a very high band width waveform recorder/digitizer.

R3-2.2 *MM ESD Simulator-component level* — The procedure for using this simulator to stress test devices or wafers is based upon the standard requirements. The ESD S5.2 approved MM standard specifies a specific device pin combination sequence for stress testing. This test procedure is also generally referred to as a Pin to Ground test since one pin is always grounded while the selected second pin is stressed. This procedure is exactly the same as for HBM. Calibration before use requires added equipment components like a current probe, high bandpass cable, short wire, a 500 ohm resistor and a very high band width waveform recorder/digitizer.

R3-2.3 *CDM ESD Simulator-component level* — The procedure for using this simulator to stress test devices or wafers is based upon the standard requirements. The ESD STM 5.3.1 approved CDM standard does not use a pin combination procedure. Here the device sits on a charge plate (CP) "dead-bug" style (package on CP and leads/pins vertical) and each pin is discharged successively after each charge to the device package. This procedure is different from that of HBM and MM. Calibration before use requires added equipment components like a capacitance/inductance calibrator, high bandpass cable and a very high band width waveform recorder/digitizer.

R3-2.4 *HBM-metal Simulator- system level* — The procedure for using this hand-held simulator for testing systems (ATE testers, Automatic handlers, computers, printers, ESD Simulators etc) is based upon the standard requirements. The IEC 61000-4-2, 1996 (formally-801-2,1992) standard uses direct contact or air discharge to the system under test and is a different procedure from the other three procedures mentioned above. Calibration before use requires the use of a very large vertical ground plane (at least 4 ft by 4 ft square), a high BW current probe, cables and high bandwidth waveform recorder/digitizer.

R3-3 Industry Classifications

R3-3.1 *HBM classification*

1. < 250 volts
2. 250 to < 500
3. 500 to < 1000
4. 1000 to < 2000
5. 2000 to < 4000
6. 4000 to < 8000
7. = or > 8000

R3-3.2 *MM classification*

1. M1 < 100
2. M2 100 to < 200
3. M3 200 to < 400
4. M4 400 to < 800
5. M5 = or > 800

R3-3.3 *CDM classification*

1. C1 < 125
2. C2 125 to < 250
3. C3 250 to < 500
4. C4 500 to < 1000
5. C5 1000 to < 2000
6. C6 = or > 2000

R3-3.4 *Hand-Held Metal HBM classification*

Direct Contact Discharge

	Voltage	Current
1.	2,000	12.0 amps
2.	4,000	24.0
3.	6,000	36.0
4.	8,000	48.0

Air Discharge

	Voltage	Current
1.	2,000	15.0 amps
2.	4,000	25.0
3.	6,000	30.0
4.	10,000	35.0
5.	15,000	52.0

Note that the currents for the same voltage level are not the same for contact versus air discharge.

RELATED INFORMATION 4
OTHER METHODS FOR DETECTING STATIC CHARGE AND ESD EVENTS IN EQUIPMENT

NOTE: This related information is not an official part of this standard. However, it contains relevant information for using the standard in situations commonly encountered with semiconductor manufacturing facilities and equipment. Determination of the suitability of the material is solely the responsibility of the user.

R4-1 Introduction

R4-1.1 Static charge generation is unavoidable whenever materials come in contact. Without a static control program, the problems caused by static charge are also unavoidable. The most common problem caused by static charge is electrostatic discharge (ESD). ESD results in damaged semiconductor ICs, photomask defects, magneto-resistive (MR) read head defects in disk drives, and failures of the drive circuits for flat panel displays (FPD). ESD also creates a significant amount of electromagnetic interference (EMI). Often mistaken for software errors, EMI resulting from ESD interrupts the operation of production equipment. This is particularly true of equipment depending on high-speed microprocessors for control. Results include unscheduled downtime, increased maintenance requirements, and frequently, product scrap. Technology trends to smaller device geometries, faster operating speeds, and increased circuit density make ESD problems worse.[6]

R4-1.2 For many years static control programs concentrated on protecting components from the charge generated on the personnel that handled them. Many static control methods were devised to control the charge on people including wrist and heel straps, dissipative shoes and flooring, and garments. Increasingly, however, the production of electronic components is done by automated equipment, and personnel never come into contact with the static-sensitive devices. Solving the ESD problem means assuring that ESD events do not occur in the equipment used to manufacture and test electronic components.

R4.2 Static Control in Equipment

R4-2.1 An effective static control program in equipment starts with grounding all materials that might come close to, or in contact with the static sensitive components. This prevents the generation of static charge on machine components and eliminates them as a source of the charge creating ESD events. Care must be taken in a grounding program to assure that moving equipment parts remain grounded when they are in motion. In some cases, static dissipative materials may be substituted for conductive materials where flexibility, thermal insulation, or other properties not available in conductive materials are needed. If charging of components is unavoidable, static dissipative materials may be used to slow the resulting discharges and prevent component damage.

R4-2.2 Most semiconductors use insulating packaging materials such as ceramics and epoxy. Handling these insulating materials inevitably generates static charge, and this charge cannot be removed by grounding the materials. If charge generation is unavoidable, the only effective method of neutralizing the charge on insulators or isolated conductors is to use air ionization. Ionizers are typically mounted in the load stations and process chambers of the automated equipment to neutralize the static charge.

R4-3 Verifying Equipment Static Control

R4-3.1 A static control program begins when the automated equipment is designed by the OEM, and then continues throughout the lifetime of the equipment. Two basic issues need to be demonstrated. First, are all components in the product-handling path connected to ground? Second, as the product passes through the equipment, is it handled in a way that does not generate static charge above an acceptable level on the component? ESD Association Standard Practice, EOS/ESD SP 10.1-1999[7]. This document contains test methods to verify the integrity of the ground path to equipment parts, as well as to determine if the product is being charged during its passage through the equipment. The test methods are applicable during the original design of the equipment and during acceptance testing by the end user.

R4-3.2 While the test methods of EOS/ESD SP10.1-1999 can also be used for periodic verification of the equipment performance, they have one drawback. The automated equipment must be taken off-line to do the testing. This means that there is lost production time, and often the periodic testing is eliminated to maintain product throughput. Other test methods are available

7 EOS/ESD SP10.1 - 1999 "Standard Practice for Protection of Electrostatic Discharge Susceptible Items - Automated Handling Equipment", ESD Association, 700 Turin Road, Rome NY 13440.

that can be performed with the equipment operating on-line, without altering or disturbing its operation.

R4-4 ESD and EMI

R4-4.1 When ESD occurs, the discharge time is usually 10 nanoseconds or less. Discharging energy in this short time interval results in the generation of broadband electromagnetic radiation[8], as well as the heat that damages semiconductor components. This electromagnetic radiation, especially in the 10 MHz to 2 GHz frequency range, is the EMI that can affect the operation of production equipment. In addition to ESD damage to semiconductor devices and reticles, ESD-caused EMI results in a variety of equipment operating problems including stoppages, software errors, testing and calibration inaccuracies, and mishandling causing physical component damage.

R4-4.2 *EMI Locators*

R4-4.2.1 When component damage or equipment problems due to ESD are suspected, it may be useful to detect the electromagnetic interference (EMI) generated by the ESD event. This type of testing is both a starting point for determining that static charge has been generated, and it is a measurement point to ascertain that any static control methods have been successful. EMI locators measure dynamic operating conditions, as it is usually not necessary to interrupt equipment operations to make measurements.

R4-4.3 *Types of EMI Locators*

R4-4.3.1 EMI locators are available in a number of different forms. In its simplest form, it consists of an AM radio tuned off station. A popping noise will be heard when an ESD event occurs. At the most complex it consists of a wideband (greater than 1 GHz) digital storage oscilloscope with a set of appropriate antennas, probes, and software. Measurements of radiated interference can be made using antennas while probes can be connected to equipment parts or electronics and power lines.

R4-4.3.2 An oscilloscope attached to a single antenna can assist in pinpointing the actual location of the ESD event.[8, 9, 10, 11] A set of antennas can be used to not only detect the presence of an ESD event, but to determine the location of the pulse in 3 dimensions.[12, 13] Using the same concept as a global positioning system (GPS), the difference in the arrival times of the signal to multiple antennas is directly related to the difference in the distance of each antenna from the ESD source. With the time deltas and the locations of the antennas known, the location of the spark can be uniquely identified employing the appropriate analysis program.

R4-4.3.3 Several other types of EMI locating equipment are currently in use. Most consist of high frequency receiving circuitry followed by level detectors to determine the magnitude of the signal. For the purpose of detecting EMI from ESD events, the equipment should have some way of differentiating the short impulse of EMI from the ESD event from the continuous high frequency radiation of other EMI sources. Some instruments contain a counter to total the number of ESD events above the threshold, or alarms to indicate when the number of ESD events exceeds a preset number. This type of instrument can be placed near a piece of equipment that is suspected of causing ESD events and left in place to monitor.

R4-4.3.4 Several EMI Locators are battery-operated handheld devices that can be easily carried around a facility or placed directly in equipment to check for ESD events. This allows the Locator to detect signals that might otherwise be shielded by the equipment's cover panels. (Note that EMI shielding is usually an important part of the design of most production equipment to prevent radiation from the equipment. This makes the detection of ESD events outside the equipment more difficult.) It allows pinpointing of the location of an ESD event, which can then be correlated to particular machine operations.[8, 14]

R4-4.4 *Limitation in Using EMI Locators*

R4-4.4.1 One caution needs to be observed when using EMI locators to detect ESD events that cause component damage. The signal received by these devices is generated in areas usually surrounded by grounded metal components. It may have to pass through equipment panels and travel some distance through the air before it reaches the detector. There may

be other radio frequency sources and reflecting or absorbing materials in the area. The actual location of the ESD event may be a considerable distance from the EMI locator. It will be difficult to establish any correlation between the amplitude of the signal received by the EMI locator and the energy in the ESD event that produced the signal. The EMI locator primarily indicates the occurrence of an ESD event and can be used to illustrate that a particular static control method has eliminated it. It should not be assumed that every ESD event detected results in damage to components or equipment problems. Additional testing will be needed to establish that connection.

R4-5 Static Event Detectors

R4-5.1 Static event detectors (SED) are devices that are installed directly on products to detect the presence of an ESD event. They may be attached in proximity to an ESD-sensitive component, connected to the external device leads, or integrated into the device package. Typically they detect the current pulse of an ESD event through an antenna or direct connection to the device circuitry.

R4-5.2 SEDs can be useful in determining the occurrence of ESD events in operating production equipment. The SED has the ability to indicate ESD events of a known level, aiding in the design and performance verification of automated equipment. While costly analysis of failed devices can also provide this information, correlation to machine operations is usually difficult. An SED that can be monitored optically as it passes through operating equipment provides a convenient method to verify that automated equipment is not generating levels of static charge that result in ESD damage.

R4-5.3 Types of SED Devices

R4-5.3.1 In some SED devices, the signal is amplified and processed to produce a reflectance change in the built-in Liquid Crystal Display (LCD). The SED is designed to trip at a predetermined threshold voltage, detecting ESD transients above the selected amplitude. Some devices can be reset magnetically or optically making them reusable.

R4-5.3.2 Other devices use the controllable ESD damage threshold of metal oxide semiconductor field effect transistors (MOSFET). The test methodology is to amplify an ESD transient to create sufficient energy to destroy the gate oxide. The device may be used until the specified ESD level is achieved, and then the SED fails. A similar device is based on the metal oxide semiconductor capacitor (MOSCAP). The current leakage through the device significantly increases if the ESD amplitude is sufficient to damage the MOS structure. Both of these types of SED must be removed from where they are installed and require additional instrumentation to determine their status.

R4-5.3.3 Another type of SED employs the magnetic fields from a current flow to affect a series of magneto-optic thin films. The magnetic field from the ESD current alters the film's magnetic state and affects the degree of polarization of visible light reflected from the film. Varying the distance between the film and the ESD current-carrying conductor indicates different thresholds. This SED can be read using a microscope equipped with a polarizing element and does not need to be removed from the circuitry to be read. It can be reset with a magnet.[15]

R4-6 Conclusion

R4-6.1 There is little question that static charge problems continue to result in significant losses in high technology manufacturing. Increasingly, static control methods must be applied in the equipment that produces the product. It will be important to develop and utilize a range of diagnostic methods and measurement equipment for ESD in equipment.

SEMI E44-96 (Withdrawn 0301)
GUIDE FOR PROCUREMENT AND ACCEPTANCE OF MINIENVIRONMENTS

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Purpose

1.1 It is widely felt that the requirements of buyers can be standardized. The purpose of this guide is to provide standardized procedures for the procurement and acceptance of minienvironments. It should assist the buyer in producing a procurement specification by providing a comprehensive and structured overview and checklists of all the parameters relating to procurement of minienvironments.

SEMI E45-1101
TEST METHOD FOR THE DETERMINATION OF INORGANIC CONTAMINATION FROM MINIENVIRONMENTS USING VAPOR PHASE DECOMPOSITION-TOTAL REFLECTION X-RAY SPECTROSCOPY (VPD/TXRF), VPD-ATOMIC ABSORPTION SPECTROSCOPY (VPD/AAS), OR VPD/INDUCTIVELY COUPLED PLASMA-MASS SPECTROMETRY (VPD/ICP-MS)

This test method was technically approved by the Global Metrics Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1995; previously published March 2001.

1 Purpose

1.1 This test method provides the analytical procedures to determine the level of inorganic contamination from a minienvironment.

2 Scope

2.1 This document relates to inorganic impurities, which includes metallic contaminants, whether they occur as atoms, molecules, or particles. The number of metals to be analyzed is restricted to the four elements sodium (Na), calcium (Ca), iron (Fe), and copper (Cu) in order to rapidly characterize minienvironments from a practicable point of view. While Na, Ca, and Fe represent one ensemble of highly detrimental impurities with respect to contamination from human sources (Na), the environment (Ca), or from equipment and corrosive effects (Fe), Cu is analyzed due to its increasing importance in semiconductor manufacturing. Additionally, they are easily analyzed with sufficiently low detection limits. It is up to the user of this test method to quantify additional elements. A list of suggested polished wafer surface metal contamination inappropriate to circuits and devices is shown in Table 1 (based on SEMI M1). The inorganic contamination on silicon wafer surfaces is collected by VPD.

2.2 To quantify Ca and Fe, VPD/TXRF is used due to its sufficiently low detection limits. Na and Cu are quantified by VPD/GFAAS or VPD/ICP-MS. All analytical methods are widely used for the characterization of surface cleanliness.

2.3 This measurement technique can also be used to check the influence of certain process steps on minienvironments.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

Table 1 Suggested Polished Wafer Surface Metal Contamination Inappropriate to Circuits and Devices

Element	*Test Method*
Na	VPD/(AAS or ICP-MS)
Al	VPD/(AAS or ICP-MS)
K	VPD/(AAS or ICP-MS or TXRF)
Cr	VPD/(AAS or ICP-MS or TXRF)
Fe	VPD/(AAS or ICP-MS or TXRF)
Ni	VPD/(AAS or ICP-MS or TXRF)
Cu	VPD/(AAS or ICP-MS or TXRF)
Zn	VPD/(AAS or ICP-MS or TXRF)
Ca	VPD/(AAS or ICP-MS or TXRF)

4 Terminology

4.1 *Abbreviations and Acronyms*

4.1.1 *GFAAS* — Graphite Furnace Atomic Absorption Spectroscopy

4.1.2 *ICP-MS* — Inductively Coupled Plasma – Mass Spectroscopy

4.1.3 *PFA* — Perfluoroalkoxy

4.1.4 *PTFE* — Polytetrafluoroethylene

4.1.5 *PVDF* — Polyvinylidene fluoride

4.1.6 *TXRF* — Total Reflection X-Ray Fluorescence Spectroscopy

4.1.7 *ULSI* — Ultra Large Scale Integration

4.1.8 *VPD* — Vapor Phase Decomposition

4.2 *Definitions*

4.2.1 *box* — a protective portable container for a cassette and/or substrates.

4.2.2 *cassette* — an open structure that holds one or more substrates (e.g., wafer, masks).

4.2.3 *DI water* — deionized water (specified with specific resistivity ≥ 18 MΩcm, cations: Na, Cu, Fe, Ca ≤ 0.2 µg/L).

4.2.4 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people.

4.2.5 *pod* — a box having a Standard Mechanical Interface (SMIF) (See SEMI E19).

4.2.6 *reference wafer* — a cleaned wafer (see Section 8.2).

4.2.7 *sampling wafer* — a cleaned wafer (see Section 8.2), which will be or was exposed to the minienvironment for a certain time.

4.2.8 *standard mechanical interface (SMIF)* — the interface plane between a pod and another minienvironment (see SEMI E19).

4.2.9 *vapor phase decomposition* — a method in which impurities on the surface are collected by the so-called VPD procedure, i.e., the non-volatile products formed by acid decomposition of the oxide at the wafer surface are collected by a droplet of collecting agent, usually ultra-pure hydrofluoric acid or other reagent or combination of reagents, and the droplet subsequently being analyzed by AAS or ICP-MS, or dried in a manner which gives the least environmental contamination, the residue from the droplet subsequently being analyzed by TXRF.

5 Interferences

5.1 For worst cases, preconditioning of wafers can result in different surface properties indicated by different sensitivities for contamination absorption.

5.2 Non-linearity effects of the TXRF detector are significant at higher concentration levels (> 10^{13} atoms/cm^2 under the detector area).

5.3 The collection efficiency of VPD depends on:

- the chemistry of the collecting solution
- the bonding of the metal impurities to the silicon surface
- the speed of the droplet, which is rolled over the wafer surface

5.3.1 Careful control of contamination and all other factors affecting the results such as solution concentrations, scanning methods and other procedures are necessary to obtain reproducible analytical results.

5.4 The measured TXRF intensity depends on the accuracy of the procedure to localize and to adjust to the sampled residue. It also depends on the distribution of different elements in and around the residue.

5.5 The detection of Fe or Ca using ICP-MS can be interfered with by background ions originated from the plasma unless some controlled measures are taken to minimize these interferences to acceptable levels.

6 Safety Precautions

6.1 Handling hydrofluoric acid is dangerous and shall be performed according to local regulations for laboratories. Operators shall be trained to deal with dangerous chemicals and vapors, especially hydrofluoric acid and HF vapor. Protective clothes and glasses must be worn when handling hydrofluoric acid.

7 Apparatus

7.1 The VPD treatment and contamination collection particularly, but also the handling and measurement of the specimen wafer is to be carried out in a specified

2 Available from Deutches Institut für Normung e.V., Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-10787 Berlin, Germany. Website: http://www.din.de

and controlled ambient (e.g., ISO Class 4 (as defined in ISO 14644-1)).

7.2 The VPD and the advisable drying chamber(s) shall have opening(s) made of PVDF, PFA, PTFE or similar resistant and pure polymer materials that are not attacked by HF. The chamber(s) may contain one or more wafer stacks. After evacuation, the chamber shall be flushed with filtered N_2 until the complete drying of the microdroplet residue is achieved.

7.3 For the aliquots of standard stock and scanning solutions, validated micropipettes shall be used. DIN 12650 Part 6 provides an applicable validation procedure.

8 Procedure

These procedures show the determination of Na, Ca, Cu, and Fe on a silicon wafer surface with VPD/GFAAS, VPD/ICP-MS and VPD/TXRF. For achieving best detection limits, VPD/GFAAS and VPD/ICP-MS shall be used for NA and Cu whereas VPD/TXRF shall be used for Ca and Fe.

8.1 *Test Requirements* — The evaluation of the minienvironment and the analysis shall be carried out under appropriate clean conditions. Any potential for cross contamination shall be checked in advance. Possible contamination sources are:

- VPD preparation
- storage
- contaminated GFAAS or ICP-MS vessels
- environment
- measurement methods and collection efficiency of VPD
- handling

8.1.1 The capability of the analytical lab has to be checked carefully for compliance with Sections 8.2, 8.6, and 9.

8.2 *Surface Conditions and Cleaning Procedure* — Polished silicon wafers with the following specifications must be used:

- Specific resistivity = 1–100 Ωcm
- CZ crystal growth method
- Cleaned to leave a native oxide with hydrophilic surface conditions and with Na, Ca, Cu, and Fe concentrations lower than 1×10^{10} atoms/cm^2

8.2.1 Wafer cleaning must be done less than ten minutes before any further processing. This restricted time limitation is necessary to ensure cross contamination avoidance.

8.3 *VPD Preparation* — The vessel for (opening > 25 cm^2) inside the VPD box is filled with 25 vol-% HF by mixing DI water with 50 vol-% VLSI-grade hydrofluoric acid (see SEMI C28) allowing hydrofluoric acid of between 25 to 50 wt % to be used. The wafers are then exposed to the hydrofluoric acid vapor. Allow wafers exposure to hydrofluoric acid vapor for 15 to 30 minutes, at which time the wafer should become hydrophobic due to oxide removal. The liquid reaction products are collected by rolling a DI water droplet over the whole wafer surface using up to 100 µL for advisable machine operation or an appropriate volume for manual operation. Any cross contamination is minimized by using DI water as solvent.

8.4 *Collection Procedure* — An automatic scanning procedure is preferable, but if the collection procedure is manual the following procedure should be used.

8.4.1 Use appropriate method to exclude the wafer edge.

8.4.2 A droplet of collecting agent, usually ultra-pure hydrofluoric acid or another reagent or a combination of reagents, is rolled over the whole surface of the wafer in a parallel pattern.

8.4.3 The same droplet is then moved over the whole surface, this time in a pattern orthogonal to the first.

8.4.4 Finally, the droplet is rolled in a spiral pattern from the wafer periphery to its center.

8.5 *Pre-analysis Procedure*

8.5.1 *GFAAS Analysis* — The wafer droplet is diluted to 500 µL.

8.5.2 *TXRF Analysis* — The droplet is evaporated on the wafer surface in a clean environment at room temperature under a nitrogen purge.

8.5.3 *ICP-MS Analysis* — The wafer droplet is diluted to 500 µL.

8.6 *Sodium and Copper Analysis by GFAAS*

8.6.1 *Calibration Standards* — 1 µg/L for Na.

8.6.2 The calibration frequency and procedures shall be in accordance with the requirements of the ISO 9001 quality system. The temperature program for the graphite furnace (dry, ash, atomize) is optimized for maximum sensitivity. Volatility (e.g., NaF) should be avoided by spiking the liquid samples with nitric acid (VLSI grade—see SEMI C35). Prior to analysis of the liquid sample, a three-point calibration of the element with an elemental standard is carried out (blank — 0.5 µg/L – 1 µg/L).

8.6.3 A detection limit for sodium and copper better than 5×10^9 atoms/cm^2 (approximately 0.1 µg/L for GFAAS analysis) is recommended.

8.6.4 The detection limit is defined by 3 • σ • R (σ = standard deviation, R = reciprocal slope of the calibration curve).

8.6.5 The surface concentration is calculated as follows:

$$C_s = C_1 \times V \times NA \times 10^{-9} / (W \times A)$$

with:

C_s (atoms/cm^2): surface concentration

C_1 (µg/L): analyzed concentration

V(mL): volume of diluted sample

$NA = 6.023 \times 10^{23}$ mol^{-1} : Avogadro number

A (cm^2): wafer surface area

W (g/mol): atomic weight of element (22.99 for sodium, 86.54 for copper)

8.7 *Sodium and Copper Analysis by ICP-MS*

8.7.1 *Calibration Standards* — 1 µg/L for both sodium and copper.

8.7.2 A detection limit for sodium and copper better than 5×10^9 atoms/cm^2 (e.g., for 200–300 mm wafers) is recommended.

8.7.3 The detection limit is defined by 3 • σ • R (σ = standard deviation, R = reciprocal slope of the calibration curve).

8.7.4 The surface concentration is calculated as follows:

$$C_s = C_1 \times V \times NA \times 10^{-9} / (W \times A)$$

with:

C_s (atoms/cm^2): surface concentration

C_1 (µg/L): analyzed concentration

V(ml): volume of diluted sample

$NA = 6.023 \times 10^{23}$ /mol : Avogadro number

A (cm^2): wafer surface area

W (g/mol): atomic weight of element (22.99 for Na, 86.54 for copper)

8.8 *Calcium and Iron Analysis by TXRF*

8.8.1 *Calibration Standards* — The ISO 9001 quality system shall be applied to the calibration. The instrument is calibrated by analyzing the calibration wafer. The calibration wafer is prepared by dropping a solution of metal standard (e.g., Ni or Co) on a clean wafer surface. The volume of the droplet is the same as used for VPD preparation (up to 100 µL), and the resulting surface concentration must be in the lower 10^{11} atoms/cm^2 range. The droplet is then evaporated on the wafer surface at room temperature under nitrogen purge until the liquid matrix is removed. Its residue is analyzed by TXRF. The detection limit is defined by 3 • σ • R (σ = standard deviation, R = reciprocal slope of the calibration curve). Note that the droplet area must be smaller than the spot area of the detector.

8.8.2 Reproducibility shall be first established following the procedure below.

8.8.3 Define a grid of 3 × 3 measurement points with an inter distance of 3 mm. The reside position, found by optical inspection, shall be located at the center of the matrix.

8.8.4 Determine the intensity by short analyses of each of the nine measurement locations. The analysis area is at maximum intensity for the standard element of the calibration wafer.

8.8.4.1 Calibration shall be checked weekly and after each equipment service (e.g., after an exchange of filament, anode, or repair of anode) with the same calibration wafer.

8.8.4.2 The surface concentration is calculated as follows:

$$C_s = RSF_m \times (C_0/I_0) \times I$$

with:

C_s (atoms/cm^2): surface concentration of analyzed metal M

I (counts/s): analyzed intensity of metal M

C_0 (atoms/cm^2): surface concentration of standard metal S (Ni or Co) on calibration wafer

I_0 (counts/s): analyzed intensity of standard metal S on calibration wafer

RSF_m: relative sensitivity factor of investigated metal M to standard metal S

8.8.4.3 The constants RSF_m are implemented in the software of the TXRF equipment.

8.9 *Sampling Procedure* — If the average elemental concentration for the sampling wafers is higher than the average elemental concentration plus three standard deviations for the analyzed reference wafers, then the sampled minienvironment is considered to cause significant contamination.

8.9.1 *Minienvironment Exposure* — The following exposure time for sampling specific minienvironments shall be used:

Minienvironments used to store wafers: 168 h

Minienvironments as an interface to process tools: 24 h

8.9.2 *Minienvironments for Storing Wafers* — Fill the minienvironment with six wafers. Measure wafers by VPD/GFAAS or VPD/ICP-MS in front, back, and center slots. Use the adjacent wafers for VPD/TXRF.

8.9.3 *Minienvironments for Introducing Wafers to Process Tools* — Introduce six wafers into the minienvironment. Measure three wafers with VPD/GFAAS or VPD/ICP-MS, one in the center position and two at the edge positions opposite to each other. Use the adjacent wafers for VPD/TXRF. In the case of single wafer minienvironments, wafers are processed sequentially. To ensure that no cross contamination is introduced from conditions prevailing in storing, transportation, or any of the handling processes, precautions must be adhered to at all times.

9 Results

9.1 The investigated minienvironment must be described in detail (e.g., construction, materials, history, process, cleaning procedures, storage conditions). All surface concentrations must be fully reported.

9.2 The number of tested sampling and reference wafers, average elemental concentration, and standard deviation of the reference wafers, slot positions, position in the minienvironment, and number of repeated experiments (if applicable) must be documented.

9.3 All equipment, tools, and chemicals used must be specified within the report.

SEMI E46-0301
TEST METHOD FOR THE DETERMINATION OF ORGANIC CONTAMINATION FROM MINIENVIRONMENTS USING ION MOBILITY SPECTROMETRY (IMS)

This test method was technically approved by the Global Metrics Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on December 20, 2000. Initially available at www.semi.org February 2001; to be published March 2001. Originally published in 1995.

1 Purpose

1.1 The purpose of this test method is to provide an analytical procedure—Ion Mobility Spectrometry (IMS)—for the determination of organic contamination from minienvironments which has the capability of testing their construction material.

2 Scope

2.1 Silicon wafers passed through or stored in minienvironments may be affected by organic contamination originating from construction materials. Knowledge of this contamination assists the decision about the application of minienvironments in semiconductor manufacturing.

2.2 Ion Mobility Spectrometry was chosen as the method to determine this contamination because it provides an easy, widely applicable, fast and sensitive way to measure organic contamination on surfaces.

2.3 Furthermore, IMS provides the possibility of checking the contaminating effects of processing, chemical carryover, and the characterization of future polymeric materials for use in semiconductor technology.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4.9 *PFA* — Polyfluoroalkoxy

4.10 *PP* — Polypropylene

5 Summary of Method

5.1 This test method defines a fast, sensitive technique for the determination of organic contamination from minienvironments. The contamination is measured directly from the silicon surface. Three important aspects are covered:

a. Contamination due to the minienvironment alone,

b. Contamination from the use of minienvironments for wafer processing, and

c. Contamination from future materials to be used in semiconductor technology.

5.2 Silicon wafers are either placed in the minienvironment or used for headspace sampling experiments. The sample is heated and the target compound is either desorbed or outgassed. These compounds are swept by the carrier gas into the Ion Molecule Reactor. Here the molecules are chemically ionized under atmospheric pressure. The target ions are separated in a drift cell by electrophoreses in the gaseous state and detected by an electrometer. Additionally, a quadrupole mass spectrometer could be used as a second detector. The result is a quantitative value for the total amount of organic surface contamination.

6 Interferences

6.1 To adequately measure organic contaminants from minienvironments, an extremely sensitive method for analyzing volatiles is required. At this time, the only analytical method meeting these requirements is IMS. The absolute determination of organic contamination by the IMS method is still limited, especially in the presence of many analytes, but this proposed test method permits the comparison of quantitative results from different laboratories.

7 Apparatus

7.1 *Minimum Requirements for the Ion Mobility Spectrometer* — For the successful performance of the experiments using the IMS instrument, the following requirements are essential:

— minimum length of the drift cell: 4 cm

— sample inlet has to be lockable (no sniffing devices)

— sample desorption oven must have a programmable temperature control

— the electronics must guarantee a linear amplification of the observed signal

— intensity over at least five orders of magnitude

— documentation of all single measurement results.

7.2 *Measuring Parameters* — For measurements with the ion mobility spectrometer, the following parameters have to be used:

temperature of the desorption furnace: 200°C*

temperature of the drift cell and IMS detector: 205°C*

maximum dwell time or channel length corresponding to minimum time resolution: 80 µs**

measuring time per spectrum: 40 ms*

(for 200 V/cm and 10 cm length of drift cell)

gatewidth: 200 µs**

number of scans: 2000**

drift gas and carrier gas: zero grade (synthetic) air*

- approx. 10 ppm H_2O*
- max 0.1 ppmv total hydrocarbons*

carrier gas flow: 100 mL/min* (for a diameter of 3.9 mm)

drift gas flow: 500 mL/min** (for a diameter of 4.25 cm)

* specified; ** suggested

8 Reagents

8.1 The chemicals must be of the described quality or better and supplied with a certificate of analysis.

Benzene: ultrapure quality for trace residue analysis. Minimum quality: pro analysi.

- content of benzene: min. 99.8%
- content of water: max. 0.02%
- nonvolatile residue: max. 0.0005%

Ethanol: ultrapure quality for trace residue analysis. Absolute.

- content of ethanol: min. 99.8%
- content of water: max. 0.1%
- nonvolatile residue: max. 0.0005%

DOP: normal pure quality.

- content of DOP: better than 96%

HPB: normal pure quality.

- content of HPB: better than 96%

9 Safety Precautions

9.1 All preparation and measurement work has to be done according to local regulations for laboratories.

10 Procedure

10.1 *Preparation Tools and Auxiliaries* — The following equipment is needed for the preparation of polymer headspace substrates:

- protective eye wear
- 1 fume cupboard
- 1 butane burner
- 2 pairs of crucible tongs made of stainless steel
- scalpel with changeable blades
- 4 pairs of cross tweezers with tips made of steel
- 1 metal vernier calliper
- Si-wafer-chips: formate 20 × 10 mm^2
- watch glass
- weighing bottle with lid, both made of glass

  inner diameter: 80 mm

  height: 30 mm

ground joint NS80

- aluminum foil
- 2 metal saws
- table vice
- finely toothed metal file
- steel ruler (30 cm)

10.2 *Preconditioning Procedure (Thermal Decontamination)* — In order to assure that all environmental influences are eliminated, all thermal decontamination procedures described in the following have to take place immediately before the appropriate measurements or experiments are performed.

10.2.1 *Preconditioning of Aluminum Foil* — Two cross tweezers are flamed with a butane torch in the fume cupboard (1 min., red heat). A piece of aluminum foil (20×30 cm^2) is folded multiply and, by using tweezers, is carefully heated in the flame until fully converted. After cooling down, the foil is stored on a fire resistant surface (ceramics preferred).

10.2.2 *Preconditioning of Weighing Bottles* — The jaws of the crucible tongs are heated in the butane torch until they are red hot for two minutes. After a short cooling period (15 s), the bottom of the weighing bottle is picked up. For several times, the inner and the outer surfaces of the glass are heated alternately in the torch (2 minutes for each run). After approximately 30 s of cooling down - held in air by the tongs - the flamed weighing bottle is put down on the preconditioned aluminum foil. The tongs are allowed to cool for 15 s, then the lid is prepared in the same way. After 10 minutes of cooling, the lid can be placed on the weighing bottle.

10.2.3 *Preconditioning of Watch Glass* — The watch glass is picked up with preconditioned cross tweezers and carefully heated in the butane torch for 30 s (without deformation by melting).

10.2.3.1 Simultaneously, the tips of a second pair of cross tweezers are heated to red heat. After 30 s, the watch glass is transferred by these tweezers, carefully heated for another 30 s to red heat (total heating time, 1 min), and placed on the preconditioned aluminum foil. After a cooling period of 5 minutes, the watch glass is picked up with a clean pair of preconditioned cross tweezers and placed inside the weighing bottle.

10.2.4 *Preconditioning of Si-chips* — Wafers, as received, are cut into chips of 20×10 mm^2 in size. The use of cotton gloves is recommended to avoid organic contamination through fingerprints. Then one Si-chip is picked up with a pair of cross tweezers and heated to red hot in a butane torch (30 s). Simultaneously, the tips of a second pair of cross tweezers are heated to red hot. After 30 s, the Si-chip is transferred to these tweezers and heated for another 30 s to red heat (total heating time, 1 min). After cooling, the Si-chip is transferred into the preconditioned weighing bottle. The weighing bottle must be opened and closed only with the thermally decontaminated crucible tongs.

10.2.4.1 The lid must be placed only on the preconditioned aluminum foil. Five more Si-chips are preconditioned as described above and placed into the weighing bottle. The six Si-chips must not overlap or touch one another. The Si-chips should be placed on the preconditioned watch glass.

10.2.5 *Preparation of Polymer Material* — The table top vice is mounted on a clean work-bench. The cross tweezers, the blade of a metal saw, the scalpel, the metal vernier calliper (within the measuring range), the steel ruler (in the range of 0 to 3 cm), and the finely toothed metal file are thermally decontaminated. Having decontaminated the metal saw, an area of approximately 50×50 mm^2 is sawed off the polymeric material and fixed with the clean cross tweezers. This piece of polymer material is then clamped vertically between the jaws of the vice. An area 12×20 mm^2 is carefully marked with the scalpel and cut out with the metal saw. Before total separation, the polymer sample is clamped with cross tweezers while the jaws of the vice are covered with the decontaminated aluminum foil. After clamping the polymer sample between the jaws of the vice, all sides of the polymer sample are carefully filed to length wit ha metal file (size control with metal vernier caliper). Then the polymer sample is placed on a clean watch glass by cleaned tweezers. The watch glass is positioned on the thermally cleaned aluminum foil. Both parts are stored inside the preconditioned weighing bottle which is carefully closed with its lid. The weighing bottle, within which the Si-chips are stored, is wrapped in preconditioned aluminum foil for storage and transportation.

10.3 *IMS Measurements Procedure*

10.3.1 *Blank Measurement* — The background signal level (noise) of the equipment must be defined by measuring the clean and stabilized IMS-equipment, without sample, three times for each polarity.

10.3.2 *Reference Measurement* — All manipulations etc. with the reference chemicals (Hexaphenylbenzene and Dioctylphthalate) have to take place entirely in PFA containers etc. Following equipment is needed:

2 narrow necked flasks (PFA), 250 mL

2 weighing boats (PFA)

! ! low weight, diameter smaller than diameter of narrow necked flask! !

2 pipettes (glass), 100 mL

1 micro dropper with changeable tips of 2 µL (may be PP)

1 micro spatula (metal)

1 micro balance, measuring range 10^{-6} g to 1 g at least

10.3.2.1 Preparation of the reference measurement with HPB:

10.3.2.1.1 Before the HPB is weighed, the PFA-bottle and the weighing boat have to be cleaned. For this the weighing boat and 10 mL benzene are given into the bottle. The bottle is closed and shaken well for approx. 1 minute. The benzene is discarded. This procedure is repeated four times. After the last cleaning the empty open bottle and the weighing boat, placed on a decontaminated aluminum foil (see Section 10.2.1). are allowed to dry at room temperature in a fume cupboard for ten minutes. Then the bottle is closed. The weighing boat is placed onto the micro balance by thermally decontaminated cross tweezers. Approx. 5 mg of HPB are weighed into the weighing boat by use of a thermally decontaminated micro spatula. The weight is recorded exactly for the later calculation. The weighing boat is placed into the PFA bottle by the cross tweezers.

10.3.2.1.2 The volume of the benzene is measured using a 100 mL-pipette. Before use, the pipette has to be washed 5 times using 10 mL benzene each time. The 100 mL benzene are filled into the PFA flask, which is closed immediately.

10.3.2.1.3 First the bottle, now containing HPB and benzene, is shaken well for three minutes. Often this is not sufficient for a complete dissolution of the HPB (visible inspection). To assure complete dissolution, the PFA flask is placed into an ultrasonic bath for 5 minutes (not longer, because solution may get hot). Two minutes before the end of that time the preparation of the silicon chip is started. The piece of silicon is heated to red heat for one minute, placed on the thermally decontaminated aluminum foil and given 5 minutes to cool. When the treatment in the ultrasonic bath is finished, the PFA flask is shaken for three minutes again, then given 2 minutes for just standing.

10.3.2.1.4 The bottle is opened. By the micro dropper 2 µL are taken from near the surface (tip not more than 1 mm under surface of liquid). The 2 µL are spread onto the silicon chip in such a way that the liquid on the chip covers the smallest possible area. Care is to be taken to prevent large spreading or even dropping off the liquid (e.g., the Si chip has to be positioned flat). The liquid is given 5 minutes to evaporate (room temperature, no extensive blowing of air). Then the measurement of the HPB reference can be started.

10.3.2.1.5 Before each following HPB measurement the flask again has to be shaken 3 minutes, 5 minutes ultrasonic bath, shaking 3 minutes, allow two minutes of resting. The solution of the HPB in benzene must not be kept longer than 10 days.

10.3.2.1.6 The reproducibility of the integral value (see calculation) achieved by this procedure is better than 4%. Sample measurements shall be performed only, if the reference measurement has provided a reproducibility equal to or better than 10%.

NOTE 1: Hexaphenylbenzene has been chosen as a reference compound because its signal is well-defined and its mobility value is well separated from the peaks of nearly all other relevant organic contaminants. It provides positive ions only. A different reference, Dioctylphthalate, is needed for negative ions.

10.3.2.1.7 DOP-reference samples: All the same as HPB, except replacing the benzene by ethanol. The DOP is weighed using a micro dropper (not spatula).

10.3.2.1.8 The mobility spectrum of dioctylphthalate is also well separated but there are several peaks due to thermal decomposition (phthalic anhydride etc.). This compound is a frequently used plasticizer and therefore one of the most critical polymer additives.

10.3.3 *Measurement of the Headspace Samples* — Positive and negative ions are detected successively in two separate runs. At least two independent measurements are carried out for each polarity. Every measurement to be saved consists of 2000 single scans and is then repeated. Hence, an automated measurement is required.

10.3.3.1 The silicon chip is placed in the furnace of the IMS using thermally decontaminated cross tweezers. The measurement of the drift time spectrum (positive or negative polarity) has to be started immediately after loading the desorption furnace with the sample (time delay between sample introduction and starting of the measurement: 15 s).

10.3.4 *Termination of the Measurement* — The measurement is terminated when the signal intensity has decreased to about 10% above the noise of the blank measurement spectrum. If this point is not reached after two hours, the measurement should be terminated; in this case, the investigated sample does not show suitable material properties.

10.4 *Headspace Sampling in Minienvironments* — The crucible tongs are preconditioned as described in Section 10.2, and the preconditioned aluminum foil is placed beside the minienvironment that is to be examined. After opening the minienvironment, the lid of the weighing bottle is picked up with the crucible tongs and carefully placed on the aluminum foil. Both the weighing bottle (holding the Si-chips) and its lid are separately put inside the minienvironment. Then the minienvironment is closed and kept closed for a defined period of time. For this test method, one week (168 h) is defined. After expiry of the storage time, the weighing bottle is closed with its lid and removed from the minienvironment.

10.4.1 The same procedure applies to standard wafer boxes or to SMIF and similar boxes.

10.5 *Headspace Sampling of Polymer Material at Different Temperatures* — The prepared polymer material inside the wrapped weighing bottle (see Section 10.2.5) is stored:

- either under clean laboratory conditions at room temperature for a defined period of time
- or in a suitable oven at a temperature of 70°C or 120°C for exactly 1 hour followed by a cooling period of 1 hour.

10.5.1 The wrapped weighing bottle is handled with a pair of crucible tongs only.

10.6 *Testing Requirements* (check for device overload during measurement)

10.6.1 *Positive Ions: Water Cluster Signal Intensity* — The water cluster signal intensity must not decrease by more than 10% of the blank spectra intensity during measurement time; otherwise, the ion molecule reactor has been overloaded. If this is the case, the polymer sample is not likely to be suitable for use in semiconductor processing because of unacceptable properties.

10.6.2 *Negative Ions: Oxygen Cluster Signal Intensity* — The same procedure as that in Section 10.6.1 must be performed for negative ions; in this case, the oxygen cluster signal intensity must not decrease by more than 20%.

11 Calculation

11.1 *Description of Mobility Spectra Evaluation* — The signal intensities of the detected sample contaminants are integrated over a specific interval for both polarities. The background signal intensity is integrated, outside the specific measurement interval, with preference to spectral region prior to the peaks of the reactant ions. The total background intensity (integration of the relevant background signal) is subtracted from the integrated contamination intensity (background correction). The mean value of the contamination signal from the blank measurement (Section 10.3.1) spectra is subtracted accordingly. This leads to individual contamination values from each sample spectrum.

11.2 Calculation of reduced mobility:

$K = E^{-1}\, l_d / t_d$ and

$K_0 = K\,(p/p_0)\,(T_0/T)$

K : ion mobility (cm^2/Vs)

K_0 : reduced ion mobility (cm^2/Vs)

p : pressure

p_0 : standard pressure

T : temperature

T_0 : standard temperature (273.15K)

l_d : drift length (cm)

t_d : drift time (s)

E : electric field strength (V/cm)

K : Kelvin

11.2.1 Table 1 shows the specified integration range; all reduced mobility values are given in units of cm^2/Vs.

11.2.2 The resulting integrals for each spectrum are summed up for the whole desorption time. This value is compared to the appropriate value of the reference sample (HPB or DOP).

11.2.3 This procedure ensures the comparison of the evaluated sample contamination values between different laboratories and measurement equipments.

SEMI E47-0301
SPECIFICATION FOR 150 mm/200 mm POD HANDLES

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on October 26, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published in 1995; previously published October 2000.

1 Purpose

1.1 This specification provides a unified form and location for pod handles to enable automatic pod handling.

2 Scope

2.1 This specification defines the dimensions and location of handles on 150 mm/200 mm pod. These provide automatic handling and take into consideration manual handling. The design of individual manual handles is open to be accomplished within the dimensional limitations of the standard.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification applies only to automatic handling of the pod with a SMIF interface in the horizontal plane (see limitations of SEMI E19.3 and E19.4). Dimensional restrictions for manual handling are given in SEMI E15 and SEMI T4.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E19.3 — 150 mm Standard Mechanical Interface (SMIF)

SEMI E19.4 — 200 mm Standard Mechanical Interface (SMIF)

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI T4 — Specification for 150 mm and 200 mm Pod Identification Dimensions

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *standard mechanical interface (SMIF)* — the interface plane between a pod and another minienvironment per SEMI E19.

5.2 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19.

5.3 *box* — a protective portable container for a cassette and/or substrate(s).

5.4 *cassette* — an open structure that holds one or more substrates (wafer, masks, etc.).

5.5 *handle of a pod* — a mechanical aid designed for automatic handling of a pod, which may also be used for manual handling.

5.6 *handling area* — minimum free space around the pod for automatic handling.

5.7 *handling of a pod* — automatic and manual movement and/or placement of a pod.

5.8 *orientation notch* — notch located at the pod handles to allow sensing the orientation of the pod. See Figure 1.

5.9 *position notch* — notch located at the center lines of the pod handles to allow positioning. See Figure 1 (PN1 to PN4).

6 Requirements

6.1 Handling Dimensions: the handling dimensions for 150 mm and 200 mm pods shall be per Table 1 (see Figure 1 for dimensional locations).

6.2 A8 is given as a minimum and can be extended up to A1.

6.3 Number of handles shall be:

6.3.1 four (H1–H4 in Figure 2) or

6.3.2 two (H1 and H3) in Figure 2.

6.4 The handling area is defined by A5 (which is in reference to A1) and by B2. B1 is the minimum distance between the interface plane and the nearest extension of the handle.

6.5 The orientation possibilities of the pod are given in Figure 2 and Table 2.

6.6 An optional handle to be placed at the top of the pod is specified in SEMI E47.1 (Section 6.9, Figure 12, and Table 1). If used for 150 mm or 200 mm pods, this "top robotic handling flange" has to meet the required dimensions as specified in SEMI E47.1 (see Figure 12 of SEMI E47.1). Its center is to be placed above the center of the cassette in the pod with the two orientation notches at the side where the cassette is accessed to remove wafers. The orientation possibilities of the pod are then the same as described in Section 6.5 above and Table 2.

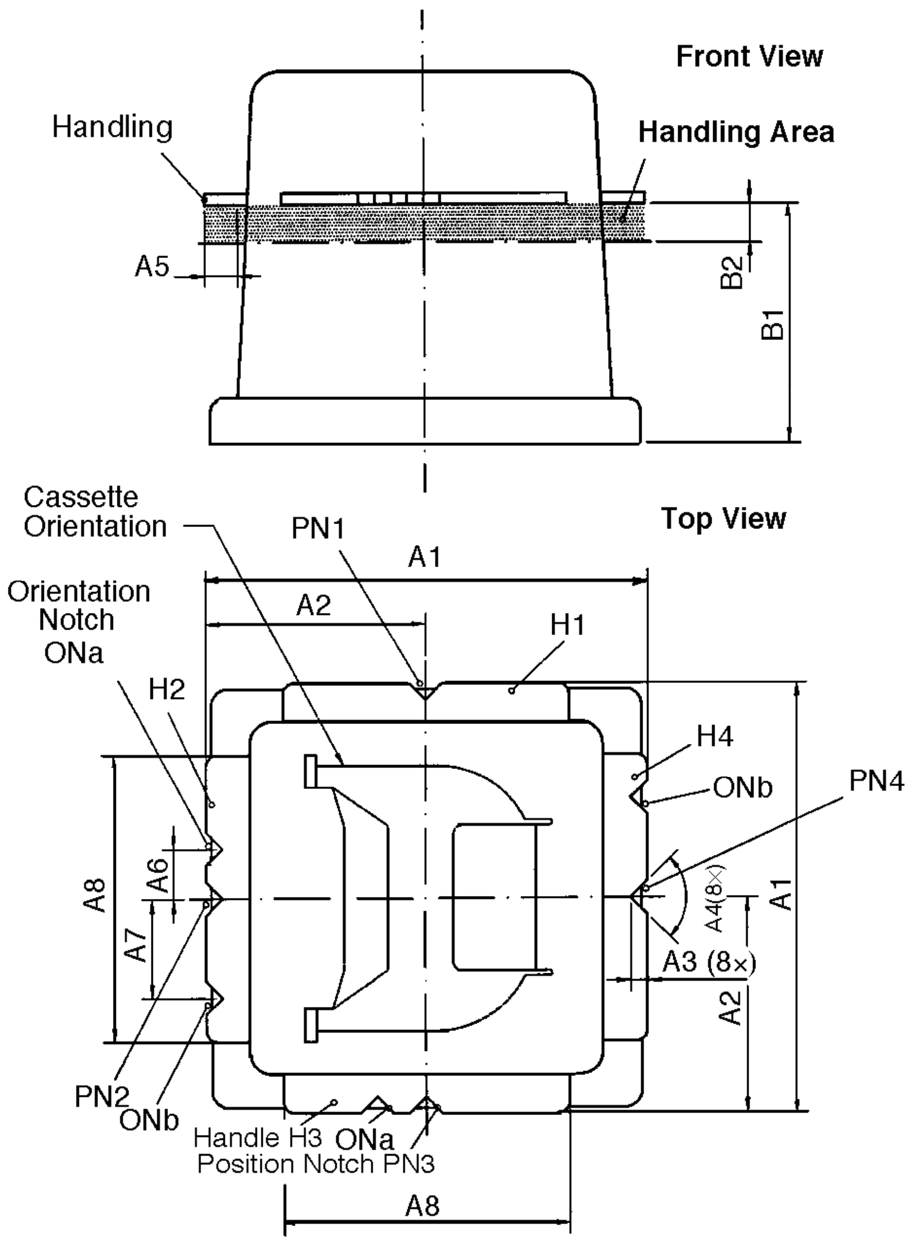

Figure 1
Pod Handling Terminology and Dimensions

Table 1

		Handling Dimensions for 150 mm (6 in.) Pod	*Handling Dimensions for 200 mm (8 in.) Pod*
Handle:	A1	215.0 mm ± 0.5 mm (8.464" ± 0.019")	305.0 mm ± 0.5 mm (12.008" ± 0.019")
	A2	107.50 mm ± 0.25 mm (4.232" ± 0.01")	152.50 mm ± 0.25 mm (6.004" ± 0.01")
	A3	6.0 mm ± 0.2 mm (0.236" ± 0.008")	5.65 mm ± 0.2 mm (0.222" ± 0.008")
	A4	90° ± 0.2°	90° ± 0.2° (90° ± 0.2°)
	A5	14 mm min. (0.551" min.)	20 mm min. (0.787" min.)
	A6	30 mm ± 0.2 mm (1.181" ± 0.008")	30.0 mm ± 0.2 mm (1.181" ± 0.008")
	A7	50 mm ± 0.2 mm (1.969" ± 0.008")	50.0 mm ± 0.2 mm (1.969" ± 0.008")
	A8	148 mm min., 215 mm max. (A1) (5.827" min., 8.464" max.)	148 mm min., 305 mm max. (A1) (5.827" min., 12.008" max.)
Handle Height:	B1	158 mm ± 1.0 mm (6.220" ± 0.039")	150.4 mm ± 1.0 mm (5.921" ± 0.039")
Handling Area:	B2	30 mm min. (1.181" min.)	30 mm min. (1.181" min.)

SEMI E47.1-1101
PROVISIONAL MECHANICAL SPECIFICATION FOR BOXES AND PODS USED TO TRANSPORT AND STORE 300 mm WAFERS

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1997; previously published July 2001.

1 Purpose

1.1 This standard partially specifies the boxes and pods used to transport and store 300 mm wafers (which may or may not be in removable cassettes) in an IC manufacturing facility.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Most of the requirements given in this specification are in the form of maximum or minimum dimensions with very few required surfaces. Only the physical interfaces (other than the door mechanism and kinematic couplings) for boxes and pods are specified; no materials requirements or micro-contamination limits are given. The enclosure specified in this standard can be a sealed minienvironment, but it could also just be a box with well-defined interfaces.

2.2 The box has the following components and subcomponents:

Key:
- • Required feature
- ◊ Optional feature

- • top
- • top handling flange
- • center hole on top handling flange
- ◊ 3 kinematic grooves on top handling flange (optional)
- • interior
  - • cassette (removable or non-removable with supports for 13 or 25 wafers)
  - • wafer capture mechanism
  - • 2 end effector exclusion zones
- • sides
  - ◊ 2 side fork-lift flanges (optional)
  - ◊ 4 side conveyor rails (bottom-opening only) (optional)
  - ◊ ergonomic manual handles (optional)
- • door (on the bottom or front)
- • holes for latch keys that lock the door to the FIMS interface when the door is unlatched from the box (front-opening only)
- • holes for registration pins
- • door sensing pads (front-opening only)
- • bottom
  - • 4 bottom conveyor rails (with the bottom of the front seal zone acting as the fourth rail and the rear rail optional in the front-opening box)
  - • 2 fork-lift pin holes (front-opening only)
  - • 5 carrier sensing pads
  - • center retaining feature (front-opening only)
  - • front retaining feature (front-opening only)
  - • 4 info pads
  - • 2 advancing box sensing pads (front-opening only)
  - • 3 features that mate with kinematic coupling pins and provide a 10 mm lead in
  - ◊ 3 features that mate with kinematic coupling pins and provide a 15 mm lead in (optional)

2.3 This standard is provisional because of concerns about the kinematic coupling pins causing excessive wear on carriers and the usefulness of the robotic handling flanges and conveyor rails. Once box testing is done, this standard should be modified and upgraded from provisional status.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Provisional Specification for 300 mm Tool Load Port

SEMI E19 — Standard Mechanical Interface (SMIF)

SEMI E19.5 — Specification for 300 mm Bottom-Opening Standard Mechanical Interface (SMIF)

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

SEMI E47 — Specification for 150 mm/200 mm Pod Handles 150 mm and 200 mm SMIF Pod Handles

SEMI E57 — Provisional Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI E62 — Provisional Specification for 300 mm Front-Opening Interface Mechanical Standard (FIMS)

SEMI S8 — Safety Guidelines for Ergonomics/Human Factors Engineering of Semiconductor Manufacturing Equipment

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

4.2 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.3 *carrier capacity* — the number of substrates that a carrier holds (as defined in SEMI E1.9).

4.4 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

4.5 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

4.6 *front-opening unified pod (FOUP)* — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a FIMS port that complies with SEMI E62).

4.7 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

4.8 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

4.9 *nominal wafer center line* — the line that is defined by the intersection of the two vertical datum planes (facial and bilateral) and that passes through the nominal centers of the seated wafers (which must be horizontal when the carrier is placed on the coupling) (as defined in SEMI E57).

4.10 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

4.11 *robotic handling flanges* — horizontal projections on the top of the box for lifting and rotating the box.

4.12 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

5 Ordering Information

5.1 *Intended Use* — This standard is intended to specify 300 mm boxes over a reasonable lifetime of use, not just those in new condition. For this reason, the purchaser needs to specify a time period and the number and type of uses to which the boxes will be put. It is under these conditions that the boxes must remain in compliance with the requirements listed in Section 6.

5.2 *Temperature Ranges* — The purchaser of 300 mm boxes needs to specify two sets of temperatures to which the boxes might be exposed. An operating temperature range is the set of environmental temperatures in which the boxes will remain in compliance with the requirements listed in Section 6. A temporary temperature range is the set of environmental temperatures to which the boxes can be exposed such that when the boxes return to the operating temperature range, the boxes will be in compliance with the requirements listed in Section 6. Limits on exposure times to elevated temperatures should be specified. Also, the purchaser needs to specify a range of temperatures for the wafers and cassettes that might be inserted in the boxes (if the cassettes are removable).

5.3 *Fire Resistance* — The purchaser of 300 mm boxes may need to consider the flammability of the boxes.

5.4 *Info Pad Configurations* — The purchaser of 300 mm carriers needs to specify the desired info pad configuration (up or down).

6 Requirements

6.1 *External Kinematic Couplings* — The physical alignment mechanism from the cassette to the box (if the cassette is removable) and from the box to the tool load-port (or a nest on a vehicle or in a stocker) consists of features (not specified in this standard) on the top entity that mate with three or six pins underneath as defined in SEMI E57. Most of the dimensions of the box are determined with respect to the three orthogonal datum planes defined in that standard: the horizontal datum plane, the facial datum plane, and the bilateral datum plane. All of the dimensions for the box are bilaterally symmetric about both the bilateral and facial datum planes with the following exceptions:

- The features that mate with the kinematic coupling pins and the box sensing pads are symmetrical only about the bilateral datum plane.
- The front-opening box has a door only on the front and conveyor rails on the left and right sides that are required to extend all the way to the front.
- The orientation notches on the robotic handling flange are different for each of the four sides.

The three features that mate with the kinematic coupling pins must provide a lead-in capability that corrects a box misalignment of up to *r*69 in any horizontal direction.

6.2 *Internal Kinematic Couplings* — If the cassette is removable, the horizontal position of each of the three primary kinematic coupling pins on the inside bottom of the box must be within *r*62 of the horizontal positions of the corresponding pin on which the box is set, so that the vertical datum planes defined by the two sets of kinematic couplings must be nearly identical. Each of the three pins on the inside bottom of the box must be *z*44 higher than the corresponding pin on which the box is set, so that the horizontal datum planes defined by the two sets of kinematic couplings will be parallel and separated by dimension *z*44.

6.3 *Nonremovable Cassettes* — If the cassette is nonremovable, there need not be a kinematic coupling between the box and cassette. However, the interior of such a box must have the interior dimensions of the cassette specified in SEMI E1.9. Many of these dimensions are measured from a horizontal datum plane, so an internal horizontal datum plane is still specified to be *z*44 above the horizontal datum plane under the box.

6.4 *Door* — There are two options for the location of the box door.

6.4.1 In the Bottom-Opening Door Option, the box door is on the bottom of the box (so the door is parallel to the wafers and the horizontal datum plane) and the door and its frame must be designed to mate with a port that conforms to SEMI E19.5.

6.4.2 In the Front-Opening Door Option, the box door is on the front side of the box (corresponding to the front side of the cassette where wafers are accessed so the door is perpendicular to the wafers and parallel to the facial datum plane), and the door and its frame must be designed to mate with a port that conforms to SEMI E62. Specifically, the box door and its frame must have surfaces that mate with the seal zones and the reserved spaces for vacuum application (which includes all of the circles bounded by *r*38 except for the holes for the registration pins at the center of each circle) defined in Sections 5.3 and 5.6 of SEMI E62 (which specifies *r*38). These box door and frame surfaces must be a distance of *y*52 from the facial datum plane and must have a flatness of *y*42. No surface on the box door may project further from the facial datum plane than the door seal zone and the reserved spaces for vacuum application. The door of the front-opening box must also be designed so that when the box is pressed against the FIMS port, both latch keys on the port are inserted to their full length. Furthermore, when the latch keys are turned more than 45° toward the position that unlocks the box door from the box, the latch key holes on the door must be such that the door is not removable from the latch keys.

6.5 *Wafer Capture and Centering* — When the box is closed, the cassette and the wafers must be captured in the box to prevent movement during transport. Wafer capture must include gently pushing the wafers to the rear of the cassette to center them.

6.6 *Internal Dimensions* — If the cassette is removable, the interior of the box (other than the kinematic coupling pins or the devices to capture the cassette and the wafers) must not intrude on any of the cassette domains defined in SEMI E1.9. Furthermore, the cassette must have a clearance of at least *r*68 in any direction while it is being inserted into the box. The interior of any front-opening box must also not intrude on the end effector exclusion zone, and the inside of the door must not intrude more that *y*51 toward the facial datum plane. If the cassette is not removable, the interior of the box between *y*11 and the door opening must not protrude higher than *z*6 above the internal horizontal datum plane and lower than *z*15 above the top nominal wafer plane. Horizontally, it must not protrude closer to the bilateral datum plane than *x*51 between *y*11 and *y*49 or closer than *x*52 between *y*49 and *y*52 (as shown in Figure 10). Dimensions *x*51, *x*52, *y*49, and *y*52 are specified in Table 1, and *y*11, *z*6, and *z*15 are specified in SEMI E1.9.

6.7 *External Dimensions* — Figures 1 through 4 respectively show the side view, rear view, top view, and bottom view for the bottom-opening box, and Figures 5 through 8 show the same views of the front-opening box. Table 1 defines all of the dimensions. In this and following figures, the heaviest lines are used for surfaces that have tolerances (not surfaces that have only maximum or only minimum dimensions). If a box identification tag is used, it must be located at the bottom rear centered on the bilateral datum plane and must be contained within the maximum outer dimensions of the box.

Table 1 Dimensions for Bottom-Opening and Front-Opening Boxes

Symbol Used	*Value Specified*		*Datum Measured From*	*Feature Measured To*
	Bottom-Opening	*Front-Opening*		
α‡	60°		bilateral datum plane	center line of the right and left kinematic grooves in the top robotic handling flange
β	45 ± 1°		nominal wafer center line	surface of the center hole in the top robotic handling flange
γ‡	52 ± 1°		bilateral datum plane or vertical plane rotated α away from it about nominal wafer center line	angled surface of the kinematic grooves in the top robotic handling flange
θ‡	45 ± 0.5°		either vertical datum plane	sides of notches in the top robotic handling flange and in the side fork-lift flanges
ϕ	not applicable	30 ± 0.5°	horizontal line on bilateral datum plane	ramp of front retaining feature
*d*63	35 ± 0.1 mm (1.378 ± 0.004 in.)		diameter centered on the nominal wafer center line	sides the center hole in the top robotic handling flange at height *z*47
*d*65	not applicable	10 ± 0.5 mm (0.39 ± 0.02 in.)	diameter centered on the intersection of *x*65 and the facial datum plane	surface of cylindrical fork-lift pin holes in left and right bottom conveyor rails
*f*60	not applicable	175 N (39.3 lbf.) minimum	not applicable	force in any direction which both retaining features are able to withstand
*r*59‡	6 mm (0.24 in.) maximum		not applicable	radius on peak of kinematic grooves in the top robotic handling flange
*r*60	not applicable	16 ± 0.5 mm (0.63 ± 0.02 in.)	nominal wafer center line	ends of slot for center retaining feature
*r*61	not applicable	16 mm (0.63 in.) minimum	nominal wafer center line	walls of chamber above slot in center retaining feature
*r*62	0.05 mm (0.002 in.) maximum		both vertical datum planes defined by the external kinematic couplings	both vertical datum planes defined by the internal kinematic couplings
*r*63‡	66 mm (2.60 in.) maximum		nominal wafer center line	near end of the right and left kinematic grooves in the top robotic handling flange
*r*64	not applicable	9.5 mm (0.37 in.) maximum	not applicable	corners of front retaining feature
*r*65	1 mm (0.04 in.) maximum		not applicable	all concave features (radius)
*r*66	2 mm (0.08 in.) maximum		not applicable	all required convex features (radius)
*r*67	not applicable	240 mm (9.45 in.) maximum for non-removable cassette and 242 mm (9.53 in.) maximum for removable cassette	*y*67 in front of nominal wafer center line	any part of box
*r*68	6 mm (0.24 in.) minimum		not applicable	clearance in any direction between the box and cassette while the cassette is being inserted or removed

Symbol Used	*Value Specified*		*Datum Measured From*	*Feature Measured To*
	Bottom-Opening	*Front-Opening*		
*r*69	10 mm (0.4 in.) minimum (required) 15 mm (0.6 in.) (recommended for ergonomic reasons)		not applicable	correctable box misalignment in any horizontal direction
*x*41	30 ± 1 mm (1.18 ± 0.04 in.)		bilateral datum plane	front right orientation notch on robotic handling flange
*x*42	50 ± 1 mm (1.97 ± 0.04 in.)		bilateral datum plane	front left orientation notch on robotic handling flange
*x*43	50 ± 1 mm (1.97 ± 0.04 in.)		bilateral datum plane	rear orientation notch on robotic handling flange
*x*44	53 mm (2.09 in.) maximum		bilateral datum plane	encroachment of box underneath robotic handling flange
*x*45	65.3 ± 1 mm (2.57 ± 0.04 in.)		bilateral datum plane	nearest point of side position and orientation notches on robotic handling flange
*x*46	71 ± 1 mm (2.80 ± 0.04 in.)		bilateral datum plane	sides of robotic handling flange
*x*47	58 mm (2.28 in.) minimum		bilateral datum plane	end of robotic handling flange front and rear
*x*50‡	not applicable	214 ± 1 mm (8.43 ± 0.04 in.)	bilateral datum plane	outer edge of side fork-lift flanges and furthest reach of human handles
*x*51	not applicable	140 mm (5.51 in.) minimum	bilateral datum plane	interior of box sides between *y*11 and *y*49 in a box with a non-removable cassette
*x*52	not applicable	170 mm (6.69 in.) minimum	bilateral datum plane	interior of box sides between *y*49 and *y*52 in a box with a non-removable cassette
*x*53	205 mm (8.07 in.) maximum	195 mm (7.68 in.) maximum for non-removable cassette and 205 mm (8.07 in.) maximum for removable cassette	bilateral datum plane	box sides (apart from human handles)
*x*54‡	204.75 ± 0.25 mm (8.061 ± 0.010 in.)	not applicable	bilateral datum plane	outside edge of upper conveyor rails
*x*55	195 mm (7.68 in.) maximum	not applicable	bilateral datum plane	box sides underneath side conveyor rails
*x*56	194.75 ± 0.25 mm (7.667 ± 0.010 in.)	194.75 ± 0.25 mm (7.667 ± 0.010 in.) for non-removable cassette and 204.75 ± 0.25 mm (8.061 ± 0.010 in.) for removable cassette	bilateral datum plane	outside edge of bottom conveyor rails
*x*57	180 mm (7.09 in.) maximum		bilateral datum plane	box sides underneath bottom conveyor rails
*x*58‡	75 mm (2.95 in.) minimum		bilateral datum plane	end of front (bottom-opening only) and rear conveyor rails
*x*59‡	199.3 ± 1 mm (7.85 ± 0.04 in.)	not applicable	bilateral datum plane	nearest point of position notch on side conveyor rails
*x*60	not applicable	8 ± 0.5 mm (0.31 ± 0.02 in.)	bilateral datum plane	sides of slot for center retaining feature
*x*61	not applicable	190.5 mm (7.50 in.) minimum	bilateral datum plane	outer edge of front clamp flange

Symbol Used	*Value Specified*		*Datum Measured From*	*Feature Measured To*
	Bottom-Opening	*Front-Opening*		
*x*62	not applicable	188.5 mm (7.42 in.) maximum	bilateral datum plane	encroachment of box behind front clamp flange
*x*63‡	not applicable	199.3 ± 1 mm (7.85 ± 0.04 in.)	bilateral datum plane	nearest point of notches in side fork-lift flanges
*x*64	not applicable	35 mm (1.38 in.) minimum	bilateral datum plane	sides of front retaining feature
*x*65	not applicable	187.5 mm (7.38 in.)	bilateral datum plane	vertical axis of cylindrical fork-lift pin holes in left and right bottom conveyor rails
*x*66	not applicable	31 mm (1.22 in.) maximum	bilateral datum plane	near side of advancing box sensing pads
*x*67	not applicable	34 mm (1.34 in.) minimum	bilateral datum plane	far side of advancing box sensing pads
*x*68	not applicable	25 mm (0.98 in.) minimum	bilateral datum plane	sides of volume above ramp on front retaining feature
*x*69‡	7.6 ± 0.1 mm (0.299 ± 0.004 in.)		bilateral datum plane or vertical plane rotated α away from it about nominal wafer center line	beginning of angled surface of the kinematic grooves in the top robotic handling flange
*y*40	not applicable	122.5 ± 2.5 mm (4.82 ± 0.10 in.)	facial datum plane	front of side fork-lift flanges and furthest reach of human handles toward the front
*y*41	30 ± 1 mm (1.18 ± 0.04 in.)		facial datum plane	left orientation notch on robotic handling flange
*y*42	not applicable	± 0.5 mm (± 0.02 in.) flatness over each area	not applicable	door and frame seal zones and the reserved spaces for vacuum application
*y*44	53 mm (2.09 in.) maximum		facial datum plane	encroachment of box underneath robotic handling flange
*y*45	65.3 ± 1 mm (2.57 ± 0.04 in.)		facial datum plane	nearest point of front and rear position and orientation notches on robotic handling flange
*y*46	71 ± 1 mm (2.80 ± 0.04 in.)		facial datum plane	front and rear edge of robotic handling flange
*y*47	58 mm (2.28 in.) minimum		facial datum plane	end of robotic handling flange sides
*y*49	not applicable	134 mm (5.28 in.) maximum	facial datum plane	interior of box sides between *x*51 and *x*52 in a box with a non-removable cassette
*y*50	not applicable	130 mm (5.12 in.) minimum	facial datum plane	rear of upper door frame volume
*y*51	not applicable	140 mm (5.51 in.) minimum	facial datum plane	rear of door
*y*52	205 mm (8.07 in.) maximum	165.5 ± 0.5 mm (6.52 ± 0.02 in.) at door and frame seal zones and at reserved spaces for vacuum application and 166 mm (6.54 in.) maximum elsewhere on door or box shell	facial datum plane	box front

Symbol Used	*Value Specified*		*Datum Measured From*	*Feature Measured To*
	Bottom-Opening	*Front-Opening*		
*y*53	205 mm (8.07 in.) maximum	190 mm (7.48 in.) maximum	facial datum plane	box rear
*y*54‡	204.75 ± 0.25 mm (8.061 ± 0.010 in.)	not applicable	facial datum plane	outside edge of front and rear upper conveyor rails
*y*55	195 mm (7.68 in.) maximum	not applicable	facial datum plane	encroachment of box front and rear upper conveyor rails
*y*56‡	194.75 ± 0.25 mm (7.667 ± 0.010 in.)	189.75± 0.25 mm (7.470 ± 0.010 in.)	facial datum plane	outside edge of front and rear bottom conveyor rails
*y*57‡	189 mm (7.44 in.) maximum	178 mm (7.01 in.) maximum	facial datum plane	encroachment of box front and rear underneath bottom conveyor rails
*y*58	75 mm (2.95 in.) minimum		facial datum plane	end of left and right conveyor rails
*y*59‡	199.3 ± 1 mm (7.85 ± 0.04 in.)	not applicable	facial datum plane	nearest point of position notch on front or rear conveyor rails
*y*60	not applicable	155 mm (6.10 in.) maximum	facial datum plane	encroachment of box behind front clamp flange
*y*61	not applicable	3.5 ± 0.5 mm (0.14 ± 0.02 in.)	front of front clamp flange at box front	rear of front clamp flange
*y*62	not applicable	28 mm (1.10 in.) maximum	facial datum plane	rear of front retaining feature
*y*63	not applicable	37.3 ± 0.5 mm (1.47 ± 0.02 in.)	facial datum plane	rear of ramp on front retaining feature
*y*64	not applicable	42.1 ± 0.5 mm (1.66 ± 0.02 in.)	facial datum plane	front of ramp on front retaining feature and front side of advancing box sensing pads
*y*65	not applicable	104 mm (4.09 in.) minimum	facial datum plane	front of front retaining feature
*y*66	not applicable	50 mm (1.97 in.) minimum	facial datum plane	rear side of advancing box sensing pads
*y*67	not applicable	25 mm (0.98 in.) for non-removable cassette and 40 mm (1.57 in.) for removable cassette	facial datum plane	origin of *r*67 on bilateral datum plane
*y*68‡	55 mm (2.17 in.) maximum		facial datum plane	near end of the front kinematic groove in the top robotic handling flange
*z*2	not applicable	2 mm (0.08 in.) maximum	horizontal datum plane	bottom of carrier sensing pads and info pads (when down)
*z*41	0 mm (0 in.) minimum		external horizontal datum plane	bottom of box
*z*43	2 ± 1 mm (0.08 ± 0.04 in.)		external horizontal datum plane	bottom conveyor rails
*z*44	11 ± 0 mm (0.43 ± 0 in.) for non-removable cassette and 25 ± 0.05 mm (0.984 ± 0.002 in.) for removable cassette		external horizontal datum plane	internal horizontal datum plane
*z*46‡	60 ± 1 mm (2.36 ± 0.04 in.)		external horizontal datum plane	bottom of side fork-lift flanges

Symbol Used	*Value Specified*		*Datum Measured From*	*Feature Measured To*
	Bottom-Opening	*Front-Opening*		
z47	210 ± 1 mm (8.27 ± 0.04 in.) for non-removable 13-wafer cassette and 330 ± 1 mm (12.99 ± 0.04 in.) for non-removable 25-wafer cassette		external horizontal datum plane	bottom of robotic handling flange
	233 ± 1 mm (9.17 ± 0.04 in.) for removable 13-wafer cassette and 353 ± 1 mm (13.90 ± 0.04 in.) for removable 25-wafer cassette	253 ± 1 mm (9.96 ± 0.04 in.) for removable 13-wafer cassette and 373 ± 1 mm (14.69 ± 0.04 in.) for removable 25-wafer cassette		
z48	15 mm (0.59 in.) minimum		bottom of robotic handling flange	encroachment of box top underneath robotic handling flange
z49	8 mm (0.31 in.) maximum		bottom of robotic handling flange	top of robotic handling flange and upper door frame volume
z50	5 mm (0.20 in.) minimum		bottom of robotic handling flange	encroachment of box top underneath the center hole in the top robotic handling flange
z59	72 mm (0.31 in.) minimum		external horizontal datum plane	top of notches in side fork-lift flanges
z60	not applicable	8.0 ± 0.5 mm (0.31 ± 0.02 in.)	external horizontal datum plane	top of slot in center retaining feature
z61	not applicable	15 mm (0.59 in.) minimum	external horizontal datum plane	top of chamber above slot in center retaining feature
z62	not applicable	18 mm (0.71 in.) minimum	external horizontal datum plane	top of front retaining feature
z63	not applicable	7.5 ± 0.5 mm (0.30 ± 0.02 in.)	external horizontal datum plane	top of ramp on front retaining feature
z65	not applicable	7 mm (0.28 in.) minimum	horizontal datum plane	upper boundary of cylindrical fork-lift pin holes in left and right bottom conveyor rails
z66	not applicable	55.5 mm (2.19 in.) maximum	external horizontal datum plane	encroachment of box behind bottom front clamp flange
z67	not applicable	79.5 mm (3.13 in.) minimum	external horizontal datum plane	encroachment of box behind bottom front clamp flange
z68	not applicable	133.5 mm (5.26 in.) maximum for 13-wafer box and 253.5 mm (9.98 in.) maximum for 25-wafer box	external horizontal datum plane	encroachment of box behind top front clamp flange
z69	not applicable	157.5 mm (6.20 in.) minimum for 13-wafer box and 277.5 mm (10.93 in.) minimum for 25-wafer box	external horizontal datum plane	encroachment of box behind top front clamp flange

‡ These dimensions define optional features.

6.8 *Human Handles* — All handles for use by humans must either be contained within the maximum outer dimensions of the box, be detached when not in use, or be retractable into the maximum outer dimensions when not in use. On the front-opening box, although such handles may extend past *x*53, they must still be contained within the upper limits of *x*50, *y*40, and *r*67. Handles for use by humans (if present) must follow SEMI S8, and they must require the use of both hands (each using a full wrap-around grip, given the minimum clearance requirement in SEMI E15.1). Automation handling features shall not be considered dual purpose unless they are designed to meet SEMI S8 guidelines.

6.9 *Automation Handling Features* — On the top of the box is a robotic handling flange for manipulating the box. Shown in Figure 12 (on the top robotic handling flange) are a center hole and 3 optional kinematic grooves (which, if present, must be implemented entirely including the radius at the peak). On the left and right sides of the box (and on the front and back of the bottom-opening box) are optional flanges (of unspecified thickness) for use with fork lifts. On the bottom of the box are rails for use with roller conveyors. Although they are only required to extend *x*58 to the rear (and front for the bottom-opening box) and *y*58 to the left and right, it is recommended that they be as long as possible. Beyond *x*58 and *y*58, only the lower bounds on *z*43 and *z*46 apply. On the bottom-opening box, optional conveyor rails (defined by *x*54, *x*55, *y*54, *y*55, and *z*46) are located on all four sides and required conveyor rails (defined by *x*56, *x*57, *y*56, *y*57, and *z*43) are located on all four bottom edges. The side fork-lift flanges and the left and right bottom conveyor rails of the front-opening box also have vertical cylindrical pin holes for fork lift centering. On the bottom edges of the front-opening box, 2 required conveyor rails (defined by *x*56, *x*57, *y*58, and *z*43) are located on the left and right, and an optional conveyor rail (defined by *x*58, *y*56, *y*57, and *z*43) is located on the rear.

6.10 *Retaining Features* — Figures 8 and 9 show two features on the bottom of the front-opening box that may be used for retaining the box onto the kinematic couplings. This may be needed to prevent the box from being knocked off the kinematic couplings by the action of pushing the box against the front-opening interface. The front retaining feature contains a ramp that a wheel might roll up while the box is being pushed toward the front-opening interface. The arm with the wheel (not specified here) then holds the box down on the kinematic couplings. The center retaining feature consists of an oblong slot with a chamber above it. The box can be clamped onto the kinematic couplings by inserting an oblong head on a shaft (not specified here) through the slot and rotating it 90° in either direction. Either retaining feature would only engage after the box is fully seated on the kinematic coupling pins. Either retaining feature must be able to withstand a force in any direction of at least *f*60. It is recommended that SEMI E15.1 tool load ports be designed to accommodate the minimum hole dimensions of the retaining features to ensure carrier interchangeability. Projections on the tool load ports that mate with the retaining features should also not interfere with the misalignment correction function of the kinematic couplings. Figures 5 through 8 also show front clamp flanges and exclusion volumes (defined by x62, y60, y61, z66, z67, z68, and z69) behind them that can be used to clamp the box to the box opener when the box is purged with Nitrogen. However, it is strongly recommended that the front clamp flanges not be used for pulling the FOUP from the undocked position into the FIMS interface. Also, all of the dimensions of the FOUP (such as the wafer location, etc.) are defined with reference to the kinematic coupling pins, and most FOUPs are designed so that all of the their features are in the proper location only when the FOUP is held in place on the kinematic coupling pins only by gravity. Thus, if the front clamp flanges are used, the wafers and the FOUP features may be in a different position than defined in SEMI E1.9 (possibly resulting in damage to wafers, wafer handlers, and the FOUP).

6.11 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*65 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*66 to prevent small contact patches with large stresses that might cause wear and particles. Note that these limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the carrier supplier. Note also that this radius applies to every required feature unless another radius is called out specifically. Here a required feature is an area on the surface of the carrier specified by a dimension (or intersections of dimensions) that has a tolerance and not just a maximum or minimum (such as the edges of the robotic handling flange).

6.12 *Box Placement Sensing Pads* — The box must have the same carrier sensing pads as is required of the cassette in SEMI E1.9, including the info pads that communicate information about the carrier such as the carrier capacity (number of wafers) and type (cassette or box). See SEMI E1.9 for information about info pad configurations for different wafer carriers similar to FOUPs including front-opening shipping boxes (as defined in SEMI M31) and single-wafer interface (SWIF) systems (as defined in SEMI E103). Two additional sensing pads (that can be used continuously while the front-opening box is advancing into the FIMS interface) must be located near the center of the bottom at the same distance from the horizontal datum plane as the carrier sensing pads. In addition, the surfaces on the door of the front-opening box that mate with the seal zones and the reserved spaces for vacuum application may also be used for door-presence sensing.

APPENDIX 1
APPLICATION NOTES

NOTE: The material in this appendix is an official part of SEMI E47.1 and was approved by full letter ballot procedures on August 27, 2001.

A1-1 The automation handling features do not need to be molded into the plastic shell of the box, but can be attached as a framework around the shell.

A1-2 To increase the stability of the box on the kinematic couplings, it is recommended that the points on the box bottom extend as close as practical to the horizontal datum plane to minimize tipping of the box.

A1-3 Skewness, warp, rock, and stiffness are implicitly defined in the geometric tolerances.

A1-4 Dimension *y*52 is given as a maximum based on the maximum distance to the port door specified in SEMI E62.

A1-5 The position tolerance of the door of the front-opening box is likely to be much larger than the position tolerance of the registration pins. To make both manual and automated door opening easier, it is recommended that the holes for the registration pins on the door of the front-opening box have openings with a lead-in capability.

NOTE A1-1: If the bottom of the box does not extend below the bottom conveyor rail, the conveyor rail may become contaminated and may distribute particles.

A1-6 Although both of the retaining features on the bottom of the front-opening box must be able to withstand a force in any direction of *f*60, continuously applied stress may result in plastic deformation.

A1-7 In order to minimize particle generation when the box door is opened or closed, it is recommended that the tolerance between the box door and its frame be larger than the tolerance between the box door registration holes and FIMS registration pins.

A1-8 One type of carrier presence sensor uses a beam of light with an optical detector that is triggered when the beam of light is attenuated as it passes through the box shell.

A1-9 The use of the registration pins for FOUP door lead-in to the loadport door is not recommended. The registration pins should be only used to limit the maximum displacement of the FOUP door while on the loadport door. Neither the FOUP nor FOUP door positions should change as a result of engaging or disengaging the registration pins. When the Loadport experiences utility loss (such as EMO, vacuum loss, electrical failure, etc.), the registration pins may be used to maintain the FOUP door's position, and to ensure that the FOUP door does not to fall off. The clearance between the Registration Pins and the Registration Pin Holes should be less than the clearance between the outer edge of the FOUP Door and the inner edge of the FOUP Door Frame. Balancing these tolerances is a FOUP design issue related to the E62 Seal Zone specification. The diameter of the Registration Pin Holes should be designed to accommodate the Registration Pin tolerance defined in E62 (x31, z31, d31) and the Registration Pin Hole location tolerance in a FOUP.

A1-10 It is recommended that the FOUP have a capability to roughly position the FOUP door in the FOUP frame during the door close sequence (during either return of the FOUP door or during latching of the FOUP door). This positioning capability should keep the clearance between the FOUP frame and the FOUP door larger than sum of the FOUP (self) tolerance and the E62 registration pin tolerance along with the FOUP door's circumference. Possible methods for accomplishing this may include positioning by latch motion and positioning by a slope between the FOUP frame and the FOUP door.

A1-11 It is recommended that the FOUP have a lead-in mechanism on its latch key holes. This lead-in mechanism should compensate for the FOUP's latch key hole location error, as shown in Figure A1-1.

A1-12 It is recommended that the latch key hole mechanisms have some flexibility in their position for compliance with the latch key positions. The purpose of this is to adjust for any discrepancy in rotation axis between the latch key and the latch key hole mechanism. As shown in Figure A1-2, if only one side of the latch key pushes on the inside of the latch key hole, the latch key can not rotate more than half way.

A1-13 It is recommended that the torque required to rotate the FOUP latch key holes be kept small enough that it will not produce movement of the FOUP door in the *x* and *z* directions during latch key rotation.

A1-14 It is recommended that the latch key holes be maintained in the position that unlocks the box door from the box ($\psi = 0 \pm 1°$ as defined in E62) while the box is open and in the position that locks the box door to the box ($\psi = 90 \pm 1°$) while the box is closed. One method to accomplish this is to have the FOUP latch key hole mechanisms snap into both end points of their rotation ($\psi = 0 \pm 1°$ and $\psi = 90 \pm 1°$) using a detent mechanism. The torque required to overcome such a detent mechanism should not exceed *f*30 (as defined in E62).

A1-15 Table A1-1 can be used for communicating the compliance of boxes to this standard and the options chosen:

Table A1-1 Optional Features Checklist

Section	*Optional Feature*	*Choice*
4.3	carrier capacity (*c*)	☐ 13 wafers or ☐ 25 wafers
6.4	door location	☐ bottom (complying with SEMI E19.5) or ☐ front (complying with SEMI E62)
6.3	cassette type	☐ removable or ☐ non-removable (complying with interior dimensions of SEMI E1.9)
6.1	full 15-mm lead in provided by 3 features that mate with kinematic coupling pins	Primary kinematic coupling pins ☐ yes or ☐ no and secondary kinematic coupling pins ☐ yes or ☐ no
6.9	4 side conveyor rails (bottom-opening only)	☐ yes or ☐ no
6.8	ergonomic manual handles	☐ yes or ☐ no
6.9	side fork-lift flanges	☐ yes or ☐ no
6.9	3 kinematic grooves on the top robotic handling flange	☐ yes or ☐ no

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E47.1, and it is not intended to modify or supercede the official standard. This information was inserted by the North America Physical Interfaces and Carriers Committee to alert the readers to potential changes to this provisional standard.

R1-1 A revision ballot will be submitted to require the same bottom carrier ID label area as in SEMI E1.9.

R1-2 A revision ballot will be submitted to increase the maximum thickness of the top robotic flange by 3 mm.

R1-3 A design exists for a box and adapter mechanism that holds only on wafer and is supposed to comply with SEMI E47.1. A new activity to standardize a "One Wafer FOUP" is being considered.

SEMI E48-1101
SPECIFICATION FOR SMIF INDEXER VOLUME REQUIREMENT

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on April 24, 2001. Initially available at www.semi.org August 2001; to be published November 2001. Originally published in 1995; previously published July 2001.

1 Purpose

1.1 The purpose of this specification is to provide the volume required within a tool that enables integration of SMIF into tools with single or multiple ports.

2 Scope

2.1 This specification defines the space necessary within a tool with respect to the interface plane. The specification refers to the Standard Mechanical InterFace (SMIF) Standard, SEMI E19.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E19 — Standard Mechanical Interface (SMIF)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *cassette* — an open structure that holds one or more substrates (e.g., wafers, masks).

4.2 *integrated SMIF* — a unit including a SMIF port and a mechanism for indexing the port door. The entire unit being incorporated within the tool.

4.3 *standard mechanical interface (SMIF)* — the interface plane between a pod and another minienvironment per SEMI E19.

4.4 *wafer transfer plane* — a plane with a maximum distance from the interface plane to the level where a wafer can be transferred.

5 Requirements

5.1 Figure 1 depicts the height dimensions and terminology for integrated SMIF. Figure 2 shows the necessary footprint for the integrated SMIF on a tool. The dimensions are given with reference to SEMI E15.

5.2 The minimum distance between the interface plane and the wafer transfer plane A1 is limited by the thickness of the port plate and any wafer sensing system. This distance should be kept as small as possible for ergonomic reasons.

5.3 The dimension A2 below the interface plane takes into account the distance A1, the cassette dimensions, and the mechanical components. Process tools must provide this free space to allow integration of SMIF.

5.4 Referring to Figure 2, it can be seen that the axis of the wafer transfer, B2, does not necessarily correspond to the center line of the integrated SMIF unit. This is to allow the indexing mechanism to be placed in different locations, so that multiple ports can be furnished, still adhering to SEMI E15.

Table 1 Integrated SMIF Dimensions

		Up to 150 mm	*200 mm*
Installation Height	A1	63 mm max. (2.48" max.)	63 mm max. (2.48" max.)
	A2	400 mm min. (15.75" min.)	400 mm min. (15.75" min.)
Footprint	B1	355 mm min. (13.98" min.)	355 mm min. (13.98" min.)
	B2	177.5 mm max. (6.99" max.)	177.5 mm max. (6.99" max.)
	B3	157 mm max. (6.18" max.)	182 mm max. (7.17" max.)
	B4	390 mm min. (15.35" min.)	390 mm min. (15.35" min.)
	B5	20 mm max. (0.79" max.)	20 mm max. (0.79" max.)
SEMI E15 (Recommendation)	S	350 mm (13.8")	400 mm (15.7")

Dimension Definitions

A1 — Maximum distance from the SMIF interface plane to the wafer transfer plane.

A2 — Minimum depth, from the interface plane, required in a tool.

B1 — Minimum width required in a tool.

B2 — Maximum distance from the side of the indexer unit to the cassette or container centroid.

B3 — Maximum distance from the front of the indexer unit to the cassette or container centroid.

B4 — Minimum breadth required for the indexer unit in a tool.

B5 — Maximum distance that can be penetrated underneath the port plate.

S — Recommended minimum spacing between cassette or container controids.

Integrated SMIF Top View

NOTICE: SEMI makes no warranties or representations as to the suitability of the specification set forth herein for any particular application. The determination of the suitability of the specification is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These specifications are subject to change without notice.

The user's attention is called to the possibility that compliance with this specification may require use of copyrighted material or of an invention covered by patent rights. By publication of this specification, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E49-0702
GUIDE FOR STANDARD PERFORMANCE, PRACTICES, AND SUB-ASSEMBLY FOR HIGH PURITY PIPING SYSTEMS AND FINAL ASSEMBLY FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT

1 Purpose

The purpose of this overview is to provide a basic set of definitions and reference documents for SEMI E49.1 - SEMI E49.9.

2 Scope

These documents reference many performance and method standards that were developed in North America. For semiconductor equipment that will be installed or manufactured in other countries, the users should request compliance to the equivalent or similar performance requirements in their equipment proposal request or purchase order documents.

2.1 The documents in this guide are organized by types of piping distribution systems — gas, DI/chemical, solvent — and by types of assembly and testing procedures — sub-assembly for stainless steel, sub-assembly for polymer and final tool assembly.

2.2 The piping distribution documents include guidelines for system design, performance, materials, and components. Two purity and performance grades are described for each of the three types of distribution systems:

2.2.1 *High Purity (HP)* — For industry standard systems consisting of high grade materials, components, and standard design/configuration, assembly method, and performance capability.

2.2.2 *Ultrahigh Purity (UHP)* — For advanced or special systems consisting of higher grade materials and components, with advanced or integrated design and configuration, the latest assembly methods, and enhanced performance capabilities, especially related to purge or rinse time and contamination levels.

2.2.3 HP systems should have only marginal effect on overall tool purchase price. UHP systems are more customized and have a higher purchase price than HP systems, but the very expensive exotic and/or highly specialized materials and components are not in the scope of UHP. Users should complete an overall tool cost of ownership analysis to determine the optimum application of HP or UHP tool features. Key parameters should include facilities cost and installation cycle time, piping system reliability and maintainability factors, tool and sub-system contribution to contamination, and resultant effects on wafer quality and wafer throughput factors.

5 Impact

5.1 The impact of improved tool quality and standardization is:

5.1.1 Reduced tool purchase price for customized piping distribution systems, by employing standard designs and practices for HP and UHP systems.

5.1.2 Reduced tool installation cost and cycle time.

5.1.3 *Reliability, Maintainability* — Improved tool up-time, repair time, and availability will positively affect cost of ownership. Primary improvement is in system MTBF and MTTR.

5.1.4 *Sub-Assembly Contamination Control* — Cost of ownership will also be improved by lower long-term contamination levels in the process chamber or bath, resulting in wafer defect reductions and/or yield improvement. Long-term flow accuracy for mass flow controllers (MFC's) will also be improved for better wafer level uniformity.

5.1.5 *Final Assembly Contamination Control* — Will result in reduced possibility of cleanroom contamination upon tool delivery, and avoid time delay of tool cleaning at wafer fab site.

SEMI E49.1-95
GUIDE FOR TOOL FINAL ASSEMBLY, PACKAGING, AND DELIVERY

1 Purpose

The objective of this document is to establish standard guidelines for cleanroom activities specific to the final assembly, packaging, and delivery of semiconductor manufacturing equipment.

2 Scope

This standard has been developed as a guide for final tool assembly and packaging. This standard covers both high and ultrahigh purity applications. Process specifications related to wafer particles and/or quality are not in the scope of this document. Parameters such as particles per wafer pass (PWP) should be in the user's specific equipment process performance specification.

3 Referenced Documents

Note: Refer to the latest version of the following documents for general cleanroom protocol.

3.1 *FED-STD Federal Standard Cleanroom and Work Station Requirements, Controlled Environment*[1]

3.2 *Institute of Environmental Sciences Documents*[2]

IES-RP-CC-001 — Recommended Practices for HEPA Filters

IES-RP-CC-002 — Recommended Practices for Laminar Flow Clean Air Devices

IES-RP-CC-003 — Recommended Practices for Garments Required in Clean Rooms and Controlled Environmental Areas

IES-RP-CC-006 — Recommended Practices for Testing Cleanrooms

4 Terminology

See Section 4 of SEMI E49.

5 Pre-Packaging Procedures

5.1 All components of the equipment should be thoroughly cleaned before assembly and assembly in at least a Class 1000/100 cleanroom (HP/UHP).

5.2 *Tools* — Maintain a set of clean tools in the clean assembly area. If this is not possible, tools should be cleaned according to the following section (cleaning) each time they reenter the clean assembly area.

5.3 *Cleaning* — Assembly tools and all system components should be vacuumed, blown off with filtered air, and cleaned with a solution of 10% IPA in DI water immediately prior to being brought in to the clean assembly area. Use swabs and wipes rated for Class 100 service.

Cutting oils, lubricants, and solder flux should be removed before parts are brought into the clean assembly area.

5.4 *Exclusions* — Machining, sawing, welding, brazing, grinding, and sanding operations must be completed before components are brought into the clean assembly area.

5.5 The equipment should be subject to a thorough cleanliness inspection. The supplier should provide a copy of the inspection results (e.g., marked checklist) with the equipment.

5.6 All equipment with water, except DI water, or other liquids should be fully emptied and completely dried using dry, oil-free air or nitrogen.

5.7 The equipment should be clearly marked showing correct lifting points for removal from shipping container.

5.8 All utility lines should be capped during shipment.

5.9 All vacuum systems should be shipped under vacuum.

6 Packaging Procedures

6.1 The equipment and separate subassemblies or support equipment should be totally enclosed and sealed in at least two layers of clean, oil-free clear 6 mil polyethylene so each layer forms a seal against moisture and particles.

6.2 A humidity indicator should be included inside of the initial wrapping layer.

6.3 *Triple Wrap Strategy* — The individual wraps are intended to be removed in stages and should adhere to the following guidelines:

6.3.1 *Inner Wrap* — This wrap should stay with the tooling all the way into the final cleanroom or a staging area of the same order wipe down. The wrap should be cleaned prior to movement into the cleanroom.

1 Available from Federal Information Processing Standard

2 Available from Institute of Environmental Sciences, 940 East Northwest Highway, Mount Prospect, IL 60056

6.3.2 *Middle Wrap* — This wrap should stay with tooling until it reaches a Class 10,000 intermediate staging area. The wrap should be cleaned before leaving the receiving area and again before it is removed in the staging area.

6.3.3 *Outer Wrap* — This wrap is used to protect the tooling while in transit to the loading dock. While the equipment is on the loading dock, outer shipping material should be removed and the wrap cleaned and removed.

6.4 *Clean Assembly Area* — Following final assembly and test, all exposed parts should be thoroughly wiped down with deionized water, using cleanroom wipes. Approved materials for cleaning are described in Section 10.3.4. Tooling should then be totally enclosed in a clean, oil-free inner wrap using transfer tape as required. If two sets of pallets are used, the inner pallet should meet the requirements of Section 5.2.2 and should be enclosed with the tool. Jacking points should be identified to facilitate rigging.

6.5 *Dedicated Packaging Area* — After the first wrap has been applied, the equipment should be moved to a dedicated clean (Class 10,000 or better) packaging area. Here the outer two wraps of clear polyethylene are installed and taped.

After the equipment is triple wrapped, it should be placed on a pallet so that the triple wrapping is not damaged or violated. The pallet should be movable (with equipment attached to it) with a conventional pallet jack or fork lift. The equipment should also be capable of placement on and removal from the pallet with a conventional pallet jack or fork lift without compromising or tearing any of the triple wrapping.

After the equipment is on the pallet, the manufacturer may use any conventional packaging materials (e.g., bubble wrap, styrofoam, or wood) to ensure that the equipment is not damaged in transit. However, these conventional materials cannot compromise or tear the triple wrapping.

6.6 *Recommended Materials*

6.6.1 For cleaning and triple wrap packaging:

- DI water, resistivity 18.0 Megohm-cm, minimum
- UHP isopropyl alcohol (IPA)
- Cleaning solution, 10% IPA + DI water
- Lintfree cleaning swabs
- Polyester cleanroom wipes with thermally sealed edges
- Oil-free 6 mil polyethylene sheeting (for middle and outer wrap)
- A non-shedding polyethylene wrap is recommended for inner wrap
- Nonparticulate adhesive tape

6.7 For packaging outside the triple wrap:

- Paper or cardboard of any type
- Wood
- Bubble wrap, styrofoam, and foam rubber
- Masking tape, duct tape, and paper tape
- Noncleanroom wipers

6.8 The equipment should be securely fastened to its shipping container.

6.9 All shipping containers should have integral pallets or be mounted securely to pallets.

6.10 Each shipping container should be clearly marked with its tare weight and an equipment identification number provided by the customer.

6.11 Each shipping container should have three axis shock sensors, tilt sensors, and temperature indicators located both inside and outside the container for parts sensitive to the above requirements.

6.12 All support hardware or separate components (e.g., cables, spare parts) should be packaged in separate containers from the main unit.

6.13 The packing list should specify which container each component is in.

7 Delivery

The equipment should be transported in air ride vans.

SEMI E49.2-0298
GUIDE FOR HIGH PURITY DEIONIZED WATER AND CHEMICAL DISTRIBUTION SYSTEMS IN SEMICONDUCTOR MANUFACTURING EQUIPMENT

1 Purpose

1.1 This document specifies guidelines for high purity (HP) deionized water and chemical distribution systems in semiconductor production equipment.

2 Scope

2.1 The distribution systems consist of polymer piping designed to supply the following types of liquid chemicals to the process:

- Acids, bases, and oxidizers
- Deionized water
- Corrosive solvents

2.2 Typical tools include wet clean stations, wafer scrubbers, and photolithography coaters and developers.

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E49 — Guide for Standard Performance, Practices, and Sub-Assembly for High Purity Piping Systems and Final Assembly for Semiconductor Manufacturing Equipment

SEMI E49.7 — Guide for Subsystem Assembly and Testing Procedures - Polymer Systems

3.2 *ASTM Standards*[1]

See Section 3.3 of SEMI E49.

4 Terminology

See Section 4 of SEMI E49.

5 Performance Guidelines

5.1 *Leak Tests*

5.1.1 *Pressure Decay Test*

- Test Media — Nitrogen (N^2)
- Pressure — 2.1 kg/cm^2 (30 psig) maximum
  — 1.75 kg/cm^2 (25 psig) minimum
- Time — 120 minutes
- Fail-Pressure Loss — > 2% of test pressure, after compensation for temperature variation.

5.1.2 *Hydrostatic Pressure Test*

- Test Media — DI water (pumped)
- Pressurization Media — Nitrogen (N_2)
- Pressure — 2 times operating pressure or 7.0 kg/cm^2 (100 psig), whichever is less
- Time — 4 hours
- Fail-Pressure Loss — Any pressure loss or any visible leakage, compensated for temperature gradient and/or material expansion.

5.2 *Purity Indices*

5.2.1 *Particle Count (ptc) at ≥ 0.5 µm Size*

- < 10 ptc/L average single count
- < 50 ptc/L maximum single count
- Test media is DI water

5.2.2 *DI Water Flush Test* — The specified limit is the difference between incoming and outgoing DI water.

- Resistivity — ± 0.5 Mega ohm-cm
- Total Organic Carbons (TOC) — < 4 ppb

5.3 All performance measures are absolute values, relative to respective test instrument background level.

5.4 See SEMI E49.7 for recommended DI/chemical system testing procedures.

5.5 *Reliability and Maintainability Indices* — Equipment supplier should provide actual DIW/Chemical system performance data and/or component reliability data, accompanied by the associated failure analysis method.

Indices	*Hours*
Mean time between failure (MTBF)	
Mean time between assists (MTBA)	
Mean time to repair (MTTR)	
Start-up time (Initial)	

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

6 Design Guidelines

6.1 All polyvinylidene fluoride (PVDF) should be thermally socket welded, as a minimum, using interactive automated welding equipment. Thermal butt welding is preferred.

6.2 All perfluoroalkoxy (PFA) tubing should be joined with flare compression type technique. Flaring can be done at room temperature or at elevated temperature, depending on the technique required by the component supplier.

6.3 All PFA pipe should be thermally butt welded, using interactive automated welding equipment.

6.4 Dead volume areas should be minimized by the use of close connected bypass or bleed-through loops. Dead legs should be < 5 pipe diameters.

6.5 System internal volume should be minimized by the use of close fit adapters and fittings. Dead Space Free (DSF) branch valves and/or multi-component integrated assemblies are optional.

6.6 The DIW distribution system should have a continuous flow with a velocity of ≥ 0.3 m/s (1 fps).

6.7 Pipe thread type connections should not be used.

6.8 Flow meters should be installed in return side of DI water system.

6.9 Backflow/back pressure protection should be included in the system.

6.10 The system should use tee fittings and branch valves to accomplish flush, test, and sample ports. Sample ports should be located as close as possible to the chemical supply point, either to bath/tank or process chamber and also at the DIW return header, immediately before exit.

6.11 Provisions to flush and drain the chemical system completely with DIW should be included in the system.

6.12 Pumping systems should include surge/pulse suppression devices and provisions for vibration isolation.

6.13 Filters should be included on all chemical mixture recirculation loops.

6.14 All filters should be able to be isolated from process stream for maintenance.

6.15 For processes requiring pressure control, regulators should be included in the system.

6.16 The system should have a means of manifolding supply and drain lines onboard, so that there is a single point of connection for each individual liquid.

7 Materials Guidelines

7.1 All polymers for wetted flow streams should be virgin materials without filler or inert additives.

7.2 *Polymer Material Types*

7.2.1 High purity grade PFA or a material specified by the customer should be used for the chemical distribution system (acids/caustics).

7.2.2 High purity grade PVDF or high purity grade PFA should be used for the DI distribution system.

7.2.3 Valves, regulators, diaphragms, and custom components in both the DI water and chemical distribution systems can also be PTFE.

7.3 *Source Material Mechanical Characteristics*

7.3.1 All piping, tubing, and other components should conform to the manufacturer's published data regarding the following: dimensional tolerances, flow characteristics, mechanical strength characteristics, and melt temperature indices.

7.3.2 When such data is unavailable from the manufacturer, historical information of most similar products should be used for comparative purposes.

7.3.3 Manufacturer should advise purchaser in writing of any liquid stream that causes degradation of the material after purchaser states the intended use of the product.

7.3.4 Components made by the same manufacturer and intended to be joined together should have inner and outer diameters within ± 2% of the wall thickness.

7.4 *Material Performance Guidelines*

7.4.1 The performance guidelines below are polymer qualification values to be demonstrated by the original component manufacturer. Semiconductor equipment suppliers should provide proof that their components conform to these requirements.

7.4.2 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically significant data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.4.3 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user's materials performance requirements.

Table 1 Summary of Recommended Specifications

Description	*Value*	*Units*
Hydraulic Pressure Test		
Maximum pressure above manufacturer's recommended working pressure	120	%
Test Period	≥ 30	min.
Test Temperature	ambient	°C
Internal Surface Defects		
Photos per test method		value
Maximum count per photo	≤ 50	value
For an example of a test method, see SEMASPEC 92010955B (SEM)		
Particulate Contribution		
at > 0.07 µm size	≤ 750	ptc/L
at > 0.1 µm size	≤ 200	ptc/L
at > 0.3 µm size	≤ 5.0	ptc/L
at > 0.5 µm size	≤ 2.0	ptc/L
at > 1.0 µm size	≤ 1.0	ptc/L
For an example of a test method, see SEMASPEC 92010949B		
Internal Surface Roughness		
Measure type	non-contact	n/a
Roughness average (R_a) for extruded surfaces	≤ 0.38 (≤ 15)	µm (µin.)
Maximum surface R_a for molded surfaces	≤ 0.51 (≤ 20)	µm (µin.)
Maximum surface R_a for machined surfaces	≤ 0.89 (≤ 35)	µm (µin.)
Test procedures per ASTM F 1438		
Total Anionic Contamination		
Ammonium	≤ 1.00	µg/comp
Bromide	≤ 0.50	µg/comp
Chloride	≤ 0.50	µg/comp
Fluoride	≤ 5.00	µg/comp
Nitrate	≤ 0.50	µg/comp
Nitrite	≤ 1.00	µg/comp
Phosphate	≤ 0.50	µg/comp
Potassium	≤ 0.50	µg/comp
Sodium	≤ 0.50	µg/comp
Sulfate	≤ 0.50	µg/comp
Test procedures per ASTM D 4327 (Total Anions)		
Total Metallic Contamination		
Aluminum	≤ 0.15	µg/comp
Boron	≤ 0.15	µg/comp
Calcium	≤ 1.00	µg/comp
Cadmium	≤ 0.10	µg/comp
Iron	≤ 1.00	µg/comp
Lead	≤ 0.15	µg/comp
Lithium	≤ 0.15	µg/comp
Magnesium	≤ 0.15	µg/comp
Nickel	≤ 1.00	µg/comp
Silver	≤ 0.15	µg/comp
Zinc	≤ 0.15	µg/comp
For an example of a test method, see SEMASPEC 92010936B (Metallics)		

Organic contamination shall be:		
Below detection limits of Fourier Transform Infrared (FTIR) spectroscopic techniques		
For an example of a test method, see SEMASPEC 92010937B (FTIR)		

7.5 *Filter Requirements*

7.5.1 The housing should be PFA or PVDF, as required.

7.5.2 *Media (Membrane, Support Cage, and Net)*

- Cartridge Type — PFA or PTFE, compatible with the chemical used in the system
- Disposable Type — PFA or PTFE media, as required

7.6 Gaskets, O-rings, and diaphragms should be chemically compatible to process or sanitation fluids and should not contribute any measurable secondary contamination.

8 Component Guidelines

8.1 Components should be tested at ≥ 1.5 times the distribution system's operating pressure, over the entire operating temperature range.

8.2 Regulators should be diaphragm type.

8.3 Check valves should be springless type with O-ring seals, as a minimum. Springless disk type check valves are optional.

8.4 Valve types should be diaphragm type or bellows.

8.5 Flow meters should be all polymer construction.

9 Subsystem Assembly Guidelines

See SEMI E49.7 for recommended polymer system assembly procedures.

5 Performance Guidelines

5.1 *Leak Tests*

5.1.1 *Pressure Decay Test*

- Test Media — Nitrogen (N_2)
- Pressure — 2.1 kg/cm^2 (30 psig) maximum
  — 1.75 kg/cm^2 (25 psig) minimum
- Time — 120 minutes (2 hours)
- Fail-Pressure Loss — > 2% of test pressure, after compensation for temperature variation.

5.1.2 *Hydrostatic Pressure Test*

- Test Media — DI water (pumped)
- Pressurization Media — Nitrogen (N_2)
- Pressure — 2 times operating pressure or 7.0 kg/cm^2 (100 psig), whichever is less
- Time — 4 hours
- Fail-Pressure Loss — Any pressure loss or any visible leakage, compensated for temperature gradient and/or material expansion.

5.2 *Purity Indices*

5.2.1 *Particle Count (ptc) at ≥ 0.2 μm Size*

- < 2 ptc/L average single count
- < 4 ptc/L maximum single count
- Test media is DI water

5.2.2 *DI Water Flush Test* — The specified limit is the difference between incoming and outgoing DI water.

- Resistivity — ± 0.2 Mega ohm-cm
- Total Organic Carbons (TOC) — < 2 ppb

5.3 All performance measures are absolute values, relative to respective test instrument background level.

5.4 See SEMI E49.7 for recommended DI/chemical system testing procedures.

5.5 *Reliability and Maintainability Indices* — Equipment supplier should provide actual DIW/Chemical system performance data and/or component reliability data, accompanied by the associated failure analysis method.

Indices	*Hours*

6 Design Guidelines

6.1 All polyvinylidene fluoride (PVDF) should be thermally butt welded, as a minimum, using interactive automated welding equipment. Thermal butt welding is preferred.

6.2 All perfluoroalkoxy (PFA) tubing should be joined with a flare compression type technique. Flaring can be done at room temperature or at elevated temperature, depending on the technique required by the component supplier.

6.3 All PFA pipe should be thermally butt welded, using interactive automated welding equipment.

6.4 Dead volume areas should be minimized by the use of close connected bypass or bleed-through loops. Dead legs should be < 3 pipe diameters.

6.5 System internal volume should be minimized by the use of Dead Space Free (DSF) branch valves and/or multi-component integrated assemblies.

6.6 The DIW distribution system should have a continuous flow with a velocity of ≥ 0.3 m/s (1 fps).

6.7 Pipe thread type connections should not be used.

6.8 Flow meters should be installed in return side of DIW system.

6.9 Backflow/back pressure protection should be included in the system.

6.10 The system should use DSF type valves to accomplish flush, test, and sample ports. Sample ports should be located as close as possible to the chemical supply point, either to bath/tank or process chamber and also at the DIW return header, immediately before exit.

6.11 Provisions to flush and drain the chemical system completely with DIW should be included in the system.

6.12 Pumping systems should include surge/pulse suppression devices and provisions for vibration isolation.

6.13 Filters should be included on all chemical mixture recirculation loops.

6.14 All filters should be able to be isolated from mainstream for maintenance.

6.15 Provisions for system sanitization (e.g., DSF injection ports) should be included.

6.16 For processes requiring pressure control, regulators should be included in the system.

6.17 The system should have a means of manifolding supply and drain lines onboard, so that there is a single point of connection for each individual liquid.

7 Materials Guidelines

7.1 All polymers for wetted flow streams should be virgin materials without filler or inert additives.

7.2 *Polymer Material Types*

7.2.1 High purity grade PFA or a material specified by the customer should be used for the chemical distribution system (acids/caustics).

7.2.2 High purity grade PVDF or high purity grade PFA should be used for the DIW distribution system.

7.2.3 Valves, regulators, diaphragms, and custom components in both the DI water and chemical distribution systems can also be PTFE.

7.3 *Source Material Mechanical Characteristics*

7.3.1 All piping, tubing, and other components should conform to the manufacturer’s published data regarding the following: dimensional tolerances, flow characteristics, mechanical strength characteristics, and melt temperature indices.

7.3.2 When such data is unavailable from the manufacturer, historical information of most similar products should be used for comparative purposes.

7.3.3 Manufacturer should advise purchaser in writing of any liquid stream that causes degradation of the material after purchaser states the intended use of the product.

7.3.4 Components made by the same manufacturer and intended to be joined together should have inner and outer diameters within ± 2% of the wall thickness.

7.4 *Material Performance Guidelines*

7.4.1 The performance guidelines below are polymer qualification values to be demonstrated by the original component manufacturer. Semiconductor equipment suppliers should provide proof that their components conform to these requirements.

7.4.2 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically significant data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.4.3 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user’s materials performance requirements.

Table 1 Summary of Recommended Specifications

Description	*Value*	*Units*
Hydraulic Pressure Test		
Maximum pressure above manufacture's recommended working pressure	120	%
Test Period	≥ 30	min.
Test Temperature	ambient	°C
Internal Surface Defects		
Surface defects	≤ 15	
Photos per test method	5	value
Maximum count per photo	≤ 40	value
For an example of a test method, see SEMASPEC 92010955B (SEM)		
Particulate Contribution		
at > 0.07 µm size	≤ 500	ptc/L
at > 0.1 µm size	≤ 100	ptc/L
at > 0.3 µm size	≤ 2.0	ptc/L
at > 0.5 µm size	≤ 1.0	ptc/L
at > 1.0 µm size	≤ 0.3	ptc/L
For an example of a test method, see SEMASPEC 92010949B		
Internal Surface Roughness		
Measure type	non-contact	n/a
Roughness average (R_a) for extruded surfaces	≤ 0.25 (≤ 10)	µm (µin.)
Maximum surface R_a for molded surfaces	≤ 0.38 (≤ 15)	µm (µin.)
Maximum surface R_a for machined surfaces	≤ 0.62 (≤ 25)	µm (µin.)
Test procedures per ASTM F 1438		
Total Anionic Contamination		
Ammonium	≤ 0.40	µg/comp
Bromide	≤ 0.10	µg/comp
Chloride	≤ 0.20	µg/comp
Fluoride	≤ 2.00	µg/comp

Nitrite	≤ 0.40	µg/comp
Phosphate	≤ 0.10	µg/comp
Potassium	≤ 0.20	µg/comp
Sodium	≤ 0.20	µg/comp
Sulfate	≤ 0.20	µg/comp
Test procedures per ASTM D 4327 (Total Anions)		
Total Metallic Contamination		
Aluminum	≤ 0.05	µg/comp
Boron	≤ 0.05	µg/comp
Calcium	≤ 0.50	µg/comp
Cadmium	≤ 0.01	µg/comp
Iron	≤ 0.50	µg/comp
Lead	≤ 0.05	µg/comp
Lithium	≤ 0.05	µg/comp
Magnesium	≤ 0.02	µg/comp
Nickel	≤ 0.50	µg/comp
Silver	≤ 0.05	µg/comp
Zinc	≤ 0.05	µg/comp

For an example of a test method, see SEMASPEC 92010936B (Metallics)		
Organic contamination shall be:		
Below detection limits of Fourier Transform Infrared (FTIR) spectroscopic techniques		
For an example of a test method, see SEMASPEC 92010937B (FTIR)		

7.5 *Filter Requirements*

7.5.1 The housing should be PFA or PVDF, as required.

7.5.2 *Media (Membrane, Support Cage, and Net)*

- Cartridge Type — PFA or PTFE, compatible with the chemical used in the system
- Disposable Type — PFA or PTFE media, as required

7.6 Gaskets, O-rings, and diaphragms should be chemically compatible to process or sanitation fluids and should not contribute any measurable secondary contamination.

8 Component Guidelines

8.1 Components should be tested at ≥ 1.5 times the distribution system's operating pressure, over the entire operating temperature range.

8.2 Regulators should be diaphragm type.

8.3 Check valves should be springless disk type. The disk should not have O-ring seals.

8.4 Valves should be diaphragm type, Weir design, or equivalent.

8.5 Flow meters should be all polymer construction.

9 Subsystem Assembly Guidelines

See SEMI E49.7 for recommended polymer system assembly procedures.

3 American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017

5 Performance Guidelines

5.1 *Leak Test and Purity Indices*

5.1.1 *Pressure Decay Test*

- Test Media — Nitrogen (N_2)
- Pressure — 2 times system operating pressure
- Time — 24 hours
- Temperature — Constant
- Fail-Pressure Loss — > 1% of test pressure

5.1.2 N_2 Particle Count (ptc), at ≥ 0.2 µm Size

- < 0.18 ptc/L (< 5 ptc/ft^3) average single count
- < 1.8 ptc/L (< 50 ptc/ft^3) maximum single count

5.2 All performance measures are absolute values, relative to respective test instrument background level.

5.3 See SEMI E49.6 for recommended gas system testing procedures.

5.4 *Reliability and Maintainability Indices* — Equipment supplier should provide actual gas system performance data and/or component reliability data, accompanied by the associated failure analysis method.

Indices	*Hours*
Mean time between failure (MTBF)	
Mean time between assists (MTBA)	
Mean time to repair (MTTR)	
Start-up time (Initial)	

6 Design Guidelines

6.1 All weld joints should be automatically orbital butt welded.

6.2 Mechanical fittings should be used where required for component removal/replacement.

6.3 Dead volumes should be less than five pipe diameters in length/height. Pressure gauges with gauge protectors should be used. Pressure transducers are optional.

6.4 A means of process liquid sampling should be installed as close as possible to point of dispense.

6.5 Incoming process liquids require filters and should be located downstream of any regulator and as close as possible to point of dispense.

6.6 Design should include a means of flow through flushing and draining for removable components or assemblies.

6.7 Pumping systems should include surge/pulse suppression devices and provisions for vibration isolation.

6.8 Supply and drain lines on a recirculation system should be separated by an isolation valve. The system should not use one line to perform both functions.

6.9 All filters should be able to be isolated from process stream for maintenance.

6.10 Backflow/back pressure protection should be included in the system.

6.11 For processes requiring pressure control, regulators should be included in the system.

6.12 The system should have a means of manifolding supply and drain lines onboard, so that there is a single point connection for each individual liquid.

7 Materials Guidelines

7.1 *Material Mechanical Characteristics - Stainless Steel*

7.1.1 All tubing greater than or equal to 1.27 cm (1/2 in.) diameter should conform to ASTM A 269.

7.1.2 Tubing less than 1.27 cm (1/2 in.) diameter should conform to ASTM A 632.

7.1.3 All bar stock should conform to ASTM A 479 or ASME SA479.

7.1.4 All steel should conform to ASM UNS S31603 for chemical composition with the following exceptions:

- Sulfur as reported by the SMTR ≤ 0.030%
- Carbon as reported by the SMTR ≤ 0.030%

7.2 Stainless steel should be 316L electropolished for solvent system wetted flow streams or as specified by the customer.

7.3 Materials for valve seats, diaphragms, gaskets, and O-rings should be chemically compatible to the process liquid.

7.4 *Material Performance Guidelines*

7.4.1 The performance guidelines below are SS qualification values to be demonstrated by the original component manufacturer. Semiconductor equipment suppliers should provide proof that their components conform to these requirements.

7.4.2 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically significant data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.4.3 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user’s materials performance requirements.

Table 1 Summary of Recommended Specifications

Description	*Value*	*Units*
Internal Surface Chemistry (AUGER) Surface chromium oxide enhanced layer thickness at 1/2 peak height of measured oxygen signal level For an example of a test method, see SEMASPEC 90120573B (ESCA)	≥ 15	Å
Internal Surface Chemistry (ESCA) Total chromium to iron ratio including both reduced and oxidized stated For an example of a test method, see SEMASPEC 90120403B (ESCA)	≥ 1.25:1	value
Internal Surface Chemistry (EDX) Surface foreign elements, those elements not in the Smelter's Test Report (SMTR) Test procedures per ASTM F 1375 (EDX)	0	value
Internal Surface Defects Photos per test method Counts per photo Test procedures per ASTM F 1375 (SEM)	5 ≤ 50	value value
Internal Surface Roughness Average surface roughness Roughness average (R_a) Maximum surface R_a (individual reading) For example of a test method, see SEMASPEC 90120400B (Contact Profilometry)	≤ 0.25 (≤ 10) ≤ 0.38 (≤ 15)	µm (µin.) µm (µin.)
Particulate Contribution at ≥ 0.1 µm size at ≥ 0.02 µm size Test procedures per ASTM F 1394 (Particles)	≤ 0.71 (20) ≤ 2.6 (75)	ptc/L (ptc/ft^3) ptc/L (ptc/ft^3)
Internal Absorbed Moisture Time to recover to base line from a 2 ppm spike for low surface area component (valve, regulator) Time to recover to baseline from a 2 ppm spike for high surface area component (filters, tubing) Test procedures per ASTM F 1397	≤ 4 ≤ 6	hour hour
Total Anionic Contamination Total anionic contamination added to test water Individual anionic contaminant Test procedures per ASTM D 4327 (Total Anions)	≤ 1 ≤ 0.2	ppm ppm
Leak Rate Inboard leak rates for He Outboard leak rate for He Cross-seat leak rates for He Test procedures per SEMI F1 (Leak Rate)	$\leq 1 \times 10^{-9}$ $\leq 1 \times 10^{-5}$ $\leq 1 \times 10^{-8}$	scc/s scc/s scc/s
Cycle Life Manual values pressure automatic valves High Pressure automatic valves Low Pressure automatic valves Test procedures per ASTM F 1375 (Cycle Life)	≥ 25 K ≥ 25 K ≥ 500 K	cycles cycles cycles

8 Component Guidelines

8.1 For component leak rate and cycle life requirements, see Section 7, Materials Guidelines.

8.2 Valves should be ball (dry assembly, lubricant-free) or bellows type. Metal diaphragm valves are optional.

8.3 Regulators should be packless in design with all metal bonnet seals.

8.4 Regulators and valve flow coefficient (C_v) should be selected based on liquid flow requirements and liquid characteristics.

8.5 Mechanical fittings should be compression type or metal face seal type with solid nickel gaskets.

8.6 Pressure gauges should be liquid-filled type with compression or metal face seal fittings. Gauge isolators are recommended.

8.7 Filters should be PTFE media rated at 0.1 µm pore size.

8.8 Check valves should be disk poppet type.

9 Subsystem Assembly Guidelines

See SEMI E49.6 for recommended SS system assembly procedures.

GUIDE FOR ULTRAHIGH PURITY SOLVENT DISTRIBUTION SYSTEMS IN SEMICONDUCTOR MANUFACTURING EQUIPMENT

1 Purpose

1.1 This document specifies guidelines for ultrahigh purity (UHP) solvent distribution systems in semiconductor production equipment.

2 Scope

2.1 The distribution systems consist of stainless steel (SS) piping designed to supply flammable solvents only.

2.2 Typical tools include photolithography track equipment, solvent wet stations, and isopropyl alcohol vapor dryers.

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E49 — Guide for Standard Performance, Practices, and Sub-Assembly for High Purity Piping Systems and Final Assembly for Semiconductor Manufacturing Equipment

SEMI E49.6 — Guide for Subsystem Assembly and Testing Procedures - Stainless Steel Systems

SEMI F1 — Specification for Leak Integrity of High-Purity Gas Piping Systems and Components

3.2 *ASM Document*[1]

ASM UNS S31603 — Composition of Standard Stainless Steels

3.3 *ASTM Standards*[2]

See Section 3.3 of SEMI E49.

4 Terminology

See Section 4 of SEMI E49.

5 Performance Guidelines

5.1 *Leak Test and Purity Indices*

5.1.1 *Pressure Decay Test*

- Test Media — Nitrogen (N_2)

Pressure — 2 times system operating pressure

- Time — 24 hours
- Temperature — Constant
- Fail-Pressure Loss — > 1% of test pressure

5.1.2 *N_2 Particle Count (ptc), at ≥ 0.1 μm Size*

- < 0.18 ptc/L (< 5 ptc/ft^3) average single count
- < 1.8 ptc/L (< 50 ptc/ft^3) maximum single count

5.1.3 *Moisture Level* — ≤ 200 ppb

5.2 All performance measures are absolute values, relative to respective test instrument background level.

5.3 See SEMI E49.6 for recommended solvent system testing procedures.

5.4 *Reliability and Maintainability Indices* — Equipment supplier should provide actual gas system performance data and/or component reliability data, accompanied by the associated failure analysis method.

Indices	*Hours*
Mean time between failure (MTBF)	
Mean time between assists (MTBA)	
Mean time to repair (MTTR)	
Start-up time (Initial)	

6 Design Guidelines

6.1 All weld joints should be automatically orbital butt welded.

6.2 Mechanical fittings should be used where required for component removal/replacement.

6.3 Dead volumes should be less than three pipe diameters in length/height. Blind runs such as pressure gauges should not be used.

6.4 A means of process liquid sampling should be installed as close as possible to point of dispense.

6.5 Incoming process liquids require filters and should be located downstream of any regulator and as close as possible to point of dispense.

6.6 The system internal volume should be minimized by use of Dead Space Free (DSF) branch valves and/or multi-component integrated assemblies.

1 American Society of Metals, Metals Park, OH 44073

2 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

6.7 Design should include a means of flow through flushing and draining for removable components or assemblies.

6.8 Pumping systems should include surge/pulse suppression devices and provisions for vibration isolation.

6.9 Supply and drain lines on a recirculation system should be separated by an isolation valve. The system should not use one line to perform both functions.

6.10 All filters should be able to be isolated from process stream for maintenance.

6.11 Ball and needle type valves should not be used.

6.12 Backflow/back pressure protection should be included in the system.

6.13 For processes requiring pressure control, regulators should be included in the system. Pressure transducers and a means of pressure display should be included on the equipment.

6.14 The systems should have a means of manifolding supply and drain lines onboard, so that there is a single point connection for each individual liquid.

7 Materials Guidelines

7.1 *Material Mechanical Characteristics - Stainless Steel*

7.1.1 All tubing greater than or equal to 1.27 cm (1/2 in.) diameter should conform to ASTM A 269.

7.1.2 Tubing less than 1.27 cm (1/2 in.) diameter should conform to ASTM A 632.

7.1.3 All bar stock should conform to ASTM A 479.

7.1.4 All steel should conform to ASM UNS S31603 for chemical composition with the following exceptions:

- Sulfur as reported by the SMTR ≤ 0.030%
- Carbon as reported by the SMTR ≤ 0.030%

7.2 Stainless steel should be 316L electropolished for solvent system wetted flow streams.

7.3 Materials for valve seats, diaphragms, gaskets, and O-rings should be chemically compatible to the process gas.

7.4 *Material Performance Guidelines*

7.4.1 The performance guidelines below are SS qualification values to be demonstrated by the original component manufacturer. Semiconductor equipment suppliers should provide proof that their components conform to these requirements.

7.4.2 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically valid data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.4.3 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user's materials performance requirements.

Table 1 Summary of Recommended Specifications

Description	*Value*	*Units*
Internal Surface Chemistry (AUGER)		
Surface chromium oxide enhanced layer thickness at 1/2 peak height of measured oxygen signal level	≥ 15	Å
For an example of a test method, see SEMASPEC 90120573B (AUGER)		
Internal Surface Chemistry (ESCA)		
Total chromium to iron ratio including both reduced and oxidized states	≥ 1.25:1	value
For an example of a test method, see SEMASPEC 90120403B (ESCA)		
Internal Surface Chemistry (EDX)		
Surface foreign elements, those elements not in the Smelter's Test Report (SMTR)	0	value
Test procedures per ASTM F 1375 (EDX)		
Internal Surface Defects		
Photos per test method	5	value
Counts per photo	≤ 50	value
Test procedures per ASTM F 1372 (SEM)		
Internal Surface Roughness		
Average surface roughness	≤ 0.25	µm
Roughness average (R_a)	(≤ 10)	(µin.)
Maximum surface R_a	≤ 0.38	µm
(individual reading)	(≤ 15)	(µin.)
For an example of a test method, see SEMASPEC 90120400B (Contact Profilometry)		
Particulate Contribution		
at ≥ 0.1 µm size	≤ 0.71 (20)	ptc/L (ptc/ft^3)
at ≥ 0.02 µm size	≤ 2.6 (75)	ptc/L (ptc/ft^3)
Test procedures per ASTM F 1394 (Particles)		
Internal Absorbed Moisture		
Time to recover to base line from a 2 ppm spike	≤ 4	hour
for low surface area component (valve, regulator)	≤ 6	hour
Time to recover to baseline from a 2 ppm spike for high surface area component (filters, tubing)		
Test procedures per ASTM F 1397		
Total Anionic Contamination		
Total anionic contamination added to test water	≤ 1	ppm
Individual anionic contaminant	≤ 0.2	ppm
Test procedures per ASTM D 4327 (Total Anions)		
Leak Rate		
Inboard leak rates for He	$\leq 1 \times 10^{-9}$	scc/s
Outboard leak rates for He	$\leq 1 \times 10^{-5}$	scc/s
Cross-seat leak rates for He	$\leq 4 \times 10^{-8}$	scc/s
Test procedures per SEMI F1 (Leak Rate)		
Cycle Life		
Manual valves	≥ 25 K	cycles
High pressure automatic valves	≥ 25 K	cycles
Low pressure automatic valves	≥ 500 K	cycles
Test procedures per ASTM F 1373 (Cycle Life)		

8 Component Guidelines

8.1 For component leak rate and cycle life requirements, see Section 7.

8.2 Valves should be springless, packless, metal diaphragm type with all metal bonnet seals.

8.3 Regulators should be threadless, packless type with all metal bonnet seals.

8.4 Regulators and valve flow coefficient (C_v) should be selected based on liquid flow requirements and liquid characteristics.

8.5 Mechanical fittings should be all metal face seal type with solid nickel gaskets.

8.6 Pressure transducers should be used in place of bourdon tube pressure gauges.

8.7 Filters should be PTFE media rated at 0.05 µm pore size.

8.8 Check valves should be disk poppet type.

9 Subsystem Assembly Guidelines

See SEMI E49.6 for recommended SS system assembly procedures.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E49.6-95
GUIDE FOR SUBSYSTEM ASSEMBLY AND TESTING PROCEDURES - STAINLESS STEEL SYSTEMS

1 Purpose

The objective of this document is to establish standard guidelines for cleanroom activities specific to the manufacturing, assembly, testing, and integration of materials and components used in stainless steel semiconductor process equipment.

2 Scope

This standard has been developed as a guide for the assembly and testing of high purity and ultrahigh purity gas and solvent subsystems.

3 Referenced Documents

Note: Refer to the latest version of the following documents for general cleanroom protocol.

3.1 *Federal Standard (FED-STD)*[1]

Federal Standard Cleanroom and Work Station Requirements, Controlled Environment

3.2 *Institute of Environmental Sciences (IES)*[2]

IES-RP-CC-001 — Recommended Practices for HEPA Filters

IES-RP-CC-002 — Recommended Practices for Laminar Flow Clean Air Devices

IES-RP-CC-003 — Recommended Practices for Garments Required in Cleanrooms and Controlled Environmental Areas

IES-RP-CC-006 — Recommended Practices for Testing Cleanrooms

4 Terminology

See Section 4 of SEMI E49.

5 Facility Guidelines

5.1 *Gowning Area Class 10,000/1,000 (HP/UHP)* — All personnel working in cleanrooms should wear paper booties prior to entering the gowning area. Personnel should wear polyester gowns, hood, and boots, pure latex gloves (no talc), and safety glasses before entering clean areas.

5.2 *Materials Staging Area Class 10,000/1,000 (HP/UHP)* — Materials used in the cleanroom should have the outer bag removed and the inner bag wiped down with cleanroom wipes saturated with a 50/50 IPA/DI mix in the materials staging area prior to entry into the cleanroom.

5.3 *Cutting Area Class 10,000 or Better* — Cutting area should be a Class 1,000 area while in normal (at rest) operation. Work areas should maintain a Class 1,000 average at all times.

5.4 *Welding and Cleaning Area Class 1,000/100 (HP/UHP)* — Welding and cleaning area — ultrasonic tanks, DI rinse stations, and dry-down stations — should be Class 1,000 or 100, depending on purity classification. After final cleaning operation, there should be a Class 100 station for final bagging of cleaned parts prior to their entry into the cleanroom.

5.5 *Assembly, Final Integration, and Final Test Class 100/10 (HP/UHP)* — All areas used for gas/liquid system assembly, integration, and test should be Class 100/10 under all working conditions. This area should be segregated by hard or soft walls from all other fabrication areas.

5.6 *Common Plenums* — Adjoining clean areas of varying classifications should be separated with floor-to-ceiling hard or soft walls, have separate return air grilles, and be positively pressurized to a minimum of 1.3 mm (0.05 in.) H_20 (W.C.) over the lower adjacent class clean area when otherwise common by access or pass-through.

6 Utility System Guidelines

6.1 *Nitrogen for Drying after Cleaning (Both HP and UHP Classes)*

- Filtration — 0.01 µm rated
- Oxygen Content — < 1.5 ppm
- Moisture Content — < 1.0 ppm
- Hydrocarbon Content — < 2.0 ppm

6.2 *Purge Gases* — Argon or nitrogen for purging gas systems during assembly and for testing, using cryogenic source and 0.01 µm filtered. The following purity levels should be as certified by the gas supplier.

1 Available from General Service Administration, Federal Supply Service Bureau, Specification Section, Suite 8167, 470 East L'Enfant Place SW, Washington, D.C. 20407.

2 Available from Institute of Environmental Sciences, 940 E. Northwest Hwy., Mount Prospect, IL 60056.

	HP	*UHP*
Oxygen Content	< 40 ppb	< 10 ppb
Moisture Content	< 20 ppb	< 10 ppb
Total Hydrocarbon Content	< 40 ppb	< 20 ppb
Particles	< 0.1 particles per ft^3 ≥ 0.1 µm and 0 > 0.2 µm (both classes)	
Purified at POC	Optional	Required

6.3 *Weld Gases* — Welding argon (minimum specification, purifiers and 0.01 µm rated filter), recommended for ID/OD purge for both HP and UHP systems):

- Oxygen Content — < 50 ppb
- CO Content — < 50 ppb
- CO_2 Content — < 50 ppb
- THC as Content — < 50 ppb
- Moisture Content — < 50 ppb
- These contaminant levels should be as measured at the POC to the parts to be welded.

6.4 *DI Water - HP/UHP Classes*

- Resistivity — ≥ 18 mega ohm-cm @ 25°c (77°F)
- TOC — < 20 ppb
- Silica — < 5 ppb
- Particles — < 1 particle/millimeter @ ≥ 0.1 µm
- Bacteria — < 10 colonies/100 millimeter
- Hot DI Temperature — 80°C (176°F), minimum

7 Materials Procedures

7.1 *Procedures for Incoming Materials and Components (Component Suppliers)*

7.1.1 *Identification Guidelines*

7.1.1.1 Every deliverable item should have some scheme of positive and permanent identification, so that traceability is provided from the steel melt source to the final metal finishing and packaging through site installation.

7.1.1.2 This identification should provide nondestructive post installation traceability.

7.1.1.3 Clearly visible labeling (without the need to open the package) should be provided at each level of packaging.

7.1.2 *Packaging and Shipping Guidelines*

7.1.2.1 Double bagging should be required.

7.1.2.2 The inner bag should be nonpermeable (minimum six mil polyethylene or Nylon 6) and should prevent damage from normal handling.

7.1.2.3 Vacuum sealing or dry inert gas purging should be used on the inner bag.

7.1.2.4 The ends of the component should be protected using some noncontaminating method.

7.1.2.5 The outer bag may be any suitable material but should be purged with a dry inert gas prior to sealing.

7.1.3 *Documentation*

7.1.3.1 Test results should be provided for each shipment.

7.1.3.2 Shipment should be in complete lot sizes.

7.1.3.3 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically valid data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.1.3.4 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user's materials performance requirements.

7.2 *Receiving*

7.2.1 All incoming material should be segregated from "acceptable material" until it has been formally accepted through documented procedure.

7.2.2 All cartons should be opened (100%); all goods should be checked visually for damage (e.g., torn bags, inadequate padding causing damage).

7.2.3 Material should be stored in original packaging. Do not open until ready to use or inspect. Inspection involving opening sealed plastic bags should be conducted within the materials staging prefab cleanroom. After inspection, purge and heat-seal the material into a clean polyethylene bag.

7.2.4 Any material failing initial inspection should be immediately "red tagged" and set aside in a "quarantine" area until the supplier of the material is notified and disposition is determined.

7.3 *Acceptance and Rejection*

7.3.1 All material should be uniquely identified with a heat number, lot number, and serial number, allowing traceability back to source and documentation. Only material so marked should be accepted.

7.3.2 All material should meet a purchasing specification and be provided with documentation demonstrating compliance. Only material so documented should be accepted.

7.3.3 A certain percentage of material should undergo incoming QA checks for parameters such as: surface contamination (e.g., hydrocarbon, particulate), tubing quality, wall thickness, nicks, scratches; surface roughness, pits, stringers, particle count, weldability, helium leak rate (inboard/outboard/across seat), and dimensions.

The material should be accepted only after these incoming QA checks are completed. A statistically valid sample size should be determined. This means that sufficient pieces must be checked to guarantee that no defective parts arrive at the buyer's location.

7.3.4 Any material that does not pass the basic incoming QA requirements should be "red tagged" and placed in "quarantine" pending final disposition.

7.3.5 Material that passes incoming QA should be uniquely tagged.

8 Construction Procedures

8.1 *Tube Cutting and Preparation*

8.1.1 Stainless steel tubing should be opened, cut, faced, and deburred in a required cleanroom environment, leaving no visible particulates inside the cut end.

8.1.2 For tube cutting, use a wheel cutter with lathe-type facing tool or a special designed power saw with alignment guide. Do not use lubricant. If any "nicks" are found, reface or discard the tube.

8.1.3 When practical during cutting and during all facing operations, use an argon or nitrogen purge (50-100 f/s) to preclude particles from entering tubing.

8.1.4 The prepared end should conform to ASTM A 632 (or ASTM A 269 ≥ 1/2" O.D.) tubing specification with regard to ovality and wall thickness.

8.1.5 The prepared end should be square to tube run within 1/4 deg. (angle).

8.1.6 After preparing, debur the inside diameter carefully and lightly. Do not scratch the inside diameter. Any scratched tubes should be reprepped or scrapped. Chamfering is not required.

8.1.7 Avoid cross-contamination from dissimilar materials.

8.2 *Tube Cleaning*

8.2.1 After cut and prep, tubing should be cleaned using a process which removes all debris and assures that the surface is totally free of hydrocarbons. This process should be custom-tailored to the supplier's need based on tubing supplier quality control (QC) and on purity grade requirement (HP/UHP).

8.2.2 If using tubing certified "hydrocarbon-free" from a tubing supplier, a cleaning procedure as follows is recommended:

- Primary rinse in cold running DI water.
- Secondary rinse in hot [80°C (176°F)] DI water.
- Final rinse in cold DI water with "pressure flush."
- Blow dry with high velocity > 305 meters/min. (> 1,000 feet/min.) hot (150°C (318°F) N_2. Ensure that drying occurs immediately after final rinse to prevent evaporation of DI from the tubing ID surface.
- Use immediately or seal in plastic sleeves.
- Document the process through ESCA elemental chemical composition analysis and SEM photographs that procedure does remove all contaminants. Once process is documented, audit periodically to assure process continues to produce noncontaminated goods.

8.3 *Orbital Welding* — All orbital welding should be performed only by certified welders. Certification procedures should include, at the minimum, producing three acceptable welds in a row of all types of typical orbital weld joints of all sizes of tubing to be welded. Welding parameters should be set by the welder without the use of any written aids. Certification process should be performed every six months.

8.3.1 *Weld Equipment Setup*

8.3.1.1 All welding fixtures should be clean and free of any particulates and excessive discoloration. Weld head should rotate freely and smoothly at all speeds. All clamping and holding fixtures should fit tightly around applicable fittings/tubing, allowing no fitting movement after clamping in excess of 0.008 cm (0.003 in.).

8.3.1.2 Electrodes should be precision ground. Electrode gap should be set using tooling and procedures which provide accurate and repeatable gaps to be set to within 0.005 cm (0.002 in.).

8.3.1.3 Documented procedures should exist for each weld configuration including all parameters (including purge times, orifice sizes, purge rates, and internal pressure).

8.3.1.4 Purge gas apparatus should be stainless steel tubing and components with face seal fittings. Plastic tubing is acceptable as the final run to allow flexibility for hook-up. Lengths should be restricted to less than ten feet. All components which come into contact with the weldment should be stainless steel.

8.3.2 *Weld Bead Characteristics*

8.3.2.1 All weld beads should conform to the following specifications:

1. All welds should exhibit complete penetration around the entire internal surface.
2. Internal weld bead width should be 1.5 times wall thickness (± 20%).
3. Bead "snaking" should not exceed 20% of bead width.
4. ID encroachment of the weld bead should not exceed 0.0013 cm (0.005") from the tubing ID surface. Weld bead should be zero undercut at all points.
5. Misalignment of welded pieces should be less than 10% of wall thickness.
6. Zero oxidation visible on internal surfaces.
7. Light straw oxidation on external surfaces permissible.

8.3.3 *Sample Welds*

8.3.3.1 Sample welds or coupons should be performed at the beginning of each shift, after breaks, and after any alteration to the weld parameters. Coupons should be cross-sectioned and inspected visually for penetration, bead concavity, bead variation, and oxidation. Coupons should be logged with the date and time and operator identification. Coupons and coupon logs should be retained for one year.

8.3.4 *Purging* — Extreme care should be taken to ensure that all contiguous flowpaths are fully purged. All dead legs must be purged out completely prior to welding. All welds should be performed with full purge flow sweeping the weld area during and after welding. Vacuum devices may be required to overcome back-pressure in components such as regulators, filters, purifiers, check valves, or others. Dead-end components such as gauges may be purged using a small-diameter tube placed inside the tubing to be welded and back-flowing purge through the weld zone. Pre-purging should occur for as long as necessary to assure that moisture and oxygen levels in the weld zone are less than 100 ppb. Post-purging should continue after the welding process until the weld zone has cooled to below 200°C (424°F). Light external oxidation should be removed with a stainless steel wire brush immediately after welding. Purge should be maintained during the brushing process, and care should be taken to perform the brushing process in an appropriate area so as not to contaminate the work area.

8.3.5 *Welding Electrode*

8.3.5.1 Welding electrodes should be changed as frequently as necessary to prevent weld deterioration. At the least, electrodes should be changed every 25 welds.

8.3.6 *Weld Inspection*

8.3.6.1 All welds should be 100% inspected to insure conformance to the weld bead specifications listed in 8.3.2 and 8.3.7.

8.3.6.2 Bore scope inspections should be performed by the welder of at least 20% of his work-in-process. All accessible welds should be bore scope inspected during final inspection process, while protecting tubing from scratches.

8.3.7 *Dimensional and Configuration Inspection* — Dimensional and configuration inspection should be performed as follows:

1. One hundred percent subassemblies should be inspected within a cleanroom of same class as assembly area.
2. Confirm spool fabrication drawing is attached to the assembly; if not, reject.
3. Use spool sheet to verify conformance of assembly to drawing. Check dimensions, squareness, offsets, straightedges, and levels to verify all dimensions.
4. Inspect each weld externally for undercut, width oxidation, overlap, uniformity, and alignment. Where possible, use sightube/bore scope to inspect interior of welds (scratch preventers essential). Where welds are not inspectable, a statistically significant sample of the welds will need to be cut out to verify that the welding is done correctly.
5. When subassemblies have passed inspection, they should be tagged as such, rebagged, and released for final testing.
6. Any items found defective during inspection and repairable may be repaired if they will not degrade the system quality measurably. If a cut must be made into a closed system, a purge from both sides (upstream and downstream) should be established.

8.4 *Subsystem Assembly Protocol* — Gas panel and solvent system assembly should be performed only by trained competent personnel. Proper procedures for tightening face seal and other connections, valve bonnets, regulator bonnets, and other components should be followed at all times. Manufacturers recommended torque values should be followed at all times, using a calibrated torque wrench. Purge gas at the required purity level should be flowing through components and subassemblies at all times during the assembly process to minimize entrained contaminants. Partially assembled gas panels should be under purge or capped at all times. Assemblers should at all times be wearing clean gloves; soiled, discolored or torn gloves should be replaced immediately. Components, assemblies or subassemblies which are dropped or damaged during the assembly process should be red-tagged and inspected before use. Face seal gaskets which are dropped should be discarded. It is recommended that two technicians should work as a team during the assembly process. One should be designated as the handler and should position all components. The other should exclusively handle the face seal gaskets and hand-tighten the mating fit set.

9 Testing Procedures

9.1 Tests should be successfully completed and results documented for all performance parameters (purity indices) specified.

9.2 Leak rate tests should be conducted on 100% of all subsystems. For UHP, use hydrocarbon free test instruments.

9.3 *Design Qualification* — Gas delivery system design performance should be qualified in three parameters: particulate generation, contaminant spike recovery, and mass flow controller replacement recovery. This testing should be performed on the initial gas delivery system prototype and on any design revision which significantly impacts the component selection or system configuration. Test results should be kept on file and made available to the end user upon request.

9.3.1 *Particulate Generation* — Static and dynamic particle testing should be performed with a flow rate of at least 3 times the maximum process flow rate at the recommended supply pressure, except during mass flow controller testing when test flow rates should be between 0% and 80% of the MFC value. Testing should be performed on all flow paths that differ significantly in components or configuration. Dynamic test protocols should be as follows:

- Each valve in the test flow path should be cycled individually.
- Starting with the valve furthest upstream, cycle each valve once every 20 seconds.
- MFC valves should be cycled from 0% to 100%.
- Test interval should last until 0.085 std. m^3/hr. (3 std. ft^3/hr.) of gas flow through the test flow path has been sampled by the particle counter.

9.3.2 *Contaminant Spike Recovery* — Contaminant spike recovery testing should be performed on all flow paths which differ significantly in configuration or components. This test should be performed at a flow rate equivalent to typical flow rates achieved in purge and vent cycles for the specific flow path. Contaminant spike recovery test protocols are:

- With all components placed in the full open position, mass flow gas moisture level should be at baseline for 30 minutes prior to testing to establish stable background.
- When a stable background is achieved, initiate a 2 ppm (v) moisture spike until the outlet moisture concentration reaches 2 ppm. (Remove the moisture source from the test gas, and monitor elapsed time until moisture level reaches specified level.)
- Spike recovery time should be ≤ 8 hours for high purity systems and ≤ 4 hours for ultra high purity systems.
- Similar procedure should be conducted for oxygen and THC level tests where required.

9.3.3 *Mass Flow Controller Replacement Recovery* — MFC replacement recovery testing should be performed on all flow paths differing significantly in components and configuration. This test should be performed with a flow rate equivalent to flow rates achieved in typical purge and vent cycles for the specific flow path. MFC replacement recovery test protocols should be:

- Valves and purge flows should be set up in the component replacement mode, and the MFC should be removed from the flow path.
- After 15 minutes, a replacement MFC should be installed.
- Cycle purging should be performed at the recommended pressures and for the recommended number of cycles.
- Typical purge and vent flow rates should then be established, and the moisture level of the test gas should be monitored over time.
- For high purity systems, the moisture level should achieve background levels within one hour.
- For ultra high purity systems, the moisture level should achieve background levels within 15 minutes.

9.4 *Manufacturing Qualification* — Manufacturing qualification tests should be performed to verify the manufacturing and quality control procedures followed in the manufacturing of the gas delivery system. As the configuration of gas systems varies greatly from process to process, no specification should be given here other than to state that static and dynamic particle testing, moisture level, oxygen level, and hydrocarbon testing should be performed to provide statistically significant data showing that the gas delivery system will meet the purity levels required.

9.5 *Certification* — Certification for gas delivery systems should include: leak rate certification, particle counts with specified flow rates at specified pressures and flow schematic indicating which flow paths were tested and which components were cycled; moisture level plotted against time with specified flow rates at specified pressures and flow schematic indicating which flow paths were tested; and oxygen or hydrocarbon levels plotted against time with specified flow rates at specified pressures and flow schematic indicating which flow paths were tested.

10 Labeling Protocol

All lines should be labeled by gas type and flow direction.

11 Pre-Packaging Protocol

11.1 After testing is completed, the subassembly should be pressurized with UHP grade Argon or N_2. Each process line should be sealed with a closed valve and metal fitting cap or plug; all nonprocess lines should be sealed with a plastic cap or plug before being shipped.

11.2 Lines separate from gas system should be shipped double bagged from the cleanroom. Bags should be nonpermeable material and purged with inert gas, then sealed from atmosphere.

12 Documentation Protocol

Documentation logs should be kept for all shop activities. Example log sheets are shown as Tables 1–6 below.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E49.7-0702
PURITY GUIDE FOR THE DESIGN AND MANUFACTURE OF ULTRAPURE WATER AND LIQUID CHEMICAL SYSTEMS IN SEMICONDUCTOR PROCESS EQUIPMENT

This guide was technically approved by the Global Liquid Chemicals Committee and is the direct responsibility of the North American Liquid Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published 1995.

This document as balloted replaces SEMI E49.7 in its entirety. The title for the previous revision of E49.7 was, "GUIDE FOR SUBSYSTEM ASSEMBLY AND TESTING PROCEDURES - POLYMER SYSTEMS."

1 Purpose

1.1 The objective of this document is to provide recommendations that will help maintain the quality of the liquid being delivered. Recommendations are given for activities specific to polymer ultrapure water and liquid chemical systems used in Semiconductor process equipment.

NOTE 1: As with any SEMI guide, the practices outlined herein are recommendations, not specifications. Users of this document should recognize that alternate practices are not excluded as long as they produce results that are equivalent to those produced using the recommendations outlined here and meet the requirements of the end user.

2 Scope

2.1 It is within the scope of this standard to recommend procedures that complement the requirements in SEMI F57 with the goal of ensuring the quality of the liquid being delivered. Recommendations are provided in the following areas:

- Manufacturing Facility
- Utilities
- System Design
- Pre-Production and Inspection
- Assembly
- System Testing
- Packaging
- Traceability

2.2 For the purposes of this document, systems include all liquid delivery components inside semiconductor process equipment and ancillary support equipment, as well as additional plumbing provided by the OEM with the processing equipment. This includes any assembly of two or more liquid delivery components provided with or within semiconductor process equipment.

2.3 Typical semiconductor process equipment with ultrapure water and liquid chemical delivery systems includes, but is not limited to the following:

- Wafer Handling Equip.
- Wafer Cleaning Systems
- Chemical Filtration/Mixing Skids provided by OEM
- Wet Clean Stations
- Wafer Scrubbers
- CMP
- Photolithography coaters and developers
- Ion Implanters
- Metrology equipment

2.4 This standard does not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not define the performance requirements of components, which may be addressed by SEMI F57. Nor does this standard define the performance requirements of equipment systems. Facility distribution systems are also outside the scope of this standard.

3.2 Organic liquids, such as isopropyl alcohol and methyl alcohol, are typically in contact with stainless steel or other non-polymeric components. The polymer systems described within this document are NOT intended for use with such organic liquids. Refer to SEMI E49.4, SEMI E49.5, and SEMI E49.6 for information on stainless steel components.

3.3 System design issues outside those that directly impact liquid purity or quality are not within the scope of this document's recommendations and are left to the individual system designers.

3.4 Polymer systems described within this document are intended for use in ultrapure water and liquid chemical delivery only. Their performance requirements may exceed the needs of systems used in drainage and other lesser quality liquids.

4.1 *SEMI Standards*

SEMI C3.28 — Standard for Nitrogen (N2), VLSI Grade in Cylinders, 99.9996% Quality

SEMI C41 — Specifications and Guidelines for 2-Propanol

SEMI E49 — Guide for Standard Performance, Practices, and Sub-Assembly for High Purity Piping Systems and Final Assembly for Semiconductor Manufacturing Equipment

SEMI E49.4 — Guide for High Purity Solvent Distribution Systems in Semiconductor Manufacturing Equipment

SEMI E49.5 — Guide for Ultrahigh Purity Solvent Distribution Systems in Semiconductor Manufacturing Equipment

SEMI E49.6 — Guide for Subsystem Assembly and Testing Procedures – Stainless Steel Systems

SEMI F34 — Guide for Liquid Chemical Pipe Labeling

SEMI F57 — Provisional Specification for Polymer Components Used in Ultrapure Water and Liquid Chemical Distribution Systems

SEMI F61 — Guide for Ultrapure Water System Used in Semiconductor Processing

4.2 *Federal Standard (FED-STD)*[1]

Fed Stand 209E — Airborne Particulate Cleanliness Classes in Cleanrooms and Clean Zones

1 Available from General Service Administration, Federal Supply Service Bureau, Specification Section, Suite 8167, 470 East L' Enfant Place SW, Washington, D.C. 20407.

4.3 *ISO Document*[2]

ISO 14644 — Cleanrooms and Associated Controlled Environments – Part 1 Classification of Air Cleanliness

NOTE 2: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 See Section 4 of SEMI E49.

6 Manufacturing Facility Recommendations

6.1 Cleanroom Class designations as used within this document are defined within Federal Standard 209E Airborne Particulate Cleanliness Classes in Clean rooms and Clean Zones. (ISO standard 14644-1 classifications are listed parenthetically.)

6.2 *Materials Storage Area* — The storage area for components and assemblies should be a dedicated enclosed area, protected from the elements and separated from other materials. Only components and assemblies that have passed inspection, and are clean and packaged should be placed in the storage area.

6.3 *Gowning Area* — Gowning area should be Class 10,000 (ISO Class 7) or better. All personnel working in cleanrooms should follow appropriate gowning protocol such as: wear booties prior to entering the gowning area; and wear gowns, hood, boots, gloves, and safety glasses before entering clean areas.

6.4 *Staging Area* — Staging Area should be Class 10,000 (ISO Class 7) or better. The staging area (if used) should be located immediately outside the assembly cleanroom, with appropriate access to the assembly cleanroom.

6.5 *Assembly Areas* — All production operations such as cutting, welding, cleaning, assembly, final integration, final test, and packaging (if applicable) should be performed in a class 10,000 (ISO Class 7) cleanroom or better.

7 Utility Recommendations

7.1 *Nitrogen* (Uses include leak testing of non-brittle materials, drying, and purging.)

- Nitrogen quality should meet requirements of SEMI C3.28.
- Particle filtration should be 99.99999% removal of 0.003 micron particles.

2 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

NOTE 3: Use 316L electropolished tubing or PFA tubing for purge piping. (Use tubing that does not degrade N_2.)

7.2 *Ultrapure Water* (Uses include cleaning and rinsing.)

- Resistivity ≥ 18 mega ohm-cm @ 25° C (77° F)
- TOC — < 20 ppb
- Silica — < 5 ppb
- Particles — < 1 particle/milliliter @ 0.1 μm size
- Bacteria — < 10 colonies/100 milliliter
- Hot Ultrapure Water Temperature — 80° C (176° F), minimum

NOTE 4: If testing requirements dictate, access to higher quality ultrapure water may be appropriate in portions of the facility. Additional information related to ultrapure water facility design and terminology may be obtained in SEMI F61.

7.3 *2-Propanol/IPA* (Uses include cleaning.)

- 2-Propanol/IPA quality should meet requirements of SEMI C41, Grade 1

7.4 *Clean Dry Air (CDA) or Oil Free Air* (Uses include pneumatic control and air actuation.)

7.4.1 CDA is not recommended for use on cleaned wetted surfaces. Nitrogen is recommended for drying cleaned wetted surfaces because the purity level is clearly defined and controlled.

8 System Design Recommendations

8.1 *General Recommendations* — The intent of this section is to recommend design practices that ensure the quality of the liquid being delivered. These recommendations should be considered along with design constraints such as minimizing liquid consumption, cost, ensuring maintainability, and limiting complexity. In addition, the appropriateness and simplicity of the facility interface should be considered.

8.2 *Component Recommendations* — Components should limit system exposure to ionic, metallic, total organic carbon, and particle contamination.

8.2.1 All applicable components should comply with SEMI F57.

8.2.2 For components not addressed in SEMI F57, a discussion of recommended materials (similar to that found in SEMI F57) may benefit the reader and is therefore provided.

8.2.2.1 Care should be taken to ensure that the materials are compatible with the liquid streams for long term applications. Additionally, it is important that the materials used be compatible with the application temperature and/or sanitization methods such as ozone, UV light and/or hydrogen peroxide.

8.2.2.2 These recommendations often imply the use of existing materials of choice, such as high purity grades of perfluoroalkoxy (PFA), polytetrafluoroethylene (PTFE), and polyvinylidene fluoride (PVDF). However, unique design specifications or new materials may result in instances where significant efficiencies may be achieved while maintaining substantially equivalent performance. These scenarios could result in the use of new or existing materials such as ethylenechlorotrifluoroethylene (ECTFE), polyether-etherketone (PEEK), polypropylene (PP), acetal resin (such as Delrin®™[3], Celcon®™[1] and others), polyvinyl chloride (PVC), perfluoromethylether-based perfluoroalkoxy (MFA), etc.

8.2.2.3 Due to purity and traceability issues, reprocessed or regrind material is not recommended.

8.3 *Joining Recommendations* — Joining technology that is free of dead space and entrapment areas is recommended to reduce negative effects such as microbial proliferation and impacts to slurry particle size distribution. For this reason pipe thread connections are not recommended.

8.3.1 Tubing should be joined with flare fittings, or similar dead space free technology. Preparation and joining of fittings should be performed in accordance with component manufacturer recommendations.

8.3.1.1 Care should be taken to ensure that dissimilar flare fittings are not joined together. When possible, one style of fitting should be used throughout the system. Manufacturers should be consulted prior to using similar style fittings from different manufacturers interchangeably.

8.3.2 Pipe should be joined with welds that minimize dead space and entrapment areas. Preparation and welding should be performed in accordance with component manufacturer's recommendations.

NOTE 5: Users of this guideline are cautioned that suitable welding methods, such as thermal butt welding, may be covered by patents or other intellectual property.

8.3.2.1 Glue, solvent, or thermal socket welding of pipe is not recommended.

8.4 *System Volume Recommendations* — When possible, dead volumes should be eliminated and overall system volume should be minimized to reduce negative effects on purity as well as flush times.

3 Delrin is a trademark of DuPont; Celcon is a trademark of Hoechst Celanese.

8.4.1 In instances where dead volumes are unavoidable, the dead leg should be ≤ 3 nominal flow path diameters.

8.4.2 Examples of components and practices which help minimize system volume include:

- Dead-space-free branch valves
- Multi-component integrated assemblies
- Use of direct flow paths
- Trickle bypass valves
- Sampling valves

8.5 *Flow Recommendations* — Due to issues related to equipment complexity and the cost of excessive liquid consumption, general flow recommendations for ultrapure water and liquid chemical delivery systems are not provided. However, Related Information 1 provides a list of practices that tend to reduce microbial proliferation in ultrapure water Systems. Because not all liquid chemicals are subject to these effects, the user is advised to obtain additional flow information related to ensuring the quality of liquid chemicals from the liquid chemical manufacturer.

8.6 *Slurry System Recommendations* — In addition to the other design recommendations within this section, the following recommendations are provided specifically for slurry liquid delivery systems used within CMP process equipment.

8.6.1 Areas of high shear can damage the quality of many slurries resulting in large particle count (LPC) growth. Sharp edges projecting into flow path, large pressure drops, tight bends, and sudden large reductions in tubing size can cause high shear.

8.6.2 Dead legs are of particular importance with respect to slurries because the abrasives may settle and agglomerate, creating LPC growth. To help minimize this issue branch lines should be oriented such that they project vertically above the main line to prevent the abrasive from settling and agglomerating.

8.6.3 If point of use filtration is incorporated, provisions to sample the slurry before and after the filter should be provided for LPC monitoring.

8.7 *Protection and Sampling Recommendations* — These recommendations are intended to protect liquids from back flow or cross contamination and to ensure that sampling is adequate for evaluating liquid quality throughout system.

8.7.1 Backflow/back pressure and cross contamination protection should be included in the system.

8.7.2 The system should have provisions to accomplish sampling. Sampling ports should be located as close as possible to the liquid supply point, to bath/tank or process chamber, and to the return header immediately before exit.

8.7.3 Provisions to completely flush, drain, and sanitize the liquid system completely (with ultrapure water or 2-propanol/IPA for example) should be included in the system.

8.8 *Filtration Recommendations* — These recommendations are intended to reduce negative effects such as particle contamination, metallic contamination, and micro bubbles.

8.8.1 Filters should be considered for all liquid delivery systems. Location, selection, installation, start up, and rinse of filters should be based on input from customer, chemical manufacturer and equipment manufacturer.

8.8.2 Process stream isolation should be provided for all filters to allow for maintenance and replacement.

8.9 *Labeling Recommendations* — In addition to the recommendations in Section 10.7, functional labels/schematics should be included with assembly for vents, drains, and other components as necessary to ensure the proper operation of the system(s).

8.10 *Maintainability Recommendations*

8.10.1 Components that require operation, inspection, or maintenance (i.e., valves, filters, pumps, gauges, etc.) should be located where readily accessible.

8.10.2 Provide support on each side of components, such as valves, where operation or assembly transmits torque to the piping/tubing.

8.10.3 Design should allow for thermal expansion if system operates at an elevated temperature.

9 Pre-Production Acceptance and Inspection Recommendations

9.1 *Identification Recommendations*

9.1.1 Applicable components should meet the traceability requirements found in SEMI F57. Where practical, the traceability requirements of SEMI F57 should also be followed for components not covered within SEMI F57 and assemblies, to ensure traceability is provided from the resin source. Component and assembly identification should provide nondestructive post installation traceability. In addition, packaging should have labels allowing for traceability as described above that are clearly visible (without the need to open the package).

NOTE 6: Practical limitations such as component size may not allow for permanent post installation marking of every component.

9.2 *Packaging Recommendations*

9.2.1 Applicable components should meet the packaging requirements found in SEMI F57. Where practical, the packaging requirements of SEMI F57 should also be followed for other components and assemblies to avoid contamination of wetted surfaces.

9.3 *Documentation*

9.3.1 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their assemblies meet the user' s performance requirements. Similar requirements for maintaining component documentation are covered in SEMI F57 and are the responsibility of the component manufacturer.

9.4 *Receiving, Inspection, and Storage*

9.4.1 All incoming components and assemblies should be segregated until they have been formally accepted through a documented procedure.

9.4.1.1 Cartons should be checked visually for damage (e.g., torn bags, inadequate padding causing damage).

9.4.1.2 A statistically significant sample size should undergo minimum QA checks such as visual inspection and critical dimension inspection. In some instances further inspection of components to ensure compliance with SEMI F57 may be required.

9.4.1.3 Components and assemblies should be stored in original packaging until ready for inspection. Inspection involving opening sealed plastic bags should be conducted within the staging prefab cleanroom. After inspection, heat-seal the component (and if appropriate the assembly) into a clean and dry polyethylene bag.

9.4.2 Any component or assembly failing initial inspection should be immediately " red tagged" and set aside in a "quarantine" area until the supplier of the component is notified and disposition is determined.

9.4.3 Components and assemblies should be accepted only after these incoming QA checks are completed.

9.4.4 Accepted component and assemblies should have traceability to the appropriate incoming QA check.

9.4.5 Components and assemblies should be stored in the original shipping containers when possible. Pipe may be stored on racks with appropriate supports.

9.5 *Staging*

9.5.1 Prior to entry into the cleanroom components and assemblies should have the outer bag removed and the inner bag wiped down with cleanroom wipes using 2-propanol/IPA or 2-propanol/IPA and ultrapure water mix in the staging area.

10 Assembly Recommendations

10.1 *General*

10.1.1 Assembly should take place in assembly/cleanroom (see Section 6.5).

10.1.2 Inner bags should be removed within the assembly/cleanroom.

NOTE 7: In the event components must be handled outside cleanroom areas, personnel should wear protective gloves at all times and components returning to the cleanroom should be clean. All ends should be capped to avoid exposure of wetted surfaces.

10.1.3 If work must stop for an extended period, assemblies should be purged with nitrogen and capped immediately to isolate wetted materials from contamination.

10.2 *Pipe/Tube Cutting*

10.2.1 Use dedicated clean tools for piping/tubing system fabrication and installation. Clean tools at the start of each shift with 2-propanol/IPA, rinse with ultrapure water, and blow dry with nitrogen. Maintain tools in accordance with manufacturers' recommendations.

10.2.2 Cut piping/tubing in accordance with manufacturers recommendations. Saws are prohibited.

10.2.3 The cut end of the pipe/tube should be finished before use to comply with the manufacturers' recommendations for squareness and finish. Cut surfaces should be clean and free of loose particles and debris.

10.3 *Component and Assembly Cleaning*

10.3.1 What follows are limited and general recommendations for cleaning components or assemblies. It is the equipment manufacturer's responsibility to ensure that cleaning procedures and solutions are adequate and do not impact equipment performance.

10.3.1.1 Every effort should be made to keep the interior of the pipe clean during cutting and prepping. If, however, the pipe has become contaminated and nitrogen (Section 7.1) will not dislodge the particles it can be cleaned by blowing an ultrapure water soaked swab (often called a "pig") through it using nitrogen (see Section 7.1). The pig should be constructed of a clean, unused, cleanroom approved, cloth soaked in ultrapure water and wrapped around a plug of a diameter less than the ID of the pipe to be cleaned. The length of the pig should be about 2× its diameter.

10.3.1.2 Components or assemblies that have become contaminated should be cleaned. The procedure for cleaning cannot be defined but frequently includes:

- Rinse in ultrapure water.
- Soak in cleaning solution if necessary and compatible with process
- Rinse in flowing ultrapure water (see Section 7.2).
- After rinse, check cleanliness.
- If necessary, repeat the procedure until clean.

10.3.2 Use 2-Propanol/IPA to remove any ink markings from the exterior of the pipe.

10.4 *Welded Connections*

NOTE 8: Refer to Sections 8.3 and 8.3.2 for general joining and weld recommendations.

10.4.1 *Welder Qualification*

10.4.1.1 Welders should have prior experience in the specific welding method of specific types of polymer components. To be qualified, the welder should be able to safely cut, prep, clean, purge, fit, and weld the sizes for which he or she is seeking qualification and produce consistently acceptable weld joints. It is recommended that welders undergo weld training and certification by a pipe manufacturer.

10.4.2 *Weld Qualification*

10.4.2.1 During fabrication, each welder should submit weld samples daily to the QA manager at the beginning of the shift. The welds should be representative of the types of welds the welder will perform during the shift.

10.4.2.2 These welds should meet a defined criteria of acceptability, which may include inspection for visible discoloration, uniformity of weld area, maximum weld misalignment, and weld bead height. These criteria may be derived from sources such as the component manufacturer, the process equipment manufacturer, and the end user. General recommendations for weld inspection are included in Section 10.4.4.

10.4.3 *Welding Procedures*

10.4.3.1 In general the use of weld methods that minimize dead space and entrapment areas are the preferred means of welding plastic pipe/tubing (i.e., PVDF, PFA, and Polypropylene). The weld method should be as shown on the fabrication drawings.

NOTE 9: Users of this guideline are cautioned that suitable welding methods, such as thermal butt welding, may be covered by patents or other intellectual property. When possible, use reduced bead welding method and fixturing to reduce areas on inside diameter where bacteria may accumulate.

10.4.3.2 Welding equipment should be maintained in accordance with manufacturer recommendations. For example, tools and heating elements should be kept clean and thermostat should be calibrated regularly.

10.4.3.3 Components should be firmly and accurately clamped in the welding equipment. Check alignment and clamp adjustment regularly.

10.4.3.4 Logs should be kept for each weld to ensure traceability back to the welding equipment, welder, date of weld, and inspector.

10.4.4 *Weld Inspection Criteria*

NOTE 10: Refer to manufacturer recommendations for socket weld inspection criteria.

10.4.4.1 All welds should exhibit little or no visible discoloration.

10.4.4.2 The maximum weld misalignment should be 10% of the wall thickness of the material.

10.4.4.3 Visual inspection for voids should be performed in accordance with manufacturers recommendations.

10.4.4.4 The physical characteristics of the weld bead should be in accordance with criteria which may be derived from component manufacturer, process equipment manufacturer, and end user recommendations.

10.5 *Mechanical Connections*

NOTE 11: Joining technology that is free of dead space and entrapment areas is recommended. See Sections 8.3 and 8.3.1 for general joining recommendations and specific mechanical connection recommendations. In the event that these recommendations cannot be followed, assembly recommendations for other commonly used mechanical connections are provided.

10.5.1 Flaring should be performed at the temperature and with the equipment recommended by the fitting manufacturer.

10.5.2 O-rings used in mechanical connections should be positioned per manufacturer recommendations before closing the fitting. Manufacturer recommendations for torque should be applied.

10.5.3 Gaskets used in flanged connections should be positioned per manufacturer recommendations before closing the fitting. Manufacturer recommendations for torque should be applied.

10.5.4 For tapered threaded connections, such as National Pipe Thread (NPT) and Japenese Industrial Standard (JIS), wrap tapered threads with a suitable tape, (such as PTFE tape) prior to assembly. Use of ¼” wide tape is recommended on nominal sizes of ½” or smaller. Wrap the threads three times in the direction that does not unravel during installation of the fitting. To reduce the possibility of tape entering the liquid stream, do not cover the last two threads at the narrow end of the fitting.

10.6 *Tubing and Pipe Support*

10.6.1 Route flexible tubing neatly and secure with tie-wraps or similar mechanical fastener.

10.6.2 Support distances and support clamps for pipe should employ the manufacturer’s recommendations, where possible. These clamps typically cradle the pipe within a plastic fixture. Metal and/or constrictive types of clamps may induce stress into piping components and should be avoided. However, if they must be used then elastomer inserts between the pipe and clamp are recommended.

10.7 *Labeling Recommendations*

10.7.1 All ultrapure water and Liquid Chemical systems should be labeled in accordance with SEMI F34 when possible.

10.7.2 Additional labeling to support proper operation of the system(s) should be included when indicated on assembly drawing(s).

10.8 *Final Assembly Inspection Recommendations*

10.8.1 Inspect the system within the appropriate assembly environment.

10.8.2 Verify the following:

- System is complete per drawings
- Critical dimensions, squareness, offsets, and straightness are per drawings and assembly specifications
- Overall configuration is correct
- Support is adequate
- No pipe, tube, or fitting is nicked, cracked, or abused
- Each weld is visually acceptable
- Gaskets are in place and bolts are torqued to proper values
- Proper installation of valves per manufacturer’s recommendations
- Unions and mechanical connections are tight
- Tubing, pipe, inlets, and outlets are labeled appropriately

10.8.3 Shop drawings that have been marked up should be returned to the engineering department for updates. The QA manager should be notified that the assembly has passed inspection, been tagged as such, and is ready for final testing.

11 System Testing Recommendations

11.1 The equipment manufacturer should successfully complete functional testing (for example leak and pressure decay testing). In addition, testing may be required to demonstrate that the system is not adversely affecting the quality of the liquid.

NOTE 12: As outlined in limitations Section 3.1, it is beyond the scope of this document to define the performance requirements of the equipment systems.

12 Packaging Recommendations

12.1 Packaging is recommended to ensure the cleanliness and dryness of wetted surfaces during transport or storage. All open connections should be capped to isolate wetted materials from contamination. Additional guidelines for packaging can be found in other SEMI documents. For smaller assemblies refer to the requirements found in SEMI F57. For larger assemblies refer to the requirements found in SEMI E49.1.

13 Traceability Recommendations

13.1 A completed assembly should have permanent identification such that it is traceable to the documentation recommended within this guide. The manufacturer is responsible for maintaining records that include but are not limited to the following:

- Test methods and results
- Final assembly inspection
- Assembly drawing modifications
- Weld logs

RELATED INFORMATION 1
FLOW CONSIDERATIONS FOR ULTRAPURE WATER SYSTEMS

NOTE: This related information is not an official part of SEMI E49.7 and was derived from North American Liquid Chemicals. This related information was approved for publication by full letter ballot on April 30, 2002.

R1-1 Ultrapure Water Considerations

R1-1.1 An ultrapure water system may benefit from maintaining continuous flow with a velocity greater than or equal to those listed in the following table:

Nom. Size	*Tube ID (inches)*	*V (ft/s)*	*Tube ID (cm)*	*V (cm/s)*
¼”	0.125	5.2	0.3175	158.1
3/8”	0.250	2.6	0.6350	79.0
½”	0.375	1.7	0.9525	52.7
¾”	0.625	1.0	1.5875	31.6
1”	0.875	0.7	2.2225	22.6

R1-1.2 For reference this information is based on the following equations, using a Reynolds number of 5000 and water at a temperature of 20°C.

$$\mathrm{Re} = \frac{\rho \cdot V \cdot D}{\mu}$$

$$V = \frac{\mathrm{Re} \cdot \mu}{D \cdot \rho}$$

example:

$$V = \frac{(5000) \cdot (0.01002)}{(0.3175) \cdot (0.9982)} = 158.1$$

Where:

Re is Reynolds number (dimensionless)
ρ is density (g/cm^3)
V is fluid velocity (cm/sec)
D is tube diameter (cm)
μ is viscosity (g/cm-s)

SEMI E49.8-0298
GUIDE FOR HIGH PURITY GAS DISTRIBUTION SYSTEMS IN SEMICONDUCTOR MANUFACTURING EQUIPMENT

1 Purpose

1.1 This document specifies guidelines for high purity (HP) gas distribution systems in semiconductor production equipment.

2 Scope

2.1 Gas distribution systems consist of stainless steel (SS) piping designed to supply the following types of gases to the process chamber:

2.1.1 *Specialty Gases* — Corrosive, flammable, pyrophoric, oxidizer, toxic, inert, and mixtures.

2.1.2 *Bulk Gases* — Nitrogen, oxygen, argon, hydrogen, and helium.

2.2 Typical processes include diffusion, anneal, plasma etch, chemical vapor deposition, physical vapor deposition, and ash.

3 Referenced Documents

2 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

3 National Fire Protection Association, Batterymarch Park, Quincy, MA 02269

4 Terminology

See Section 4 of SEMI E49.

5 Performance Guidelines

5.1 *Purity Indices*

- Particle Count (ptc), at ≥ 0.1 µm
  - — ≤ 0.18 ptc/L (5 ptc/ft^3) average single count
  - — ≤ 1.8 ptc/L (50 ptc/ft^3) maximum single count
- Moisture Level — ≤ 100 ppb
- Oxygen Level — ≤ 100 ppb
- Total Hydrocarbon (THC) — ≤ 100 ppb
- Inboard Helium Leak Rate — $\leq 10^{-9}$ atm. cc/sec.

5.2 All performance measures are absolute values, relative to respective test instrument background level.

5.3 See SEMI E49.6 for recommended gas system testing procedures.

5.4 *Reliability and Maintainability Indices* — Equipment supplier should provide actual gas system performance data and/or component reliability data, accompanied by the associated failure analysis method.

Indices	*Hours*
Mean time between failure (MTBF)	
Mean time between assists (MTBA)	
Mean time to repair (MTTR)	
Start-up time (Initial)	

6 Design Guidelines

6.1 All weld joints should be automatically orbital butt welded.

6.2 Directional changes in the process flow path should be minimized. Required directional changes should be accomplished by butt weld elbows or block components. Tube bends may be used up to sizes of $\leq$ 1/2 in. O.D., with a minimum of 8× tube diameter.

6.3 Metal face seal type mechanical fittings should be used where required for component removal/replacement.

6.4 Dead volumes and system internal volume should be minimized by use of miniature type weld fittings. Multi-valve arrangements are optional.

6.5 Purge and vent connections to process gas stream should be accomplished by tee fittings and branch valves. Flow through branch valves or multivalve block arrangements are optional.

6.6 All corrosive, toxic, and flammable gases (i.e., reactive) should have upstream and downstream purge/vacuum capability for MFC maintenance. A gas should be defined to be reactive if it has a Hazardous Production Material (HPM) rating of 3 or 4 per NFPA 49 and NFPA 704.

6.7 All inert gases should have downstream purge capability as a minimum. Atmospheric gas services (e.g., N_2, Ar) can use the process gas as a purge gas.

6.8 For low pressure equipment, the vacuum path from the MFC manifold to the pump should be through the process chamber as a minimum. Piping for chamber bypass to vacuum pump foreline is optional.

6.9 For atmospheric pressure equipment, a vacuum venturi to vent/exhaust method should be required for reactive gases.

6.10 Design should include a means of flow-through purging for removable components or component sticks for reactive gases and should include a means of flow-through purging for all removable components.

6.11 Backflow/back pressure protection should be included for all gases in the system.

6.12 All incoming gas lines should have filters included. Filters for process gases should be located downstream of any regulator or check valve and upstream of any MFC. Screen filters (e.g., wire mesh) should not be used.

6.13 6.13 Any additional filters for reactive gases, located at point of use before a process chamber or loadlock, should have a means of isolation from atmosphere.

6.14 For processes requiring pressure control, regulators should be included in the gas system and located upstream of MFC's. Pressure gauges or transducers, with a display, should be used for process measurement.

6.15 The gas system should have a means of manifolding supply lines onboard, so that there is a single point connection for each individual gas (consisting of the same chemical composition and purity level).

7 Materials Guidelines

7.1 *Material Mechanical Characteristics - Stainless Steel*

7.1.1 All tubing greater than or equal to 1.27 cm (1/2 in.) diameter should conform to ASTM A 269.

7.1.2 Tubing less than 1.27 cm (1/2 in.) diameter should conform to ASTM A 632.

7.1.3 All bar stock should conform to ASTM A 479.

7.1.4 All steel should conform to ASM UNS S31603 for chemical composition with the following exceptions:

- Sulfur as reported by the SMTR $\leq$ 0.030%
- Carbon as reported by the SMTR $\leq$ 0.030%

7.2 Stainless steel should be 316L electropolished for gas system wetted flow streams and/or as specified by the customer.

7.3 Materials for valve seals, diaphragms, gaskets, and O-rings should be chemically compatible with the process gas.

7.4 Material Performance Guidelines

7.4.1 The performance guidelines below are SS qualification values to be demonstrated by the original component manufacturer. Semiconductor equipment suppliers should provide proof that their components conform to these requirements.

7.4.2 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically significant data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.4.3 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user's materials performance requirements.

Table 1 Summary of Recommended Specifications

Description	*Value*	*Units*
Internal Surface Chemistry (AUGER)		
Surface chromium oxide enhanced layer thickness at 1/2 peak height of measured oxygen signal level	≥ 15	Å
For an example of a test method, see SEMASPEC 90120573B (AUGER)		
Internal Surface Chemistry (ESCA)		
Total chromium to iron ratio including both reduced and oxidized states	≥ 1.25:1	value
For an example of a test method, see SEMASPEC 90120403B (ESCA)		
Internal Surface Chemistry (EDX)		
Surface foreign elements, those elements not in the Smelter's Test Report (SMTR)	0	value
Test procedures per ASTM F 1375 (EDX)		
Internal Surface Defects		
Photos per test method	5	value
Counts per photo	≤ 50	value
Test procedures per ASTM F 1372 (SEM)		
Internal Surface Roughness		
Average surface roughness	≤ 0.25	µm
Roughness average (R_a)	(≤ 10)	(µin.)
Maximum surface R_a	≤ 0.33	µm
(individual reading)	(≤ 15)	(µin.)
For an example of a test method, see SEMASPEC 90120400B (Contact Profilometry)		
Particulate Contribution		
at ≥ 0.1 µm size	≤ 0.71 (20)	ptc/L (ptc/ft^3)
at ≥ 0.02 µm size	≤ 2.6 (75)	ptc/L (ptc/ft^3)
Test procedures per ASTM F 1394 (Particles)		
Internal Absorbed Moisture		
Time to recover to base line from a 2 ppm spike for low surface area component (valve, regulator)	≤ 4	hour
Time to recover to baseline from a 2 ppm spike for high surface area component (filters, tubing)	≤ 6	hour
Test procedures per ASTM F 1397		
Total Anionic Contamination		
Total anionic contamination added to test water	≤ 1	ppm
Individual anionic contaminant	≤ 0.2	ppm
Test procedures per ASTM D 4327 (Total Anions)		
Leak Rate		
Inboard leak rates for He	$\leq 1 \times 10^{-9}$	scc/s
Outboard leak rates for He	$\leq 1 \times 10^{-5}$	scc/s
Cross-seat leak rates for He	$\leq 4 \times 10^{-8}$	scc/s
Test procedures per SEMI F1 (Leak Rate)		
Cycle Life		
Manual valves	≥ 25 K	cycles
High pressure automatic valves	≥ 25 K	cycles
Low pressure automatic valves	≥ 500 K	cycles
Test procedures per ASTM F 1373 (Cycle Life)		

8 Component Guidelines

8.1 For component leak rate and cycle life requirements, see Section 7.

8.2 Valves should be springless and packless inverted bellows type with all metal bonnet seals. Springless diaphragm type valves are optional.

8.3 Regulators should be a threadless type (wetted stream) with all metal bonnet seals and should meet the following minimum requirements:

- Supply Pressure Effect — ≤ 0.021 kg/cm^2 rise/7 kg/cm^2 drop (≤ 0.3 psi rise/100 psi drop)
- Repeatability — ± 0.5% of outlet pressure range
- Setpoint Sensitivity — ≤ 0.0175 kg/cm^2 (≤ 0.25 psi)
- Setpoint Stability — ± 1% of setpoint

For an example of a test method, see SEMASPEC 90120392B.

8.4 Regulators and valve flow coefficient (C_v) should be selected based on gas flow requirements and gas characteristics. For an example of a test method, see SEMASPEC 90120394B.

8.5 Filter performance should be 9-LOG retention value at most penetrating particle size and should meet the following minimum requirements.

- Media-rated at 0.01 µm pore size
- PTFE or stainless steel media for noncorrosive gases
- PTFE or nickel media for corrosive gases
- Sized for 0.35 kg/cm^2 (5 psi) maximum pressure drop at design flow conditions

For an example of a test method, see SEMASPEC 90120393B.

8.6 MFC's should have as a minimum:

- Metal seals and seats for reactive gases.
- Optional soft start feature.
- High flow purge capability of ≥ 50 times full scale flow for range for MFC's sized for ≤ 200 sccm in reactive gas service. High flow purge feature is optional for all other gases and flow rates.

8.7 All mechanical fittings should be a metal face seal type with solid nickel gaskets.

8.8 Pressure gauges should be a compound type and have metal face seal connections. Pressure gauges or transducers should be used for process measurement.

8.9 Pressure transducers should be flow-through or flush-mount, with digital displays. No deadleg-type transducers or pressure gauges should be used for process gas streams. Pressure transducers should meet the following minimum requirements.

- Accuracy (combined linearity, hysteresis, and repeatability) — ± 0.25% of full scale maximum
- Repeatability — ± 0.08% of full scale maximum
- Span Shift — ± 0.1% of full scale maximum due to change in ambient conditions
- Functionally unaffected by RFI/EMI (radio frequency interference/electromagnetic interference) in frequency ranges up to 350 – 950 Mhz, at a distance of 0.61 m (2 ft.) from a 2W source.

8.10 Check valves should be a disk poppet type.

9 Subsystem Assembly Guidelines

See SEMI E49.6 for recommended SS system assembly procedures.

10 Controls Guidelines

10.1 The cycle purge and flow-through purge sequences may be operated by manual means such as toggle switches and push buttons. Automatic controllers for gas system maintenance are optional.

10.2 Detailed instructions for purge sequence operation should be included with equipment.

5 Performance Guidelines

5.1 *Purity Indices*

Particle Count (ptc), at $\geq$ 0.02 µm

— $\leq$ 0.18 ptc/L (5 ptc/ft^3) average single count

— $\leq$ 1.8 ptc/L (50 ptc/ft^3) maximum single count

Moisture Level — $\leq$ 20 ppb

Oxygen Level — $\leq$ 10 ppb

Total Hydrocarbon (THC) — $\leq$ 20 ppb

Inboard Helium Leak Rate — $\leq 10^{-10}$ atm. cc/sec.

5.2 All performance measures are absolute values, relative to respective test instrument background level.

5.3 See SEMI E49.6 for recommended gas system testing procedures.

5.4 *Reliability and Maintainability Indices* — Equipment supplier should provide actual gas system performance data and/or component reliability data, accompanied by the associated failure analysis method.

Indices	*Hours*
Mean time between failure (MTBF)	
Mean time between assists (MTBA)	
Mean time to repair (MTTR)	
Start-up time (Initial)	

6 Design Guidelines

6.1 All weld joints should be automatically orbital butt welded.

6.2 Directional changes in the process flow path should be minimized. Required directional changes should be accomplished by butt weld elbows or block components. Tube bends may be used up to sizes of $\leq$ 12 in. O.D., with a minimum of 10× tube diameter.

6.3 Metal face seal type mechanical fittings should be used where required for component removal/replacement.

6.4 Dead volumes should be minimized in the process gas stream. There should be no blind runs such as pressure gauges. Bypasses should not be used for MFC's.

6.5 The system internal volume should be minimized by using multi-component weldments, dead space free (DSF) branch valves, multi-valve block arrangements, and weld fittings.

6.6 All corrosive, toxic, and flammable gases (i.e., reactive) should have upstream and downstream purge/vacuum capability for MFC maintenance. A gas should be defined to be reactive if it has a Hazardous Production Material (HPM) rating of 3 or 4 per NFPA 49 and NFPA 704.

6.7 All inert gases should have downstream purge capability as a minimum. Atmospheric gas services (e.g., N_2, Ar) can use the process gas as a purge gas.

6.8 For low pressure equipment, the vacuum path from the MFC manifold to the pump should bypass the process chamber and should connect directly to the foreline.

6.9 For atmospheric pressure equipment, a vacuum venturi to vent/exhaust method should be required for reactive gases.

6.10 Design should include a means of cycle purging upstream and downstream of removable components or components sticks for reactive gases and should include a means of flow-through purging for all removable components.

6.11 Backflow/back pressure protection should be included for all gases in the system.

6.12 All incoming gas lines should have filters included. Filters for process gases should be located downstream of any regulator and upstream of any MFC. Screen filters (e.g., wire mesh) should not be used.

6.13 Any additional filters for reactive gases, located at point of use before a process chamber or loadlock, should have a means of isolation from atmosphere.

6.14 Test/sample ports should be located on each process chamber supply line or the designated purge/vent line. Ports should be isolated from gas stream by DSF branch valves or multivalve blocks.

6.15 For processes requiring pressure control, regulators should be included in the gas system and located upstream of MFC's. Transducers should be used for pressure measurement.

6.16 A means of pressure display should be included on the equipment.

6.17 For processes requiring purified gases, purifiers should be included in the gas system and located upstream of MFC's. The system should include a means of purging and removing purifiers in a safe manner.

6.18 The gas system should have a means of manifolding supply lines onboard, so that there is a single point connection for each individual gas (consisting of the same chemical composition and purity level).

7 Materials Guidelines

7.1 *Material Mechanical Characteristics - Stainless Steel*

7.1.1 All tubing greater than or equal to 1.27 cm (1/2 in.) diameter should conform to ASTM A 269.

7.1.2 Tubing less than 1.27 cm (1/2 in.) diameter should conform to ASTM A 632.

7.1.3 All bar stock should conform to ASTM A 479 or ASME SA479.

7.1.4 All steel should conform to ASM UNS S31603 for chemical composition with the following exceptions:

7.1.4.1 *Sulfur as Reported by the SMTR*

Tubing ≥ 1.27 cm (1/2 in.) 0.005 – 0.015%

Tubing ≤ 1.27 cm (1/2 in.) ≤ 0.003 – 0.012%

Bar Stock ≤ 0.015%

7.1.4.2 *Carbon as Reported by the SMTR* — ≤ 0.030%

7.2 Stainless steel should be 316L electropolished secondary remelt for gas system wetted flow streams or as specified by the customer.

7.3 Materials for valve seals, diaphragms, gaskets, and O-rings should be chemically compatible with the process gas.

7.4 *Material Performance Guidelines*

7.4.1 The performance guidelines below are SS qualification values to be demonstrated by the original component manufacturer. Semiconductor equipment suppliers should provide proof that their components conform to these requirements.

7.4.2 The performance tests should be considered production qualification tests. It is the responsibility of the component manufacturer to provide statistically significant data which correlates their production tests to these qualification tests (e.g., Statistical Process Control, MIL-STD-105D).

7.4.3 The equipment supplier should be responsible for maintaining and supplying, upon request, documentation that proves their components meet the user's materials performance requirements.

Table 1 Summary of Recommended Specifications

Description	*Value*	*Units*

8 Component Guidelines

8.1 For materials guidelines and component leak rate and cycle life requirements, see Section 7.

8.2 Valves should be springless, packless diaphragm type with all metal bonnet seals.

8.3 Regulators should be threadless type (wetted stream) with all metal bonnet seals and should meet the following minimum requirements:

- Supply Pressure Effect — ≤ 0.021 kg/cm^2 rise/7 kg/cm^2 drop (≤ 0.3 psi rise/100 psi drop)
- Repeatability — ± 0.5% of outlet pressure range
- Setpoint Sensitivity — ≤ 0.0175 kg/cm^2 (≤ 0.25 psi)
- Setpoint Stability — ± 1% of setpoint

For an example of a test method, see SEMASPEC 90120392B.

8.4 Regulator and valve flow coefficient (C_v) should be selected based on gas flow requirements and gas characteristics. For an example of a test method, see SEMASPEC 90120394B.

8.5 Filter performance should be 9-LOG retention value at most penetrating particle size and should meet the following minimum requirements.

- Media-rated at 0.01 µm pore size
- Predried to ≤ 10 ppb H2O and sealed from atmosphere
- PTFE or stainless steel media for noncorrosive gases
- PTFE or nickel media for corrosive gases
- Sized for 0.14 kg/cm^2 (2 psi) maximum pressure drop at design flow conditions

For an example of a test method, see SEMASPEC 90120393B.

8.6 MFC's should have as a minimum:

- Metal seals and seats for reactive gases.
- Metal seals for inert and atmospheric gases.
- Optional soft start feature.
- High flow purge capability of ≥ 50 times full scale flow control range.

8.7 Mechanical fittings should be all metal face seal with solid nickel gaskets and antitorque capability.

8.8 Pressure transducers should be flow-through or flush-mount, with digital displays. No deadleg-type transducers or pressure gauges should be used for process gas streams. Pressure transducers should meet the following minimum requirements.

- Accuracy (combined linearity, hysteresis, and repeatability) — ± 0.25% of full scale maximum
- Repeatability — ± 0.08% of full scale maximum
- Span Shift — ± 0.1% of full scale maximum due to change in ambient conditions
- Functionally unaffected by RFI/EMI (radio frequency interference/electromagnetic interference) in frequency ranges up to 350 – 950 Mhz, at a distance of 0.61 m (2 ft.) from a 2W source.

8.9 Mechanical type check valves should not be used. Required backflow protection should be by other means, such as electronic pressure sensing and appropriate valve interlocks.

9 Subsystem Assembly Guidelines

See SEMI E49.6 for recommended SS system assembly procedures.

10 Controls Guidelines

10.1 The equipment controller should be capable of automatic purge sequences for gas system maintenance.

10.2 The equipment controller should be capable of automatic vent-then-run sequences included in the process recipe.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E51-0200
GUIDE FOR TYPICAL FACILITIES SERVICES AND TERMINATION MATRIX

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org January 2000; to be published February 2000. Originally published in 1995; previously published February 1998.

1 Purpose

1.1 The objectives of this guide are to ensure a timely and cost-effective tool installation with minimum impact on the existing customer facilities, systems, and services, and to insure that the quality of facilities supplied (e.g., water, gases, chemicals, electricity) is not compromised once internal to the tool.

1.2 This guide provides the equipment supplier with an understanding of the facilities available at the point of connection (POC) at the "typical" customer site. If these typical facility services are considered by tool manufacturers during their tool design, additional cost and lead times associated with customizing each tool installation can be minimized resulting in reduced costs to build and install semiconductor equipment.

2 Scope

2.1 This document does not include site-specific conditions. The Typical Facilities Services and Termination Matrix Example—United States (see Table 1) identifies utilities, performance, and connections at typical semiconductor facilities. When site specifications differ, the user should create a Site-Specific Facilities Services and Termination Matrix (see Table 2) that is submitted with the request for a quote. Each tool should be supplied in a "facility ready" state. This document represents the range of conditions in which equipment should be capable of operating.

2.2 This guide does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Impact

3.1 A reference to this guide and the Typical Facilities Services and Termination Matrix (see Table 1) or a completed Site-Specific Facilities Services and Termination Matrix (see Table 2) should be included with other applicable tool purchase specifications. When the supplier receives these documents, a dialogue can be established to resolve any installation issues prior to customer purchase or tool installation. Any additional facility requirements not identified should be determined when the tool quote is reviewed.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *amb* — ambient temperature conditions

1 American National Standards Institute (ANSI), 11 W. 42nd Street, New York, NY 10036

2 Institute of Electrical and Electronic Engineers (IEEE), 445 Hoes Lane, P.O. Box 1331, Piscataway, NJ 08855-1331

3 National Fire Protection Association (NFPA), 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101

5.1.2 *atm* — atmospheric conditions, 14.7 psi at sea level

5.1.3 *CPVC* — chlorinated polyvinyl chloride

5.1.4 *Cu* — copper

5.1.5 *EP* — electropolished

5.1.6 *Galv.* — galvanized

5.1.7 *Hg* — mercury

5.1.8 kPa — kiloPascals

5.1.9 *µ* — micron

5.1.10 *NFPA* — National Fire Protection Association

5.1.11 *NPT* — National Pipe Thread (U.S. Standard)

5.1.11.1 *FNPT* — Female National Pipe Thread

5.1.11.2 *MNPT* — Male National Pipe Thread

5.1.12 *NW Flange* — ISO NW flange

5.1.13 *P. Flange* — ANSI B16.5 pipe flange (for the purpose of this guide)

5.1.14 *PFA* — Perfluoralkoy, resin

5.1.15 *POC* — point of connection (POC is the point where the facility utility connects to the exterior of the tool.)

5.1.16 *POU* — point of use

5.1.17 *PP* — Polypropylene

5.1.18 *psia* — pounds per square inch, absolute

5.1.19 *psig* — pounds per square inch, gauge

5.1.20 *PVC* — Polyvinyl Chloride

5.1.21 *PVDF* — Polyvinylidene Fluoride

5.1.22 *RES.* — resistivity

5.1.23 *S.M. Flange* — sheet metal flange

5.1.24 *SS* — stainless steel

5.1.25 *Stub* — pipe or tube stub

6 Typical Facilities Services and Termination Matrix

6.1 This section of the guide identifies utilities, performance and connections at typical semiconductor facilities. This includes a Typical Facilities Services and Termination Matrix Example—United States (see Table 1). The guide identifies typical utilities and is not intended to be limited to the listed utilities. A Site-Specific Facilities Services and Termination Matrix (see Table 2) is also provided to document differences from Table 1 utilities.

6.2 The following is an explanation of the table headings in the Typical Facilities Services and Termination Matrix.

6.2.1 *Utilities* — This is a list of process or process-related services typically found in semiconductor facilities. The list is divided into water service, gas service, drains, bulk chemical distribution, exhaust and electrical services.

6.2.2 *Supply Temperature* — Temperature and ranges are measured in °C (°F). Equipment or tool cooling systems should be sized to accommodate these ranges.

6.2.3 *Supply/Return Pressure* — Pressure and ranges are measured in kPa (psig). Where possible, equipment should be designed to operate at lower pressure which reduces energy and safety risks. Regulators should be specified by the customer and provided with the tool by the supplier.

6.2.4 *Filtration* — Filtration provides an indicator of particle size expectation at POC to the tool. The fabrication and quality of point of use (POU) filtration should be specified by the customer and provided with the tool by the supplier.

6.2.5 *Specification* — The specification column is a condensed version of typical customer specifications. The column should be used by customers to specify service quality at POC to the tool. Specified quality should not be compromised or lessened in any way internally by the supplier's tool. When the tool purchase specification is prepared, expanded, and detailed, quality requirements should be documented.

6.2.6 *POC Material* — Material that the facility typically uses for connections to tools. Additional material quality characteristics should be identified in the tool purchase specification. Interior piping or tubing should be specified by the customer and provided with the tool by the supplier to meet or exceed the facility POC material quality. (See SEMI E49.)

6.2.7 *POC Fitting* — Compatible connectors are critical to ensure that a tool is "facility ready" once it arrives at a customer site. It is recommended that equipment be supplied with matching connections as requested by customer.

6.2.8 *Notes* — Special conditions or exceptions.

7 General Considerations

7.1 In addition to typical utilities, other facility-related issues should be addressed prior to tool installation.

7.1.1 *Point of Connection Locations* — Due to age of construction or design, all semiconductor facilities are not the same. To interface with equipment or tool, three suggested POC locations have been determined.

(See Figure 1). The POC locations are the top, the bottom, or the back of the tool. The customer should identify a POC location in the tool purchase specification. Suppliers should design tools to allow for internal routing to all locations, to avoid customization for every installation.

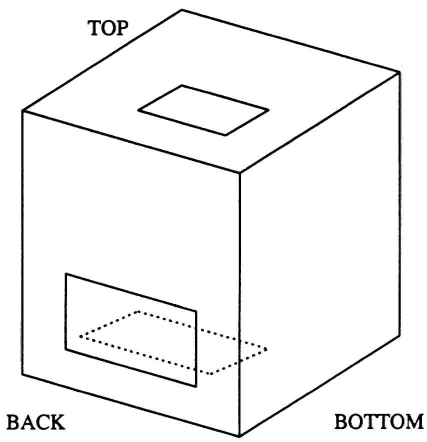

Figure 1
Three Point of Connection Locations

7.1.2 *Seismic* — The customer should specify the applicable earthquake zone for the installation site. The supplier should provide appropriate seismic restraints and installation instructions.

7.1.3 *Vibration* — The customer should specify that the supplier should provide the vibration sensitivity of the tool prior to purchase. (See SEMI E6.)

7.1.4 *Control and Signal Circuits* — The customer should specify and the supplier should provide control and signal circuits that when routed external to the tool are compliant with Article 725, Class 1, Class 2, and Class 3, Remote Control, Signaling and Power Limited — Control Circuits of the National Electrical Code. (See NFPA 70.)

Class 1 — No power limitation, 600 volts max.

Class 2 — Derived from listed Class 2 power supply.

Class 3 — Derived from listed Class 3 power supply.

7.1.5 *Installation Requirements Provided by Suppliers* — See SEMI E6.

7.1.6 *High Purity Distribution Systems Recommendations* — See SEMI E49.

7.1.7 *POC Labeling* — To ensure accurate connection of facility utilities to each tool POC, the customer should specify and the supplier should provide labeling for each POC. Service labeling should match descriptions listed in the supplier provided installation documentation. (See SEMI E6.)

7.1.7.1 If required, mechanical POC labels should include:

- Service purpose,
- Maximum pressure or pressure range, and
- Flow rate (if appropriate).

POC Label Example: Process Purge, Nitrogen, 80 psig Max.

7.1.7.2 If required, electrical power POC labels should include:

- Service purpose,
- Voltage & phase, and
- Current (Full load ampere continuous).

POC Label Example: Cryo Pump No. 2, 208 V, 1-phase, 28.2 FLA

7.1.7.3 If required, control and signaling POC labels should include:

- Purpose, and
- Class of control (see Section 7.1.4).

POC Label Example: Cryo Pump No. 2 Control, Class 2

SEMI E52-0302
PRACTICE FOR REFERENCING GASES AND GAS MIXTURES USED IN DIGITAL MASS FLOW CONTROLLERS

This practice was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standard Committee on November 27, 2001. Initially available at the www.semi.org December 2001; to be published March 2002. Originally published in 1995; previously published October 2000.

NOTE: This document was entirely rewritten for publication in 2002.

1 Purpose

1.1 To provide a numerical index of gases and gas mixtures used in the semiconductor industry that will give an ordered reference for the gases and gas mixtures when used in mass flow devices. This index or list will facilitate the production and use of digital mass flow devices.

2 Scope

2.1 The list includes gases, gas mixtures, and vaporizable materials that can be used in mass flow devices. The list will supplement, not replace, existing DOT/OSHA or other identification systems. For ease of use, the list is presented sorted by gas code, gas name, and symbol for gases and vaporizable materials and by code and mixture percentage for gas mixtures.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This list does not provide information related to the safe use and intended application of listed materials.

5 Terminology

5.1 *formula* — The structural representation of a gas, indicating the molecular groupings. Formulas are unique and unambiguous except in the case of isomers.

5.2 *gas code* — An integer that is uniquely associated with a particular gas.

5.3 *gas name* — The accepted name for a gas as specified in *Nomenclature of Organic Chemistry*.

5.4 *symbol* — Commonly accepted, unambiguous, and unique identification using ASCII characters with no subscripts, superscripts, or parenthesis.

6 Gas Table Sorted by Code

Table 1 Gases Sorted by Code

Code	*Gas Name*	*Symbol*	*Formula*	*Synonym*	*Ref*
1	Helium	He	He		1
2	Neon	Ne	Ne		1
3	Radon	Rn	Rn		2
4	Argon	Ar	Ar		1
5	Krypton	Kr	Kr		1

SEMI E56-1296
TEST METHOD FOR DETERMINING ACCURACY, LINEARITY, REPEATABILITY, SHORT-TERM REPRODUCIBILITY, HYSTERESIS, AND DEADBAND OF THERMAL MASS FLOW CONTROLLERS

1 Purpose

The purpose of this document is to provide a standardized method to quantify the accuracy, linearity, repeatability, short-term reproducibility, hysteresis, and deadband of a thermal mass flow controller.

The intent of this document is not to suggest any specific testing program but to specify the test method to be used when testing for parameters that are covered by this method. The user might use this document to check significant performance characteristics such as accuracy, precison, bias, repeatability, linearity, short-term reproducibility, and deadband under a set of closely controlled test conditions.

The significance of the accuracy calculations in this method is to allow an MFC user to transfer a process from one manufacturing tool to another and to exchange MFCs within a single manufacturing tool while maintaining process control.

2 Scope

2.1 This document describes the conditions and procedures for testing the accuracy, linearity, repeatability, hysteresis, and deadband of thermal mass flow controllers (MFCs). Because of the generic nature of this document, not all test procedures apply to all types of MFCs.

2.2 This document provided a common basis for communication between manufacturers and users.

3 Limitations

It is not practical to evaluate performance under all possible combinations of operating conditions. This test procedure should be applied under laboratory conditions; its intent is to collect sufficient data to form a judgement of the field performance of the MFC being tested.

5.1.22 *j* — Cycle for a given setpoint

5.1.23 *k* — Up cycle number for a given setpoint

5.1.24 *kPa* — Kilopascal

5.1.25 *LD* — Linearity of DUT

5.1.26 *LS* — Linearity of setpoint

5.1.27 *m* — Slope

5.1.28 *m* — Down cycle number for a setpoint

5.1.29 *n* — Number of up scale readings

5.1.30 *NC* — Normally closed

5.1.31 n_j — Number of readings at a setpoint at a given cycle

5.1.32 *NO* — Normally open

5.1.33 *P* — Precision

5.1.34 *psia* — Pounds per square inch absolute

5.1.35 *RPD* — Repeatability of the DUT

5.1.36 *RPS* — Repeatability at a setpoint

5.1.37 *S* — Setpoint

5.1.38 S_a — Average of setpoint

5.1.39 *sccm* — Standard cubic centimeters per minute

5.1.40 S_l— Setpoint, down cycle

5.1.41 S_u — Setpoint, up cycle

5.1.42 *slm* — Standard liters per minute

5.1.43 *SRD* — Short-term reproducibility of the device

5.1.44 *SRS* — Short-term reproducibility at a setpoint

5.1.45 v_i — The ith measured value at a setpoint for a given cycle

5.1.46 *Y* — Ideal linearity value

5.1.47 *Z* — Zero offset of DUT

5.1.48 Z_a — Indicated flow at zero actual flow

5.2 *Definitions*

5.2.1 *accuracy* — The closeness of agreement between an observed value and the true value; the total uncertainty of an observed value, including both precision and bias.

5.2.2 *accuracy curve* — The curve fitted through the average measured values over the specified range of the device under test.

5.2.3 *accuracy device* — The total uncertainty over a specified range of the device. Device accuracy over a range is stated as the worst case accuracy taken over all tested setpoints in this range.

5.2.4 *actual flow* — The gas flow as measured by an external standard, not the electrical output of a mass flow meter.

5.2.5 *bias* — The difference, at a setpoint, between the measured value and the sum of the setpoint value and the zero offset. The measured values of a flow standard include its total uncertainty.

5.2.6 *cardinal setpoint* — A specific setpoint to assess the accuracy of the device under test (DUT). For this test method, the cardinal setpoints are 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, and 100% of full scale.

5.2.7 *deadband* — The range through which a setpoint may be varied, upon reversal of direction, without initiating an observable change in output signal.

5.2.8 *device under test* — Mass flow device is being tested by this method.

5.2.9 *downscale reading* — A reading approached from a setpoint greater than the current setpoint and beyond the deadband.

5.2.10 *downscale value, average* — The sum of all downscale readings, in one cycle, at a single setpoint, divided by the number of these values.

5.2.11 *drift* — The change in output over a specified time period for a constant input under specified reference operating conditions.

5.2.12 *drift, long-term* — The drift between a series of tests over a specified time interval. This specified time interval is generally much greater than the time necessary to run an individual test.

5.2.13 *drift, short-term* — The drift between sets of measurements over the duration of the test.

5.2.14 *hysteresis* — That property of an element evidenced by the dependence of the value of the output, for a given excursion of the input, upon the history of the prior excursions and the direction of the current traverse.

5.2.15 *indicated flow* — Flow indicated by MFC under test. Electrical output of the DUT.

5.2.16 *linearity* — The closeness to which a curve approximates a straight line.

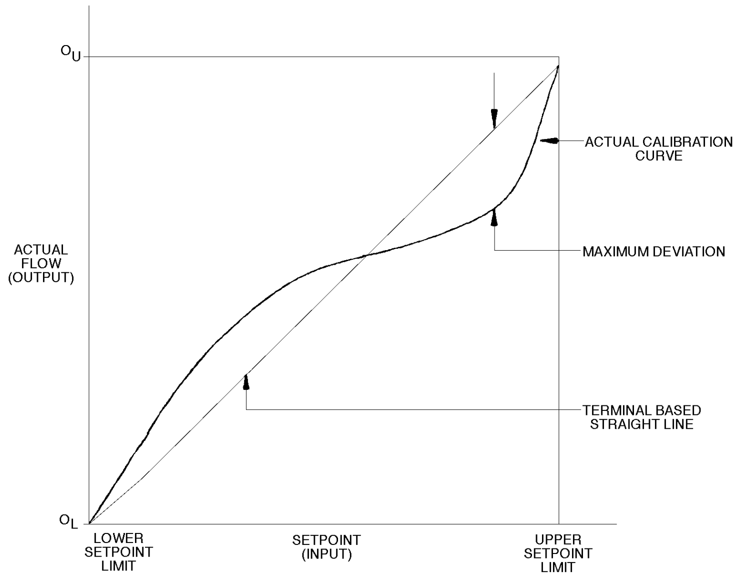

Figure 1
Terminal-Based Linearity for Mass Flow Controller

5.2.17 *linearity, terminal-based* — The maximum absolute value of the deviation of the accuracy curve (average of upscale and downscale values) from a straight line through the upper and lower setpoint limits of the accuracy curve (see Figure 1).

5.2.18 *measured value* — The actual flow through a device under test, expressed in sccm or slm, as measured by a standard, preferably primary.

5.2.19 *measured value, average* — The sum of all readings (both upscale and downscale) for all cycles, at a single setpoint, divided by the number of these readings.

5.2.20 *operating conditions, normal* — The range of operating conditions within which a device is designed to operate and for which operating influences are stated [ISA S51.1].

5.2.21 *operating conditions, reference* — The range of operating conditions of a device within which operating influences are negligible [ISA S51.1].

5.2.22 *operating influence* — The change in a performance characteristic caused by a change in a specified operating condition from reference operating conditions, all other conditions being held within the limits of reference operating conditions [ISA S51.1].

5.2.23 *pneumatic noise* — Localized, random variations in pressure and flow.

5.2.24 *precision* — The closeness of agreement among the measured values at a setpoint. It is often expressed as a standard deviation.

5.2.25 *repeatability* — The closeness of agreement among a number of measured values at a setpoint, under the same operating conditions, operator, apparatus, laboratory, and short intervals of time. It is usually measured as a nonrepeatability and expressed as a repeatability in percent of reading.

5.2.26 *reproducibility* — The closeness of agreement among repeated measured values at a setpoint, within the specified reference operating conditions, made over a specified period of time, approached from both directions. Reproducibility includes hysteresis, deadband, long-term drift, and short-term reproducibility.

NOTE: Between repeated measurements, the input may vary over the range, and operating conditions may vary within normal operating conditions.

5.2.27 *reproducibility, short-term* — The closeness of agreement among a number of measured values at a setpoint, under the same operating conditions, operator, apparatus, laboratory and short intervals of time, approached from both directions. The approach must be from beyond the deadband. Short-term reproducibility includes repeatability, hysteresis, deadband, and short-term drift.

5.2.28 *setpoint* — The input signal provided to achieve a desired flow, reported as sccm, slm, or percent-full scale.

5.2.29 *setpoint limit, lower* — The lowest setpoint at which the instrument is specified to operate.

5.2.30 *setpoint limit, upper* — The highest setpoint at which the instrument is specified to operate, usually full scale.

5.2.31 *settling time* — The time between the set point step change and when the actual flow remains within the specified band (see SEMI E17).

5.2.32 *span* — The full-scale range of the DUT.

5.2.33 *stability* — The ability of a condition to exhibit only natural, random variation in the absence of unnatural, assignable-cause variation.

5.2.34 *standard conditions* — 101.32 kPa, 0.0°C (14.7 psia, 32°F)

5.2.35 *uncertainty, total* — The range within which the true value of the measured quantity can be expected to fit; an indication of the variability associated with a measured value that takes into account the two major components of error, bias and the random error attributed to the imprecision of the measurement process.

5.2.36 *upscale reading* — A reading approached from a setpoint less than the current setpoint and beyond the deadband.

5.2.37 *upscale value, average* — The sum of all upscale readings, in one cycle, at a single setpoint, divided by the number of these values.

5.2.38 *zero drift* — The undesired change in electrical output, at a no-flow condition, over a specified time period, reported in sccm or slm.

5.2.39 *zero offset* — The deviation from zero, at a no-flow condition, reported in sccm or slm.

6 Summary of Test Method

Specific procedures are given for characterizing MFCs discharging to atmospheric pressure or into a vacuum using accepted reference standards to determine accuracy, linearity, repeatability, short-term reproducibility, hysteresis, and deadband (see Figure 2).

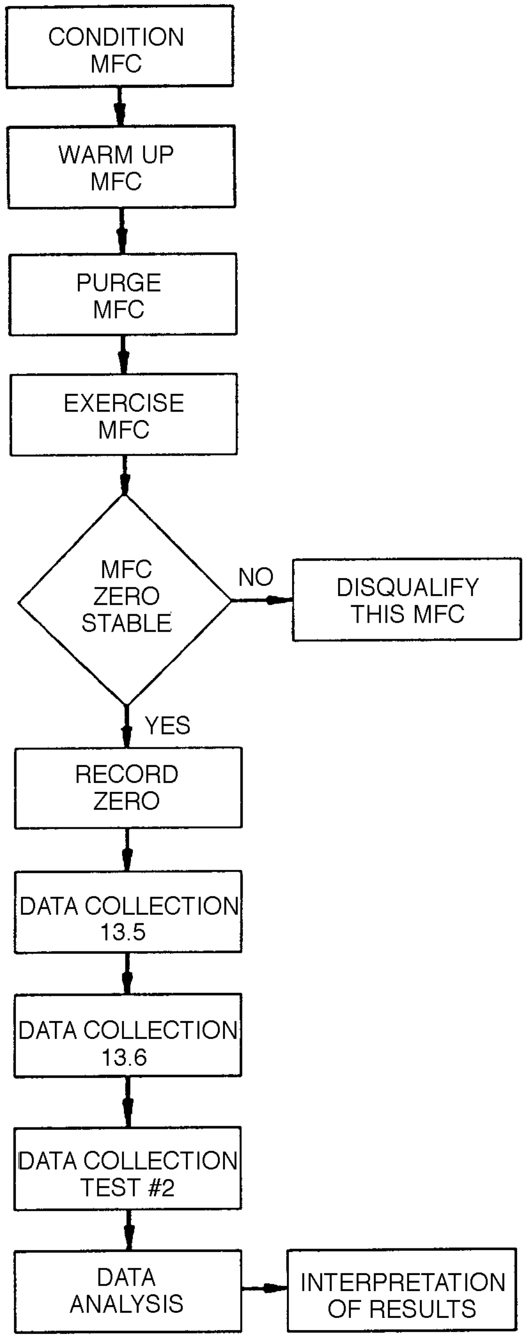

Figure 2
Test Flowchart

7 Interferences

7.1 The accuracy rating of the measuring equipment must include superior measurement capability compared with that of the DUT. In no instance should the accuracy rating of the measuring equipment be less than twice that of the DUT (e.g., if the accuracy of the DUT is ± 1 sccm, then the accuracy of the measuring device must be better than or equal to ± 1/2 sccm). The traceability of all the pertinent measuring instruments and devices should be realistically established and quantified.

In addition, take care when using test instruments with a specified accuracy expressed in percent of full scale. For example, if an instrument with a specified accuracy of ± 0.1% of full scale is used to measure the output of the DUT, but this output signal falls only within the lower third of the scale of the instrument, the effective accuracy over the range of the instrument being used may be ± 0.3%, which is unsuitable for many applications.

7.2 Use special precautions to ensure that minimum effects result from pneumatic noise in flow lines. Monitor pressure both upstream and downstream of the MFC to ensure that pneumatic noise is minimized.

7.3 The DUT should be installed so that the inlet flow can be fully developed, pulsation-free, for the specific conditions. This can be achieved by plumbing a straight length of tubing 40–50 diameters long upstream and another straight length 5 diameters long downstream of the DUT. (For additional information about inlet effects, refer to ASME MFC-10M.)

7.4 At regular calibration intervals, verify electrical signals directly at the MFC connector to ensure that there are no unacceptable line losses in the cables.

8 Apparatus

8.1 heat exchanger

8.2 flow standard

8.3 pressure transducer

8.4 back pressure regulator

8.5 temperature probe

8.6 digital voltmeter

8.7 setpoint generator

8.8 power supply

9 Technical Precautions

9.1 Many analog-to-digital converter cards do not differentiate between measurements of less than zero and zero. It may be necessary to use a digital voltmeter to record measurements below zero volts. Some MFCs do not differentiate between measurements of less than zero and zero. This may bias the results.

9.2 The manufacturer’s specifications and instructions for installation and operation must be applied during all testing.

9.3 All electrical measurements should be read on devices with at least 4.5 digits of resolution. These devices must have valid calibration certifications.

9.4 The mounting position of the device must be in accordance with the manufacturer's specifications. No external mechanical constraints beyond the manufacturer’s recommended mounting position shall be permitted.

10 Preparation of Apparatus

Figure 3 is a representation of a recommended generic testing apparatus. The flow standard is shown downstream of the device under test (DUT). It may be placed upstream of the DUT if the flow standard cannot be exposed to a low pressure environment. In this case, the user should be aware of possible back pressure effects on the flow standard.

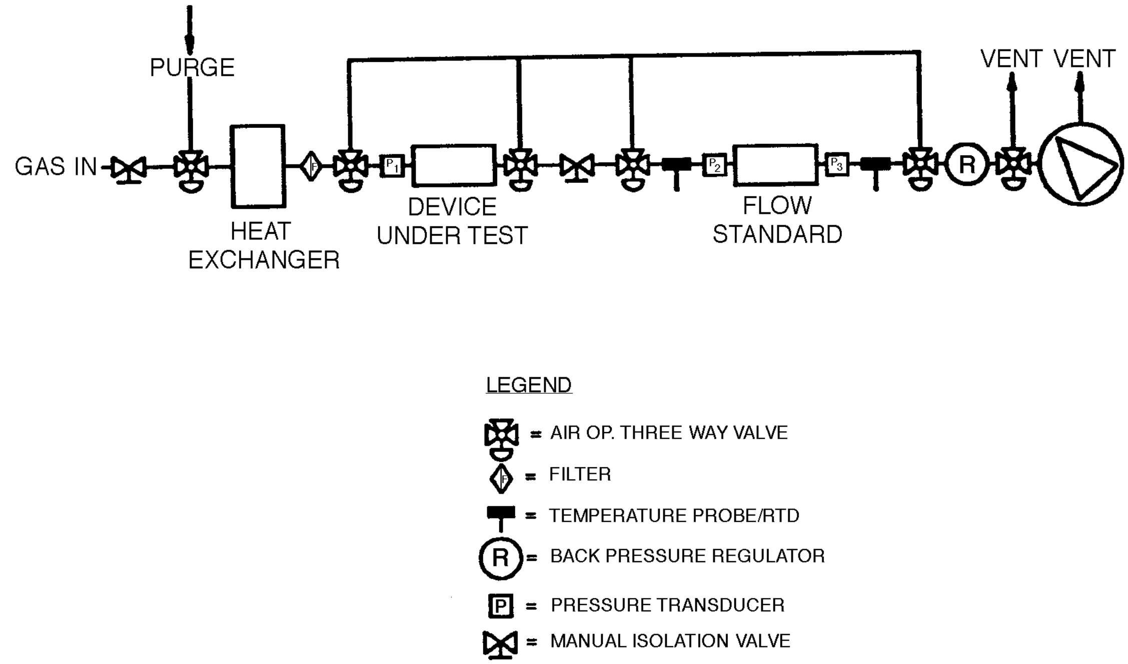

Figure 3
Mass Flow Controller Test Fixture

11 Calibration Standardization

All measurement devices must have valid calibration certificates.

12 Conditioning

12.1 Place the MFC to be tested in the testing environment. Apply power to the MFC for the 24 hours prior to initiating warm-up as defined by the manufacturer. The valve should be in its "off" position (closed for a NC valve, open for a NO valve).

12.2 Following the conditioning period, install and warm up the device according to manufacturer's specifications.

12.3 Purge the MFC with clean, dry nitrogen or argon following the warm up period.

12.4 Allow the test gas to flow through the DUT for a minimum of 10 minutes at 100% of flow.

12.5 Apply a 100% full-scale setpoint to the DUT and wait for the flow to stabilize for 10 seconds. Apply the lower setpoint limit to the DUT and wait for the flow to stabilize for 10 seconds. Repeat this cycle two more times. This process exercises the device before initiating the test.

12.6 *Test Conditions*

12.6.1 The reference operating conditions shall be as follows if the downstream pressure is atmospheric pressure:

Table 1

Ambient temperature	23 ± 2°C
Gas temperature	Same as actual ambient
Ambient pressure	101.32 kPa. (+ 4.7 or – 15.3 kPa)
Gas pressure P_1, Inlet	274 ± 34 kPa
Gas pressure P_3, Outlet	101.32 kPa. (+ 4.7 kPa or – 15.3 kPa)
Relative humidity	40% ± 10%, noncondensing
Magnetic field	≤ 50 µT
Electromagnetic field	< 100 µ V/m
Vibration	< 0.5 m/s
Shock	≤ 3 g

12.6.2 The reference operating conditions shall be as follows if the downstream pressure is at vacuum:

Table 2

Ambient temperature	23 ± 2°C
Gas temperature	Same as actual ambient
Ambient pressure	101.32 kPa. (+ 4.7 or – 15.3 kPa)
Gas pressure P1, Inlet	172 ± 34 kPa
Gas pressure P3, Outlet	< 0.13 kPa
Relative humidity	40% ± 10%, noncondensing
Magnetic field	≤ 50 µT
Electromagnetic field	< 100 µ V/m
Vibration	< 0.5 m/s
Shock	≤ 3 g

12.7 *Power Supply Conditions*

12.7.1 The reference power supply conditions used shall be the reference values specified by the manufacturer. For those instances when a range of values is specified rather than a reference value, the midpoint of the range shall be taken to be the reference value.

12.7.2 The reference power supply must be sufficiently rated for the DUT. In addition, the following supply conditions and tolerances shall apply:

Table 3

DC supply reference voltage	± 0.1% of operating voltage
Noise and ripple of DC supply	≤ 0.1% rms

13 Procedure

13.1 *Zero Offset* — Close the gas shut-off valve upstream of the DUT and apply a 100% setpoint to the DUT to equilibrate the pressure across the MFC. Wait for the flow to stabilize at a value near zero; then close the downstream shut-off valve. Deactivate the MFC's control valve (open for (NO) valves, closed for (NC) valves), and allow the MFC to auto-zero if the an auto-zero option is available. After the electrical output signal has stabilized for at least three minutes, record the MFC zero offset in Table 1. (Consult the manufacturer's specifications for the stabilization time and report this time on Table 2.)

13.2 Use the cardinal setpoints and any other setpoints of specific interest. These setpoints will be used to determine the accuracy of the MFC. The setpoint increments should exceed the expected deadband of the DUT.

13.3 At each setpoint under test, maintain the input signal until the output of the DUT becomes stabilized at its apparent final value. Observe and record the output values in Table 1 for each input value.

13.4 Record five readings at each setpoint during testing. The time between readings shall be between 1 and 100 times the settling time of the DUT.

[NOTE: If the data points show a trend in one direction, either up or down, the DUT is not stable enough for the test to proceed to the next setpoint. Record another five readings at this setpoint. If the results continue to show a trend, repeat the measurements at the previous setpoint. If the results are not satisfactory at this setpoint, stop the test for this MFC. If the results are not satisfactory, halt the test and verify the performance of the testing apparatus.]

13.5 *Test for Accuracy, Linearity, Repeatability, Short-Term Reproducibilty, and Hysteresis*

NOTE: Record data in Table 1.

13.5.1 Provide a setpoint to the DUT of 40% and hold it there for 5 minutes. Do not collect any data at this point. Apply a 50% setpoint to the MFC and record data.

13.5.2 Begin collecting data at the midpoint of the span. Use data tabulation table in Table 1.

13.5.3 Step the MFC's setpoint to the upper setpoint limit in the increments previously chosen; record data at each setpoint.

13.5.4 After data is recorded at the upper setpoint limit, step the setpoint to the lowest setpoint chosen, again taking data at each of the intermediate setpoints.

13.5.4.1 If the lowest setpoint chosen is greater than the lower setpoint limit, apply the lower setpoint limit to the device and wait for five minutes. This allows hysteresis to be calculated at the lowest setpoint chosen.

13.5.5 Continue collecting data, increasing the setpoint until the midpoint of the span is reached again.

13.5.6 Perform the cycle described in Sections 13.5.1–13.5.4 a total of three times.

13.6 *Test for Deadband*

13.6.1 Begin collecting data at the lowest setpoint chosen. Record on Table 3.

Table 6 Data Tabulation Table Two

90%		
100%		

13.6.2 Step the MFC's setpoint to the highest setpoint chosen that is less than the upper setpoint limit in the increments previously chosen; record data at each setpoint.

13.6.3 At each setpoint, slowly increase the setpoint signal to the DUT until a detectable flow output change is observed in the flow standard.

13.6.4 Record the setpoint signal when the flow output changes and call this the upper deadband value.

13.6.5 Return to the setpoint selected in Section 13.6.3.

13.6.6 Slowly decrease the setpoint signal until a detectable flow output change is observed.

13.6.7 Record the setpoint signal and call it the lower deadband value. Use Table 3.

14 Data Analysis

14.1 *Calculations*

NOTE: Record calculations on Table 4.

Over-all									

14.1.1 *Accuracy*

14.1.1.1 Determine the precision at a setpoint by calculating the standard deviation of all the measured values (both upscale and downscale) for that setpoint. Perform this calculation at each setpoint.

$$P = \frac{\sqrt{\Sigma(\Sigma(v_i - A_a)^2)_j}}{\Sigma n_j}$$

P = Precision

v_i = The ith measured value at a setpoint for a given cycle

A_a = Average measured value

n_j = Number of readings at a setpoint at a given cycle

i = Reading number in a cycle for a given setpoint

j = Cycle for a given setpoint

14.1.1.2 Determine the bias at a setpoint by averaging the difference between the measured value and the sum of the setpoint and zero offset. Perform this calculation at each setpoint.

$$B = \frac{\Sigma[\Sigma(A - S - Z)_i]_j}{\Sigma n_j}$$

B = Bias

A = Measured Value

S = Setpoint

Z = Zero offset of DUT

14.1.1.3 Determine the accuracy at each setpoint by summing the absolute values of the precision and bias. Divide the sum by the average of the setpoint and multiply by 100%. The sign of the accuracy is the same as the sign of the bias. Perform this calculation at each setpoint.

$$AS\% = \frac{|P| + |B|}{S_a} \times 100 \times \left(\frac{B}{|B|}\right)$$

AS = Accuracy of setpoint

S_a = Average of setpoint

14.1.1.4 Determine the overall accuracy of the DUT by adding the absolute value of the flow standard accuracy to the maximum absolute accuracy value from Section 14.1.1.3. This value is expressed as ± percentage of reading.

NOTE: This assumes that the flow standard accuracy is expressed as a percentage of reading.

$$\pm AD\% = |AS|_{MAX} + |AD_f|$$

AD = Accuracy of the DUT

AD_f = Accuracy of the flow standard

14.1.2 *Linearity*

14.1.2.1 Determine an equation for the straight line passing through the indicated flow at zero actual flow and the average measured value at a 100% setpoint.

$$m = \frac{A_a - Z_a}{100}$$

$$Y = mS + b$$

Z_a = Indicated flow at zero actual flow

A_a = Average measured value at 100% setpoint

m = Slope

Y = Ideal linearity value

14.1.2.2 Determine the linearity at a setpoint by averaging the difference between the measured value and the value of y at a given setpoint. Divide this number by the full scale range of the DUT and multiply by 100. Perform this calculation at each setpoint. Record this value in Figure 7.

$$LS\% = \frac{\Sigma[\Sigma(A - Y)_i]_j}{FS\,\Sigma n_j} \times 100$$

LS = Linearity of setpoint

FS = Full scale flow rate

14.1.2.3 The overall linearity of the DUT is the maximum absolute value calculated in 14.1.2.2. This value is expressed as a ± percentage of full scale.

$$\pm LD\% = |LS|_{max}$$

LD = Linearity of DUT

14.1.3 *Repeatability*

14.1.3.1 Determine the intermediate value by calculating the standard deviation of the measured values for all cycles approaching from a given direction. Divide this by the average setpoint for these cycles. Perform this calculation at each setpoint for both directions. The 100% setpoint will only be approached from the upscale direction.

$$I\% = \frac{\sqrt{\frac{\Sigma(v_i - A_a)^2}{n_i}}}{S_a} \times 100$$

I = Intermediate value

14.1.3.2 The repeatability at a setpoint is the maximum intermediate value at each setpoint calculated in Section 14.1.3.1. This value is expressed as a ± percentage of reading. Perform this calculation at each setpoint.

$$\pm RPS = I_{max}$$

RPS = Repeatability at a setpoint

14.1.3.3 The overall repeatability of the DUT is the maximum value calculated in Section 14.1.3.2.

$$\pm RPD = RPS_{max}$$

RPD = Repeatability of the DUT

14.1.4 *Short-Term Reproducibility*

14.1.4.1 Determine the short-term reproducibility at a setpoint by dividing the precision of the setpoint by the average setpoint. This is expressed as a percentage of reading. Perform this calculation a each setpoint.

$$SRS = \frac{P}{S_a} \times 100$$

SRS = Short-term reproducibility at a setpoint

14.1.4.2 The overall short-term reproducibility of the DUT is the maximum value calculated in Section 14.1.4.1.

$$\pm SRD = SRS_{max}$$

SRD = Short-term reproducibility of the device

14.1.5 *Deadband*

14.1.5.1 Determine the absolute deadband value by subtracting the lower deadband value from the upper value at each setpoint. Perform this calculation at each setpoint.

$$D = D_u - D_l$$

D = Deadband value

D_u = Upper deadband value

D_l = Lower deadband value

14.1.5.2 Determine the deadband at setpoint by dividing the absolute deadband value by the initial setpoint and multiplying by 100. This is expressed as a percentage of reading. Perform this calculation at each setpoint.

$$DBS = \frac{D}{S} \times 100$$

DBS = Deadband of setpoint

14.1.5.3 The overall deadband of the DUT is the maximum value calculated in Section 14.1.5.2.

$$\pm DBD = DBS_{max}$$

DBD = Deadband of device

14.1.6 *Hysteresis*

14.1.6.1 Determine the hysteresis plus deadband by subtracting the average of the difference between the downscale measured value and the downscale setpoint from the average of the difference between the upscale measured value and the upscale setpoint. Perform this calculation at each setpoint.

$$HDBS = \frac{\Sigma[\Sigma(A_u - S_u)_i]_k}{\Sigma n_k} - \frac{\Sigma[\Sigma(A_l - S_l)_i]_n}{\Sigma n_m}$$

$HDBS$ = Hysteresis plus deadband at a setpoint

A_u = Measured value, up cycle

A_l = Measured value, down cycle

S_u = Setpoint, up cycle

S_l = Setpoint, down cycle

n = Number of up scale readings

k = Up cycle number for a given setpoint

m = Down cycle number for a setpoint

14.1.6.2 Determine the hysteresis by subtracting the deadband from hysteresis plus deadband and divide the result by the initial setpoint and multiply by 100. This is expressed as a percentage of reading. Perform this calculation at each setpoint.

$$HS = \frac{HDBS - D}{S} \times 100$$

HS = Hysteresis at a setpoint

14.1.6.3 The overall hysteresis of the DUT is the maximum value calculated in Section 14.1.6.2.

$$\pm HD\% = HS_{max}$$

HD = Hysteresis of device

15 Data Presentation

15.1 *Accuracy* — Plot the accuracy data at each setpoint on a graph. The x-axis is the setpoint, and the y-axis is accuracy as a percentage of the reading.

15.2 *Linearity* — Plot the linearity at each setpoint on a graph. The x-axis is the setpoint, and the y-axis is linearity as a percentage of full scale.

15.3 *Repeatability* — Report a single number, as calculated above, as a percentage of the reading.

15.4 *Hysteresis* — Report a single number, as calculated above.

15.5 *Deadband* — Report a single number, as calculated above.

SEMI E57-0600
MECHANICAL SPECIFICATION FOR KINEMATIC COUPLINGS USED TO ALIGN AND SUPPORT 300 mm WAFER CARRIERS

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the North American Physical Interfaces and Carriers Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org April 2000; to be published June 2000. Originally published in 1996; previously published February 1999.

1 Purpose

1.1 This standard specifies the mechanical couplings used to ergonomically align and precisely support 300 mm wafer carriers (including transport cassettes, process cassettes, quartz boats, pods, lot boxes, and shipping boxes). Such a kinematic coupling can be used at several interfaces, including:

- between a box or cassette and a tool load-port or vehicle nest,
- between a transport cassette and a box, and
- between a process cassette or quartz boat and the floor of a process chamber.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Only the bottom half of the kinematic coupling is specified so that suppliers can be flexible in designing wafer carriers that can mate with it.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

SEMI E19.4 — 200 mm Standard Mechanical Interface (SMIF)

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

3.2 *ISO Document*[1]

ISO 4287 — Geometrical Product Specifications (GPS) — Surface texture: Profile method — Terms, definitions and surface texture parameters

4 Terminology

4.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes.

4.2 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.3 *cassette* — a open structure that holds one or more substrates (as defined in SEMI E44).

4.4 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded.

4.5 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface.

4.6 *nominal wafer center line* — the line that is defined by the intersection of the two vertical datum planes (facial and bilateral) and that passes through the nominal centers of the seated wafers (which must be horizontal when the carrier is placed on the coupling).

4.7 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

4.8 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

---

1 ISO Central Secretariat, 1, rue de Varembé, C.P. 56, CH-1211 Genève 20, Switzerland; available in the U.S. from American National Standards Institute, 11 West 42nd Street, 13th Floor, New York, NY 10036

5 Requirements

5.1 *Kinematic Coupling Pin Shapes* — The physical alignment interface on the bottom of the wafer carrier consists of features (not specified in this standard) that mate with six pins underneath. As shown in Figure 1 and defined in Table 1, each pin is radially symmetric about the vertical center axis line and can be seen as the intersection of a cylinder of diameter *d*91 and a sphere of radius *r*93 (which might contact a flat plate). An additional rounding radius *r*95 provides contact with angled mating surfaces, and blend radii *r*94 and *r*96 smooth the resulting edges. The final roughness height of the over-all surface finish must be less than or equal to *r*97. Dimensions *r*92 and *z*91 have zero tolerance because they only give a distance to another toleranced dimension. (Dimensions in parenthesis are not part of the requirements in this standard but are intended to clarify the preparation of manufacturing instructions.)

5.2 *Kinematic Coupling Pin Locations* — The pins are arranged in three sets with two pins in each set. As shown in Figure 2, the outer pin in each set is designated the primary pin for use on a tool load-port or vehicle nest or inside a box, and the inner pin in each set is designated the secondary pin for use on a robotic arm that would pick up the carrier (typically from the side opposite the load face plane). The location of each pin is determined with respect to the three orthogonal datum planes defined in Section 4: the horizontal datum plane, the facial datum plane, and the bilateral datum plane. Figure 3 shows the locations of the kinematic coupling pins as viewed from above, and Table 2 defines the locations (all of which are bilaterally symmetric about the bilateral datum plane). Angle θ is shown in Figure 3 for clarity and is not part of the requirements in this standard.

5.3 *Empirical Determination of Datum Plane Locations* — Given a set of three primary or secondary kinematic coupling pins, the datum planes should be determined as follows. The two pins that are closest together are the front pins which (along with a known vertical direction) define a Cartesian coordinate system. The center axis line of each pin is defined to be the vertical line whose *x* (left-right) coordinate is the average of the maximum protrusions of the pin to the left and to the right and whose *y* (front-back) coordinate is the average of the maximum protrusions of the pin to the front and to the back. The bilateral datum plane is defined to be the vertical plane that contains the center axis line of the rear pin and that is equally distant from the center axis lines of the front pins. The facial datum plane is defined to be the vertical plane that is perpendicular to the bilateral datum plane and whose distance to the center axis line of the rear pin is 1.5 times the average of the distances to the center axis lines of the front pins. The horizontal datum plane is defined to be the horizontal plane that is 13 mm (0.51 in.) below the average of the heights of the highest and lowest pin tops. Once these datum planes have been determined, the three kinematic coupling pins can be evaluated to see if they conform to Section 5.1 and 5.2 of this specification. If they comply, the kinematic coupling pins and datum planes can be used to evaluate the compliance of carriers to standards cited in Section 6.

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E57 but was approved for publication by full letter ballot procedures. It is not intended to modify or supercede the official standard.

R1-1 The three features on the bottom of the wafer carrier that mate with the six pins underneath are not specified in this standard. These three features are recommended to be inverted V-shaped grooves, each of which extends along a line that is perpendicular to, and co-planar with, the nominal wafer center line (as shown in Figure R1-1). Such grooves are likely to work well even when shrunken or slightly misaligned (such as when they do not all line up with the nominal wafer center line). Other mating features are also possible, such as those shown in Figure R1-2 where one pin is contacted on the top. Front-opening boxes may need to contact the pins on the side to provide pressure against a front mechanical interface. Such options are why the top and sides of the pins are toleranced so tightly. When designing the mating features on the bottom of the wafer carrier, it is suggested that designers follow the recommendations given in the book (listed in Section 6) by Dr. Alexander H. Slocum.

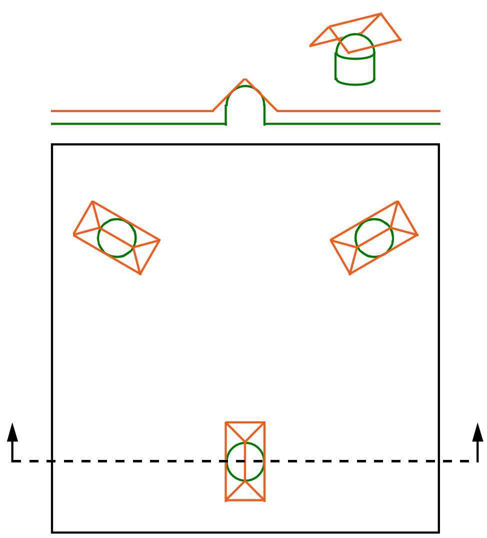

Figure R1-1
Recommended Mating Features

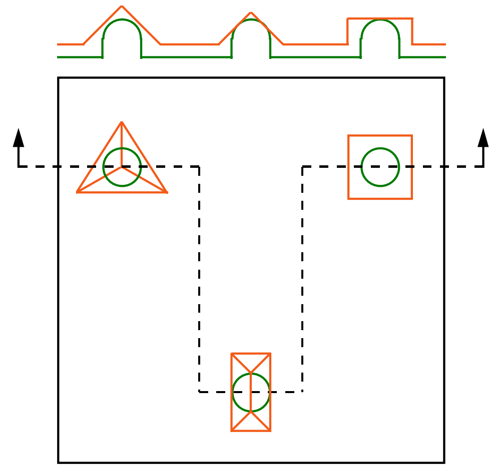

Figure R1-2
Alternative Mating Features

R1-2 All of the dimensions for the kinematic coupling pin surfaces and locations are given as ranges so that any roundness, cylindricity, perpendicularity, bending, or misalignment of the pins must be contained within the limits given.

R1-3 As shown in Figure R1-3, these couplings can also be used to support 200 mm pods as an addition to the requirements given in SEMI E19.4. However, concurrent implementations for both 200 and 300 mm wafer carriers may be covered by patent claims.

Application to 200 mm Pods

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E62-0302A
PROVISIONAL SPECIFICATION FOR 300 mm FRONT-OPENING INTERFACE MECHANICAL STANDARD (FIMS)

This provisional specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces & Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on December 3, 2001. Initially available at www.semi.org January 2002; to be published March 2002. Originally published in 1997; previously published November 2001.

NOTE: This document was published twice during the March 2002 (0302) publishing cycle.

1 Purpose

1.1 This standard specifies the tool side of the interface between a process or metrology tool and a front-opening box used to transport and store 300 mm wafers (which may or may not be in removable cassettes) in an IC factory.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Only the physical interface is specified; no materials requirements or micro-contamination limits are given. The interface specified in this standard can be for a sealed mini-environment, but it could also just be a well-defined automation interface.

2.2 This standard is provisional because the front-opening interface is a new technology. Once interface testing is done, this standard should be modified and upgraded from provisional status.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

ISO 4287 — Geometrical Product Specifications (GPS) — Surface texture: Profile method — Terms, definitions and surface texture parameters

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *Definitions*

4.1.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

4.1.2 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.1.3 *carrier capacity* — the number of substrates that a carrier holds (as defined in SEMI E1.9).

4.1.4 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

4.1.5 *door seal zone* — a surface on the exterior side of the port door for sealing to the box door.

4.1.6 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

1 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

4.1.7 *frame seal zone* — a surface on the exterior side of the frame of the port door for sealing to the frame of the box door.

4.1.8 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

4.1.9 *load face plane* — the furthest physical vertical boundary plane from the cassette centroid or carrier centroid on the side (or sides) of the tool where loading of the tool is intended (as defined in SEMI E15).

4.1.10 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

4.1.11 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

4.1.12 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

5 Requirements

5.1 *Datum Planes* — The physical alignment mechanism from the box to the tool load port consists of features (not specified in this standard) on the box that mate with three or six pins underneath as defined in SEMI E57. Most of the dimensions of the interface from the box to the tool load port are determined with respect to the three orthogonal datum planes defined in that standard: the horizontal datum plane, the facial datum plane, and the bilateral datum plane. However, the dimensions in this standard do not apply when the box is placed on the load port, but rather when the box has been moved horizontally into place against the front-opening interface. Otherwise, the front-opening interface would interfere with the kinematic coupling during loading, and the minimum rear clearance in E15 would be violated.

5.2 *Symmetry* — All of the dimensions for the interface are bilaterally symmetric about the bilateral datum plane and about a plane *z*30 above the horizontal datum plane with the following exceptions (as viewed by a person standing in front of the tool and facing the interface):

- The registration pins are in the lower right and upper left quadrants of the port door.
- The areas reserved for purge ports are in the upper right and lower left quadrants of the port door.
- Both latch keys turn 90° counter-clockwise from vertical to unlatch the box door from the box.

5.3 *Door Alignment Maintenance Mechanism* — The two registration pins that are used to limit the maximum displacement of the box door while on the port door are shown in Figures 1 and 2 and specified in Table 1. The over-all surface finish of the registration pins must have a final roughness height less than or equal to *r*47. The registration pins are surrounded by reserved space for optional vacuum application.

5.4 *Locking Mechanism* — The box door is locked and unlocked by a set of two 13.5 mm by 5 mm heads on shafts that have a 5 mm diameter. These latch keys must unlatch the box door from the box by rotating counter-clockwise to horizontal and must latch the box door to the box by rotating clockwise to vertical (as viewed by a person standing in front of the tool facing the *interface*). The latch keys must not rotate beyond these limits of the rotation angle ψ. To allow seal compression by latches, the torque delivered by the port to turn the latch keys must be at least *f*30. Thus, it is recommended that no box door be designed that needs more torque than this. Figure 3 shows front, side and top views of the latch keys. In addition, convex features on the outer edges of the latch keys (adjacent to the surface defined by *y*36) must have a blend radius of *r*41 to prevent small contact patches with large stresses that might cause wear and particles. Other convex features on the latch keys need only be de-burred and rounded off. The over-all surface finish of the latch keys must have a final roughness height less than or equal to *r*47.

5.5 *Seal Zones* — On the exterior side of the port must be two areas for sealing to the box. The door seal zone must be just inside the rim of the port door in the area between *x*32 and *x*33 from the facial datum plane and between *z*32 and *z*33 from the vertical center line of the port (which is *z*30 above the facial datum plane). Similarly, the frame seal zone must be on the frame of the port door in the area between *x*34 and *x*35 from the facial datum plane and between *z*34 and *z*35 from the vertical center line of the port. The door and its frame must be designed to mate with a front-opening box that conforms to SEMI E47.1. Specifically, the port door and its frame must have surfaces that mate with the seal zones and the reserved spaces for vacuum application (which includes all of the circles bounded by r38 except for the holes for the registration pins at the center of each circle). It is recommended that a gap be maintained between mating surfaces on the box and load port (unless the minienvironment is purged with an inert gas, in which case a tight seal is recommended).

5.6 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*45 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*46 to prevent small contact patches with large stresses that might cause wear and particles. Note that these limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the interface supplier. Note also that this radius applies to every required feature unless another radius is called out specifically.

5.7 *Force Between Box and Port* — The force with which the load port holds the box in place against the FIMS interface must be greater than the force with which the load port presses the box door into the box.

5.8 *Force Between Box Door and Box* — The load port must press the box door into the box with a force of *f*34.

5.9 *Door Return Repeatability* — The load port must return the port door to the closed position after opening with a repeatability given by the dimensions *x*37 and *z*37.

5.10 *Force Applied by Latch Keys* — If the load port uses retracting latch keys, once the latch keys have been turned to the position that unlocks the box door from the box (ψ = 0±1°), the force (in a direction perpendicular to the facial datum plane) applied by each latch key to the FOUP door must be no greater than *f*35.

5.11 *Door Accommodation* — The load port must mate completely with the box at the FIMS interface. One method to accomplish this is to have the load port door protrude sufficiently (with some cushioning ability) to meet the FOUP door (however far the FOUP door protrudes within what SEMI E47.1 allows). The load port door (at least on the seal zone plate) must also accommodate variations in angle (with respect to the Facial Datum Plane) of the FOUP door (however much the FOUP door varies in angle within what SEMI E47.1 allows).

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was approved as an official part of SEMI E62, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 Perpendicularity and parallelism are implicitly defined in the geometric tolerances.

A1-2 Section 5.1 discusses the need for clearance between the box and the tool's front-opening interface when the box is placed on the load port. After the box is placed on the load port, the kinematic couplings will move the box forward to engage with the tool's front-opening interface. The possibility of human fingers being pinched between the box and the tool's front-opening interface may be a safety concern for tool designers.

SEMI E63-0600A

MECHANICAL SPECIFICATION FOR 300 mm BOX OPENER/LOADER TO TOOL STANDARD (BOLTS-M) INTERFACE

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org April 2000; to be published June 2000. Originally published in 1997, previously published February 2000.

NOTE: This document was published twice during the June 2000 (0600) publishing cycle.

1 Purpose

1.1 This standard specifies the tool side of the mechanical interface between the main part of a process or metrology tool and the component that opens boxes and presents the boxes to the tool wafer handler for unloading and loading 300 mm wafers. The box opener/loader unit would include one or more load ports (that would conform to SEMI E15.1) as well as storage capacity for empty boxes or waiting lots (if needed by the tool throughput). The box opener/loader unit might not only be configured to handle boxes (that would conform to SEMI E47.1, SEMI E62, or SEMI E19.5) but also to open cassettes (that would conform to SEMI E1.9). This standard defines one interface for all such carriers and for any carrier capacity (13 and 25 wafers).

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Only the mechanical interface is specified; no materials requirements or micro-contamination limits are given. The interface specified in this standard is designed for a tool with a sealed minienvironment, but it could also just be a well-defined automation interface. This interface is not intended to provide high repeatability or rapid removal (both of which can be provided by other couplings in the box opener/loader unit). This specification also does not apply when load ports are stacked one on top of the other. This specification does not apply when inserting open cassettes into load-lock chambers directly.

2.2 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3.2 *ISO Specification* [1]

ISO/DIS 68-1 — ISO General Purpose Screw Threads – Basic Profile – Part I: Metric Screw Threads

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

1 This ISO specification is available from ANSI: American National Standards Institute, 11 West 42nd St., 13th Floor, New York, NY 10036

4.2 *BOLTS plane* — a plane parallel to the facial datum plane near the front of the tool where the box opener/loader is attached.

4.3 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.4 *box opener/loader* — the equipment component that opens wafer carriers (if needed) and presents the carriers to the equipment's wafer handler for unloading and loading wafers.

4.5 *carrier capacity* — the number of substrates that a carrier holds (as defined in SEMI E1.9).

4.6 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

4.7 *equipment front end module (EFEM)* — consists of the carrier handler that receives carriers from the factory material handling system on one or more load ports (as specified in *SEMI E15.1*), opens the carriers (if needed), and may include a substrate handler for unloading and loading wafers from the carrier to the process part of the equipment.

4.8 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

4.9 *horizontal datum plane* — a horizontal plane from which project the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

4.10 *load face plane* — the furthest physical vertical boundary plane from the cassette centroid or carrier centroid on the side (or sides) of the tool where loading of the tool is intended (as defined in SEMI E15).

4.11 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

4.12 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

4.13 *seal zone* — a surface on the tool at the BOLTS plane for sealing to the box opener/loader.

4.14 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

5 Requirements

5.1 *Datum Planes* — The physical alignment mechanism for the box consists of features (not specified in this standard) on the box that mate with three or six pins underneath as defined in SEMI E57. Many of the dimensions of the BOLTS interface are determined with respect to the three orthogonal datum planes defined in that standard: the horizontal datum plane, the facial datum plane, and the bilateral datum plane. The BOLTS plane is defined to be parallel to and at a distance *y*70 from the facial datum plane of the carrier (when the carrier is docked and in position for wafer extraction and insertion). If the carrier is rotated after being placed on the loadport, the facial datum plane of the carrier and the BOLTS plane may no longer be parallel to the load face plane of the equipment. If the carrier is not rotated, the distance (called the docking stroke) between the facial datum plane when the carrier is placed on the loadport (undocked) and the facial datum plane when the carrier is in position for wafer extraction and insertion (docked) must be *y*76 (but this is only a requirement for equipment delivered in the year 2000 or later). The tolerance on *y*70 is the installation tolerance. The cycle-to-cycle repeatability on *y*70 (without replacing the box opener/loader unit) must be within *y*75.

5.2 *Symmetry* — All of the dimensions for the interface are bilaterally symmetric about the bilateral datum plane. These dimensions are shown in Figure 1 and specified in Table 1.

5.3 *Hole Opening* — The BOLTS interface consists of a hole in the front of the tool at the BOLTS plane, a seal zone surrounding the hole, six threaded holes for bolting on the box opener/loader, reserved spaces for the box opener/loader inside the tool from the hole, and an exclusion volume for the box opener/loader outside of the hole. The dimensions of the hole are defined by *x*71, *z*71, and *z*76.

5.4 *Seal Zone* — On the BOLTS plane surrounding the hole opening must be a flat area for sealing between the tool and the box opener/loader. The inner dimensions of the seal zone are the same as the hole opening, and the outer dimensions of the seal zone are defined by *x*72, *z*72, and *z*77. The flatness of the seal zone must be within *y*71, and the perpendicularity of the seal zone to the facial and horizontal datum planes must be within σ.

5.5 *Bolt Holes* — At six points on the BOLTS plane there must be threaded holes for bolting on the box opener/loader. The opening of the threaded holes must be within the flatness of the seal zone (*y*71), and the holes must be at least *y*73 deep. The internal threads must conform to the ISO/DIS 68-1 specification which has a nominal diameter of 8 mm (0.31 in.), a thread pitch of 1.25 mm (0.05 in.), a normal length of engagement from 4 to 12 mm (0.16 to 0.47 in.), and no allowance (variation from basic diameter). The centers of the threaded holes are to be located at *x*73 to the left and right of the bilateral datum plane, and centers of the top, middle, and bottom pairs of threaded holes are to be located at *z*78 above, *z*75 below, and *z*73 below the horizontal datum plane, respectively. Not all of these bolt holes need to be used by every box opener/loader, but all six threaded holes must be present on the tool. Note that the middle pair of threaded holes is in the seal zone, and so it may be covered up by some gaskets (which are not specified here).

5.6 *Reserved Spaces* — Inside the tool from the BOLTS plane are volumes reserved for the box opener/loader into which tool and its wafer handler may not protrude. A permanent reserved space is bounded by *x*70, *y*74, *z*70, and *z*80. When the door is closed, there is an additional temporary reserved space bounded by *x*70, *y*72, and *z*81. When the door is being opened or closed by the box opener/loader, there is a further temporary reserved space bounded by *x*70, *y*74, and *z*81. When the door is fully open, it will be withdrawn into the permanent reserved space, and the tool wafer handler may extend into the box to extract or insert wafers.

5.7 *Exclusion Volume* — Outside the tool from the BOLTS plane is a volume reserved for the box opener/loader into which the exterior of the tool may not protrude. This exclusion volume is bounded by *x*74, *z*79, and the floor. Within these boundaries and outside of the seal zone, no part of the tool may protrude closer to the facial datum plane than the closest point of the seal zone. Also, it is recommended that no part of the tool should overhang the box opener/loader, even above *z*79. Note that *x*74 has been chosen to allow the minimum width between adjacent load ports defined in SEMI E15.1.

5.8 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*75 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*76 to prevent small contact patches with large stresses that might cause wear and particles. Note that these limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded-off too much. The lower bound on the radius is up to the tool supplier. Note also that this radius applies to every required feature unless another radius is called out specifically.

Table 1 Dimensions for Box Opener/Loader to Tool Standard (BOLTS) Interface

Symbol	*Value Specified*	*Datum Measured from*	*Feature Measured to*
σ	0 ± 0.1°	facial and horizontal datum planes	perpendicularity of seal zone
*r*75	1 mm (0.04 in.) maximum	not applicable	all concave features (radius)
*r*76	2 mm (0.08 in.) maximum	not applicable	all required convex features (radius)
*x*70	207 mm (8.15 in.) minimum	bilateral datum plane	encroachment of tool on the sides of the reserved spaces inside the tool
*x*71	208 ± 1 mm (8.19 ± 0.04 in.)	bilateral datum plane	edge of hole opening and inside edge of seal zone
*x*72	236 mm (9.29 in.) minimum	bilateral datum plane	outside edge of seal zone
*x*73	215 ± 0.1 mm (8.465 ± 0.004 in.)	bilateral datum plane	center of threaded holes
*x*74	237.5 mm (9.35 in.) minimum	bilateral datum plane	encroachment of tool on the sides of the box opener/loader outside of the BOLTS plane
*y*70	173 ± 3 mm (6.8 ± 0.1 in.)	facial datum plane (when carrier is docked)	BOLTS plane (including seal zone and boundaries of equipment exclusion zones) installation tolerance
*y*71	± 1 mm (± 0.04 in.) flatness over seal zone	facial datum plane (when carrier is docked)	surface of seal zone
*y*72	57 mm (2.24 in.) minimum	facial datum plane (when carrier is docked)	encroachment of tool on the reserved space inside the tool when the door is closed
*y*73	40 mm (1.57 in.) minimum	facial datum plane (when carrier is docked)	depth of threaded holes
*y*74	100 mm (3.94 in.) minimum	facial datum plane (when carrier is docked)	encroachment of tool on the permanent reserved space and on the reserved space when the door is opening or closing
*y*75	± 0.5 mm (± 0.02 in.)	not applicable	the docked facial datum plane of the box opener/loader
*y*76	70 +2 –0 mm (2.76 +0.07 –0 in.)	facial datum plane when the carrier is undocked	facial datum plane when the carrier is docked
*z*70	20 mm (0.79 in.) maximum	horizontal datum plane	encroachment of tool on the top of the permanent reserved space inside the tool
*z*71	794 ± 1 mm (31.26 ± 0.04 in.)	horizontal datum plane	bottom edge of hole opening and inside edge of seal zone
*z*72	822 mm (32.36 in.) minimum	horizontal datum plane	outside edge of seal zone on bottom
*z*73	832 ± 0.1 mm (32.756 ± 0.004 in.)	horizontal datum plane	center of bottom threaded holes
*z*75	150.25 ± 0.1 mm (5.915 ± 0.004 in.)	horizontal datum plane	center of middle threaded holes
*z*76	395 ± 1 mm (15.55 ± 0.04 in.)	horizontal datum plane	top edge of hole opening and inside edge of seal zone
*z*77	423 mm (16.65 in.) minimum	horizontal datum plane	outside edge of seal zone on top
*z*78	455.5 ± 0.1 mm (17.933 ± 0.004 in.)	horizontal datum plane	center of top threaded holes
*z*79	486 mm (19.13 in.) minimum	horizontal datum plane	encroachment of tool on the top of the box opener/loader between the BOLTS plane and the load face plane
*z*80	793 mm (31.22 in.) minimum	horizontal datum plane	encroachment of tool on the bottom of the permanent reserved space inside the tool
*z*81	394 mm (15.51 in.) minimum	horizontal datum plane	encroachment of tool on the top of the reserved space inside the tool when the door is closed or is opening or closing

R1-1 Unless otherwise stated, perpendicularity and parallelism are implicitly defined in the geometric tolerances.

SEMI E64-0600
SPECIFICATION FOR 300 mm CART TO SEMI E15.1 DOCKING INTERFACE PORT

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on April 10, 2000. Initially available at www.semi.org April 2000; to be published June 2000. Originally published in 1997; previously published June 1998.

1 Purpose

1.1 This specification defines a standard location on SEMI E15.1-compliant tools and requirements to be used for installing a docking interface for carrier transport carts. It is intended to promote a consistent interface location between carrier transport carts and SEMI E15.1-compliant wafer process or inspection equipment.

2 Scope

2.1 This standard covers 300 mm SEMI E15.1-compliant tools only. Similar requirements for other tools are not defined here.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not define interface functionality, lead-in, accuracy, carrier transfer, compliance, impact, or vibration restrictions. Cart and docking interface designs should comprehend physical limitations of tools to which they are being applied.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Specification for 300 mm Tool Load Port

SEMI E23 — Specification for Cassette Transfer Parallel I/O Interface

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *automatic docking* — Contact motion is controlled or limited by the design of the cart or interface.

5.2 *carrier* — Any cassette, box, pod, or boat that contains wafers (per SEMI E15).

5.3 *cart* — A floor-based carrier transfer vehicle.

5.4 *docking* — The act of locating a floor-based carrier transport vehicle for carrier transfer to/from equipment.

5.5 *load face plane* — The furthest physical vertical boundary plane from carrier centroid on the side(s) of the equipment where loading of the tool is intended (per SEMI E15).

5.6 *load port* — The interface location on a tool where carriers are placed to allow the tool to process wafers (per SEMI E15).

5.7 *manual docking* — Contact motion controlled by the operator of the cart.

5.8 *transfer* — To either load or unload (per SEMI E15).

6 Requirements

6.1 The following exclusion volume is reserved on SEMI E15.1-compliant tools for the installation of a docking interface device. This volume is referred to as Zone L.

6.1.1 *Interface Zone L* — A volume, just above floor level, reserved in SEMI E15.1 for installation of a contact docking device.

6.1.1.1 The vertical bounds of Zone L are defined by the floor from which Dimension H is measured in SEMI E15.1 and the Height L_h, per Table 1.

6.1.1.2 The depth of Zone L into the tool is L_d, measured from the load face plane as defined in SEMI E15.1.

6.1.1.3 The width of Zone L, L_w, is the full width of the tool measured at the load face plane.

6.1.1.4 A device mounted in Zone L is to be physically isolated from the tool and should be mounted such that the tool and tool load port are protected from the impact incurred during docking.

6.1.1.5 Since docking devices must be mounted on the floor in Zone L, the equipment must not require the use of support pedestals or other support structures under the floor below Zone L.

Table 1 Dimensional Requirements for Docking Zone L

Dimension	*Value, mm (in.)*
Zone L depth, L_d	100 (3.9)

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E64 but was approved for publication by full letter ballot procedures.

R1-1 The intent of this standard is (1) To provide manually guided 300 mm carrier transport carts a standard location for docking to process and other tools; and (2) To facilitate development of a rapid repeatable cart to load port carrier transfer method or mechanism. Standardization of the size and location will allow for a modularity of the docking interface while minimizing limits on functionality of the interface.

R1-2 Zone L is defined as an exclusion zone in tools that comply with SEMI E15.1. It is intended that the tool side of a “cart/tool” docking interface be mounted in this zone.

R1-3 The docking interface (cart or tool side) may include all or some of the following features/functionality:

- Stopping cart motion,
- Dampening impact of docking,
- Compliance, Lead-in guidance for cart,
- Alignment of cart to docking interface, and
- Securely locking position of cart during carrier transfer.

R1-4 It is likely that the alignment error and tolerance stack-up between a device in Zone L and the tool port will not provide sufficient accuracy alone for accurate pick/placement of a carrier onto the kinematic couplings on the load port.

R1-5 Possible sources of alignment errors are

- Cleanroom floor height and level,
- Cart wheels and framework,
- Installation accuracy of device in Zone L, and
- Stability of mounting (floor changes).

R1-6 It may be necessary to use additional alignment methods to improve accuracy of carrier placement onto the kinematic couplings.

R1-7 It is expected that the interface device will be floor-mounted. SEMI E64 allows for automatic docking but does not specify the means or interfaces required. Cart/interface designers may find it advantageous to add registration features to the tool or load port which facilitate automatic docking and/or carrier transfer.

NOTE R1: Exclusion Zone L partially overlaps the installation space for the photo-coupled interface in SEMI E23. Compliance with both standards is possible. Suppliers should be aware of both standards and design accordingly.

R1-8 Compatibility with SEMI E23 can be maintained by reserving the area just above Zone L for installation of the photo-coupled I/O interface specified in SEMI E23 as shown in Figure R1-1.

R1-9 Zone L should remain clear of any physical obstructions to allow for installation of docking interface devices. End users may require other features that occupy this space, but should be aware that this could limit cart to tool docking solutions.

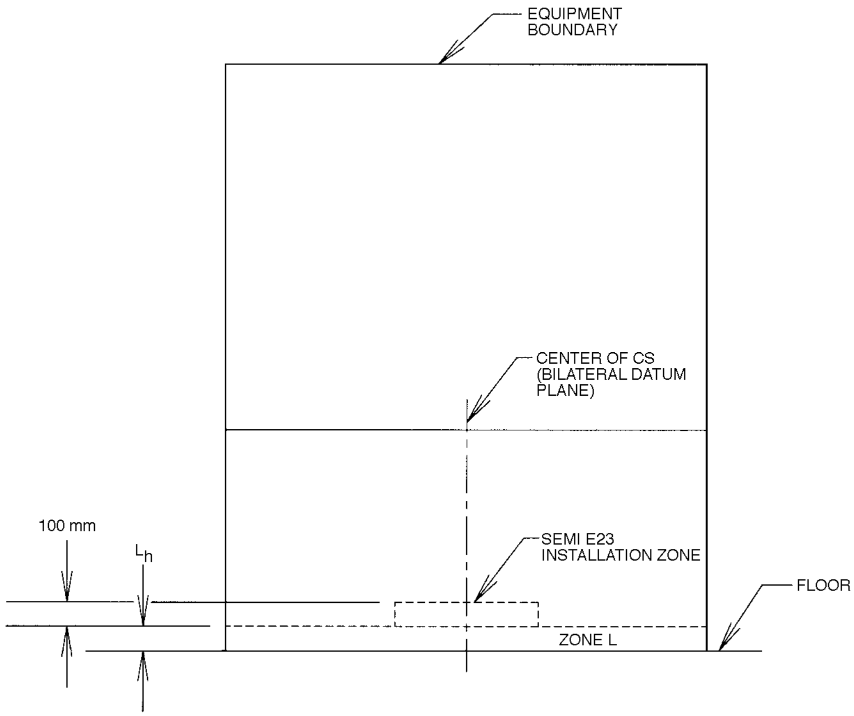

Figure R1-1
Front Elevation View

R1-10 Note that an installed docking interface may cause a potential trip hazard as shown in Figure R1-2. Equipment suppliers and/or docking interface suppliers may be required to eliminate the potential of this hazard (e.g., by adding covers or shields).

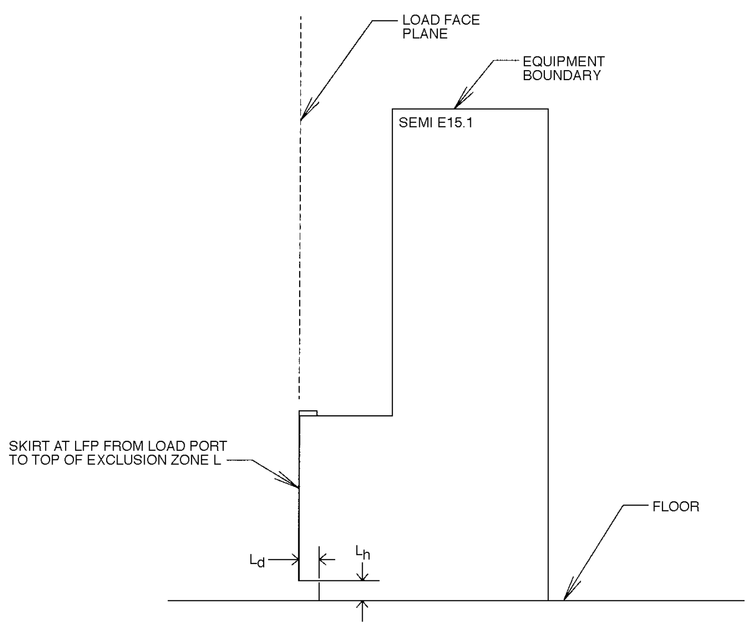

Figure R1-2
Side Elevation View

NOTICE: SEMI makes no warranties or representations as to the suitability of the specification set forth herein for any particular application. The determination of the suitability of the specification is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These specifications are subject to change without notice.

The user's attention is called to the possibility that compliance with this specification may require use of copyrighted material or of an invention covered by patent rights. By publication of this specification, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E66-0997
TEST METHOD FOR DETERMINING PARTICLE CONTRIBUTION BY MASS FLOW CONTROLLERS

1 Purpose

1.1 The purpose of this test is to measure particle contribution by mass flow controllers (MFCs) in high-purity gas systems.

2 Scope

2.1 This document describes a test method that yields statistically significant comparisons of particle contribution among mass flow controllers under test conditions.

3 Limitations

3.1 This document is not intended as a method for monitoring in situ particulate performance once a particular MFC has been tested.

3.2 The test medium is limited to nitrogen. Actual performance under normal operating conditions may differ.

3.3 The accuracy of the data generated by this method is limited to the accuracy of the particle measuring instruments used.

3.4 This test method is intended for use by operators who understand the use of the apparatus at a level equivalent to one year of experience.

3.5 This test method should not be expected to yield comparable results from one test set up to another, due to the limitations of current particle counting technology.

3.6 Results may be compromised by the methods used to construct the apparatus.

5.1.17 *slpm* — standard liters per minute

5.1.18 *SPC* — statistical process control

5.2 *Definitions*

5.2.1 *background counts* — Counts contributed by the test apparatus (including counter electrical noise) with the spool piece in place of the test object.

5.2.2 *condensation nucleus counter (CNC)* — A light scattering instrument that detects particles in a gaseous stream by condensing supersaturated vapor on the particles.

5.2.3 *dynamic control mode test* — A test performed to determine particle contribution as a result of test flow

1 Naval Publications and Forms Center, 5801 Tabor Avenue Philadelphia, PA 19120

2 American National Standards Institute, 1430 Broadway, New York, NY 10018

variation within the normal range of MFC operation (i.e., 0 to 100% flow).

5.2.4 *impact or vibration test* — A test performed to determine particle contribution as a result of test flow variation within the normal range of MFC operation (i.e., 10 to 100% flow).

5.2.5 *normal statistical distribution* — Measurements that randomly fall about an average, within a range of ± 3 standard deviations.

5.2.6 *observation* — A 10-minute sample/data collection period.

5.2.7 *purge mode* — Control valve fully open.

5.2.8 *sample flow* — The volumetric flow drawn by the counter for particle detection.

5.2.9 *sampling time* — The time increment over which counts are recorded.

5.2.10 *spool piece* — A null component consisting of a straight piece of electropolished tubing and appropriate fittings used in place of the test component to establish the background.

5.2.11 *stable particle level* — Particle level that has been consistent, as described in Appendix 1, for at least eight consecutive readings.

5.2.12 *standard reference conditions* — 101.32 kPa, 0.0_C (14.7 psia, 32_F) (see SEMI E29)

5.2.13 *statistical process control* — A method used by this standard for analyzing experimental data that follows a normal statistical distribution to determine if the test is stable.

5.2.14 *steady state control mode test* — A test performed to determine particle contribution during steady state test flow within the normal operating range of the MFC (i.e., 10 to 100% full scale).

5.2.15 *supply pressure* — Pressure immediately upstream of filter F1. (See Figures 1 and 2.)

5.2.16 *test flow* — Mass flow through the device under test.

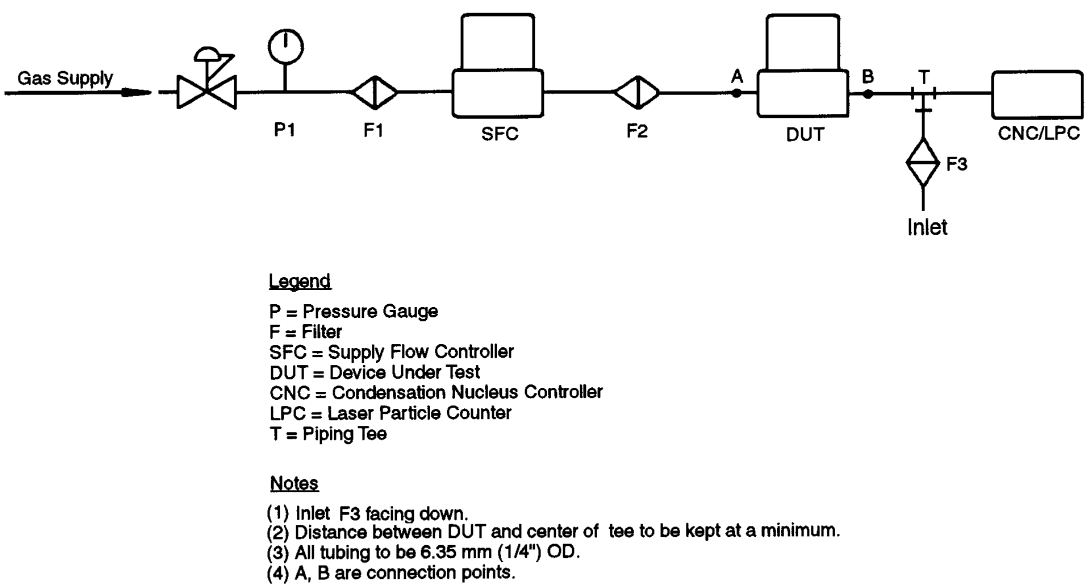

Figure 1
Test Set-Up when Test Flow < Sample Flow

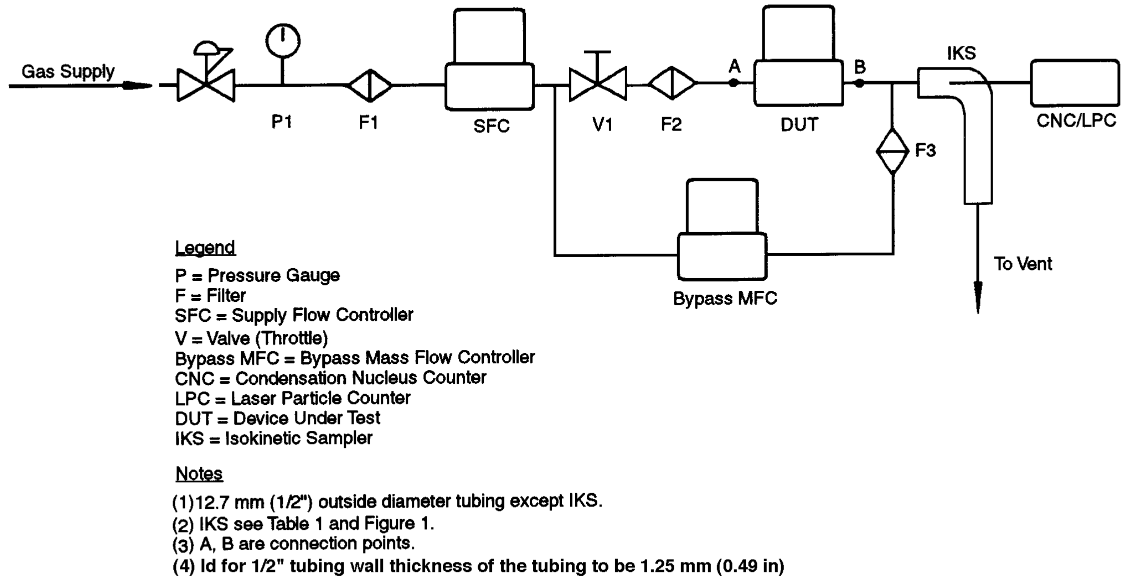

Figure 2
Test Set-Up when Test Flow > Sample Flow

6 Summary of Test Method

6.1 Background count is determined for steady state control, dynamic control, and impact tests. The steady state control mode test, dynamic control mode test, and impact test are run by counting particles for the time necessary to achieve a stable particle level. Background testing is performed again.

7 Significance and Use

7.1 The significance of this test method is that it defines a procedure for testing mass flow controllers intended for installation into a high-purity gas system. It is intended for use by manufacturers and end users.

8 Apparatus

8.1 *Test Gas* — Nitrogen of minimum dryness, with -40°-C (-40_°F) dew point at 790.57 kPa (100 psig) and with < 10 ppm of total hydrocarbons.

8.2 *Membrane Filters* — To provide filtered test gas, nine-log retentive to larger than 0.01 mm particles, with a pressure drop of less than 7.91 kPa (1 psid) at 283,170 sccm (10 scfm) for a 790.57 kPa (100 psig) inlet, and capable of achieving less than one particle[3] 0.01 mm per cubic foot of test gas under test conditions.

8.3 *Pressure Regulator* — Made of electropolished 316L stainless steel, with an internal surface finish of 0.18 mm (7 µin.) R_a and 0.25 mm (10 µin.) Rmax, to maintain system test pressure.

8.4 *Pressure Gauge or Transducer* — Made of electropolished 316L stainless steel, with an internal surface finish of 0.18 mm (7 µin.) R_a and 0.25 mm (10 µin.) Rmax, to monitor system test pressure.

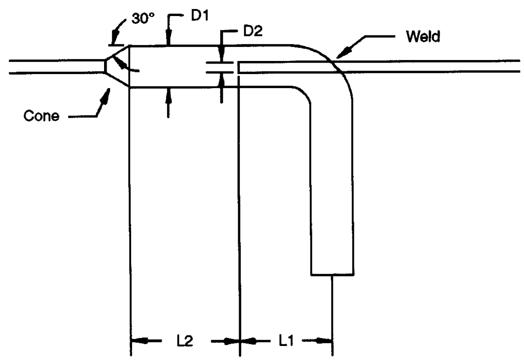
8.5 *Throttle Valve* — Made of electropolished 316L stainless steel, with an internal surface finish of 0.18 mm (7 µin.) R_a and 0.25 mm (10 µin.) Rmax, to proportion flow in test system.

8.6 *Tubing* — Made of electropolished 316L stainless steel, with an internal surface finish of 0.18 mm (7 µin.) Ra and 0.25 mm (10 µin.) Rmax.

8.7 *Supply Flow Controller (SFC)* — Metal-sealed, used to establish a flow rate through the spool piece in the absence of the DUT, with a settling time less than or equal to that of the DUT. More than one range SFC may be required to run all the tests.

8.8 *Sampler* — Constructed according to the drawing and design parameters shown in Figure 3 and Table 1, to collect gas from the stream exiting the test device, where the sample is near-isokinetic in design.

8.9 *Upstream Adapter* — To connect 12.7 mm (1/.2 in.) tubing to the test device. For 12.7 mm (1/.2 in.) test devices, the adapter is a simple face-seal connector. For 6.35 mm (1/4 in.) test devices, the adapter is a tapered cone between 6.35 mm and 12.7 mm (1/4 in. and 1/2 in.) face-seal connections.



D1 = Sampler Diameter
D2 = Probe Diameter
L1 = Length of Sampling Tube (minimum 15 x D1)
L2 = Length of Straight Section (minimum 15 x D1)

Notes

1. Transition cone to be 30°.
2. Material: Electropolished 316L, (0.25 mm) Ra, (0.375 mm) Rmax.
3. The volume of tubing downstream of the 90 degrees bend in the IKS must be large enough to contain the volume of gas drawn by the CNC/LPC when a DUT with a full scale equal to the IKS maximum is at 10% command to prevent ambient air from being sampled.

Figure 3
Isokinetic Sampler Design

Table 1

Maximum IKS Inlet Flow (liters/min.)	*ID Probe D_2 (note)mm (inches)*	*ID Sampler D_1 - mm (inches)*	*Worst-Case Dilution*
300	4.62 (0.180)	68.58 (2.700)	3:1
100	4.62 (0.180)	39.62 (1.560)	3:1
30	4.62 (0.180)	21.44 (0.844)	3:1
10	4.62 (0.180)	11.99 (0.472)	3:1
3	7.75 (0.305)	12.57 (0.495)	2:1

NOTE: For 300,000 to 10,000 cc/min. test flow:

- Constant sample velocity = 132 cm/sec.
- D2 = 4.57 mm (0.180 in.) ID standard 6.35 mm (1/4 in.) tubing (see Figure 3)
- For 1.41 l/min. CNC

NOTE: For 3,000 cc/min. test flow:

- Constant sample velocity = 49.9 cm/sec.
- D_2 = 7.75 mm (0.305 in.) ID standard 9.53 mm (3/8 in.) tubing (see Figure 3)
- For 1.41 l/min. CNC

8.10 *Downstream Adapter* — To connect 12.7 mm (1/2 in.) sampler tubing to the test device. For 12.7 mm (1/2 in.) test devices, the adapter is a simple face-seal connector. For 6.35 mm (1/4 in.) test devices, the adapter is a tapered cone between 6.35 mm and 12.7 mm (1/4 in. and 1/2 in.) face-seal connections.

8.11 *Spool Pieces* — Of the same inside diameter as the inside diameter fittings on the test piece and of a length representative of the DUT, to be installed in the system in place of the test device while obtaining background counts for the system.

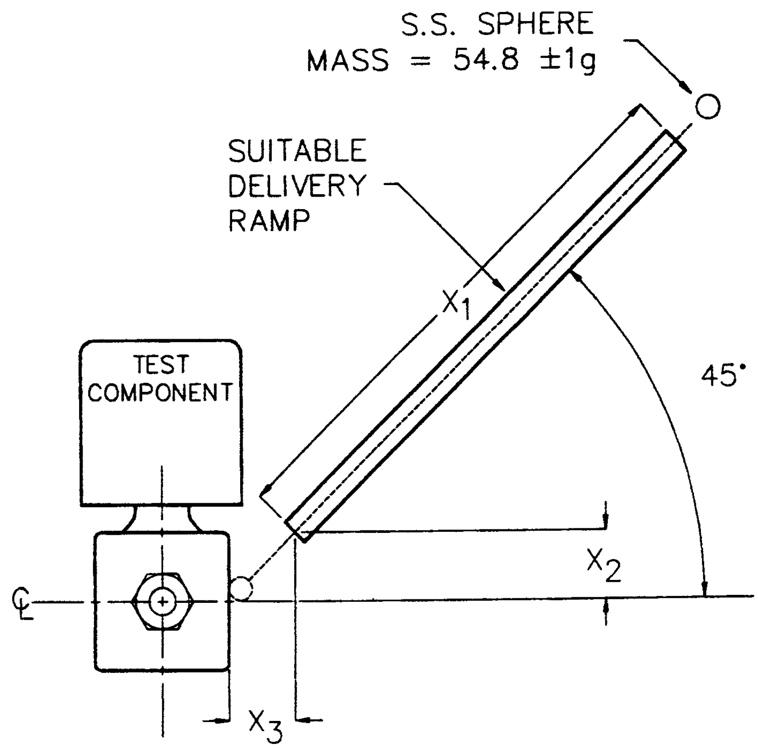
8.12 *Fittings* — Face seal connectors or compression fittings, depending on test component end connections. The end connection fittings of each DUT being compared must be of the same type.

8.13 *Metal Gaskets* — New gaskets should be used for each new connection.

8.14 *Mechanical Shock Device* — To provide mechanical shock by impact to the test device. (See Figure 4.)

8.15 *Instrumentation* — Condensation nucleus counter (CNC) or laser particle counter (LPC) to collect particle count data.

8.16 *Isokinetic Sampler (IKS)* — A static device used to collect a representative sample that is not influenced by flow characteristics and/or particle size (see Figure 3). Other designs of isokinetic samplers are permitted as long as they collect a representative sample of the flow.



NOTE: X_3 WILL CHANGE WITH A CHANGE IN SPHERE SIZE.
X_1 = 30.5cm ±0.5cm
X_2 = 0cm OR VERY CLOSE TO IT(DUE TO ANGLE AND BALL SIZE)
X_3 = 2.4cm ±0.1cm(DIA OF THE SS SPHERE)

Figure 4
Mechanical Shock Test Device

NOTE: Position the delivery ramp so that the position of impact is at the midpoint of the axial centerline of the device under test.

9 Sampling, Test Specimens, and Test Units

9.1 MFCs regulate flows greater than or less than the flow requirements of particle counters; therefore, two different sampling techniques have been defined, isokinetic sampling and direct sampling.

9.1.1 *Direct Sampling* — The direct sampling method is used when the test flow is less than or equal to the sample flow. (See Figure 1.)

9.1.1.1 In this case, gas exiting the DUT is introduced directly into the CNC. A tee, equipped with a filtered branch, is inserted between the DUT and the CNC to provide make-up flow to the CNC. The volume and overall length of the tubing connecting the DUT to the tee assembly should be minimized.

9.1.2 *Isokinetic Sampling* — Isokinetic sampling is used when the test flow is greater than the sample flow. (See Figure 2.)

NOTE 1: An alternative size IKS may be substituted for the IKS described in Sections 9.2.1 through 9.2.8 as long as it collects a representative sample of particles that is not influenced by flow characteristics and/or particle size.

9.1.2.1 Select the appropriate IKS (see Figure 3) from Table 1 for the test flow. This is the smallest IKS that exceeds the flow of the DUT.

9.1.2.2 The average velocity of the gas through the sampling probe shall approximate the average velocity in the tubing in which the sampling probe is inserted. The sample flow used to calculate the sampling probe diameter is the total flow drawn by the counter.

9.1.2.3 The tip of the sampling probe is to have a 30_ taper on the outside diameter.

9.1.2.4 The pick-off point is to be centered within the flow stream.

9.1.2.5 The pick-off point is to be at a minimum distance of 15 diameters of the primary flow tube upstream or downstream from any connection.

9.1.2.6 Flow stability within the isokinetic sampler is maintained by the bypass MFC.

9.1.2.7 To determine the dimensions of the isokinetic sampler, as shown in Table 1, the following equations and conditions are used:

10 Preparation of Apparatus

10.1 *Setup and Schematic for Direct Sampling* — See Figure 1.

10.1.1 Install the spool piece between points A and B.

10.1.2 Set nominal supply pressure to 308.10 kPa (30 psig).

10.1.3 Cycle the supply MFC, switching between a low flow and maximum purge flow as quickly as is reasonably possible. Cycle every five seconds for at least 30 minutes. The maximum purge flow should be as high as possible and no less than twice the test rate. During this initial cleanup, the particle counter should be off-line.

10.1.4 Moisture from an inboard leak can cause particle counts on some particle counters. Test the system for leak integrity per SEMI F1 – Subsystems Inboard Leak Test.

10.2 *Setup and Schematic for Isokinetic Sampling* — See Figure 2.

10.2.1 Install the spool piece between points A and B.

10.2.2 Set nominal supply pressure to 308.10 kPa (30 psig).

10.2.3 Cycle the supply MFC, switching between a low flow and maximum purge flow as quickly as is reasonably possible. Cycle every five seconds for at least 30 minutes. The maximum purge flow should be as high as possible and no less than twice the test rate. During this initial cleanup, the particle counter should be off-line.

10.2.4 Moisture from an inboard leak can cause particle counts on some particle counters. Test the system for leak integrity per SEMI F1 – Subsystems Inboard Leak Test.

10.3 Select the appropriate isokinetic sampler based on the maximum test flow of the DUT, using Table 1 and Figure 3. The size of the sampler should be equal to or greater than the maximum test flow.

11 Calibration and Reference Standards

11.1 Calibrate instruments regularly according to the manufacturer's recommendations.

12 Test Procedure

The test apparatus is to be enclosed in a Class 100 environment (in accordance with FED-STD 209). Test must be performed in the sequence described below. (See Figures 5 and 6.)

Measure DUT in purge mode to determine flow or use the value supplied by the manufacturer. This will determine which apparatus to use, direct sampling (Figure 1) or IKS (Figure 2). Both of the test apparatus may be required for testing a wide range of flow controllers.

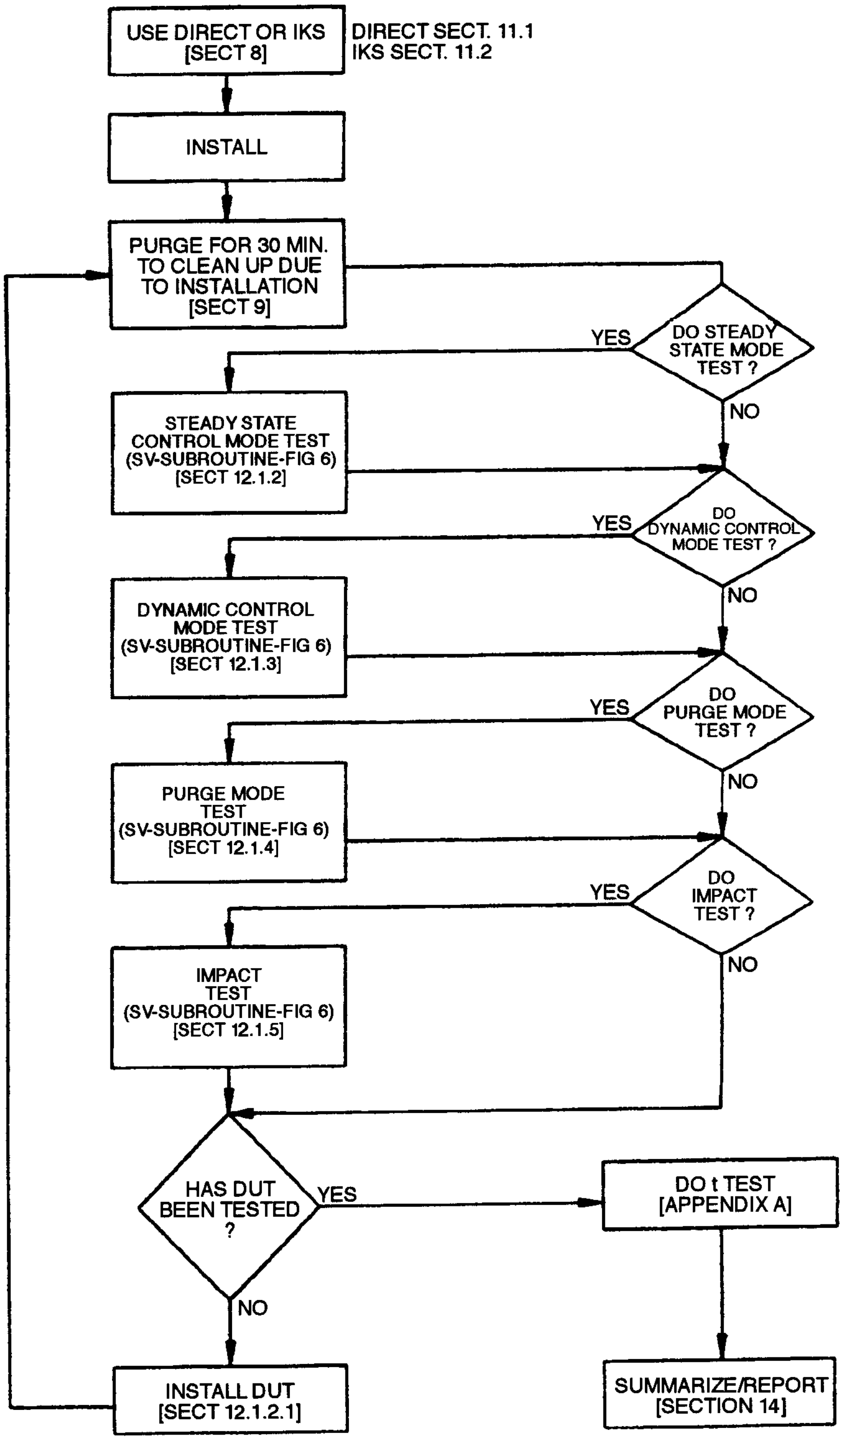


Figure 5
Particle Test Flow Chart

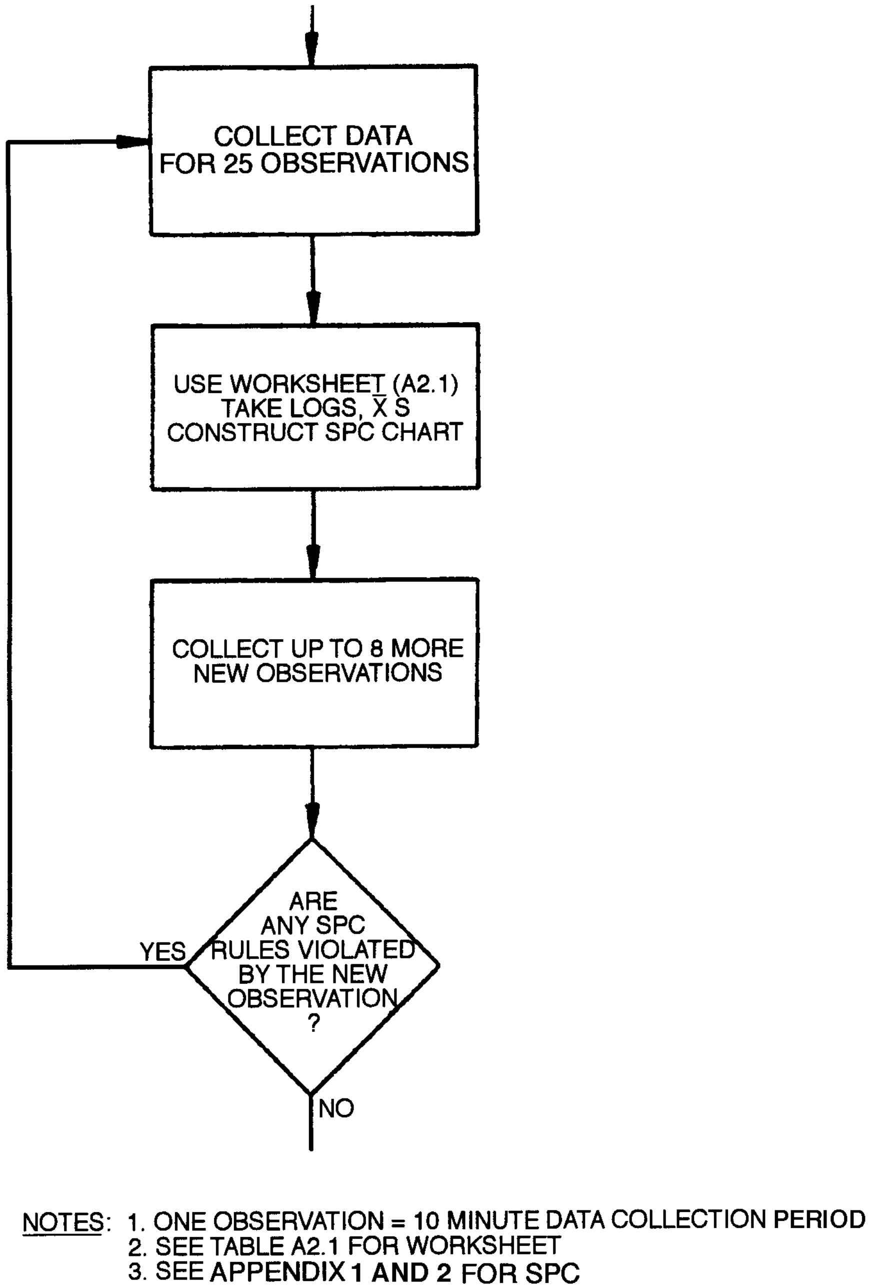

Figure 6
Statistical Validity Subroutine

12.1 *Procedure for Direct Sampling* — See Figures 5 and 6.

12.1.1 *Background Count Determination* — Insert spool piece between points A and B (see Figure 1).

12.1.2 *Steady State Control Mode Background Test* — Set supply MFC (SFC) to the intended test flow value of the DUT. For this test, the 100% full scale value is recommended.

12.1.2.1 Count particles for the time necessary to achieve a stable particle level.

12.1.3 *Dynamic Control Mode Background Test* — Cycle the SFC from 10% to 100% of the DUT's rated flow. The cycle period is equal to two times the settling time of the DUT with the longest settling time. (This will ensure that all MFCs in a given test are tested at the same cycle time.)

12.1.3.1 Count particles for the time necessary to achieve a stable particle level.

12.1.4 *Purge Mode Background Test* — Set the SFC to 100% of the rated flow of the DUT.

12.1.4.1 Count particles for the time necessary to achieve a stable particle level.

12.1.5 *Impact Background Test (optional)* — Set the SFC to the intended flow value of the DUT. For this test, the 100% full scale (FS) value is recommended.

12.1.5.1 Maintain the test flow in the spool piece to achieve a constant particle level. Strike the spool piece once a minute (using the mechanical shock device) until a constant particle level is achieved. (See Figure 4.)

12.1.5.2 Count particles for the time necessary to achieve a stable particle level.

12.1.6 *Steady State Control Mode Test* — Set SFC to 10% setpoint of the DUT's rated flow.

12.1.6.1 Remove the spool piece by disconnecting the downstream fitting and then the upstream fitting. Immediately install the test component in a fully open position by connecting the upstream fitting and then the downstream fitting. Take extreme care to minimize contamination of the test apparatus during this operation.

12.1.6.2 Set the SFC in purge mode (emulates tubing).

12.1.6.3 Set the DUT to the desired flow. For this test, the 100% full scale value is recommended.

12.1.6.4 Count particles for the time necessary to achieve a stable particle level.

12.1.7 *Dynamic Control Mode Test* — Keep the SFC in purge mode (emulates tubing).

12.1.7.1 Cycle the DUT from 10% to 100% of the DUT's rated flow. The cycle period is equal to two times the settling time of the DUT with the longest settling time. (This will ensure that all MFCs in a given test are tested at the same cycle time.)

12.1.7.2 Count particles for the time necessary to achieve a stable particle level.

12.1.8 *Purge Mode Test* — Set SFC to 100% of the DUT's rated flow.

12.1.8.1 Operate DUT in the purge mode until a stable particle level is achieved.

12.1.9 *Impact Test (optional)* — This test is to immediately follow the purge mode test.

12.1.9.1 Keep the SFC set to 100% of the DUT's rate flow.

12.1.9.2 Operate the DUT in the purge mode until a stable particle level is achieved.

12.1.9.3 Strike the DUT once a minute until consistent particle transients are achieved using the mechanical shock device. (See Figure 4.)

12.1.10 *Background Test* — Repeat all background tests performed in Section 12.1.1.

12.1.10.1 *Procedure for Isokinetic Sampling* — Follow the procedures described in Section 12.1, with the following exceptions:

12.1.10.2 To establish the background, see Figure 2 and the example below. With the spool piece in place, the throttle valve V1 fully open, and the bypass MFC in purge mode, set the SFC to the maximum inlet flow of the IKS. Adjust V1 and monitor the flow through the bypass MFC until the difference between the SFC flow and the bypass MFC flow is equal to the intended test flow of the DUT. The throttle valve V1 should remain fully open for all other tests that use the test set-up in Figure 2.

Example	*Given Test Flow:*	*Set SFC Flow:*	*Adjust V1 for Bypass MFC Flow:*
	25 slpm	30 slpm	5 slpm
	50 slpm	100 slpm	50 slpm

12.1.10.3 During steady state and dynamic testing of the DUT, use the bypass MFC to make up the difference between the intended flow value of the DUT and the maximum inlet flow of the sampler selected from Table 1.

13 Data Analysis

13.1 Appendix 1 contains information on statistical process control charting. Appendix 2 contains information on performing the t-test, a statistical method of comparing the mean background particle count with the mean device particle count.

14 Data Presentation

14.1 The following test conditions are to be reported in the data presentation:

14.1.1 Date and time of test

14.1.2 Operator

14.1.3 Test flow rate (sccm)

14.1.4 Test pressure (kPa)

14.1.5 Ambient temperature (_C)

14.1.6 MFC orientation

14.1.7 MFC location in test bed if multiple station test set-up used.

14.1.8 Cleanroom or environment classification

14.1.9 MFC type, manufacturer, serial number, sample flow rate (sccm), model number, calibration date, and particle range

14.1.10 Test gas type and dew point (_C)

14.1.11 A schematic of the test apparatus, including manufacturers and model numbers of all test apparatus components

14.1.12 Calibration dates for the flow meters

14.2 Refer to Figure A1-2 as an example of a typical cleanup curve. Graph the static, dynamic, and impact portions of the test separately as counts/minute (measured by the counter) versus time. Include the appropriate background (measured with the spool piece in place) for each. Also graph the entire data set as counts per minute versus time. If different MFCs are to be compared, graph their entire data sets together.

14.3 Present the entire raw data set in tabular form (see Table A2-1).

15 Precision and Bias

15.1 The precision and bias of the data generated by this test method is limited to the precision and bias of the particle measuring instruments used.

16.2 *Manufacturer's Document*

Manufacturers Operating Manual — The appropriate particle counters manufacturer operating and maintenance manuals should be consulted when using this test method.

APPENDIX 1
STATISTICAL PROCESS CONTROL CHARTING

NOTE: This appendix was approved as an official part of SEMI E66 by full letter ballot procedure.

The following rules should be used to interpret the statistical process control chart, Figure A1-1:

1. If one observation is outside UCL/LCL, the process is out of control.
2. If two consecutive observations are > halfway, the process is out of control.
3. If at least eight successive points are in control, the process is stable.

It has been assumed that the data is approximately normal under log transform and that samples are independent.

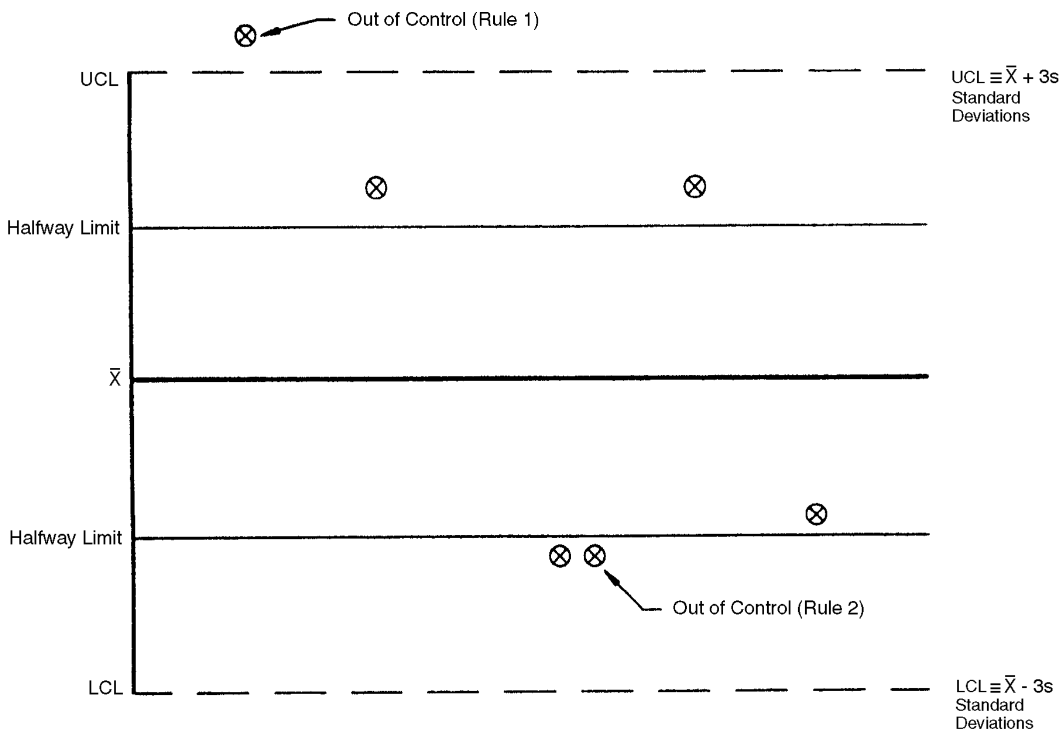

Figure A1-1
Statistical Process Control Chart

$$S = \sqrt{\frac{\sum_{1}^{n}(x_i - \bar{x})^2}{n-1}}$$

where n = # of observations

Figure A1-2 gives an overall picture of the data collection specified by Table A2-1 for both “BACKGROUND” and “DEVICE”. There are three phases of data collection:

1. Cleanup
2. Steady-state performance
3. Statistical process control (SPC)

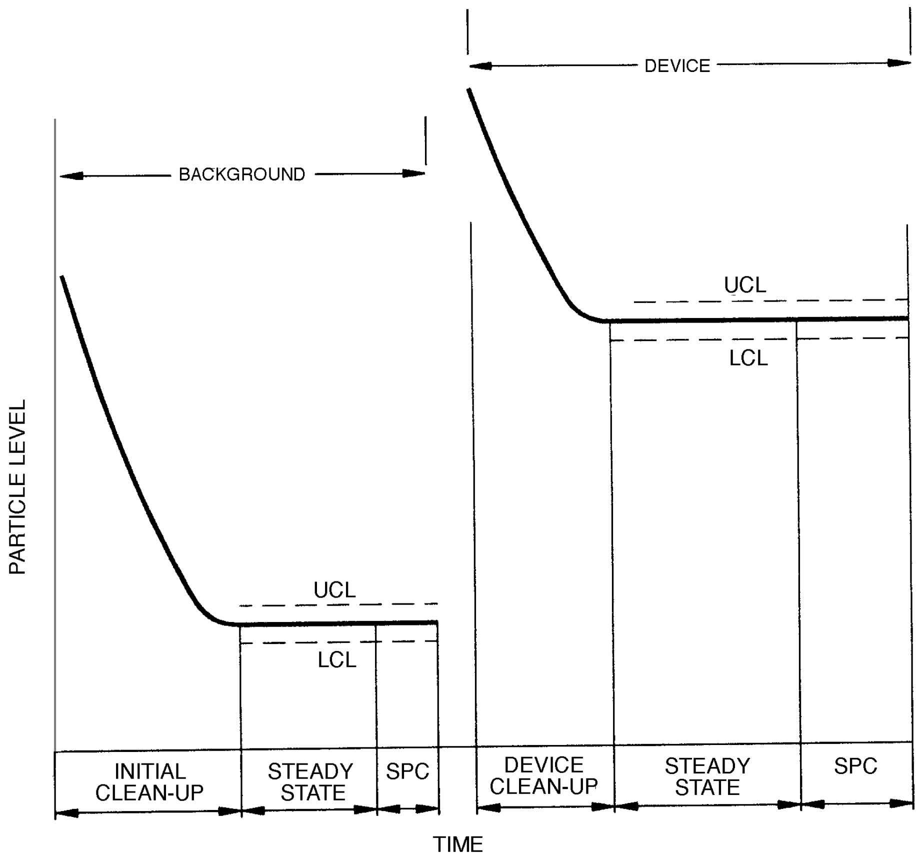

Figure A1-2
Graphical Representation of Data Collection

APPENDIX 2
t-TESTING; COMPARISON OF BACKGROUND MEAN AND DEVICE MEAN

NOTE: This appendix was approved as an official part of SEMI E66 by full letter ballot procedure.

A2-1 The background and DUT are expected to have low particle counts. Therefore, a statistical method is needed to determine if there is a difference between background and DUT particle counts. The t-test is a method of determining the actual statistical difference between the mean background particle count and the mean device particle count. It can be used to characterize the particle contribution by the MFC Record results in Table A2-1.

Table A2-1 Test Worksheet

	#	*Observation*	*log Observation*	*Remarks*
Spool Cleanup	1 ... Nx			All computations are in the logs of original observations.
Stable Level		X1 ... X25		Compute $X_{1, S1, UCL, LCL.}$
SPC		X26 ... X334		Use all 8 values to recompute new values ($X_{1,S1}$).
Connect Device				
Device Cleanup		X34 ... X35 + n		
Stable Level		X34 + n + 1 ... X34 + n + 25		Compute $X_{2, S2, UCL, LCL}$.
SPC		X34 + n + 26 ... X34 + n + 34		Use all 8 values to recompute new values ($X_{2, S2}$).

NOTE: Use t-test to compare X's. (See Appendix 2.)

A2-2 Calculate pooled standard deviation using the following equation:

$$S_{pooled} = \sqrt{\frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2}}$$

where :

S_1 = background standard deviation

S_2 = device standard deviation

n_1 = background sample size

n_2 = device sample size

A2-3 Calculate the value of T (the t-test's namesake) as follows:

$$t = \frac{\bar{X}_1 - \bar{X}_2}{S_{pooled} \cdot \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

where :

1 = background mean

2 = device mean

A2-4 The degrees of freedom (dof) is $n_1 + n_2 - 2$. For example, if $n_1 = n_2 = 8$, then dof = 14.

A2-5 Interpretation

If | t| ≥ $t_{.975}$, then the two means are significantly different at the 95% level. If | t| ≥ $t_{.995}$, then the two means are significantly different at the 99% level (e.g., by “95% confidence,” it is meant that the difference/no-difference decision based on the t-test will be correct 95% of the time).

$t_{.975}$ = 2.145 (2-sided)

$t_{.995}$ = 2.977 (2-sided)

NOTE:

- All readings are log particle counts, not particle counts.
- Since logs are used, zeros have to be replaced by positive values (e.g., 1/2).
- To determine t value for a particular confidence level and (dof), refer to any statistical reference book.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. SEMI E67-0997
TEST METHOD FOR DETERMINING RELIABILITY OF MASS FLOW CONTROLLER

1 Purpose

This document describes a method to help determine the ability of an MFC to meet the manufacturer's published specifications over its life time. The results of the test will also be useful in the comparison of MFCs.

2 Scope

This procedure applies to MFCs used in semiconductor gas systems.

3 Limitations

3.1 This procedure is to be used only in conjunction with another existing parametric test for mass flow controllers to obtain the reliability data for that particular parametric test.

3.2 New MFCs shall be used for reliability testing. An MFC that has been put through this test method may be tested for reliability again.

3.3 In addition to this procedure, the parametric test may also cycle the valve. These cycles should be ignored for determining the cumulative cycles that are described in the data table.

3.4 This test will not address root cause analysis of failures.

3.5 Read points have been selected for this test procedure so that the test will take approximately six months to complete. The read point schedule given is only a suggested schedule and if the user feels that a different read point schedule would better suit his needs, this test method can still be used to obtain reliability data.

4.3 *Other Document*

Nelson, Wayne, Applied Life Data Analysis, New York, NY Wiley, 1982 (see Annex)

5 Terminology

5.1 *Acronyms*

5.1.1 *MFC* — Mass flow controller

5.1.2 *UHP* — Ultra-high purity

5.2 *Definitions*

5.2.1 *cycle* — A repeating sequence of setpoints applied to the MFC.

5.2.2 *hard failure* — A catastrophic mechanical failure or electrical failure that results in an inoperable MFC, or a deviation from a user-defined specification that results in a condition that makes the MFC inadequate for the user's process.

5.2.3 *parametric test* — The test method that determines the data for which reliability information is sought (e.g., accuracy test or particle test, SEMASPECs or 92071226B).

5.2.4 *readpoint* — Cumulative cycles applied to the MFC.

5.2.5 *reliability* — The probability that the equipment will perform its intended function, within stated conditions, for a specified period of time.

5.2.6 *soft failure* — Failure that occurs when an MFC no longer meets the manufacturer's specification for the parameter under test.

6 Summary of Test Method

The MFC is installed in a fixture capable of applying and recording a number of flow cycles. When the

1 SEMATECH, 2706 Montopolis Drive, Austin, TX 78741

number of cycles specified in the readpoint schedule is reached, cycling is suspended, parametric tests are performed, and the cycling is resumed until either the next readpoint is reached, or the MFC experiences a hard failure. After the cycling is completed, the parametric test data is analyzed to determine the reliability of each parameter.

7 Significance and Use

7.1 This test provides an estimate of the reliability of a mass flow controller. The results of the test will also be useful in the comparison of MFCs. The data provided by this test can help end users determine the reliability of equipment that uses MFCs.

7.2 The following parameters and associated test methods should be tested with this test method to obtain reliability data:

Parameter	*Test Method*
Particle Contribution	SEMASPEC 90171226B-STD
Reproducibility & Zero Drift	SEMASPEC 90171222B-STD
Helium Leak Rate	SEMASPEC 90120391B-STD
Step Response	SEMI E17

7.3 The following modifications to the preceding parametric test methods are suggested to abbreviate the time required to complete the reliability test:

7.3.1 *SEMASPEC 90171226B-STD (Particle Contribution)* — Abbreviate this test method to perform only the dynamic control mode test. Perform Sections 11.1.1.2 and 11.1.3, and eliminate Sections 11.1.1.1, 11.1.1.3, 11.1.1.4, 11.1.2, 11.1.4, 11.1.5, and 11.1.6. Refer to Sections 3.2.1 (Background), 3.2.3 (Dynamic), and Figure 5 (Particle Test Flow Chart).

7.3.2 *SEMASPEC 90171222B-STD (Reproducibility & Zero Drift)* — Omit Sections 10.1, 10.2, 11.5.3, 11.5.5, 11.5.6, 11.6, and 11.7.

7.3.3 *SEMI F1 (Leak Integrity)* — The intent of the reliability test method is to detect the development of gross leaks in the DUT due to cycling of the DUT valve. The inboard component leak test portion of this standard should be performed.

7.3.4 *SEMI E17 (Step Response)* — No abbreviation is necessary for this test. However, perform this test with the modifications noted in the SEMATECH Guide to Provisional Test Methods for Mass Flow Controllers, SEMASPEC 92071220B-STD.

7.4 Change in the performance characteristics of the MFC, as measured by the above tests, may also be monitored and analyzed as indicative of drift.

8 Apparatus

8.1 In addition to the apparatus listed below, the user must also acquire any apparatus required to perform the parametric test for which reliability data is needed. (See documents cited in Section 7.2.)

8.1.1 power supply

8.1.2 *NIST (or equivalent recognized standards agency)* — traceable flow calibration system

8.1.3 MFC control cables, as many as required in Section 8.1.4

8.1.4 mass flow controllers for controlling test flows in addition to the DUT MFCs, as many as required for the test setup

8.1.5 cycling fixture

9 Materials

9.1 In addition to the materials listed below, the user must also acquire any materials required to perform the parametric test for which reliability data is needed. (See documents cited in Section 7.2.) Since reliability data for leak integrity is being sought, helium cannot be used during the cycling procedure.

9.1.1 source of nitrogen (99.999%)

10 Sampling, Test Specimens, and Test Units

Three MFCs are required for meaningful data analysis. However, 20 to 30 MFCs are a recommended minimum. A larger sample size provides a more precise estimate of reliability.

11 Preparation of Apparatus

The setup for the parameter under test is described in the document for that particular parameter (see Section 7.2).

12 Calibration and Reference Standards

Any required instrument calibration or use of reference standards must be done in accordance with the particular parametric test for which reliability data is needed.

13 Conditioning

Conditioning requirements are those of the particular parametric test for which reliability data is needed.

14 Procedure

14.1 Connect all MFCs under test in parallel.

14.2 Perform the parametric test before any cycling is done and note the resulting data on the data sheet (Table 1). This is the first readpoint (see Figure 1).

Table 1 Data Sheet for Reliability Testing

READPOINT (Cumulative cycles applied to the MFC)	*FAILURE TYPE — SOFT OR HARD*	*SOFT FAILURE TYPE**
0 (baseline)		
10,000		
40,000		
100,000		
200,000		
300,000		
450,000		
600,000		
750,000		
875,000		
1,000,000		

*Use the following soft failure types:

A = Accuracy/Repeatability

P = Particles

S = Step Response

L = Leakage

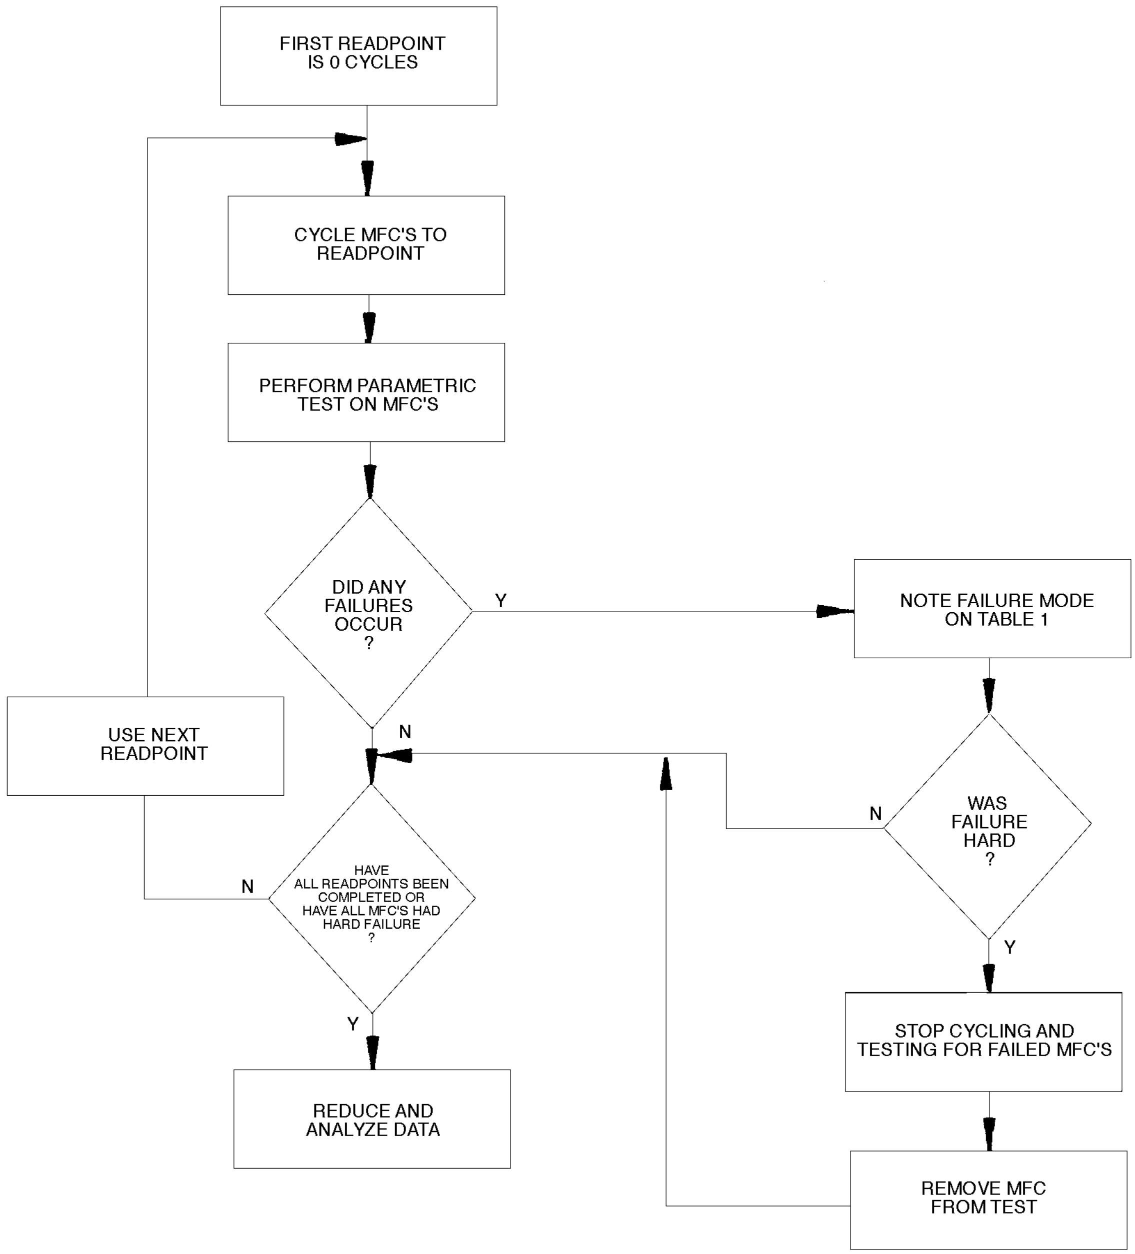

Figure 1
Flowchart for Reliability Test Procedure

NOTE: Do not count the cycles that occur during the parametric test.

14.3 Cycle the MFCs to the next readpoint in Table 1. Two types of cycles are applied to the MFC to simulate more realistically the MFC's field environment. Alternate between the two types of cycles as illustrated in Figure 2. Maintain each setpoint for a fixed period of time. Use one of the following times based upon the settling time of the slowest DUT. If the settling time is less than or equal to 1.25 seconds, use a time period of 2.5 seconds. If the settling time is less than or equal to 2.5 seconds and greater than 1.25 seconds, use a time period of 5 seconds. If the settling time is greater than 2.5 seconds, use a time period of twice the settling time.

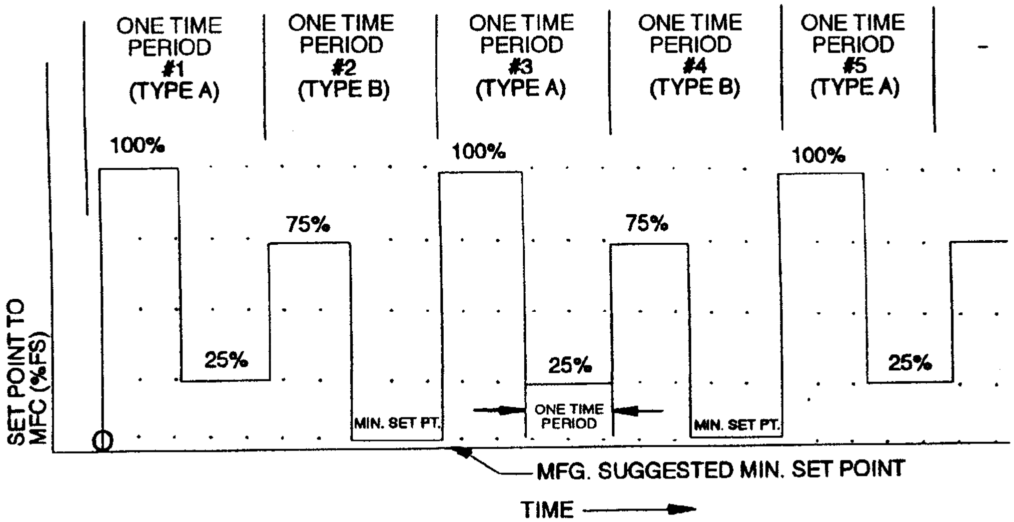

Figure 2
Types of Cycles

14.4 Discontinue cycling. Perform the parametric tests on all MFCs and record the results on the data sheet. If any MFC experiences a soft failure, record the data but do not stop the cycling procedure. However, if an MFC experiences a hard failure, record the data, discontinue testing this MFC, and take appropriate action to maintain system integrity.

NOTE: The test does not require mention of the cause for hard failure, as it is beyond the scope of this document.

14.5 The parametric tests should be performed in the following order: particle, accuracy, response, and leak.

14.6 Perform all of the parametric tests on a single MFC before proceeding to the next one. Record the order of the MFCs tested and the time since the test stand was idled.

14.7 If the readpoint is reached during a time when it is not possible to start the parametric testing, continue cycling until it is possible to begin. Record the number of cycles that occurred before beginning testing.

14.8 Average the particle count information over a 10-minute interval. Count particles for six 10-minute intervals. Record the data from only the last three 10-minute intervals.

14.9 Repeat steps 14.4 through 14.8 until all the readpoints have been completed or until all MFCs have experienced hard failures.

15 Data Analysis

15.1 *Calculations* — See Appendix 1 for a discussion on reliability calculation.

15.2 *Interpretation of Results* — The readpoints included in Table 1 are approximately equidistant on a log scale, and as data is collected, the number of readpoints needed to show trends and estimate life will decrease significantly.

16 Data Presentation

16.1 Plot each performance measure over number of cycles to look for trends and shifts as a function of use (see Figure 3). This gives a picture of dynamic performance vs. use.

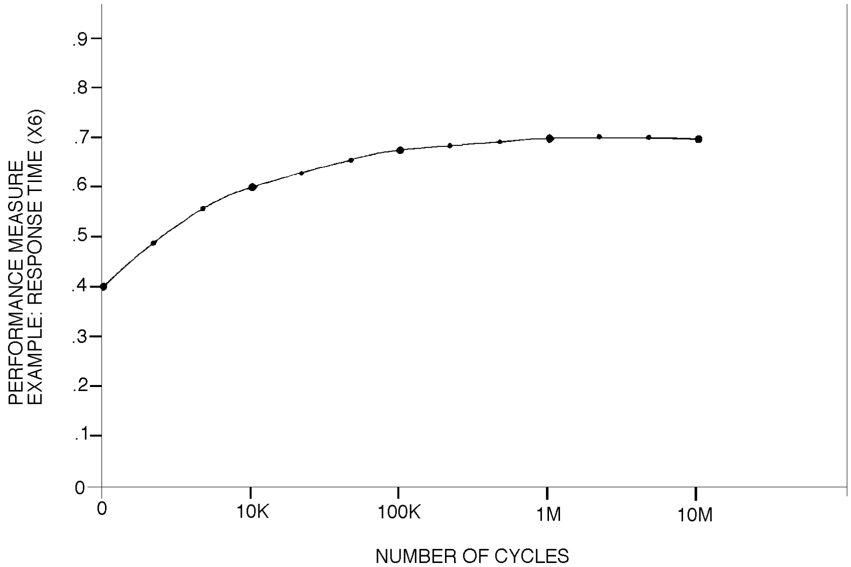

Figure 3
Typical Performance Measure vs. Number of Cycles

16.2 Record time to failure and plot failure times on lognormal or Weibull probability scales (see Figure 4). This plot gives an estimate of the useful life of an MFC (see Sections A1-1.1.4 – A1-1.1.5). Record data for the parameter tested in the data sheet given within the parametric test method.

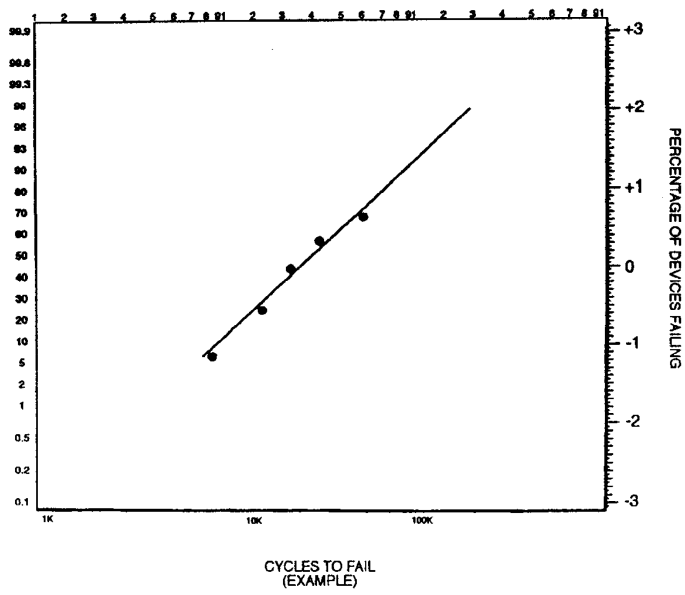

Figure 4
Time to Fail vs. Failure Percentage

16.3 Record data for the parameter tested in the data sheet given within the parametric test method.

16.4 The following test conditions are to be reported in the data presentation:

16.4.1 date and time of test

16.4.2 operator

16.4.3 test flow rate (SLM)

16.4.4 test pressure (kPa)

16.4.5 ambient temperature (°C)

16.4.6 MFC orientation

16.4.7 MFC location in test bed

16.4.8 cleanroom or environment classification

16.4.9 MFC type, manufacturer, serial number, lot number, and model number

16.4.10 LPC/CNC manufacturer, serial number, sample flow rate (SLM), model number, calibration date, particle range, and efficiency

16.4.11 test gas type and dew point (°C)

16.4.12 a schematic of the test apparatus, including manufacturers and model numbers of all test apparatus components

16.4.13 calibration dates for the flow meters

16.4.14 cycle time used for test

17 Precision and Bias

Precision and bias in this test are a function of the uncertainty of the measurement equipment used. The tester or end user is responsible for determining the precision and bias of a particular setup and test.

APPENDIX 1

NOTE: This appendix was approved as an official part of SEMI E67 by full letter ballot procedure.

NOTE: The method for reliability analysis provided herein is one of many possible methods which may be used. It is up to the user to determine if this method or another (e.g., Weibull) is to be used for determination of MFC reliability.

A1-1 Reliability Analysis

A1-1.1 Almost all reliability studies of entities whose failure is unplanned, focus on the time until a small percentage has failed (time until 10% of the population has failed, for example). Focus is on the left tail of the time-to-failure probability distribution. Nelson's book, *Applied Life Data Analysis*, (Wiley, 1982) gives a simple method for estimating the time to 10% failure for a lognormal distribution (n = 2 to 10) from units put on test. Table A1 (from page 272 of Nelson's book) can be used as follows:

A1-1.1.1 Calculate the % failed from the following equation:

Plot % failed vs. # cycles to failure for each MFC that failed on lognormal probability paper (see Figure 4).

A1-1.1.2 Estimate the mean, **μ***, and the standard deviation, **σ***, from the plot with the following equations:

A1-1.1.3 Calculate a 90% lower confidence limit for the (log of) 10% failure percentile ($y_{10,\ lcl}$) from the following equations:

$$y^* = \text{LOG}\ (y_{10,\ \text{lcl}}) = \mu^* + t^*\ [\delta = 0.10,\ P = 0.10,\ n = \#\ \text{tested},\ r = \#\ \text{failed}] \times \sigma^*$$

where t * is found from *Applied Life Data Analysis*, Table A1

$$y_{10,\ \text{lcl}} = 10^{y^*}$$

A1-1.1.4 Here is a sample set of data to illustrate the procedure.

i	*Cycles to Failure*	*% Failed*
1	6.3 K	8.3
2	15.8 K	25.0
3	25.1 K	41.7
4	40 K	58.3
5	63 K	75.0
6	did not fail	did not fail

The % failed column was calculated from the equation in Section A1-1.1.1.

A1-1.1.5 See Figure 4 for a plot of this data.

A1-1.1.6 Use Figure 4 to calculate **μ*** and **σ***.

\# of cycles to 50% failure = 3000 from graph

$\mu^* = \text{LOG}$ (# of cycles to 50% failure)

$\mu^* = \text{LOG}\ (30000)$

$\mu^* = 4.477$

\# of cycles to 16% failure = 11000 from graph

$\sigma^* = \mu^* - \text{LOG}$ (# of cycles to 16% failure)

$\sigma^* = 4.477 - \text{LOG}\ (11000)$

$\sigma^* = 4.477 - 4.041$

$\sigma^* = 0.436$

A1-1.1.7 From Table A1 (from page 272 of Nelson’s book), look up t*:

This data indicates, with a 90% confidence limit, that 10% of the devices will fail by 2443 cycles.

A1-1.1.8 Table A1 percentiles t* (d: 10, n, r) for limits for $y_{.10}$.

nφ	*rφ*	*pÆ* 0.005	*0.01*	*0.025*	*0.05*	*0.1*	*0.5*	*0.9*	*0.95*	*0.975*	*0.99*	*0.995*
2	2	-183.9	-88.09	-36.3	-16.4	-7.869	-1.405	-0.327	-0.118	0.083	0.444	0.888

SEMI E68-0997
TEST METHOD FOR DETERMINING WARM-UP TIME OF MASS FLOW CONTROLLERS

1 Purpose

1.1 The purpose of this method is to provide a standardized method for quantifying the warm-up time of an MFC.

NOTE: Warm-up times affect the initial performance of a mass flow controller (MFC). Warm-up time is necessary information in deciding if a process tool is ready to be put back into service. In addition, warm-up data will be useful in calibration labs.

2 Scope

2.1 The test conditions in this method are intended to simulate bench top warm-up, with an MFC that has been equalized to ambient conditions for 24 hours before the application of power.

3 Limitations

3.1 Conditions in the lab may be different from conditions found in the field and may influence test results. This test is intended to measure warm-up under a controlled condition.

3.2 The MFC is to be at ambient temperature before the beginning of the test.

3.3 Due to manufacturing variability, warm-up times may vary for the same model of MFC. This specification addresses a method for taking a single data point repetitively from the same MFC. Resulting data will show exactly how warm-up effects change the delivered flow of that particular MFC. To statistically quantify warm-up time for a particular model of MFC, multiple samples should be tested.

4 Referenced Documents

None.

5 Terminology

5.1 *Acronyms*

5.1.1 *DUT* — Device under test

5.1.2 *FS* — Full scale

5.1.3 *MFC* — Mass flow controller

5.2 *Definitions*

5.2.1 *device under test* — The MFC being tested for warm-up time.

5.2.2 *indicated flow* — Flow indicated by the MFC under test. Electrical output of the DUT.

5.2.3 *stability* — A condition that exhibits only natural, random variations in the absence of unnatural, assignable-cause variations. For the several purposes of this test, stability is defined as ±10% of the accuracy of the DUT at full scale.

5.2.4 *steady state* — State at which the indicated flow is stable for a 15-minute time period.

5.2.5 *warm-up* — A process where the MFC goes from an unpowered condition to a condition where the output is within ±1% full scale, of the final steady state output.

6 Summary of Test Method

6.1 The DUT is connected in series with shut-off valves on either side of the DUT. With no gas flow and the DUT powered, indicated flow is monitored until steady state is achieved. Power is briefly disconnected then reconnected and indicated flow is again monitored until steady state is achieved.

7 Significance and Use

7.1 Data generated by this method is used to estimate the amount of time an MFC should be powered up in a process tool before resuming production. When calibrating an MFC, the warm-up time can be used to estimate the waiting time before calibration. For power interruptions, the power interruption warm-up time may be used to determine the time required following a power interruption to resume production or calibration.

8 Apparatus

8.1 See Figure 1.

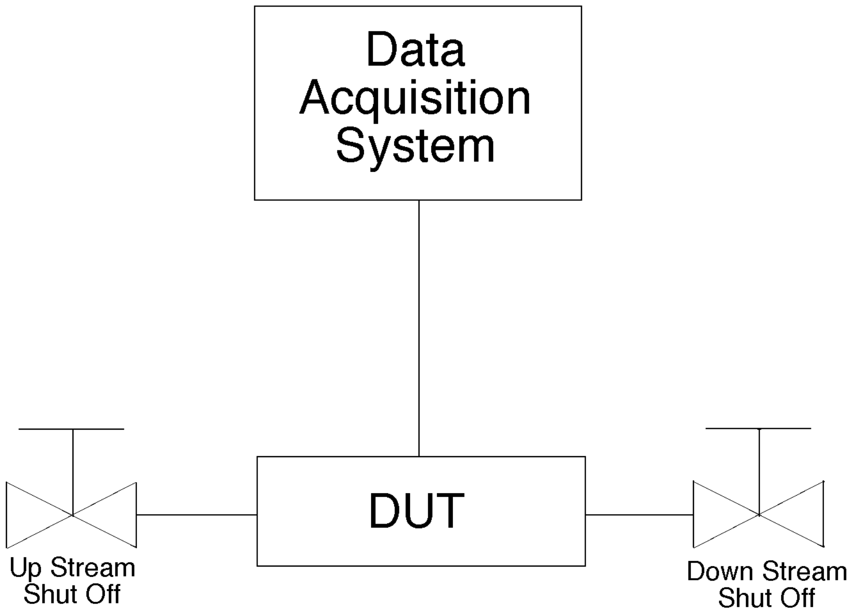

Figure 1
Test Set Up

8.2 *Time-Keeping Apparatus* — Capable of keeping accurate records within ± 10 seconds. Time-keeping requirements are not stringent, and almost any apparatus is acceptable.

8.3 *Data Acquisition System* — Having a resolution of one mV or better and a sample rate of one Hz.

9 Conditioning

9.1 Ambient temperature must be controlled and stable between 20°C and 25°C during testing for all tests. The DUT must be exposed to the ambient environment for 24 hours before the beginning of the test so that it is in equilibrium. The gas temperature must be measured and verified to be at equilibrium with both the DUT and with ambient temperature. Temperatures are in equilibrium if they are within 1°C of each other. Lab temperature may not change more than 1°C during test.

10 Procedure

10.1 Connect the DUT in series with the two shut-off valves, one upstream of the DUT and the other downstream. Electronically connect the DUT to a data acquisition system capable of recording indicated flow from the DUT. The test set-up should be set to give appropriate signals to the DUT so the DUT control valve will not dissipate power. For normally closed MFC's, the setpoint should be zero, and for normally open MFC's, the setpoint should be 100%. Suggested orientation of the DUT is horizontal (base down). If the DUT is positioned otherwise, the orientation should be reported in the test data (see Figure 1). Valves are to be opened in a downstream-to-upstream sequence and closed in reverse fashion. The data acquisition system must be warmed up as per the manufacturer's instructions.

10.2 Close shut-off valves.

10.3 In Table 1, record the time of day when power was applied to the DUT. Begin recording the indicated flow from the DUT at one sample per second.

Table 1 Format for Data Presentation

Warm-up Time	Date:____________		
	± 1% FS	Time to Achieve Steady State	Steady State Value
Cold Start			
Power Interruption			

10.4 *Cold Start* — Apply power to the DUT and continue collecting data until the indicated flow achieves a steady state value.

10.5 *Power Interruption* — Continue to collect data while disconnecting power from the test unit for 120 ± 10 seconds. Reconnect power to the DUT and monitor indicated flow until steady state is again achieved.

11 Data Analysis

11.1 Graph the data collected from the six test scenarios as directed in Section 10.

11.2 The time required for the DUT to achieve a steady state value can be visually determined from the graph of each test scenario. This data can be used to predict the warm-up times required by an MFC experiencing a field condition similar to the test scenario.

12 Data Presentation

For the two tests in Section 10, plot DUT indicated flow vs. time as illustrated in Figures 2 and 3. Note the following on these graphs and in Table 1.

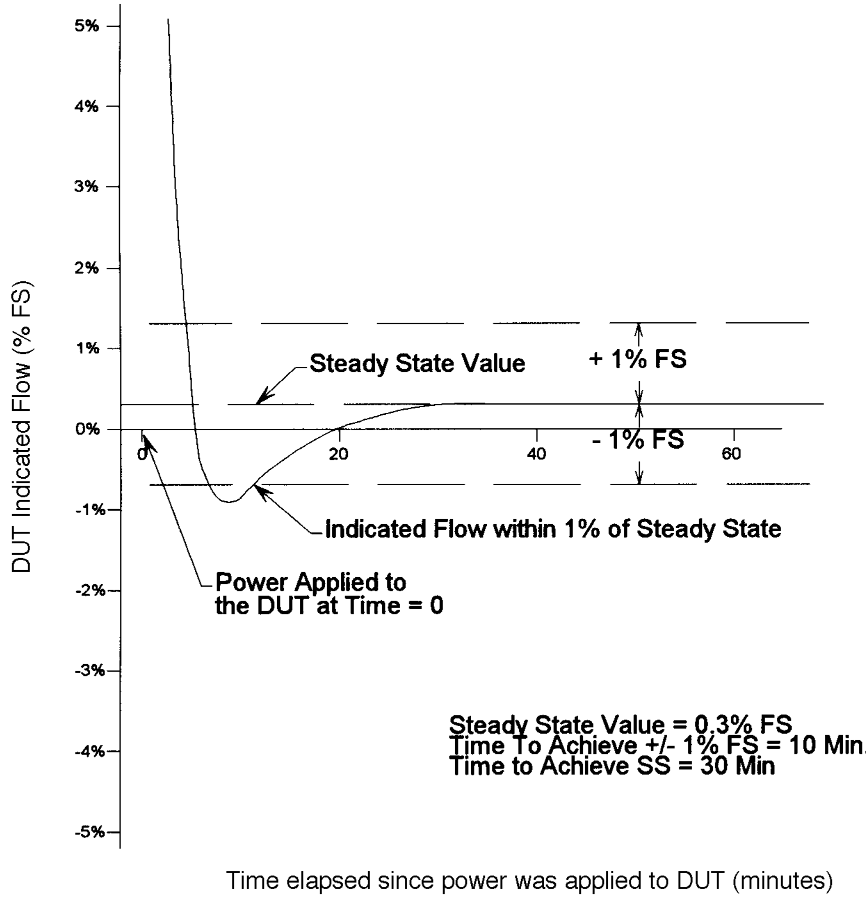

Figure 2
Cold Start Warm-Up Time

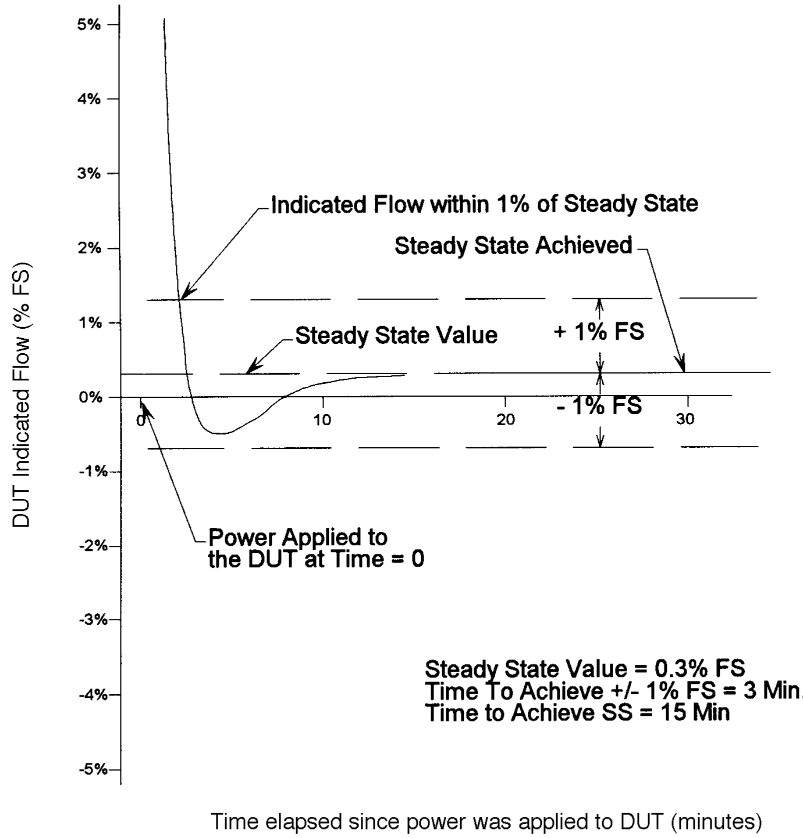

Figure 3
Two-Minute Power Interruption Warm-Up Time

12.1 Final steady-state value of the DUT.

12.2 Time to achieve a steady state value.

12.3 Use Table 1 to summarize warm-up times associated with each of the test scenarios.

13 Precision and Bias

13.1 Precision and bias in this test are a function of the uncertainty of the measurement equipment used. The tester or end user is responsible for determining the precision and bias of a particular setup and test.

Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E69-0298
TEST METHOD FOR DETERMINING REPRODUCIBILITY AND ZERO DRIFT FOR THERMAL MASS FLOW CONTROLLERS

1 Purpose

1.1 The purpose of this document is to provide a standardized method to quantify the reproducibility and zero drift of a thermal mass flow controller.

1.2 The intent of this document is not to suggest any specific testing program but to specify the test method to be used when testing for parameters that are covered by this method. The user might use this document to check significant performance characteristics, such as reproducibility and zero drift, under a set of closely controlled test conditions.

1.3 The significance of the accuracy calculations in this method is to allow an MFC user to transfer a process from one manufacturing tool to another and to exchange MFCs within a single manufacturing tool while maintaining process control.

2 Scope

2.1 This document describes the conditions and procedures for testing the reproducibility and zero drift of thermal mass flow controllers (MFCs). Because of the generic nature of this document, not all test procedures apply to all types of MFCs.

2.2 This document provides a common basis for communication between manufacturers and users.

3 Limitations

3.1 It is not practical to evaluate performance under all possible combinations of operating conditions. This test procedure should be applied under laboratory conditions; its intent is to collect sufficient data to form a judgement of the field performance of the MFC being tested.

5 Terminology

5.1 *Acronyms*

5.1.1 *FS* — Full scale

5.1.2 *kPa* — Kilopascal

5.1.3 *MFC* — Mass flow controller

5.1.4 *NC* — Normally closed

5.1.5 *NO* — Normally open

5.1.6 *psia* — Pounds per square inch absolute

5.1.7 *sccm* — Standard cubic centimeters per minute

5.1.8 *slm* — Standard liters per minute

5.2 *Definitions*

5.2.1 *accuracy* — The closeness of agreement between an observed value and the true value; the total

1 American National Standards Institute, Inc., 1430 Broadway, New York, NY 10018

2 American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017

3 International Electrochemical Commission, 3, rue de Varembe, CH-1211 Geneva 20 Switzerland

4 Instrument Society of America, 67 Alexander Drive, Research Triangle Park, NC 27709

uncertainty of an observed value, including both precision and bias.

5.2.2 *accuracy curve* — The curve fitted through the average measured values over the specified range of the device under test (DUT).

5.2.3 *accuracy, device* — The total uncertainty over a specified range of the device. Device accuracy over a range is stated as the worst case accuracy taken over all tested setpoints in this range.

5.2.4 *bias* — The difference, at a setpoint, between the measured value and the sum of the setpoint value and the zero offset. The measured values of a flow standard include its total uncertainty.

5.2.5 *cardinal setpoint* — A specific setpoint to assess the accuracy of the device under test. For this test method, the cardinal setpoints are 10%, 50%, and 100% of full scale.

5.2.6 *deadband* — The range through which a setpoint may be varied, upon reversal of direction, without initiating an observable change in output signal.

5.2.7 *downscale reading* — A reading approached from a setpoint greater than the current setpoint and beyond the deadband.

5.2.8 *downscale value, average* — The sum of all downscale readings, in one cycle, at a single setpoint, divided by the number of these values.

5.2.9 *flow standard* — A device used to measure the actual mass flow through the DUT.

5.2.10 *linearity* — The closeness to which a curve approximates a straight line. It is measured as a non-linearity and expressed as a linearity.

5.2.11 *linearity, terminal-based* — The maximum absolute value of the deviation of the accuracy curve (average of upscale and downscale values) from a straight line through the upper and lower setpoint limits of the accuracy curve (see Figure 1).

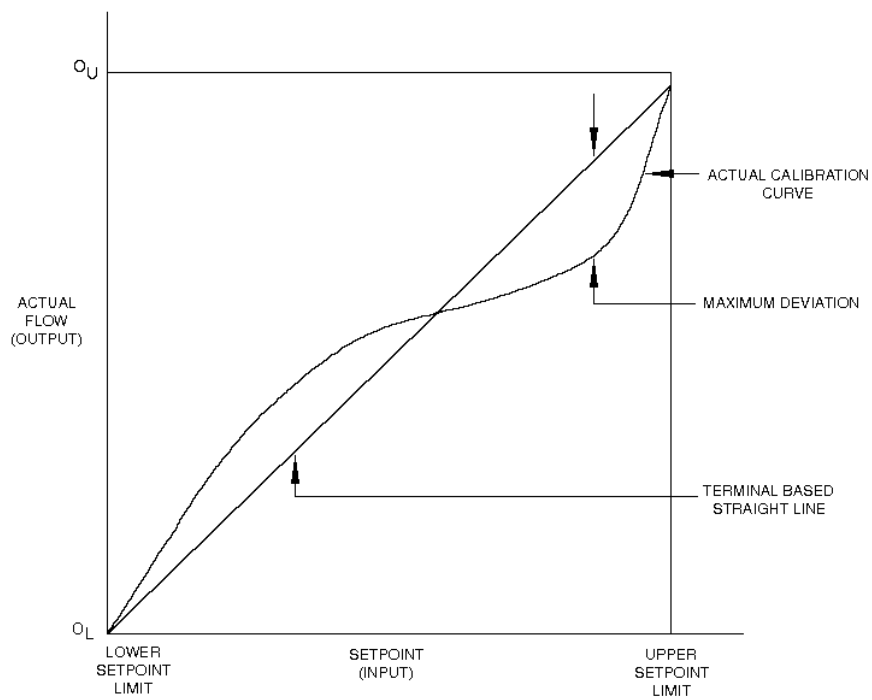

Figure 1
Terminal-Based Linearity for Mass Flow Controller

5.2.12 *measured value* — The actual flow through a device under test, expressed in sccm or slm, as measured by a standard, preferably primary.

5.2.13 *measured value, average* — The sum of all readings (both upscale and downscale) for all cycles, at a single setpoint, divided by the number of these readings.

5.2.14 *operating conditions, normal* — The range of operating conditions within which a device is designed to operate and for which operating influences are stated [ISA S51.1].

5.2.15 *operating conditions, reference* — The range of operating conditions of a device within which operating influences are negligible [ISA S51.1].

5.2.16 *operating influence* — The change in a performance characteristic caused by a change in a specified operating condition from reference operating conditions, all other conditions being held within the limits of reference operating conditions [ISA S51.1].

5.2.17 *precision* — The closeness of agreement among the measured values at a setpoint. It is often expressed as a standard deviation.

5.2.18 *repeatability* — The closeness of agreement among a number of measured values at a setpoint, under the same operating conditions, operator, apparatus, laboratory, and short intervals of time. It is usually measured as a nonrepeatability and expressed as a repeatability in percent of reading [ISA S51.1].

5.2.19 *reproducibility* — The closeness of agreement among repeated measured values at a setpoint, within the specified reference operating conditions, made over a specified period of time, approached from both directions. It is usually measured as a non-reproducibility and expressed as a reproducibility in percent of average reading. Reproducibility includes hysteresis, deadband, long-term drift, and short-term reproducibility [ISA S51.1].

NOTE: Between repeated measurements, the input may vary over the range, and operating conditions may vary within normal operating conditions.

5.2.20 *reproducibility, short-term* — The closeness of agreement among a number of measured values at a setpoint, under the same operating conditions, operator, apparatus, laboratory, and short intervals of time, approached from both directions. The approach must be from beyond the deadband. It is usually measured as a nonreproducibility and expressed as a reproducibility in percent of reading. Short-term reproducibility includes repeatability, hysteresis, deadband, and shortterm drift.

5.2.21 *setpoint* — The input signal provided to achieve a desired flow, reported as sccm, slm, or percent-full scale.

5.2.22 *setpoint limit, lower* — The lowest setpoint at which the instrument is specified to operate.

5.2.23 *setpoint limit, upper* — The highest setpoint at which the instrument is specified to operate, usually full scale.

5.2.24 *span* — The full-scale range of the DUT.

5.2.25 *stability* — The ability of a condition to exhibit only natural, random variation in the absence of unnatural, assignable-cause variation.

5.2.26 *standard conditions* — 101.32 kPa, 0.0°C (14.7 psia, 32°F)

5.2.27 *uncertainty, total* — The range within which the true value of the measured quantity can be expected to fit; an indication of the variability associated with a measured value that takes into account the two major components of error — bias and the random error attributed to the imprecision of the measurement process.

5.2.28 *upscale reading* — A reading approached from a setpoint less than the current setpoint and beyond the deadband.

5.2.29 *upscale value, average* — The sum of all upscale readings, in one cycle, at a single setpoint, divided by the number of these values.

5.2.30 *zero drift* — The undesired change in electrical output, at a no-flow condition, over a specified time period, reported in sccm or slm.

5.2.31 *zero offset* — The deviation from zero, at a no-flow condition, reported in sccm or slm.

6 Summary of Test Method

6.1 Specific procedures are given for characterizing MFCs discharging to atmospheric pressure or into a vacuum using accepted reference standards to determine reproducibility and zero drift (see Figure 2).

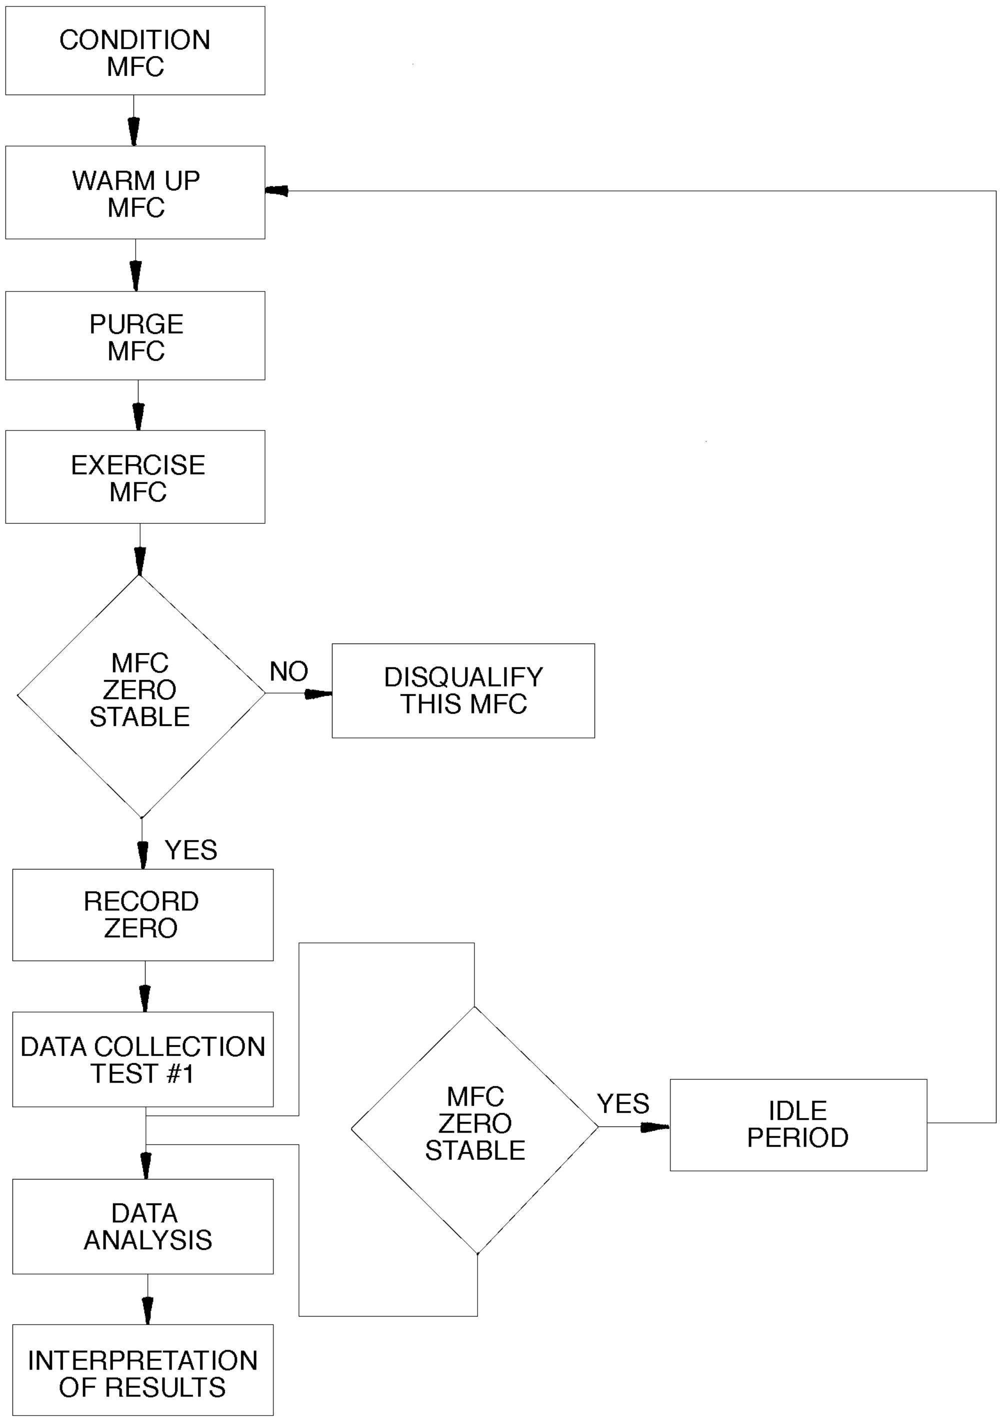

Figure 2
Test Flowchart

7 Interferences

7.1 The accuracy rating of the measuring equipment must include superior measurement capability compared with that of the DUT. In no instance should the accuracy rating of the measuring equipment be less than twice that of the DUT (e.g., if the accuracy of the DUT is ± 1 sccm, then the accuracy of the measuring device must be better than, or equal to, ± 1/2 sccm). The traceability of all the pertinent measuring instruments and devices should be realistically established and quantified.

7.1.1 In addition, take care when using test instruments with a specified accuracy expressed in percent of full scale. For example, if an instrument with a specified accuracy of ± 0.1% of full scale is used to measure the output of the DUT, but this output signal falls only within the lower third of the scale of the instrument, the effective accuracy over the range of the instrument being used may be ± 0.3%, which is unsuitable for many applications.

7.1.2 Use special precautions to ensure that minimum effects result from pneumatic noise in flow lines. Monitor pressure both upstream and downstream of the MFC to ensure that pneumatic noise is minimized.

7.1.3 The DUT should be installed so that the inlet flow can be fully developed, pulsation-free, for the specific conditions. This can be achieved by plumbing a straight length of tubing 40–50 diameters long upstream and another straight length 5 diameters long downstream of the DUT. (For additional information about inlet effects, refer to ASME MFC-1M.)

7.1.4 At regular calibration intervals, verify electrical signals directly at the MFC connector to ensure that there are no unacceptable line losses in the cables.

8 Apparatus

8.1 back pressure regulator

8.2 digital voltmeter

8.3 flow standard

8.4 heat exchanger

8.5 power supply

8.6 pressure transducer

8.7 setpoint generator

8.8 temperature probe

9 Precautions

9.1 *Technical Precautions*

9.1.1 Many analog-to-digital converter cards do not differentiate between measurements of less than zero and zero. It may be necessary to use a digital voltmeter to record measurements below zero volts. Some MFCs do not differentiate between measurements of less than zero and zero. This may bias the results.

9.1.2 The manufacturer's specifications and instructions for installation and operation must be applied during all testing.

9.1.3 All electrical measurements should be read on devices with at least 4.5 digits of resolution. These devices must have valid calibration certifications.

9.1.4 The mounting position of the device must be in accordance with the manufacturer's specifications. No external mechanical constraints beyond the manufacturer's recommended mounting position shall be permitted.

10 Preparation of Apparatus

10.1 Figure 3 is a representation of a recommended generic testing apparatus. The flow standard is shown downstream of the device under test (DUT). It may be placed upstream of the DUT if the flow standard cannot be exposed to a low pressure environment. In this case, the user should be aware of possible back pressure effects on the flow standard.

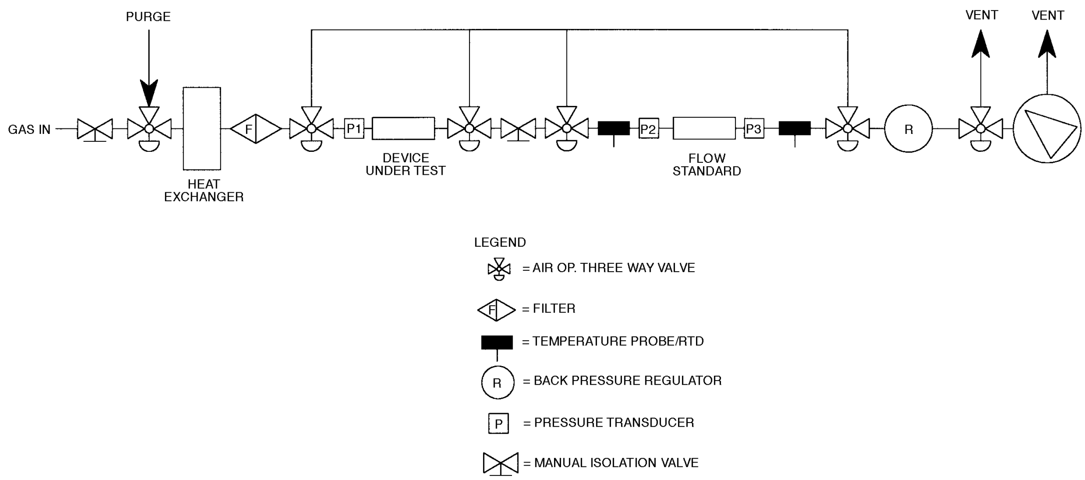

Figure 3
Mass Flow Controller Test Fixture

11 Calibration Standardization

11.1 All measurement devices must have valid calibration certificates.

12 Conditioning

12.1 Place the MFC to be tested in the testing environment. Apply power to the MFC for the 24 hours prior to initiating warm-up as defined by the manufacturer. The valve should be in its "off" position (closed for an NC valve, open for an NO valve).

12.2 Following the conditioning period, install and warm up the device according to manufacturer's specifications.

12.3 Purge the MFC with nitrogen or argon following the warm up period.

12.4 Allow the test gas to flow through the DUT for a minimum of 10 minutes at 100% of flow.

12.5 Apply a 100% full-scale setpoint to the DUT and wait for the flow to stabilize for 10 seconds. Apply the lower setpoint limit to the DUT and wait for the flow to stabilize for 10 seconds. Repeat this cycle two more times. This process exercises the device before initiating the test.

12.6 *Test Conditions*

12.6.1 The reference operating conditions shall be as follows if the downstream pressure is atmospheric:

Ambient temperature	23 ± 2°C
Gas temperature	Same as actual ambient
Ambient pressure	101.3 kPa (+ 4.7 or - 15.3 kPa)
Gas pressure P_1, Inlet	274 ± 34 kPa
Gas pressure P_3, Outlet	101.3 kPa (+ 4.7 kPa or - 15.3 kPa)
Relative humidity	40% ± 10%, noncondensing
Magnetic field	≤ 50 µT
Electromagnetic field	< 100 µV/m
Vibration	< 0.5 m/s
Shock	≤ 3 g

12.6.2 The reference operating conditions shall be as follows if the downstream pressure is at vacuum:

Ambient temperature	23 ± 2°C
Gas temperature	Same as actual ambient
Ambient pressure	101.3 kPa (+ 4.7 or - 15.3 kPa)
Gas pressure P_1, Inlet	172 ± 34 kPa
Gas pressure P_3, Outlet	< 0.13 kPa
Relative humidity	40% ± 10%, noncondensing
Magnetic field	≤ 50 µT
Electromagnetic field	< 100 µV/m
Vibration	< 0.5 m/s
Shock	≤ 3 g

12.7 *Power Supply Conditions*

12.7.1 The reference power supply conditions used shall be the reference values specified by the manufacturer. For those instances when a range of values is specified rather than a reference value, the midpoint of the range shall be taken to be the reference value.

12.7.2 The reference power supply must be sufficiently rated for the DUT. In addition, the following supply conditions and tolerances shall apply:

DC supply reference voltage	± 0.1% of operating voltage
Noise and ripple of DC supply	≤ 0.1% rms

13 Procedure

13.1 *Zero Offset*

13.1.1 Close the gas shut-off valve upstream of the device under test and apply a 100% setpoint to the DUT to equilibrate the pressure across the MFC. Wait for the flow to stabilize at a value near zero, then close the downstream shut-off valve. Deactivate the MFC's control valve (open for (NO) valves, closed for (NC) valves), and disable the MFC to auto zero if an auto-zero disable option is available. After the electrical output signal has stabilized for at least three minutes, record the MFC zero offset on Table 1. (Consult the manufacturer's specifications for the stabilization time and report this time on Table 2.)

13.1.2 Use the cardinal setpoints and any other setpoints of specific interest. These setpoints will be used to determine the reproducibility of the MFC. The setpoint increments should exceed the expected deadband of the DUT.

13.1.3 At each setpoint under test, maintain the input signal until the output of the DUT becomes stabilized at its apparent final value. Observe and record the output values in Table 1 for each input value.

13.1.4 Record five readings at each setpoint during testing.

NOTE: If the data points show a trend in one direction, either up or down, the DUT is not stable enough for the test to proceed to the next setpoint. Record another five readings at this setpoint. If the results continue to show a trend, repeat the measurements at the previous setpoint. If the results are not satisfactory at this setpoint, stop the test for this MFC. If the results are not satisfactory, halt the test and verify the performance of the testing apparatus.

13.1.5 At each point under test, maintain the input signal until the output of the device under test becomes stabilized at its apparent final value. Observe and record the output values for each input value.

13.2 *Reproducibility and Zero Drift Test*

13.2.1 Apply a 50% setpoint to the MFC and record data.

13.2.2 Move the setpoint to 100% and record data.

13.2.3 Move the setpoint to 50% and record data.

13.2.4 Move the setpoint to 10% and record data.

13.2.5 After recording data at 10%, apply a 5% setpoint for 10 minutes, but do not record any data at this setpoint.

13.2.6 Move the setpoint back up to 10% and record data.

13.3 Repeat Sections 13.2.1–13.2.6, for a total of three times, until at least six sets of data have been collected at each setpoint (with the exception of 100%).

13.4 Repeat Sections 13.1.1–13.3 weekly for a period of at least 12 weeks. During the idle time, the MFC should be continuously powered, with any exceptions so noted. Gas flow is not required during the idle time, but any gas flow shall be recorded. Finally, record all details about the conditions of the MFC during the idle time.

14 Data Analysis

14.1 *Calculations*

14.1.1 Determine the precision at a setpoint by calculating the standard deviation of all the measured values (both upscale and downscale) for that setpoint. Perform this calculation at each setpoint:

$$P = \sqrt{\frac{\sum\left(\sum (V_i - A_a)^2\right)_i}{n_j}}$$

P = Precision

V_i = The i th reading at a setpoint for a given cycle

A_a = Average measured value

n_j = Number of readings at a setpoint for a given cycle

14.1.2 Determine the short-term reproducibilty at a setpoint by dividing the precision of the setpoint by the average setpoint. This is expressed as a percentage of reading. Perform this calculation at each point:

$$SRS\% = \frac{P}{S_a} \times 100$$

14.1.3 The long term reproducibility at a setpoint is the greatest absolute weekly reproducibility at a setpoint.

Determine the precision over the test period at a setpoint by calculating the standard deviation of all the measured values (both upscale and downscale) for that setpoint. Perform this calculation at each setpoint:

$$P_L = \sqrt{\frac{\sum\left(\sum\left(\sum (V_i - A_a)^2\right)_j\right)_w}{\sum\left(\sum n_j\right)_w}}$$

P_L = Precision over the test period

V_i = The i[th] reading at a setpoint for a given

A_a = Average measured

n_j = Number of readings at a setpoint for a given cycle

w = Number of weeks

14.1.4 Determine the reproducibility at a setpoint by dividing the precision over the test period at this setpoint by the average setpoint. This is expressed as a percentage of reading. Perform this calculation at each setpoint:

$$RS\% = \frac{P_L}{S_a} \times 100$$

14.1.5 The overall reproducibility of the DUT is the maximum value calculated in Section 14.1.4:

$$\pm RD\% = RS_{max}$$

RD = Reproducibility of the device

14.1.6 Calculate zero drift by subtracting the minimum zero value from the maximum zero value and dividing by two. This number is reported as ± sccm or slm over the specified time period.

15 Data Presentation

15.1 Plot the average measured value of each setpoint (10%, 50%, 100%) for each measurement period on a graph, with the *x*-axis representing time, and the *y*-axis showing the actual flow output in sccm or slm.

15.2 Plot the measured value at zero for each measurement period on a graph, with the *x*-axis representing time and the *y*-axis showing flow output signal in sccm or slm.

15.3 *Reproducibility* — Report a single number, as calculated above, as a percentage of reading stated, with the time period of the test.

15.4 *Zero Drift* — Report a single number, as calculated above, stated with the time period of the test.

SEMI E70-0698
GUIDE FOR TOOL ACCOMMODATION PROCESS

NOTE: This entire document was revised in 1998.

1 Purpose

1.1 This document will provide an overview of the various elements of Tool Accommodation, a methodology by which semiconductor processing equipment is installed in a cost-effective and timely manner. This addition to the SEMI Tool Accommodation Standards set describes the process by which the referenced SEMI documents can be effectively used to achieve tool installation cost and schedule goals.

2 Scope

2.1 This overview document will provide process development, facilities, manufacturing, and sales engineers (as well as purchasing agents and managers) with a basic understanding of the various elements in a Tool Accommodation methodology. This process emphasizes quality, completeness, timeliness, and cost-effectiveness as key elements of successfully installing semiconductor processing equipment into wafer fabrication facilities. By describing a generic process flow, this document identifies a road map for using published standards that comprehend all the procedures involved in tool accommodation from procurement through acceptance. As a common ground for communication and comparison, terms and definitions are also included.

4 Summary of Referenced Documents

4.1 *SEMI E6* — Facilities Interface Specifications Guideline and Format

4.1.1 Purpose of SEMI E6 is to communicate from supplier to user the facilities requirements of semiconductor equipment.

4.1.2 Benefits of SEMI E6 include assurance of effective communication of process tool installation requirements.

4.1.3 *Roles and Responsibilities for SEMI E6* — Tool supplier submits information requested in SEMI E6, facilities interface specification. Equipment engineer, facilities engineer, and installation manager use tool requirements information provided by supplier to prepare facility and efficiently install the tool.

1 Institute of Environmental Sciences & Technology, 940 East NW Highway, Mount Prospect, IL 60056, 847.255.1561

Table 1 SEMI Tool Accommodation Standards

	Facility Services	*Process Tool*	*Process Tool Subsystems (internal distribution system for)*

4.2 *SEMI E49* — Guide for Standard Performance, Practices, and Sub-Assembly for High Purity Piping Systems and Final Assembly for Semiconductor Manufacturing Equipment

4.2.1 Purpose of SEMI E49 is to specify requirements for process distribution systems located inside of, and provided with, semiconductor processing tools. (SEMI E49 acts as a reference document for the series of SEMI E49 standards, SEMI E49.1 through SEMI E49.9. See Table 1, SEMI Tool Accommodation Standards for an explanation of the ten documents included in the SEMI E49 series.)

4.2.2 Benefits of the SEMI E49 series include assurance of compatibility in purity and performance between the tool and facility distribution systems.

4.2.3 *Roles and Responsibilities for SEMI E49 Series* — Facilities engineer and installation manager submit appropriate SEMI E49 requirements, either HP or UHP. Tool supplier uses information provided to ensure distribution system compatibility.

4.3 *SEMI E51* — Guide for Typical Facilities Services and Termination Matrix

4.3.1 Purpose of SEMI E51 is to communicate from customer to supplier factory facilities available at the utility point of connection (UPOC) for a semiconductor tool.

4.3.2 Benefits of SEMI E51 include assurance of cost-effective and timely tool installation with minimum retrofit to customer site.

4.3.3 *Roles and Responsibilities for SEMI E51* — Facilities engineer and installation manager submit utility specifications requested in SEMI E51 matrixes, either typical or site-specific. Tool supplier uses information provided about facility to assist in configuration of the process tool.

5 Terminology

5.1 *acceleration cost* — Additional costs incurred to complete the project sooner than the original scheduled baseline plan.

5.2 *as-built drawings* — Documentation describing the actual configuration and dimensions at the end of construction.

5.3 *base build* — Installation of base building, services, and equipment to establish functional environmental controls and utilities to support production equipment installation.

5.4 *bidding* — Obtaining sealed quotes for a defined scope of work.

5.5 *burdened/unburdened* — Identification of costs included or excluded from contractual labor rates.

5.6 *capital equipment* — Equipment that is depreciated according to tax guidelines for durable goods. Generally has a value greater than $1,000.00 and a useful life greater than 5 years.

5.7 *change order* — A document defining a formal change in drawings, specifications, and/or scope of work.

5.8 *cleanroom* — Confined area in which the humidity, temperature, particulate matter, and contamination are precisely controlled within specified parameters. Cleanroom classes are defined in Federal Standard 209, Airborne Particulate Cleanliness Classes in Clearness and Clean Zones.

5.9 *conditioned power* — Electrical power that is manipulated to maintain specified tolerances.

5.10 *construction* — The set of activities that transforms plans and specifications into functional systems capable of performing to specification.

5.11 *construction consumable* — Any material used up during construction.

5.12 *construction management* — The set of activities that define, direct, monitor, and report construction activities such as workmanship, adherence to design, cost, and schedule conformance.

5.13 *contingency* — A reserve of funds, time, and/or material that is allocated to maintain schedule and budget. A reserve for scope changes, unforeseen site conditions, change in material prices, or unanticipated events.

5.14 *contract award* — Notification to the successful bidder and subsequent signing of contract documents.

5.15 *contractor* — A licensed company hired to accomplish a contractually specified scope of work.

5.16 *cost of ownership (COO)* — The total lifetime cost associated with acquisition, installation, and operation of fabrication equipment [SEMI E35].

5.17 *cycle time, gross installation* — Total time to install and commission process equipment, typically starting from dock date to release for vendor startup.

5.18 *cycle time, net installation* — Actual time devoted to construction activities related to tool hookup from dock date to ready for inspection.

5.19 *damage* — Destruction or unintentional alteration resulting in a liability.

5.20 *dedicated truck* — Exclusive drayage of a shipment.

5.21 *design build* — A contract method whereby the contractor assumes responsibility for design generation and construction to accomplish a specified performance criteria.

5.22 *design start* — A milestone event that designates the initial conversion of equipment specifications and design concepts into engineering plans and specifications.

5.23 *detailing* — Generation of dimensioned shop fabrication plans based on process and instrumentation drawings (P&ID), field surveys, and configuration verifications.

5.24 *direct/indirect cost* — Direct costs are the cost of anything physically associated with the installation, removal, or modification of equipment. Indirect costs cannot be associated with a specific piece of equipment. Profit, overhead, and administrative costs are typically considered indirect.

5.25 *distribution system* — The collection of subsystems and components used in a semiconductor manufacturing facility to control and deliver process chemicals from source to point of use for wafer manufacturing processes.

5.26 *dock date* — The date when the fab equipment, including all ancillary components, is on-site at the loading dock.

5.27 *emergency power* — Electrical power supplied by alternate sources or backup systems, like generators that come on line when the main utility power supply fails.

5.28 *equipment engineering* — A group that focuses primarily upon the electrical, electronic, and mechanical characteristics of production equipment. Depending upon the site and the fab area, Equipment Engineering may be a distinct organization, or the equipment engineering responsibilities may be handled by other groups, such as Process Engineering or Manufacturing Engineering. Equipment Engineering is typically responsible for selection and physical configuration of production equipment.

5.29 *facilities interface specification* — Documentation provided by a tool supplier that contains the tool requirements for utilities and installation as defined in SEMI E6. So-called equipment data sheets are one section of this document that also includes requirements for safety, facilities services, shipping and receiving, install, startup, acceptance, and training.

5.30 *fast track* — A scheduling method that eliminates float and maximizes parallel activities, thereby reducing overall project duration. Selective use of overtime is typically used to reduce the duration of critical path activities.

5.31 *field change order* — A document defining a formal change in drawings, specifications, and/or scope of work generated after contract award by on-site personnel to incorporate conditions identified during construction.

5.32 *field fabrication* — Assembly and/or modification of components on the job site to accommodate site-specific conditions.

5.33 *float* — Unallocated time created when tasks are completed ahead of schedule or a task's duration is less than the allotted amount.

5.34 *free on board (FOB)* — Goods placed on a truck or other means of transportation at a point specified by the seller without charge to the buyer, but with all further transportation at the buyer's expense.

5.35 *gas cabinet* — A metal enclosure that is intended to provide local exhaust ventilation, protection for the gas cylinder from fire from without the cabinet, and protection for the surroundings from fire from within [SEMI S4].

5.36 *gas interface box (GIB)* — An enclosure located between the tool mainframe and facility services containing components for pressure regulation and filtration. Functions to consolidate all gas requirements to single points of connection. Provides location and ability to pre-facilitate tool hookups in advance of tool delivery.

5.37 *grounding* — Electrical wiring system to provide earth ground.

5.38 *hookup* — The set of activities and organization required to accept incoming process equipment, move it into place, connect the equipment to all facilities, and test the connections. The connection of all necessary facilities and interconnects required to make the equipment package fully operational. The hookup activity is complete when all of the following are met.

- The equipment positioning and bolting down is complete.
- The final equipment utility connections and interconnects are complete, tested, and certified.
- The process piping certification is complete. The wall system, including bulkheads as required, is complete.
- The final decontamination is complete.
- Government inspections have been conducted as required.

5.39 *inertia base* — A structural unit using mass damping to attenuate vibration for production equipment.

5.40 *interconnect* — Connections between tool mainframe and peripheral tool subsystem equipment [SEMI E6].

5.41 *issue for construction (IFC)* — A milestone event that identifies when drawings and specifications are released to subcontractors for construction.

5.42 *labor rate* — The contractually stipulated cost of labor.

5.43 *laterals/sublaterals* — Intermediate facility service distribution lines that run between mains and equipment-specific isolation valves.

5.44 *layout fixed* — The milestone date when the physical layout of equipment and components is fixed and all stockholders complete approval sign-off.

5.45 *local abatement* — Treatment of emissions at the point of generation at the tool.

5.46 *long lead materials* — Material requiring early ordering due to availability or long manufacturing time.

5.47 *mains/submains* — Central distribution lines from a facility services source to which laterals are connected. Individual equipment is not connected directly to mains.

5.48 *minienvironment* — A localized environment created by an enclosure to isolate the product from contamination and people [SEMI E44, SEMI E45].

5.49 *mobilization* — Initial assignment of resources to a project resulting in measurable work being accomplished.

5.50 *move-in* — The movement of the process equipment from the loading dock into the fab area, and into the final taped position. The piece of equipment is defined as the main body of the equipment and all its subsystems, assemblies, and components, excluding the hookup. If major subsystems such as pumps or chillers are missing, move-in will not be considered complete until they arrive.

5.51 *move-in date* — Milestone date indicating completion of step when processing equipment is moved into designated location in fab.

5.52 *not-to-exceed (NTE)* — An agreement to guarantee that the charges for a service or services will not be greater than a specified amount.

5.53 *on-the-job training (OJT)* — The instruction of personnel in the operation or maintenance, or both, of equipment done during the course of normal work functions. On-the-job training typically does not interrupt operation or maintenance activities and, therefore, can be included in any equipment state without special categorization [SEMI E10].

5.54 *overtime* — Time spent in excess of normal working hours.

5.55 *owner buys* — Material purchased by the owner and consigned to subcontractors for use in construction.

5.56 *pedestal* — Structural support element upon which equipment or raised floor rests.

5.57 *permits* — Legal governmental documents granting permission for specific construction activities.

5.58 *prefacilitation* — A stage in the equipment installation process that follows base build and precedes tool hookup. Prefacilitation brings the various facilities services close to the new equipment location, including new facilities services and structural modifications required to prepare the facility to accept the equipment.

Also known as rough-in, this step is performed as a time-saving operation. The activity requires the following conditions to be met:

- The raised floor is in (if required).
- The ceiling is in.
- The seismic or isolation frame is in.
- All utilities are within 1.8 meters (6 feet) of the equipment or terminated in a utility box.
- The floor is taped with the equipment location.

5.59 *prepurchase* — Purchase of materials and equipment in advance of total scope definition to accommodate long lead times.

5.60 *process and instrumentation drawing (P&ID)* — A diagram using graphic engineering symbols to represent the components, flows, and functions that make up a process delivery system.

5.61 *project management* — The set of activities that design, define, direct, monitor, and report on factory building construction.

5.62 *protocol* — Description of procedures, materials, and practices used to define a methodology for accomplishing a specific task. Typically refers to material and personnel handling to maintain cleanroom integrity.

5.63 *punch list* — A list of corrective actions required to fulfill contractual obligations.

5.64 *purchase order (P.O.)* — A document used by a buyer to acquire a product or service that usually contains the terms and conditions (including price) governing the sale.

5.65 *qualification* — Certification of compliance with contractual stipulations before release to manufacturing production use.

5.66 *quality assurance/quality control (QA/QC)* — Activities performed to ensure compliance with contractually stipulated conditions.

5.67 *raised floor* — The removable floor system installed above the actual building floor within cleanroom environments to control air flow and allow access for utility routing and connection.

5.68 *request for information (RFI)* — Documentation from contractor to request clarification.

5.69 *request for proposal (RFP)* — Documentation from purchasing agent to vendor to request a proposal to provide product and/or services.

5.70 *request for quote (RFQ)* — Documentation from purchasing agent to vendor to request a firm price to provide product and/or services.

5.71 *seismic bracing* — Structural reinforcement to minimize damage due to earthquakes.

5.72 *shifts* — Duration of routine work day, typically an 8, 10, or 12 hour as required to accrue a minimum of 40 equivalent hours (or local equivalent) within a 7-day (one week) period.

5.73 *single line drop* — A hookup strategy where a piece of processing equipment has only one point of connection per facility service. All manifolding for an individual service is handled with in the tool.

5.74 *site-specific facilities services and termination matrix* — A compilation of service types, quality, and capacity available for use at utility point of connection for a tool (see SEMI E51).

5.75 *slurry system* — A distribution system to convey abrasive slurries for use in chemical mechanical polishing (CMP) systems.

5.76 *source inspection* — Inspection at the equipment manufacturer's factory to confirm configuration details, review modifications, and confirm installation designs prior to shipment of equipment.

5.77 *specialty gas* — Non-bulk process gases typically stored in cylinders and used to supply one or more process tools through specialized manifolds.

5.78 *subfab* — The area within the cleanroom boundaries directly below the production level.

5.79 *submittal* — A written presentation for signed acceptance of a proposal in response to a request for services.

5.80 *support equipment* — Ancillary equipment not part of the main chassis.

5.81 *time and materials (T&M)* — A contracting method whereby cost is determined by the actual requirements of the project as opposed to an estimate and a fixed cost system.

5.82 *tool* — Any piece of semiconductor fabrication or inspection equipment designed to process wafers. Often used synonymously with equipment in the silicon wafer processing industry.

5.83 *tool accommodation* — A methodology by which semiconductor processing equipment is installed in a cost-effective and timely manner.

5.84 *turnkey* — Delivery of a fully functional and tested system.

5.85 *utility point of connection (UPOC)/tool point of connection (TPOC)* — UPOC is a fitting typically located at a valve on a lateral to provide service for a tool, the facilities end/termination of the hookup. TPOC is a fitting typically at a valve on a processing tool (either external or internal), the tool end/termination of the hookup.

5.86 *uninterruptable power supply (UPS)* — A power supply that provides an uninterrupted or continuous supply of electrical power even during a failure in the main utility power supply.

5.87 *union labor* — A group of trained craftpersons that are represented by a single bargaining organization. A labor bargaining unit.

5.88 *value engineering* — A set of reviews to determine minimum requirements at a minimum cost.

5.89 *valve manifold box (VMB)/valve manifold panel (VMP)* — A metal enclosure and/or panel including distribution valves and components required to distribute gases or liquids to multiple points of use from a single source.

6 Roles and Responsibilities

6.1 Definition and responsibility assignment are critical to a successful project. Communications mechanisms must be established as early as possible. SEMI E6 provides a template for establishing a format for administrative interface. Using this format for establishing interfaces will improve communication and avoid cost and schedule impacts that might arise from equipment or facilities modifications during the procurement cycle. (See Figure 1.)

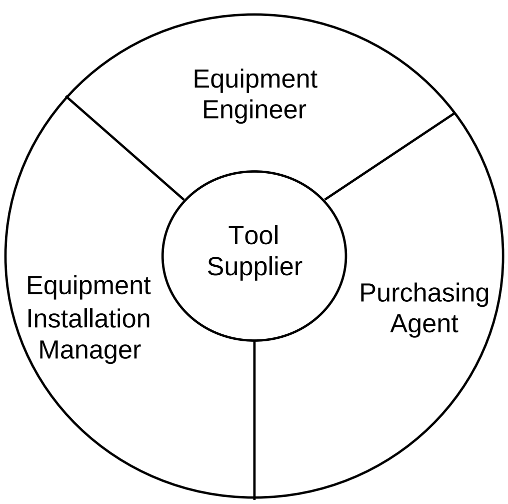

Figure 1
Information Exchange Relationships

7 Process

7.1 The following 15 steps describe a generic process flow for using published tool accommodation standards to achieve cost and schedule goals in a cycle of procurement through acceptance for a particular process tool. (See Figure 2.)

7.1.1 *Process Requirement Defined by Customer* — Process parameters are defined and documented by the process engineer and equipment engineer. Specific performance targets are established that are consistent with production requirements and cost of ownership expectations.

7.1.2 *Process Tool Location Identified by Customer* — Physical location is determined by collaboration between production, industrial, and facilities engineering. The location is typically selected to optimize production flow within the facility while minimizing accommodation costs and production interruptions. A layout document of record is generated and approved by all affected parties.

7.1.3 *Customer Generates Facilities Services Matrix* — Equipment and facilities engineering establish site-specific parameters by using the SEMI E51 format to define the available utilities and physical environment within which the production tool will have to function.

7.1.4 *Customer Specifies Internal Tool Piping and Distribution System Requirements* — Site-specific exceptions to SEMI E49 through SEMI E49.9 are identified and reviewed with equipment suppliers to determine the most cost- and schedule-efficient configuration.

7.1.5 *Customer Issues Formal Request for Quote* — A formal request for quotation (RFQ) is generated by the customer's procurement department soliciting quotations from qualified manufacturers. SEMI E49 and SEMI E51 data are included with request for quotation.

7.1.6 *Supplier Submits Quote Including the Facilities Interface Specification in SEMI E6 Format* — A "Statement of Conformance" to specified standards is normally required for a quotation to be considered valid. Exceptions to performance specifications must be thoroughly documented and resolved. Multiple re-quotation is sometimes required to establish a contractually valid agreement.

7.1.7 *Contractual Terms Finalized and Order is Placed by Customer* — Terms and conditions of the purchase agreement based upon the finalized quotation are negotiated and approved by all stakeholders.

7.1.8 *Supplier Manufactures Equipment* — Equipment is manufactured per purchasing agreement. To prevent errors and omissions during installation, change orders are documented, approved prior to implementation, and copies are distributed per administrative interfaces as defined in SEMI E6.

7.1.9 *Installation Detailed and Prefacilitation Performed by Customer* — Installation design documentation is generated, approved, and distributed to subcontractors for pricing. Long lead-time hookup materials are identified and prepurchased. Prefacilitation is performed to insure accurate and quick hookup of tool on arrival.

7.1.10 *Customer Source Inspects Equipment* — Source inspection is the final validation of all designs and capabilities of the specific tool. Functionality testing is performed and documented. Physical configuration is confirmed. Modifications to configurations are documented so that installation pricing can be adjusted accordingly.

7.1.11 *Supplier Ships Equipment to Customer* — Equipment is packaged per SEMI E49.1 and shipped as defined in SEMI E6. Equipment is shipped per purchase order stipulations. Customs clearance is obtained as required.

7.1.12 *Customer Verifies Equipment Matches Supplier Provided Facilities Interface Specification* — Upon arrival at the customer site, verification of compliance to purchase order is determined. Verification of physical dimensions, point of connections, and interface cabling and tubing is performed.

7.1.13 *Equipment Hookup by Customer* — Mechanical, electrical, process piping, and life safety system hookups are done, and all functional testing is completed. Equipment is ready for vendor startup and commissioning. Final payment to hookup contractor is authorized, and upon payment, construction liens are released. As-built drawings showing newly installed tool are updated and submitted to owner for inclusion in permanent records.

7.1.14 *Equipment Is Qualified and Customer Verifies Contract Completion* — Equipment startup is complete and functional testing to verify compliance to purchase agreement is complete and documented. Final payment to equipment vendor is released.

7.1.15 *Actual Cost and Schedules Are Reviewed* — Final accounting is performed to determine actual costs associated with the project. Actual duration of all activities is compared to original schedule to determine areas for improvement. Estimating models for future installations are updated to reflect new information.

Tool Accommodation Process Flow Chart

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E72-0600
SPECIFICATION AND GUIDE FOR 300 mm EQUIPMENT FOOTPRINT, HEIGHT, AND WEIGHT

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org April 2000; to be published June 2000. Originally published in 1998, previously published June 1999.

1 Purpose

1.1 Currently, device manufacturers cannot easily plan or retrofit their fabs, because equipment volumes are not predictable. Similarly, equipment suppliers cannot predict fab designs, because there are too many configurations. In general, fab space is not used efficiently, and there seems to be a trade-off between space efficiency and maintainability. This standard is a guide for equipment design and a specification for maximum limits on equipment volume and weight.

2 Scope

2.1 This standard specifies limits on the footprint, height, and weight of equipment for 300 mm fabs. Separate limits are given for the parts of the equipment in the main fab and in the sub-fab. Separate limits are also given for the equipment after it is installed and for the components of the equipment as it is moved into the fab. The actual footprint may vary by equipment type.

2.2 This standard is intended to set an appropriate level of specification that places minimal limits on supplier innovation while ensuring opportunities for users to be globally (though possibly not locally) efficient with equipment volumes.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Specification for 300 mm Tool Load Port

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *cost footprint* — the area (A) of the smallest horizontal rectangle that contains all of the shadow footprint and half of the easement space around the equipment (for use as the floor space metric in Cost of Ownership calculations). As shown in Figure 1, this is computed as

$$A = [Wt + ½\,(Ws – Wt)] \times [Dt + ½\,(Ds – Dt)]$$
$$= ¼\,(Wt + Ws) \times (Dt + Ds)$$

Where W represents width and D represents depth

4.2 *depth* — the horizontal dimension perpendicular to the load face plane.

4.3 *easement space* — the floor space that must remain clear to the rear and sides of the equipment (but not in front of the load face plane). This includes safety aisles, ergonomic maintenance access space, component removal space, and room for doors to swing out (see Figure 1).

4.4 *load face plane* — the furthest physical vertical boundary plane from the cassette centroid or carrier centroid on the side (or sides) of the tool where loading of the tool is intended (as defined in SEMI E15).

4.5 *shadow footprint* — the area of the floor space directly under every part of the equipment during its operation (see Figure 1). This includes any temporary projections from the equipment during loading or processing (such as carriers that stick out from the equipment or equipment load ports that protrude only when the equipment is being loaded).

4.6 *width* — the horizontal dimension parallel to the load face plane.

5 Requirements and Recommendations

The dimensions cited in the following sections are specified in Table 1.

5.1 *Sub-Fab vs. Main Fab Footprint*

5.1.1 *Requirements* — Both the cost footprint and the shadow footprint of the remote parts of any equipment in the sub-fab must be less than or equal to the cost footprint and the shadow footprint (respectively) of the parts of that equipment in the main fab (the cleanroom including both bays and chases, if any). Furthermore, the remote parts of the equipment in the sub-fab must be capable of being installed so that the rectangle defining the cost footprint in the sub-fab is entirely underneath the rectangle defining the cost footprint in the main fab. In some fab designs (such as slab on grade), there is no sub-fab (or basement). In such cases, these requirements apply to the remote parts of the equipment in whichever equipment support area contains the same remote parts of the equipment as a sub-fab. Also, some fabs have multiple sub-fab levels. In such cases, these requirements apply to the remote parts of the equipment in all sub-fab levels.

5.1.2 *Recommendations* — Since the sub-fab is likely to have more columns than the main fab, it is recommended that the remote parts of the equipment in the sub-fab come in modules that can be arranged to accommodate a variety of layouts.

5.2 *Equipment Height*

5.2.1 *Requirements* — The maximum height of any equipment (other than a stocker) must be less than or equal to *H* in the main fab and *Hs* in the sub-fab. Any connections for utilities and required overhead maintenance access must also be included within these limits. These limits also apply during installation, so if a part of the equipment must be rotated up into place, the diagonal measurement must be less than these limits.

5.2.2 *Recommendations* — Thus, equipment suppliers are advised to not plan on ceilings higher than these limits.

5.3 *Floor Loading*

5.3.1 *Requirements* — The maximum mass of any equipment in the main fab divided by its shadow footprint must be less than or equal to *M* (except when support pedestals are used). Furthermore, the maximum weight on any 0.6 m by 0.6 m (2 ft. by 2 ft.) floor tile (in any installation configuration) must be less than or equal to *Mt.* These limits also apply when the equipment is being moved into the fab and installed, unless spreader plates are used.

5.3.2 *Recommendations* — It is recommended that seismic loading also be considered when designing equipment weight distribution.

5.4 *Move-In-Size*

5.4.1 *Requirements* — To clarify the size of the doors and hallways needed in the fab, this paragraph specifies the size of the equipment's components after it has been uncrated, while it is being moved into the fab, and before it is installed. All parts of the equipment destined for the main fab must come in packages that are no taller than *Z* and that are smaller than *X* by *Y* in two orthogonal horizontal dimensions. All parts of the equipment destined for the sub-fab must come in packages that are no taller than *Zs* and that are smaller than *Xs* by *Ys* in two orthogonal horizontal dimensions. Furthermore, none of these packages may weigh more than *Mm* each. This paragraph does not apply to stockers and AMHS transport equipment.

5.4.2 *Recommendations* — Equipment suppliers and device manufacturers might also consider carrier stocker size, move-in timing, and move-in path during stocker and facility design. Equipment that conforms to these limits may still be too large to fit into standard truck trailers or aircraft cargo bays.

5.5 *Maintenance Access*

5.5.1 *Requirements* — To avoid interfering with carrier transport systems, equipment must not require regularly scheduled maintenance from the front. This requirement does not apply to maintenance performed on user interfaces, cart-docking interfaces, load ports, carrier buffers, and load locks.

5.5.2 *Recommendations* — It is recommended that as little regularly scheduled maintenance as possible be required from the side.

5.6 *Width vs. Depth*

5.6.1 *Recommendations* — In general, to minimize the number of bays required in a fab, it is recommended that equipment be designed to minimize width rather than depth.

5.7 *Linked Equipment*

5.7.1 *Recommendations* — To make linked equipment (such as cluster tools or steppers with litho tracks) jointly space efficient, it is recommended that they be designed to minimize the cost footprint of the entire system as a whole.

Equipment Footprint Dimensions

Table 1 Equipment Footprint, Height, and Weight Dimensions

Symbol Used	*Value Specified*	*Dimension Description*
H	3.5 m (11 ft. 5 in.) maximum	height of equipment in the main fab
Hs	2 m (6 ft. 6 in.) maximum	height of equipment in the sub-fab
M	1500 kg/m^2 (2.1 lbm./$in.^2$) maximum	mass of equipment divided by its shadow footprint
Mm	6000 kg (13227 lbm.) maximum	mass of equipment move-in packages
Mt	1000 kg (2204 lbm.) maximum	mass of equipment on any 0.6 m by 0.6 m (2 ft. by 2 ft.) floor tile
X	2.2 m (7 ft. 2 in.) maximum	Length (perpendicular to Y) of equipment move-in packages destined for the main fab
Xs	2 m (6 ft. 6 in.) maximum	Length (perpendicular to Ys) of equipment move-in packages destined for the sub-fab
Y	2.8 m (9 ft. 2 in.) maximum	Length (perpendicular to X) of equipment move-in packages destined for the main fab
Ys	1.7 m (5 ft. 6 in.) maximum	Length (perpendicular to Xs) of equipment move-in packages destined for the sub-fab
Z	2.8 m (9 ft. 2 in.) maximum	Height of equipment move-in packages destined for the main fab
Zs	2 m (6 ft. 6 in.) maximum	Height of equipment move-in packages destined for the sub-fab

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E72 but was approved for publication by full letter ballot procedures.

R1-1 The maximum height of equipment in the main fab was set so that the equipment could be installed in existing fabs with ceilings just above the equipment height of 3.5 m (11 ft. 5 in) or in fabs with ceiling heights of 3.66 m (12 ft. 0 in.) where more clearance is provided for such things as parts of some overhead carrier transport systems, fire sprinkler systems at the ceiling, and/or extra room for installation of equipment.

R1-2 The maximum height of equipment in the sub-fab was set so that no part of the equipment (other than connections to the main fab area) sticks up into the piping and duct-work immediately under the waffle slab. In those cases where a part of the equipment must be taller than 2 m (6 ft. 6 in.), it is recommended that it not be taller than 2.5 m (8 ft. 2 in.) to stay under the waffle slab.

R1-3 If equipment must have easement space on the side, it is recommended that they be designed in mirror-image configurations with easement space needed on only one side or the other, so that half of the total easement space on the sides can be deleted. However, it is recommended that the resulting increase in equipment cost, complexity, and spare parts inventory be taken into account.

R1-4 Equipment that conforms to the limits given in this standard may be too large or heavy to fit into buildings that were originally designed for equipment that processes smaller wafers.

SEMI E73-0301
SPECIFICATION FOR VACUUM PUMP INTERFACES - DRY PUMPS

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces & Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on December 1, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published June 1998; previously published February 1999.

1 Purpose

1.1 This standard specifies the physical and electrical interfaces for dry pump (DRP) type vacuum pumps. Standardization of pump interfaces will allow for interchangeability of pumps. Device manufacturers use this standard when procuring processing equipment to specify to the equipment supplier the interface required for interchangeability of pumps. This document is also used by semiconductor processing equipment suppliers to specify standardized interfaces to pump suppliers.

2 Scope

2.1 This standard applies to vacuum pumps supplied with 300 mm semiconductor processing equipment.

2.2 The standard specifies the mechanical and electrical interfaces for dry pumps including the following.

- Mechanical connectors
- Control signals and connector
- Power supply and connector

2.3 Figure 1 shows the scope of the standardized interface.

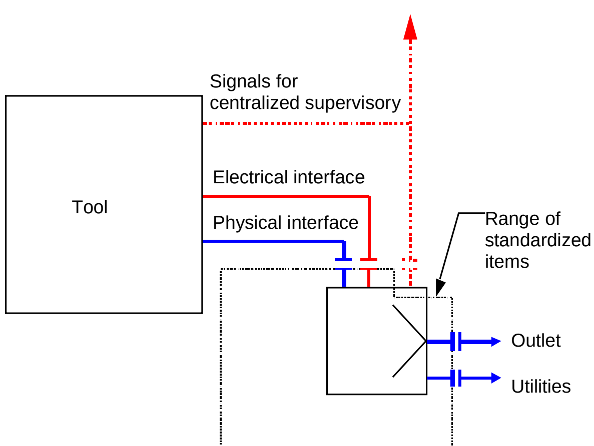

Figure 1
Scope of Standardized Interface

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guide is not intended to dictate how to build a vacuum pump but to specify interfaces that will allow for interchangeabilty of individual pumps.

3.2 This standard does not include specifications for sensor-bus compliant interfaces.

3.3 This standard is not intended to address design issues related to safety considerations and containment issues which are addressed elsewhere in the SEMI guidelines.

3.4 International, national, and local codes, laws, and regulations should be consulted to ensure that the equipment meets regulatory requirements in each location of use.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

ISO 1609 — Vacuum Technology - Flange dimensions

ISO 2861-1 — Vacuum technology - Quick-release couplings - Dimensions - Part 1: Clamped type

5 Terminology

5.1 *dry pump (DRP)* — Dry pumps are a type of mechanical vacuum pump. Dry pumps can work at

1 International Organization for Standardization, C.P. 56 CH-1211 Geneva 20, Switzerland

atmospheric pressure. They are called dry pumps because no liquid sealing materials are used on any surface contacted by gases. Hereafter, the term "DRP" is substituted for "dry pump".

5.2 *pump alarm* — A cautionary signal that the pump has stopped.

5.3 *pump warning* — A state of an abnormal or extraordinary event during pump operation which means there is a probability the pump will stop.

5.4 *vacuum pump* — A pumping apparatus which exhausts gas or air from an enclosed space to achieve a desired degree of vacuum.

6 Requirements

6.1 *Mechanical Interfaces* — Table 1 specifies the required DRP connector type and size by flange/port.

Table 1 Mechanical Connectors

No.	*Items*		*Connector Type*	*Connector Size*	*Referenced Standard*	*Remarks*
1	Inlet flange	Nominal bore 50 mm or less	ISO KF flange	≤ 50 mm Connector dimensions should be based on the referenced standard	ISO 2861-1	A port flange which connects the pump to a process tool to evacuate gases.
		Nominal bore over 63 mm size	ISO clamped flange	≥ 63 mm Connector dimensions should be based on the referenced standard	ISO 1609	
2	Outlet flange		ISO KF flange	Connector dimensions should be based on the referenced standard	ISO 2861-1	A port flange which connects the pump to the facility evacuation system.
3	Duct port (Option)		Not specified	50 mm or 100 mm diameter port		Port to connect duct for evacuating flames inside the pump.
4	Purge gas port		Compression type*	1/4" Connector		A connection port used to supply inert gas, typically N_2, to the pump. The purge gas protects the inside of the pump from corrosion due to process gases.
5	Cooling water port		ISO taper pipe thread (female on pump side)	1/4" or 3/8"	ISO 7-1	A connection port to supply water used to keep the pump cool.

* For example Swagelock®

6.2 *Electrical Interfaces*

6.2.1 *Control Signals*

6.2.1.1 Table 2 specifies the required DRP control signals. Table 3 and Figure 2 specify the required response time for DRP control signals. Table 4 specifies the required power and contacts for DPR control signals. Tables 5 and 6 and Figure 3 specify the required connector and pin assignments for DRP control signals.

Table 2 I/O Signals

No.	*Signal Name*	*Direction*	*Type*		*Remarks*
1	Start (Run)/Stop	Input signal to Pump	Alternate	Pump runs when closed	
2	Start (Run)/Stop	Output signal from Pump	Alternate	Close on pump start	Running status signals When input power is OFF, output status signals should become open (normally open).
3	Remote/Local	Output signal from Pump	Alternate	Close during remote operation	
4	Pump Warning	Output signal from Pump	Alternate	Open at warning	
5	Pump Alarm	Output signal from Pump	Alternate	Open at alarm	

Table 3 Response Time for Signals

No.	*Items*	*Acceptable Response Time*	*Remarks*
1	Input Power ON	Under 10 seconds After input power turns on	Objects: All status signals shall be ready.
2	Control Signals	Under 2 seconds After receiving a signal	See Figure 2 Objects: a) Start signal (input) ->> Start status (output) b) Stop signal (input) ->>Stop status (output)

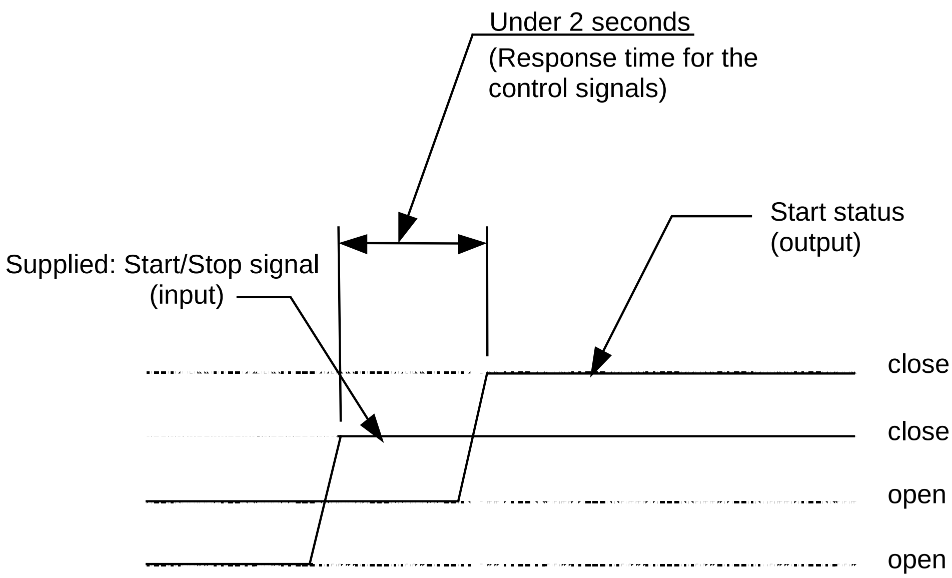

Figure 2
Example of Response Time for Start Signal and Start Status

Table 4 Signal Power and Contacts

No.	*Items*	*Power*		*Remarks*
1	Signal power supply	Input signals to DRP (Control signal)	Input signals shall be driven by the DC power supply in DRP.	Example: See Figure 4. a) Photocoupler Input. b) Relay Input.
		Output signals from DRP (Running status signal)	Output signals shall be driven by DC power supply in tools.	Example: See Figure 5. a) To photocoupler unit. b) To relay unit. c) To TTL unit.
2	Signal power supply voltage	Signal power supply voltage is between 5 V_{DC} and 24 V_{DC}		
3	Acceptable range of signal power supply voltage	Acceptable voltage range is 4 V_{DC} minimum, and 30 V_{DC} maximum.		
4	Running status signal contact	Dry contact or open collector	Acceptable current 100 mA maximum.

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E73 and is not intended to modify or supercede the official standard. This related information is optional and contains information that is not required to conform to this standard.

NOTE 1: While this standard was developed to specify vacuum pumps installed with 300 mm equipment, the standard should also be applied to vacuum pumps installed with 200 mm equipment.

NOTE 2: Signal items for centralized supervisory diagnostics and maintenance could not be standardized, because they are not consistent or technically well-established. Additional work is required for standardization of these signals.

NOTE 3: In order to save space and reduce cost, the connector for the control and running status signals should be the minimum size required for the number of pins specified in the standard. If additional signal connections are required, another connector should be added to the pump.

NOTE 4: Utilizing a 200 VAC system (range: 200 to 230 VAC) rather than a 400 VAC system (range: 380 to 480 VAC) can lower costs associated with manufacturing and purchasing pumps. To help minimize pump costs, this standard incorporates AC supply voltages in the range of 200 to 230 VAC. Many 400 VAC systems are now in use and may be more widespread in the future. However, standardizing on supply voltage of 200 VAC can reduce pump costs now without complications as long as pump manufactures accommodate customers requesting 400 VAC units.

SEMI E74-0301
SPECIFICATION FOR VACUUM PUMP INTERFACES - TURBOMOLECULAR PUMPS

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces & Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on December 1, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published June 1998; previously published February 1999.

1 Purpose

1.1 This standard specifies the physical and electrical interfaces for turbomolecular pump (TMP) type vacuum pumps. Standardization of pump interfaces will allow for interchangeability of pumps. Device manufacturers use this standard when procuring processing equipment to specify to the equipment supplier the interface required for interchangeability of pumps. This document is also used by semiconductor processing equipment suppliers to specify standardized interfaces to pump suppliers.

2 Scope

2.1 This standard applies to vacuum pumps supplied with 300 mm semiconductor processing equipment.

2.2 The standard specifies the mechanical and electrical interfaces for turbomolecular pumps, including the following:

- Mechanical connectors and locations
- Control signals and connector
- Power supply and connector

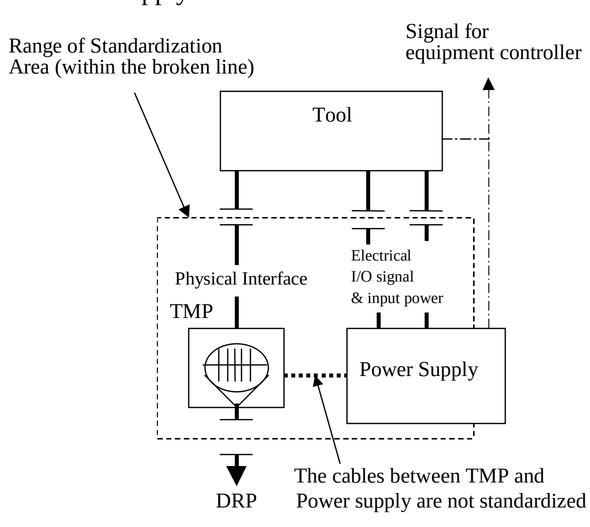

Figure 1
Scope of Standardized Interface

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard is not intended to dictate how to build a vacuum pump, but to specify interfaces that will allow for interchangeability of individual pumps.

3.2 This standard does not include specifications for sensor-bus compliant interfaces.

3.3 This standard is not intended to address design issues related to safety considerations and containment issues which are addressed elsewhere in the SEMI guidelines.

3.4 International, national and local codes, regulations and laws should be consulted to ensure that the equipment meets regulatory requirements in each location of use.

3.5 This standard does not apply to turbomolecular pumps less than 300 l/s or greater than 3000 l/s. Pumps less than 300 l/s are too small and pumps greater than 3000 l/s pumps are not commonly used.

3.6 Double flow turbomechanical pumps are excepted from this standard, because their shapes and structures are different from turbomolecular pumps to be applied this standard.

ISO 7-1 — Pipe threads where pressure-tight joints are made on the threads - Part 1: Dimensions, tolerances and designation

1 International Organization for Standardization, C.P. 56 CH-1211 Geneva 20, Switzerland

ISO 1609 — Vacuum Technology - Flange dimensions

ISO 2861-1 — Vacuum technology - Quick-release couplings - Dimensions - Part 1: Clamped type

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *pump alarm* — A cautionary signal that the pump has stopped or is to be stopped.

5.2 *pump warning* — A state of an abnormal or extraordinary event during pump operation which means there is a probability the pump will stop.

5.3 *turbomolecular pump (TMP)* — Equipment used to create a high vacuum. Rapidly rotating blades force molecules to the bottom for removal by a mechanical pump.

5.4 *Vacuum Pump* — A pumping apparatus which exhausts gas or air from an enclosed space to achieve a desired degree of vacuum.

6 Requirements

6.1 *Mechanical Interfaces*

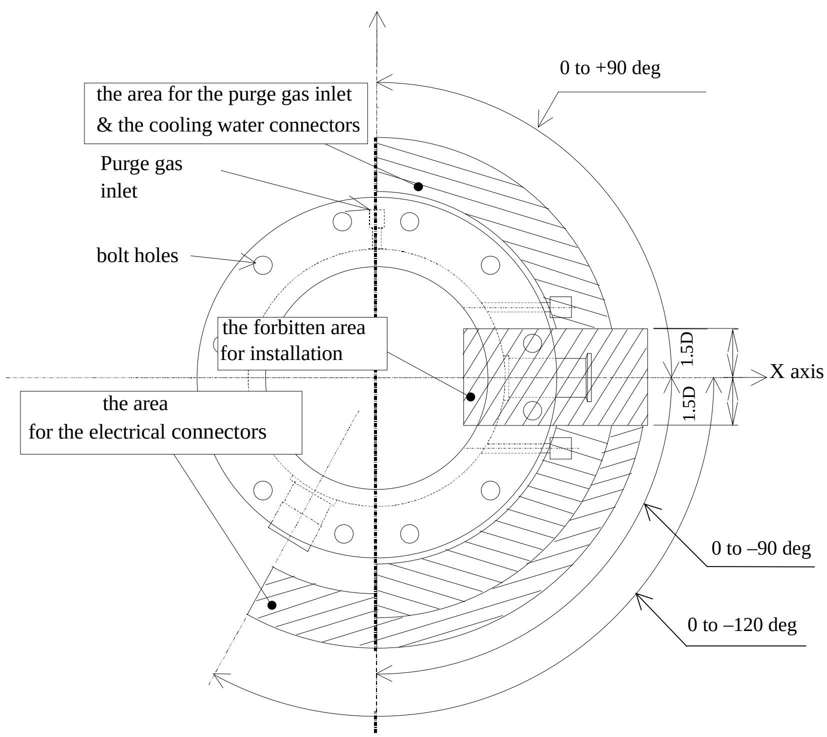
6.1.1 Table 1 specifies the required TMP connector type and size by flange/port. Axial orientation and position of the connectors are specified in Table 2 and Figure 2. Port and connector positions shall be at the periphery of the pump. Put inlet port on the *z*-axis and the outlet port on the *x*-axis. Other connector locations are specified by the angle between the *x*-axis and the center of the connector.

Table 1 Mechanical Connectors

No.	*Items*	*Connector Type*	*Connector Size*	*Referenced Standard*	*Remarks*
1	Inlet flange	ISO bolted flange	Connector dimensions should be based on the referenced standard	ISO 1609	A port flange which connects the pump to a process tool to evacuate gases.
2	Outlet flange	ISO KF flange	Connector dimensions should be based on the referenced standard	ISO 2861-1	A port flange which connects the pump to the DRP (Dry Pump).
3	Purge gas port	ISO KF flange	Size 10 or 16 connector	ISO 2861-1	A connection port used to supply inert gas, typically N_2, to the pump. The purge gas protects the inside of the pump from corrosion due to process gases.
4	Cooling water port	ISO taper pipe thread (female on pump side)	1/4" or 3/8"	ISO 7/1	A connection port to supply water used to keep the pump cool.

Table 2 Connector Locations

No.	*Items*	*Connector Location*	*Connector Angle (degrees)*	*Remarks*
1	Inlet flange	*z*-axis		Flange bolt holes shall be symmetrically located at equal distance from the center line of the outlet flange.
2	Outlet flange	transverse	0°	
3	Purge gas port	transverse	- 90° to + 90°	The forbidden area shall be symmetrically located at equal distances from the center of the outlet flange. Distance from the *x*-axis shall be more than 1.5 times the nominal bore of the outlet flange.
4	Cooling water port	transverse	- 90° to + 90°	
5	Electrical connections	transverse	0° to -120°	
6	Other ports	transverse	- 90° to + 90°	



D: nominal bore of the outlet flange

Connector Locations

6.2 *Electrical Interfaces*

6.2.1 *Control Signals*

6.2.1.1 Table 3.1 specifies the required TMP control signals. In cases where TMP are backed up by battery or regeneration power while input power failure, the status of output signals follows Table 3.2. Table 4 and Figure 3 specify the required response time for TMP control signals. Table 5 specifies the required power and contacts for TMP control signals. Tables 6 and 7 and Figure 4 specify the required connector and pin assignments for TMP control signals.

Table 3.1 I/O Signals

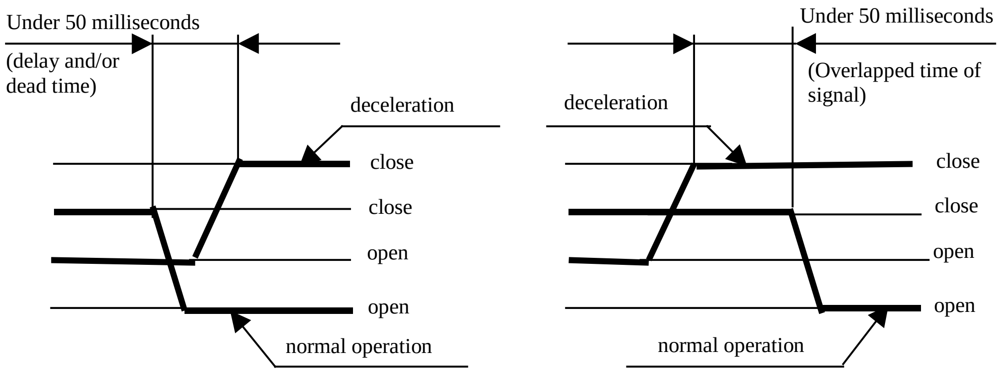
No.	*Signal Name*	*Direction*	*Type*		*Remarks*
1	Start (Run)/Stop	Input signal to Pump	Alternate	Pump runs when closed	
2	Acceleration	Output signal from Pump	Alternate	Close during acceleration	Running status signals When input power is OFF, output status signals should become open (normally open).
3	Normal operation	Output signal from Pump	Alternate	Close during normal operation	
4	Deceleration	Output signal from Pump	Alternate	Close during deceleration	
5	Remote/Local	Output signal from Pump	Alternate	Close during remote operation	
6	Pump Alarm	Output signal from Pump	Alternate	Open at alarm	

Table 3.2 Status of output signals during back up operation mode

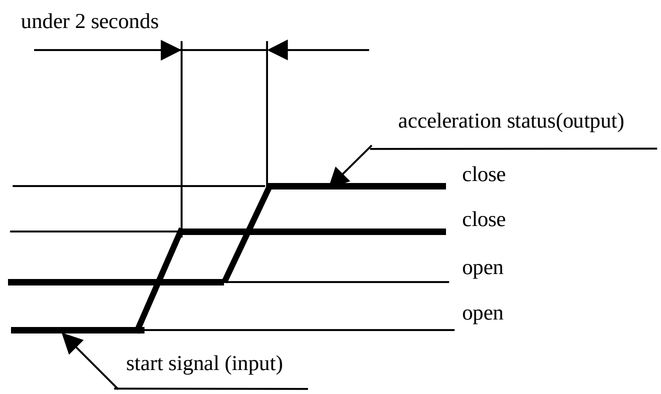
Status of pump	*Signal Name*	*Status of signals*
During back up operation mode	Acceleration	Open
	Normal operation	Open
	Deceleration	Close
	Remote/Local	Close during remote operation
	Pump alarm	Open

Table 4 Response Time and Timing for Signals

No.	*Items*		*Acceptable Response Time*	*Remarks*
1	Response Time	Input Power ON	Under 10 seconds After input power turns on	Objects All status signals shall be ready.
2		Control Signals	Under 2 seconds After receiving a signal	Objects Start signal (input) ->> Acceleration (output) Stop signal (input) ->> Deceleration (output)
3	Timing	Running status signals	Under 50 milliseconds Acceptable delay and/or dead time in a moment of shift of the running status Under 50 milliseconds Acceptable overlapped time in a moment of shift of the running status	Objects (Example) Normal ->> Deceleration The running status signals of alarm and remote/local can be overlapped with other signals.



Timing for the running status signals



Response Time and Timing for Control Signals

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E74 and is not intended to modify or supercede the official standard. This related information is optional and contains information that is not required to conform to this standard.

NOTE 1: While this standard was developed to specify vacuum pumps installed with 300 mm equipment, the standard should also be applied to vacuum pumps installed with 200 mm equipment.

NOTE 2: ICF flange is available on request for inlet flange.

NOTE 3: In order to save space and reduce cost, the connector for the control and running status signals should be a minimum size required for the number of pins specified in the standard. If the additional signal connections are required another connector should be added to the pump.

SEMI E75-0698 (Withdrawn 0301)
PROVISIONAL MECHANICAL SPECIFICATION FOR BOX/POD COMPATIBLE CASSETTES USED TO TRANSPORT AND STORE 300 mm WAFERS

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Purpose

1.1 This standard specifies the box/pod compatible cassettes used to transport and store 300 mm wafers in an IC manufacturing facility. This includes both manual and auto-transport use, as well as high-speed extraction of the wafers in processing equipment.

SEMI E76-0299
GUIDE FOR 300 mm PROCESS EQUIPMENT POINTS OF CONNECTION TO FACILITY SERVICES

This Guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on August 15, 1998. Initially available at www.semi.org January 1999; to be published February 1999. Originally published September 1998.

This document replaces E76-0998 in its entirety.

1 Purpose

1.1 Factory design variations make it difficult for equipment manufacturers to predict or agree on consistent points of connection for hookup of equipment to facility services. Similarly, device manufacturers cannot easily pre-facilitate their factories for equipment because the connections on the equipment are not consistently located. Standardization of connection locations and utilizing pre-facilitation strategies decreases the cost of and time required for equipment installation.

1.2 This document is a guide for 300 mm equipment manufacturers to define the positioning of the equipment points of connection (EPOC), required on semiconductor processing equipment for hookup to facility utility services. The document identifies locations for the EPOC's and provides EPOC consistency recommendations that should allow for efficient equipment installation. In addition, this document defines strategies to support the device manufacturer's ability to pre-facilitate the utility point of connection (UPOC). Recommendations for supplier-provided EPOC documentation are also included.

2 Scope

2.1 This guide addresses three areas that are necessary to improve the efficiency of and reduce the duration of equipment installations.

a) Recommendations for EPOC location, grouping, consistency and reduction to increase confidence in the accuracy and repeatability of EPOC's, and reduce the amount of work required to hookup equipment. As a result, device manufacturers can employ standard pre-facilitation strategies and increase the efficiency of equipment installation.

b) Pre-facilitation recommendations that provide the ability for UPOC's to be efficiently and accurately installed prior to equipment delivery, thus allowing immediate hook-up of the equipment upon arrival in the wafer fab. This includes recommendations for jigs, templates, mating pedestal bases, and associated interface panels.

c) Documentation recommendations to be required by the device manufacturer and provided by the equipment supplier relative to EPOC location, group, consistency, pre-facilitation strategies and hardware. This includes additional documentation recommended to support equipment installations but not directly related to EPOC's.

2.2 This guide applies to 300 mm semiconductor processing equipment and any supplier-provided support equipment for installation into new factories.

2.3 The following groups of utilities are covered in this guide.

- Electrical Power
- Data communications
- Exhaust and other process effluents
- Process fluids (liquids and gases)
- Support equipment interconnects

2.4 The primary focus for this guide is hookup of semiconductor processing equipment including but not limited to the following equipment types.

- Etch equipment (Dry and Wet)
- Film deposition equipment (CVD, PVD and Plating)
- Thermal equipment
- Surface prep and clean
- Photolithography equipment (Stepper and Tracks)
- Chemical Mechanical Polishing equipment
- Ion Implant equipment
- Metrology equipment

3 Limitations

3.1 This standard does not apply to assembly and test equipment.

3.2 International, national, and local codes, regulations and laws should be consulted to ensure that the equipment meets regulatory requirements in each location.

3.3 This guide is not intended to address design issues related to safety. Safety issues are addressed in other SEMI standards (See SEMI S2).

4 Referenced Documents

4.1 *SEMI documents*

SEMI E6 — Facilities Interface Specifications Guideline and Format

SEMI S2 — Safety Guideline for Semiconductor Manufacturing Equipment

NOTE: All documents cited will be the latest published versions.

5 Terminology

5.1 *bottom feed* — Equipment utility supply lines enter the equipment from its underside typically through the floor.

5.2 *equipment configuration* — Specifically, the arrangement, location, type and quantity of EPOC's needed for installation. Also know as tool configuration.

5.3 *equipment point of connection (EPOC)* — A fitting or other terminal provided with the processing equipment (either external or internal) for utility connection, the equipment end/termination of the hookup. Also know as tool point of connection.

5.4 *external connection* — An external connection is located outside the main frame of equipment.

5.5 *facilities interface specification* — Documentation provided by an equipment supplier that contains the equipment requirements for utilities and installation [SEMI E6].

5.6 *facility services* — Any gas, exhaust, liquid, power, data communications or other material which are supplied to or carried away from the equipment and used in the process. Also referred to as utilities or facilities.

5.7 *footprint* — The total area or floor space consumed by a piece of equipment when viewed perpendicular to the area of reference (e.g., normally, when viewed from directly overhead and considering the floor).

5.8 *hazardous production materials (HPM)* — A solid, liquid, or gas that has a degree of hazard rating in health, flammability, or reactivity of class 3 or 4 as ranked by NFPA 704 and that is used directly in research, laboratory, or production processes that have as their end product materials that are not hazardous.

5.9 *hookup* — The set of activities and organization required to accept incoming process equipment, move it into place, connect the equipment to all facilities, and test the connections. The connection of all necessary facilities and interconnects required to make the equipment package fully operational.

5.10 *interconnect* — Connections between equipment mainframe and peripheral equipment subsystem equipment [SEMI E6].

5.11 *internal connection* — An internal connection is a utility connection to the equipment which is located internal to the equipment and typically associated with hazardous utilities.

5.12 *interface box* — An enclosure located between the equipment mainframe and facility services typically containing components for pressure regulation and filtration. It functions to consolidate facility service requirements to single points of connection. The interface box can provide location and ability to pre-facilitate equipment hookups in advance of equipment delivery.

5.13 *jig* — A three dimensional fixture, typically a frame that contains equipment installation aides which serve to indicate location and type of connection needed for equipment hook-up.

5.14 *location plane* — The common area on a piece of equipment where EPOC's may be located (e.g., back, side, top, bottom).

5.15 *pedestal* — Structural support element upon which equipment or raised floor rests.

5.16 *pre-facilitation* — The stage in the equipment installation process that follows base build and precedes equipment delivery/equipment hookup. Pre-facilitation brings the various facilities services close to the new equipment location, including new facilities services and structural modifications required to prepare the facility to accept the equipment.

5.17 *pre-facilitation pedestal* — A matching equipment floor mounting surface intended to act as a means to expedite equipment hookup, as well as, save fab floor space by having pre-plumbed connections. Ideally, the pedestal would be installed and facilitated to the UPOC's prior to the equipment arrival.

5.18 *raised floor* — The removable floor system installed above the actual building floor within cleanroom environments to control air flow and allow access for utility routing and connection.

5.19 *seismic bracing* — Structural reinforcement to minimize damage due to earthquakes.

5.20 *single line drop* — A hookup strategy where a piece of processing equipment has only one point of connection per facility service. All manifolding for an individual service is handled with in the equipment.

5.21 *specialty gas* — Non-bulk process gases typically stored in cylinders and used to supply one or more process equipment through specialized manifolds.

5.22 *subfab* — The area below or outside of the cleanroom production area that can be a single or multiple levels and may or may not be clean.

5.23 *support equipment* — Ancillary equipment not part of the main chassis.

5.24 *template* — Provides a dimensional outline of the equipment footprint including overall dimensions, equipment datum point, utility connection/penetration locations, equipment interconnect/penetration locations, maintenance and access spaces, and wafer load/unload stations. It can be made from any cleanroom compatible material.

5.25 *tool* — Any piece of semiconductor fabrication or inspection equipment designed to process wafers. Often used synonymously with equipment in the silicon wafer processing industry.

5.26 *tool accommodation* — A methodology by which semiconductor processing equipment is installed in a cost-effective and timely manner.

5.27 *top feed* — Where utility supply lines enter the equipment from the topside.

5.28 *utility point of connection (UPOC)* — The mating fitting or terminal provided by the facility for interconnection with the EPOC for utility supply, the facility end/termination of the hookup at the equipment.

Table 1. Equipment Point of Connection Location Recommendations

Facility Service / Utility	**Bottom Location Plane Preference**	**Back Location Plane Alternate**	
Gas, Bulk	Bottom	Back (lower)	
Gas, Specialty	Bottom	Back (lower)	Back
Exhaust, Corrosive	Bottom	Back (lower)	Back
Exhaust, Flammable	Bottom	Back (lower)	Back
Exhaust, Solvent	Bottom	Back (lower)	Back
Exhaust, General	Bottom	Back (lower)	Back
Chemical Supply, Inorganic	Bottom	Back (lower)	
Chemical Supply, Organic	Bottom	Back (lower)	
Ultrapure Water	Bottom	Back (lower)	
Cooling Water	Bottom	Back (lower)	
Hot Ultrapure Water	Bottom	Back (lower)	
Drain, Inorganic	Bottom	Bottom	Back (lower)
Drain, Waste Chemical, Organic	Bottom	Bottom	Back (lower)
Power, 100V	Bottom	Back (above wet EPOC)	
Power, 200/400V	Bottom	Back (above wet EPOC)	
Fire Suppression	Bottom	Back	
Ancillary Component Interconnect	Bottom	Back (above wet EPOC)	
Signal Cable	Bottom	Back (above wet EPOC)	
Vacuum Foreline	Bottom	Bottom	Back
Process Vacuum	Bottom	Back	

NOTE: Connections located on the top are not recommended because of possible interference with overhead wafer handling and minienvironment equipment.

Table 2. EPOC Consistency Recommendations

Equipment Delivered Compared to	EPOC Locations	EPOC Types	EPOC Sizes
Supplier-provided Facilities Interface Specification	Should match	Should match	Should match
Similar Equipment (Same Model and Revision) for Same Process Application	Should match	Should match	Should match
Similar Equipment (Same Model and Revision) for Different Process Application	Should match for same utilities. Could match unique utilities to unique locations within the appropriate EPOC group.	Should match	Could match, technical reasons should exist for differences.
Similar Equipment (Different Model) for Same Application	Could match	Could match	Could Match

6 EPOC Recommendations

6.1 *Equipment Point of Connection Locations*

6.1.1 Table 1, EPOC Location Recommendations identifies the locations for the specified facility utility services. The locations noted apply to all equipment types, as listed in the document scope, and all equipment configurations including but not limited to boxed equipment, linked equipment, and cluster equipment.

6.1.2 Bottom Location Plane: Facility services are typically provided from the subfab below the waffle slab. The bottom location of EPOC's allows for straight up routing of supply lines, thus reducing equipment footprint and easing facilitation. The locations of EPOC's need to be readily accessible to facilitate hook-up to the UPOC (i.e., accessible from the back or sides). (See Table 1.)

6.1.3 Back Location Plane: If the bottom location plane option is not utilized for hookup, EPOC's should be on back plane of equipment just above the raised floor. (See Table 1.)

6.2 *Equipment Point of Connection Groups*

6.2.1 Equipment points of connection should be grouped together by service type to ensure ease of hookup and qualification of the equipment. The following groups should be considered during the configuration of the equipment.

a) Electrical Power Connections — Includes but is not limited to connections for main electrical utility power supply.

b) Data Communications Connections — Includes but is not limited to factory systems, automated material handling system, and support equipment communication cables and interface connectors.

c) Gas Delivery System Connections — Includes but is not limited to fittings for bulk and specialty gas lines.

d) Liquid Delivery System Connections — Includes but is not limited to fittings for liquid chemical, slurry, ultra pure water, process cooling water, temperature control unit fluids, and industrial water lines.

e) Equipment Effluent Connections — Includes but is not limited to fittings for exhaust, drain, and vacuum lines.

f) Life and Safety System Connections — Includes but is not limited to fire protection, leak detection, emergency machine off (EMO), and hazard warning systems.

6.2.2 A hierarchy should be adhered to when locating these groups of connections on equipment. Data communication wiring should be routed separately from power wiring and connections. Radio frequency (RF) interconnects should be routed and grouped separately. All electrical and electronic wiring should be away from and above water and drain lines.

6.3 *Equipment Point of Connection Consistency*

6.3.1 This section provides key elements to ensure the required consistency of the equipment points of connection. Connection locations on the equipment should be consistent with those defined in the Facilities Interface Specification and should not deviate from equipment to equipment of a specific model and revision. EPOC tolerances need to be +/- 6.35 mm (+/- 1/4 inch) in all directions as measured from the supplier defined equipment datum point. Tighter tolerances should be considered for inflexible or difficult to move hookups such as large diameter (over 2 inch) exhaust or water lines. Connector sizes and types should match exactly.

6.3.2 Table 2 - EPOC Consistency Recommendations identify equipment variations and levels of consistency required for equipment points of connection location, connector type and size.

6.3.3 In Table 2, the term “Should Match” identifies areas that have traditionally been the most costly and where significant gains can be made in achieving installation efficiency . The term “Could Match” identifies areas where modest gains can be made in installation efficiency .

6.4 *Equipment Point of Connection Reduction*

6.4.1 The number of connection points to the equipment should be kept to a minimum. The EPOC’s located on wafer processing equipment should follow a strategy commonly referred to as single line drops, where there is only one point of connection per service per piece of equipment. Where feasible, distribution of a particular facility (e.g., chilled water, waste drains for the same type of chemicals) should be distributed through internal manifolding. Internal equipment manifolding should be configured to allow for configurable equipment sub-systems like process chambers and gas panels. In addition to manifolding, all other interface box functions should be configured on-board the equipment this includes any required shut-off valves, regulators, filters, QC sample valves and pressure indicators.

6.5 *Equipment Point of Connection Interface Panel*

6.5.1 Once EPOC locations and groupings have been defined and standardized for purposes of consistency, the supplier could utilize an interface panel concept for simplifying equipment hook-up. The interface panel should consist of a physical panel that becomes part of the permanent equipment installation. All EPOC’s should be comprehended in the layout of the interface panel using the recommendations for location, grouping, and consistency as discussed in Sections 6.1, 6.2, and 6.3. The supplier should design a standard interface panel layout that supports a given equipment type and all associated revisions.

6.5.2 Common connector technologies, types, and sizes should be utilized along with provisions for containment of hazardous materials. Typically, hazardous production material connections are contained within the equipment

6.5.3 Spacing of multiple gas and liquid connections on the interface panel should provide sufficient access and spacing for installation and maintenance for multiple lines (i.e., orbital weld head, wrench, and test fittings).

7 Pre-facilitation Recommendations

7.1 The pre-facilitation strategy should provide the device manufacturer with the ability to efficiently and accurately install UPOC’s prior to equipment delivery, allowing immediate hook-up of the equipment upon arrival to the fab. The equipment supplier should provide a template and/or jig, as well as a EPOC interface panel (if applicable) or pre-facilitation pedestal prior to the equipment delivery as part of a strategy to support accurate pre-facilitation of utility points of connection. In situations where a pedestal is being utilized (see Section 7.4), the pedestal can serve as an aide to pre-facilitation. The supplier and device manufacturer should discuss and agree on the chosen strategy.

7.2 Templates: The template provides a two-dimensional guide that projects EPOC locations to a two-dimensional surface, typically the floor. This would allow the device manufacturer to open popouts, core holes, etc., and pre-facilitate to a point close to, but not necessarily including, the UPOC. See Figure 1 for a representative example of a Template.

7.3 Jigs: The jig provides a guide that locates the -EPOC’s in three-dimensional space. This would allow the device manufacturer to pre-facilitate to the UPOC’s or at least prefabricate the facility lines and UPOC’s such that final hookup could be accomplished immediately after setting the equipment. See Figure 2 for a representative example of a Jig.

7.4 Pre-facilitation Pedestal: Application notes and three representative examples of using pedestals to support pre-facilitation are included in the related information section at the end of this document.

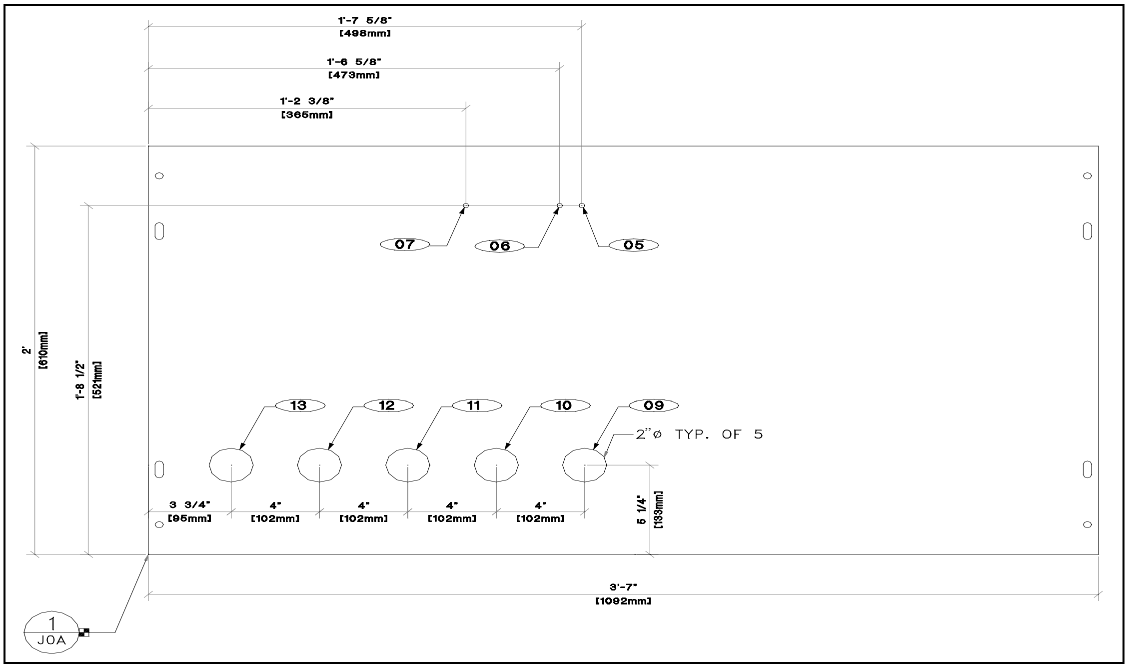

Figure 1
Template Example

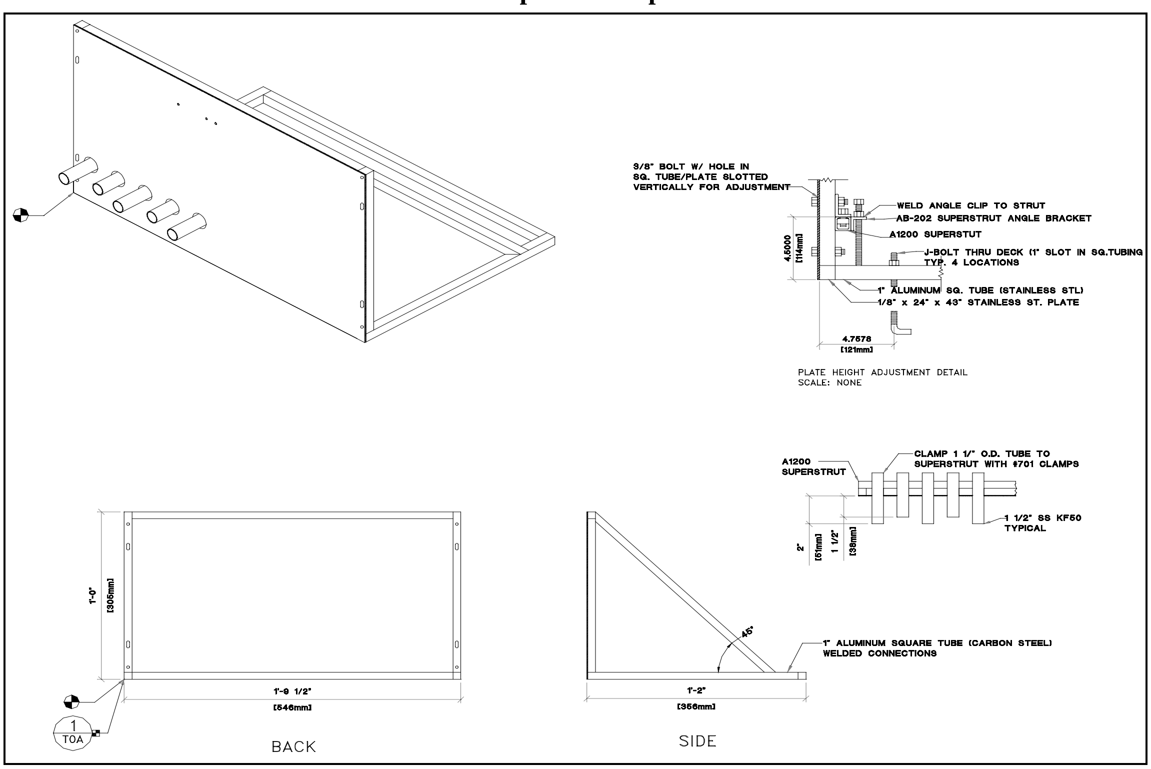

Figure 2
Jig Example

8 Documentation Recommendations

8.1 Equipment suppliers should provide the following documentation concerning equipment point of connections and/or template, jig, and pre-facilitation pedestal to the device manufacturers. The device manufacturer should provide to the supplier, the dates the documentation is required if it is not already specified in this guide.

a) All documentation should be supplied prior to the equipment delivery to the device manufacturer (as deemed appropriate by both the device manufacturer and supplier) and includes a minimum of two sets per piece of equipment .

b) Text and step-by-step procedures should be written in a concise, coherent manner enabling the device manufacturers to achieve and sustain all system performance goals.

c) All drawing documentation provided electronically should be in a format which is compatible with standard computer aided design (CAD) software used by device manufacturers. The CAD format should be compatible with common CAD systems, to include but not limited to, .DWG, .DXF, .DXB, .PS, and .WMF file extensions.

d) The documentation should match the revision of the equipment delivered.

8.2 The equipment supplier should notify the device manufacturer within 30 days of any equipment configuration changes which have an impact on the facility or installation requirements. These changes include, but are not limited to, equipment dimensions, equipment elevation, and equipment points of connection. There should be no changes made within 3 weeks of equipment shipment.

8.3 *EPOC Documentation*

8.3.1 Equipment requirements for utilities and installation should be provided by the equipment supplier. Included EPOC documentation should contain but not be limited to the following information.

a) Floor space requirements (footprint).

b) EPOC matrix indicating service, size/type of connection, location plane, and x,y,z dimensions relative to equipment datum point.

c) Two dimensional drawings showing the equipment points of connection that specify the protrusion depths.

8.3.2 For interface panels, the equipment supplier should provide documentation that includes clear instruction for assembly and positioning the interface panel, a key that clearly identifies which EPOC's are included, and appropriate design drawings such that the device manufacturer can include the interface panel in their respective construction designs.

8.3.3 The following documentation is also required to support the equipment installation activity but is not directly related to the EPOC.

a) Equipment elevation drawings representing all sides of the equipment.

b) Air conditioning and ventilation requirements (acceptable temperature and humidity ranges, exhaust plumbing, etc.).

c) Vibration requirements (acceptable amplitude and frequency).

d) Electrical requirements (voltage, current, wattage, number of phases, power quality, supply voltage wave form requirements, etc.).

e) Vacuum amounts, gases (grade and flow), chilled water flow and other environmental requirements including plumbing requirements (type, size, etc.) for each.

f) A section detailing the procedures to be followed during equipment unpacking and inspection.

g) A section detailing step-by-step set-up procedures that will specifically outline machine assembly and installation on the factory floor.

8.4 *Template, Jig, or Pre-facilitation Pedestal Documentation.*

8.4.1 For templates, jigs, and pre-facilitation pedestals, the equipment supplier should provide documentation that includes clear instruction for assembly, clear instruction for aligning the template, jig, or pre-facilitation pedestal relative to the equipment datum point, and a key that clearly identifies which EPOC's are included. The documentation should also clearly indicate which pieces of equipment (model and revision number) that are supported by a specific template, jig, or pre-facilitation pedestal.

8.4.2 For pre-facilitation pedestals, the equipment supplier should also provide appropriate design drawings and information such that the device manufacturer can include the pedestal design in their respective construction designs. In addition, the supplier should provide applicable documentation required for structural certification.

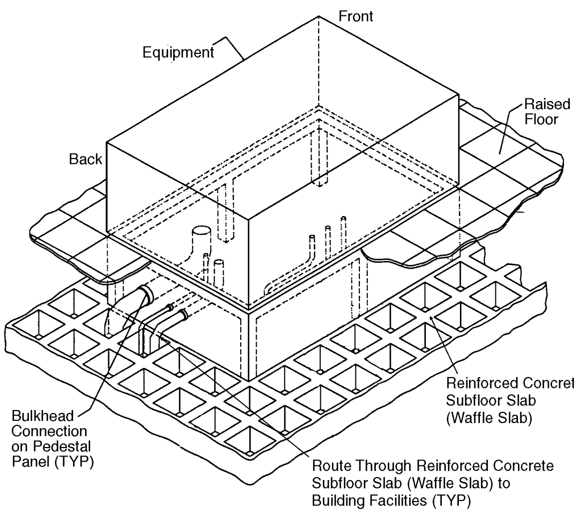
RELATED INFORMATION 1
Pre-facilitation Pedestal Application Notes

NOTE: This related information was balloted, but is not an official part of SEMI E76 and is not intended to modify or supersede the official standard. It has been derived from the work of the originating task force. Determination of the suitability of the material is solely the responsibility of the user.



NOTE: This is only a representative example, a pre-facilitation pedestal can be of an open frame or enclosed box design. Due to bay design and pass thru hole locations a pedestal leg may sometimes become located over an opening thus, a design that allows flexible leg or foot locations should be incorporated.

Figure R1-1

Pre-facilitation Pedestal Example

R1-1. Pre-facilitation Pedestal

R1-1.1 A pedestal provides a permanent base or frame to support the equipment and could be considered an extension of the equipment mainframe In addition, the pedestal could emulate a docking station concept whereby all utilities points of connection could be located and installed prior to equipment delivery. Once the equipment is set on this pre-facilitation pedestal, hookup is relatively quick and easy. When a pre-facilitation pedestal is used, both the device manufacturer and supplier should agree who is responsible for coordinating space utilization within the pedestal.

R1-1.2 When pre-facilitation pedestals are used, the physical location of the EPOC's and corresponding UPOC's can be determined by utilizing templates, jigs, and/or EPOC interface panels in conjunction with the pedestal. The facility utility lines can be prefabricated and installed to the UPOC's prior to setting the equipment on the pre-facilitation pedestal. See Figure R1-1 for a representative example of a Pre-facilitation Pedestal.

R1-1.3 The pre-facilitation pedestal should be provided by the equipment supplier and standardized for a equipment type. In addition, the equipment supplier is responsible for providing the engineering and design of the pre-facilitation pedestal (with input from the device manufacturer as required). Installation of hardware within the pedestal should be done during manufacturing or during pre-facilitation. The following pedestal features (as required by the equipment supplier and end user) are the responsibility of the pre-facilitation pedestal supplier.

a) Vibration isolation, leveling, seismic reinforcing, and load distribution point loading.

b) Connection points from the pedestal to the facility which can be from any plane but should take into consideration potential interference with adjacent tools.

c) Routing of the plumbing and harnesses within the pedestal.

d) Containment of gases and liquids within the pedestal, including possible HPM.

e) Support equipment interconnects within the pedestal

R1-1.4 To use the pre-facilitation pedestal, the distance from the highest point on the waffle slab to the bottom of equipment (typically the top of the raised floor) should be equal to or greater than 0.6 meters (2 feet).

R1-1.5 The pre-facilitation pedestal is recommended for use when these conditions apply.

a) connections located on the bottom of the equipment,

b) maintenance access to the bottom of the equipment as required,

c) repair and spilled liquids access is required underneath the equipment,

d) pedestal is required as an appropriate structural base to set the equipment on,

e) large footprint and/or multiple module for equipment,

f) large number of connections required for the equipment (more than 10), and

g) peripheral components for the equipment (pumps, RF generators, chiggers, etc.) are typically located beneath the equipment in a subfab area.

R1-1.6 The pre-facilitation pedestal is not recommended for use when these conditions apply.

a) small table mounted equipment,

b) no more than one connection on the bottom of the equipment,

c) other connections located on back, top, or side,

d) no maintenance, repair, or spill clean up access requirements beneath equipment,

e) few connections required (less than 10), and

f) few if any peripheral components required or located below equipment in subfab area.

R1-1.7 These conditions are only recommendations and dialog between the supplier and device manufacturer is recommended to determine if a pre-facilitation pedestal is necessary or beneficial for a specific application.

R1-1.8 The Figure R1-2 shows the facility utility lines running up through the waffle slab directly underneath the equipment. The UPOC - EPOC connections occurs at the EPOC interface panel which is located on the top plane of the pre-facilitation pedestal. This concept is preferred by device manufacturers as the number of connections are minimized, no additional space is required on the sides or in back of the equipment for routing, and the HPM lines can be pre-facilitation to the UPOC without additional connections or special double containment requirements.

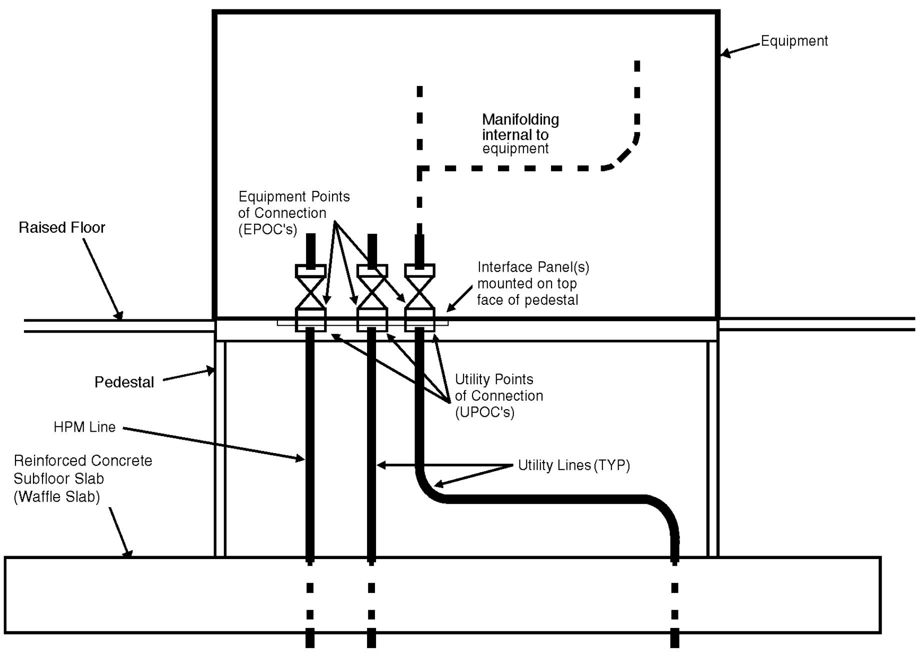


Figure R1-2
Pre-facilitation Pedestal with Top Mounted Interface Panel

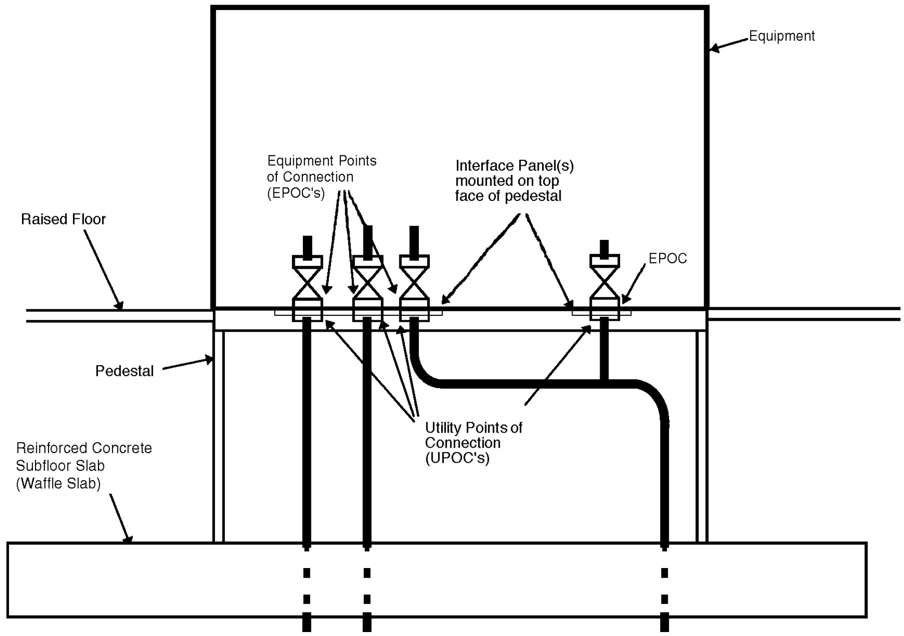

Figure R1-3
Pre-facilitation Pedestal with Multiple Top Mounted Interface Panels

R1-1.9 The Figure R1-3 also shows the facility line running through the waffle slab directly underneath the equipment. In addition, this example depicts situations where there is a physical requirement to manifold connections underneath the equipment. The same advantages as Example #1 apply with the exception of minimizing the number of connections to the equipment.

R1-1.10 The Figure R1-4 shows the facility utility lines running up through the waffle slab to the side/back of the pre-facilitation pedestal and connecting to the EPOC interface panel mounted on the side/back of the pre-facilitation pedestal. In this example a short section of line is required to complete the connection from the EPOC interface panel to the connection within the equipment itself. This short section of line should be prefabricated such that final hookup to the equipment can be accomplished quickly once the equipment is set. It is important to note that this option requires careful consideration on how to accommodate HPM lines. It is generally undesirable to have additional connections in HPM lines or to design the pre-facilitation pedestal itself to provide secondary containment. In this example, the equipment supplier is responsible for the volume in the pre-facilitation pedestal to route and manifold the plumbing as required

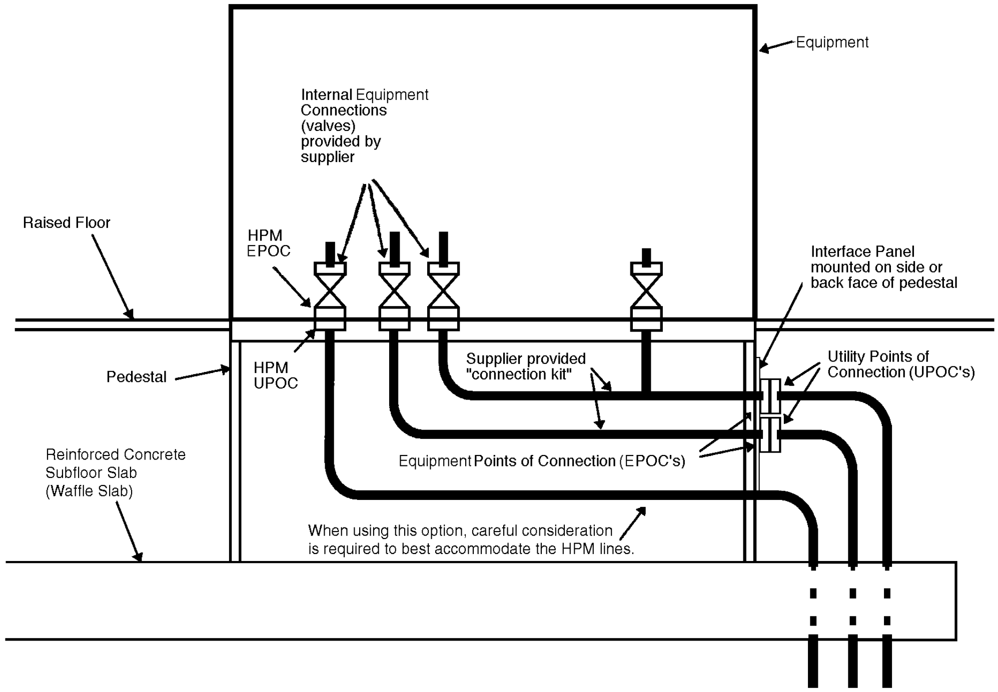

Figure R1-4
Pre-facilitation Pedestal with Side/Back Mounted Interface Panels

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E77-0998
TEST METHOD FOR CALCULATION OF CONVERSION FACTORS FOR A MASS FLOW CONTROLLER USING SURROGATE GASES

1 Purpose

1.1 The purpose of this test method is to quantify a nominal average conversion factor from one gas to another for an MFC and to quantify the conversion factor as function of flow for an MFC.

2 Scope

2.1 This procedure describes a method to determine the MFC conversion factor and function between two gases.

2.2 This document provides a common basis for communication between manufacturers and users.

2.3 The intent of this document is not to suggest any specific testing program, but to specify the test method to be used when testing for parameters covered by this method. Reference operating conditions represent the environmental conditions where the "best" performance can be expected.

3 Limitations

3.1 It is not practical to evaluate performance under all possible combinations of operating conditions. This test procedure should be applied under laboratory (reference) conditions; its intent is to collect sufficient data to form a judgment of the field performance of the MFC being tested.

3.1.1 The results from this test represent the performance of the specific device tested (i.e., make, model, full scale flow and operating conditions). The results may not apply to devices of different manufacture, model, full scale flow or under different operating conditions.

4 Referenced Documents

None.

5 Terminology

5.1 *Acronyms*

5.1.1 *CF (gasA/gasB)* — Conversion factor from Gas A to Gas B.

5.1.2 *D.U.T.*— Device under test

5.1.3 *kPa* — kiloPascal

5.1.4 *MFC* — Mass flow controller

5.1.5 *psia* — Pounds per square inch absolute

5.1.6 *sccm* — Standard cubic centimeters per minute

5.1.7 *slm* — Standard liters per minute

5.1.8 *%F.S.* — Percent full scale

5.2 *Definitions*

5.2.1 *actual flow* — The flow rate as determined by the flow standard used in the test procedure.

5.2.2 *conversion factor* — The ratio of the mass flow-rate of Gas A flowing through an MFC for a given setpoint to the mass flow rate of Gas B flowing through the same MFC and setpoint.

5.2.3 *conversion function* — A relationship that describes the flow dependency of the conversion factor. The conversion function is graphically determined.

5.2.4 *indicated flow* — The flow rate as determined by the output of the D.U.T.

5.2.5 *mean* — The sum of a group of measurements divided by the number of measurements; average.

5.2.6 *measured value* — The actual flow through a D.U.T., expressed in sccm or slm.

5.2.7 *measured value, average* — The sum of all readings (both upscale and downscale) for all cycles, at a single setpoint, divided by the number of these readings.

5.2.8 *nameplate gas* — The gas intended to be controlled by the MFC in operation.

5.2.9 *range* — The algebraic difference between the maximum and minimum values.

5.2.10 *setpoint* — The input signal provided to achieve a desired flow, reported as sccm, slm, or percent full scale.

5.2.11 *span* — The full scale range of the D.U.T.

5.2.12 *surrogate gas* — The gas substituted for the nameplate gas during the calibration process.

5.2.13 *zero drift* — The undesired change in electrical output (i.e., indicated flow), at a no-flow condition, over a specified time period, reported in sccm or slm.

5.2.14 *zero offset* — The deviation from zero at a "no-flow" condition reported in sccm, slm, or mV.

6 Summary of Test Method

6.1 Gas flow and setpoint data are collected for two gases. This data is reduced to quantify the relationship between the flow measurement by the MFC on one gas to another gas.

6.2 This method allows the user to determine the conversion factor between two gases for the MFC and to determine the onset of errors in the MFC calibration due to the conversion factor/function effects.

7 Interferences

7.1 The accuracy rating of the measuring equipment shall be superior to that of the D.U.T. Preferably the measuring equipment will have an accuracy that is four times better than the D.U.T. Calibration equipment must have a valid calibration certificate.

7.2 Take care when using test instruments with a specified accuracy expressed in percent of full scale.

7.3 Installation effects on the flow should be minimized. Monitor pressure upstream of the D.U.T. to ensure that flow variations due to pressure are minimized.

7.4 Verify electrical signals directly at the D.U.T. connector to ensure that the signals at the D.U.T. and standard agree with the signals at the data recording equipment.

7.5 Certain gases will contaminate the D.U.T. This test should be considered a destructive test in such cases.

7.6 All electrical measurements should be read on devices with at least 4.5 digits of resolution. These devices must have valid calibration certifications.

7.7 The device mounting position must be in accordance with the manufacturer's specifications.

8 Apparatus (see Figure 1)

8.1 *Flow Standard* — A device or system that accurately measures the flow and reports the actual flow.

8.2 *Data Acquisition System* — The system that measures the electrical signals from the device under test. The data acquisition system may also read the signals from the flow standard, record test data and control the test sequence.

8.3 *Temperature Probe* — A device to measure the temperature of the flowing gas.

8.4 *Three-Way Valve* — A special valve to switch the system from one gas source to another.

8.5 *Manual Isolation Valves* — Valves that will positively shut off the gas line.

8.6 *Pressure Regulator* — A device that regulates gas pressure to a set value.

8.7 *Pressure Transducer* — An instrument to measure the gas pressure and report it as an electrical signal.

9 Materials

9.1 *Clean, Dry* N_2 — With 99.999% minimum purity, to be used for purging.

9.2 Test Gas "A"

9.3 Test Gas "B"

10 Safety Precautions

10.1 This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and to determine the applicability of regulatory limitations before using this method.

10.2 Follow the manufacturer's specifications and instructions for installation and operation whenever possible. Note any exceptions in the test report.

11 Test Specimen

11.1 Allow all components in the test apparatus to warm up following the manufacturer's specification.

11.2 Take necessary steps when switching gases to ensure that only the desired gas is in the D.U.T. and flow standard at the time the test is performed.

12 Preparation of Apparatus

12.1 Locate the D.U.T. in the test environment to stabilize temperature for 24 hours prior to warm up.

12.2 The reference operating conditions shall be as follows:

12.2.1 *Ambient Temperature* — 23 ± 2°C

12.2.2 *Gas Temperature* — Same as ambient. In the case of a condensible gas, the gas temperature should be maintained as a gradient, with highest temperature at the outlet end of the test set up, and slightly reduced temperatures back to the source. This will ensure that condensing vapors do not accumulate in the test set up. Gradient should simulate actual process parameters where the MFC will be installed.

12.2.3 *Ambient Pressure* — 101.3 kPa (+ 4.7 or – 15.3 kPa)

12.2.4 *Gas Pressure, Inlet* — 172 ± 34 kPa unless the gas is not capable of delivering this pressure, then normal fab operating conditions should be observed.

12.2.5 *Gas Pressure, Outlet* — < 80 kPa

12.2.6 *Relative Humidity* — 40% ± 5%, non-condensing (suggestion: record if outside this range)

12.2.7 *Magnetic Field* — ≤ 50 µT

12.2.8 *Electromagnetic Field* — ≤ 100 µV/m

12.2.9 *Vibration* — ≤ 0.5 m/s at 50 to 200 Hz

12.3 Following the conditioning period (12.1), warm up the device according to manufacturer's specifications.

12.4 Perform an adequate nitrogen purge to ensure all previous gases and moisture have been removed from the system. Prior to corrosive gas testing, a cyclic pump and purge operation is recommended, alternately backfilling with nitrogen, and evacuating the test manifold.

12.5 Leak check the manifold, using available methodologies to verify the test system leak integrity. Introduce the test gas at a sufficient rate and time to ensure the test apparatus is completely filled with the test gas and only the test gas.

12.6 Record the zero offset with line pressure inside the MFC to best simulate normal operating conditions. Line pressure during testing is to be 170.30 kPa (24.7 psia) unless safety practices for the gas under test dictate that a lower line pressure be used.

NOTE: In addition, if this test is performed on hazardous gases, bleeding off gas pressure to obtain atmospheric pressure inside the MFC may not be easy to do.

12.7 Command 100%, and establish flow, then close the downstream isolation valve; then close the upstream isolation valve (see Figure 1).

12.8 With both isolation valves closed, and a 100% setpoint wait until the pressure drop across the MFC is dissipated, ensuring a "no flow" condition through the MFC. Dissipation of the pressure across the MFC is indicated when the indicated flow drops to a steady state value near zero.

12.9 After the electrical output signal has stabilized for at least three minutes, record the MFC zero offset in Table 1.

NOTE: 0%*; the MFC is not controlling gas flow in this state but rather is in a no-flow condition during which MFC zero offset is to be recorded.

12.10 Set the D.U.T. output to zero per the manufacturer's procedure. This may entail automatic re-zeroing of the device, or may require an adjustment by the operator.

12.11 Record the adjusted zero reading in Table 1.

12.12 The reference supply conditions used shall be the reference values specified by the manufacturer. For those instances when a range of values is specified rather than a reference value, the midpoint of the range shall be taken to be the reference value.

12.13 The power supply must be sufficiently rated for the device under test. In addition, the following supply conditions and tolerances shall apply reference voltage:

12.13.1 *AC Supply* — ± 1%

12.13.2 *DC Supply* — ± 0.1%

12.13.3 *Reference Frequency* — ± 0.1 Hz

12.13.4 *Harmonic Distortion of AC Supply* — ≤ 1%

12.13.5 *Ripple of DC Supply* — ≤ 0.1% rms

13 Procedure

13.1 For the gas of interest, collect flow data for five cycles of 11 different setpoints. The setpoints are 100%, 90%, 80%, 70%, 60%, 50%, 40%, 30%, 20%, 10%, and 0% of full scale. Begin collecting data at the 50% level then 60%, 70% and so on. Record the data on the form in Table 1.

13.1.1 When a non-zero setpoint is given, allow the MFC to stabilize at the desired setpoint by observing the reading on the flow standard. Record the data once the MFC has stabilized at the current setpoint.

NOTE: If, during data acquisition at a nominal setpoint, the instrument fails to stabilize, the D.U.T. is not stable enough for the test to proceed.

13.1.2 When a zero setpoint is given, perform the procedure described in Section 12.7–12.9 (do not rezero the MFC) to ensure a "no-flow" condition through the MFC and record the zero offset indicated by the MFC's output in Table 1.

13.2 Use Table 1 to record the following:

13.2.1 *Column A* — D.U.T. setpoint (% F.S.)

13.2.2 *Column B* — D.U.T. flow indication (% F.S.)

13.2.3 *Column C* — Raw flow standard reading (sccm)

14 Calculations or Interpretation of Results

14.1 For each test gas, calculate the mean and standard deviation of the corrected flow readings, for common setpoints on the same gas. For example, calculate the mean and standard deviation for all the 0% readings for a given gas, then repeat the calculations for the 10% readings, etc. Record the results on Table 2 in Columns B and C. Plot the result as illustrated in Figure 2.

14.2 *Conversion Factors* — The conversion factor between any Gas A and any Gas B at each setpoint is calculated as follows:

$$\textit{conversion factor (Gas A / Gas B) @ X\% setpoint} = \frac{\textit{average actual flow @ X\% setpoint on Gas A}}{\textit{average actual flow @ X\% setpoint on Gas B}}$$

where X = setpoint value

14.3 Calculate the conversion factors for the gas tested and record in Table 3.

SEMI E78-0998
ELECTROSTATIC COMPATIBILITY - GUIDE TO ASSESS AND CONTROL ELECTROSTATIC DISCHARGE (ESD) AND ELECTROSTATIC ATTRACTION (ESA) FOR EQUIPMENT

1 Purpose

1.1 The purpose of this document is to minimize the negative impact on productivity caused by static charge in semiconductor manufacturing environments. It is a guide for establishing electrostatic compatibility of equipment used in semiconductor manufacturing.

1.2 Electrostatic surface charge causes a number of undesirable effects in semiconductor manufacturing environments. Electrostatic discharge (ESD) damages both products and reticles. ESD events also cause electromagnetic interference (EMI), resulting in equipment malfunctions. Charged wafer and reticle surfaces attract particles (electrostatic attraction or ESA) and increase the defect rate. Charge on products can also result in equipment malfunction or product breakage. Operating problems and additional product defects due to static charge can have a negative impact on the cost of ownership of semiconductor manufacturing equipment (refer to SEMI E35).

1.3 An increasing amount of semiconductor production is done in minienvironments or within the production equipment. The majority of static related problems occur while the product is in its carriers, or being transferred from them, by the production equipment.

1.4 Static control methods can be incorporated in the equipment design to reduce static charge to acceptable levels. This guide will be used primarily by equipment manufacturers during the design of their equipment. There are test methods available (see Sections 6 and 7 of this guide) to demonstrate the effectiveness of the static control methods. The end user will be able to use the same test methods to verify compliance with an equipment purchase specification.

2 Scope

2.1 The scope of this document is limited to methods of measurement and a guide for the maximum recommended level of static charge on:

— Product or reticles

— Carriers

— Parts of the input/exit ports of equipment and minienvironments

2.2 This document presents a matrix of maximum recommended levels of static charge on products, reticles, carriers, and the input and exit ports of production equipment or minienvironments. The purpose is to:

— Reduce product, reticle, and equipment damage due to ESD

— Reduce equipment lock-up problems due to ESD events.

— Reduce the attraction of particles to charged surfaces.

2.3 This document references SEMI E43 and other methods of measuring static charge. Related Information 1 of this document contains a theoretical investigation of electrostatic particle attraction, as well as case histories from users and equipment manufacturers as to the static charge problems encountered and how they were solved. A bibliography of related technical papers is also included. Related Information 2 describes static control methods commonly used in semiconductor manufacturing.

3 Limitations

3.1 *Static Measurements* — Measurements of electrostatic quantities such as charge, electric field, and voltage are difficult to make. The nature of the object (insulator or conductor), its geometry, its surroundings, and the measuring equipment itself, are only a few of the factors affecting the accuracy of an electrostatic measurement.

3.1.1 Similarly, it is difficult to relate the measurement of an electrostatic quantity to its effect on products or equipment. For example, an ESD simulator produces a standardized discharge waveform when a capacitor is discharged at a known voltage. This device is used to establish the ESD damage threshold for semiconductor products, or the effect of ESD on equipment. While the amount of charge transferred is known ($q = CV$), the maximum current that results is not. There is no guarantee that the same amount of charge would produce the same results if different values of capacitance and voltage were used.

3.2 *Location* — The test methods and maximum recommended levels of static charge on product, reticles, and carriers are meant to be applied at the input/exit ports of production equipment, and when possible within the equipment. This document is not meant to be applied in any way that affects the process within the equipment.

3.3 *Test Methods* — The test methods referenced in this document do not guarantee precise measurements of static charge levels. The maximum static charge levels recommended in this document have large tolerances. (See Section 15.1.)

3.4 *Static Charge Control* — There are a variety of static related issues in a semiconductor manufacturing environment. The issues are complex due to the wide range of electrostatic problems, and device or equipment sensitivities to these problems. This guide contains general recommendations. Users of this document are cautioned that specific static related problems may require or allow different levels of static charge than are recommended in this document.

5 Terminology

5.1 *Definitions*

5.1.1 *deposition velocity* — Particle flux to a surface (number of particles deposited per unit area per unit time) divided by the particle concentration adjacent to the surface boundary layer.

5.1.2 *electromagnetic interference (EMI)* — Any electrical signal in the non-ionizing (sub-optical) portion of the electromagnetic spectrum with the potential to cause an undesired response in electronic equipment.

5.1.3 *electrostatic attraction (ESA)* — The force between two or more oppositely charged objects. The result is increased deposition rate of particles onto charged surfaces, or movement of charged materials.

5.1.4 *electrostatic compatibility* — Charge control adequate for interequipment transfer of products, reticles, and carriers without electrostatic problems.

5.1.5 *electrostatic discharge (ESD)* — The rapid spontaneous transfer of electrostatic charge induced by a high electrostatic field.

NOTE: Usually the charge flows in a spark between two objects at different electrostatic potentials.

5.1.6 *equipment interrupt* — Any variance from the specifications of equipment operation, whether or not the equipment recovers automatically. Interrupts include, but are not limited to, equipment stoppage, equipment data errors, and physical mishandling of products (reference SEMI E10).

5.1.7 *ESD simulator* — An instrument providing a specified electrostatic discharge current waveform when discharged directly to a product or equipment part.

5.1.8 *input and exit ports* — The locations where product and/or product carriers are placed to allow the equipment to process them, or where they are removed from the equipment after processing.

5.1.9 *minienvironments* — A localized environment created by an enclosure to isolate the product from contamination and people.

5.1.10 *product* — Any unit intended to become a functional semiconductor device.

1 ESD Association, 7900 Turin Road, Rome, NY 13440

5.1.11 *sensitivity level 1* — Product, reticles, and equipment are extremely vulnerable to damage and/or problems from static charge.

5.1.12 *sensitivity level 2* — Product, reticles, and equipment are highly vulnerable to damage and/or problems from static charge.

5.1.13 *sensitivity level 3* — Product, reticles, and equipment have nominal vulnerability to damage and/or problems from static charge.

5.1.14 *sensitivity level 4* — Product, reticles, and equipment have negligible vulnerability to damage and/or problems from static charge.

5.2 *Description of Terms Specific to this Standard*

5.2.1 *carrier* — A device for holding wafers, dies, packaged integrated circuits, or reticles for various processing steps in semiconductor manufacturing.

6 Requirements

6.1 *Measurement Methods and Instrumentation* — No single method of testing for static charge can determine a "safe" level. The amount of static charge, the distribution of static charge on an object, and the nature of the static discharge will all interact to determine if the charge level is safe. It will be difficult to determine levels that ***guarantee*** static related problems are totally eliminated. The goal of this guide is to assist the user in identifying static charge levels likely to cause problems in process equipment. This guide should provide the user with enough insight to define a test methodology for each static problem and understand its limitations.

6.2 *ESD Damage*

6.2.1 When considering direct ESD damage to an object (product, reticle, or equipment), the important parameter is the current accompanying the charge transfer to or from the object. Under a fixed set of test parameters, the damaging amount of current due to the charge transfer to or from the object can be determined. Established test methods exist for determining the threshold of damage to a particular object. ESD simulators of various types are used for this purpose. Refer to EOS/ESD Association Standards listed in Section 4 for further information concerning device testing.

6.2.2 The end user should determine what is damaging current level due to charge transfer to product or reticles that will be handled in a particular piece of production equipment.

6.2.3 In the context of production equipment, it appears important to know the charge on the product, its carriers, and any other objects that might directly contact the product. Charge is measured in coulombs, or more conveniently in nanocoulombs (10^{-9} coulombs) for this purpose. The measurement is made with instrumentation known as a Faraday Cup, as shown in Section 7, Figure 1.

6.2.4 A charged object, like an integrated circuit, is placed in the Faraday Cup and a reading is taken of the charge on it. It will be necessary to obtain an instrument with a large enough "cup" for wafers, cassettes, and other equipment parts. It will also be necessary to get the objects into the cup without altering their charge levels. Further information on making these measurements should be available from the manufacturers of the measuring equipment.

6.2.5 The user should determine with an ESD simulator what levels of ESD cause product, or reticle damage. The equipment manufacturer will need to determine with an ESD simulator what levels of static charge cause equipment damage.

6.2.6 It will be the responsibility of the equipment manufacturer to demonstrate that equipment operation does not generate more than the allowable amount of charge on product, carriers or equipment parts. This is shown in Section 7, Figure 2.

6.3 *Particle Attraction*

6.3.1 Electrostatic attraction (ESA) of particles can occur due to the electrostatic field created by the charge on the surface of an object. Both the field strength and, usually to a lesser degree, the divergence of the field influence the electrostatic contribution to particle deposition velocity. Electrostatic particle deposition velocity also depends on particle size and particle electrical charge. Unfortunately, even under controlled laboratory conditions, accurate measurements of electric field strength, particle size distribution, and, especially, particle charge, are difficult. Of these three parameters, electric field measurements are the most likely to be available.

6.3.2 Measurements of electrostatic field can be made with a commonly available electrostatic fieldmeter. The units of electrostatic field are volts/cm (volts/inch). Precise measurements will be difficult as the presence of the measuring instrument changes the field characteristics and may overstate the actual level of electrostatic field. This is shown in Section 7, Figure 3. SEMI E43 describes measurement techniques using an electrostatic fieldmeter.

6.3.3 Electrostatic deposition velocity depends only on electric field, particle size and particle charge. However, the concentration of particles deposited on a surface also depends on the particle concentration in the equipment area and the length of the exposure time during which particle deposition occurs. Mechanisms other than electrostatic deposition, such as gravitational settling and diffusion, can also contribute to particle deposition. The concentration of particles deposited by these non-electrostatic mechanisms will also vary with particle concentration in the equipment ambient and exposure time.

6.3.4 Comparisons of the electrostatic deposition velocity with the deposition velocities associated with these other deposition mechanisms is the key for determining threshold values of allowed electrostatic field from the viewpoint of particle deposition. Such comparisons are the basis for estimating the allowed values of electrostatic field presented in Appendix A1-2.2 and Related Information R1-2. Users and equipment manufacturers should determine and agree on ambient particle sizes and concentrations, and product exposure times.

6.4 *Equipment ESD*

6.4.1 Equipment ESD immunity is being addressed in general through a number of international standards including IEC 1000-4-2 and EN50082-2 for European CE compliance. Measurements are made using an ESD simulator which is described in these standards.

6.4.2 The ESD simulator is used to create both a direct discharge to the surface of the equipment and an air discharge to a surface 10 cm (4 inches) away from the equipment. The ESD simulator charges a 150 picofarad capacitor (C) to a known voltage (V) and then discharges it to produce a standardized discharge waveform. Knowing the voltage and capacitance involved in this test means the total charge can be calculated by the equation $q = CV$. For example, a 4000 volt discharge (IEC 1000-4-2 test level) transfers a charge, $q = 600$ nanocoulombs.

6.4.3 The value of the capacitor (C) in the ESD simulator is specified in the international standards. It should not be assumed that a different value of capacitance and voltage that produce the same charge transfer of 600 nanocoulombs would have the same affect on a specific piece of equipment. Discharge currents will vary with the impedance of the discharge path and with the voltage. It is, however, impractical to test all possible combinations. For the purposes of this guide, the parameters of the ESD simulator specified in the standards for equipment ESD immunity will be used.

6.4.4 For true ESD immunity, an ESD event in equipment must not disturb either the equipment it occurs in, or another nearby piece of equipment. Charge on product or carriers transferred from one piece of equipment must not disturb the operation of subsequent equipment. It will be a systems issue to make sure that **all** equipment in a facility meets the required ESD immunity standards.

6.4.5 The range of reactions in equipment to an ESD event runs from *transient errors* that are automatically corrected, to *hard errors* that cannot be corrected without manual intervention or damage the equipment. While small numbers of transient errors may be acceptable from the point of view of equipment operation, they may still cause unacceptable product losses.

6.4.6 The user and manufacturer must determine with an ESD simulator what levels of ESD cause equipment interruptions. The user must determine if any of these equipment interruptions caused by ESD are acceptable.

6.4.7 In setting a level to provide ESD immunity for an individual piece of equipment from static charge on products and carriers, the charge on these items should be kept below the levels determined by ESD simulator testing.

6.4.8 The Faraday Cup measurement can be used for this purpose. If equipment has been tested for ESD immunity and passes a 4000 volt test, then total charge on product and carriers leaving this equipment should be kept below 600 nanocoulombs. Any product transferred at this level should not be handled by other equipment with a lower ESD immunity. A possible implementation of this test method is shown in Section 7, Figure 4.

7 Apparatus

7.1 *ESD Damage* — The apparatus for determining the ESD damage thresholds for products will depend on the test methods used. See Section 4 for additional information. For measuring the charge generated on product, reticles, or carriers, the Faraday Cup test method is shown in Figure 1.

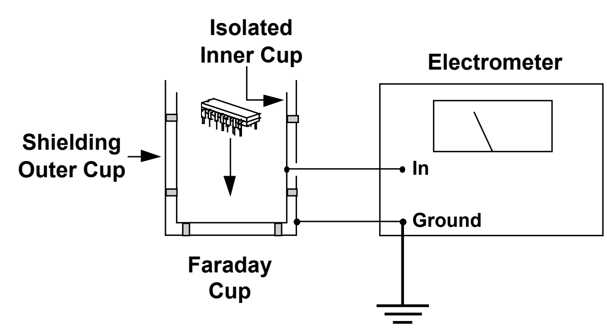

Figure 1
Faraday Cup Charge Measurement

7.1.1 The relationship between ESD simulator testing for product damage and charge measurements using the Faraday cup is shown in Figure 2.

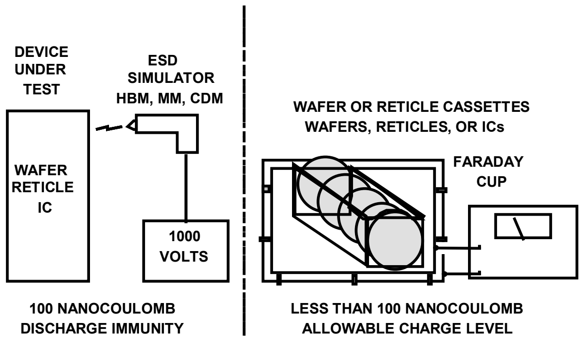

Figure 2
ESD Damage Testing

7.2 The instrument used for making electrostatic field measurements is known as an electrostatic fieldmeter. Instructions concerning its use should be obtained from the instrument manufacturer and SEMI E43. The measurement configuration shown in Figure 3 illustrates the effect of the instrument on the measurement. In most cases the presence of the fieldmeter will increase both the flux from the charged surface and the divergence of the electric field lines. The fieldmeter will generally indicate a higher value of electric field than would be present without the fieldmeter.

7.3 The instrumentation and test methods for determining the ESD sensitivity of equipment are described by IEC 1000-4-2 or other acceptable test methods. The amount of static charge determined by this test method is to be compared with the charge measured on products and carriers with the Faraday Cup test method. Figure 4 illustrates the two methods.

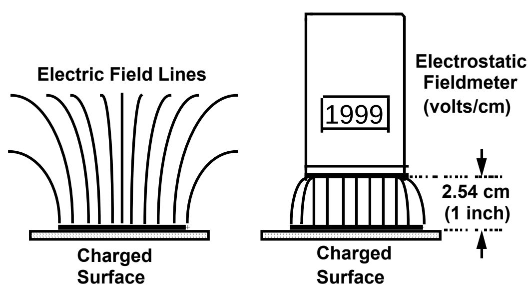

Figure 3
Electrostatic Field Measurement

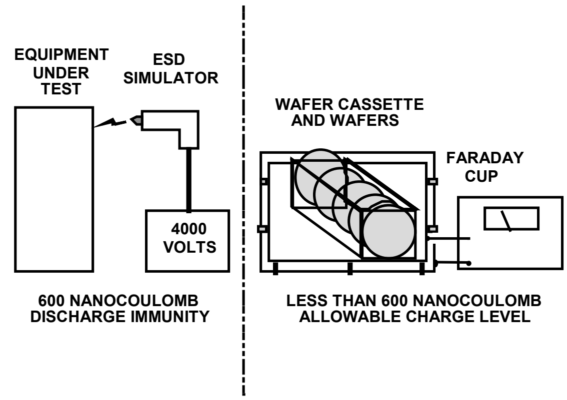

Figure 4
ESD Immunity Testing

8 Safety Precautions

8.1 *Personnel* — Static charges can create safety hazards during some semiconductor production processes. ESA or ESD events that result in the jamming or breakage of product in high speed equipment may create a personnel hazard. ESD events that produce sparks must be prevented in areas that use flammable or explosive chemicals or gases. ESD events to personnel are usually not harmful, but they may result in an unwanted reflex, or "startle" reaction. This reflex may create a personnel hazard, particularly in the vicinity of moving equipment or where caustic chemicals are in use. It may be necessary to use additional static charge control methods, beyond those used inside the equipment, to minimize these personnel hazards.

8.2 *Measurement Safety* — Users should exercise caution while making static charge measurements in the vicinity of moving parts of production equipment, or in areas where static potentials on ungrounded conductors may exceed 30,000 volts. Refer to SEMI E43 for additional measurement safety considerations.

9 Test Specimen

9.1 The user and equipment manufacturer will need to agree on:

— The type(s) of testing to be performed.

— Who will do the testing.

— The number and type of test samples.

— The number of measurements.

— Acceptable test results.

9.2 The operating history of the equipment prior to, or during testing (e.g., warm-up time, type of carrier, number of products processed, operating speed), and all appropriate environmental conditions (e.g., temperature, humidity, airflow) should be agreed upon and documented.

10 Preparation of Apparatus

10.1 Depending on the type of testing to be done, consult the appropriate testing document for apparatus preparation. See Sections 4 and 16 for additional information.

11 Calibration and Standardization

11.1 Depending on the type of testing to be done, consult the appropriate testing document for apparatus calibration and verification. See Sections 4 and 16 for additional information.

12 Procedures

12.1 Refer to Sections 6 and 7 and the appropriate test methods of Sections 4 and 16.

12.2 *ESD Damage*

12.2.1 Users shall establish product damage thresholds for their products. Measurement methods for integrated circuits are described in the documents contained in Sections 4 and 16. Appropriate measurement methods for ESD damage to wafers, reticles, and other items may be adapted from the instrumentation used in these test methods. Appendix A1-2.1 and Related Information R1-1 contain additional information to select an appropriate sensitivity level to reduce ESD damage.

12.2.2 Measurement of ESD damage thresholds are made in units of nanocoulombs (nC = 10^{-9} coulombs).

12.2.3 The Faraday Cup method is used to determine the static charge levels on products, product carriers and equipment parts. Each item shall be transported to the Faraday cup in a way that does not alter its charge level. Consult the measurement equipment manufacturer's instructions for recommendations on how to achieve this.

12.2.4 Measurements should be made of products, carriers, and materials in the equipment input/exit ports after significant amounts of product have been handled under normal manufacturing conditions. Measurements should be made of products and their carriers after they have undergone normal processing in the equipment under test. Typically five measurements of products and/or carriers should be sufficient to demonstrate compliance with the selected Sensitivity Level.

12.2.5 Measurements should be made on each of three successive days after equipment has stabilized in its normal operating mode (e.g., after two hours).

12.3 *Particle Attraction*

12.3.1 Users should work with equipment manufacturers to determine ambient particle levels and product exposure times during processing. Appendix A1-2.2 and Related Information R1-2 contain information to select an appropriate Sensitivity Level to reduce electrostatic attraction of particles.

12.3.2 Electrostatic field measurements on products, product carriers, and equipment surfaces should be made in at least three different locations on any item. Locations should be separated by approximately three times the distance between the measuring instrument and the measurement location. For most electrostatic fieldmeters measuring at 25.4 mm (1 inch), the measurement locations will be 76.2 mm (3 inches) apart. Refer to SEMI E43 for additional measurement considerations. Measurements of electrostatic field are expressed in volts/cm or volts/inch.

12.3.3 Measurements should be made on products, carriers, and materials in the equipment input/exit ports after significant amounts of product have been handled under normal manufacturing conditions. Measurements should be made of products and their carriers after they have undergone normal processing in the equipment under test. Typically five measurements of products and/or carriers should be sufficient to demonstrate compliance with the selected Sensitivity Level.

12.3.4 Measurements should be made on each of three successive days after equipment has stabilized in its normal operating mode (e.g., after two hours).

12.4 *Equipment ESD*

12.4.1 Equipment manufacturers should determine the effects of ESD on their equipment using an ESD Simulator and the appropriate test methods (IEC 1000-4-2 or others). Users should agree on the types of equipment interrupts that are acceptable (if any). Appendix A1-2.3 and Related Information R1-3 contain additional information to select an appropriate sensitivity level to reduce ESD-related equipment interruptions.

12.4.2 Compliance with the desired Sensitivity Level may be demonstrated using the Faraday Cup method described in Sections 6.4 and 7.3.

12.4.3 Measurements should be made on products, carriers, and materials in the equipment input/exit ports after significant amounts of product have been handled under normal manufacturing conditions. Measurements should be made of products and their carriers after they have undergone normal processing in the equipment under test. Typically, five measurements of products and/or carriers should be sufficient to demonstrate compliance with the selected Sensitivity Level.

12.5 Equipment used in semiconductor manufacturing should meet the following levels shown in Table 1 for protection from problems caused by static charge.

Table 1 Recommended Sensitivity Levels

	Electrostatic Discharge (Nanocoulombs)	*Particle Attraction (Volts/cm)*	*Equipment Malfunction (Nanocoulombs)*
Level 4	100	4000	1200
Level 3	50	400	600
Level 2	10	200	300
Level 1	1	100	150

12.5.1 Sensitivity Level 4 compliance means that products, reticles, and carriers can leave the equipment with up to the recommended amounts of static charge or electrostatic field measured on them according to the test method used. This level essentially states that the equipment is used in a process that has no significant problems handling charged product, nor are there issues associated with contamination or ESD damage.

12.5.2 At levels 1, 2, or 3 a decision should be made as to what is the most serious static charge problem. The Sensitivity Level and test methods are chosen accordingly. The lower the level of static charge allowed, the more static control measures the equipment manufacturer may need to install.

12.5.3 Level 1 may be used primarily by manufacturers of specialized components such as: gallium arsenide semiconductors or magneto-resistive (MR) disk drive read heads; those experiencing significant losses due to contamination; or those using specialized equipment with low immunity to ESD or EMI.

12.6 The levels listed in Table 1 have been determined as the result of analysis of working conditions, or experiments done in operating semiconductor facilities. Justifications for these levels are found in Appendix 1. The actual levels to be used for any piece of production equipment may be decided by agreement between the user and manufacturer of the equipment.

12.7 Other levels may be appropriate under specific equipment conditions and for specific devices.

13 Calculations

13.1 A series of five measurements should be made. The average of the five measurements should not exceed the recommended level.

14 Reporting Results

14.1 Data records should contain the following information:

— Description of equipment under test including model and serial numbers.

— Description of the equipment operating conditions and environment.

— Measurement equipment and last calibration date.

— Description of objects measured and measurement locations.

— Humidity and temperature at measurement location when measurements were made.

— Results of measurements.

— Personnel making the measurements.

— Any other relevant comments.

15 Precision and Accuracy

15.1 *Accuracy of Test Methods* — The test methods referenced in this document do not guarantee precise measurements of static charge levels. Similarly, maximum static charge levels recommended in this document are not stated as precise requirements. Accuracy of approximately ± 20% is acceptable in all measuring instrumentation. At low static charge levels or for more accurate measurements, alternative instrumentation and test methods may need to be used.

APPENDIX 1
DETERMINING STATIC SENSITIVITY LEVELS

NOTE: This appendix was approved as an official part of SEMI E78 by full letter ballot procedure. This appendix offers information related to the Sensitivity Levels contained in Section 12.5.

A1-1 Recommended Levels

The recommended charge and electrostatic field levels in this guide are not based on specific protection thresholds for individual devices or process tools. Rather, their aim is to classify the types of ESD events or static levels that are likely to be of concern. Tool manufacturers and users should determine the type of events that are of most concern to their products and process, so as to apply this guide to their needs. Information on specific device damage thresholds and tool sensitivities is best determined on an individual basis.

A1-2 Justification of Guide Recommendations in Section 12.5 and Table 1

A1-2.1 *Recommendations for ESD Damage*

A1-2.1.1 Related Information R1-1 discusses test methods for determining ESD damage thresholds for semiconductor devices. Devices are qualified according to the highest ESD stresses they can withstand without measurable change in their operating parameters. This section attempts to develop guide recommendations for minimizing ESD damage based on that discussion.

A1-2.1.2 *Industry Device Damage Levels* — Each of the test methods, HBM, MM, and CDM have a set of qualification levels defined. These are contained below.

HBM Classification Levels

Class	*Voltage*
0	< 250
1A	250–499
1B	500–999
1C	1000–1999
2	2000–3999
3A	4000–7999
3B	≥ 8000

MM Classification Levels

Class	*Voltage*
M1	< 100
M2	100–199
M3	200–399
M4	≥ 400

CDM Classification Levels

Class	*Voltage*
C1	< 125
C2	125–249
C3	250–499
C4	500–999
C5	1000–1499
C6	1500–1999
C7	≥ 2000

A1-2.1.3 *Charge Levels for ESD Damage* — As discussed in Related Information R1-1.4, ESD Simulator testing uses different capacitances for each model. For HBM it is 100 picofarads, for MM it is 200 picofarads, and for CDM it depends on the capacitance of the actual device being tested. In any case, it is charge (charge = voltage × capacitance) that damages the device. It would seem appropriate, therefore, that the guide recommendations in Table 1 Section 12.5 be stated in units of charges (e.g. nanocoulombs).

A1-2.1.4 *Guide Recommendations* — Based on industry testing reflected in device data sheets, there appears to be a wide range for ESD immunity in semiconductor devices. This document deals primarily with ESD occurring within equipment. HBM type ESD discharges are the least likely to occur within equipment. Charged equipment parts contacting devices (MM) and charged devices contacting machine parts (CDM) are the most likely causes of ESD damage to devices in equipment. The following sensitivity levels are defined with respect to the existing industry MM and CDM classifications.

Level 4 — Devices are essentially unaffected by any reasonable level of ESD encountered in equipment. Devices pass testing at levels higher than MM Class M4 (400 volts × 200 picofarads = 80 nanocoulombs). Equipment should not create or store charge on itself or on devices in excess of the guide recommendation.

Guide recommendation (table 1 in Section 12.5) – 100 nanocoulombs.

Level 3 — Devices are affected by moderate levels of static charge in equipment. Devices pass testing for MM Class M4 (400 V × 200 picofarads = 80 nanocoulombs) and most of MM Class M3 (over 250 volts × 200 picofarads = 50 nanocoulombs). Guide recommendation (Table 1 in Section 12.5) – 50 nanocoulombs.

Level 2 — Devices are damaged by lower levels of static charge in equipment. Devices pass testing at MM Class M1 (100 V × 200 picofarads = 20 nanocoulombs) and CDM Class C4 (1 kV × 10 picofarad device = 10 nanocoulombs). Guide recommendation (Table 1 in Section 12.5) – 10 nanocoulombs.

Level 1 — Devices are easily damaged by even low levels of static charge in equipment. Devices pass testing at CDM Class 1 (125 V × 10 picofarads device = 1.25 nanocoulombs). In most cases simulator equipment is not designed to do testing at these very low levels for MM. Guide recommendation (Table 1 in Section 12.5) – 1 nanocoulombs.

A1-2.2 *Recommendations for Particle Deposition*

A1-2.2.1 Related Information R1-2 discusses the enhancement of particle deposition due to electrostatic fields from charges on the wafer surface. This section attempts to develop the guideline recommendations for minimizing particle deposition based on that discussion.

From Equation 3 of Related Information R1-2.2,

$$N/A = cv_{elect}t \qquad (12)$$

where N/A equals the particulate burden added to a wafer during exposure time t, exposed to a particle concentration c, in an environment characterized by an electrostatic particle deposition velocity, v_{elect}.

Target values for N/A are given in the National Technology Roadmap for Semiconductors (NTRS, 1994). These target values vary from 0.02–0.01 defects/cm^2, depending on the critical dimensions of the technology, and represent an upper value of the acceptable particulate concentration on a wafer at the conclusion of the fabrication sequence. For individual processing steps making up the fabrication sequence the target values are lower yet.

The variables c and t are process step dependent and may or may not be controllable. Clearly minimizing both of these variables is desirable in order to minimize particle deposition on a wafer in any environment.

The only variable in Equation 12 that depends on electrical forces is v_{elect}. Both the particle charge and the electric field in the vicinity of the wafer affect the magnitude of v_{elect}. Particle charge is generally unknown unless it is deliberately controlled by a neutralizing action, such as flooding the environment with both positive and negative charges. Under these conditions a Fuchs type charge distribution is a reasonable assumption for the particle charge. This assumption was used to calculate the values of E_0 in Table R1-2 of Related Information R1-2.3.2.

When the environmental electric field is less than E_0, deposition of electrically "neutralized" particles is dominated by diffusion. When the environmental electric field is greater than E_0, electrostatic forces dominate particle deposition even when particle charge has been "neutralized." Values of E_0 for a Fuchs charge distribution can be calculated from Related Information R1-2.3.2 Equation 10. For particle charge greater than the Fuchs charge, v_{elect} increases by a factor of q/q_{Fuchs}. Unfortunately, the actual particle charge q is generally unknown.

Using the process step values of c and t and the value of v_{elect} calculated from Equation 10, the value of N/A for any process step can be estimated. Alternatively, having a target value of N/A and estimating the value of v_{elect} as outlined in the previous paragraphs, allows one to calculate the tolerable value of ct:

$$ct = [N/A]/v_{elect} \qquad (13)$$

Setting N/A = 0.01/cm^2 and using Equation 10 to calculate v_{elect} for a 0.1 µm particle at various values of electric field and particle charge, target values of ct can be calculated from Equation 13. The allowed exposure times in an ISO Class 1 environment ($c \leq 10^{-5}$ particles/cm^3) can be deduced as shown in the following table:

Table A1-1 Allowed Exposure Times in an ISO Class 1 Environment

E V/cm at One Wafer Radius	q/q_{Fuchs}	v_{elect} cm/sec	*ct sec/cm^3*	*max t in ISO Class 1 sec*
4000	1	0.8	0.01250	1250
	2	1.6	0.00625	625
	10	8.0	0.00125	125
400	1	0.08	0.1250	12500
	2	0.16	0.0625	6250
	10	0.8	0.0125	1250
200	1	0.04	0.250	25000
	2	0.08	0.125	12500
	10	0.4	0.025	2500
100	1	0.02	0.50	50000
	2	0.04	0.25	25000

	10	0.2	0.05	5000

Using higher values of *N/A* in Equation 13 will increase the acceptable values of *ct* and max *t*. Accepting higher values of *c* will reduce max *t*. The guideline table provides an order of magnitude assessment of the degree of electric field and charge control needed in specific operations. Minimum field and minimum particle charge are always the goal but usually not practically achievable. This guideline table provides background estimates of envelopes for acceptable operation in electrically charged environments.

A1-2.2.2 The following simplified table is offered as an alternative to Table A1-2 based on the following assumptions:

1. Calculations made for Federal Standard 209E Class 1 ($c \leq 0.00124$ particles/cm^3).
2. The value of the electrostatic field is referenced at a distance of one wafer radius from the wafer. While electrostatic field measurements can certainly be made at this distance, they are typically made at 2.5 cm (1 inch) with common instrumentation. This is described in SEMI E43. Measurements made at this smaller distance will be proportionally higher, but under varying measurement conditions, it is difficult to determine a precise relationship between electric field and measurement distance. To provide a suitable safety factor, assume a linear relationship, rather than one proportional to the square of the distance. For example, with a 200 mm wafer, 4000 Volts/cm at 2.5 cm would result in 1000 Volts/cm at 10 cm, rather than 250 Volts/cm.
3. The proportionality effect of q/q_{Fuchs} has been explained, as has the difficulty in actually determining any value for it. For simplicity, the table includes only the $q = q_{Fuchs}$ condition.
4. *N/A* = 0.016 defects/cm^2 as specified for 0.25 µm technology in the National Technology Roadmap for Semiconductors.

Table A1-2.1 Alternative to Allowed Exposure Times in an ISO Class 1 Environment

EV/cm at 2.5 cm	*N/A defects per cm^2*	v_{elect} cm/sec	*ct sec/cm^3*	*max t in Class 1 sec*
4000	0.016	0.21	0.0762	61
400	0.016	0.021	0.762	610
200	0.016	0.0105	1.524	1220
100	0.016	0.00525	3.048	2440

A1-2.3 *Guide Recommendations for Equipment Malfunctions*

A1-2.3.1 *Equipment Survey* — Most semiconductor production equipment should comply with the ESD immunity requirements of the European Economic Community (EEC). The testing mandated by the EEC uses the test methods and ESD immunity levels specified in IEC 1000-4-2. A recent survey of 262 semiconductor equipment suppliers revealed that 71% were compliant with the EEC requirements. There is an expectation that all equipment to be used in future 300 mm wafer fabrication will meet or exceed the ESD immunity requirements of IEC 1000-4-2.

To test for compliance, measurements were made with the ESD simulator described by IEC 1000-4-2 on a representative sample of semiconductor equipment. The results were as follows:

ESD Simulator Testing Direct Contact Discharge

Equipment	*Test Voltage Level 1 (2 kV)*	*Test Voltage Level 2 (4 kV)*	*Test Voltage Level 3 (8 kV)*	*Test Voltage Level 4 (15 kV)*	*Test Voltage Level X (NOTE 1)*
A			X		
B			X		
C					X
D			X		
E					X
F		X			
G			X		
H			X		
I			X		
J			X		

"X" indicates that the equipment passes ESD simulator testing at this level.

NOTE 1: This level is subject to negotiation and has to be specified in the dedicated equipment specification. If higher voltages than those shown are specified, special test equipment may be needed.

A1-2.3.2 *Static Audit* — While equipment may meet the ESD immunity levels specified in IEC 1000-4-2, it should be remembered that static charge levels in manufacturing environments may be substantially higher. Direct measurements of static charge are difficult, and the presence of a charge does not always imply that an ESD event causing an equipment malfunction will occur. Some information may be gained by using a fieldmeter to measure the electrostatic field created by the surface charge. Instruments known as EMI locators may also be used in some cases to determine if ESD-related EMI is occurring. Some representative measurements of electric fields from objects in various areas of a semiconductor wafer fab are as follows:

— *Wet Etch* — 0.1 kV/inch to 30 kV/inch

— *Planarization* — 0.1 kV/inch to 20 kV/inch

— *Lithography* — 0.1 kV/inch to 20 kV/inch

— *Dry Etch* — 0.1 kV/inch to 15 kV/inch

— *Thin Film* — 0.1 kV/inch to 15 kV/inch

— *Diffusion* — 0.1 kV/inch to 30 kV/inch

— *Implant* — 0.1 kV/inch to 15 kV/inch

A knowledge of object capacitance and other physical properties is needed to determine if any of the above measurements indicate an equipment hazard due to ESD events. However, the range of the measurements strongly indicate that such ESD events can occur. The examples in Related Information R1-3.3 support this conclusion.

A1-2.3.3 *Guide Recommendations* — Based on the static audits and equipment test data, there appears to be a wide range of static immunity in equipment as well as in the static charge levels in work environments. As stated previously, it is difficult to establish a direct correlation between ESD events and fieldmeter measurements made on products, carriers, or any other objects in the work environment. The following sensitivity levels are defined with recommended test levels for each.

Level 4 — Field measurements of static charge at input/exit ports are expected to exceed 10 kV/inch. Equipment should pass ESD simulator testing at 8 kV direct contact discharge, 18 kV air discharge. Guide recommendation (Section 12.5) - 1200 nanocoulombs (8 kV × 150 picofarads).

Level 3 — Field measurements of static charge at input/exit ports are expected to exceed 4 kV/inch, but are less than 10 kV/inch. Equipment should pass ESD simulator testing at 4 kV direct contact discharge, 8 kV air discharge. Guide recommendation (Section 12.5) - 600 nanocoulombs (4 kV × 150 picofarads).

Level 2 — Field measurements of static charge at input/exit ports are expected to exceed 500 V/inch, but are less than 4 kV/inch. Equipment should pass ESD simulator testing at 2 kV direct contact discharge, 4 kV air discharge. Guide recommendation (Section 12.5) - 300 nanocoulombs (2 kV × 150 picofarads).

Level 1 — Field measurements of static charge at input/exit ports are expected to exceed zero, but are less than 500 V/inch. Equipment should pass ESD simulator testing at 1 kV direct contact, 2 kV air discharge. Guide recommendation (Section 12.5) - 150 nanocoulombs (1 kV × 150 picofarads).

R1-1 ESD Damage

Contributed by Leo G. Henry, Ph.D., Advanced Micro Devices, EOS/ESD/LU/EMC Department, Sunnyvale, CA 94538, leog.henry@amd.com.

R1-1.1 *Introduction* — ESD damage to devices occurs when they come into contact with personnel and equipment. Either may store a residual charge large enough to destroy the device if a discharge occurs. In the semiconductor industry, it has been established that a significant proportion of customer field returns are attributed to damage resulting from ESD.

R1-1.2 *Description of ESD Damage Mechanisms* — ESD failures are the result of either a current-induced phenomenon or a charge-induced phenomenon, and the damage can either be junction, contact, dielectric or oxide related. The apparent similarity in current-induced damage resulting from ESD due to human body model discharges (HBM) or machine model discharges (MM) results from the thermal nature of both of these process. The HBM and MM damages result when the temperature (joule heating) of the region dissipating the ESD pulse energy reaches a critical value and melting occurs.

Charge-induced phenomena are predicted by the charged device model (CDM). For CDM type discharges, oxide punch through occurs when the ESD voltage applied across the oxide creates a high enough field to break down the oxide. Excessive current flow results, causing an oxide short, but there is no heat transfer (adiabatic process).

It should be noted here that the time duration for typical ESD events from charged objects and personnel ranges from 10 to 100 nanoseconds, while CDM type events occur in less than 1 nanosecond.

R1-1.3 *Device Testing Models*

R1-1.3.1 *Human Body Model (HBM)* — The Human Body Model is the oldest and the most widely used of the three ESD models. The model attempts to replicate the discharge from a real human when the latter touches a device that is at a lower potential. The human capacitance and resistance have been ideally chosen to be 100 picofarads and 1500 ohms respectively. The values were chosen after measurements were made on humans in varying positions with respect to their surroundings. The resulting discharge waveform has a double exponential shape with risetime range of 2–10 nsec and a decay constant (1/e position) of 150 ± 20 nsecs. The typical peak currents range from 0.67 Amps at 1000 volts to 2.67 Amps at 4000 volts.

R1-1.3.2 *Machine Model (MM)* — The Machine Model is described by Electronic Industries Association of Japan (EIAJ) as a worst case HBM. The model attempts to replicate the discharge from a metallic arm of an automatic handler coming into contact with the metallic leads of a semiconductor device which is at a lower potential. A capacitance of 200 picofarads and ideally zero resistance produces a sinusoidal decaying waveform with an effective pulse duration of 200 nsec. The typical peak currents range from 1.75 Amps at 100 volts to 14.0 Amps at 800 volts. Note that MM failures occur at 5–10 times lower voltage than HBM.

R1-1.3.3 *Charged Device Model (CDM)* — The Charged Device Model in its purest form is actually a field induced model because the device is actually part of model. This model attempts to describe a device which itself becomes charged due to an external field, or due to triboelectric charging of the device surfaces. During discharge, the parasitics (capacitance, inductance and impedance) in the device play a significant role in the resulting failure. The discharge pulse is a sinusoidal waveform with an extremely fast risetime of less than 500 picoseconds. The waveform decays rapidly with a total pulse duration of less than 5 nano-seconds. The peak currents range from 2.0 Amps at 250 volts charging voltage, to 18.0 Amps at 2000 volts charging voltage.

R1-1.3.4 *Correlation Between Models* — There is much debate on whether or not there is any type of correlation between HBM and MM. While some companies report a correlation of roughly 10:1 between the two models, other companies have seen anywhere from 5–20:1 differences in passing voltages between the two models. There is also no established voltage correlation between CDM damage and HBM or MM ESD events. In equipment, ESD damage events will be related to the MM or CDM types of ESD. Users will need to determine the type of ESD hazard to their devices and choose the test method accordingly.

R1-1.4 *ESD Laboratory Simulation Testing*

R1-1.4.1 *Description of Test Methods* — Test procedures discussed here for ESD simulation conform to those established by the ESD Association Standards ESD STM 5.1 (for HBM), ESD S5.2 (for MM), and MIL-STD-883, C/3015.7-method 8. The ESD Association is presently considering two documents related to CDM Testing. Details are to be found in these standards.

Devices are qualified at a level corresponding to the highest ESD stress they are able to withstand. These levels are discussed in more detail in Appendix A1-2.1.

R1-1.4.2 *Simulation Test Results* — In general all units must be data-logged both pre- and post-stress test. Any leakage current equal to or greater than a specific amount (company dependent — typically 10 micro-amps or less) is “flagged” as a failure, and any current shift greater than about 200 nano-Amp is marked on the record.

R1-1.4.3 *HBM Stress Testing* — An R-C network is used to simulate the ESD event. In an HBM ESD Simulator, a high voltage is used to charge the capacitor (100 pF) which discharges through the resistor (1500 ohms) into the device under test. The present draft standard (1997) requires a minimum of two discharges (1 positive and 1 negative) per voltage level.

R1-1.4.4 *MM Stress Testing* — An R-C network is also used in the MM ESD Simulator for ESD testing. High voltage charges the capacitor (200 pF) which discharges through the short wire (zero ohm) into the device under test. The present standard requires a minimum of six discharges (3 positive and 3 negative).

R1-1.4.5 *CDM Stress Testing* — The package and leadframe of the device are charged by direct charging or field induction. For the Direct Charging Method, direct contact is made to one of the device leads connected to the substrate or bulk material of the device. The device is then discharged via a one ohm resistor to ground.

For the Field Induced Method, the device is placed on a metallic charging plate with the device packaging material touching the plate. The potential of the device is raised by applying a voltage to the charging plate. The induced voltage on the device is discharged to ground through a 1 ohm resistor that contacts each device lead. The present draft standard (1996) requires a minimum of 6 discharges (3 positive and 3 negative) from each device lead.

R1-1.5 *Examples of Damage from Device Testing*

R1-1.5.1 *HBM ESD Damage*

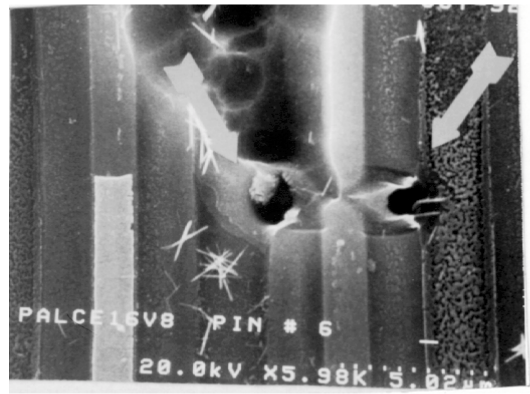

Figure R1-1
Example of HBM Damage

In this example of HBM damage (refer to Figure R1-1), de-processing (removal of the processed layers) down to the poly level and very high magnification (SEM) examination were required in order to see the failure site morphology of arcing from source to drain within the ESD protective structures. The electrical characteristics found were: resistive shorts, leakages, low breakdown voltages and Icc failures.

R1-1.5.2 *MM ESD Damage*

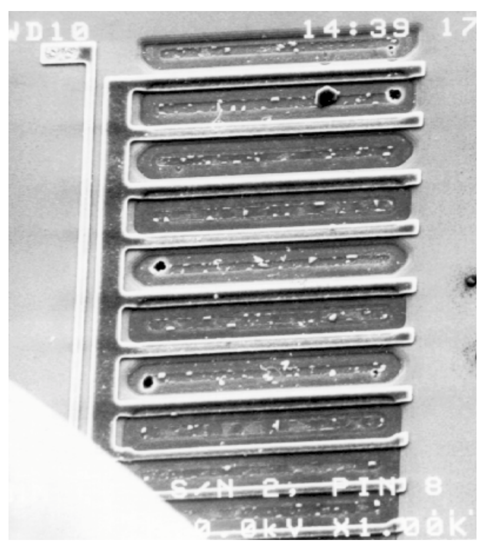

Figure R1-2
Example of MM Damage

In the above MM example (refer to Figure R1-2), the damage was more severe than for HBM. De-processing down to the poly level and the SEM examination showed the failure site morphology of large deep pits occurring at the contact(s) suggesting high current parasitic bipolar action deep in the substrate and also within the ESD protective structures. The electrical characteristics found also resistive shorts, leakages, low breakdown voltages and Icc failures.

R1-1.5.3 *CDM ESD Damage*

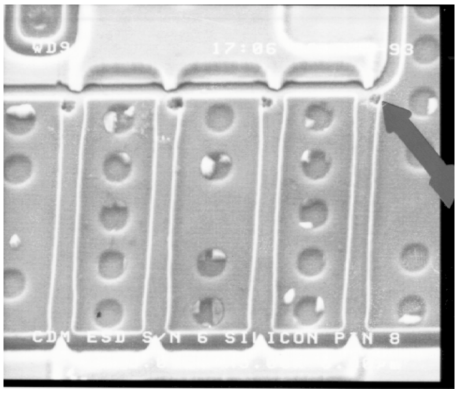

Figure R1-3
Example of CDM Damage

In the above CDM example (refer to Figure R1-3), the gate oxide damage is seen as a unique failure signature beyond the input protection structures at an internal location of the die. Most often the oxide failure is located beneath the poly at the field oxide edge, or is located at the poly edge adjacent to the source/drain junction. To date all CDM ESD damage has been found in the gate oxide at the input buffer circuitry.

R1-2 Enhanced Particle Deposition Attributable to Electrical Charge on a Wafer

Contributed by Douglas W. Cooper, Ph.D., The Texwipe Company, Upper Saddle River, NJ 07458.

R1-2.1 *Introduction* — The presence of excess electrical charge on a wafer can create an electrostatic field that will lead to accelerated deposition of particles onto the wafer. This undesirable consequence is but one of several threats to product yield posed by the presence of excess electrical charge on a wafer. Sections R1-1 and R1-3 of this related information discuss two other important and potentially damaging consequences of surface charge.

The purpose of the discussion in this section is to estimate the magnitude of electrostatic field that can be tolerated before electrostatically enhanced particle deposition becomes the dominant particle deposition mechanism. Over the particle size range 0.01 to 0.3 µm, diffusion is the dominant, non-electrostatic mechanism of particle deposition. Thus, values of electrostatic fields that do not produce particle deposition velocities greater than those attributable to particle diffusion will be deemed tolerable. A set of such values calculated under a specific and very restrictive set of conditions are presented in this section.

R1-2.2 *Theoretical Background* — Although there are numerous electrostatic interactions between particles and surfaces, the dominant one is almost always the "Coulombic" interaction: the attraction (or repulsion) of a charged particle by a charged surface. This is the only electrostatic effect considered here.

For particles of one diameter, d, and one charge, q, the particle deposition flux, j, (the number of particles deposited per unit area per unit time) is the product of aerosol particle number concentration, c; particle charge, q; the electric field created by the charged wafer, E; and particle mechanical mobility, B (terminal velocity per unit external force):

$$j = cqEB \qquad (1)$$

The group qEB is the "electrostatic deposition velocity", v_{elect}

$$v_{elect} = qEB = j/c \qquad (2)$$

The variables q and E are those containing the electrical parameters that affect the magnitude of v_{elect}; B depends on particle diameter but not electrical properties.

It is the v_{elect} values that will be calculated for comparison with those of v_{diff} , the particle deposition velocity attributable to particle diffusion. Values of E for which $v_{elect} < v_{diff}$ will be those deemed tolerable in wafer manufacturing.

Note that the total number of particles, N, deposited on a wafer, obtained by integrating Equation (1) over the wafer area, A, and the time of exposure, t, depends on c as well as the deposition velocity:

$$N = cqEBAt \text{ or } N / A = ctv_{elect} \qquad (3)$$

Reducing c obviously reduces N, but the relative importance of the differing deposition mechanisms and the values of the deposition velocities associated with these mechanisms are assumed to not depend upon c, at least to a first-order approximation (see, for example, Peters and Cooper, 1991).

R1-2.2.1 *Effect of the Particle Charge, q* — There are many charging and discharging mechanisms for particles, so q is hard to predict and likely to be highly variable. In a normal atmosphere the positive and negative air ions tend to have roughly equal effectiveness in charging particles, so that the number of positively charged particles is roughly equal to the number of negatively charged particles. Thus, about half the particles will be attracted and half repelled by a net charge on the wafer. Special circumstances, such as corona discharge ionizers that are not balanced, could alter this conclusion. Without ionizers, cleanrooms tend to have relatively low levels of ions compared to the outdoor or other indoor atmospheres, because the HEPA/ULPA filters efficiently remove ions from the recirculating air.

A Boltzmann charge equilibrium, the charge distribution approximated by aerosol particles exiting a radioactive neutralizer, is a plausible *lower limit* for particle charge and will be assumed in the calculations of v_{elect}, using an improved version of this distribution developed by Fuchs (1964). *Upper limits* on particle charge are determined by ion emission limits or, in the case of water droplets, the Rayleigh limit. However, assuming higher particle charge distributions usually means that $v_{elect} > v_{diff}$ for virtually any value of $E > 0$ and that the only method for avoiding electrostatically enhanced particle deposition is to reduce wafer charge to zero. Thus, the Fuchs charge distribution will be assumed in calculating v_{elect} even though it represents the most favorable particle charge distribution for minimizing electrostatically enhanced particle deposition. Under many practical circumstances the particle charge will be greater and the maximum tolerable electrostatic field will be lower than that calculated for the Fuchs charge levels.

R1-2.2.2 *The Electrostatic Field, E, Induced by the Wafer Surface Charge* — The electrostatic field will depend on the charge on the wafer divided by a quantity with the units of length squared; either a distance squared (far from the wafer) or an area (close to the wafer) or some combination at intermediate distances. While field is not properly measured as a voltage, measuring the voltage, V, at a fixed distance, s, from the wafer allows inferring the field from V/s and the appropriate geometric and dimensional factors. The electrostatic field to be used in Equation (2) can be estimated from the ratio of the wafer charge to the wafer surface area, or the average field near the surface at the center, E_0.

Very far from the wafer, many wafer diameters away, the field created by the net wafer charge, Q, will be similar to that from a point charge:

$$E_1 = k_1 \; Q/r^2 \qquad (4)$$

where k_1 depends on the system of units used; and r is the distance from the center of the wafer to the particle.

Very close to the wafer, a fraction of a wafer diameter away, the field created by the net wafer charge is:

$$E_2 = k_2 \; Q'/r^2 \qquad (5)$$

where Q' is the net wafer charge, assumed to be uniformly distributed, contained within the intersection of a sphere of radius, r, and centered on the point of the wafer closest to the particle.

This equation indicates that the charge distribution on the wafer can make a difference close to the wafer. For an insulating wafer with a uniform charge and a radius, R:

$$E_2 = E_0 = k_2 \; Q/\pi R^2 \quad (6)$$

at a distance $r = R$ from the center of the wafer.

For a conductive wafer, or for a wafer with localized regions of charge, the electric field will vary over the surface, causing greater and lesser deposition velocities. A conductive wafer will have the charge concentrated near the edges, producing a relatively high field there and much lower fields as the center is approached.

Note that both E_1 and E_2 are proportional to Q and therefore, other variables being equal, electrostatic deposition is expected to be proportional to Q. Thus, the criterion to be specified is not the tolerable charge on the wafer but the tolerable electrostatic field near the wafer surface (such as that evaluated at a distance of one radius perpendicular to the wafer surface above its center), E_0. A maximum tolerable value of E_0 will be estimated by calculating the maximum E_0 values for which $v_{elect} < v_{diff}$, assuming a Fuchs distribution for the particle charge.

R1-2.3 *Tolerable Electrostatic Field*

R1-2.3.1 *Particle Deposition Velocity Attributable to Convective Diffusion (vdiff)* — In a microelectronics cleanroom, airflow is generally laminar ("unidirectional") downward at about 50 cm/sec (100 ft/min). If the flow is perpendicular to a surface, such as a wafer of diameter, *Dw*, a boundary layer forms across which particles diffuse to the surface. Liu and Ahn (1987) adapted the correlation of Sparrow and Geiger (1985) and obtained a correlation for the average diffusive deposition velocity as:

$$v_{diff} = 1.08 \, Sc^{1/3} Re^{1/2} D^{*}/D_w \quad (7)$$

where $Sc = \mu/\rho D^{*}$ is the Schmidt Number

μ is the gas viscosity

ρ is the gas density

and $D^{*} = kTB$ is the particle diffusivity

k is the Boltzmann constant

T is the absolute temperature and

B is the particle mobility

and $Re = \rho U D_w / \mu$ is the Reynolds number

U is the gas velocity and

D_w is the wafer diameter

Bae et al. (1994) reviewed the experimental work of others and presented their own, supporting this correlation; Cooper et al. (1990) obtained a similar equation by a somewhat different method. Oh et al. (1996) summarized prior experimental and theoretical work and extended the numerical analysis with a turbulent transport properties model, finding a small increase in deposition for the conditions modeled. These authors' publications support the approximation that the diffusional deposition velocity is about 0.006 cm/sec at particle diameter of 0.25 µm and about 0.03 cm/sec at particle diameter of 0.01 µm, or:

$$v_{diff} = (0.03 \; cm/sec)/(d/0.01 \; \mu m)^{1/2} \quad (8)$$

for $0.01 \; \mu m \le d \le 0.3 \; \mu m$ in cleanroom air.

R1-2.3.2 *Particle Deposition Velocity Attributable to Electrostatic Forces (v_{elect})* — Using a power law to approximate the Fuchs particle charge distribution yields the following approximation for electrical mobility (Cooper et al., 1990):

$$Z = qB = (0.002 \; cm/s)/(d/0.01 \; \mu m)(1 \; V/cm) \quad (9)$$

from which the deposition velocity attributable to electrostatic forces becomes:

$$v_{elect} = (0.002 \; cm/s)[E_0/(V/cm)]/(d/0.01 \; \mu m) \quad (10)$$

Setting $v_{elect}/v_{diff} = 1$ results in the following expression for tolerable E_0:

$$[(E_0/(V/cm)] = 15 \; [d/(0.01 \; \mu m)]^{1/2} \quad (11)$$

Table R1-2 lists the values of tolerable electrostatic field adjacent to a wafer surface as calculated from Equation (11). Note that the electrostatic fields are calculated at a distance of one wafer radius from the center of the wafer. E_0 is the value of electric field at which electrostatically enhanced particle deposition is estimated to match the particle deposition velocity attributable to diffusion, assuming a Fuchs charge distribution on the particles. This charge distribution represents a minimal particle charge. With most particle charge distributions to be encountered in practice, even lower values of electrostatic fields will produce enhanced deposition. A safe conclusion is that there is no safe value of electrostatic field that will avoid enhanced particle deposition unless neutralization of particle charge has been achieved, in which case the very modest values of electrostatic fields calculated from Equation (11) and tabulated in Table Rl-2 should be tolerable.

Table R1-2 Tolerable Levels of Electrostatic Field at a Distance of One Radius from the Center of a Wafer, Assuming a Fuchs Charge Distribution on the Particles

Minimum Particle Diameter d in µm	*Tolerable Field E_0, in Volts/cm*
0.01	15
0.02	21
0.03	26
0.05	34
0.10	47
0.20	67

0.30	82

R1-2.4 *Conclusions* — As indicated in Table R1-2, the calculated value of tolerable electrostatic field (the value of electrostatic field above which electrostatic particle deposition becomes the dominant mechanism of particle deposition) is just 47 V/cm for particles of 0.1 µm diameter when the particle electrical charge is that described by the Fuchs charge distribution, a minimum value of particle charge that is normally exceeded in most environments. In most realistic environments the particle charge will be greater and the tolerable electrostatic field, even lower. Hence the conclusion that in all practical processing environments electrical forces will be the dominant mechanism of particle deposition on wafers.

In a Federal Standard 209E Class 1 environment ($c \leq$ 0.00124 particles/cm^3) with v_{elect}, ~ 0.01 cm/s (the value predicted by Equation 10 for a 0.1 µm particle in an electric field of 47 Volts/cm) the target areal particle densities (N/A = 0.016 particles/cm^2 for the 0.25 µm technology of 1998) specified in the National Technology Roadmap for Semiconductors (NTRS, 1994) will be reached after an exposure time of about 1300 seconds, assuming c is at its maximum allowed concentration.

With less favorable electrical conditions, or higher particle concentration, the maximum allowed exposure time becomes shorter. In addition, the target values for N/A continue to decrease with each technology generation. Fortunately, one or more of the parameters, particle concentration in the ambient, the charge level on a surface, or the time a charged surface is exposed to a given particle ambient, can be controlled.

Charge Neutralization — Achieving the Fuchs charge distribution by means of radioactive isotopes or balanced corona neutralizers — is the first step in controlling particle deposition on wafers. This step, while clearly necessary, is unlikely to be sufficient to guarantee meeting the NTRS requirements of the future. Steps to minimize environmental particle concentration, c, and time of exposure, t, will have to be part of the strategy for creating acceptable processing environments. Minimizing these variables reduces particle deposition attributable to all mechanisms, not just electrostatic deposition.

Contemporary standards recognize the need for reduced particle concentrations in wafer environments. For example, the classification ISO Class 1 (of the proposed international standard for classifying cleanrooms according to concentration of airborne particulate cleanliness) describes an environment in which the concentration of particles > 0.1 µm is 10^{-5} particles/cm^3 or less. In an environment of this quality, wafer exposure can be as long as 10^5 seconds at the deposition velocity predicted for neutralized 0.1 µm particles (~0.01 cm/s) and still meet the target defect density that the NTRS recommends for the 0.1 µm technology anticipated in 2007. Fractional increases in the electric field above 47 Volts/cm will decrease the allowed exposure time by that same fraction (Equations 10, 12) — an electric field of 94 Volts/cm reduces the allowed exposure time to 5×10^4 seconds, etc.

Deposition of 0.1 to 1.0 Micron Particles, Including Electrostatic Effects, onto Silicon Monitor Wafers (Experimental)

William J. Fosnight, Vaughn P. Gross, Kenneth D. Murray, Richard D. Wang, IBM Corporation published in 1993 Microcontamination Conference proceedings

Summary: Submicron particle contamination continues to be a concern in the manufacture of integrated circuits. Quantifying particle deposition velocity (the ratio of particle deposition rate to airborne particle concentration) is of fundamental importance in understanding the defect-density impact of airborne contamination.

As particle size decreases, the effect of electrostatic charge plays an increasing role in the deposition of particles onto surfaces. This four-trial study examines the deposition of 0.1 to 1.0 micron particles onto horizontal, grounded and electrostatically charged, silicon monitor wafers in an 80 feet per minute vertical unidirectional airflow. The experimental deposition velocity results were compared to theoretical predictions found in the literature.

Three primary observations were obtained from this study. First, measured values of deposition velocity agreed reasonably well with predicted values. However, deposition velocity was not observed to increase below 0.2 micron. Secondly, particles less than 0.5 micron were observed to deposit onto charged wafers approximately three to ten times faster than onto grounded (not charged) wafers. Finally, settling monitor wafers may be a time consuming (and expensive) means of certifying the cleanliness of a "clean" (less than 10 ppcf at scanner threshold particle size) environment. However, settling-monitor studies should not be confused with particles-per-wafer-pass (PWP) measurements; PWP measurements often provide useful information regarding the performance of the automation and/or process of a tool, even if it is in a very clean environment.

R1-3 ESD Impacts in Semiconductor Equipment

Contributed by Julian A. Montoya, Intel Corporation, 5200 NE Elam Young Parkway, Hillsboro OR, 97124-6497.

R1-3.1 *Introduction* — Electrostatic phenomena impact semiconductor manufacturing in many ways. These range from increased particle accumulation on wafer surfaces to electrostatic discharge (ESD) events which impact equipment performance, and in some cases impact factory yields and throughput.

All areas within a semiconductor manufacturing environment must be concerned with electrostatic control. This encompasses initial wafer receiving to shipping of final product. In addition, the equipment which will be housed within that environment must also be concerned with electrostatic control and electrostatic immunity.

This section highlights issues associated with static charge and ESD in a semiconductor manufacturing environment and its effects on production equipment.

R1-3.2 *Overview* — Static charge issues in semiconductor manufacturing manifest themselves in many ways. Problems occur by direct contact with charged items, by induction from electrostatic fields, and indirectly by radiated and conducted electromagnetic interference (EMI) emitted into the environment as a result of the ESD event.

R1-3.3 *Equipment ESD Examples* — The following section presents real world examples of the cause and impacts associated with electrostatic discharge and semiconductor manufacturing equipment.

R1-3.3.1 Charged operators came into direct contact with diffusion furnace control panel. Process aborted on many occasions resulting in loss of product and reduced equipment utilization.

R1-3.3.2 Numerous instances where charged reticles (photomasks) came into direct contact with a grounded object. This caused damage to reticles and impacted factory throughput. Costs were associated with replacing damaged reticles and requalifying reticle sets.

R1-3.3.3 Charged operators came into direct contact with electronic card cage of chemical vapor deposition tool. This resulted in process abort, loss of product, and reduced equipment availability.

R1-3.3.4 Charged wafer cassette induced charge onto robot arm on wafer transfer tool. Robot arm came into contact with grounded screw creating an ESD event. This resulted in data corruption which caused robot arms to open, dropping fully loaded wafer cassettes to the floor. Costs were associated with loss of product.

R1-3.3.5 Automated material handling system "car" became charged while coming in close proximity to ionizer. Car came into contact with grounded object during charging; creating data corruption which resulted in system downtime, impact to factory throughput, and cost associated with the replacement of control electronics.

R1-3.3.6 Wafer taping/detaping tool generated charge during normal operation. Chassis ground of the tool was inadvertently removed, causing high charge to be developed within the tool. Electrostatic Discharge occurred at random time intervals within the tool. Impact to equipment availability, and long solution time.

R1-3.3.7 Wafers became charged during spin rinse process. During transfer to wafer metrology tool electrostatic discharge occurred, causing data corruption. This resulted in unexpected tool lockups, and reduced equipment availability.

R1-3.3.8 Ungrounded wall panels became charged and generated ESD events. EMI produced from ESD events coupled into photolithography equipment and created data corruption. This resulted in impacts to equipment utilization. Long solution time.

R1-3.3.9 Insulative ceiling panels became charged and generated ESD events which produced high levels of radiated and conducted EMI in a test area. EMI coupled into tester/handler and produced data scramble. This resulted in reduced equipment availability.

R1-3.3.10 Finished product became charged during manual handling. Product came into direct contact with test/handler equipment. This resulted in damaged circuit cards which needed to be replaced, and decreased equipment availability.

R1-3.3.11 Wafer transfer cart became charged while rolling over temporary "insulative" floor. Cart came into contact with plasma etcher control cabinet. Resulting ESD event caused product loss and reduced equipment availability.

R1-3.3.12 Wafer polisher robot arm became charged during normal operation. Chassis ground wire for robot left off. ESD event occurred causing data scramble which resulted in process being aborted.

R1-3.4 *Conclusion* — Electrostatic Discharge (ESD) affects semiconductor manufacturing equipment in many ways. The issues are wide ranging from trivial lock-ups and aborts of process equipment to factory throughput and yields impacts. The scope of the ESD problem is very broad and encompasses every aspect of semiconductor manufacturing.

RELATED INFORMATION 2
STATIC CONTROL METHODS

NOTE: This related information is not an official part of SEMI E78 and is not intended to modify or supercede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

R2-1 Static Charge Control

It is usually impossible to totally eliminate static electricity from work areas, but with proper use of equipment and remedial procedures, most static problems can be controlled. Many approaches to controlling static charge have been tried over the years and it is clear that there exists no single method for controlling all static charge problems.

R2-2 Grounding Conductors and Static Dissipative Materials

An important consideration in selecting a method is whether the charged material is a conductor or an insulator. Static dissipative materials are created by lowering the resistivity of insulating materials through the addition of metal or carbon particles, or other chemical additives. Static charge on a conductive or static dissipative object can be easily controlled if the object is provided with a path for the charge to flow to earth ground. While charge is mobile in a conductor (or in a static dissipative material), in insulators charge is not mobile, and earth grounding is not an effective means of eliminating the static charge.

Equipment manufacturers can use both conductive and static dissipative materials to reduce the presence of static charge. If there is a path for the charge to flow to earth ground, the static charge on equipment, and materials handled by the equipment, can be rapidly, and harmlessly, neutralized. Obviously, the success of earth grounding depends on maintaining the integrity of the ground path. This is sometimes a problem when high-speed, moving parts of equipment must be connected to earth ground.

Static dissipative materials will need to retain their dissipative properties over the range of temperature and humidity conditions they will encounter, and not change significantly over time. In cleanrooms they must also meet requirements for avoiding micro-particle production and outgassing. As long as the ground connection is maintained, these "passive" procedures offer reasonable protection to the equipment and product from sources of static charge.

Unfortunately, these methods do not provide complete protection from static-related problems. Even when earth grounding is an option, it is subject to human error. In applications where contamination is an issue, additives and carbon particles used in static-dissipative materials may become sources of contamination themselves. When earth grounding or the use of dissipative materials is either inappropriate or not cost effective, ionization can be used.

R2-3 Ionization

More often than not, the product itself uses insulating materials, making earth grounding unavailable as an option. While silicon is a semiconductor, its oxide coating transforms it into an insulator. Teflon is used in many chemical processes, and quartz in high temperature processes. Epoxy and ceramic packages are used for integrated circuits. Insulators are easily charged, retain their charge for long periods of time, and are often close to the product. Dealing with static charge on insulators and isolated conductors will often require the use of some type of ionization. Ionizers are the most effective means of dealing with static charges on insulators and isolated conductors.

For purposes of static charge control, ions are molecules of the gases in air (nitrogen, oxygen, water vapor, and carbon dioxide) that have lost or gained an electron. Ions are present in normal outside air but are removed when air is subjected to filtration and air conditioning. Ionization systems work by increasing the conductivity of the air with the ionized gas molecules. When ionized air comes in contact with a charged surface, the charged surface attracts ions of the opposite polarity. As a result, the static electricity that has built up on products, equipment and surfaces is neutralized.

The most common methods of producing air ions are radioisotopes and "corona discharge" resulting from the electric field created when high voltage is applied to a sharp point.

The radioisotope most commonly used to produce ionization is Polonium^{210}, an alpha particle emitter. The alpha particle collides with the surrounding gas molecules, dislodging electrons, which results in pairs of positive and negative ions.

The corona discharge method produces a very high electric field that interacts with the electrons in the surrounding gas. The polarity of the ions depends on the polarity of the high voltage on the emitter point. Ions of opposite polarity to the charged surface are required. Either polarity of static charge may be created in the equipment or on the product.

Ionizers in equipment must deliver ionization over a wide range of humidity and temperature conditions. Back-end assembly and test areas often do not have the level of temperature and humidity control found in front-end wafer production. Ionizers installed in the cramped spaces of production equipment will be close to the product, in areas surrounded by grounded metal parts. Ionizers should isolate the emitter points from both the product and adjacent grounded surfaces. Ionizers should produce sufficient ions to discharge static on surfaces and products moving at high speeds despite losses to ground. Most ionizers require maintenance and periodic verification of their performance.

R2-4 Problem of Controlling Static Charge in Manufacturing Equipment

The interior of high speed production equipment presents a challenge to most static control methods. The cost of production space is high and requires that equipment occupying the space be compact and operate at as high a speed as practical. Product is moved through small spaces at high speed by a variety of robotic and other mechanisms. Triboelectric charging (charge generation due to friction or contact and separation of dissimilar materials) and contact with ground are almost unavoidable. Grounding of equipment parts that contact the product presents added difficulties when the equipment parts are moving at high speeds. Dissipating charge from insulating surfaces and integrated circuit (IC) packages may be difficult if the charged surfaces are not accessible. Using ionizers in these confined spaces presents challenges.

SEMI

SEMI E79-0200
STANDARD FOR DEFINITION AND MEASUREMENT OF EQUIPMENT PRODUCTIVITY

This standard was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org February 2000; to be published February 2000. Originally published February 1999.

NOTE: This document was rewritten in its entirety in 2000.

1 Purpose

1.1 The document provides metrics for measuring equipment productivity.

2 Scope

2.1 The document defines metrics and calculations for measurement of equipment productivity.

2.2 In the context of this document, it is important to note that "equipment productivity" is impacted greatly by factors far beyond the equipment itself, including (operator, recipe, facilities, material availability, scheduling requirements, etc.).

2.3 Effective application of this standard requires that equipment performance is tracked using the metrics for Equipment Reliability, Availability, and Maintainability (RAM) established in SEMI E10. Additionally, the Automated Reliability, Availability, and Maintainability Standard (ARAMS) SEMI E58 can be used for equipment with ARAMS capability. Productivity metrics for flexible-sequence cluster tools require tracking of SEMI E10 equipment states and recipes at the level of individual processing modules. Productivity performance of a flexible-sequence cluster tool is then calculated as the aggregate productivity performance of its individual processing modules.

2.4 This document is currently limited to measuring equipment productivity using Overall Equipment Efficiency (OEE) as the metric, and does not address the impact of productivity changes on cost, cycle time, or other measures. This document does not address any RAM issues over and above those in SEMI E10.

2.5 The previous SEMI E79 Standard (SEMI E79-0299) defined measurement of an Overall Equipment *Effectiveness* metric. In this revision of SEMI E79, the Overall Equipment Effectiveness metric has been renamed Overall Equipment *Efficiency*. The important differences include (1) the efficiency metric is expressed entirely in terms of time, while the effectiveness metric involved both factors expressed in terms of time and factors expressed in terms of production units, and (2) the efficiency metric is applicable to flexible-sequence cluster tools, while the effectiveness metric was not. The Overall Equipment Efficiency metric is a better estimate measure of true equipment efficiency, and it is applicable for the efficiency assessment of all semiconductor processing equipment.

2.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

CSM 42: Productivity Metrics for Flexible-Sequence Cluster Tools; Engineering Systems Research Center, University of California, Berkeley, 1998.

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *Terminology Applicable to Computation of the OEE Metric*

4.1.1 *actual unit output* (units) — the number of units processed by the equipment during production time.

4.1.2 *availability efficiency* (time divided by time) — the fraction of total time that the equipment is in a condition to perform its intended function.

4.1.3 *cluster tool* — a manufacturing system made up of integrated processing modules mechanically linked together (the modules may or may not come from the same supplier) (SEMI E10).

4.1.4 *downtime (equipment downtime)* (time) — the time when the equipment is not in a condition, or is not available, to perform its intended function. It does not include any portion of non-scheduled time (SEMI E10).

4.1.5 *effective unit output* (units) — the number of units processed by the equipment during production time that were of acceptable quality, i.e., actual unit output less equipment assignable rework and equipment assignable scrap.

4.1.6 *equipment-assignable rework* (units) — any units being reworked due to a fault or defect assignable to the subject equipment. The units may be reworked at the equipment where the fault or defect occurred, or at other equipment.

4.1.7 *equipment-assignable scrap* (units) — any units that are permanently removed from production due to a fault or defect assignable to the subject equipment. The units may be removed from production at the operation where the fault or defect occurred, or at a subsequent operation.

4.1.8 *fixed-sequence cluster tool* — a cluster tool in which all units of production visit all processing modules making up the tool in a fixed sequence (CSM 42).

4.1.9 *flexible-sequence cluster tool* — a cluster tool in which the units of production visit a subset of the processing modules of the tool in sequences that may vary from unit to unit. In such tools, the processing modules that are engaged in processing activity vary from unit to unit according to dispatching decisions made by software internal to the tool (CSM 42).

4.1.10 *non-scheduled time* (time) — time when the equipment is not scheduled to be used in production (SEMI E10).

4.1.11 *operational efficiency* (time divided by time) — the fraction of equipment uptime that the equipment is processing actual units.

4.1.12 *operations time* (time) — total time minus non-scheduled time (SEMI E10).

4.1.13 *overall equipment efficiency (OEE)* (time divided by time) — a metric of equipment performance, expressing the theoretical production time for the effective unit output divided by the total time (CSM 21).

NOTE 2: The overall equipment efficiency metric accounts for all losses that reduce equipment performance from its maximum potential performance taking the existing equipment design and recipe specifications as given.

4.1.14 *performance efficiency* (time divided by time) — the fraction of equipment uptime that the equipment is processing actual units at theoretically efficient rates.

4.1.15 *processing module* — an indivisible production entity within an equipment system, e.g., a processing chamber or station within a cluster tool.

4.1.16 *processing module recipe* — all processing steps of a recipe performed within a single processing module without requiring reloading of that processing module (CSM 42).

4.1.17 *production time* (time) — sum of all periods of time in which a processing module is performing its intended function. For a non-cluster tool, a fixed-sequence cluster tool or an individual processing module within a flexible-sequence cluster tool, production time is equivalent to the SEMI E10 productive time for that entity. For a flexible-sequence cluster tool, production time is the aggregate of the production times for all processing modules encompassed by the cluster tool (CSM 42).

4.1.18 *productive state* — a period of time (*production time*) when the equipment is performing its intended function (SEMI E10).

4.1.19 *quality efficiency* (time divided by time) — the theoretical production time for Effective Units divided by the theoretical production time for Actual Units.

4.1.20 *rate efficiency* (time divided by time) — the fraction of production time that equipment is processing actual units at theoretically efficient rates.

4.1.21 *recipe* — the pre-planned and reusable portion of the set of instructions, settings, and parameters under control of a processing agent that determines the processing environment seen by the material. *Recipes* may be subject to change between runs or processing cycles (SEMI E38, SEMI E40, SEMI E42).

4.1.22 *theoretical production time per unit (THT)* (time per unit) — for a given production recipe performed by a given processing module, the minimum time to complete processing on one unit of production assuming no efficiency losses are present. The determination of theoretical production time per unit is based on continuous operation of the processing module, where the module is assumed to operate in an ideal condition. For equipment cycles that simultaneously process more than one unit, theoretical production time per unit is the minimum time to perform the cycle on an equipment load whose size is optimized for throughput divided by the number of units in that optimized load (CSM 21, CSM 42).

NOTE 3: Theoretical production time per unit varies by recipe.

4.1.23 *theoretical production time* (time) — production time during a period that is theoretically required to complete the unit quantities of the production recipes undertaken during the period. Theoretical production time is computed as the aggregation over all recipes of the theoretical production time per unit for the recipe applied to the unit quantity of that recipe (CSM 21, CSM 42).

NOTE 4: For flexible-sequence cluster tools, theoretical production time is the aggregate of the theoretical production times for the set of processing modules.

4.1.24 *theoretical unit throughput by recipe* (units per time) — for a given production recipe, the number of units per period of time that theoretically could be processed by the equipment. For each recipe, theoretical unit throughput is equal to the reciprocal of theoretical production time per unit.

4.1.25 *total time* (time) — all time (at the rate of 24 hours per day, seven days per week) during the period being measured. In order to have a valid representation of *total time* all six basic equipment states must be accounted for and tracked accurately (SEMI E10). For a flexible-sequence cluster tool, total time is defined as the aggregate total time of the set of processing modules encompassed by the cluster tool (CSM 42).

4.1.26 *unit* — any wafer, die, packaged device, or piece part thereof (includes product and non-product units) (SEMI E10).

4.1.27 *uptime (equipment uptime)* (time) — the hours when the equipment is in a condition to perform its intended function. It includes *production, standby, and engineering time,* and does not include any portion of *non-scheduled time* (SEMI E10). For a flexible-sequence cluster tool, uptime is defined as the aggregate uptime of the set of processing modules encompassed by the cluster tool (CSM 42).

4.1.28 *virtual machine* — an individual processing module within a flexible-sequence cluster tool, in combination with the transport module(s) serving that processing module. A flexible-sequence cluster tool has one virtual machine defined for each of its processing modules (CSM 42).

4.2 *Terminology Applicable to Computation of Additional Productivity Metrics Defined in Appendix 2*

4.2.1 *demand equipment efficiency (DEE)* (time divided by time) — a measure of equipment productivity during the time that products are planned to be available to process at the equipment.

NOTE 5: *DEE* is based on theoretical production time for effective units and the portion of operations time that excludes planned no product time. A factory model or production schedule that defines the expected or planned idle time at the equipment is required to calculate *DEE.*

4.2.2 *engineering overall equipment efficiency (E-OEE)* (time divided by time) — a measure of equipment productivity assuming process specifications are optimized for minimum production time.

NOTE 6: *E-OEE* is based on the *engineering theoretical production time per unit* and *total time.*

4.2.3 *engineering theoretical production time per unit (ETHT)* – (time per unit) – the theoretical time required to process a given recipe assuming the recipe specification is optimized for minimum production time. *ETHT* is based on minimum durations for the objective processing steps, e.g., implant time for ion implant systems, plus minimum allowances for any additional supporting process steps, e.g., heating, cooling, gas stabilization, that are deemed absolutely necessary.

NOTE 7: *ETHT* must be defined to be less than or equal to the corresponding *theoretical time per unit (THT)* used in calculating *OEE.*

4.2.4 *equipment down no product time* (time) — the period of *equipment downtime* during which there are no units available at the equipment to process.

4.2.5 *intrinsic equipment efficiency (IEE)* (time divided by time) — a measure of equipment productivity that considers the combined effect of rate efficiency losses, recipe design, and equipment design.

NOTE 8: *IEE* is based on *value-added in-process theoretical production time for actual units* and *production time*.

4.2.6 *no product time* (time) — the period of *standby time* that the equipment is idle because there are no units available at the equipment to process.

4.2.7 *planned no product time* (time) — the period of *operations time* that the factory model or production schedule expects the equipment to be idle because there are no units available to process at the equipment.

4.2.8 *production equipment efficiency (PEE)* (time divided by time) — a measure of equipment productivity during the time that products are available to process at the tool.

NOTE 9: One application of *PEE* is to measure the productivity of non-constraint tools that are expected to have periods of idle time due to lack of available work. *PEE* is based on *theoretical production time for effective units* and the portion of *operations time* that excludes *no product time* and *equipment unavailable no product time*.

4.2.9 *reference overall equipment efficiency (R-OEE)* (time divided by time) — a measure of equipment productivity relative to a benchmark theoretical production time.

NOTE 10: R-OEE is based on the reference theoretical production time per unit and total time.

4.2.10 *reference theoretical production time per unit (RTHT)* (time per unit) — the theoretical time required to process a given recipe on benchmark equipment (i.e., the fastest equipment model of similar type), for a benchmark product and process design.

NOTE 11: *RTHT* must be defined to be less than or equal to the corresponding *theoretical time per unit* (*THT*) used in calculating *OEE*.

4.2.11 *value-added in-process overall equipment efficiency (VA-OEE)* (time divided by time) — a measure of equipment productivity assuming all time except the value-added portion of processing cycles is wasted equipment time.

NOTE 12: *VA-OEE* is based on the *value-added in-process theoretical production time per unit* and *total time*.

4.2.12 *value-added in-process theoretical production time per unit (VTHT)* (time per unit) — theoretical production time per unit that credits only the objective processing steps that add value to products.

NOTE 13: *VTHT* must be defined to be less than or equal to *engineering theoretical production time per unit* (*ETHT*) used in calculating engineering OEE (*E-OEE)*.

5 Equipment Productivity Measurement

5.1 The OEE calculation has been stated in terms that are consistent with SEMI E10. Reference may be made to Figure 1.

5.1.1 Figure 2 indicates how total time may be divided into portions representing theoretical production time for effective units and various sources of productivity loss. The domain for productivity improvement of all losses except operational efficiency is shared between the equipment supplier and equipment user. Productivity improvement of operational efficiency is the exclusive domain of the equipment user.

5.1.2 The formulas introduced in this section require as inputs the following fundamental quantities: total time, equipment uptime, production time, and theoretical production time. Sample calculations for each of the formulas are provided in Appendix 1.

5.1.3 For efficiency measurement of individual processing modules or of fixed-sequence cluster tools, the fundamental quantities may be tallied in a straightforward manner, and consequently the formulas of this section may be applied in a straightforward fashion.

5.1.4 For efficiency measurement of flexible-sequence cluster tools, determination of the fundamental quantities requires more involved calculations. Formulas are provided in Section 6 for computing the fundamental quantities for flexible-sequence cluster tools. These fundamental quantities then may be used as inputs to the formulas of this section to compute the efficiency of a flexible-sequence cluster tool.

5.1.5 Additional supplemental efficiency metrics that will enable users to assess more specific aspects of equipment productivity are:

- Reference OEE,
- Engineering OEE,
- Value-Added In-Process OEE,
- Demand Equipment Efficiency,
- Production Equipment Efficiency, and
- Intrinsic Equipment Efficiency.

Definitions and formulas for these metrics are presented in Appendix 2.

5.2 *Overall Equipment Efficiency (OEE)* — The fraction of total time that equipment is producing effective units at theoretically efficient relates

Overall Equipment Efficiency (OEE)
= (Theoretical Production Time for Effective Units)
÷ (Total Time)
= (Availability Efficiency) X (Performance Efficiency)
X (Quality Efficiency)

5.2.1 *Availability Efficiency* — The fraction of total time that the equipment is in a condition to perform its intended function.

Availability Efficiency =
(Equipment Uptime) ÷ (Total Time)

5.2.2 *Performance Efficiency* — The fraction of equipment uptime that the equipment is processing actual units at theoretically efficient rates.

Performance Efficiency =
(Operational Efficiency) X (Rate Efficiency)

5.2.2.1 *Operational Efficiency* — The fraction of equipment uptime that the equipment is processing actual units.

$$\textit{Operational Efficiency} = (\textit{Production Time}) \div (\textit{Equipment Uptime})$$

5.2.2.2 *Rate Efficiency* — The fraction of production time that equipment is processing actual units at theoretically efficient rates.

$$\textit{Rate Efficiency} = (\textit{Theoretical Production Time for Actual Units}) \div (\textit{Production Time})$$

5.2.2.3 *Theoretical Production Time (for Actual Units or for Effective Units)* — Production time (for actual units or for effective units) during a period of observation that is earned at strictly theoretically efficient rates and assumes no efficiency losses.

$$\textit{Theoretical Production Time for Actual Units} = \Sigma_I (\textit{Actual Units of Recipe I x } THT_I)$$

$$\textit{Theoretical Production Time for Effective Units} = \Sigma_I (\textit{Effective Units of Recipe I x } THT_I)$$

where

THT_I = *theoretical production time per unit of recipe$_I$*

NOTE 14: Theoretical Production Time (for actual units or for effective units) may be calculated in terms of theoretical unit throughput by recipe.

$$\textit{Theoretical Production Time for Actual Units} = \Sigma_i (\textit{Actual Units of Recipe i} \div UPH_i)$$

$$\textit{Theoretical Production Time for Effective Units} = \Sigma_i (\textit{Effective Units of Recipe} \div UPH_i)$$

where

UPH_i = *theoretical unit throughput by recipe of recipe i*

5.2.3 *Quality Efficiency* — The theoretical production time for Effective Units divided by the theoretical production time for Actual Units.

$$\textit{Quality Efficiency} = (\textit{Theoretical Production Time for Effective Units}) \div (\textit{Theoretical Production Time for Actual Units})$$

Stack Chart of Productivity Losses and Improvement Domains

6 Flexible-Sequence Cluster Tools

6.1 This section provides definitions and formulas applicable to flexible-sequence cluster tools for computing the following fundamental quantities: theoretical production time, production time, equipment uptime and total time. These quantities serve as inputs to the formulas of Section 5 for efficiency measurement.

6.1.1 Flexible-sequence cluster tool productivity is measured at the individual processing module level of detail according to a virtual machine model described in this section. Productivity performance for the entire flexible-sequence cluster tool is then calculated as the aggregate productivity performance of its individual processing modules.

NOTE 15: Evaluation of flexible-sequence cluster tool productivity does not necessarily apply to the evaluation of flexible-sequence cluster tool RAM.

6.2 *Virtual Machine Model*

6.2.1 A virtual machine is an individual processing module in combination with the transport mechanisms that serve that processing module. When a transport mechanism is engaged in a material handling operation that does not involve a particular processing module, it is not considered to be operating as part of the virtual machine defined for that processing module.

6.2.2 Theoretical production time per unit for a recipe is the sum of theoretical times for all required operational elements:

- Wafer loading,
- Elements occurring within a process module, and
- Wafer unloading.

6.2.2.1 Where appropriate, a combined loading and unloading time may be replaced with a single theoretical value for a *wafer exchange*.

6.3 *Fundamental Quantities for Processing Modules and Flexible-Sequence Cluster Tools* — This section defines fundamental quantities that are evaluated for individual processing modules and flexible-sequence cluster tools as inputs to the formulas presented in Section 5.0. In each case, the fundamental quantity is determined for each individual processing module within a flexible-sequence cluster tool. The equivalent fundamental quantity for the flexible-sequence cluster tool is the sum of the quantities for the individual processing modules.

NOTE 16: It is recognized that application-specific interactions between processing modules within flexible-sequence cluster tools may impose varying amounts of standby time on the individual processing modules. This approach treats these interactions as standby losses for the flexible-sequence cluster tool and does not make any allowances for them in either production time or theoretical production time.

6.3.1 *Theoretical Production Time (for Actual Units and for Effective Units)*

6.3.1.1 *Processing Module Theoretical Production Time (for Actual Units and for Effective Units)* — Theoretical production time earned by an individual processing module according to the virtual machine model.

Processing Module
Theoretical Production Time for Actual Units =
Σ_i*[(Theoretical Production Time Per Unit*
for Processing Module Recipe i)
X (Actual Units of Processing Module Recipe i)]

Processing Module
Theoretical Production Time for Effective Units
=Σ_i*[(Theoretical Production Time Per Unit*
for Processing Module Recipe i)
X (Effective Units of Processing Module Recipe i)]

6.3.1.2 *Flexible-Sequence Cluster Tool Theoretical Production Time (for Actual Units and for Effective Units)* — Aggregate theoretical production time earned by all processing modules according to the virtual machine model.

Flexible-Sequence Cluster Tool
Theoretical Production Time for Actual Units
= Σ_j*(Theoretical Production Time*
for Actual Units for Processing Module j)

Flexible-Sequence Cluster Tool
Theoretical Production Time for Effective Units
= Σ_j*(Theoretical Production Time*
for Effective Units for Processing Module j)

6.3.2 *Production Time*

6.3.2.1 *Processing Module Production Time* — The sum of all periods of manufacturing time in which a processing module or the transport module serving that processing module are performing operations according to the virtual machine model. When SEMI E10 equipment states are tracked at the virtual machine level, processing module production time is equivalent to *E10 productive time*. Automated tracking is required for accurate results.

6.3.2.2 *Flexible-Sequence Cluster Tool Production Time* — Aggregate production time for all processing modules tracked according to the virtual machine model.

Flexible-Sequence Cluster Tool Production Time =
=Σ_j*(Production Time for Processing Module j)*

NOTE 17: In this quantity, elapsed times for transport operations that reposition units from one processing module to another are intentionally credited to both modules. Also note that this aggregate measure may be larger than the elapsed time observed and can only be compared with similar aggregate flexible-sequence cluster tool metrics.

6.3.3 *Equipment Uptime*

6.3.3.1 Equipment uptime is defined to measure the total time, during a period of observation, that a processing module or a flexible-sequence cluster tool is in a condition to perform processing in some form.

6.3.3.2 SEMI E10 defines equipment uptime as including E10 productive time, engineering time, and standby time. This definition applies to individual processing modules of a flexible-sequence cluster tool. For the flexible sequence cluster tool as a whole, production time is the sum of production times for the individual processing modules. This production time is used in lieu of productive time.

NOTE 18: This representation of flexible-sequence cluster tool equipment uptime is for productivity purposes only, and may not apply for the determination of flexible-sequence cluster tool RAM.

6.3.3.3 *Processing Module Equipment Uptime*

Processing Module Equipment Uptime =
Processing Module Production Time
+ Processing Module Engineering Time
+ Processing Module Standby Time

6.3.3.3.1 *Processing Module Engineering Time* — The sum of all periods of time in which a processing module is user-selected for the exclusive use of engineering product, process, and/or equipment experiments. Engineering time may be declared for one processing module without having to declare engineering time for all processing modules.

6.3.3.3.2 *Processing Module Standby Time* — The sum of all periods of manufacturing time not counted in production time, when the virtual machine is *capable* of starting new work.

6.3.3.4 *Flexible-Sequence Cluster Tool Equipment Uptime*

Flexible-Sequence Cluster Tool Equipment Uptime =
Σ_j*(Processing Module Equipment Uptime*
for Processing Module j)

6.3.4 *Total Time*

6.3.4.1 *Processing Module Total Time* — For individual processing modules, processing module total time is trivially defined as all time observed (at the rate of 24 hours per day and seven days per week).

6.3.4.2 *Flexible-Sequence Cluster Tool Total Time*

Flexible-Sequence Cluster Tool Total Time =
Σ_j*(Processing Module Total Time*
for Processing Module j) =
(Total Time Observed) X (Number of Processing Modules)

APPENDIX 1
CALCULATING PRODUCTIVITY METRICS

NOTE: The material in this appendix is an official part of SEMI E79 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A1-1 Example Calculations for an Individual Processing Module or a Fixed-Sequence Cluster Tool

A1-1.1 Sample Data — The calculations in this section are based on the following sample data. The sample data is for a seven-day period.

Non-Scheduled Time	*0.00 hours*
Unscheduled Downtime	*4.00 hours*
Scheduled Downtime	*8.00 hours*
Engineering Time	*3.00 hours*
Standby Time	*6.00 hours*
Production Time	*147.00 hours*
Total Time	*168.00 hours*

Recipe	*Theoretical Production Time Per Unit*	*Theoretical Units Per Hour*	*Actual Units of Recipe*	*Effective Units of Recipe*
A	0.03333 hr/unit	30.00 units/hr	1420	1400
B	0.04000 hr/unit	25.00 units/hr	600	600
C	0.05000 hr/unit	20.00 units/hr	800	800
D	0.06667 hr/unit	15.00 units/hr	500	480

A1-1.2 Fundamental Quantities

Equipment Uptime
= (Production Time) + (Standby Time) + (Engineering Time)
= (147.00 hours) + (6.00 hours) + (3.00 hours)
= 156.00 hours

Production Time (given)

Theoretical Production Time for Actual Units
$= \sum_i$ *(Actual Units of Recipe i X* THT_i *)*
= [(1420 units X 0.03333 hr/unit)
+ (600 units X 0.04000 hr/unit)
+ (800 units X 0.05000 hr/unit)
+ (500 units X 0 .06667 hr/unit)]
= 144.66 hours

Theoretical Production Time for Effective Units
$= \sum_i$ *(Effective Units of Recipe i X* THT_i *)*
= [(1400 units X 0.03333 hr/unit)
+ (600 units X 0.04000 hr/unit)
+ (800 units X 0.05000 hr/unit)
+ (480 units X 0.06667 hr/unit)]
= 142.67 hours

A1-1.3 Productivity Metrics

Availability Efficiency
= (Equipment Uptime) ÷ (Total Time)
= (156.00 hours) ÷ (168.00 hours)
= 0.9286

Operational Efficiency
= (Production Time) ÷ (Equipment Uptime)
= (147.00 hours) ÷ (156.00 hours)
= 0.9423

Rate Efficiency
= (Theoretical Production Time for Actual Units)
÷ (Production Time)
= (144.66 hours) ÷ (147.00 hours)
= 0.9840

Performance Efficiency
= (Operational Efficiency) x (Rate Efficiency)
= (0.9423) X (0.9840)
= 0.9272

Quality Efficiency
= (Theoretical Production Time for Effective Units)
÷ (Theoretical Production Time for Actual Units)
= (142.67 hours) ÷ (144.66 hours)
= 0.9862

Overall Equipment Efficiency (OEE)
= (Theoretical Production Time for Effective Units)
÷ (Total Time)
= (142.67 hours) ÷ (168.00 hours)
= 0.8492

A1-2 *Example Calculations for a Flexible-Sequence Cluster Tool*

A1-2.1 Sample Data — The calculations in this section are based on the following sample data. The sample data is over a seven-day period for a flexible-sequence cluster tool encompassing three processing modules. This example will calculate the theoretical OEE for the cluster tool without consideration of OEE degrading module interactions.

	Processing Module A	*Processing Module B*	*Processing Module C*
Non-Scheduled Time	*0.00 hours*	*0.00 hours*	*0.00 hours*
Unscheduled Downtime	*5.00 hours*	*5.00 hours*	*0.00 hours*
Scheduled Downtime	*0.00 hours*	*5.00 hours*	*0.00 hours*
Engineering Time	*3.00 hours*	*5.00 hours*	*0.00 hours*
Standby Time	*10.00 hours*	*5.00 hours*	*88.00 hours*
Production Time	*150.00 hours*	*148.00 hours*	*80.00 hours*
Total Time	*168.00 hours*	*168.00 hours*	*168.00 hours*

Process Sequence for Flexible-Sequence Cluster Tool	*Processing Module A Recipe*	*Processing Module B Recipe*	*Processing Module C Recipe*	*Actual Units of Sequence*	*Effective Units of Sequence*
S1	R1	R2		300	275
S2		R2	R4	100	100
S3	R2	R3		250	240
S4		R3	R4	400	400

Processing Module Recipe	*Theoretical Production Time Per Unit (THT_i) including Load/Unload Time*
R1	*0.3000 hr/wafer*

= (130.50 hours) ÷ (140.00 hours)	= (139.00 hours) ÷ (145.00 hours)	= (75.00 hours) ÷ (75.00 hours)
= 0.9321	= 0.9586	= 1.0000

Flexible-Sequence Cluster Tool Quality Efficiency
=(Processing Module Theoretical Production Time for Effective Units)
÷ (Processing Module Theoretical Production Time for Actual Units)
= (344.50 hours) ÷ (360.00 hours)
= 0.9569

Processing Module Overall Equipment Efficiency (OEE)
= (Processing Module Theoretical Production Time for Effective Units) ÷ (Processing Module Total Time)

Processing Module A	Processing Module B	Processing Module C
= (130.5 hours) ÷ (168.00 hours)	= (139.00 hours) ÷ (168.00 hours)	= (75.00 hours) ÷ (168.00 hours)
= 0.7768	= 0.8274	= 0.4464

Flexible-Sequence Cluster Tool Overall Equipment Efficiency (OEE)
=(Flexible-Sequence Cluster Tool Theoretical Production Time for Effective Units)
÷ (Flexible-Sequence Cluster Tool Total Time)
= (344.50 hours) ÷ (504.00 hours)
= 0.6835

APPENDIX 2
SUPPLEMENTAL PRODUCTIVITY METRICS FOR FOCUSED PRODUCTIVITY STUDIES

NOTE: The material in this appendix is an official part of SEMI E79 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A2-1 Supplemental Productivity Metrics with Total Time as the Denominator

A2-1.1 OEE is based on "as-is" assumptions with respect to process specifications (recipes), equipment type, and equipment design. In this way, OEE measures the performance of the organizations of the manufacturer and the equipment supplier as they attempt to drive equipment performance to a potential defined by given process specifications and a given equipment type and design.

A2-1.2 This section presents three variations on the OEE calculation that additionally measure the performance of engineering and design organizations as they attempt to improve equipment selection, process specifications and equipment design. These three variants are each based on more discriminating definitions of the theoretical production time per unit, as shown in Figure A2-1. Total time is the denominator for each metric.

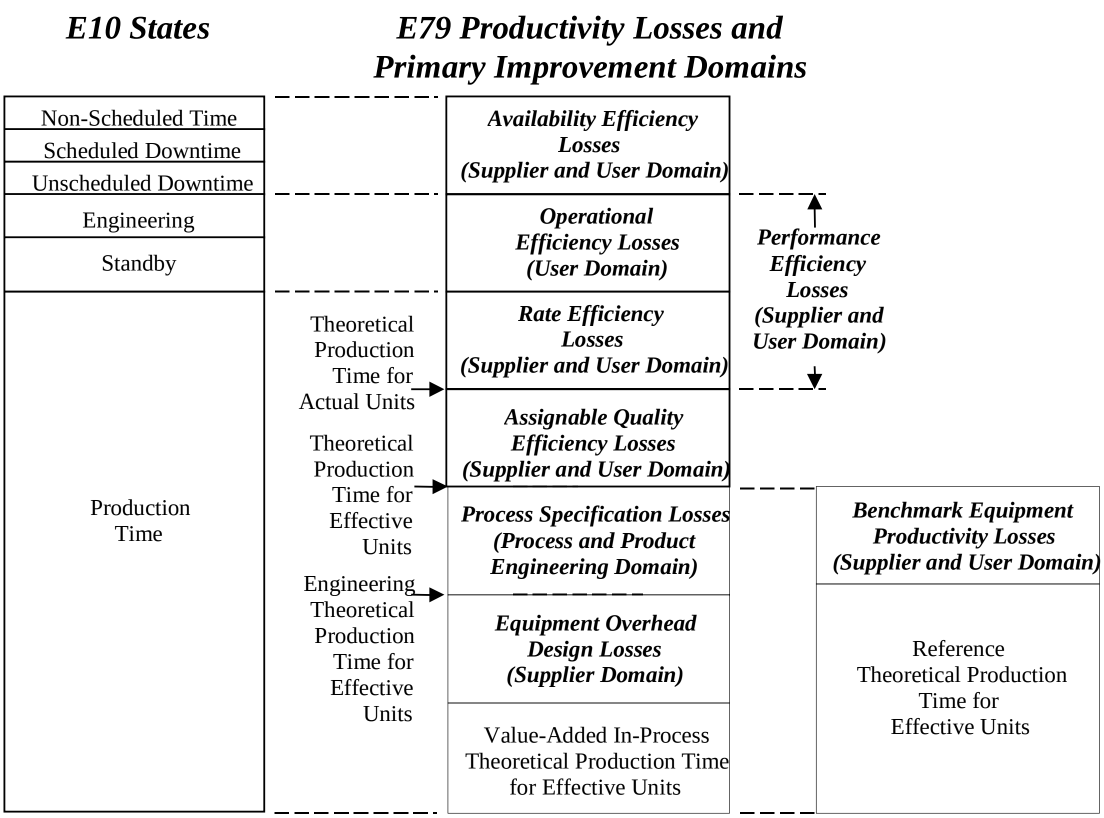

Figure A2-1
Incompatibility of R-OEE with E-OEE and VA-OEE
(Data for sample calculations are given on the following page.)

Operations Time = 168 hours
Theoretical Production Time
for Effective Units = 146 hours
No Product Time = 6 hours
Equipment Unavailable No Product Time = 4 hours
Planned No Product Time = 8 hours

Recipe	*Theoretical Production Time Per Unit (THT_i)*	*Reference Theoretical Production Time Per Unit ($RTHT_i$)*	*Engineering Theoretical Production Time Per Unit ($ETHT_i$)*	*Value-Added In-Process Theoretical Production Time Per Unit ($VTHT_i$)*	*Actual Units of Recipe*	*Effective Units of Recipe*
A	0.03333 hr/unit	0.03333 hr/unit	0.02500 hr/unit	0.01000 hr/unit	1500	1500
B	0.04000 hr/unit	0.03333 hr/unit	0.02000 hr/unit	0.00500 hr/unit	600	600
C	0.05000 hr/unit	0.03333 hr/unit	0.01500 hr/unit	0.00500 hr/unit	800	800
D	0.06667 hr/unit	0.03333 hr/unit	0.03250 hr/unit	0.01000 hr/unit	500	480

A2-1.3 *Reference OEE (R-OEE)*

A2-1.3.1 Reference OEE provides a measure of equipment productivity relative to a benchmark theoretical production time. The reference theoretical production time per unit for a given recipe is the time required by the benchmark equipment (i.e., the fastest equipment model of similar type), running the comparable recipe for a benchmark product and process design. Reference theoretical production time per unit (RTHT) must be defined to be less than or equal to theoretical time per unit (THT) used in calculating standard OEE. The *R-OEE* score may be compared against the standard *OEE* score to assess the productivity loss arising from the application of inferior equipment.

$$\text{Reference OEE (R-OEE)} = [\textstyle\sum_i (\text{Effective Units of Recipe } i \times RTHT_i)] \div (\text{Total Time})$$

where $RTHT_i$ = reference theoretical production time per unit of recipe *i* (based on the benchmark equipment performing a comparable recipe for a benchmark product and process design).

NOTE: Reference OEE utilizes an incompatible definition of theoretical production time for effective units compared to that utilized in Engineering OEE and Value-Added In-Process OEE. Productivity losses indicated by R-OEE and by E-OEE and VA-OEE may overlap. (See Figure A2-1.)

Sample *Reference OEE (R-OEE)* Calculation

Reference OEE (R-OEE)
$= [\sum_i (\text{Effective Units of Recipe } i \times RTHT_i)]$
$\div (\text{Total Time})$
$= [(3380 \text{ units} \times 0.03333 \text{ hr/unit})] \div (168.00 \text{ hours})$
$= 0.6706$

A2-1.4 *Engineering OEE (E-OEE)*

A2-1.4.1 Engineering OEE provides a measure of equipment productivity assuming process specifications are optimized for minimum production time. Engineering theoretical production time per unit (ETHT) must be defined to be less than or equal to theoretical time per unit (THT) used in calculating standard OEE. Engineering theoretical production time per unit may include minimum durations for the objective processing steps, e.g., implant time for ion implant systems, and minimum allowances for any additional supporting process steps, e.g., heating, cooling, gas stabilization, only if those steps are deemed absolutely necessary. Time to perform test wafers, sample wafers, send-aheads, clean cycles, seasoning cycles, and allowances for non-continuous cascading of lots through tools are to be specifically excluded.

$$\text{Engineering OEE (E-OEE)} = [\textstyle\sum_i (\text{Effective Units of Recipe } i \times ETHT_i)] \div (\text{Total Time})$$

where $ETHT_i$ = engineering theoretical production time per unit of recipe *i*.

Sample *Engineering OEE (E-OEE)* Calculation

Engineering OEE (E-OEE)
$= [\sum_i (\text{Effective Units of Recipe } i \times ETHT_i)]$
$\div (\text{Total Time})$
$= [(1500 \text{ units} \times 0.02500 \text{ hr/unit})$
$+ (600 \text{ units} \times 0.02000 \text{ hr/unit})$
$+ (800 \text{ units} \times 0.01500 \text{ hr/unit})$
$+ (480 \text{ units} \times 0.03250 \text{ hr/unit})] \div (168 \text{ hours})$
$= 0.4589$

A2-1.5 *Value-added In-Process OEE (VA-OEE)*

A2-1.5.1 Value-added In-Process OEE provides a measure of equipment productivity assuming the non-value-added portion of processing cycles is wasted equipment time. The non-value-added time should be the focus of efforts by the equipment supplier to reduce or eliminate it through improved equipment design. Value-added In-Process theoretical production time per unit (*VTHT*) must be defined to be less than or equal to engineering theoretical production time per unit (*ETHT*) used in calculating engineering E-OEE (OEE).

Value-Added In-Process OEE (VA-OEE)
= [Σ_i (Effective Units of Recipe i X $VTHT_i$)]
÷ (Total Time)

where $VTHT_i$ = value-added in-process theoretical production time per unit of recipe *i*.

A2-1.5.2 Value-added in-process theoretical production time per unit credits time only for the objective processing steps. The objective processing steps for recipes performed by major types of wafer fabrication equipment are indicated in Table A2-1.

A2-1.5.3 Value-added in-process theoretical production time per unit specifically excludes the following items (partial list):

- All wafer handling time,
- All load-lock time,
- Pre-etch and pre-deposition time,
- Thermal stabilization time,
- Gas stabilization time,
- Wafer heating and cooling time,
- Time for clean cycles, and
- High-etch and seasoning time.

Sample Value-Added In-Process OEE (VA-OEE) Calculation

Value-added In-Process OEE (VA-OEE)
= [Σ_i (Effective Units of Recipe i X $VTHT_i$)]
÷ (Total Time)
= [(1500 units X 0.01000 hr/unit)
+ (600 units X 0.00500 hr/unit)
+ (800 units X 0.01000 hr/unit)
+ (480 units X 0.0050 hr/unit)] ÷ (168 hours)
= 0.1690

Table A2-1 Identification of Objective Process Steps for Value-Added In-Process Theoretical Time Per Unit

Equipment Type	*$VTHT_i$ Includes*	*$VTHT_i$ Excludes*
Resist Processing	Coat, Develop, Bake, Cool Time at process temperature	Temp. ramp up/down
Photolithography Exposure	Exposure Time	Pre-Alignment, Align, Stepping Time
Etch, Oxide, Metal, Poly	Flood Expose Time	Chamber clean Time
Asher, Dry	Ashing Time	
Clean Wet Processing Station	Acid, Rinse and Dry Time	Robot Transport Time
Furnace Atmospheric Process, Furnace LPCVD Process, and Rapid Thermal Processing	Main Oxidation, Anneal Time at defined fixed process temperatures resulting in thermal (film) treatment	Ramp up/down, boat push/pull
Implanter HC, MC, HE …	Implant Time	Beam Setup Time
Metal Deposition - PVD, CVD	Metal Deposition Time	Chambers Clean Time
Dielectric - CVD	Dielectric Deposition Time	Chambers Clean Time
CMP Planarization	Polishing Time	Pad Dressing dedicated Time
Measure CD SEM	Measurement Time	Pattern Recognition Time
Measure Overlay	Measurement Time	Pattern Recognition Time
Defect Detection Patterned Wafers	Scanning Measurement Time	Pattern Recognition Time
Defect Detection Unpatterned Wafers	Scanning Measurement Time	
Measure Film Thickness	Measurement Time	Pattern Recognition Time

A2-2 Additional Productivity Metrics Involving Denominators Other Than Total Time

A2-2.1 This section presents three productivity metrics for assessing efficiency of the equipment resource relative to a time frame less than total time.

A2-2.2 *Production Equipment Efficiency* and *Demand Equipment Efficiency* exclude portions of *no product time* from productivity losses, as depicted in Figure A2-2. While the idle time due to no product is excluded from the operational losses in these particular measures of equipment efficiency, the user should be aware that the additional productivity losses due to sub-optimal load or batch sizes may also be present as rate efficiency losses. Such losses, which result from fluctuations in product flow or tool loading policies, are considered in any equipment efficiency calculation that uses theoretical time per unit.

A2-2.3 *Production Equipment Efficiency (PEE)* — A measure of equipment productivity during the time that work is available to process at the tool. One application of *PEE* is to measure the productivity of non-constraint tools, which are expected to have periods of idle time due to lack of available work.

Production Equipment Efficiency (PEE)
= (Theoretical Production Time for Effective Units)
÷ [(Operations Time) - (No Product Time)
- (Equipment Down No Product Time)]

= Overall Equipment Efficiency X Total Time
÷ [(Operations Time) - (No Product Time)
- (Equipment DownNo Product Time)]

A2-2.3.1 Sample *Production Equipment Efficiency (PEE)* Calculation

Production Equipment Efficiency (PEE)
= (146 hours) ÷ [(168 hours) - (6 hours) - (4 hours)]
= 0.9241

A2-2.4 *Demand Equipment Efficiency* (DEE) — A measure of equipment productivity during the time that work is planned to be available to process at the equipment. A factory model or production schedule that defines the expected or planned idle time at the equipment is required to calculate *Demand Equipment Efficiency*. *DEE* measures the productivity of the equipment relative to the requirements of the factory model or production schedule.

Demand Equipment Efficiency (DEE)
= (Theoretical Production Time for Effective Units)
÷ [(Operations Time) - (Planned No Product Time)]

= Overall Equipment Efficiency X Total Time
÷ [(Operations Time) - (Planned No Product Time)]

A2-2.4.1 Sample *Demand Equipment Efficiency (DEE)* Calculation

Demand Equipment Efficiency (DEE)
= (146 hours) ÷ [(168 hours) - (8 hours)]
= 0.9125

A2-2.5 *Intrinsic Equipment Efficiency (IEE)* — A measure of equipment productivity that compares value-added, in-process theoretical production time to the actual production time. IEE measures the combined productivity losses due to rate efficiency losses, recipe design, and equipment design.

Intrinsic Equipment Efficiency (IEE)
$= [\sum_i (\text{Actual Units of Recipe } i \ X \ VTHT_i)]$
$\div (\text{Production Time})$

where $VTHT_i$ = value-added in-process theoretical production time per unit for recipe *i*. See section A2-1.3.

A2-2.5.1 Sample *Intrinsic Equipment Efficiency (IEE)* Calculation

Production Time = 155.00 hours

Intrinsic Equipment Efficiency (IEE)
$= [\sum_i (\text{Actual Units of Recipe } i \ X \ VTHT_i)]$
$\div (\text{Production Time})$
= [(1500 units X 0.01000 hr/unit)
+ (600 units X 0.00500 hr/unit)
+ (800 units X 0.01000 hr/unit)
+ (500 units X 0.0050 hr/unit)] ÷ (155 hours)
= 0.1839

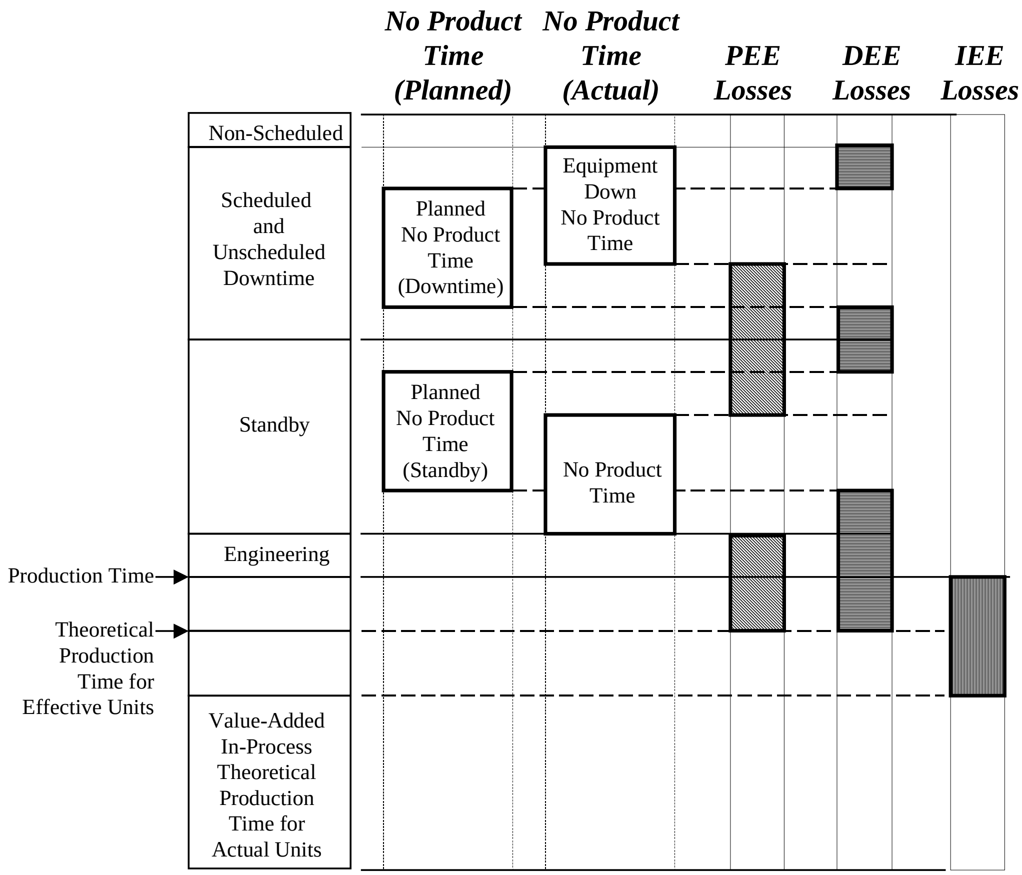

Figure A2-2
Productivity Losses Included in PEE and DEE, and IEE Metrics (shaded regions)

RELATED INFORMATION 1
GUIDELINES FOR DETERMINING THEORETICAL PRODUCTION TIME PER UNIT

NOTE: This related information is not an official part of SEMI E79. This related information was approved for publication by vote of the responsible committee on December 15, 1999.

R1-1 Background

R1-1.1 Overall Equipment Efficiency (OEE) is computed in terms of the theoretical production time per unit for each recipe performed. This theoretical time per unit is based on the actual recipe, the actual equipment design in use, and an assumed load size that optimizes equipment throughput (expressed in units of output per hour) for that recipe.

R1-1.2 OEE is intended to express the true efficiency of the equipment resource. A score of 50% OEE indicates that exactly half of the maximum productive potential of the equipment resource is being realized; a score of 100% indicates that no further increase in productivity is feasible, taking the existing process recipes and equipment design as given.

R1-1.3 To accurately calculate OEE in turn requires that theoretical production times per unit be accurately defined. In particular, theoretical production times per unit must be defined so that the speed losses are always non-negative, i.e.,

Speed Losses
= (Production Time) - (Theoretical Production Time for Actual Units) >= 0

R1-1.4 According to now-classical industrial engineering practice, standards for ideal performance are determined by application of the following:

- Break work methods down into their *operational elements* (hereafter simply referred to as *elements)*.
- Study each of these elements separately to determine its ideal duration.
- Design a new ideal method offering the shortest sequence of only the necessary elements (where the term “sequence” as used herein may involve parallel performance of some or all elements).

R1-1.5 It is remarked that even when the durations of all elements are ideal, if the sequence of elements is not ideal, ideal overall performance cannot be achieved. Based on this understanding, theoretical processing time for an equipment recipe must be based on both an ideal element sequence as well as ideal durations for all elements.

R1-2 Modeling Operational Element Sequences

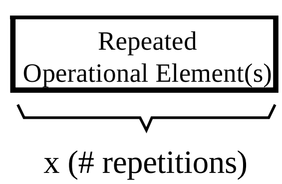
R1-2.1 A graphical model of the sequence of operational elements comprising the performance of an equipment recipe can be helpful for determining theoretical production time per unit. This model has the following components:

R1-2.2 *Resource Utilization Chart* — a Gantt chart displaying a separate timeline for each primary resource within the equipment. Utilization sequences displayed for each primary resource may be used to show how each resource within an equipment system is utilized, and how resources may interact.

R1-2.3 *Operational Element* — An operational element occurring within a utilization sequence is depicted by a box-shaped bar with a label. The time for this element to execute may be fixed, recipe-dependent, or calculated from parameters. Operational elements that are not related to material handling operations have a thick outline.

R1-2.3.1 Material handling elements have a thin outline.

R1-2.4 *Repeated Groups* — A bracket underneath a group of operational elements indicates that the group repeats multiple times based on the parameter shown. For elements that occur conditionally, the number of repetitions may be zero. These repetitions apply to all elements in all timelines positioned in the vertical range of the bracket.



R1-2.5 *Sub-Sequences* — A number in front of an element label indicates that the element represents a group of elements defined elsewhere. This group is referred to as a sub-sequence.

1.1 Sub-Sequence Operational Element

R1-2.6 *Calculating Theoretical Production Time Per Unit* — Any element sequence may be modeled as an activity-on-node network derived from precedence constraints on the operational elements and precedence constraints on the allocation of equipment resources to the elements. Using the network model, the duration of the element sequence is simply the duration of the critical path through the network.

R1-2.6.1 Theoretical production time per unit is then the theoretical duration for the element sequence divided by the number of units processed during the sequence.

Theoretical Production Time Per Unit for recipe i [THT_i] =
= (Theoretical Duration for the Element Sequence)
÷ (Number of Units Processed During Sequence)

R1-2.7 *Allowances for Non-Steady-State Processing* — For complicated batch-load equipment models, it is useful to divide resource sequences into a beginning phase, a steady-state-phase, and an ending phase. For modeling theoretical time, it is important to determine what allowances to make, if any, for the beginning and ending phases. For machines that are limited in the number of lots that can be processed in a continuous cascade, appropriate allowances must be made for beginning and ending phases. However, for machines that are capable of running continuously, the beginning and ending phases should not be considered in determining theoretical production time.

R1-2.7.1 Under certain conditions, setup type operations that are not tracked as part of downtime must be considered as part of the theoretical resource sequence for a tool. These conditions include operations that must occur in every machine cycle, e.g. recipe download, as well as operations that occur on other regular intervals, e.g., one clean cycle every 75 wafers. In general, any activity that occurs on predictable intervals and is a necessary part of a recipe specification should be considered in the equipment sequence for determining theoretical production time.

R1-2.7.2 Operations that occur at irregular intervals or that apply to an unpredictable quantity of wafers, lots, or loads are not counted. An example of an unpredictable frequency setup is a recipe changeover, when the machine is changed from the requirements of one process recipe to meet the needs of another, e.g., a species change as on an ion implant system. The ideal frequency of these events is taken as zero.

R1-2.8 *Optimality* — Theoretical sequences must be designed so as to optimize equipment throughput by using only the best configuration of elements and an optimal load size. Optimal sequences may differ for different recipes performed on the same machine. Optimal load sizes are not necessarily maximum load sizes.

R1-2.9 *Error-Checking Element Sequences* — Once a theoretical sequence is specified for a piece of equipment, it can be compared against actual equipment operations to check for errors. If discrepancies are found, three possibilities to investigate are:

- The sequence contains extraneous elements.
- The sequence is missing necessary elements.
- The series and parallel relationships between elements are not correctly specified.

R1-2.9.1 What may at first appear to be sequence specification errors may in fact be undiscovered rate efficiency losses embedded in the equipment sequence. Because sequences are fundamental to overall performance, it is important to rule out sequence specification errors to preclude erroneous assignment of rate efficiency losses to individual elements.

R1-2.10 *Example Resource Utilization Sequence* — An example of a resource utilization sequence is given in Figure R1-1. This example represents a particular instance of a photolithography stepper that exposes patterns from a reticle onto a wafer. This example assumes that the stepper receives individual unexposed wafers from a linked coat track and transfers individual exposed wafers to a linked develop track.

R1-2.10.1 First, a reticle box must be loaded into the stepper reticle handling system (“load box”). Before a wafer may be exposed, the reticle must be set and aligned. A wafer must also be loaded onto the pre-align chuck, pre-aligned, and transferred to the exposure stage. Each wafer is exposed then transferred to a post processing relay chuck. The transfer operation simultaneously removes an exposed wafer and replaces it with an unexposed wafer.

R1-2.10.2 The expose operation is represented by the sub-sequence shown in Figure R1-2. Depending on the recipe to be executed, the expose sub-sequence may consist of several different reticle images requiring changes of “blade” positioning. For each image, there is one “align” operation. For each individual exposure, there is a “step” operation, a “level” operation, and the “expose” operation itself. Within the same image, different exposures may require different leveling times, as well as different stepping times.

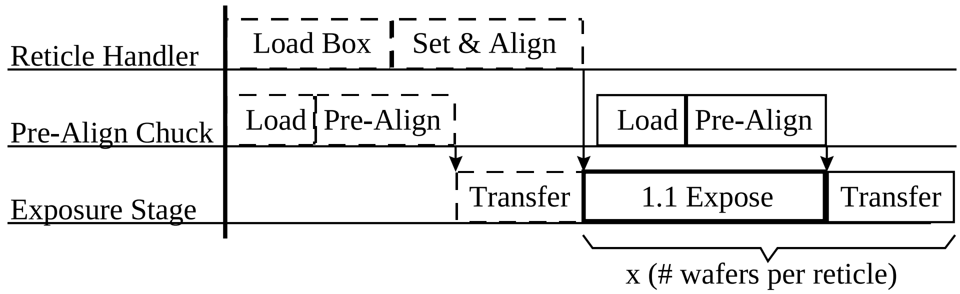


Figure R1-1
Example Resource Utilization Sequence

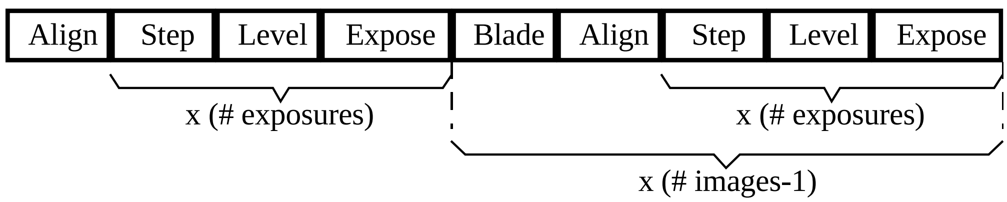

Figure R1-2
Example of Equipment Sub-Sequence

R1-2.10.3 The operations indicated by dashed boxes represent the beginning phase of the main equipment sequence. If the stepper is capable of processing wafers of the same reticle indefinitely, then the beginning phase is not included in theoretical production time. If, however, there is a hardware and/or software limit to the number of wafers that may be run consecutively, then the beginning phase must be counted in theoretical production time.

R1-3 Modeling Theoretical Durations for Operational Elements

R1-3.1 Once a theoretical equipment sequence is defined, the next step is to measure and/or model theoretical durations for each operational element in the sequence. As a rule, it is preferable to acknowledge in the model an elemental speed loss that can never be recovered in lieu of inadvertently overlooking another loss that could be reduced or eliminated.

R1-3.2 *Legitimate Observations* — Each theoretical element duration should always be less than or equal to any *legitimate observation* for that element, where a legitimate observation is a traceable instance of an operational element that does not result in a loss of quality. The time for any legitimate observation that is less than the existing theoretical element duration should become the new theoretical element duration. For legitimate instances of the same operational element on different instances of identically configured equipment, the best time observed among all equipment of that type should be used as the theoretical element duration.

R1-3.3 *Basis for Theoretical Element Durations* — Theoretical element durations may be based on time studies, nominal parameters, and/or parametric modeling.

R1-3.3.1 *Time Studies* — Most mechanical operational elements that have fixed execution times, like transport and load lock operations, can be accurately determined by time studies using either stopwatches, equipment data acquisition systems, timing systems built into the equipment, or stand-alone data acquisition systems that use sensors to detect equipment events and/or state changes.

R1-3.3.1.1 When it is difficult to directly measure individual elements, collections of elements may be observed and timed instead. On systems where a number of consecutive identical elements occur too fast to be measured individually, a set of elements should be timed, and the time should be divided by the number of elements in the set. For even more complicated situations, element times may be derived algebraically from observations of several linearly independent sets of operational elements.

R1-3.3.2 *Nominal Parameters* — There are instances where it is desirable to use nominal parameters to represent theoretical conditions rather than using direct observations, such as when:

- Nominal parameters are more representative of the physical systems being studied.
- Nominal parameters are more representative of the desired system performance.
- It is not practical to obtain reliable data.

R1-3.3.3 *Parametric Models* — For cases where the time for an operational element may have a range of values that are dependent on recipe specifications, theoretical time is best represented by a parametric model. Parametric models for representing semiconductor operations may be based on mathematical formulas, e.g., implant time versus beam current, and/or “lookup” tables, e.g., best observed etch time vs. etch end point.

R1-3.3.3.1 For the photolithography example, one of the recipe parameters is the exposure energy (EE). Given the ideal or theoretical lamp intensity (LI) of the stepper, the theoretical duration per exposure (THT_{EX}) for the recipe may be calculated as THT_{EX} = EE / LI .

RELATED INFORMATION 2
RAPID CHARACTERIZATION OF INTRINSIC EQUIPMENT EFFICIENCY (IEE) AND THE PRODUCTIVITY EFFICIENCY PLANE

NOTE: This related information is not an official part of SEMI E79. This related information was approved for publication by vote of the responsible committee on December 15, 1999.

R2-1 Rapid Characterization of Intrinsic Equipment Efficiency

R2-1.1 IEE may be rapidly characterized as follows using a limited number of production experiments.

R2-1.2 *Step 1: Design Production Experiments* — Select a limited number of scenarios to execute as equipment experiments. It may be of interest to characterize IEE according to either operating modes, processing diversity, or a combination of operating modes and process diversity.

R2-1.2.1 Determine the value-added in-process theoretical production time per unit (VTHT) – (time per unit) for all recipes involved. This information is required for determining IEE. See Table A2-1.

R2-1.2.2 For assessment of operating modes, experiments should examine only a single typical recipe that is likely to be used most frequently. Each experiment should examine a separate operating mode, where examples of various equipment operational modes may be as follows:

One wafer at a time mode (production monitor wafer).

One batch is run, then the tool stops.

Two batches are run, then the tool stops.

Three batches are run, then the tool stops.

Continuous (cascade) mode. A larger number of batches is run, then the tool stops.

R2-1.2.3 For assessment of process diversity, select a limited number of representative recipes that will be processed by a tool. This population should include at least one recipe representing the minimum expected processing duration and one representing the maximum.

R2-1.2.4 Each experiment should be designed and executed to eliminate rate efficiency losses to the greatest extent possible. It is further assumed that quality efficiency losses are zero. Under this approximation, (VA-OEE) = (OEE) x (IEE).

R2-1.3 *Step 2: Execute Process Experiments* — Perform process experiments recording all relevant input variables including the configuration of lots and wafers, and recipes. For each experiment, record the elapsed production time using convenient means, e.g., stopwatch or existing data acquisition system.

R2-1.4 *Step 3: Calculate Results* — Calculate IEE and throughput for each experiment. IEE may be used to measure the effect of *non-value-added overhead time* during equipment processing. Approximately:

Intrinsic Equipment Efficiency (IEE)
= (Value-Added In-Process Theoretical Time)
÷ (Non-Value-Added Overhead Time
+ Value-Added In-Process Theoretical Time)

R2-1.4.1 Hence, *non-value-added overhead time* for each experiment may be calculated as:

Non-Value-Added Overhead Time
= [(Production Time)
- (Value-Added In-Process Theoretical Time)]

R2-1.4.2 It should be the focus of efforts by the equipment supplier and the end-user to reduce or eliminate non-value-added overhead time through improved equipment design, including scheduling software, as well as hardware components (carrier and wafer handling systems, valves, pumps, heaters, coolers, etc.).

R2-1.4.3 Results may be shown in either tabular form or plotted graphically on a Productivity Effectiveness Plane. See next section R2-2.

Sample Rapid Characterization of Intrinsic Equipment Efficiency (IEE)

Four experiments were designed and executed with the following results:

Exp.	*Units of Recipe i per experiment*	*Value-Added In-Process Theoretical Production Time Per Unit ($VTHT_i$)*	*Production Time Per Experiment*
1	*50 of recipe A*	*0.00670 hr/unit*	*3.3333 hr*
2	*100 of recipe B*	*0.00550 hr/unit*	*5.0000 hr*
3	*150 of recipe B*	*0.00550 hr/unit*	*6.0000 hr*
4	*300 of recipe A*	*0.00670 hr/unit*	*10.0000 hr*

Effective Unit Throughput Per Experiment
= (Total Units Per Experiment)
÷ (Production Time Per Experiment)

Intrinsic Equipment Efficiency (IEE) Per Experiment
= [Σ_i (Units of Recipe i Per Experiment X $VTHT_i$)
÷ (Production Time Per Experiment)] X 100%

Non-Value-Added Overhead Time Per Experiment
= [(Production Time Per Experiment)
- Σ_i (Units of Recipe i Per Experiment X $VTHT_i$)]

Experiment	*Effective Unit Throughput*	*Intrinsic Equipment Efficiency*	*Non-value-added Time in Hours*
1	*15 units/hr*	*10.05%*	*2.9983 hr*
2	*20 units/hr*	*11.00%*	*4.4500 hr*
3	*25 units/hr*	*13.75%*	*5.1750 hr*
4	*30 units/hr*	*20.10%*	*7.9900 hr*

R2-2 Productivity Efficiency Plane (PEP)

R2-2.1 It is recognized that OEE and throughput are separate metrics whose relationship may not be straightforward. Because theoretical production time per unit may vary widely by recipe, good throughput performance may not indicate correspondingly good performance in terms of overall equipment efficiency. Similarly, a high OEE score may not be indicative of high throughput. Given this disparity, it is essential that both metrics be analyzed and compared as separate entities.

R2-2.2 Data from rapid characterization experiments may be displayed graphically on a Productivity Effectiveness Plane (PEP) diagram, Figure R2-1.

R2-2.3 In PEP diagrams, IEE is plotted as a function of throughput. Points that appear further to the right have higher throughput and points that appear higher up have higher IEE. It is desired to have combined equipment and process designs whose performance would appear in the upper right quadrant of the plane for the entire operating range of the tool.

R2-2.4 The four experimental data points from the sample problem are plotted in Figure R2-1 and, when connected, appear to approximate an upward sloping curve. This curve is referred to as a *tool signature*.

R2-2.5 Tool signatures may be used to describe tool performance relative to isolated variables. This representation helps equipment suppliers and users visualize the effects of tool operating modes on IEE and throughput. For more complex multi-dimensional experiment sets, the tool signature would appear as a hyper-surface.

R2-2.6 OEE can be plotted for comparison against tool signatures. In Figure R2-1, an OEE measurement of a typical week is plotted. For the known throughput corresponding to this OEE score, the value of IEE on the tool signature for the same throughput may be used to approximate the IEE score for the week without calculating IEE explicitly.

SEMI E80-0299
TEST METHOD FOR DETERMINING ATTITUDE SENSITIVITY OF MASS FLOW CONTROLLERS (MOUNTING POSITION)

1. Purpose

1.1 The purpose of this test method is to provide a standardized method for quantifying the effect of mounting attitude on an MFC.

1.2 This document provides a common basis for communication between manufacturers and users regarding testing and describing MFC mounting effects.

2. Scope

2.1 This procedure describes a method to determine the effect of attitude (mounting position) of a Mass Flow Controller on flow span and zero.

2.2 The intent of this document is not to suggest any specific testing program but to specify the test method to be used when testing for parameters covered by this method. Reference operating conditions represent the environmental conditions where the "best" performance can be expected.

2.3 The minimum test described in this document is to test one MFC in 5 common mounting positions using Nitrogen gas at 135.8 kPa (19.7 psia) and 308 kPa (44.7 psia). This test method can be used to evaluate additional gases, pressures or mounting attitudes.

3. Limitations

3.1 It is not practical to evaluate performance under all possible combinations of operating conditions. This test procedure should be applied under laboratory (reference) conditions; its intent is to collect sufficient data to form a judgment of the field performance of the MFC being tested.

3.2 The results from this test represent the performance of the specific device tested i.e., make, model, full scale flow and operating conditions. The results may not apply to devices of different manufacture, model, full scale flow or under different operating conditions.

3.3 Due to manufacturing variability, attitude sensitivity may vary for the same model of MFC. To statistically quantify attitude sensitivity for a particular model of MFC, multiple samples should be tested.

4. Referenced Documents

4.1 None.

5. Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *% F.S.* — Percent full scale

5.1.2 *DUT* — Device under test

5.1.3 *HBD* — Horizontal Base Down. Mounting attitude 1 as shown in Figure 1.

5.1.4 *HED* — Horizontal Either side Down. Mounting attitude 3 as shown in Figure 1.

5.1.5 *HUD* — Horizontal Upside Down. Mounting attitude 5 as shown in Figure 1.

5.1.6 *kPa* — KiloPascal

5.1.7 *MFC* — Mass flow controller

5.1.8 *psia* — Pounds per square inch absolute

5.1.9 SAS_{max} — The maximum Span Attitude Sensitivity between two attitudes

5.1.10 SAS_{nm} — Span Attitude Sensitivity between attitudes n and m

5.1.11 *Sccm* — Standard cubic centimeters per minute

5.1.12 *Slm* — Standard liters per minute

5.1.13 *VFD* — Vertical Flow Down. Mounting attitude 2 as shown in Figure 1.

5.1.14 *VFU* — Vertical Flow Up. Mounting attitude 4 as shown in Figure 1.

5.1.15 *VID* — Vertical Inlet Down. Mounting attitude 4 as shown in Figure 1.

5.1.16 *VIU* — Vertical Inlet Up. Mounting attitude 2 as shown in Figure 1.

5.1.17 ZAS_{max} — The maximum Zero Attitude Sensitivity between two attitudes

5.1.18 ZAS_{nm} — Zero Attitude Sensitivity between attitudes n and m

5.2 *Definitions*

5.2.1 *actual flow* — The flow rate as determined by the flow standard used in the test procedure.

5.2.2 *attitude* — The mounting position of the MFC with respect to the surface of the earth as shown in Figure 1.

5.2.3 *indicated flow* — The flow rate as determined by the output of the DUT.

5.2.4 *measured value* — The actual flow through a DUT, expressed in sccm or slm.

5.2.5 *nameplate gas* — The gas intended to be controlled by the MFC in operation.

5.2.6 *setpoint* — The input signal provided to achieve a desired flow, reported as sccm, slm, or percent full scale.

5.2.7 *span* — The full scale range of the DUT.

5.2.8 *zero offset* — The deviation from zero at a "no-flow" condition reported in sccm, slm, % F.S. or mV.

5.2.9 *zero drift* — The undesired change in electrical output (i.e., indicated flow), at a no-flow condition, over a specified time period, reported in sccm or slm.

6. Summary of Test Method

6.1 Gas flow, indicated flow and setpoint data are collected for an MFC. This data is reduced to quantify the relationship between the flow control by the MFC and its relationship to the attitude of the MFC.

6.2 This method allows the user to determine the effect of different mounting attitudes on MFC zero and span.

6.3 The standard test is determining the effect of changing between attitudes 1 and 2 on Nitrogen. Other typical MFC attitudes and gases may also be tested. (See Figure 1.)

7. Interferences

7.1 The accuracy rating of the measuring equipment shall be superior to that of the DUT. Preferably the measuring equipment will have an accuracy that is four times better than the DUT. Calibration equipment must have a valid calibration certificate.

7.2 Take care when using test instruments with a specified accuracy expressed in percent of full scale.

7.3 Installation effects on the flow should be minimized. Monitor pressure upstream of the DUT to ensure that flow variations due to pressure are minimized.

7.4 Verify electrical signals directly at the DUT connector to ensure that the signals at the DUT and standard agree with the signals at the data recording equipment.

7.5 All electrical measurements should be read on devices with at least 4.5 digits of resolution. These devices must have valid calibration certifications.

7.6 All instrumentation in the test apparatus must remain in a constant orientation except the device under test.

8. Significance and Use

8.1 The data generated by this method is used to estimate the effect-mounting attitude will have on the performance of a mass flow controller. It would typically be used to estimate the potential flow error caused by using an MFC in attitude other than the one it was calibrated for.

9. Apparatus (see Figure 2)

9.1 *Flow Standard* — A device or system that accurately measures the flow and reports the actual flow.

9.2 *Data Acquisition System* — The system that measures the electrical signals from the device under test. The data acquisition system may also read the signals from the flow standard, record test data and control the test sequence.

9.3 *Isolation Valves* — Valves that will positively shut off the gas line.

9.4 *Pressure Regulator* — A device that regulates gas pressure to a set value.

9.5 *Pressure Transducer* — An instrument to measure the gas pressure and report it as an electrical signal.

9.6 *Flexible Gas Line* — Flexible tubing that will allow the DUT to be moved to the various test attitudes while the other components can remain in a fixed position.

10. Materials

10.1 Clean, Dry N_2, with 99.9% minimum purity.

10.2 MFC Calibration Test Gas as desired.

11. Safety Precautions

11.1 Follow the manufacturer's specifications and instructions for installation and operation whenever possible. Note any exceptions in the test report.

12. Test Specimen

12.1 Allow all components in the test apparatus to warm up following the manufacturer's specification.

12.2 Take necessary steps when switching gases to ensure that only the desired gas is in the DUT and flow standard at the time the test is performed.

13. Preparation of Apparatus

13.1 Locate the DUT in the test environment to stabilize temperature prior to warm up.

13.2 The reference operating conditions shall be as follows:

13.2.1 *Ambient temperature* — 21 ± 4 °C

13.2.2 *Ambient Temperature Stability* — Ambient temperature to stay constant within ± 1 °C during data acquisition period.

13.2.3 *Gas temperature* — Same as ambient.

13.2.4 *Gas pressure, Outlet* — Ambient Pressure

13.3 Following the conditioning period (Section 12.1), warm up the device according to manufacturer's specifications.

13.4 Perform an adequate purge to ensure all previous gases and atmospheric moisture have been removed from the system.

13.5 Leak check the test set up, using available methodologies to verify the test system leak integrity.

13.6 The power supply must be sufficiently rated for the device under test.

14. Procedure

14.1 Open V1 and V2. DUT and allow the flow to stabilize. Adjust the inlet pressure to 135.8 kPa (19.7 psia).

14.2 Close the downstream isolation valve (V2); then close the upstream isolation valve (V1). (See Figure 2.)

14.3 With both isolation valves closed, and a 100% setpoint wait until the pressure drop across the MFC is dissipated, ensuring a "no flow" condition through the MFC. Dissipation of the pressure across the MFC is indicated when the indicated flow drops to a steady state value near zero.

14.4 Once the indicated flow has dropped to a steady value set the MFC setpoint so there is no power being dissipated by the control valve. For a normally closed valve this is 0% and for a normally open control valve it is 100%.

14.5 After the electrical output signal has stabilized for at least three minutes, record the MFC indicated zero in Table 1.

14.6 Open V1 and V2, command 100%.

14.7 After the electrical output signal has stabilized for at least three minutes, record the actual flow as reported by the flow standard and the indicated flow in Table 1.

14.8 Change the attitude of the DUT to the next desired attitude.

14.9 Close the downstream isolation valve (V2); then close the upstream isolation valve (V1). (See Figure 2.)

14.10 With both isolation valves closed, and a 100% setpoint wait until the pressure drop across the MFC is dissipated, ensuring a "no flow" condition through the MFC. Dissipation of the pressure across the MFC is indicated when the indicated flow drops to a steady state value near zero.

14.11 Once the indicated flow has dropped to a steady value set the MFC setpoint so there is no power being dissipated by the control valve. For a normally closed valve this is 0% and for a normally open control valve it is 100%.

14.12 After the electrical output signal has stabilized for at least three minutes, record the MFC indicated zero in Table 1.

14.13 Open V1 and V2, command 100%.

14.14 After the electrical output signal has stabilized for at least three minutes, record the actual flow as reported by the flow standard and the indicated flow in Table 1.

14.15 Repeat Sections 14.8 to 14.14 for each of the desired attitudes.

14.16 Return the DUT to attitude 1.

14.17 Adjust the inlet pressure to 308 kPa (44.7 psia).

14.18 Repeat Sections 14.8 to 14.14.

15. Calculations or Interpretation of Results

15.1 Attitude sensitivity between two mounting positions is calculated as follows:

$$ZAS_{nm} = Z_m - Z_n$$

Where,

ZAS_{nm} = Zero attitude Sensitivity between attitude n and attitude m
Z_n= zero indication at attitude n

Z_m= zero indication at attitude m

$$SAS_{nm} = S_n - S_m$$

Where,

SAS_{nm} = Span attitude Sensitivity between attitude n and attitude m
S_n= Actual flow in attitude n

S_m= Actual flow in attitude mZAS_{max} = The maximum zero attitude sensitivity for all attitudes.

SAS_{max} = The maximum span attitude sensitivity for all attitudes

15.2 *Interpretation*

15.2.1 Table 2 shows examples of raw and reduced data. For the MFC tested, the maximum zero shift was 0.3% F.S. and the maximum span shift was 0.4% F.S.

SEMI E83-1000
SPECIFICATION FOR 300 mm PGV MECHANICAL DOCKING FLANGE

This Provisional Specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on July 14, 2000. Initially available at www.semi.org August 2000; to be published October 2000. Originally published June 1999.

1 Purpose

1.1 This specification is intended to promote consistent interface features between Person Guided Vehicles and SEMI E15.1 equipment.

2 Scope

2.1 This specification defines a mechanical standard for the stationary (equipment) side of the docking flange used by 300 mm Person Guided Vehicles (PGVs). This flange is to be mounted to the floor within the volume defined by SEMI E64 at SEMI E15.1 and SEMI E64 compliant equipment.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not define the PGV (active) side of the docking interface or carrier transfer. The PGV and the PGV side of the docking interface designs should comprehend the physical limitations of equipment to which they are being applied.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Provisional Specification for 300 mm Tool Load Port

SEMI E64 — Provisional Specification for 300mm Cart to SEMI E15.1 Docking Interface Port

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *PGV* — Person Guided Vehicle (cart)

5.2 *Definitions*

5.2.1 *carrier* — Any cassette, box, pod, or boat that contains wafers (per SEMI E15).

5.2.2 *cart* — A floor based carrier transfer vehicle (per SEMI E64).

5.2.3 *docking* — The act of locating a floor-based carrier transport vehicle for carrier transfer to/from equipment (per SEMI E64).

5.2.4 *facial datum plane* — A vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (per SEMI E57).

5.2.5 *load face plane* — The furthest physical vertical boundary plane from carrier centroid on the side(s) of the equipment where loading of the tool is intended (per SEMI E15).

5.2.6 *load port* — The interface location on a tool where carriers are placed to allow the tool to process wafers (per SEMI E15).

5.2.7 *transfer* — To either load or unload (per SEMI E15).

6 Requirements

6.1 The dimensions that define the universal docking flange are listed in Table 1 and shown on Figure 1.

6.1.1 The minimum length of the docking flange is defined by $2 \times w11$. This minimum length is intended to fit under the shadow of the smallest possible width SEMI E15.1 compatible load port. The PGV and PGV docking must provide full functionality given a minimum length docking flange. No maximum length has been specified.

6.1.2 One vertical pin (labeled VP in Figure 2) is intended to be used for horizontal registration of the PGV to the docking flange. This pin is also intended as a feature for an active mechanism on the PGV to lock on to.

6.2 There are three surfaces on the flange and a vertical pin that can be used as the initial docking contacts point(s) with the PGV. These have been identified as surfaces A, B and C and pin VP as shown in Figure 2. These features are the primary load bearing features during the act of docking, no other features or surfaces shall be used as initial docking contact points.

Table 1 Dimensional Requirements

Symbol	*Value, mm (in.)*	*Tolerance (mm)*	*Type*
a11	0 deg.	+/- 0.25 deg.	angle
∅d11	15.0 (.591)	+/- 0.2	diameter
d12	33.0 (1.299)	+/- 0.2	distance
d13	39.0 (1.535)	+/- 0.2	distance
d14	62.0 (2.441)	+/- 0.2	distance
d15	80.0 (3.150)	+/- 0.2	distance
d16	237.5 (9.350)	+/- 2.5	distance
d17	68.0 (2.677)	minimum	distance
h11	24.0 (.945)	+/- 0.2	distance
h12	39.0 (1.535)	+/- 0.2	distance
h13	40.0 (1.575)	+/-0.2	distance
h14	83.0 (3.268)	+/-0.2	distance
h15	20.0 (.787)	maximum	distance
r11	2.0 (.079)	+/-0.2	radius
r13	4.0 (.157)	+/-0.2	radius
r14	5.0 (.197)	+/-0.2	radius
w11	200 (7.874)	minimum	distance

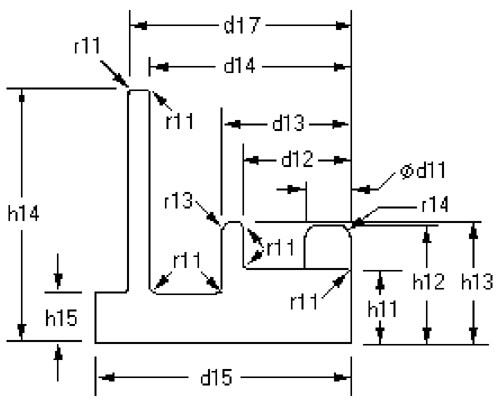

Figure 1
Side Elevation View I

6.3 The flange must be installed such that the vertical pin (VP) is capable of being aligned with the load port bilateral datum plane (as defined in SEMI E15.1) and surface A is a distance of *d*16 from the load port facial datum plane (as defined in SEMI E15.1). The angle of incidence between surface A and the facial datum plane should be capable of adjustment to *a*11 listed in Table 1.

6.3.1 The docking flange is to be physically isolated from the equipment and should be mounted such that the equipment and equipment load port are protected from the impact incurred during docking.

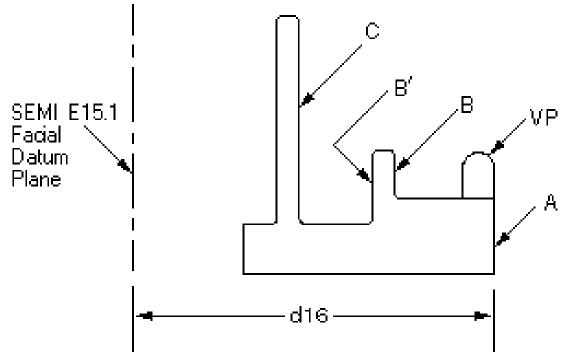

Figure 2
Side Elevation View II

6.4 When the flange is removed, no mounting hardware shall remain protruding from the floor.

6.5 Surfaces A, B, B' and C shown on Figure 2 must exist per tolerances listed in Table 1.

Front Elevation View

NOTICE:. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E83, but was approved for publication by full letter ballot procedures on July 14, 2000.

R1-1 The intent of this standard is to provide manually guided 300mm carrier transport PGVs a standard flange for docking and to facilitate a safe, quick, and repeatable PGV to load port carrier transfer method or mechanism. Standardization of features on the flange is intended to allow for interoperability between PGV designs and the docking flange.

R1-2 SEMI E64 defines Zone L as an exclusion zone in SEMI E15.1 compliant tools. It is intended that the docking flange be mounted in this zone.

R1-3 The docking interface flange includes features to allow for the following minimum functionality of the PGV to flange docking procedure:

- Stopping PGV motion
- Guidance of PGV to flange
- x, y & theta alignment of the PGV to the flange
- Locking of PGV to flange
- Docking parallel or perpendicular to the flange

R1-4 The PGV side of the interface may include additional features to allow for all or some of the following functionality:

- Compliance to the docking flange
- To dampen impact of docking forces

R1-5 No features on the standard docking flange provide an adjustable feature to indicate the height (dimension as H defined by SEMI E15.1) the load port horizontal datum plane has been adjusted to.

R1-6 It is likely that the alignment error and tolerance stack up between the docking interface flange and the equipment load port will not provide sufficient accuracy alone for accurate pick/placement of a pod onto the kinematic couplings on the load port.

R1-7 Possible sources of alignment error are:

- Cleanroom floor height and level
- PGV wheels and framework
- Installation accuracy of docking interface flange
- Stability of mounting

R1-8 It may be necessary to use additional alignment methods to improve accuracy of pod placement onto the kinematic couplings.

R1-9 It is expected that the interface device be floor mounted. Thus, the equipment must not require the use of support pedestals or other support structures under the floor below Zone L.

R1-10 The docking flange should sustain docking impact for the lifetime of the flange without any performance degradation.

- Assume 90kg (200lb) PGV moving at 0.3m/s (1ft/sec)
- Assume 250,000 docking cycles within a flange lifetime
- Recommended to design for 3x safety factor for single docking cycle

R1-11 Flange must be quick remove, replace, align and calibrate.

R1-12 Surface B' (shown on Figure 2) allows docking mechanism designs to grab onto the docking flange without using the docking pin for support.

R1-13 The method of attaching the vertical pin to the flange is not defined in this standard. Docking flange designers should be aware of the docking forces incurred on this pin and design the attachment method accordingly.

R1-14 The method of attaching the flange to the floor is not defined in this standard. Docking flange designers should be aware of the docking forces incurred on the flange and/or pin and design the attachment method accordingly.

R1-15 This standard specifies the radii of certain edges found on the docking flange. It is recommended that edges that do not have a specified radius are radiused or broken to eliminate sharp edges.

R1-16 It is left to user to define the needed flange length ($w2\times2$) at the time of placing an order.

respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E84-0302
SPECIFICATION FOR ENHANCED CARRIER HANDOFF PARALLEL I/O INTERFACE

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published June 1999; previously published November 2001.

1 Purpose

1.1 Due to the migration to large wafer sizes, future semiconductor factories will use extensive automated material handling systems (AMHS) to transfer wafer carriers, including FOUPs and open cassettes, of increasing weight. The parallel input/output (PI/O) control signals between the production equipment and the AMHS must be better defined for more reliable and efficient carrier handoffs (load/unload) at production equipment load ports.

1.2 The purpose of this specification is to enhance the capabilities of the parallel I/O interface defined in SEMI E23 in order to support improvements in the reliability and efficiency of carrier transfer. The enhanced capabilities include continuous handoff, simultaneous handoff, and the capabilities of error detection on the interface.

NOTE 1: The specifications in this document shall be considered independent from the specifications in SEMI E23; therefore, use of this specification does not require SEMI E23.

2 Scope

2.1 The scope of this specification is limited to communications associated with the material handoff operations between the active equipment (for example, AMHS equipment including AGV, RGV and OHT) and the passive equipment (for example, production equipment including process and metrology equipment; stockers, etc). This scope also extends to interbay AMHS active equipment (i.e., OHS and stockers equipped with transfer devices) and passive equipment (i.e., OHS and stockers not equipped with transfer devices). This specification defines the enhanced parallel I/O interface signals used to handoff carriers between the production equipment and the AMHS. Figures 1 and 2 show examples of types of AMHS equipment.

2.2 This enhanced carrier handoff parallel I/O interface specification includes:

- Signal definition including load port assignment signals (see Section 6.1),
- Carrier handoff sequence definitions and time diagrams (see Section 6.2),
- Error indication, detection, and recovery (see Sections 6.3 and 6.4),
- Connector type, signal, and pin assignment (see Section 6.4), and
- Interface sensor unit size to be located at load port defined by SEMI E15.1 (applicable for systems designed to handle 300 mm wafer carriers).

2.3 The enhanced carrier handoff parallel I/O interface controls the handoff of a carrier to and from the passive equipment by the active equipment. This parallel I/O interface only controls the automated handoff operation of the carrier. The handoff is the operation in which a carrier is transferred from one piece of equipment to another. Both the active and passive equipment manage this operation. The factory level controller (i.e., host) does not manage the handoff operation. Figure 3 shows applications for the parallel I/O interface specified in this document.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Data for the material that is transferred (handed off) is managed through the equipment's factory interface. Material management by the factory level controller is outside the scope of this document.

3.2 This specification defines the signals used to select a load port. The physical correspondence of the parallel I/O interface to the load port is not defined in this document.

3.3 Error recovery procedures may need operator assistance and/or proprietary procedures specific to the equipment. Therefore, error recovery procedures are not defined in this document.

3.4 Signal time diagrams apply to only one parallel I/O interface.

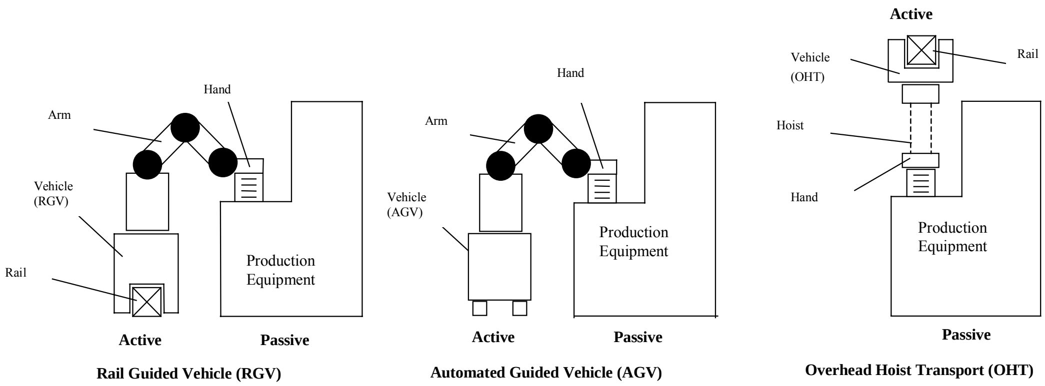

Figure 1
Examples of Automated Material Handling System Equipment (RGV, AGV, and OHT)

Figure 2
Examples of Interbay Automated Material Handling System Equipment (Stockers and OHS)

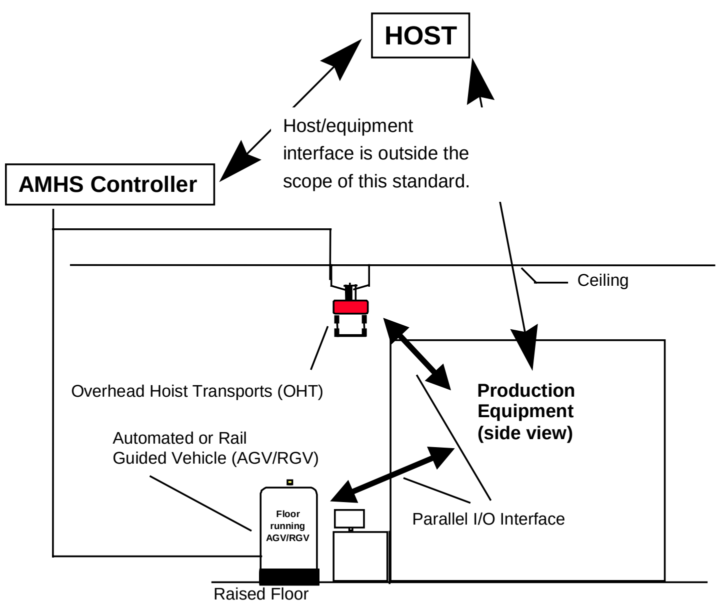

Figure 3
Examples of Enhanced Carrier Handoff Parallel I/O Interface Applications

3.5 The installation positions of the parallel I/O interface and the connector on the active and passive equipment are not defined.

3.6 The swap handoff will be considered beyond the scope of the standard for interbay AMHS equipment (i.e., OHS, stockers). During a swap handoff, loading and unloading occur simultaneously on the same loadport.

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E87 — Provisional Specification for Carrier Management (CMS)

4.2 *ISO Standard* [1]

ISO 4902 — Information technology — Data communication — 37-pole DTE/DCE interface connector and contact number assignments

NOTE 2: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *access mode* — a mode in which passive equipment knows which AMHS equipment (i.e. RGV, AGV, and OHT/OHV) or operator is permitted to make a material handoff. In the case of interbay AMHS, this is a mode in which the passive equipment knows which AMHS equipment (i.e., OHS and stockers equipped with transfer devices) is permitted to make a material handoff.

5.2 *active equipment* — equipment that loads a cassette onto the cassette stage of another piece of equipment or unloads a cassette from the cassette stage of another piece of equipment [SEMI E23].

5.3 *active OHS vehicle* — an active OHS vehicle that contains a device that loads or unloads the carrier from one piece of equipment to another.

5.4 *automated material handling system (AMHS) equipment* — a piece of equipment which has a carrier transfer robot that transfers carriers from and to passive equipment. It includes rail guided vehicles (RGV), automated guided vehicles (AGV), overhead hoist transports (OHT), overhead shuttles (OHS), and stockers.

5.5 *automatic access mode* — a mode in which AMHS equipment performs a material handoff rather than an operator.

5.6 *boundary* — a change in the timing single state.

5.7 *carrier* — any cassette, box, pod, or FOUP that contains wafers [SEMI E1.9]. Also known as wafer carrier.

5.8 *cassette* — an open structure that holds one or more substrates [SEMI E1.9]. Also known as open cassette (OC).

5.9 *continuous handoff* — successive handoffs of two carriers. Continuous handoff is in series, meaning one carrier transfer occurs and is then immediately followed by another. The continuous handoff may involve: load and load, unload and unload, or unload and load operations.

5.10 *front opening unified pod (FOUP)* — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (FIMS) [SEMI E47.1].

5.11 *handoff* — is the operation in which a carrier is transferred (loaded or unloaded) from one piece of equipment to another.

5.12 *handoff conflict area* — an area where the active equipment resource could interfere with the passive equipment resource during the handoff operation.

5.13 *handoff interlock abnormal* — the state, which indicates the passive equipment, has detected abnormal conditions in the handoff operation. It may indicate the possibility that the interference of the active equipment resource with the passive equipment resource has occurred in the handoff conflict area.

5.14 *handoff unavailable* — the state, which indicates the passive equipment, is not available for material handoff operation.

5.15 *load port* — the interface location on a tool where wafer carriers are placed to allow the tool to process wafers [SEMI E15].

1 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

5.16 *manual access mode* — an access mode in which an operator performs a material handoff of a carrier rather than the AMHS equipment.

5.17 *overhead shuttle (OHS)* — an AMHS vehicle that does not use a vertical hoist mechanism to transfer the carrier from one piece of equipment to another. An OHS is typically supported on top of transport rail while overhead hoist transport (OHT) vehicles hang from underneath the transport rail.

5.18 *passive equipment* — equipment that is loaded or unloaded by active equipment [SEMI E23]. Passive equipment includes process equipment, metrology equipment, stockers, etc.

5.19 *passive OHS vehicle* — An active OHS vehicle that does not contain a device that loads or unloads the carrier from one piece of equipment to another.

5.20 *simultaneous handoff* — concurrent handoff operations of two carriers. Simultaneous handoff is in parallel, meaning two carriers are transferred at the same time.

5.21 *single arm/double hand AMHS equipment* — AMHS equipment which hands off two carriers using a single arm mechanism with two hands (dual end effectors).

5.22 *single arm/single hand AMHS equipment* — AMHS equipment which hands off a carrier using a single arm mechanism with a single hand (single end effector).

5.23 *single handoff* — the transfer of a single carrier in a handoff operation.

5.24 *zone* — term used for describing the intervals during PIO communication.

6 Enhanced Carrier Handoff Parallel I/O Interface Requirements

6.1 *Signal Definitions*

6.1.1 Table 1 shows the signals required for the enhanced carrier handoff parallel I/O interface. The table defines signal name, the direction of the information (P/A: P represents passive equipment and A represents active equipment), and the description. In the description, the meaning of the signal and the indication of the signal level, and comments. Signals defined in Table 1 are:

VALID	Indicates that the signal transition is active and selected.
CS_0	Carrier Stage 0
CS_1	Carrier Stage 1
TR_REQ	Transfer Request
L_REQ	Load Request
U_REQ	Unload Request
READY	READY for Transfer
BUSY	BUSY for Transfer
COMPT	Complete Transfer
CONT	Continuous Handoff
HO_AVBL	Handoff Available
ES	Emergency Stop
VA	Vehicle arrived *
AM_AVBL	Transfer Arm Available *
VS_0	Carrier Stage 0 from Passive OHS Vehicle *
VS_1	Carrier Stage 1 from Passive OHS Vehicle *

* The VA, AM_AVBL, VS_0,1 signals are intended only for use with interbay AMHS equipment (passive OHS vehicles).

The VALID, CS_0, CS_1 signals are not intended for use with interbay AMHS equipment (passive OHS vehicles).

6.1.2 *Load Port Assignment Signals*

6.1.2.1 The signals CS_0 and CS_1 are used to select load ports to be used for the handoff. For the parallel I/O interface which is dedicated to a single load port, the signals must be set:

CS_0 ON

CS_1 OFF

See Figures 4 and 5.

6.1.2.2 The capability to control two load ports by a common parallel I/O interface is required; therefore, it is assumed in this specification that a common parallel I/O interface can be used to control handoffs of two load ports.

6.1.2.3 The assignment of the load port is relevant when two load ports use a common parallel I/O interface. The active equipment shall select the load port by means of the CS_0 and/or CS_1 signals (see Figure 6).

CS_0 selects the left hand load port as viewed when facing towards the equipment's load ports.

CS_1 selects the right hand load port as viewed when facing towards the equipment's load ports.

6.1.2.4 For the simultaneous handoff, both of CS_0 and CS_1 must be set to ON at the handoff. Figure 8 shows a piece of passive equipment with four load ports (LP1, LP2, LP3, LP4) and two parallel I/O interfaces (PI/O#1, PI/O#2), where PI/O#1 is common to load ports LP1 and LP2 and PI/O#2 is common to load ports LP3 and LP4. Tables 2 and 3 show the range of signal combinations.

6.1.3 *Load Port Assignment Signals for OHS (Passive type)*

6.1.3.1 The signals VS_0 and VS_1 are used to select load ports to be used for the handoff. For the parallel I/O interface which is dedicated to a single load port, the signals must be set;

VS_0 ON

VS_1 OFF

6.1.3.2 Two load ports can be controlled by using VS_0 and VS_1.

VS_0 ON: Selects left hand Load port.

OFF: Does not select Left hand Load port.

VS_1 ON: Selects Right hand Load port.

OFF: Does not select Right hand Load port.

VS_0 and VS_1 are controlled individually.

Table 1 Signals for the Enhanced Carrier Handoff Parallel I/O Interface

Signal Name	*P/A*	*Description*
VALID	A -> P	Indicates that the interface communication is valid. ON: the communication is valid OFF: the communication is not valid Before this signal is turned ON, the load port must be specified by the signal CS_0 and/or CS_1.
CS_0	A -> P	Specifies the load port used for carrier handoff (see Section 6.1.2, Load Port Assignment Signals). One PI/O device per load port ON: Use the load port for carrier handoff OFF: N/A One PI/O device per 2 load ports ON: Use the left load port for handoff OFF: Do not use the left load port of handoff
CS_1	A -> P	Specifies the load port used for carrier handoff (see Section 6.1.2, Load Port Assignment Signals). One PI/O device per load port Not used (OFF) One PI/O device per 2 load ports ON: Use the right load port for handoff OFF: Do not use the right load port of handoff
TR_REQ	A -> P	Requests the handoff to the passive equipment. ON: the active equipment has requested the handoff OFF: the active equipment has not requested the handoff This signal is turned OFF when the BUSY signal transitions to OFF.
L_REQ	P -> A	Indicates the load port is assigned to load a carrier. L_REQ always indicates a carrier transfer from Active to Passive equipment. ON: The load port is assigned to load a carrier OFF: The load port is not assigned to load a carrier This signal is turned ON when the load port is specified by CS_0 and/or CS_1 and the VALID signal is turned ON. This signal is turned OFF when the load port detects the carrier in the correct position. In simultaneous handoff, the carrier on both load ports shall not be present when this signal is turned ON, and the carriers shall be present in correct position on both load ports when this signal is turned OFF.

Signal Name	*P/A*	*Description*
U_REQ	P -> A	Indicates the load port is assigned to unload a carrier. U_REQ always indicates a carrier transfer from Passive to Active equipment. ON: The load port is assigned to unload a carrier OFF: The load port is not assigned to unload a carrier This signal is turned ON when the load port is specified by CS_0 and/or CS_1, and the VALID signal is turned ON. This signal is turned OFF when the carrier on the load port is removed. In simultaneous handoff, the carrier on both load ports shall be present in correct position when this signal is turned ON, and the carriers shall not be present on both load ports when this signal is turned OFF.
READY	P -> A	Indicates the passive equipment has accepted the transfer request from the active equipment. ON: the passive equipment is ready for the handoff OFF: the passive equipment is not ready for the handoff This signal is turned ON when the passive equipment accepts the transfer request, and it is turned OFF when the COMPT signal is turned ON.
BUSY	A -> P	Indicates the handoff is in progress by the active equipment. ON: the handoff is in progress OFF: no handoff is in progress This signal is turned ON when the active equipment starts handoff operation. READY must be ON when BUSY is turned ON. It must be turned OFF after the active equipment has completed the handoff and the active equipment resource position is outside the handoff conflict area. The passive equipment must not perform any mechanical action in the handoff conflict area while this signal is ON. The active equipment turns the BUSY OFF after confirming the L_REQ or U_REQ OFF.
COMPT	A -> P	Indicates the active equipment has completed the handoff operation. ON: the handoff is completed OFF: the handoff is not completed This signal is turned ON when the active equipment has completed the handoff (BUSY OFF), and it is turned OFF after the passive equipment has completed the handoff operation (READY OFF).
CONT	A -> P	Specifies the handoff is continuous handoff. ON: continuous handoff OFF: not continuous handoff This signal is turned ON by BUSY ON for the first carrier handoff, and it is turned OFF by BUSY ON for the last carrier handoff operation. If the passive equipment has a mechanism that interferes with the handoff (such as a shutter door), that mechanism must be held in the non-interfering state (the door must remain open) during the continuous handoff.
HO_AVBL	P -> A	Indicates the passive equipment is not available for the handoff operation. It may also indicate error in the passive equipment. ON: handoff is available OFF: handoff is unavailable with any error This signal is ON while the passive equipment’s operation is normal. This signal is turned OFF by VALID ON or TR_REQ ON when the passive equipment detects some exceptions at the load port specified by CS_0 and/or CS_1. This signal might be kept OFF, when other load ports of the passive equipment detects exceptions. The exceptions include: - Carrier detection is not correct. - The passive equipment has been changed to manual access mode. - The passive equipment is in handoff unavailable state. This signal indicates the state of the passive equipment to the active equipment before the start of handoff operation. See SEMI E87 for additional information and requirements about loadport access modes and availability states.

Signal Name	*P/A*	*Description*
ES	P -> A	Request to stop active equipment activity immediately. ON: normal operation OFF: request to stop Normally active equipment may monitor the ES signal from VALID ON to VALID OFF. This signal is turned OFF to stop the handoff operation immediately when a hazardous situation is detected by the passive equipment. Hazardous situations include possible harm to material, product, or operation. This signal is ON while the passive equipment's operation is normal. It turns OFF when the passive equipment needs to stop the activity of the active equipment. The passive equipment may turn the ES signal off when the ES button is pressed or, a handoff interlock abnormal has occurred.
VA	P -> A	Notifies active entity of passive OHS vehicle arrival. Indicates that the interface communication is valid when the vehicle has arrived at the load port. ON: Vehicle has arrived and communication is valid. OFF: Vehicle has not arrived and communication is not valid. Before this signal is turned ON, the load port must be specified by the signal VS_0 and/or VS_1. Note: This signal is for interbay passive OHS vehicle use only.
AM_AVBL	A -> P	Notifies passive OHS vehicle of handling arm availability. Indicates the active stocker is not available for handoff operation. It may also indicate error in the active stocker. ON: Handoff is available. OFF: Handoff is unavailable with any error. This signal is ON while active stocker's operation is normal. This signal is turned OFF, when the active stocker detects some exceptions. This signal might be kept OFF, when loader's of the active stocker detects exceptions. The exceptions include: - The active stocker has been changed to manual access mode. - The active stocker is in handoff unavailable state. - When the active stocker detected off the HO_AVBL signal of passive OHS. This signal indicates the state of the active stocker to the passive OHS vehicle before the start of handoff operation. Note: This signal is for interbay passive OHS vehicle use only.
VS_0	P -> A	Signal for the passive OHS vehicle to notify the active of the load or unload position. Specifies the load port used for carrier handoff. One PI/O device per Load Port. ON: Use the load port for carrier handoff. OFF: N/A One PI/O device per 2 load ports; but vehicle does not move when accessing to 2 load ports. ON: Use the left load port for handoff. OFF: Do not use the left load port for handoff. Note: This signal is for interbay passive OHS vehicle use only.
VS_1	P -> A	Signal for the passive OHS vehicle to notify the active of the load or unload position. Specifies the load port used for carrier handoff. One PI/O device per Load Port. OFF: Not used One PI/O device per 2 load ports. ON: Use the right load port for handoff. OFF: Do not use the right load port for handoff. Note: This signal is for interbay passive OHS vehicle use only.

6.2 *Carrier Handoff Sequences*

6.2.1 The signals of the enhanced carrier handoff para-llel I/O interface compliant to this specification must follow these defined sequences. The time diagrams of the carrier handoff sequences are shown in Figures 10–22. Figure 10 is a summary of various handoffs including load/unload and single/simultaneous/continuous handoff sequences. Figure 11 is a transition model of zones. Each change in signal state is numbered in the time diagrams. These numbers are for reference only and may not correspond with the handoff steps or signal order requirements in Section 6.2.

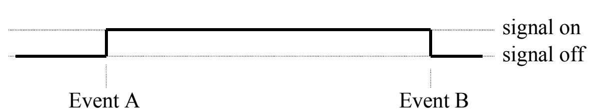

Figure 9
Key for Timing Diagram Signal States

6.2.2 *Load/Unload Boundaries*

6.2.2.1 Changes in the signal state are shown and described as boundaries to clarify each step during handshake and transfer as seen in the signal time diagram in Figure 10 and Tables 5 and 6.

Table 5 Boundary Description

	Description
A	Active equipment starts specifying the port
B	Active equipment tries to engage with the passive equipment in a transfer validating its request
C	Passive equipment indicates to the active equipment that it accepts to be engaged in a transfer based in its load port condition (Load or unload).
D	Active equipment agrees with passive equipment intent and indicates is ready for the transfer.
E	Passive Equipment replies it is also ready for transfer.
F	Start of physical handoff (Assign/resign continuous handoff).
G	Passive equipment detects that a carrier has been placed/removed.
H	Active equipmrent signals the end of physical handoff.
I	Active equipment terminates request for transfer.
J	Active equipment signals that the transfer engagement has completed.
K	Passive equipment indicates that no further transfer activity will occur between them.
L	Active equipment signals acknowledgement of completion of intent to transfer.
M	Active equipment indicates passive equipment no intent of further handshake.
N	Active equipment drops port request signal to leave.

6.2.3 *Zone*

6.2.3.1 Specific time intervals are clarified in nesting structure and defined as zones. Each zone is defined in Figure 10 and Table 6.

Table 6 Zones

Zone	*Definition/Description*
Handshake Active B to M	This zone indicates the state of communication that active equipment is intending to communicate with passive equipment. Start at: VALID ON End at: VALID OFF (last VALID OFF for continuous handoff) Requirements – Passive equipment is not bounded to any transfer activity previous to or after these transitions.
Handshake Engaged C to L	This zone is included in “Handshake Active”. This zone indicates the state of communication that passive equipment is responding to active equipment. Start at: L_REQ ON or U_REQ ON End at: COPY OFF (last COMPT OFF for continuous handoff) Requirement – Passive equipment does not perform any physical activity that changes the load or unload conditions in the equipment after setting L-REQ or U-REQ. Passive equipment shall perform necessary operation such as clamping or docking after the load operation only after it sets Ready signal OFF.
Handoff Request C to L	This zone is included in “Handoff Engaged”. The zone indicates the state of communication that load or unload is engaged between active equipment and passive equipment. Load Motion is engaged if L_REQ is ON and unload motion is engaged if U_REQ is ON. Start at: L_REQ ON or U_REQ ON End at: COMPT OFF Requirement – FOUP shall be kept Docked/Clamped while this request is becoming active and passive equipment shall not perform any physical action during the physical handoff other than the actions required to be ready for active handoff.

Zone	*Definition/Description*
Handoff Active E to J	This zone is included in “Handoff Request”. This zone indicates the state if communication and physical condition that passive equipment is ready for active equipment to perform “Physical Handoff”. Start at: READY ON End at: COMPT ON Requirement – Passive equipment is required to undock/unclamp the FOUP and place it at the load port if the FOUP is not at the port prior to enter this zone during unload. Passive equipment shall not activate dock/undock motion and clamp/unclamp motion during loading in this zone.
Physical Handoff F to H	This zone is inclued in “Handoff Active”. This zone indicates that the active equipment is engaged in physically delivering or removing FOUP to/from the equipment. One carrier is loaded or unloaded if CS_0 or CS_1 is ON. Two carriers are loaded or unloaded if CS_0 or CS_1 are ON Start at: BUSY ON End at: BUDY OFF Requirements – Active equipment is required to start the movement to load/unload carrier and completely move out from handoff conflict area.

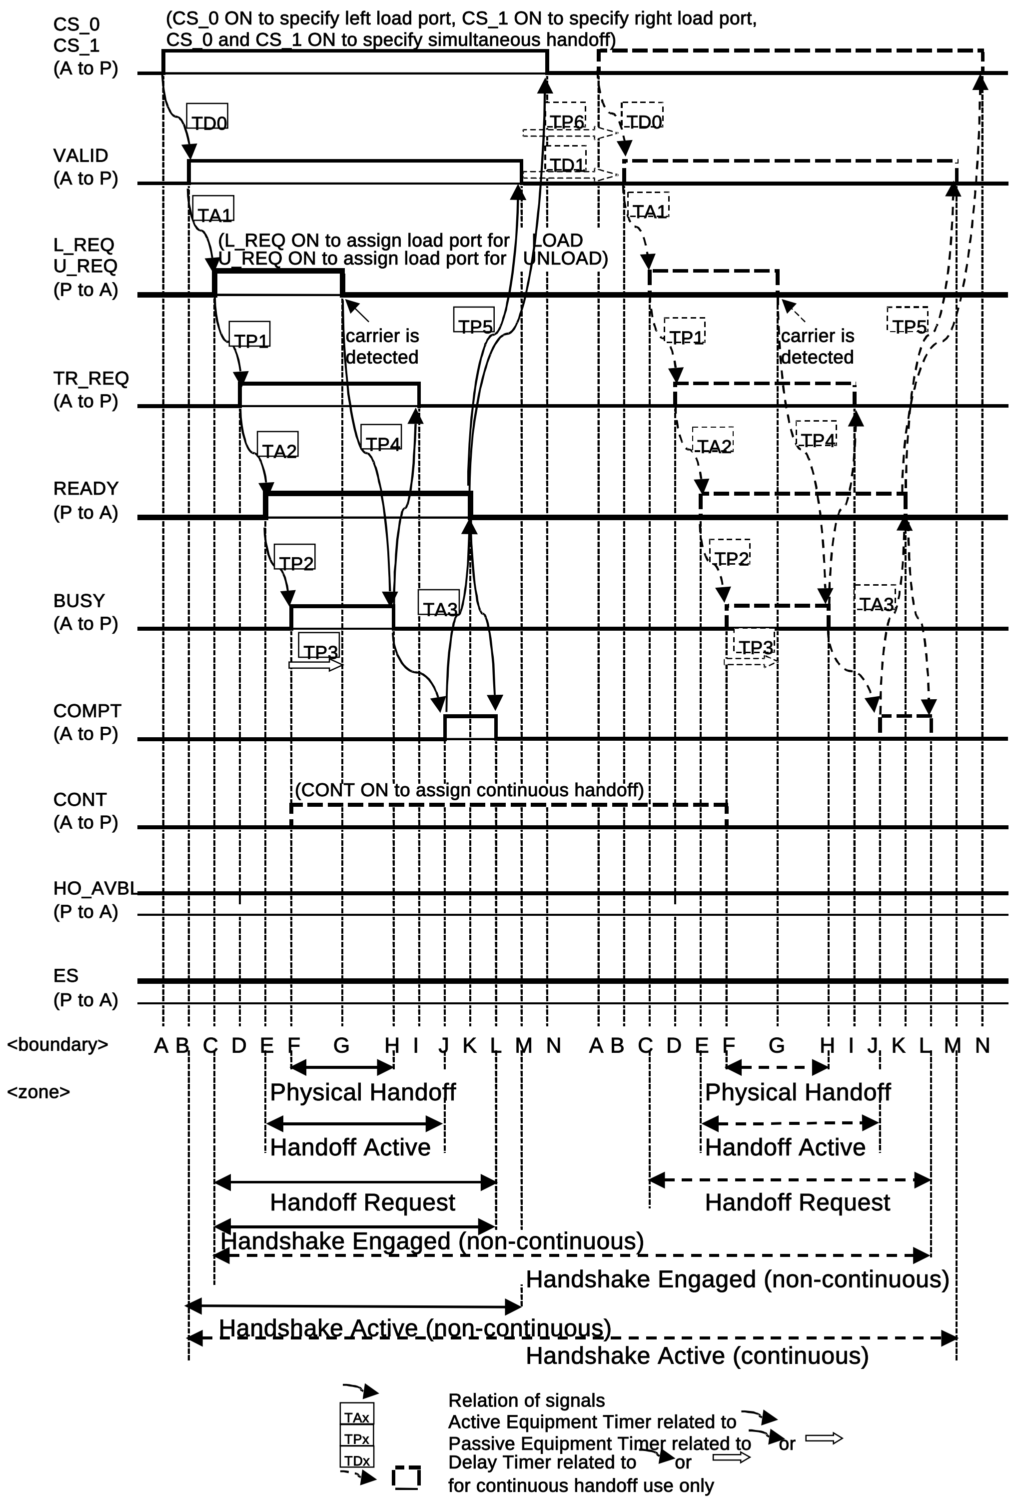

Figure 10
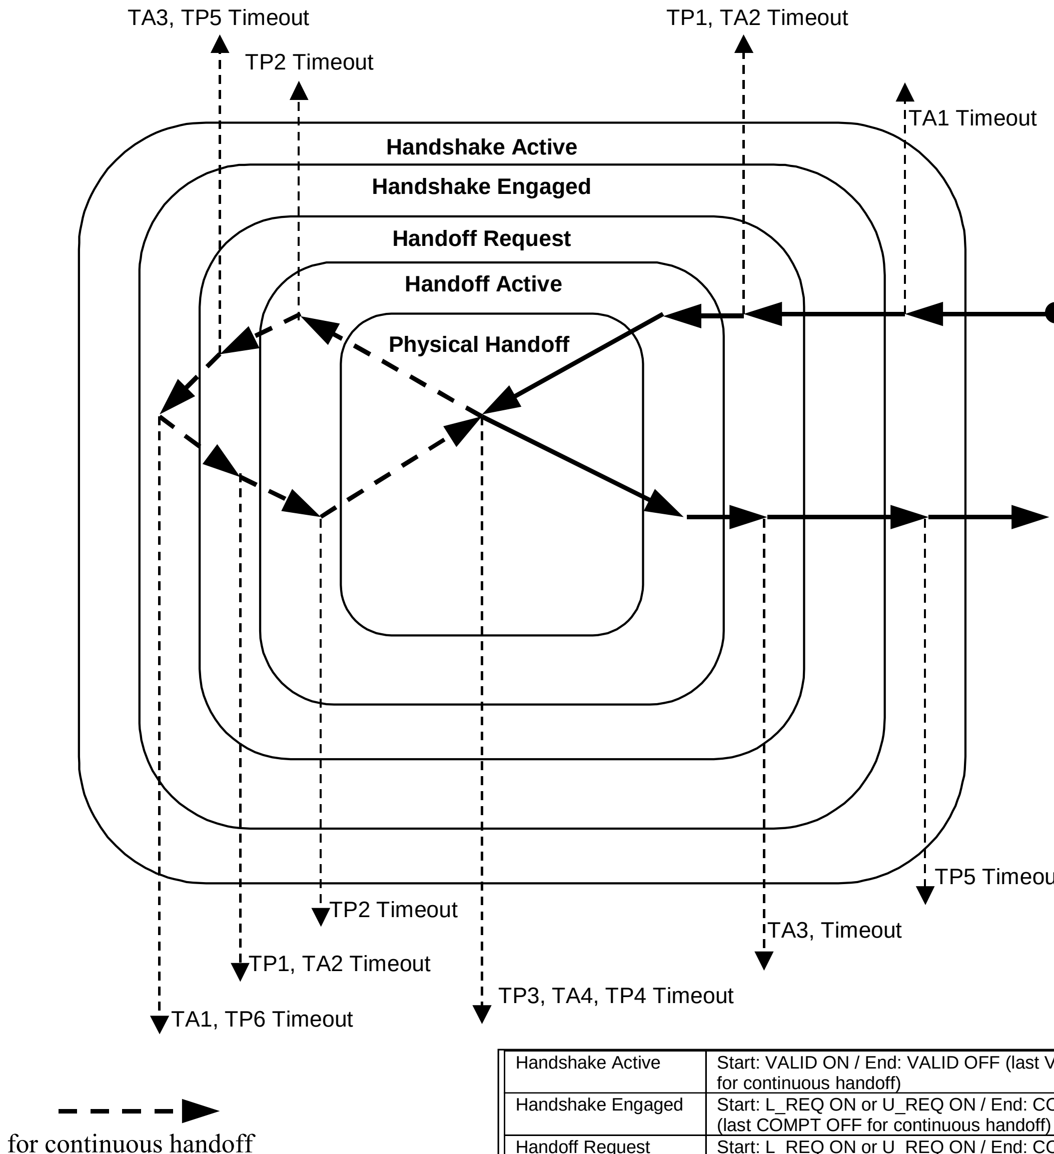
Summary of Time Diagram



Handshake Active	Start: VALID ON / End: VALID OFF (last VALID OFF for continuous handoff)
Handshake Engaged	Start: L_REQ ON or U_REQ ON / End: COMPT OFF (last COMPT OFF for continuous handoff)
Handoff Request	Start: L_REQ ON or U_REQ ON / End: COMPT OFF
Handoff Active	Start: READY ON / End: COMPT ON
Physical Handoff	Start: BUSY ON / End: BUSY OFF

Figure 11
State Transition Model

6.2.4 *Single Handoff Sequence (loading/unloading)*

6.2.4.1 The time diagrams of the loading and unloading operations in single handoff are shown in Figures 12 and 13, respectively. The sequence shown in Figures 12 and 13 is:

1) After the active equipment (AMHS equipment) reaches the handoff location in front of the load port, the active equipment specifies the load port number at which the active equipment is to handoff a carrier to the passive equipment using CS_0 and CS_1.

2) The active equipment turns the VALID signal ON. It shows that the signal transition of CS_0 and CS_1 is valid.

NOTE 3: The passive equipment should not verify if the CS_0 or CS_1 signals are ON until after the active equipment has turned the VALID signal ON, which signifies the interface communication is valid.

3) The passive equipment turns the L_REQ signal ON if the load port is ready to perform loading operation and turns the U_REQ signal ON if the load port is ready to perform unloading operation.

4) To request the passive equipment to start the carrier handoff operation, the active equipment turns the TR_REQ signal ON.

5) The passive equipment turns the READY signal ON when the passive equipment is ready for the handoff of the carrier.

6) After confirming the READY signal is ON, the active equipment turns the BUSY signal ON and starts the handoff operation.

7) The passive equipment turns the L_REQ (U_REQ) signal OFF when a carrier is placed correctly on the load port (when the carrier on the load port is removed).

8) After the completion of the load or unload operation and after the active equipment is clear of the handoff conflict area, the active equipment turns the BUSY signal OFF. The active equipment must confirm L_REQ signal (U_REQ signal) is turned OFF before the BUSY signal turn OFF.

9) The active equipment turns the TR_REQ signal OFF after the BUSY OFF.

10) The active equipment turns the COMPT signal ON to inform the passive equipment about the completion of the handoff operation.

NOTE 4: If the passive equipment verifies the BUSY and TR_REQ signals are OFF, it should verify these signals only after the active equipment has turned the COMPT signal ON, which signifies the active equipment has completed the handoff operation.

11) After confirming that the active equipment turned the COMPT signal ON, the passive equipment turns the READY signal OFF.

12) After the READY signal is turned OFF, the active equipment turns the COMPT, VALID, CS_0, and CS_1 signals OFF.

13) The handshake with the passive equipment is closed when the VALID signal is turned OFF.

NOTE 5: If the passive equipment checks for COMPT, VALID and CS_0 or CS_1 signals, it should allow the signals to turn OFF in any order without reporting an error.

6.2.4.2 This section defines the Single Handoff Sequence between the OHS (interbay passive type vehicle) and Stocker. The time diagrams of the loading and unloading operations in single handoff are shown in Figures 14 and 15, respectively. The sequence shown in Figure 14 and Figure 15 is:

1) When the passive equipment (i.e., OHS) arrives at the active equipment (i.e., STOCKER), the passive equipment specifies to the active equipment where the handoff will take place using VS_0 and VS_1.

2) At the same time as VS_set, the passive equipment turns the L_REQ signal ON if the load port is ready to perform a loading operation or turns the U_REQ signal ON if the load port is ready to perform an unloading operation.

3) The passive equipment turns the VA signal ON. It shows that the signal transition of VS_0 and VS_1, L_REQ or U_REQ is valid.

4) After the active equipment recognizes the VA signal, it checks the VS_0 and VS_1, L_REQ and U_REQ signal and turns the TR_REQ signal ON to request the passive equipment to start the carrier handoff operation.

5) The passive equipment turns the READY signal ON when the passive equipment is ready for the handoff of the carrier.

6) After confirming the READY signal is ON, the active equipment turns the BUSY signal ON and starts the handoff operation.

7) The passive equipment turns the L_REQ (U_REQ) signal OFF when a carrier is placed correctly on the load port (When the carrier on the load port is removed).

8) After the completion of the load or unload operation and after the active equipment is clear of the handoff conflict area, the active equipment turns

the BUSY signal OFF. The active equipment must confirm L_REQ signal (U_REQ) is turned OFF before the BUSY signal is turned OFF.

9) The active equipment turns the TR_REQ signal OFF at the BUSY OFF.

10) The active equipment turns the COMPT signal ON to inform the passive equipment about the completion of the handoff operation.

11) After confirming that the active equipment turned the COMPT signal ON, the passive equipment turns the READY signal OFF.

12) After the READY signal is turned OFF, the active equipment turns the COMPT OFF.

13) After confirming that the active equipment turned the COMPT signal OFF, the passive equipment turns the VS_0, VS_1 and VA OFF.

14) The handshake with the passive equipment is closed when the VA signal is turned OFF.

(Interbay Passive OHS only)

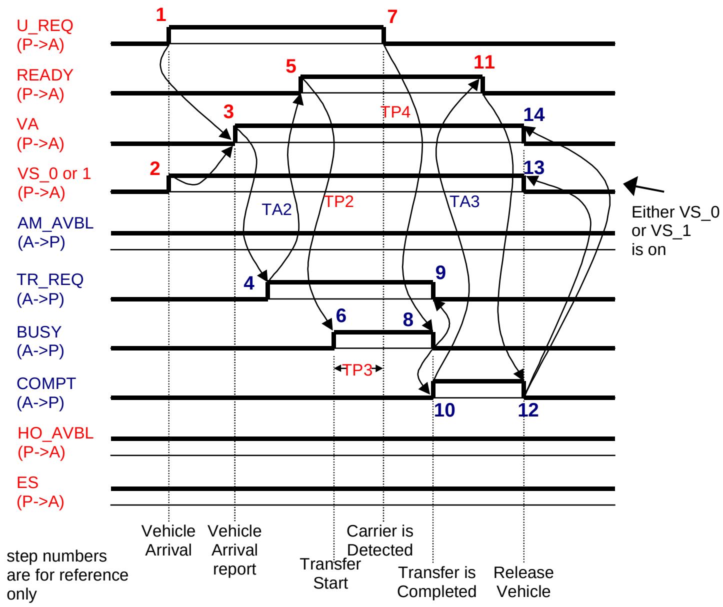

Figure 15
Signal Time Diagram for Single Handoff (UNLOAD)
(Interbay Passive OHS only)

6.2.5 *Simultaneous Handoff Sequence (loading)*

6.2.5.1 This specification defines the capability to control simultaneous handoff. Simultaneous handoff is the handoff operation in which active equipment transfers two carriers to two load ports simultaneously in a single transfer operation. Some types of AMHS equipment are able to transfer two carriers simultaneously in a transfer operation. The capability can be applied to increase the performance of the transfer. For example, simultaneous handoff can be applied to single arm/double hand AMHS equipment capable of transferring two carriers in a single transfer operation.

6.2.5.2 The time diagram of simultaneous handoff is shown in Figure 16. The figure shows only the load operation; however, L_REQ may be changed to U_REQ for the unload operation. The sequence of the simultaneous handoff is the same as that of the single handoff except that the specification of the load port with CS_0 and CS_1 signals and the definition of ON/OFF of the L_REQ and U_REQ signals are different. The following list describes the sequence which is different from Figures 12 and 13:

1) The active equipment turns the signals CS_0 and CS_1 ON to inform the passive equipment it is simultaneous handoff.

2) The active equipment turns the VALID signal ON after the transition of CS_0 and CS_1 is effective.

3) The passive equipment turns the L_REQ (U_REQ) signal ON when both carriers in the specified load ports (load ports of both CS_0 and CS_1) are ready to be loaded (unloaded).

4) When both carriers are detected (removed) at the two load ports, the L_REQ (U_REQ) signal is turned OFF.

6.2.5.3 This specification defines the capability to control simultaneous handoff. Simultaneous handoff is the handoff operation in which active equipment transfers two carriers to two load ports simultaneously in a single transfer operation. Some types of interbay AMHS equipment (i.e. stockers) are able to transfer two carriers simultaneously in a transfer operation. The capability can be applied to increase the performance of the transfer. For example, simultaneous handoff can be applied to single arm/double hand AMHS equipment capable of transferring two carriers in a single transfer operation.

6.2.5.3.1 The time diagram of simultaneous interbay handoff using a passive OHS vehicle is shown in Figure 15. The figure shows only the load operation, however L_REQ may be changed to U_REQ for the unload operation. The sequence of the simultaneous handoff is the same as that of the single handoff except that the specification of the load port with VS_0 and VS_1 signals and the definition of ON/OFF of the L_REQ and U_REQ signals are different.

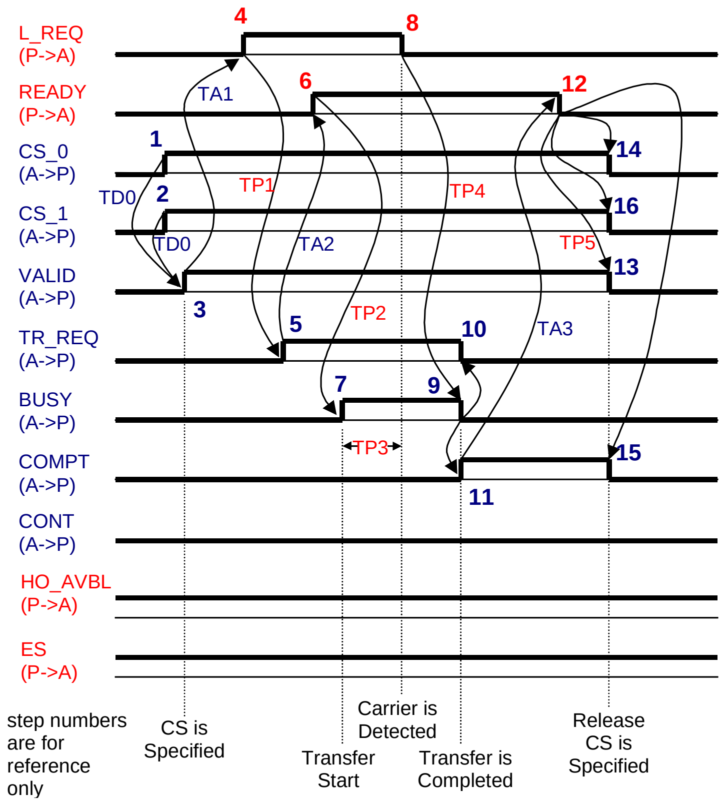

Figure 16
Signal Time Diagram for Simultaneous Handoff (LOAD)

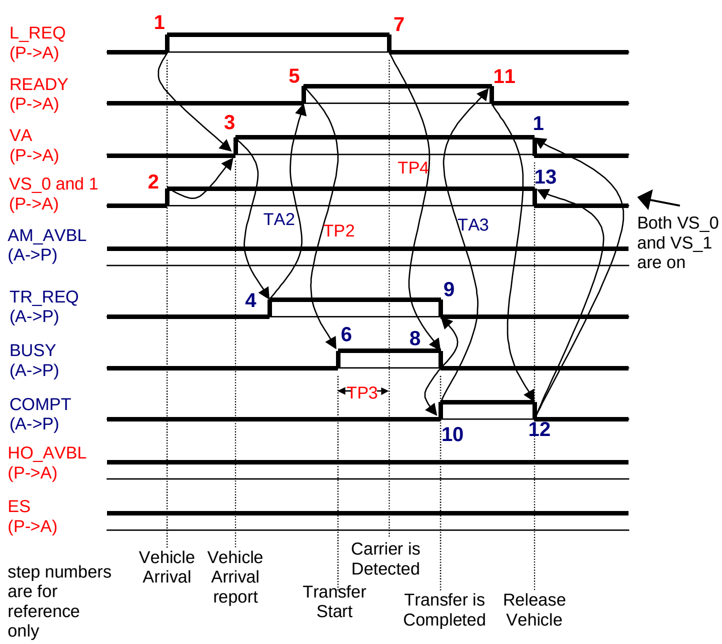

Figure 17
Signal Time Diagram for Interbay Simultaneous Handoff (LOAD) using a Passive OHS Vehicle

6.2.6 *Continuous Handoff Sequence*

6.2.6.1 This specification defines the capability to control continuous handoff. Continuous handoff is the handoff operation in which the active equipment transfers two or more carriers sequentially and continuously in a carrier transfer operation. Some types of AMHS equipment are able to handoff more than two carriers in a transfer operation. This capability can be applied to increase the performance of the transfer.

6.2.6.2 When the passive equipment has a door in front of the load port, the door on passive equipment must be opened before the carrier handoff starts by the active equipment. It is redundant to open and close the door for a carrier handoff when two or more carriers are transferred. Therefore, the door shall be kept open during the carrier transfer operation. Continuous handoff is applied to the transfer operation to avoid redundant operations.

6.2.6.3 Continuous handoff sequence for handoffs at a load port (Unload -> Load): The example time diagram for continuous handoff is shown in Figure 18. This example shows the sequence of unload and load operations performed continuously at the load port. Each sequence in the continuous handoff is the combination of the single handoff sequence. In addition, the CONT signal is used to indicate a continuous handoff. In the sequence shown in Figure 10, the carrier on the load port is unloaded first, and a new carrier is loaded on the load port. The CONT signal is turned ON at the time of active equipment BUSY ON of the first handoff to indicate that the handoff is continuous. In successive load sequences, the same load port number (CS_0 in this example) is specified to use the same load port. In this example, there are no more carriers that are to be transferred after the second load sequence, therefore the active equipment turns the CONT signal OFF when the BUSY signal is turned ON in the second handoff to indicate the continuous handoff is complete.

6.2.6.4 Continuous handoff sequence for handoffs at different load ports (Load -> Load): The example time diagram for continuous handoff on the different load ports is shown in Figure 19. In this example, the active equipment first transfers a carrier to the load port corresponding to CS_0, then another carrier is transferred to the load port corresponding to CS_1. In this example, the sequence is the same as that of the continuous handoff (handoff at a load port: Unload -> Load) shown in section above except for the specification of the load ports.

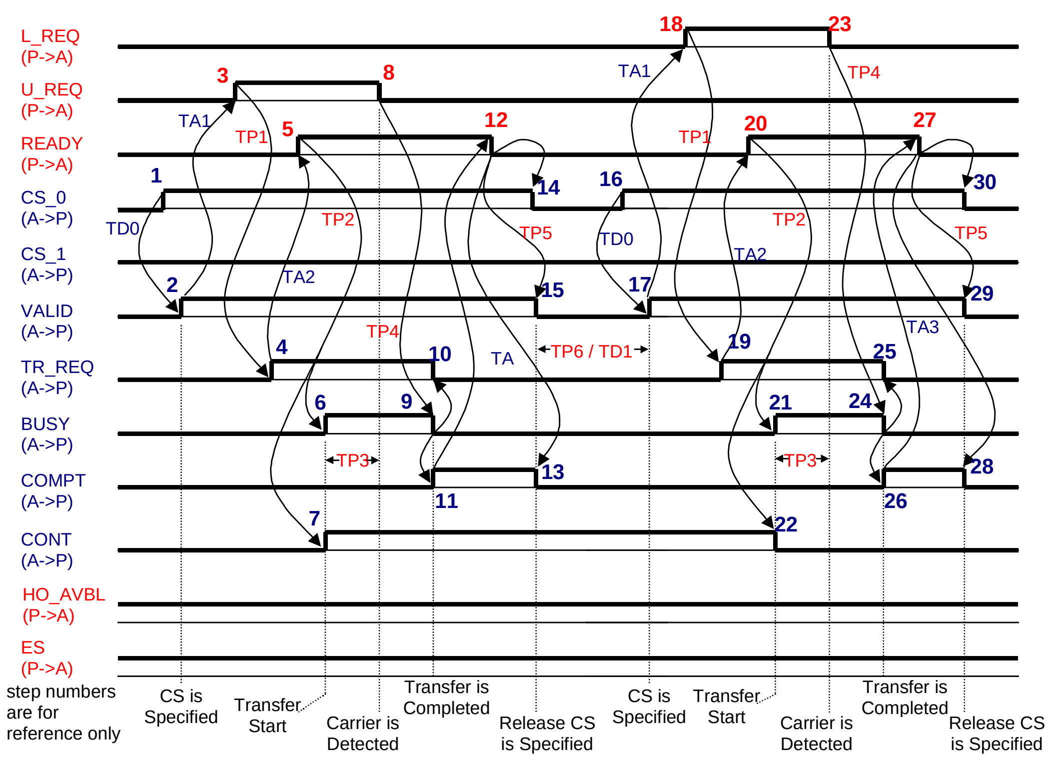

Figure 18
Signal Time Diagram for Continuous Handoff (UNLOAD and LOAD)

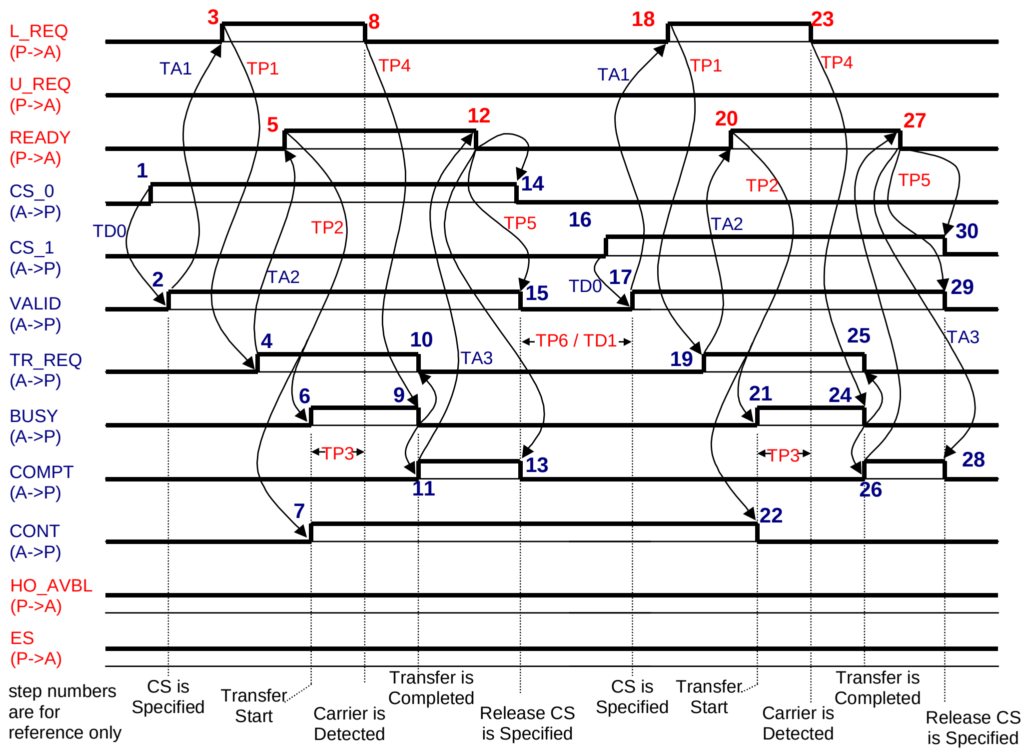

Figure 19
Signal Time Diagram for Continuous Handoff (LOAD and LOAD)

6.2.7 *Handoff Available Signal Operation Sequence (HO_AVBL)*

6.2.7.1 Example time diagrams for the HO_AVBL signal are shown in Figures 20 and 21. The HO_AVBL signal is ON during passive equipment normal operations and shall be turned OFF when the passive equipment detects any exception for the handoff. The active equipment is informed of the exception condition by the HO_AVBL signal. The active equipment is expected to confirm the HO_AVBL signal in the following periods:

a) From the time at which the VALID signal is turned ON to the time at which the L_REQ or U_REQ signal is turned ON.

b) From the time at which the TR_REQ signal is turned ON to the time at which the READY signal is turned ON.

6.2.7.2 Figure 20 is the time diagram to explain situation a) in section above. The active equipment stops the handoff operation when it detects that the HO_AVBL signal is turned OFF by the passive equipment. The active equipment turns the VALID signal OFF to close the handshake by the information (CS_0 and CS_1 signals must be set to OFF at this time). The passive equipment turns the HO_AVBL signal ON after the VALID signal is turned to OFF (L_REQ or U_REQ must be set to OFF).

6.2.7.3 Figure 21 is the time diagram to explain situation b) in section above. The active equipment stops the handoff operation when it detects that the HO_AVBL signal is turned OFF by the passive equipment. The active equipment turns the VALID signal OFF to close the handshake by the information (CS_0, CS_1, and TR_REQ signals must be set to OFF). The passive equipment turns the HO_AVBL signal ON after the VALID signal is turned to OFF (L_REQ or U_REQ must be set to OFF).

6.2.8 *Handoff Available Signal Operation Sequence (for interbay passive OHS and Stocker)*

6.2.8.1 Example time diagrams for the HO_AVBL signal are shown in Figures 20 and 21. The HO_AVBL signal is ON during passive OHS normal operations and shall be turned OFF when the passive OHS detects any exception for the handoff. The active stocker is informed of the exception condition by the HO_AVBL signal. The active stocker is expected to confirm the HO_AVBL signal in the following period:

a) From the time at which the TR_REQ signal is turned ON to the time at which the READY signal is turned ON.

6.2.8.2 Figure 22 is a diagram explaining the above item a). The active stocker stops transferring when the active stocker detects that the HO_AVBL signal has been turned OFF by the passive OHS. By turning off the AM_AVBL signal, the active Stocker closes the transfer sequence. In such a case, the TR_REQ signal must go OFF as the transfer sequence as ended. Also, the passive OHS must turn OFF the VS_0 and VS_1 signals. Next, the passive OHS must turn ON the HO_AVBL signal after the VA signal has gone OFF (the L_REQ or U_REQ must be set OFF).

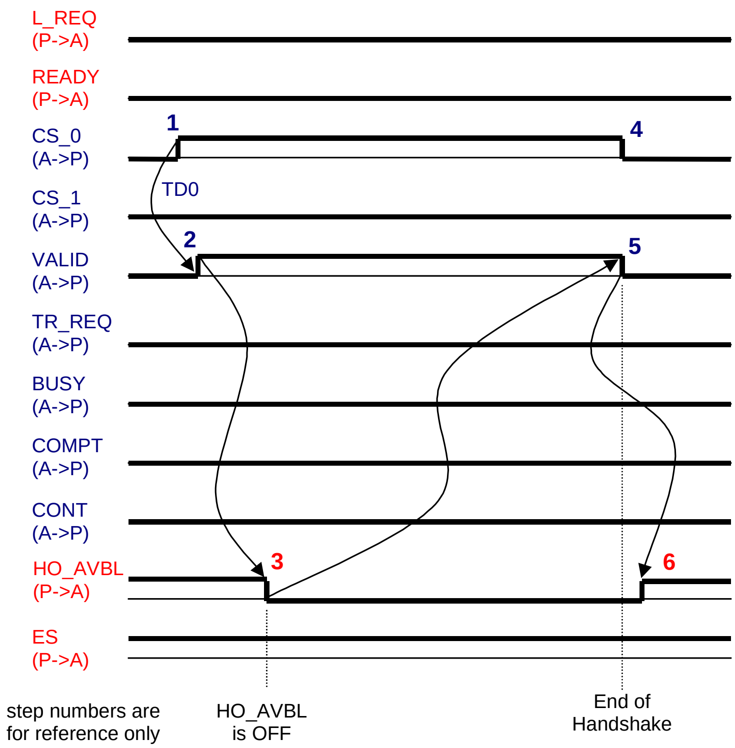

Figure 20
Example of Handoff Available Signal

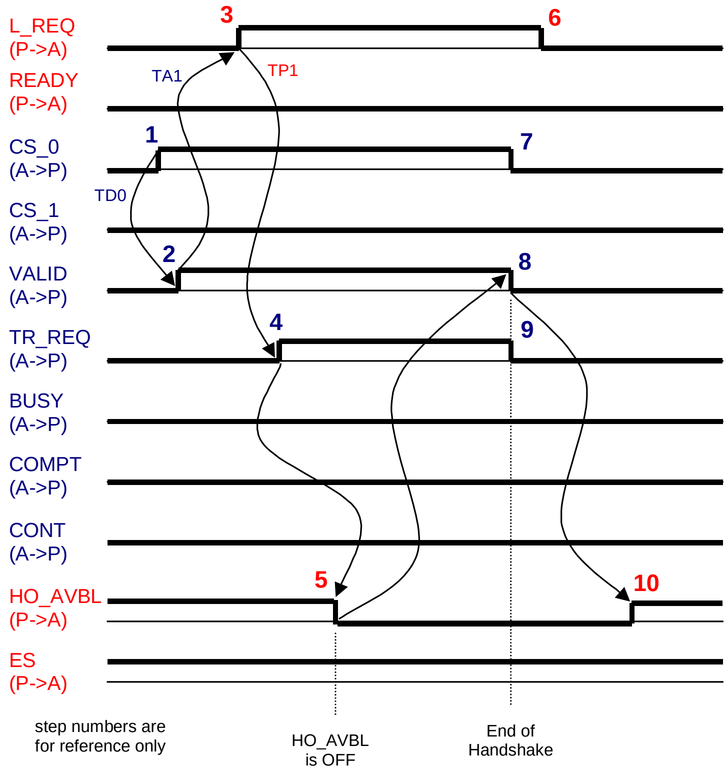

Figure 21
Example of Handoff Available Signal

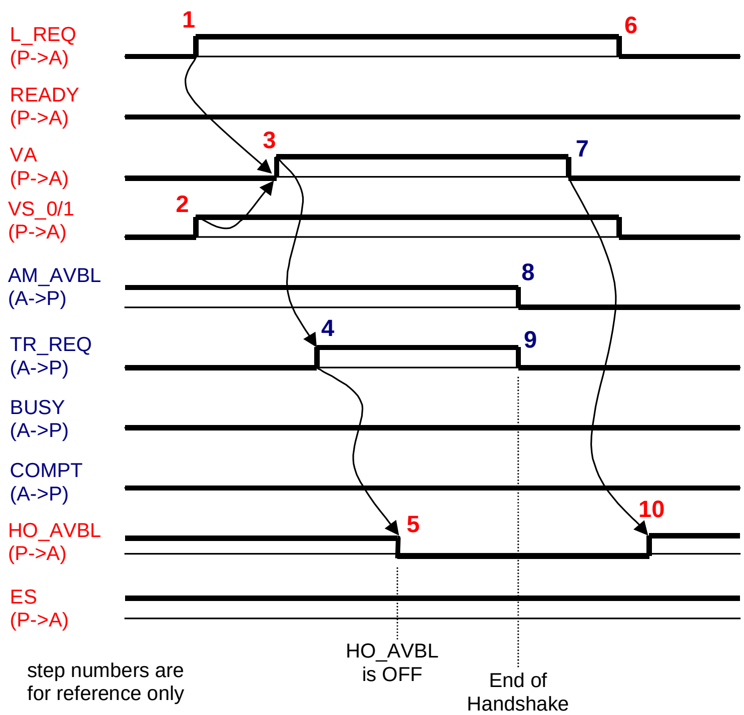

Figure 22
Example of Handoff Available Signal
(interbay passive OHS only)

6.3 *Error Indication and Detection*

6.3.1 *Error Indication*

6.3.1.1 To support operational reliability, this specification will define the following capabilities to indicate errors on the interface:

a) inform handoff unavailable which means the passive equipment (or passive OHS) is not available for material handoff operation to the active equipment.

b) inform emergency stop request to the active equipment (or active stocker).

c) inform handoff timeout error.

6.3.2 *Error Detection*

6.3.2.1 Interlock timeouts are required to detect handoff sequence error between the active and passive equipment. This specification defines the interlock timeouts to be monitored by the active equipment and the passive equipment. Table 7 shows the interlock timeouts for active equipment. Table 8 shows the timeouts for the passive equipment. TAx (x is a number) represents the timer for the active equipment, and TPx (x is a number) represents the timer for the passive equipment. The range for all timers (except TD0) shall be from 1 second to 999 seconds. All timer setpoints shall be user programmable.

6.3.2.2 The delay timer specifies the delay time between VALID signals within one continuous sequence of handoffs. Specifically, it signifies the delay following the VALID signal turning OFF on the completion of the first handoff and the VALID signal turning ON at the start of the second handoff. The delay timer is required because the passive equipment may need a certain time margin to detect the second VALID signal transition to ON. Table 9 shows the delay timer. All timer setpoints shall be user programmable.

6.3.2.3 The recommended and optional delay timer TD0 defines the timing between CS_0 or CS_1 ON and VALID ON for the active equipment as shown in the signal time diagrams. In this way, the passive equipment can predict the timing in which the active equipment will output the signal allowing the transfer interlock to be performed accurately.

Table 7 Active Equipment Timer

Timer Name	*Period (Signal Status) to Monitor the Timer*	*Range (SEC)*	*TYP (SEC)*
TA1	VALID ON - L_REQ ON VALID ON - U_REQ ON	1–999	2
TA2	TR_REQ ON - READY ON	1–999	2
TA3	COMPT ON - READY OFF	1–999	2

NOTE 1: The minimum timer value does not define the response time of the active equipment.

NOTE 2: These timer values must be implemented for detecting timeouts and are not meant to specify the delay time between signals. The equipment response time must be faster than the timeout of the timer.

Table 8 Passive Equipment Timer

Timer Name	*Period (Signal Status) to Monitor the Timer*	*Range (SEC)*	*TYP (SEC)*
TP1	L_REQ ON - TR_REQ ON U_REQ ON - TR_REQ ON	1–999	2
TP2	READY ON - BUSY ON	1–999	2
TP3	BUSY ON - CARRIER DETECT BUSY ON - CARRIER REMOVE	1–999	60
TP4	U_REQ OFF - BUSY OFF L_REQ OFF - BUSY OFF	1–999	60
TP5	READY OFF - VALID OFF	1–999	2
TP6	VALID OFF - VALID ON (Continuous handoff)	1–999	2

NOTE 1: The minimum timer value does not define the response time of the passive equipment.

NOTE 2: These timer values must be implemented for detecting timeouts and are not meant to specify the delay time between signals. The equipment response time must be faster than the timeout of the timer.

Table 9 Delay Timer

Timer Name	*Period (Signal Status) to Monitor the Timer*	*Range (SEC)*	*TYP (SEC)*
TD0	CS ON - VALID ON	0.1–0.2	0.1
TD1	VALID OFF - VALID ON	1–999	1

6.3.3 *Error Recovery*

6.3.3.1 Error recovery procedures are not defined in this specification. Recovery procedures may require operator assistance and/or proprietary procedures specific to the equipment. It is recommended that the recovery procedure (ex, abort interlock sequence and set to restart/complete) be provided on the active equipment and the passive equipment.

6.4 *Connector Type, Signal, and Pin Assignment*

6.4.1 The connector type for the passive equipment side must be type DB-25 socket housing (female) as specified in ISO 4902. The connector will have female 4-40 threaded jack screw locks. Suitable 25 pin connectors known as Type "D" are similar to Amphenol MIN RAC 17 series with jack screw locks. It is recommended that the connector on the passive equipment should be appropriately labeled. As shown in Figure 22, this standard specifies the connector on the passive side optical PI/O for floor based vehicles (RGV, AGV, others) (case 1), as well as the active to passive connector between an overhead delivery system and production equipment (case 2). Figure 23 defines the PI/O point of interface for the interbay AMHS (OHS and stocker). If the OHS is the active device in the interbay AMHS then the stocker is the passive device. Likewise, if the OHS is the passive device, then the stocker is the active device.

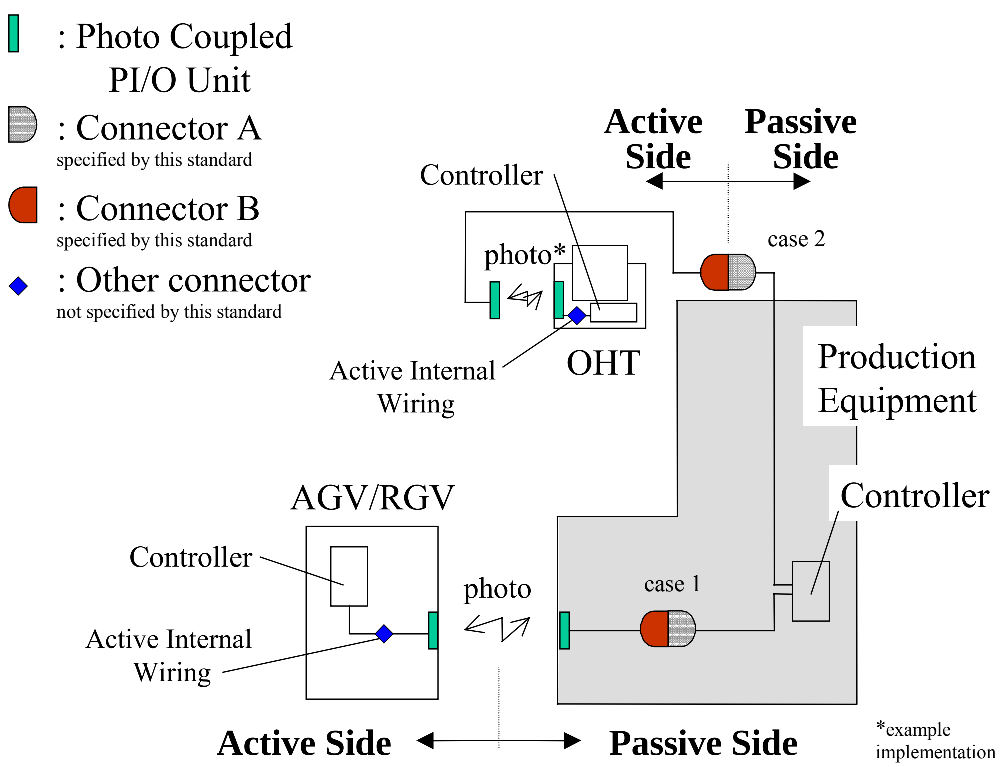

Figure 23
Connector Locations

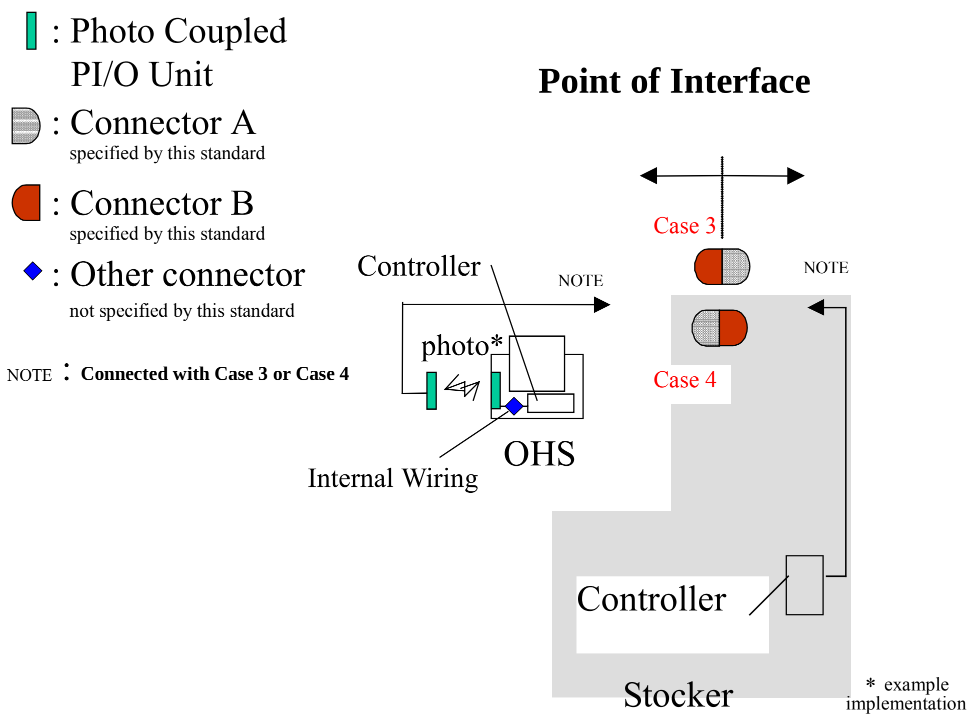

Figure 24
Connector Location Schematic for Interbay AMHS (i.e., OHS and STOKER)

6.4.2 Power and signal specifications are as follows:

Table 10 Input/Output Specifications

Active/Passive	*On State*		*Off State*	
	Current	*Voltage*	*Current*	*Voltage*
Input	Max. 10mA	Max.1.8 Vdc	Max. 200µA	Max. 30 Vdc
Output	Min. 25mA Sink	Max 1.8 Vdc	Max. 100µA Source	Max. 30 Vdc

6.4.2.1 Power Supply Voltage: +24 Vdc Nominal (Min. +18 Vdc, Max. +30 Vdc) from no load to full load (100mA).

6.4.2.2 For hardwired applications the power and power common of the passive must be isolated from the power and power common of the active. Also, internally to either the active or passive equipment, the power and power common must be isolated from the signal common.

6.4.3 Bit assignments are specified in Figure 27.

6.4.4 Connector pin assignments where required in Section 6.4.1 and Figures 23 and 24 are specified in Figures 28 and 29 and Table 11.

6.4.5 All configurations will include signal optoisolation within each equipment conforming to this standard to allow for optical transmission or hardwired configuration to coexist. See Figures 25 and 26 below.

6.4.6 Timing diagram signal state of Off corresponds to no current flow for the hardwired configuration or no optical signal transmitted for the optical transmitter configurations.

6.5 *Interface Sensor Unit Size*

6.5.1 The maximum dimensions in millimeters of the interface sensor are indicated in Figure 30. This size includes volume needed for rigid portions of the sensor's electrical connector and cable. For systems which are designed to handle 300 mm wafer carriers, the interface sensor unit must be designed in a way that allows mounting of the unit within the exclusion volume as defined per SEMI E15.1 with the optical axis centered in this exclusion volume.

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was balloted as an official part of SEMI E84, but the recommendation in this application note is optional and is not required to conform to this standard. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such, they are to be considered reference material only.

A1-1 If the connection to the equipment for overhead delivery is made using an electrical connector, Figure A1-1 defines a zone on the process or metrology equipment where the plug can be located. This zone is independent of the exclusion zones for parallel I/O devices defined by SEMI E15.1. The zones defined in SEMI E15.1 are designed to be used primarily for photo-coupled floor based delivery systems such as AGVs or RGVs, while the zone defined here on the top of the passive equipment applies primarily to a plug for overhead communication. The plug should be on the top or top edge of the equipment as shown and could be on either side of the bay/chase wall, depending on the location of the wall. In some implementations, the wall may not exist.

A1-2 Due to the inherent nature of parallel I/O communication the distance between the driver and receiver should be as close as possible. Optical transmission devices may further decrease this distance, consult the device manufacture.

A1-3 No application of parallel I/O communication can provide perfect isolation due to Electro-magnetic radiation into and between parallel conductors. Precautions should be taken, by all equipment suppliers, including but not limited to insuring a minimum capacitance of signal lines to reduce susceptibility to noise introduced into the equipment.

A1-4 There are two types of equipment, internal buffer equipment and fixed buffer equipment. Internal buffer equipment is equipment that uses locations other than load ports within the equipment to store carriers. Fixed buffer equipment is production equipment that has only fixed load ports and no internal buffer for carrier storage. Wafers are loaded and unloaded directly from the carrier at the load port for processing.

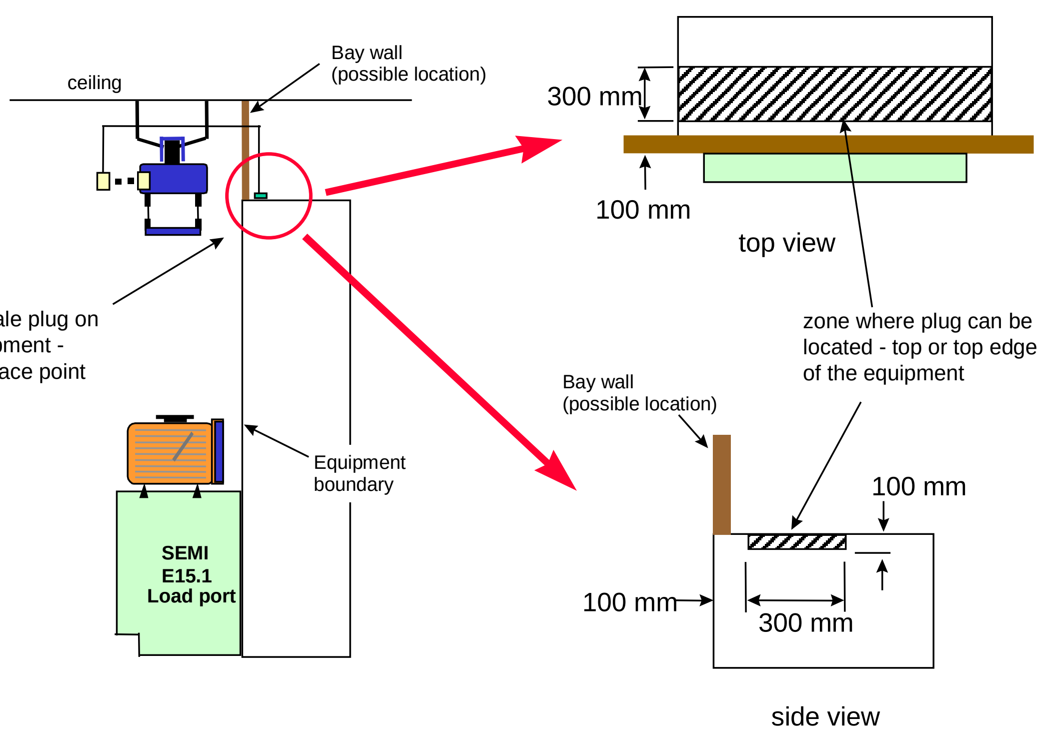

Figure A1-1
Connection Plug Location for Overhead Delivery

A1-5 This standard specifies two different PI/O configurations, one PI/O per load port and one PI/O per two load ports (Figure A1-2). Carrier transfer throughput and efficiency is higher if more than one carrier is transferred at the same time. Carrier transfer time is also reduced if the intrabay AMHS equipment can deliver two or more carriers at the same time from one parked position. Typically internal buffer equipment that allows hand-off of two carriers to two load ports either simultaneously or continuously can best take advantage of these throughput improvements. Thus, internal buffer equipment will require either one PI/O per load port (Figure A1-3, Concept A) or one PI/O per two load ports (Figure A1-3, Concept B), depending on the AMHS delivery system. Fixed buffer equipment will require one PI/O device per load port (Figure A1-4). Based on their production equipment and AMHS systems, end users will specify the SEMI E84 concept (one PI/O per load port or one PI/O per two load ports) and location that will be required on the manufacturing equipment.

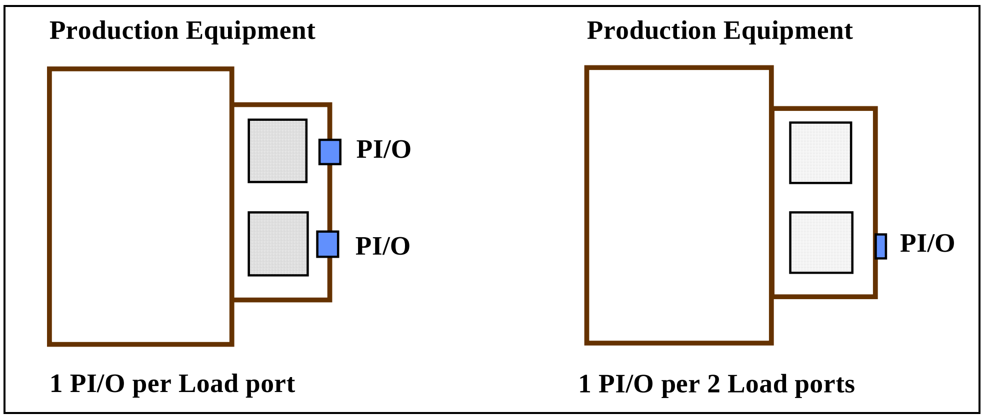

Figure A1-2
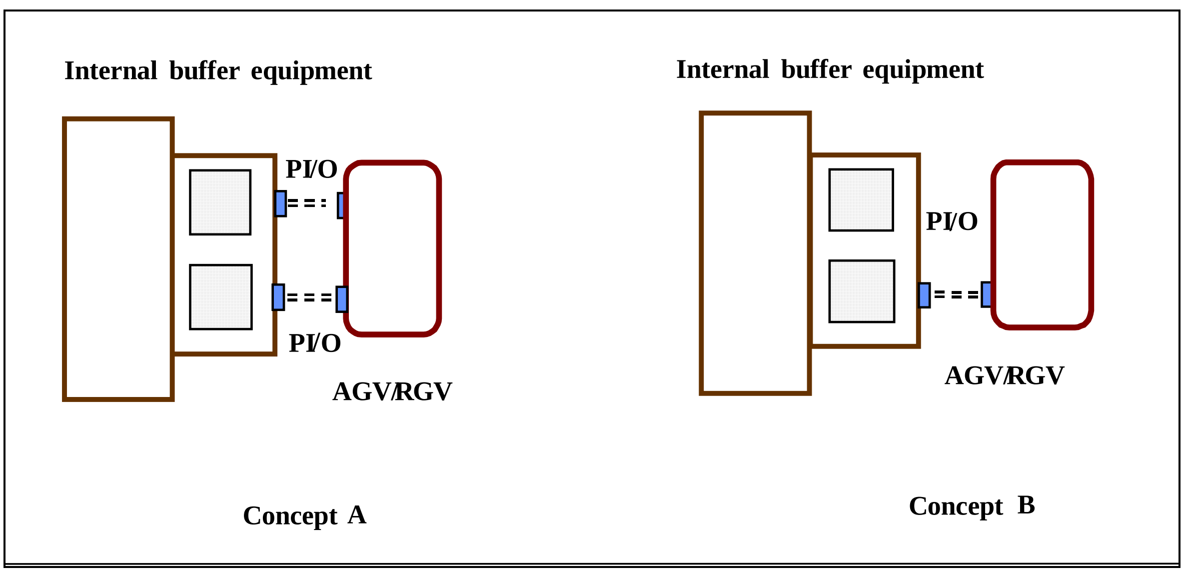
Two Different PI/O Configurations



NOTE 1: Simultaneous hand-off: use two PI/O at the same time.

NOTE 2: Continuous hand-off for different load port: use each PI/O sequentially.

Figure A1-3
Optional PI/O Configuration for Internal Buffer Equipment

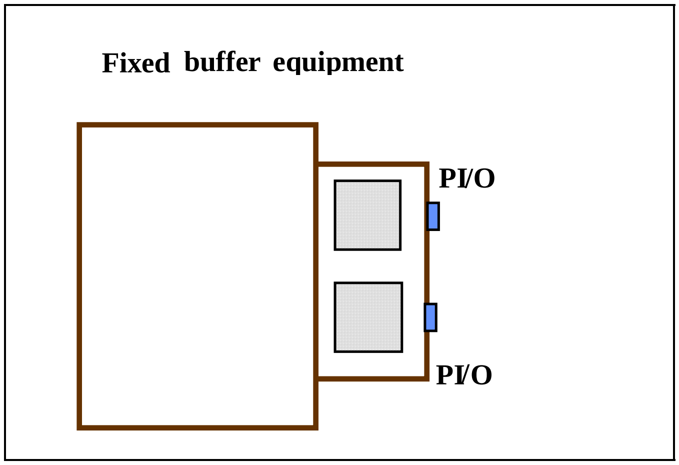


Figure A1-4
Typical PI/O Configuration for Fixed Buffer Equipment

A1-6 Figure 17 does not define a particular orientation of the PI/O interface sensor unit. Figure A1-5 shows how to orient the PI/O device for AGV/RGV of the exclusion volume in the load port. Refer to SEMI E15.1 for descriptions of D7, D8, H7, H8, and W8.

A1-7 This standard specifies a signal "on" state as 1.8 Vdc or less. Typical TTL circuits typically require a pull-down to 0.8 Vdc or less. For hard-wired connections, some TTL input circuits might not be able to sense an "on" state between 0.8 Vdc and 1.8 Vdc. One possible implementation is to provide an input receiver circuit.

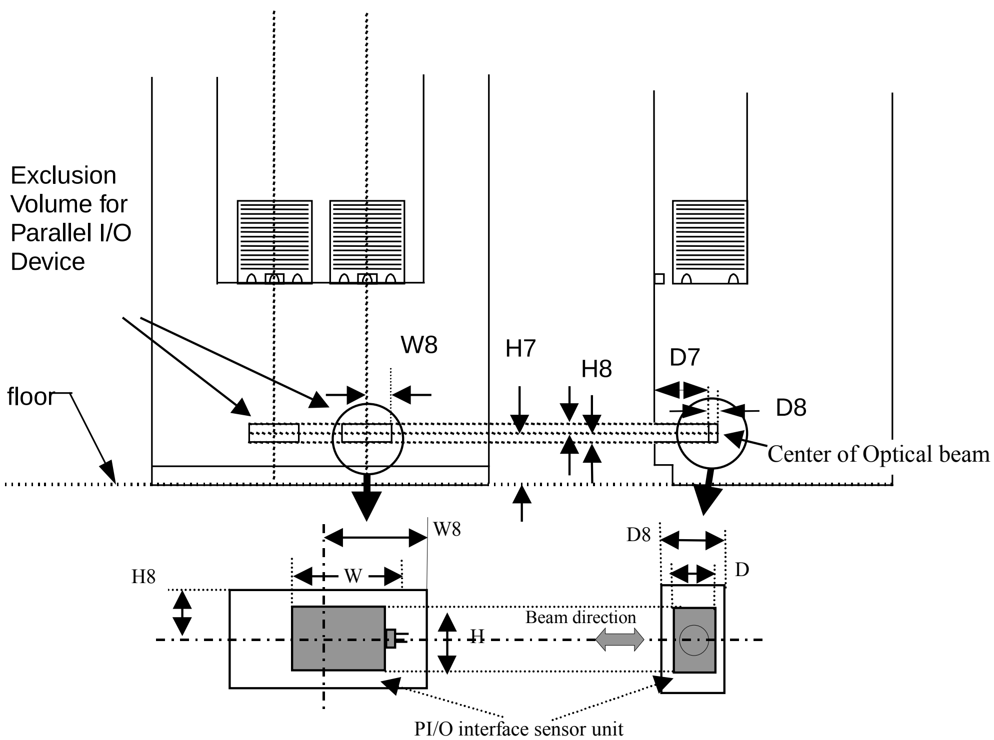

Figure A1-5
Example of the PI/O Interface Sensor Unit Implementation at Load Port for AGV/RGV

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information section was balloted as an official part of SEMI E84, but the recommendations in this section are optional and are not required to conform to this standard. Rather, these notes are provided primarily as a source of information to aid the in application of the standard. As such, they are to be considered reference material only.

This section describes error generation and recovery examples (mainly for active equipment) for interbay AMHS (i.e., OHS, stockers). The following are errors that could conceivably occur during transfer operations (load, unload). The procedures are designed for a technician with considerable knowledge of AMHS equipment. Error recovery should always follow the recovery procedures specified in the equipment manuals.

R1-1 OHS (Active Type) Error Examples

Table R1-1 Load Operation Errors

No.	*Error Description*	*OHS Reaction*
1	The L_REQ does not go OFF in the allotted amount of time during a load transaction.	The load operation sequence is stopped and an error is displayed.
2	Anytime during the transfer a load operation failure or stop positioning failure is detected.	
3	Anytime during the load operation the load presence status on the loader does not match the actual conditions of the current operation.	
4	The READY signal does not go ON within the specified amount of time after the TR_REQ signal is output.	
5	The READY signal goes OFF during the load operation.	
6	The L_REQ signal remains ON after the load operation is completed.	
7	The READY signal does not go OFF within the specified amount of time after the COMPT signal is output.	
8	Anytime during the load operation the optical transmission beam is interrupted.	

Table R1-2 Unload Operation Errors

No.	*Error Description*	*OHS Reaction*
1	The OHS moves to the stocker (for an unload operation) and outputs the VALID signal, but the U_REQ signal remains OFF for a specified amount of time.	The unload operation sequence is stopped and an error is displayed.
2	Anytime during the transfer an unload operation failure or stop positioning failure is detected.	
3	Anytime during the unload operation the load presence status on the loader does not match the actual conditions of the current operation.	
4	The READY signal does not go ON within the specified amount of time after the TR_REQ signal is output.	
5	The READY signal goes OFF during the unload operation.	
6	The U_REQ signal remains ON after the unload operation is completed.	
7	The READY signal does not go OFF within the specified amount of time after the COMPT signal is output.	
8	Anytime during the unload operation the optical transmission beam is interrupted.	

R1-1.1 *Example of the Signal Status When an Error is Generated During Transfer Operations*

R1-1.1.1 *OHS Side Error Generation*

R1-1.1.1.1 *OHS Side Signals* — When an error is generated, the BUSY signal must stay ON. This is to prevent secondary accidents due to the other device operating on its own.

R1-1.1.1.2 *Stocker Side Signals* — When an error is generated, each signal (except for the READY signal) should remain in the status it was in at the time of the error. The READY signal should go OFF.

R1-1.1.2 *Stocker Side Error Generation*

R1-1.1.2.1 *Stocker Side Signals* — When an error is generated, each signal should remain in the status it was in at the time of the error.

- The READY signal should be OFF.
- The ES signal should be OFF.
- HO_AVBL should be OFF.

R1-1.1.2.2 *OHS Side Signals* — When an error is generated, only the BUSY signal should go ON. All remaining signals should go OFF.

R1-1.2 *Recovery Sequences*

R1-1.2.1 Should an error occur during transfer operations (refer to Tables 1 and 2), the recovery should begin by returning the carrier to the stocker or OHS. Then, the error should be recovered. The four recovery scenarios are:

1. Load operation, carrier is returned to the stocker.
2. Load operation, carrier is returned to the OHS
3. Unload operation, carrier is returned to the stocker
4. Unload operation, carrier is returned to the OHS

R1-1.3 *Recovery Method*

R1-1.3.1 *OHS Side*

- In the case of sequence 2 (above), the load/unload sequence should be started over from the beginning.
- In the case of sequence 3 (above), the corresponding transfer operation should be canceled.
- In the case of sequences 1 and 4 (above) the corresponding transfer operation should be considered completed.

R1-1.3.2 *Stocker Side*

- In the case of sequences 1 and 4 (above) the corresponding transfer operation should be considered completed.
- In the case of sequences 2 and 3 (above), the load/unload sequence should be started over from the beginning.

R1-2 Stocker (Active Type) Error Examples

Table R1-3 Load Operation Errors

No.	*Error Description*	*Stocker Reaction*
1	The L_REQ does not go OFF in the allotted amount of time during an unload transaction.	The load operation sequence is stopped and an error is displayed.
2	Anytime during the transfer a load operation failure or stop positioning failure is detected.	
3	Anytime during the load operation the load presence status on the loader doesn't match the actual conditions of the current operation.	
4	The READY signal does not go ON within the specified amount of time after the TR_REQ signal is output.	
5	The READY signal goes OFF during the load operation.	
6	The L_REQ signal remains ON after the load operation is completed.	
7	The READY signal does not go OFF within the specified amount of time after the COMPT signal is output.	
8	Anytime during the load operation the optical transmission beam is interrupted.	

Table R1-4 Unload Operation Errors

No.	*Error Description*	*Stocker Reaction*
1	The stocker (for an unload operation) outputs the VALID signal, but the U_REQ signal remains OFF for a specified amount of time.	The unload operation sequence is stopped and an error is displayed.
2	Anytime during the transfer an unload operation failure or stop positioning failure is detected.	
3	Anytime during the unload operation the load presence status on the loader doesn't match the actual conditions of the current operation.	
4	The READY signal does not go ON within the specified amount of time after the TR_REQ signal is output.	
5	The READY signal goes OFF during the unload operation.	
6	The U_REQ signal remains ON after the unload operation is completed.	
7	The READY signal does not go OFF within the specified amount of time after the COMPT signal is output.	
8	Anytime during the unload operation the optical transmission beam is interrupted.	

R1-2.1 *Example of the Signal Status When an Error is Generated During Transfer Operations*

R1-2.1.1 *Stocker Side Error Generation*

R1-2.1.1.1 *Stocker Side Signals* — When an error is generated, the BUSY signal must stay ON. This is to prevent secondary accidents due to the other device operating on its own.

R1-2.1.1.2 *OHS Side Signals* — When an error is generated, each signal (except for the READY signal) should remain in the status it was in at the time of the error. The READY signal should go OFF.

R1-2.1.2 *OHS Side Error Generation*

R1-2.1.2.1 *OHS Side Signals* — When an error is generated, each signal should remain in the status it was in at the time of the error.

- The READY signal should be OFF.
- The ES signal should be OFF.
- HO_AVBL should be OFF.

R1-2.1.2.2 *Stocker Side Signals* — When an error is generated, only the BUSY signal should go ON. All remaining signals should go OFF.

R1-2.2 *Recovery Sequences*

R1-2.2.1 Should an error occur during transfer operations (refer to Tables 3 and 4), the recovery should begin by returning the carrier to the stocker or OHS. Then, the error should be recovered. The four recovery scenarios are:

1. Load operation, carrier is returned to the OHS.
2. Load operation, carrier is returned to the stocker
3. Unload operation, carrier is returned to the OHS
4. Unload operation, carrier is returned to the stocker

R1-2.3 *Recovery Method*

R1-2.3.1 *Stocker Side*

- In the case of sequences 2 and 3 (above), the load/unload sequence should be started over from the beginning.
- In the case of sequences 1 and 4 (above) the corresponding transfer operation should be considered completed.

R1-2.3.2 *OHS Side*

- In the case of sequences 1 and 4 (above) the corresponding transfer operation should be considered completed.
- In the case of sequences 2 and 3 (above), the load/unload sequence should be started over from the beginning.

RELATED INFORMATION 2
APPLICATION NOTES

NOTE: This related information section was balloted as an official part of SEMI E84, but the recommendations in this section are optional and are not required to conform to this standard. Rather, these notes are provided primarily as a source of information to aid the in application of the standard. As such, they are to be considered reference material only.

If the stocker is the active side of the interbay AMHS (i.e., OHS and stockers) it is conceivable that the loader will interfere with the OHS passing by the stocker in failure scenarios. As a result of this possibility, it is necessary for interbay AMHS equipment makers to establish an OHS "PASS OK" signal separate from the SEMI E84 interlock. However, this note has no direct bearing on the contents of SEMI E84. Therefore, readers of SEMI E84 should only treat this as a reference item.

Pass Interlock

Interlock Signal

Signal Name	*P/A*	*Description*
PASS OK	A->P	When this signal is HIGH (ON), the vehicle may pass. When this signal is LOW (OFF), the vehicle may not pass.

SEMI E85-0302

SPECIFICATION FOR PHYSICAL AMHS STOCKER TO INTERBAY TRANSPORT SYSTEM INTEROPERABILITY

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on October 14, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in June 1999; previously published in November 2001.

1 Purpose

1.1 This specification defines the dimensional requirements for the interbay load ports of 300 mm AMHS equipment. It is intended to promote a list of required features and dimensions that define the physical interfaces between different types of interbay equipment, to facilitate the use of different automated transport systems in order to meet the different material handling requirements found throughout the factory. This is done by defining six options of interfaces that both the stocker and interbay transport system must comply with. Options defined are as follows:

- Option A: Active transport loads a carrier to an internal stocker position
- Option B: Active transport loads a carrier to an external stocker position
- Option C: Passive transport presents a carrier to an internal stocker position
- Option D: Passive transport presents a carrier to an external stocker position (kinematic coupling pin pick-up)
- Option E: Passive transport presents a carrier to an external stocker position (conveyor flange pick-up)
- Option F: Passive transport presents a carrier to an external stocker position for pickup with either (a) all 3 kinematic pins, (b) all 3 secondary kinematic pins or (c) top robotic flange. Carrier is oriented with front of carrier perpendicular to load face plane.

2 Scope

2.1 This is a standard covering physical interface of 300 mm AMHS interbay equipment only. Similar requirements covering 300 mm AMHS intrabay equipment are covered in SEMI E15.1.

2.2 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not specify that every type of 300 mm stocker has to interface with every type of 300 mm interbay transport system. It only specifies six different options of physical interface. Within any option however, all stockers must be able to physically interface with all interbay transports. This standard only specifies single carrier handoff and not dual simultaneous handoffs as implied by the dimensions in the rest of this document.

4.1 *SEMI Standards*

SEMI E1.9 — Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Specification for 300 mm Tool Load Port

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E57 — Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O Interface

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

NOTE 2: For many of the used terms, see SEMI E15.1.

5.1 *Abbreviations and Acronyms*

5.1.1 *AMHS* — Automated Material Handling Systems

5.2 *Definitions*

5.2.1 *active interbay transport system* — an interbay transport system that transfers the carrier to and from the stocker interbay load port itself using robotics that are located on the transport.

5.2.2 *drive through interbay transport (DT)* — an interbay transport system where the track runs internal to the stocker boundary for the entire width of the stocker (Option C application defined in Section 7.5.3).

5.2.3 *external stocker load port* — an interbay load port that is external to the stocker equipment boundary similar to a shelf or ledge on the stocker.

5.2.4 *horizontal transfer interbay transport (HT)* — an interbay transport system where a section of the track transfers or slides into an opening in the side of the stocker to present a passive interbay transport system to the stocker robot (Option C application defined in Section 7.5.3).

5.2.5 *interbay load port* — the interface location on a stocker where the interbay transport places wafer carriers to allow the stocker to store the carriers.

5.2.6 *interbay transport system* — is defined as the track and vehicle (if applicable) that transports the carrier to and from the interbay stockers.

5.2.7 *internal stocker load port* — an interbay load port that is recessed from the stocker equipment boundary (a cavity or cutout in the stocker).

5.2.8 *overhead delivery* — an interbay transport system that transfers the carrier to and from the stocker interbay load port itself from directly above the load port (raises and lowers the carrier to the load port).

5.2.9 *passive interbay transport system* — an interbay transport system that requires the stocker to transfer the carrier to and from the stocker interbay load port (stocker has robotics that transfers the carrier).

5.2.10 *stocker* — an AMHS storage device.

6 Ordering Information

6.1 Per Section 6 of SEMI E15, except for Sections 6.1.3 and 6.1.4.

6.2 The user and AMHS supplier will jointly own the responsibility of defining the height of the interbay load port defined by dimension H (the distance from the horizontal datum plan to the raised floor).

6.3 The user must specify which of the options (defined in Section 7.5) is required for each interbay load port. The user must also specify which carrier will be used: front-opening box or open cassette.

6.3.1 If the user specifies Option C, the user must also specify:

a) Which type of interbay transport system will be used. Dimensions A1 and S do not apply if it is a drive through (DT) type. Dimensions A1 and S do apply if it is a horizontal transfer (HT) type (defined in Section 7.5.3).

b) Which height of exclusion volume in the stocker will be used defined as dimension T3 in Tables 1 and 2.

c) Which length of center exclusion volume in the interbay transport will be used defined as dimension D10 in Tables 1 and 2.

6.3.2 If the user specifies Option D, the user must specify which length of exclusion volume will be used in the interbay transport as defined by dimension D10 in Tables 1 and 2.

6.3.3 If the user specifies Option E, the user must specify which length of exclusion volume will be used in the interbay transport as defined by dimension D10 in Tables 1 and 2.

6.3.4 If the user specifies option F, the user must specify top (robotic flange pickup) or bottom access (secondary kinematic pins pickup).

7 Requirements

7.1 The dimensional requirements for the load port of a storage device and the interbay transport system are given in Table 1 for front-opening box and Table 2 for open cassette.

7.2 The carriers shown in these figures are intended to represent any type of carrier (open cassette or front-opening box). Figure 11 is only applicable for open cassette type carriers.

7.2.1 Except for option F, the carrier shall be loaded and unloaded with its front parallel to and away from the load face plane as illustrated in Figures 1–11.

7.3 The wafers in the front-opening box are to be oriented horizontally face up with zero nominal tilt at the time they are placed on the load port. The tolerance in the horizontal plane is determined by the registration and alignment feature between the carrier and the load port, as specified in SEMI E57. The wafers in the front-opening open cassette are to be oriented horizontally face up with 2 degree nominal tilt at the time they are placed on the load port.

7.4 Dimension H of the load port is to be specified by the user and the AMHS supplier (Section 6.2). The height of the interbay transport system is to be fully configurable using the track hangers. The precision with which the interbay transport delivery system height must be maintained is dictated by the needs of the interbay load port.

7.5 AMHS interbay equipment load ports must conform to one of the following configuration options (see Section 6.3).

7.5.1 In Option A, an active transport loads a carrier to an internal stocker position. The stocker interbay load port must therefore maintain the center exclusion volume below the HDP defined in Section 7.6 and shown in Figures 1 and 10. This exclusion volume in the stocker load port facilitates carrier delivery from an active interbay transport system. The interbay transport may transfer the carrier to the passive stocker using the SEMI standard carrier handling features, which are compatible with the exclusion volumes in the stocker defined in this standard. Examples include the secondary set of kinematic pins and the top robotic flange. The use of the primary kinematic pins is reserved for the stocker load port. The two front kinematic pins and a guide are used to interface with a SEMI defined accurate outer carrier surface defined in SEMI E47.1 (front-opening box) or SEMI E1.9 (open cassette). Refer to Figure 1 and the Related Information for detail. The open volume internal to the stocker above the HDP is defined by dimensions A1, S, and a clearance C3 above the maximum height of the carrier.

7.5.2 In Option B, an active transport loads a carrier to an external stocker position. The stocker interbay load-port must therefore maintain the two fork-lift or conveyor exclusion volumes as defined in SEMI E15.1 to allow for an active interbay transport system to transfer a carrier to the fork-lift or conveyor rails. The stocker interbay load port must also be open from above to facilitate delivery from an overhead transport system. The open volume required for vertical delivery is defined by a projection of the stocker load port area. The stocker interbay load port features, exclusion volumes, and dimensions are defined in SEMI E15.1 with the exception of dimension S and H. This option is illustrated in Figure 2.

7.5.3 In Option C, a passive transport presents a carrier to an internal stocker position. The passive interbay transport must therefore maintain the center exclusion volumes defined in Section 7.6 and shown in Figures 3, 4, and 10 in order to facilitate automatic carrier transfer by the active stocker. The stocker may transfer the carrier to the passive interbay transport system using the SEMI standard carrier handling features, which are compatible with the exclusion volumes in the interbay transport system defined in this standard. Examples include the secondary set of kinematic pins and the top robotic flange. The use of the primary kinematic pins is reserved for the interbay transport system. The two front kinematic pins and a guide are used to interface with a SEMI defined accurate outer carrier surface defined in SEMI E47.1 (front-opening box) or SEMI E1.9 (open cassette). Refer to Figure 3 and the Related Information for detail. The open volume internal to the stocker to allow for the interbay transport to enter is defined by dimensions T3 and C5. This option is illustrated in Figures 3 and 4.

7.5.3.1 Option C allows for two different types of interbay transport (Section 6.3.1). The first type is a drive though (DT) interbay transport that will drive through the entire length of the stocker as illustrated in Figure 3. Dimensions A1 is therefore not applicable for this type of Option C interbay transport delivery. The other type of interbay transport is a horizontal transfer (HT) were a section of the track slides or advances into a predefined open volume in the side of the stocker as illustrated in Figure 4. Dimensions A1 and S are applicable for this type of Option C interbay transport delivery.

7.5.3.2 Option C prime (C’) is different from Option C in that the pins used to transfer the carrier are different. In Option C’, the transport vehicle uses the two front secondary, and single rear primary kinematic pins. This enables the stocker end-effector to use the two front primary pins and be of a wider configuration (see Figure 3a). All elevation dimensions for C’ are the same as for Option C.

7.5.4 In Option D, a passive transport presents a carrier to an external stocker position. The passive interbay transport must maintain the center exclusion volume shown in Figures 5 and 10 to allow for the stocker to use the secondary kinematic pins or top robotic flange to transfer the carrier. No open volume internal to the stocker is required.

7.5.4.1 Option D prime (D’) is different from Option D in that the pins used to transfer the carrier are different. In Option D’, the transport vehicle uses the two front secondary, and single rear primary kinematic pins. This enables the stocker end-effector to use the two front primary pins and be of a wider configuration (see Figure 4a). All elevation dimensions for Option D’ are the same as for Option D.

7.5.5 In Option E, a passive transport presents a carrier to an external stocker position. The passive interbay transport must maintain the side fork-lift/conveyor rail exclusion volumes shown in Figure 6 to allow the stocker to use the fork-lift/conveyor rails to transfer the carrier. No open volume internal to the stocker is required.

7.5.6 In option F and F’ the carrier is oriented with the front of the carrier perpendicular to the load face plane by a passive transport for pickup by an active stocker. In option F the transport uses the kinematic coupling pins (all 3 may be used) and the stocker uses either the secondary kinematic coupling pins (all 3 accessible) or the top robotic flange for pickup. In Option F' (F Prime) the transport uses the kinematic coupling pins, the secondary kinematic coupling pins or the conveyor runners, and the stocker uses the top robotic flange for pickup.

7.6 The center exclusion volume below the horizontal datum plane of the stocker for Option A (Section 7.5.1) or interbay transport system for Options C and D (Sections 7.5.3 and 7.5.4), is defined by dimensions H2, A2, and D (Figure 1 and 10). For Options C (Section 7.5.3) and D (Section 7.5.4), there are additional requirements that the center exclusion volume, defined by H2 and A2 extend from the facial datum plane a distance D10 (Sections 6.3.1 and 6.3.2), increase both in depth defined by dimension H4 and in width defined by dimension A3 from the plane defined by dimension D10 extending outwards for the rest of the interbay transport system. The conveyor flange exclusion volume below the horizontal datum plane of the interbay transport system (Section 7.5.4), is defined by dimensions H2, H4, A6, A8, and D10 (Figure 6). The center exclusion volume below the horizontal datum plane of the stocker for option F is defined by Figure 10, "Exclusion zone detail for option F". No exclusion volumes are required for option F' since stocker access is with the top robotic flange only. These exclusion volumes need to be open only during the carrier handoff between the stocker and the interbay transport system. For example, the stocker can temporarily occupy these exclusion volumes when transferring the carrier from the interbay load port to an internal shelf location.

7.7 Clearance C3 in Option A is defined with respect to the maximum dimensions of the carrier (defined in SEMI E47.1 for a box or in SEMI E1.9 for an open cassette), not to the rectangular wafer carrier envelope (defined in SEMI E15).

7.8 Dimension S specifies the required range for spacing between carrier centroids.

7.9 For active interbay transports (Option A) and passive interbay transports (Options C, D, and E and F), the communication method will be defined by SEMI E84 (same as OHT), and the available SEMI E84 connector areas are defined by the following dimensions, and are illustrated in Figure 9.

- Dimensions of the SEMI E84 connector zone are as follows:
- Width (measured from BDP) = 225 mm
- Depth (measured from Stocker facial plane) = 200 mm
- Height (measured from HDP) = 300 mm

NOTE 3: The bottom of the SEMI E85 exclusion volumes defines the top of the SEMI E84 connector zones. For Option A, the top of the connector zone is defined by dimension H2. For Option B, the top of the connector zone is defined by dimension H0. For Options C, D, and E and F, the top of the connector zone is defined by dimension H4.

Table 1 Dimensional Requirements for 300 mm AMHS Interbay Load Ports (FOUP ONLY)

Dim	*Definition*	*Option A*	*Option B*	*Option C*	*Option D*	*Option E*	*Option F*
θ (deg)	tilt of the open cassette when placed to the load port	0	SEMI E15.1	0	0	0	N/A
A1	minimum width of the load port cavity or cut-out in the stocker measured from the facial datum plane to the nearest obstruction on the stocker	375 mm	N/A	600 mm for HT only (See NOTE 1.)	N/A	N/A	N/A
A2	width of the exclusion zone for center pickup using the secondary kinematic coupling pins (symmetric about the bilateral datum plane)	213 + 2/-0 mm	N/A	213 + 2/-0 mm	213 + 2/-0 mm		213 + 2/-0
A3	Minimum width if the exclusion zone (starting at a distance D10 from the FDP) for center pickup using the secondary kinematic coupling pins (symmetric about the bilateral datum plane)	N/A	N/A	225 mm	225 mm	N/A	N/A
A6	maximum protrusion of the interbay transport measured from the facial datum plan of the transport (start of the exclusion volume for fork-lift or	N/A	SEMI E15.1	N/A	N/A	165 mm	N/A

Dim	Definition	Option A	Option B	Option C	Option D	Option E	Option F
	conveyor rail transfer)						
A8	minimum width of the exclusion volume for the fork-lift or conveyor rail transfer mechanism measured from the facial datum plane (end of the exclusion volume for fork-lift or conveyor rail transfer)	N/A	N/A	N/A	N/A	245 mm (80 wide)	N/A
C3	height of the nearest stocker obstacle above the carrier during transfer measured from the HDP of the transport—the maximum height of the carrier. This creates an exclusion zone for use of the top robotic flange.	150 mm	SEMI E15.1	N/A	N/A	N/A	N/A
C5	distance from the facial datum plane of the transport to the internal stocker boundary	N/A	SEMI E15.1	250 ± 50 mm	N/A	N/A	250 ± 50 mm

By publication of this specification, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E85. This related information was approved for publication by full letter ballot procedures on July 19, 2001.

R1-1 Except for Option F and F', the carrier may only rest on two of the three kinematic pins as defined in SEMI E57 to allow for transfer using the secondary set of kinematic pins. The AMHS supplier must allow the rear of the carrier to rest on a SEMI defined surface defined in SEMI E47.1 (front-opening box) or SEMI E1.9 (open cassette) to ensure the carrier is properly supported. The AMHS supplier should also investigate the stability of the FOUP if it rests on only two pins. One possible solution would be to add a lead-in or retaining feature that interfaces with a SEMI defined outer carrier surface defined in SEMI E47.1 (front-opening box) or SEMI E1.9 (open cassette).

R1-2 To avoid interfering with the lead-in capability (misalignment correction) function of the kinematic couplings, it is recommended that no part of the storage device (other than the kinematic couplings) come horizontally closer than 10 mm (0.39 in.) to the carrier.

R1-3 It is recommended that the systems that deliver carriers to AMHS interbay load ports have a mechanism to correct for misalignment of storage devices and load ports.

R1-4 The dimension H2 which defines the depth of the exclusion zone that allows for carrier transfer using the secondary set of kinematic pins, might be reduced in the future.

R1-5 Dimension C5 (for Option C) and D5 (for Option D) define the range required for stocker reach. Through teaching or adjustment the stocker must be able to transfer carriers from passive interbay transport systems which have a centerline within this range (250 $\pm$ 50 mm). This dimension is measured from the center point of the wafers on the interbay transport system.

R1-6 AMHS equipment can be configured with a variety of load ports chosen from the options defined in Section 7.5. Figure R1-1a shows a storage device with two Option A interbay load ports, which may work with an active transport and any carrier.

R1-7 An IC manufacturer or user could also specify the same Option A stocker, but with only one interbay load port. Figure R1-1b shows a storage device with two Option B interbay load ports, which may work with carriers delivered by a passive transport or an overhead transport system. Again, an IC manufacturer or user could also specify the same Option B stocker, but with only one interbay load port.

R1-8 For Example Only: AMHS suppliers may implement lead-in features in various methods which promote registration using any of the SEMI defined dimensions and features of the carrier.

SEMI E89-0999
GUIDE FOR MEASUREMENT SYSTEM CAPABILITY ANALYSIS

This guide was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999.

1 Purpose

1.1 The purpose of this guide is to provide a consistent set of terminology and describe a constructive experimental approach to planning and carrying out a measurement system capability analysis.

2 Scope

2.1 Primary focus is on describing and estimating measurement uncertainty associated with the behavior of automated wafer measurement systems under normal operating conditions, but the definitions and methodologies are extendible to many other measurement situations involving items such as wafers, dies, packaged devices, flat panel displays, piece parts, etc. While examples are included to illustrate concepts, the intent is to avoid specific measurement situation details wherever possible and focus instead on general planning and analysis issues.

2.2 This guide does not address those aspects of measurement uncertainty associated with change in the object being measured, either spatially or temporally.

2.3 This guide does not address those aspects of measurement uncertainty associated with calibration of the measurement system.

2.4 This guide does not address estimating measurement capability in the case of destructive measurements on samples, or when the metrology system alters the object being measured as the measurement is made.

2.5 This guide does not apply to inter-laboratory measurements designed to measure inter-laboratory precision.

2.6 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standard*

SEMI M27 — Practice for Determining the Precision over Tolerance (P/T) Ratio of Test Equipment

3.2 *ISO Standards*[1]

Guide to the Expression of Uncertainty in Measurement

International Vocabulary of Basic and General Terms in Metrology, Second Edition

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *General Definitions*

accuracy — closeness of agreement between a measurement made on an object and its true value [International Vocabulary of Basic and General Terms in Metrology].

NOTE 2: This is a qualitative term measured by bias.

bias — the difference between the average of measurements made on the same object and its true value. Sufficient measurements are needed to mitigate the effects of variability.

NOTE 3: In many cases the true value is unknown. A value established by reference instruments or a consensus value might be used as a substitute.

capability (C_p) — a dimensionless figure of merit that indicates how many times larger the tolerance (see Section 4) is than the measurement system precision (see Section 4). Example: for a two sided specification, if USL is the upper specification limit, LSL is the lower limit and σ_R is reproducibility (see Section 4.1), then $C_p = (USL - LSL)/6\sigma_R$.

NOTE 4: This defines C_p for the measurement system in a particular application. If $\sigma_{Product}$ (see Section 4.1) is used, instead of σ_R, then C_p defines process capability.

gauge — any tool used to assign a value to a quantitative or qualitative characteristic of a physical entity or phenomenon. Example: film thickness is a quantitative characteristic and defect type is a qualitative characteristic.

gauge repeatability and reproducibility (R&R) study — see Section 4.1, measurement system capability analysis.

1 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland

linearity — the absence of changes in bias as measurements are made at different points within the measurement range. Bias and linearity issues are related to calibration and are beyond the scope of this document.

NOTE 5: Traditional definitions of linearity ignore the fact that variability can change over the measurement range, as well as bias. The assumption of constant variability over the measurement range should be verified during the measurement system capability study.

lower specification limit (LSL) — the lower (or minimum) engineering specification limit for a given parameter.

measurement — the value a gauge assigns to a characteristic. In most cases, measurements will be numerical, although this is not a requirement. Example: defect classification equipment assigns non-numerical types to wafer defects.

NOTE 6: Measurement may also be used as an adjective when referring to the measurement process of assigning a value to an object.

measurement subsystem — any set of entities, processes or conditions that share a common purpose in the measurement.

NOTE 7: A subsystem may contain one or more of its own subsystems. For example, a wafer handling mechanism may be further composed of wafer loading and wafer positioning subsystems.

measurement system — all entities, processes, and conditions that may affect measurements made

- on the same object or identical objects (apart from true value differences)
- with a specific set of measurement tools and
- under normal operating conditions as described in gauge specifications.

The measurement system may include, but is not limited to, operators, setup mechanics, wafers, locations on a wafer, environmental conditions, software used by the gauge, measurement method, etc. The system may be comprised of measurement subsystems.

NOTE 8: The purpose of a measurement system capability analysis is to characterize sources of variation associated with the measurement system. In most cases, however, the total number of contributors is exceedingly large. Typically, one focuses on a subset that accounts for a large portion of total measurement system variability.

measurement system capability analysis — the technique by which one estimates all relevant individual sources of variability associated with a gauge in a measurement system. It is also called a gauge study or a gauge repeatability and reproducibility (R&R) study.

measurement uncertainty — parameter, associated with a measurement, that characterizes the dispersion of values that can be reasonably attributed to the object being measured [International Vocabulary of Basic and General Terms in Metrology].

precision — a multiple of σ_R, often chosen to be $6\sigma_R$.

NOTE 9: The QS9000 Standard, as well as other automotive industry documents, uses $5.15\sigma_R$.

precision over tolerance (P/T) ratio — a relative comparison that shows how much of the tolerance (see Section 4) is used up by the measurement instrument's precision (see SEMI M27). Example: $P/T = 6\sigma_R/(USL - LSL) = 1/C_p$, where C_p is the measurement system capability defined in Section 4. P/T is often expressed as a percent, by multiplying the previous ratio by 100.

product variability ($\sigma_{Product}$) — the population standard deviation associated with the distribution of measurements taken on all possible realizations of an entity manufactured under specified operating conditions. It is estimated by taking a representative sample from the population and calculating its sample standard deviation ($s_{Product}$).

repeatability (σ_r) — the variability associated with repeated measurements taken under the most ideal (identical) conditions. The ideal estimate would require instantaneous measurements taken under conditions that hold all elements of the measurement system constant. Two different methods of estimating repeatability are common, because of the different ways measurement instruments are used. They are:

dynamic repeatability — the standard deviation of measurements taken under the following conditions:

- A very small amount of time, typically minutes or seconds, has lapsed between the first and last measurements.
- All factors that may influence the measurement are held constant.
- The object is removed and immediately put back into the gauge between measurements.

NOTE 10: When it is possible to calculate both kinds of repeatability, the Root Sum of Squares (RSS) difference (see Section 4.2) between dynamic repeatability and static repeatability is a measure of the variability introduced by the wafer insertion (or stage accuracy) process.

static repeatability — the standard deviation of measurements taken under the following conditions:

- A very small amount of time, typically minutes or seconds, has lapsed between the first and last measurements.
- All factors that may influence the measurement are held constant.
- The object is not reloaded in the gauge between measurements.

reproducibility (σ_R) — the total variability associated with the measurement system when measurements are made under different (but typical) conditions. Changes associated with subsystems or conditions are potential sources of variation to be estimated. Reproducibility is measured by the square root of the sum of all sources of variation. Repeatability is one of these sources. Other relevant sources of variability may include time, operator, wafer, location on a wafer, environment, etc. Reproducibility does not include variability due to measuring objects with different "true" measurement values.

resolution — the ability of the measurement system to detect and faithfully indicate small changes in the characteristic of the measured result.

NOTE 11: A general rule of thumb is that a gauge should have resolution that is more than two digits beyond what is required for the measurement result.

signal to noise ratio (SNR) — the ratio of the variation in the manufactured product to the precision of the measurement instrument. Since it is difficult to directly measure the standard deviation of the product without including variation due to the measurement instrument, SNR is generally defined as:

$$SNR = \sqrt{\frac{\sigma_{Total}^2 - \sigma_R^2}{\sigma_R^2}},$$

where σ_{Total}^2 is the variance obtained by measuring a large representative sample of the product.

NOTE 12: SNR is an objective measurement in the sense that it does not depend on a specification, which can be changed at any time. In practice, a SNR of 10 or more generally means the instrument is suitable for the product, while an SNR less than 3 or 4 might be a concern in a particular situation.

stability — the absence of additional variability due to taking measurements over time (typically several days or longer).

tolerance — the difference between the maximum and minimum engineering specification limits (as used in P/T ratio) for a given parameter. This is just (USL – LSL).

total variability (σ_{Total}) — the square root of the product variability squared plus the reproducibility squared.

$$\sigma_{Total} = \sqrt{\sigma_{Product}^2 + \sigma_R^2}$$

upper specification limit (USL) — the upper (or maximum) engineering specification limit for a given parameter.

4.2 *Statistical Definitions*

effect — the coefficient, or its estimate, associated with an input variable. It is a measure of influence that a particular variable level has on the output variable.

crossed effect — effects that do not possess a hierarchical relationship.

fixed effect — an effect associated with input variables that have a limited number of levels or in which a limited number of levels are of interest to the experimenter.

nested effect — an effect that is part of a hierarchical relationship such that it is contained within another effect.

random effect — an effect associated with input variables chosen at random from a population having a large or infinite number of possible values.

level — unique value associated with a nominal or categorical variable (see Section 4.2). Also called setting of a variable.

(statistical) model — a mathematical function relating one or more responses to known and measurable inputs plus one or more unknown stochastic (error) terms. The errors represent values from the distribution of differences between the model and observed values. An example of a statistical model is:

$$Y_j = \sum_{i=1}^{p} \beta_i X_i + e_j$$

where Y_j is the jth observation, β_i and X_i the ith input variable and its corresponding coefficient, respectively, and e_j the error associated with the jth observations. In many cases the error distribution(s) are specified before the model is fit (e.g., normal). If the model contains nested effects (see Section 4.2) there may be more than one error term.

root sum of squares (RSS) sum — the RSS sum of two or more numbers is the square root of the sums of the squares of the numbers.

root sum of squares (RSS) difference — the RSS difference of two numbers is the square root of the difference of the squares of the two numbers.

standard deviation — a numerical measure of dispersion.

population standard deviation — the square root of the population variance.

sample standard deviation — the square root of the sample variance.

variable — a quantitative or qualitative characteristic of an object, processes, or state that may take on more than one value. When the values occur unpredictably, it is a random variable.

variance — a numerical value that measures dispersion.

population variance (σ^2) — a measure of dispersion associated with a population distribution. For continuous distributions, it is the second central moment.

sample variance (s^2) — a measure of dispersion associated with a sample. The average squared deviation from the mean for a set of numbers. If X_i is an individual observation, $\overline{X}$ the average across all observations, and n the number of observations, then

$$s^2 = \frac{\sum_{i=1}^{n}(X_i - \overline{X})^2}{n-1}$$

NOTE 13: The denominator value of $n - 1$ is used to make the sample variance an unbiased estimator of the population variance.

5 Measurement System Capability Analysis Considerations

5.1 The goal of a measurement system capability analysis is to characterize the measurement system by dividing the total measurement variability into portions coming from each significant source of variability. Tests of gauge tool performance should characterize the simultaneous performance capability of the various aspects of accuracy and repeatability just as the tool would be used in a manufacturing or laboratory setting.

5.1.1 Picture the total measurement system variability as a large bucket filled with contributions that come from many smaller buckets. Some of the variability in the smaller buckets causes erroneous measurement readings and some is due to real differences in what is being measured. A number of the buckets are "owned" by the measurement instrument, while some are "owned" by the user and some arise from possibly unavoidable conditions. Accurately identifying the size and nature of all these buckets allows one to know whether the instrument is capable of performing its intended function. Moreover, a well-designed measurement system capability analysis will identify and quantify which areas need the most improvement.

5.2 *Steps in Planning a Measurement System Capability Analysis*

5.2.1 List specific goals for the study. One or more of the following typical goals might be included:

- Assess gauge accuracy (requires standards or "golden specimens" with known true measurement values or agreed upon consensus values).
- Insure the gauge repeatability, precision and P/T is acceptable. Rule of thumb: a P/T based only on repeatability should be less than 0.05 and a full P/T should be under 0.3.
- Learn which are the largest sources of variability affecting measurements made by a given gauge (for focussing improvement efforts).
- Institute an appropriate routine of statistical process control for a gauge.
- Understand whether the gauge behaves linearly across the measurement range.
- Understand whether the gauge is stable over a period of days or possibly months. (Gauge maintenance and calibration schedules play a key role in determining how long a gauge needs to be stable.)

5.2.2 Obtain standards or specimens with consensus values, if possible. Bias can only be measured when true values are known.

5.2.3 Review prior studies – what sources of variability were significant and what were the repeatability and precision?

5.2.4 List all sources of variability (factors) and reach consensus on those that might be significant. Some of these might be:

- Operator
- Set-up procedure
- Shift
- Wafer handling hardware
- Location on a wafer
- Test wafer
- Environment conditions
- Temperature
- Humidity
- Day or week

5.2.5 Determine if the tool needs to be calibrated. Calibrate, if necessary, following the manufacturer's recommended procedure. Do not recalibrate during the gauge study unless specified by normal operating procedure.

5.2.6 An experiment to estimate bias, repeatability and reproducibility should be a goal of the study. As a general rule of thumb, a minimum of 16 measurements on a standard are needed to estimate bias, and 30 measurements (taken throughout the experiment, under repeatability conditions) are needed to estimate repeatability. Several examples of every factor that was decided on in Section 5.2.4 should be included.

5.2.6.1 Linearity should be estimated by taking a sample of observations that adequately span the measurement range.

5.2.6.2 To estimate stability over the long term, measurements should be taken over an appropriate time period (5 or more days is typical), and then, if behavior over longer periods is important, repeat the experiment several weeks or months later.

5.2.6.3 In order to plan and analyze an experiment properly, it is useful to write a statistical model for the experiment (see Appendix 1).

5.2.7 Carry out the experiment, randomizing both the sample specimens chosen and the order measurements are made, wherever possible. Keep track of the actual order all measurements are made.

5.2.8 Analyze the measurement data, calculating repeatability, reproducibility, system measurement error, P/T and all significant sources of error contributing to reproducibility. Check short term and long term stability by plotting repeatability measurements in time order within a day, and measurement averages and spread from day to day. Compare precision results obtained on a specimen to specimen basis, to check linearity.

6 Example of a Measurement Capability Analysis

6.1 The following example illustrates how a measurement capability analysis was performed on an automated wafer film thickness tool. The tool was calibrated prior to the analysis (the presence of bias, however, would not affect the estimation of variance components as long as the amount of bias does not change over the course of the measurement system capability analysis). Different wafer types were selected to span the range of both possible wafer types and typical thicknesses. Five standard wafers were manufactured with characteristics as shown in Table 1.

6.2 Wafers were measured on eight days, evenly spaced over a two-week period. Each day of the study each wafer was chosen twice, loaded each time into the tool and measured twice without unloading. The order of selection was at random. Therefore, on a given day, each wafer was measured exactly four times. Measurements were taken at three points on the wafers and averaged. The model (see Appendix 1) used was

$$M_{hkji} = \mu + d_h + w_k + wd_{hk} + c_{hkj} + r_{hkji}$$

where the terms are defined as follows:

M_{hkji} Measurement taken on day h, wafer k, cycle j, and repeat i.

μ The grand mean across all conditions.

d_h Effect or contribution due to day h = 1, .., 8. This measures stability and its variability is a part of reproducibility.

w_k Effect or contribution due to wafer k = 1, .., 5.

wd_{hk} Effect or contribution due to wafer by day interaction. Variability contributed by this term is part of reproducibility.

c_{hkj} Effect or contribution due to cycle j = 1, 2. Nested in wafer k and day h. Variability contributed by setting up for each cycle is part of reproducibility.

r_{hkji} Effect or contribution due to repeat i = 1, 2. Nested in cycle j, wafer k, and day h. Variability contributed by this term is repeatability.

Table 1 Wafers Used for Analysis

Film Type	*Total Thickness (Å)*
Oxide (wafers 1, 2, 3)	40, 1000, 8000 (for wafers 1, 2, 3, respectively)
Polysilicon over Oxide (wafer 4)	2500
Deep UV Resist over ARC over Oxide (wafer 5)	13000

NOTE: UV — Ultra Violet, ARC — Anti Reflective Coating.

6.3 Most analysis software programs report estimates as variances and produce the variance components analysis shown in Table 2. Sources of variation, such as σ_r and σ_R, are standard deviations found by taking the square roots of the appropriate variance component or sum of components.

6.4 Wafer variability (σ_{wafer}) was not reported because it is associated with a fixed effect. Variance components are only estimated for random effects. If, for example, the five wafers were randomly selected from a distribution for a single wafer type, wafer variability would be included in the table and could be used to estimate the SNR. However, wafer variability would still not be part of σ_R. For further details, see Appendix 1.

Table 2 Variance Components Estimates — All 5 Wafers

Variance Component	*Estimated Variance*	*Estimated Sigma*
DAY	11.183	3.344
REPEAT	0.286	0.535
CYCLE	0.797	0.893
WAFER*DAY	447.940	21.165

6.5 Reproducibility (σ_R) is calculated as the square root of the sum of the estimates, i.e.,

$$\sigma_R = \sqrt{11.183 + 0.286 + 0.797 + 447.940} = 21.452\,.$$

6.6 Repeatability (σ_r) is estimated by the repeated measurements.

$$\sigma_r = \sqrt{0.286}$$
$$= 0.535$$

6.7 Stability is estimated by the square root of the DAY component of the study, $\sigma_{stability} = 3.344$.

6.8 Figure 1 shows a Pareto chart of the effects sigmas.

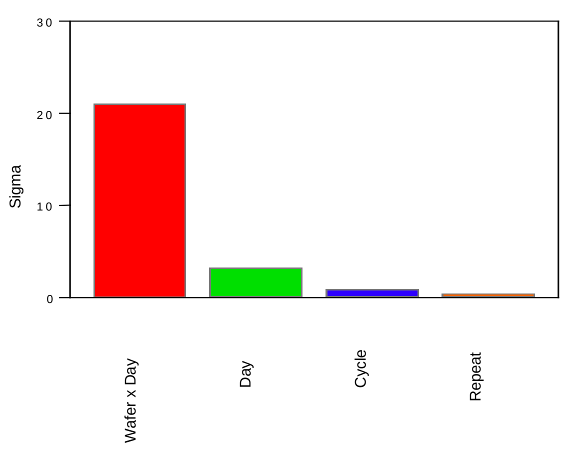

Figure 1
Pareto Chart for Effects Sigmas (All Five Wafers)

6.9 Linearity is more difficult to estimate. In general, it is measured by the differences in variability associated with the different wafer types. The large wafer by day interaction suggests that there may be a linearity problem. An examination of the standard deviations for each group by day (See Figure 2) indicates that Wafer Type 5 (Deep UV resist) may be responsible. These standard deviations were calculated from the 4 measurements made on every wafer each day.

6.10 When the variance components analysis was rerun, excluding Wafer Type 5 data, the new estimates obtained confirmed that Wafer Type 5 was problematic. An investigation into the potential cause suggested that the tool was degrading the resist at the point of measurement, causing the readings to decrease over time.

6.11 If one were interested in measuring only Wafer Types 1 through 4 (employing a different gauge for Wafer Type 5, for example), the improved variance components estimates from Table 3 could be used.

Table 3 Variance Components Estimates Wafers 1 – 4

Variance Component	*Estimated Variance*	*Estimated Sigma*
DAY	0.347	0.589
REPEAT	0.130	0.360
CYCLE	0.244	0.493
WAFER*DAY	1.023	1.011

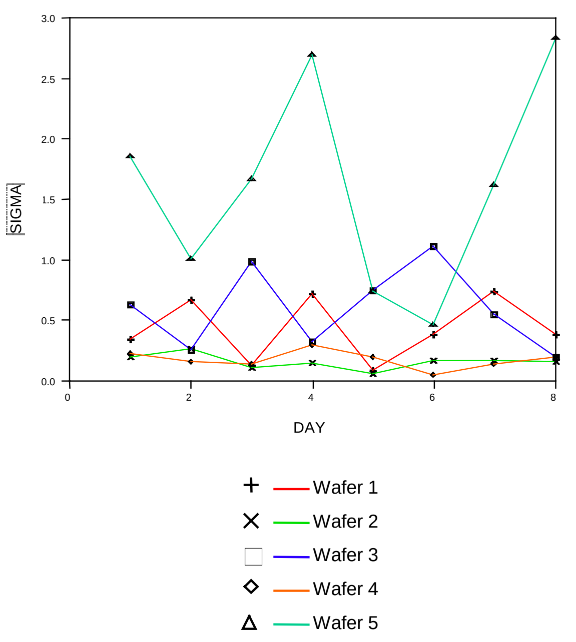

Figure 2
Wafer Sigmas by Day

6.12 The new estimates for σ_r and σ_R, are 0.360 and 1.271, respectively. Stability, as measured by day to day variability, improves to 0.589. The new Pareto chart of the effects sigmas is shown in Figure 3.

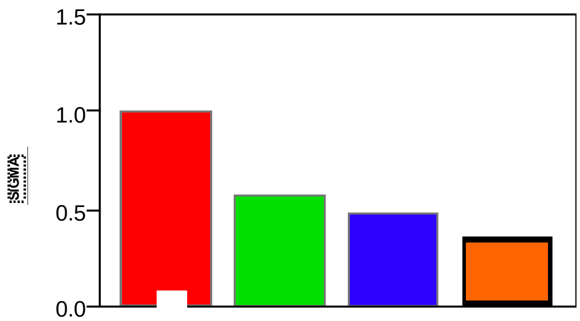

Figure 3
Pareto Chart for Effects Sigmas
(Wafer Type 5 Removed)

6.13 The specification range for the tool was given as 10Å, thus the capability for Wafer Types 1 to 4 is

$$Cp = \frac{10}{6*1.321} = 1.262$$

6.14 The P/T ratio is the reciprocal of this number, or P/T = 0.79. Since this is well above the "rule of thumb" 0.30 value, the gauge might not be suitable for some applications. Improvement activities would begin with an investigation of why the WAFER*DAY sigma is so large. This term indicates differences between the way certain wafers vary from day to day (stability differences between wafers).

APPENDIX 1
MODELS FOR MEASUREMENT CAPABILITY ANALYSIS STUDIES

NOTE: This appendix was balloted as an official part of SEMI E89 by full letter ballot procedure, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 This is a more detailed theoretical explanation that extends ideas described earlier in this guideline.

A1-2 A measurement model expresses each observed measurement value as the sum of a "true value" plus "bias" plus "random error". The "true value" may be the actual value for the object being measured or the average population value if a sample of objects are measured in the study. The random error term is further broken up into contributions from all the significant sources of error under investigation. If the experiment is well designed, standard statistical techniques (known as Analysis of Variance, or ANOVA) can be used to estimate the standard deviation contribution from each source of error, and from this the repeatability, reproducibility and precision of the measurement instrument are determined.

A1-3 Note that any instrument which is composed of several measurement subsystems (such as spectrometry and ellipsometry), designed for the measurement of different characteristics or types of samples, must be treated as composed of separate gauges which need to be analyzed independently.

A1-4 Writing an appropriate measurement model is the starting point, after which many software packages can be used to design the gauge study and calculate ANOVA estimates from the resulting measurement data.

A1-5 An example will illustrate what is meant by a measurement model.

A1-5.1 *Example of a Measurement Model* — A wafer oxide thickness measuring gauge is under investigation. A wafer is placed in the instrument, which then automatically positions the wafer and takes a measurement. While the wafer is positioned, the measurement can be repeated as many times as desired. Sources of variability that might affect a measurement include basic repeatability on a positioned wafer, variability due to the automatic positioning process, variability over time and variability from measuring several different wafers (to cover a range of "true" measurement values).

A1-5.2 An experiment that separates out all these possible sources of variability is the following: 10 wafers are chosen at random from normal production. Each wafer is put in the instrument in a random order and measured 3 times (3 repeats) on day 1 (cycle 1). Immediately after the thirty measurements are recorded, the same measurement process is repeated on the ten wafers (cycle 2). On day two, the same wafers are again measured using exactly the same procedure. This is repeated for a total of 5 days, yielding $3 \times 10 \times 2 \times 5 = 300$ measurements.

A1-5.3 Assuming the instrument has been calibrated (or bias is not a concern at the moment), a model for variability is constructed as follow: let $h = 1, 2, .., 5$, index the days; let $k = 1, 2, .., 10$, index the wafers; let $j = 1, 2$, index the repositions (cycles) each day and let $i = 1, 2, 3$, index the repeat measurements (taken under repeatability conditions) on a positioned wafer.

A1-5.4 The model for the i-th measurement at the j-th repositioning on the k-th wafer on the h-th day is:

$$M_{ijkh} = \mu + d_h + w_k + p_{hkj} + r_{hkji}$$

where:

- μ is the true oxide thickness average value for the population of wafers,
- d_h is an error term associated with the h-th day (due to day to day stability variation),
- w_k is the offset from the average due to the true thickness of the wafer k,
- p_{hkj} is the (short term) error due to the j-th positioning of the k-th wafer on the h-th day,
- r_{hkji} is the repeatability error term.

A1-5.5 In this model, the quantities d_h , p_{hkj} , and r_{hkji} are random error terms. They are usually assumed to have a normal distribution with zero mean and standard deviations σ_d, σ_p and σ_r, respectively. The wafer term w_k may be either a random term or a "fixed effect", depending on whether we consider the wafers measured to be a random sample from the entire population of possible wafers, or a fixed population used for experimental purposes. In either case, the estimates of repeatability and reproducibility will be the same.

A1-5.6 When error terms are known to have non-normal distributions, special methods and/or software (beyond the scope of this guide) are needed.

NOTE 14: The model might also include a "wafer/day" random error term wd_{hki}, if it is suspected that measurements made from day to day on some wafers might vary differently than measurements made from day to day on other wafers, and it is desired to obtain an estimate of this component of reproducibility.

A1-5.7 Reproducibility includes everything but wafer to wafer true thickness variability, so

$$\sigma_R = \sqrt{\sigma_d^2 + \sigma_p^2 + \sigma_r^2}\ .$$

A1-5.8 The ANOVA for this experiment provides all the variance estimates needed to calculate repeatability, reproducibility and precision. If the wafer term w_k is random, the ANOVA will also estimate σ_d, which is useful for characterizing the wafer population variability.

NOTE 15: When inputting this model into a statistical analysis program, the factors “day” and “wafer” are said to be *crossed*, since every wafer is measured on every day. The factor “positioning” is *nested* within wafer and day, and “repeatability“ is the residual error term and is *nested* within positioning, wafer and day. A factor “A” is *nested* within another factor “B” if the levels or values of “A” are different for every level or value of “B”.

A1-5.9 This example shows how a fairly complicated measurement capability analysis study can be set up. Each particular situation can lead to a different model and experimental design, depending upon the goals and agreed upon sources of (possibly significant) variation.

SEMI E92-0302
SPECIFICATION FOR 300 mm LIGHT WEIGHT AND COMPACT BOX OPENER/LOADER TO TOOL-INTEROPERABILITY STANDARD (BOLTS/LIGHT)

This provisional specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces & Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on December 3, 2001. Initially available at www.semi.org January 2002; to be published March 2002. Originally published September 1999.

1 Purpose

1.1 *Provide Standard for Box Opener/Loader Interoperability* — This standard is intended to provide standard specifications such as interfaces between the component that opens the boxes and presents the boxes to the equipment wafer handler for unloading and loading 300 mm wafers (BOLTS/Light unit) and higher level part of equipment and its functions to provide: (see Figure 1)

- High level of interchangeability/ interoperability,
- Quick attachment/detachment capability with high mechanical repeatability,
- Light weight, and
- Compactness.

1.1.1 In order to provide a high level of interchangeability and interoperability, this standard specifies not only interfaces but also some of the box opener/loader's functions that affect interoperability.

1.2 *Usage of This Standard* — Interoperability specifications defined by this standard are intended to be used as interfaces and functionality between BOLTS/Light compliant box opener/loader and:

- A BOLTS/M compliant loadport unit (that would conform to SEMI E63).
- An integrated loadport such as four box opener/loader in one chassis.
- High-densely packaged equipment that uses the space under the box opener/loader.

1.3 *SEMI Standards Compatibility* — This standard is compatible with 300 mm SEMI standards including SEMI E15.1, E47.1, E1.9, E62, E63 and E64.

1.4 *Open Cassette Application* — The BOLTS/Light unit might be configured to handle boxes that would conform to SEMI E47.1 and SEMI E62.

1.5 A similar unit may be compatibly designed which does not have box opener capability, but facilitates placement of an open cassette (that would conform to SEMI E1.9).

1.6 *Carrier Capacities* — This standard defines one interface for 13 or 25 carrier capacity box opener/ loaders.

1.7 The interface specified in this standard is designed for equipment with a sealed mini-environment, but it is not limited to such.

2 Scope

2.1 *Items Specified* — This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity, interchange-ability, and interoperability including:

- Box opener/loader functions that affect interoperability.
- Mechanical interface features between the box opener/loader and equipment.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification does not apply to the following application:

- Direct insertion of open cassettes into load-lock chambers.

4 Referenced Standards

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AMHS* — Automated Material Handling System

5.2 *Definitions*

5.2.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

5.2.2 *BOLTS/Light exclusion volume* — a volume reserved by equipment or loadport unit to put BOLTS/Light compliant box opener/loader.

5.2.3 *BOLTS/Light plane* — a vertical plane that interfaces BOLTS/Light compliant box opener/loader and equipment.

5.2.4 *bottom interface plane*— an interface means between the equipment and box opener/loader.

5.2.5 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

5.2.6 box opener/loader — the equipment component that opens wafer carriers (if needed) and presents the carriers to the equipment's wafer handler for unloading and loading wafers.

5.2.7 *carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E1.9). Also known as wafer carrier.

5.2.8 *carrier capacity* — the number of substrates that a carrier holds (as defined in SEMI E1.9).

5.2.9 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

5.2.10 *control connection area* — an area to be used for placement of connectors for electrical signals, power supplies, and other inlets/outlets.

5.2.11 *docked facial datum plane* — a vertical plane that bisects the wafers at the carrier docked position. It is also parallel to the load face plane specified in SEMI E15.

5.2.12 *docking stroke* — the travel distance of the carrier center between its load position (facial datum plane) and the position where the door opening/closing is done.

5.2.13 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On equipment load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the equipment where the carrier is loaded and unloaded (as defined in SEMI E57).

5.2.14 *front-opening unified pod (FOUP)* — a box (that complies with SEMI E47.1) with a nonremovable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a FIMS port that complies with SEMI E62) (as defined in SEMI E47.1).

5.2.15 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On equipment load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

5.2.16 *load face plane* — the furthest physical vertical boundary plane from the cassette centroid or carrier centroid on the side (or sides) of the equipment where loading of the equipment is intended (as defined in SEMI E15).

5.2.17 *loading slider area* — two flat surfaces on equipment which may be used by a maintenance supporting mechanism (not defined in this standard) to support the box opener/loader during attachment and detachment.

5.2.18 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

5.2.19 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

5.2.20 *seal zone* — a surface on the equipment at the BOLTS/Light plane for sealing to the box opener/loader.

5.2.21 *side interface feature* — an interface means to perform a seal between the mini-environment of the equipment and box opener/loader.

5.2.22 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

6 Functional Requirements

6.1 This standard does not define actual implementation but requires functional compliance with the following standards for interchangeability and interoperability of box opener/loader.

6.2 The box opener/loader of this standard should be compliant with related sections of factory interface standards such as SEMI E15.1, SEMI E57, SEMI E47.1 and SEMI E62.

6.3 *Outer Dimensions and Physical Factory Material Delivery Interface Compatibility* — Physical dimensions, such as clearances and trenches required for factory delivery systems (human or automated), should be compliant with SEMI E15.1.

6.3.1 *Carrier Registration* — The physical alignment mechanism for the box consists of features (not specified in this standard) on the box that mate with three pins underneath as defined in SEMI E57. Primary kinematic coupling pins should be used.

6.3.2 *Loadport Pitch* — The loadport pitch which conforms to this standard is $S \geq 475$ mm (minimum value for FOUP without handles as defined in SEMI E15.1).

6.4 *Carrier ID Reader/Writer Head Exclusion Volume* — The box opener/loader compliant with this standard should have a carrier ID reader/writer head exclusion volume defined in SEMI E15.1 for automated units that read or write to an ID tag. Regarding the box opener/loader, the front end of this exclusion volume is limited by *y111*. And the rear end of this exclusion volume is defined in SEMI E15.1 D3. The difference between *y111* and SEMI E15.1 D4 should be supplied by the equipment.

6.5 *Carrier Sensing* — The box opener/loader compliant with this standard has to have the following capabilities:

6.5.1 *Carrier Presence Sensor* — Carrier sensing capability which detects carrier presence regardless of its correct placement.

6.5.2 *Carrier Placement Sensor* — Carrier sensing capability which detects correct carrier placement on the kinematic coupling.

6.6 *Info-pad Interfaces* — Optional info-pad sensing/detecting capability as defined in SEMI E1.9 and SEMI E15.1.

6.6.1 *Info-pad A, B Sensors* — Optional carrier sensing capability which detects carrier type as defined in SEMI E1.9 and SEMI E15.1.

6.6.2 *FEOL/BEOL Lockout Pin* — Optional pin that physically detects/rejects a misplaced carrier by using info-pads C and D to distinguish a FEOL carrier vs. a BEOL carrier. This pin should be capable of being installed easily after the equipment is delivered.

6.7 *Box to Equipment Sealing Interface and Door Lock/Unlock Interface* — This standard requires a box to equipment seal interface and door lock/unlock interface compliant with SEMI E47.1 and SEMI E62. This standard does not specify any of the actual design.

7 Mechanical Requirements

7.1 *Datum Planes and Dimensioning Rules* — Dimensions defined in this standard are determined with respect to the following datum planes and default dimensioning rules.

NOTE 2: Unless otherwise stated, perpendicularity and parallelism are implicitly defined in the geometric tolerances.

7.1.1 *Three Common Datum Planes* — Many of the dimensions of the BOLTS/Light interface are determined with respect to the three orthogonal datum planes defined in SEMI E57: the horizontal datum plane, the facial datum plane, and the bilateral datum plane.

7.1.2 *Symmetry* — All of the dimensions for the interface are bilaterally symmetric about the bilateral datum plane unless otherwise noted. These dimensions are shown in Figures 2 and 3 and specified in Table 1.

7.1.3 *Inner and Outer Radii* — All required concave features may have a radius of up to *r100* to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r101* to prevent small contact patches with large stresses that might cause wear and particles. Note that these limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the equipment supplier. Note also that this radius applies to every required feature unless another radius is called out specifically.

7.2 *BOLTS/Light Exclusion Volume* — Equipment or loadport unit compliant with this standard must provide a BOLTS/Light exclusion volume defined in this section. BOLTS/Light exclusion volume consists of multiple sub-volumes and spaces defined in this section. The box opener/loader compliant with this standard must be compatible with BOLTS/Light exclusion volume. Bolts/Light exclusion volume is shown in Figure 2.

7.2.1 *Loader Exclusion Volume* — Loader exclusion volume is an exclusion volume for the main part of box opener/loader that is defined by *x108, y101, y110, y111,* and *z107. y111* is intentionally shorter than SEMI E15.1 D dimension in order to allow the equipment integrators to place a safety door, a carrier ID reader/writer, and/or any other features required by the user. An additional removable cover can be mounted on the box opener/loader if it is to be supplied as a complete unit compliant with the SEMI E15.1 D dimension.

7.2.2 *Door Seal Exclusion Volume* — Door seal exclusion volume is an exclusion volume for the door seal portion of box opener/loader that is defined by the distance between the plane at the SEMI E15.1 D1 and *y101, x108,* and *z109.*

7.2.3 *BOLTS/Light Opening Exclusion Volume* — BOLTS/Light opening exclusion volume is an exclusion volume for the box opener/loader encroachment of equipment from BOLTS/Light plane at portion above the permanent reserved space. There should be an opening when the door is opened. Through this opening substrates may be moved between the box on the BOLTS/Light compliant box opener/loader and the equipment by a wafer handler in the equipment. BOLTS/Light opening exclusion volume is defined by *x102, y103, z103,* and *z108*.

7.2.4 *Permanent Reserved Space* — Space that is reserved permanently in the equipment defined by *x102, y102, z105,* and *z108*.

7.2.5 *Temporarily Reserved Space* — Space that is reserved temporarily during a door open/close motion is being done and when the door is closed. The temporarily reserved space during a door open/close is defined by *x102, y102, y103, z103,* and *z108*. The temporarily reserved space when a door is closed is defined by *x102, y103, y112, z103,* and *z108*.

7.2.6 *The Loader Bottom Flange Exclusion Volume* — The loader bottom flange exclusion volume is an exclusion volume for fixing the box opener/loader to bottom interface plane. Loader bottom flanges are located on the both bottom side of the box opener/loader and directly mounted on bottom interface plane. The loader bottom flange exclusion volume is defined by *x108, x109, y115, y116,* and *z113 measured* from the bottom end of *z107.*

NOTE 3: The spaces to access the fixing bolt should be reserved by equipment side. This document does not define these spaces.

7.3 *Side Interface Features* — This standard defines the equipment side of the side interface features. Side interface features are defined with respect to "Docked facial datum plane" instead of "Facial datum plane". The box opener/loader should mate with these features to provide the seal to the equipment. The side interface features are shown in Figure 2.

7.3.1 *BOLTS/Light Plane* — The BOLTS/Light plane is defined to be parallel to and at a distance *y101* from the docked facial datum plane. The Seal Zone is on this plane.

7.3.2 *Cycle-to-Cycle Repeatability* — The cycle-to-cycle repeatability of *y101* must be within *y113.*

7.3.3 *Seal Zone* — The equipment side of the BOLTS/Light plane specified by *x101, x103, z101, z102, z104,* and *z106* must be a flat area for sealing between the equipment and the box opener/loader.

7.3.3.1 The flatness of the seal zone must be within *y114* and the perpendicularity of the seal zone to the facial and horizontal datum planes must be within $\sigma 1$.

7.3.3.2 This standard only defines the seal zone on the equipment side. The actual seal is not defined in this standard, but should be mounted on the box opener/loader.

7.3.4 *Wafer Position* — This standard defines a typical wafer position when the box opener/loader positions the wafers to the equipment. The facial datum plane of a docked carrier is defined by *y110* from the facial datum plane. This provides compatible wafer center positions from the facial datum plane.

NOTE 4: This means that this standard defines a specified typical docking stroke.

7.4 *Bottom Interface Features* — This standard defines mainly the equipment side of the bottom interface features. Bottom Interface Features are shown in Figure 3.

7.4.1 Regarding the box opener/loader, parallelism of the bottom interface feature and the horizontal datum plane must be within $\sigma 2$.

7.4.2 *Bottom Interface Planes* — The Bottom Interface Feature should have two Bottom Interface Planes defined by *x104, x105, y104, y105,* and *z107*. Nothing other than locating pins can protrude above these planes. During maintenance, the front end of the loading slider area should be open *z112* under the bottom interface planes.

7.4.3 *Loader Locating Pins* — Equipment must have two Loader locating pins to locate the box opener/loader so as to provide highly repeatable and quick attachment/detachment. Horizontal locations of the loader locating pins are defined by *x106* and *y106*. Height of the loader locating pins is defined by *z110*. Diameter of the loader locating pins is defined by *d1*. A box opener/loader compatible with this standard must refer these two Loader Locating pins.

7.4.3.1 *Positioning Pin* — Loader locating pin on the left side from operator is a positioning pin that is used to hold box opener/loader both in *x* and *y* directions.

7.4.3.2 *Anti-Rotation Pin* — Loader locating pin on the right side from operator is an anti-rotation pin that is used to hold box opener/loader in *y* direction only (see Figure 4).

7.4.4 *Locking Screws* — Four locking screws defined by *x106, y107,* and *y108* to tighten the box opener/loader.

7.4.4.1 The equipment should have M8-16 tapped holes at these locations.

7.4.5 *Control Connection Area* — Area used to pass connectors, wires, and tubes for electrical signals, power supply and other inlets/outlets.

7.4.5.1 The control connection area is defined at the same height as the the bottom interface planes by *x107* and *y109*.

NOTE 5: This standard only defines the connection area for the box opener/loader itself. It is recommended that connectors will be located above this area for quick maintainability.

7.4.5.2 Other connections which will possibly be located in this area for other functions are listed below and may be defined in separate standards:

- Carrier ID reader/writer head interface (automated units that read or write to an ID tag defined in SEMI E15.1)
- Manual operation panel
- Wafer mapper

7.5 *Panel Interface Height* — This standard defines an optional panel interface height so as to provide panel installation height to enclose box opener/loader in the equipment. Panel interface height is defined by *z111* from horizontal datum plane. In case this option is used, both equipment and the box opener/loader should have forklifts exclusion volume defined by SEMI E15.1 H0.

Usage of Loader Locating Pins

Table 1 Dimensions for Light-Weight and Compact Box Opener/Loader to Tool Standard (BOLTS/Light) Interface

Symbol	*Value Specified*	*Datum Measured from*	*Feature Measured to*
σ1	0 ± 0.1°	Facial and horizontal datum planes	Perpendicularity of seal zone.
σ2	0 ± 0.1°	Horizontal datum plane	Parallelism of bottom interface plane.
d1	12 ± 0.05 mm	-	Loader locating pin diameter.
r100	1 mm maximum	not applicable	All concave features. (radius)
r101	2 mm maximum	not applicable	All required convex features. (radius)
x101	200 ± 1 mm	Bilateral datum plane	Edge of hole opening and inside edge of seal zone.
x102	199 mm minimum	Bilateral datum plane	Encroachment of equipment on the sides of the reserved spaces inside the equipment.
x103	207 ± 1 mm	Bilateral datum plane	Outside edge of seal zone.
x104	235 ± 2 mm	Bilateral datum plane	Outside edge of bottom interface plane.
x105	200 ± 2 mm	Bilateral datum plane	Inside edge of bottom interface plane.
x106	220 ± 0.05 mm	Bilateral datum plane	Center of positioning pin location and tightening locking screw location.
x107	175 +5/-0 mm	Bilateral datum plane	Outside edge of control connection area.

Symbol	*Value Specified*	*Datum Measured from*	*Feature Measured to*
x108	207 ± 1 mm	Bilateral datum plane	Width of the door seal exclusion volume. Width of the loader exclusion volume. Width of the loader bottom flange exclusion volume. (Inside)
x109	235 mm minimum	Bilateral datum plane	Width of the loader bottom flange exclusion volume. (Outside)
y101	170 ± 2 mm	Docked Facial datum plane	BOLTS/Light plane. Seal surface on equipment.
y102	80 mm minimum	BOLTS/Light plane	Encroachment of equipment on the permanent reserved space and on the reserved space when the door is opening or closing.
y103	3 mm minimum	BOLTS/Light plane	Encroachment of equipment.
y104	200 + 0/-10 mm	Facial datum plane	Rear edge of bottom interface plane.
y105	220 + 0/-10 mm	Facial datum plane	Front edge of bottom interface plane.
y106	180 ± 0.05 mm	Facial datum plane	Positioning pin location.
y107	100 ± 0.3 mm	Facial datum plane	Front locking screw location.
y108	100 ± 0.3 mm	Facial datum plane	Rear locking screw location.
y109	110 + 0/-5 mm	Facial datum plane	Rear edge of control connection area.
y110	[E63]	Facial datum plane	Docked-facial datum plane.
y111	220 ± 2 mm	Facial datum plane	Front end of the loader exclusion volume.
y112	31 mm minimum	BOLTS/Light plane	Encroachment of equipment on the reserved space when the door is closed.
y113	± 0.5 mm	-	Cycle-to-cycle repeatability of y101.
y114	± 1 mm	-	Flatness of seal zone.
y115	220 mm minimum	Facial datum plane	Front face of the loader bottom flange exclusion volume.
y116	200 mm minimum	Facial datum plane	Rear face of the loader bottom flange exclusion volume.
z101	402 ± 1 mm	Horizontal datum plane	Outside edge of seal zone on top.
z102	478 ± 1 mm	Horizontal datum plane	Outside edge of seal zone on bottom.
z103	394 mm minimum	Horizontal datum plane	Encroachment of equipment on the top of the permanent reserved space inside the equipment.
z104	395 ± 1 mm	Horizontal datum plane	Top edge of hole opening and inside edge of seal zone.
z105	470 mm minimum	Horizontal datum plane	Encroachment of equipment on the bottom of the permanent reserved space inside the equipment.
z106	471 ± 1 mm	Horizontal datum plane	Bottom edge of hole opening and inside edge of seal zone.
z107	480 ± 1 mm	Horizontal datum plane	Height of the bottom interface planes.
z108	45 ± 2 mm	Horizontal datum plane	Encroachment of equipment on the top of the permanent reserved space inside the equipment.
z109	402 ± 2 mm	Horizontal datum plane	Encroachment of equipment on the top of the box opener/ loader between the BOLTS/Light plane and the SEMI E15.1_D1 plane.
z110	10 ± 1 mm	Bottom end of z107	locating pins height.
z111	45 ± 2 mm	Horizontal datum plane	Panel Interface Height.
z112	15 mm minimum	Bottom end of z107	Docking space to bottom interface plane during maintenance.
z113	30 mm minimum	Bottom end of z107	Height of loader bottom flange exclusion volume.

APPENDIX 1
APPLICATION NOTES

NOTE: The material in this appendix is an official part of SEMI E92 and was approved by full letter ballot procedures on December 3, 1999 by the Japanese Regional Standards Committee.

A1-1 NOTICE: Usage of Loader Locating Pins

A1-1.1 In order to provide quick interchangeability with accurate repeatability, it is recommended to use V shaped groove to couple with the positioning pin and use flat plane to couple with the anti-rotation pin as shown in Figure 4.

A1-2 NOTICE: BOLTS/Light Shelf

A1-2.1 BOLTS/Light Shelf may be used in order to keep compatibility with BOLTS/M interface. In this case, BOLTS/M interface provides backward compatibility of equipment interface and BOLTS/Light interface provides standardized precise quick attachment/ detachment interface. BOLTS/Light shelf is shown in Figure A-1.

A1-3 NOTICE: Box Opener/Loader Compatibility

A1-3.1 It is recommended that equipment suppliers design their process equipment to be capable of accepting box opener/loaders that interface with either a BOLTS/M interface or a BOLTS/Light interface. This standard has been structured to make the BOLTS/Light interface a component capable of being attached to a BOLTS/M interface. (It is not physically feasible to make the BOLTS/M interface an optional component capable of being attached to a BOLTS/Light interface).

A1-3.2 If an equipment supplier provides a BOLTS/M interface, their process equipment can be modularly configured to interface with either type of box/opener loader. This type of approach allows “two-way compatibility”:

- Process equipment with a BOLTS/M interface can attach a BOLTS/Light interface. This enables the process equipment to now accept a box opener/loader with a BOLTS/Light interface.
- Process equipment with a BOLTS/Light interface can remove the BOLTS/Light interface to expose a BOLTS/M interface. This enables the process equipment to now accept a box opener/loader with a BOLTS/M interface.

Equipment suppliers may provide only a BOLTS/Light interface at their discretion. However, it should be understood that process equipment designed in this manner can not be modularly configured to accept a box/opener loader with a BOLTS/M interface.

A1-4 NOTICE: Docking Stroke Variation for Backward Compatibility

A1-4.1 In order to provide the “Backward compatibility” requested in I300I/J300 GJG[1], vendors who want to use this standard to put BOLTS/Light unit in their existing BOLTS/M compliant loadport unit may vary docking stroke as their option to accommodate their existing designs. The unit that has a different docking stroke is no more a BOLTS/Light-Full-Compliant unit, but could be called as BOLTS/Light-Quasi-Compatible unit.

A1-5 NOTICE: Sliding Mechanism

A1-5.1 Actual design of the sliding mechanism is left to the box opener/loader and/or equipment designer. The equipment provides bottom interface planes as the loading slider areas.

A1-5.1.1 This implies several types of bottom interface planes are acceptable by the equipment; e.g., roller guided, plastic material based, etc.

A1-6 NOTICE: Maintenance Cart

A1-6.1 If the box opener/loader is too heavy to attach/detach manually by maintainer, this standard provides for the possibility/capability of cart-based maintenance.

A1-6.2 The cart may use the same cart to equipment docking mechanism as the cart for FOUP delivery.

A1-6.3 The maintenance cart may also use a connection with the bottom interface planes that are defined in this standard. Specification of how to make the carts is outside the scope of this standard.

A1-7 NOTICE: Finger Pinch Sensor

A1-7.1 This document does not define or specify a finger pinch sensor. Considering finger pinching with edges, the following approach may be recommended.

- Finger pinching with edges is more serious than it is with flat surfaces. So, it is recommended not to place the box flange seal in a narrow tunnel structure which have sharp edges but place it on a flat surface (or in a dimple that has chamfered edges).

1 I300I/J300 GJG — I300I/J300 Global Joint Guidance for 300 mm Semiconductor Factories. SEMATECH, 2706 Montopolis Drive, Austin, TX, 78741. http://www.sematech.org

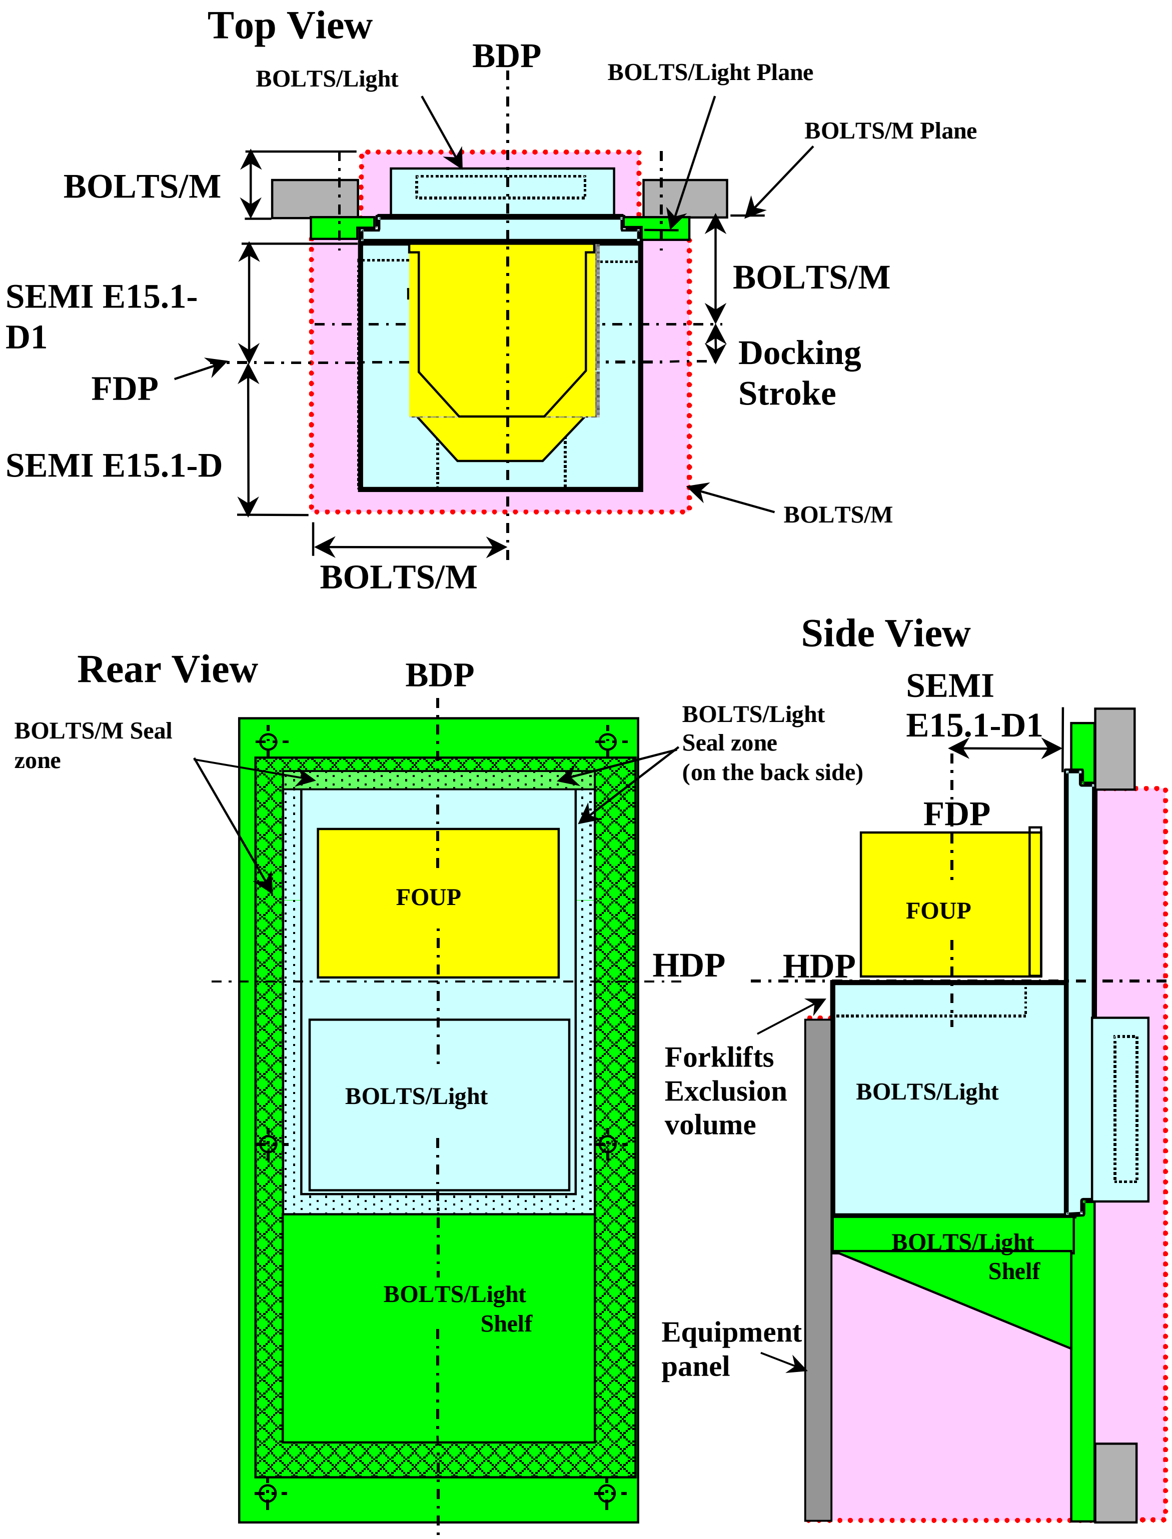

Figure A-1
Usage of BOLTS Shelf (Adopter)

- Placement of a finger pinch sensor in the approximately 11 mm space behind SEMI E15.1 D1 is recommended.

A1-8 NOTICE: Adjustment of BOLTS/Light Unit

A1-8.1 In order to maintain quick interchangeability and interoperability and quick attachment/detachment, adjustment capability should be provided separately by the box opener/loader and equipment to ensure the port is positioned correctly with respect to the wafer handling robot.

A1-8.2 As a result, adjustment means will be necessary on both the box opener/loader and the equipment. The box opener/loader may have a capability to calibrate its critical dimensions in advance, for example, the parallelism between bottom interface surface and HDP. In this case, it is not necessary to adjust the box opener/loader after installation. The equipment should have a capability to adjust bottom interface plane with respect to the wafer-handling robot. In case of changing the box opener/loader in the field, adjustment might then not be necessary on both the box opener/loader and the equipment side.

A1-8.3 A fixture may help facilitate this adjustment.

A1-8.4 If fine adjustment is needed after reattaching the box opener/loader (due to deficient adjustment of the box opener/loader or equipment side), it may be done on the equipment side by means of adjusting screws or other mechanism at bottom interface plane.

A1-9 NOTICE: Control Connection Area

A1-9.1 Connection should be completed after sliding in the box opener/loader. Disconnection should be completed before sliding out the box opener/loader.

SEMI E99-1000^E
THE CARRIER ID READER/WRITER FUNCTIONAL STANDARD: SPECIFICATION OF CONCEPTS, BEHAVIOR, AND SERVICES

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces and Carriers Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available at www.semi.org August 2000; to be published October 2000. Originally published February 2000; previously published June 2000.

E This document was modified in October 2000 to correct a typographical error. Changes were made to Table 7. This document was modified in December 2001 to correct a typographical error. Changes were made to Table R1-1 and Table R1-2.

1 Purpose

1.1 The purpose of the Carrier ID Reader/Writer Functional Standard effort is to provide a common specification for concepts, behavior, and services (functions) provided by a Carrier ID Reader and a Carrier ID Reader/Writer to an upstream controller. A standard interface will increase interchangeability of Carrier ID Reader/Writers so that users and equipment suppliers have a wider range of choices.

2 Scope

2.1 The Carrier ID Reader/Writer Interface Standard addresses the functional requirements for a generic Carrier ID Reader/Writer interface with an upstream controller.

2.2 The specification includes required behavior and required communications for both a Carrier ID Reader and a Carrier ID Reader/Writer.

2.3 This specification does not require, define, or prohibit asynchronous messages sent by the Carrier ID Reader or Reader/Writer.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not define the specific protocol to be used for the Carrier ID Reader/Writer. Supplements to this standard are required to describe how the functions of the Carrier ID Reader/Writer are implemented for specific protocols.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E1.9 — Provisional Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

SEMI E15 — Specification for Tool Load Port

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E62 — Provisional Specification for 300 mm Front-Opening Interface Mechanical Standard (FIMS)

SEMI E87 — Provisional Specification for Carrier Management (CMS)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CIDRW* — represents both the Carrier ID Reader and the Carrier ID Reader/Writer

5.1.2 *FOUP* — Front Opening Unified Pod

5.2 *Definitions*

5.2.1 *attribute* — information about or associated with some entity or object.

5.2.2 *carrier* — 1. a container, such as a FOUP or open cassette, with one or more positions for holding substrates (SEMI E87). 2. any cassette, box, pod, or boat that contains wafers.

5.2.3 *carrier ID* — an identifier for a carrier. A value that uniquely identifies a given carrier in a factory. The identifier may be represented physically with any one of various technologies. For electronic tags with read/ write capability, in some cases the user may designate a portion of the data to be used as a carrier ID.

5.2.4 *carrier ID reader* — a unit (subsystem) that detects and decodes data from the ID tag.

5.2.5 *carrier ID reader/writer* — a unit (subsystem) with the functionality of both a carrier ID reader and a carrier ID writer.

5.2.6 *carrier ID tag (tag, ID tag)* — a physical device for storing Carrier ID and other information. There are two basic types of tags, read-only tags and read/write tags.

5.2.7 *carrier ID writer* — a unit which encodes data for and writes it to the carrier ID tag.

5.2.8 *cassette* — an open structure that holds one or more substrates (SEMI E44).

5.2.9 *controller* — a system that provides control (performs required operations when certain conditions occur or when interpreting and acting upon instructions) and communicates with a higher level manager. Controllers exist at all levels within a factory. Examples of controllers include the Multiple ID Reader/Writer Controller, the Equipment Controller, and the Load Port Controller.

5.2.10 *front-opening unified pod (FOUP)* — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a FIMS port that complies with SEMI E62).

5.2.11 *fundamental requirements* — the requirements for information and behavior that must be satisfied for compliance to a standard. Fundamental requirements apply to specific areas of application, objects, or services.

NOTE 2: All portions of the carrier ID reader/writer specification are considered to be fundamental requirements unless explicitly described as optional. See also optional requirement.

5.2.12 *load port* — the interface location on a tool where wafer carriers are delivered. It is possible that wafers are not removed from, or inserted into, the carrier at this location.

5.2.13 *message interleaving* — the practice of sending a new message request before receiving the reply to an earlier request.

5.2.14 *multiple ID reader/writer controller* — a unit controlling the Reader/Writer function of one or multiple ID Reader/Writer Heads, communicates the command/data with the equipment controller or the equivalent controller such as Load port Controller in the equipment configuration.

5.2.15 *optional capability* — a specification that is not required for an implementation to be compliant to a standard. The supplier developing the CIDWR has the option to provide these additional capabilities or not depending on supplier's product configuration. See also fundamental requirement.

5.2.16 *reader/writer head* — a structured portion which functions to detect the ID code and/or to write the ID code. The ID reader/writer unifying a head function inside its body can be placed as a head. The ID reader/writer not unifying a head function will be located separately from the head.

5.2.17 *tag fault* — any condition that causes errors when reading or writing to the tag, including power faults and tag damage.

5.2.18 *upstream controller* — a controller that directs the Carrier ID Reader/Writer through the communication interface.

5.3 *Data Types*

5.3.1 *enumerated* — may take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

5.3.2 *form* — type of data: positive integer, unsigned integer, integer, floating point (float), enumerated, boolean, text, formatted text, structure, list, ordered list.

5.3.3 *integer* — may take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

5.3.4 *structure* — a specific set of items, of possibly mixed data types, in a specified arrangement.

5.3.5 *text* — a character string. Messaging protocol may impose restrictions, such as length or ASCII representation.

5.3.6 *unsigned integer* — may take on the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

6 Conventions

6.1 *State Model Methodology*

6.1.1 This document uses the Harel state chart convention for describing dynamic operation of defined objects. The outline of this convention is described in an attachment of SEMI E30. The official definition of this convention is described in "State Charts: A Visual Formalism for Complex Systems" written by D. Harel in Science of Computer Programming 8, 1987[1].

1 Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.htt

6.1.2 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition table contains columns for Transition number, Previous State, Trigger, New State, Actions, and Comments. The "trigger" (column 3) for the transition occurs while in the "previous" state. The "actions" (column 5) includes a combination of:

- Actions taken upon exit of the previous state.
- Actions taken upon entry of the new state.
- Actions taken which are most closely associated with the transition.

6.1.2.1 No differentiation is made between these cases.

6.2 *Object Notation*

6.2.1 The object models in Related Information 2 use the Object Modeling Technique (OMT) developed by Rumbaugh, James, et al, in Object-Oriented Modeling and Design.[2] An overview of this notation is provided in SEMI E39, Object Services Standard: Concepts, Behavior, and Services.

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*

6.3 *Service Message Representation*

6.3.1 Services are functions or methods that may be provided by either the equipment or the host. A service message may be either a request message, which always requires a response, or a notification message, that does not require a response.

6.3.2 *Service Definition*

6.3.2.1 A service definition table defines the specific set of messages for a given service resource, as shown in the following table:

Message Service Name	*Type*	*Description*

Type can be either "N" = Notification or "R" = Request & Response.

6.3.2.2 Notification type messages are initiated by the service provider (e.g., the equipment) and the provider does not expect to get a response from the service user. Request messages are initiated by a service user (e.g., the host). Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

6.3.3 *Service Parameter Dictionary*

6.3.3.1 A service parameter dictionary table defines the description, format and its possible value for parameters used by services, as shown in the following table:

Parameter Name	*Description*	*Format: Possible Value*

6.3.3.2 A row is provided in the table for each parameter of a service.

6.3.4 *Service Message Definition*

6.3.4.1 A service message definition table defines the parameters used in a service, as shown in the following table:

2 James Rumbaugh, Michael Blaha, William Premerlani, Frederick Eddy, William Lorensen, Object-Oriented Modeling and Design, Englewood Cliffs, New Jersey: Prentice-Hall, 1991.

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*

6.3.4.2 The columns labeled REQ/IND and RSP/CNF link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication" or the request. The receiver may then send a "Response" which the original sender terms the "Confirmation".

6.3.4.3 The following codes appear in the REQ/IND and RSP/CNF columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

Code	*Description*
M	Mandatory Parameter — Must be given a valid value.
C	Conditional Parameter — May be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of the other parameter.
U	User-Defined Parameter.
-	The parameter is not used.
=	(For response only.) Indicates that the value of this parameter in the response must match that in the primary (if defined).

7 Overview

7.1 The Carrier ID Reader/Writer Model defines the behavior and services (functions) for both Carrier ID Readers and Carrier ID Reader/Writers. The Carrier ID Reader/Writer is a small intelligent system, typically used as a subsystem within equipment.

7.1.1 The primary functionality of the Carrier ID Reader/Writer is to read the identifier of the carrier (Carrier ID) from the Carrier ID tag. Various technologies may be used to encode the Carrier ID and to read it. Some technologies do not allow data to be written.

7.1.2 The acronym CIDRW is used to refer to both the Carrier ID Reader and the Carrier ID Reader/Writer. The requirements for the Carrier ID Reader are a subset of the requirements for the Carrier ID Reader/Writer.

7.1.3 An object model for the CIDRW is provided in Related Information 2 – Object Model.

7.2 *Number of Heads*

7.2.1 A Reader/Writer Head is a device that is positioned on a load port for reading or reading/writing information from a Carrier ID tag. A Carrier ID Reader/Writer provides one or more ID Reader/Writer Heads and is connected to an upstream controller by a single interface. This allows the upstream controller to control either one head or multiple heads using the same interface specification.

7.2.2 *Single Head Configuration*

7.2.2.1 In the case of a single head, the head may be presented as an integrated part of the CIDRW.

7.2.3 *Multiple Head Configuration*

7.2.3.1 In the case of multiple heads, some services are logically performed by the CIDRW, and the individual heads logically perform others. The individual heads are numbered sequentially and may be referenced individually by the upstream controller. Note that the upstream controller does not communicate directly with the heads. All communications are between the upstream controller and the CIDRW unit.

7.2.3.2 In the multi-head case, the CIDRW shall allow independent control of the heads. Multiple transactions invoking services performed by the individual heads may be open at the same time. For example, when a read command is sent to one head, the host can send additional commands such as a read command and a status confirmation command to another head before the first head sends the response to the first command.

7.3 *Upstream Controller*

7.3.1 The CIDRW provides certain services when requested by the upstream controller. The upstream controller sends a message requesting the specified service, and the CIDRW sends a message with the response.

7.3.2 This standard assumes that an upstream controller initiates each service message to the CIDRW, and the CIDRW sends its response to the upstream controller. The upstream controller must watch the response time to monitor the communication timeout. This standard will define the recommended method for handling exceptions caused by timeouts.

7.3.3 In addition, some CIDRW may provide asynchronous notification to the upstream controller. Examples of this include, but are not limited to, the detection of a fault condition resulting in an alarm. Asynchronous notification is not required for compliance to this standard.

8 Attributes

8.1 An attribute is an item of information about an entity that is maintained and is available by request. There is certain information concerning the CIDRW that is of potential interest to the upstream controller, including the manufacturer, the model, and the serial number of the device. This information is considered as attributes of the CIDRW and is available on request.

8.2 *CIDRW Attribute Definition Table*

8.2.1 Table 1 defines the attributes of the Carrier ID Reader/Writer subsystem.

Table 1 CIDRW Attribute Definitions

Attribute Name	*Description*	*Access*	*Reqd*	*Form*
Fundamental				
Configuration	Number of heads.	RO	Y	Text
Alarm Status	Current CIDRW substate of ALARM STATUS.	RO	Y	Enumerated: 0 = NO ALARMS 1 = ALARMS
Operational Status	Current CIDRW substate of OPERATIONAL.	RO	Y	Enumerated: IDLE BUSY MAINTENANCE
SoftwareRevisionLevel	Revision (version) of software.	RO	Y	Text
Optional				
DateInstalled	Date the subsystem was installed.	RO	N	Protocol dependent.
Device Type	Identifiers subsystem as either a Carrier ID Reader or a Carrier ID Reader/Writer.	RO	N	Text
HardwareRevisionLevel	Revision number of the hardware.	RO	N	Text
MaintenanceData	Supplier dependent.	RO	N	Text
Manufacturer	The name or identifier of the manufacturer.	RO	N	Protocol dependent.
ModelNumber	The manufacturers model designation.	RO	N	Text
SerialNumber	Subsystem serial number assigned by manufacturer.	RO	N	Protocol dependent.

8.3 *Read/Write Head Attributes*

8.3.1 Table 2 defines the attributes for the Read/Write Head.

NOTE 3: In the case of an integrated single head, the attributes in Table 2 are regarded as an extension of Table 1.

8.3.2 In the case of multiple heads, it must be possible to distinguish between the attributes of different heads.

Table 2 Read/Write Head Attribute Definitions

Attribute Name	*Description*	*Access*	*Reqd*	*Form*
Fundamental				
HeadStatus	The current state.	RO	Y	Enumerated: IDLE, BUSY, NOT OPERATING
HeadID	Head number 0–31	RO	Y if multi-head	Text. 2 digits.
Optional				
Cycles	Number of read and write operations performed.	RO	N	Unsigned integer
HeadCondition	The current Maintenance status.	RO	N	Enumerated: No alarms Needs Maintenance Read/Write fault Read/Write rate fault No power.
HeadDateInstalled	Date this head was installed.	RO	N	Protocol dependent.
HeadMaintenance-Data	Supplier dependent	RO	N	Text

9 State Models

9.1 To facilitate independent control of the individual heads, this section defines two separate state models, one for CIDRW subsystem and one to be applied to each of the individual heads.

9.2 *CIDRW State Model*

9.2.1 This section defines the state model for the CIDRW subsystem. Figure 1 shows the diagram for this model.

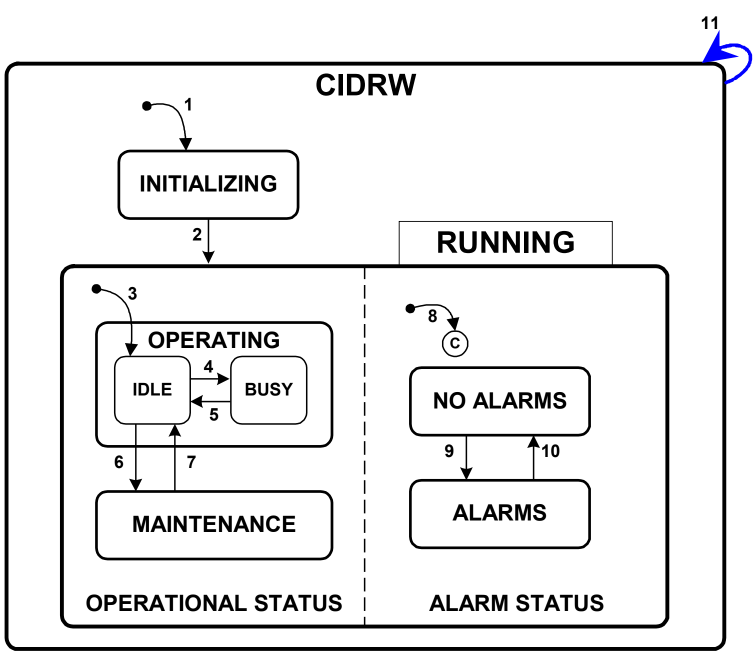

Figure 1
CIDRW State Model Diagram

9.2.2 Table 3 defines the states of the CIDRW. Definitions are in alphabetical order.

Table 3 CIDRW Subsystem State Definitions

State	*Definition*
ALARM STATUS	Shows the presence or absence of alarms.
ALARMS	An alarm condition exists.
BUSY	A service is being performed that affects the state of the hardware.
CIDRW	Superstate of CIDRW State Model. Always active when CIDRW powered on.
IDLE	No service is being performed. All heads are idle.
INITIALIZING	CIDRW is performing initialization and self diagnostics. Presence or absence of alarms is initially determined in this state.
NO ALARMS	No alarm conditions exist.
OPERATING	Normal operational states where reading and/or writing operations can be performed.
OPERATIONAL STATUS	The CIDRW is fully capable of performing all services that it supports.
RUNNING	The CIDRW is operational and able to communicate.
MAINTENANCE	Internal setup and maintenance activities.

9.2.3 Table 4 defines the transitions of the CIDRW State Model.

Table 4 CIDRW State Transitions

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(Any)	Powerup or reset	INITIALIZING	Initialize hardware and software components.	Default entry on powerup.
2	INITIALIZING	Initialization is complete.	RUNNING	None	The CIDRW is now able to communicate.
3	INITIALIZING	Default entry into OPERATING.	IDLE	None	Internal
4	IDLE	A service request to read or write or perform diagnostics is received.	BUSY	None	
5	BUSY	All service requests that affect the state of the hardware are completed.	IDLE	None	
6	IDLE	A user selects the MAINTENANCE state and all heads are idle.	MAINTENANCE	None	The upstream controller may send a request or the operator may set a switch to select the OPERATING or the MAINTENANCE state. Maintenance and setup activities may now be performed.
7	MAINTENANCE	A user selects the OPERATING state and all heads are idle.	IDLE	None	The upstream controller may send a request or the operator may set a switch to select the OPERATING or the MAINTENANCE state. Normal operating activities may now be performed.
8	INITIALIZING	Default entry into ALARM STATUS.	ALARMS or NO ALARMS	None	
9	NO ALARMS	An alarm condition is	ALARMS	None	

		detected.			
10	ALARMS	All alarm conditions have cleared.	NO ALARMS	None	
11	Any	A reset service request is received.	CIDRW	None	

9.3 *Read (Write) Head State Model*

9.3.1 For a CIDRW with multiple heads, this state model shall be provided for each Read/Write Head.

9.3.2 For the single head case, these states are covered in the CIDRW state model and no additional state model for the head is required. IDLE and BUSY correspond to substates of the same names in the CIDRW state model. If any head is NOT OPERATING, then the active substate of ALARM STATUS in the CIDRW state model is ALARMS.

9.3.3 The NOT OPERATING state is not required, if it is not possible to detect alarms related to the head. Note also that some alarm conditions are fatal (so that the head cannot operate with full functionality) while others may not be fatal.

9.3.4 Figure 2 shows the diagram for the Read (Write) Head State Model.

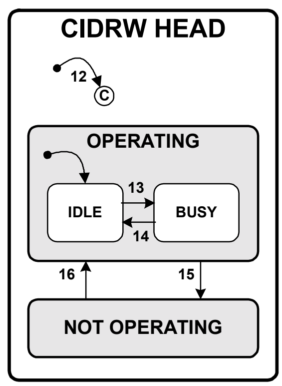

Figure 2
Read (Write) Head State Model

9.3.5 Table 5 defines the states for the Read (Write) Head.

Table 5 Read (Write) Head State Definitions

State	*Definition*
NOT OPERATING	Head is in a non-operational state or has reduced functionality. Maintenance is required.
OPERATING	Head is active and fully functional.
IDLE	Head is not performing a service.
BUSY	Head is performing a service.

9.3.6 Table 6 defines the transitions of the Read (Write) Head State Model.

Table 6 Read (Write) Head State Transitions

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
12	(unknown)	Initialization on powerup or reset.	Either NOT OPERATING or OPERATING	None	Default entry on power-up.
13	IDLE	Request to perform a service.	BUSY	None	
14	BUSY	Completion of service.	IDLE	None	

#	Previous State	Trigger	New State	Actions	Comments
15	OPERATING	An alarm condition is detected.	NOT OPERATING	None	
16	NOT OPERATING	Self-Diagnostic Service	OPERATING	None	All alarm conditions are clear.

10 Alarm Conditions

10.1 An alarm condition exists whenever one or more faults or exceptions that interfere with normal read/write operations is detected. A maintenance condition exists when the CIDRW determines the need for either maintenance (repair) or preventive maintenance activities.

10.2 The CIDRW is able to detect and report alarm conditions through its status attributes (when queried by the upstream controller). It may additionally report changes in alarm conditions asynchronously through alarm or event reports.

11 Services

11.1 To be compliant with this standard, the CIDRW shall support all services that are indicated as required. In addition, if the CIDRW provides other services that have the same or similar functionality as services defined in this document, then compliance to this standard requires they shall satisfy the requirements of the service as defined.

11.2 *List of Services*

11.2.1 Table 7 lists the services defined by this standard and indicates which are optional and which are required.

Table 7 List of Services

Service Name	*Description*
Fundamental Requirements	
Get Attributes	Get specified information about the CIDRW.
Get Status	Get the current status of the CIDRW.
Read ID	Read ID.
Requirement for Reader/Writer	
Read Data	Read back data written previously (not applicable to read-only devices).
Write Data	Write data (not applicable to read-only devices).
Optional Capabilities	
ChangeState	Change to MAINTENANCE state or to OPERATING state. This is required if the device supports the optional WriteID service.
Perform Diagnostics	Perform diagnostic tests.
Reset	Reset CIDRW hardware and software.
Set Attributes	Write specified information.
Write ID	Write ID field (device must also support ChangeState service).

11.3 *Parameter Definitions*

11.3.1 Table 8 defines the parameters that are used in one or more services, including individual items within parameter structures. Parameters are listed in alphabetical order.

Table 8 Parameter Definitions

Parameter	*Form*	*Description*
Action	Protocol-specific.	Specifies diagnostic action to perform.
Attribute ID	Text	Attribute identifier. Name of attribute.
Attribute Value	Varies with attribute.	Attribute value.

Parameter	*Form*	*Description*
Carrier ID	Text	User data.
Data	Text	User data.
DataSeg	Protocol-specific.	Indicates specific section of data to read or write.
DataSize	Unsigned integer	Indicates the number of bytes of data to read or write.
Head ID	Number 0–31	Identifies either an individual head (non-zero) or the CIDRW subsystem itself (zero).
PM Information	Enumerated: -Normal execution -Maintenance required	Preventive Maintenance Information
Result Status	Enumerated: -Normal operation -Execution Error -Communication Error -Hardware Error -Tag Fault	Result information on the status of the request concerning the service request. *Execution Error*: cannot read Tag data. Cannot Read ID sequence. But equipment is normal. *Communication Error*: syntax error of Message or Message format or Value. *Hardware Error*: ID reader/writer head fault, ID reader/writer head is powered off. Tag Fault: power fault, exceeded retry limit
Status	Structure	Information about the status of the CIDRW. Consists of PM Information and the current values of the CIDRW attributes AlarmStatus, OperationalStatus, and HeadStatus.

11.4 *Service Definitions*

11.4.1 This section defines the parameters used for each CIDRW service.

11.4.2 *ChangeState*

11.4.2.1 ChangeState is an optional service that requests the CIDRW to change its operational substate to MAINTENANCE or to OPERATING. Table 9 defines the parameters used for the ChangeState service.

Table 9 ChangeState Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
StateRequest	M	-	Specifies either MAINTENANCE or OPERATING substate.
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.3 *Get Attributes*

11.4.3.1 Get Attributes is a required service used to request the attributes of the CIDRW.

Table 10 Get Attributes Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head or Subsystem.
(list of) Attribute ID	M	-	Identifiers of one or more attributes
(list of) Attribute Value	-	M	Attribute Values in order as requested
Result Status	-	M	Result information on the status of the request

11.4.4 *Get Status*

11.4.4.1 Get Status is a required service used to get the current status of the CIDRW. The upstream controller may request current status at any time.

Table 11 Get Status Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head or Subsystem.
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.5 *Perform Diagnostics*

11.4.5.1 Perform Diagnostics is an optional service used to request the CIDRW perform its internal diagnostics. The supplier shall document the specific diagnostics performed.

Table 12 Perform Diagnostics Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head or Subsystem.
Action	C		Specifies diagnostic action to perform.
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.6 *Read Data*

11.4.6.1 Read Data is used to request a generic block of data by an ID Reader/Writer Head. This service is required for the Carrier ID Reader/Writer type and is optional otherwise. The Carrier ID Reader/Writer is not required to understand the content of the data.

Table 13 Read Data Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head.
DataSeg	C	-	Indicates specific section of data.
DataSize	C	-	Indicates number of bytes to read.
Data	-	M	Data Read from Head
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.7 *Read ID*

11.4.7.1 Read ID is used to request the Carrier ID be read by an ID Reader/Writer Head. This service is a fundamental requirement.

Table 14 Read ID Service Message Parameter Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head.
Carrier ID	-	M	Carrier ID
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.8 *Reset*

11.4.8.1 Reset is an optional service used to re-initialize the CIDRW.

Table 15 Reset Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Result Status	-	M	Result information on the status of the request

11.4.9 *Set Attributes*

11.4.9.1 Set Attributes is used to set attributes of the CIDRW that have read/write (R/W) access. This is an optional service. Attempts to set attributes with read-only (RO) access shall be denied. Attribute values returned are those as read following the set operation.

Table 16 Set Attributes Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head or Subsystem.
Attributes ID	M	-	Attribute Ids
Attribute Values	M	-	Attribute Values
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.10 *Write Data*

11.4.10.1 Write Data is used to request a generic block of data to an ID Reader/Writer Head. This service is required for the Carrier ID Reader/Writer type and is optional otherwise. The Carrier ID Reader/Writer is not required to understand the content of the data.

Table 17 Write Data Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head.
DataSeg	C	-	Indicates specific section of data.
DataSize	C	-	Indicates number of bytes to read.
Data	M	-	Write Data (from Host)
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.4.11 *Write ID*

11.4.11.1 Write ID is used to set the field for Carrier ID to an ID Reader/Writer Head. This service is optional. This shall be a protected operation that can be performed only in the MAINTENANCE state to prevent accidental overwriting of the ID field.

Table 18 Write ID Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Head ID	M	M	Specifies Head.
Data (ID)	M	-	Write ID Data.
Result Status	-	M	Result information on the status of the request
Status	-	M	Status information

11.5 *Service Operability*

11.5.1 Some services are performed by the CIDRW and others are logically performed by the individual heads. It is expected that the CIDRW will support multiple interleaved transactions to the various independent logical units. Table 19 shows which of the various services can be performed by the CIDRW when the CIDRW and its heads are in various individual states. Note that when in the initializing state after powerup or the reset service, the CIDRW may not be able to communicate.

Table 19 Valid Services per State

	Service									
	Write ID	*Write Data*	*Set Attributes*	*Reset*	*Read ID*	*Read Data*	*Perform Diagnostics*	*Get Status*	*Get Attributes*	*ChangeState*
CIDRW State										
INITIALIZING										
OPERATING		X	X	**X**	**X**	**X**	**X**	**X**	**X**	**X**
MAINTENANCE	X		X	**X**	**X** (See NOTE 1.)		**X**	**X**	**X**	**X**
Head State										
NOT OPERATING									**X**	
IDLE									**X**	
BUSY									**X**	

NOTE 1: May not be supported by all Readers.

12 Event Notifications

12.1 Event Notification is an optional capability where the CIDRW is able to detect events and report state and status changes independently of a service request from the upstream controller.

RELATED INFORMATION 1
SCENARIOS

NOTE: This related information is not an official part of SEMI E99. This related information was approved for publication by full letter ballot procedures on September 3, 1999.

R1-1 This section provides examples of typical scenarios for a CIDRW with two read heads.

Table R1-1 Reset Scenario

Controller	*CIDRW*			*Head 1*		*Head 2*	
Msg.	Msg.	Action	State	Action	State	Action	State
Reset→		Perform Reset	Init State		NORMAL		NORMAL
	←Reset Reply		Operating or Maintenance		Idle or NORMAL		Idle or NORMAL

Table R1-2 Get Status Scenario

Controller	*CIDRW*			*Head 1*		*Head 2*	
Msg.	Msg.	Action	State	Action	State	Action	State
Get Status 0→		Determine Status	Operating or Maintenance		Any		Any
	←Status Reply		Same		Any		Any

	← Write Data Reply 02		Operating		Idle		Idle

RELATED INFORMATION 2
OBJECT MODEL

NOTE: This related information is not an official part of SEMI E99. This related information was approved for publication by full letter ballot procedures on August 28, 2000.

R2-1 Object models provide a graphic representation of entities. The models in this section use the Object Modeling Technique (OMT) described in Object-Oriented Modeling and Design. Object types are represented by rectangles with one, two, or three sections. The name of the object type is in the first, or only section. Attributes, information about the object, are shown in the second section. Operations or services are shown in a third section. Lines between objects represent relationships.

R2-2 Three models are shown for purposes of illustration. The general multi-head case is shown first with only the required attributes and services. Next, the full model for the multi-head case is shown with all attributes and services defined in this standard. Finally, the full model for the integrated single-head case is shown.

R2-3 Note that the Upstream Controller sends all service requests to the CIDRW controller, including services shown for the individual heads. Services shown on these models for CIDRW are those with a Head ID service parameter value of zero while services shown for the Head are those with a Head ID service parameter value between one and thirty-one.

R2-4 Fundamental Requirements Example Object Models

R2-4.1 The object model in Figure R2-1 shows objects for the general (multi-head) CIDRW satisfying fundamental requirements only. It shows the CIDRW subsystem as made up of one or more heads. It also illustrates the required attributes and services provided by the CIDRW and its relationships with its upstream controller and with its heads.

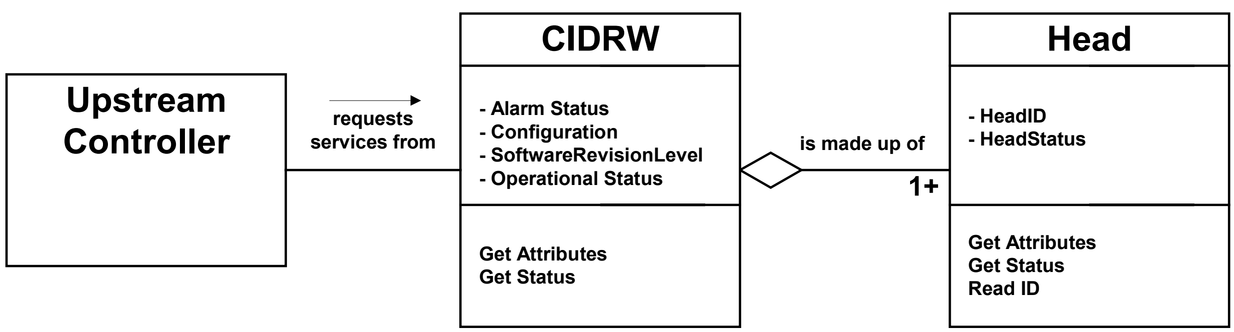

Figure R2-1
Object Model for Fundamental Requirements

R2-5 Full Capabilities

R2-5.1 Figure R2-2 shows the object model for a CIDRW with full capabilities, so that all optional attributes and services are supported.

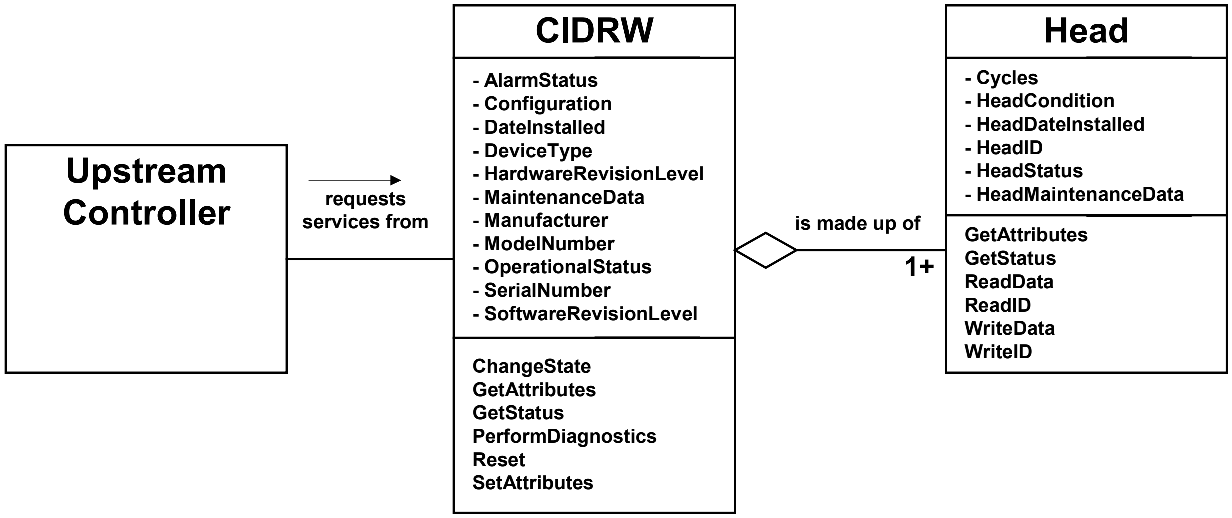

Figure R2-2
Object Model for Full Capabilities

R2-6 Integrated Model

R2-6.1 Figure R2-3 shows the object model for a CIDRW with full capabilities and a single integrated head. The head is not shown as a separate component in this case, and the head attributes and services have become part of the CIDRW subsystem itself.

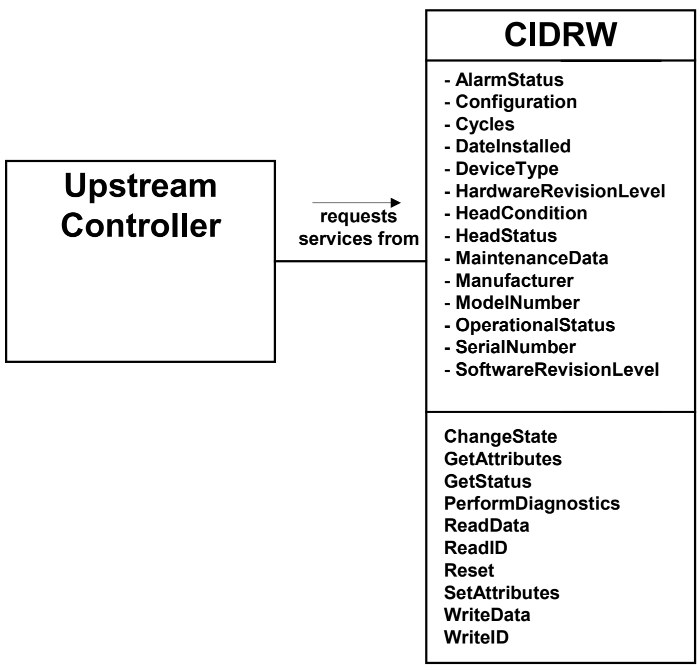

Figure R2-3
Integrated Model with Full Capabilities

SEMI E99.1-0600^{E}
SPECIFICATION FOR SECS-I AND SECS-II PROTOCOL FOR CARRIER ID READER/WRITER FUNCTIONAL STANDARD

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces and Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on January 14, 2000. Initially available at www.semi.org March 2000; to be published June 2000.

E This document was modified in December 2001 to reflect a typographical error. Changes were made to Table 5 in Section 8.2.1.

1 Purpose

1.1 This document maps the services and data of the Carrier ID Reader/Writer (CIDRW) standard to SECS-II streams and functions and data definitions.

2 Scope

2.1 This document applies to all implementations of CIDRW that use the SECS-II message protocol (SEMI E5).

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *Abbreviations and Acronyms*

4.1.1 *CIDRW* — Carrier ID Reader/Writer; represents both the Reader and the Read/Writer.

4.1.2 *SECS* — SEMI Equipment Communications Standard

5 Physical Requirements

5.1 The CIDRW using the SECS-I protocol shall use a 9-pin female connector.

6 Service Message Mapping

6.1 Table 1 shows the specific SECS-II streams and functions that shall be used for SECS-II implementations of the service messages defined in SEMI E99.

6.2 Request and notification messages are mapped to primary (odd-numbered) SECS-II functions and response messages are mapped to secondary (even-numbered) SECS-II functions.

6.3 In some cases, a common set of parameters allows more than one service to be mapped to the same stream and function, with an additional SECS-II data item used to differentiate between the two services.

Table 1 Services Mapped to SECS-II Messages

Message Name	*Stream,Function*	*SECS-II Name*
ChangeState	S18,F13/F14	Subsystem Command Request/Acknowlege
Get Attributes	S18,F1/F2	Read Attribute Request/Data
Get Status	S18,F13/F14	Subsystem Command Request/Acknowledge
Perform Diagnostics	S18,F13/F14	Subsystem Command Request/Acknowledge
Read Data	S18,F5/F6	Read Request/Data
Read ID	S18,F9/F10	Read ID Request/Data
Reset	S18,F13/F14	Subsystem Command Request/Acknowledge
Set Attributes	S18,F3/F4	Write Attribute Request/Acknowledge
Write Data	S18,F7/F8	Write Request/Acknowledge
Write ID	S18,F11/F12	Write ID Request/Acknowledge

7 Service Parameter to Data Item Mapping

7.1 Table 2 shows the mapping between message parameters defined by CIDRW and data items defined by SECS-II. For parameters specified in the definitions of a CIDRW service, either the parameters themselves, or individual elements of complex parameters, map to a specific data item.

Table 2 Service Parameters to Data Item Mapping

Parameter Name	*SECS-II Data Item*	*Format*	*Values*
Attribute ID	ATTRID	20	Name of attribute
Attribute Value	ATTRVAL	20	
Carrier ID	MID	20	
Data	DATA	20	All characters 00H-0FFH
DataSize	DATALENGTH	52	
DataSeg	DATASEG	20	
PM Information	STATUS	20	"NE" = Normal execution, "MR" = Maintenance required
Result Status	SSACK	20	"NO" = Normal operation; "EE" = Execution error; "CE" = Communication error; "HE" = Hardware error; "TE" = Tag error
Status	List of STATUS	L,4 1. <PMInformation> 2. <AlarmStatus> 3. <OperationalStatus> 4. <HeadStatus>	Current values of PM Information with the corresponding attributes for CIDRW and Head (if applicable). See Tables 4 and 5.
StateRequest	CPVAL	20	"OP","MT"

NOTE 1: There are also data items used in SECS-II messages that do not map to specific services parameters. Services with the same set of parameters are mapped to the same SECS-II message by adding an additional data item to differentiate between the services. Table 3 contains the SECS-II data items that have not a corresponding CIDRW service parameter:

Table 3 Additional Data Requirements Table

SECS-II Data Item	*Function*	*Value*
SSCMD	Used to differentiate between different subsystem commands indicated.	"ChangeState" "GetStatus" "Perform Diagnostics" "Reset"

8 Data

8.1 *CIDRW Attributes*

8.1.1 Table 4 specifies the values for the CIDRW attribute identifiers and limitations on values.

Table 4 CIDRW Attribute Definitions

Attribute Name	*Description*	*Access*	*Format*	*Value*
Fundamental				
"Configuration"	Number of heads.	RO	20	"01"–"31"
"AlarmStatus"	Current CIDRW substate of ALARM STATUS	RO	20	"0" = NO ALARMS "1" = ALARMS

Attribute Name	*Description*	*Access*	*Format*	*Value*
"OperationalStatus"	Current CIDRW substate of OPERATIONAL	RO	20	"IDLE", "BUSY", "MANT"
"SoftwareRevisionLevel"	Revision (version) of software	RO	20	8 byte maximum
Optional				
"DateInstalled"	Date the subsystem was installed	RO	20	"YYYYMMDD" format
"DeviceType"	Identifies subsystem as either a Carrier ID Reader or a Carrier ID Reader/Writer.	RO	20	"CIDR_" or "CIDRW"
"HardwareRevisionLevel"	Revision number of the hardware	RO	20	8 byte maximum
"MaintenanceData"	Supplier dependent	RO	20	80 byte maximum
"Manufacturer"	The name or identifier of the manufacturer	RO	20	20 byte maximum
"ModelNumber"	The manufacturers model designation	RO	20	20 byte maximum

RELATED INFORMATION 1
SCENARIOS

NOTE: This related information is not an official part of SEMI E10#. This related information was approved for publication by full letter ballot procedures on January 14, 2000.

This section provides examples of typical scenarios for a Carrier ID Reader/Writer.

R1-1 Read ID

R1-1.1 The upstream controller sends a Read ID Request message to the CIDRW for Head 1. The CIDRW Head 1 reads the ID, and the CIDRW returns the ID to the upstream controller.

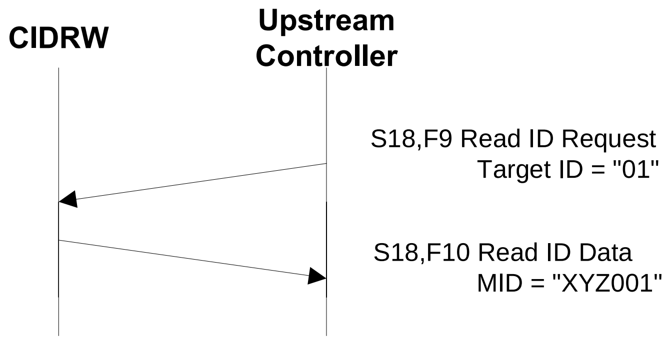

Figure R1-1
Read ID Scenario

R1-2 Read Data

R1-2.1 The upstream controller sends a Read Data Request message to the CIDRW for Head 1 and DataSeg 1. The CIDRW Head 1 reads the data, and the CIDRW returns the data to the upstream controller.

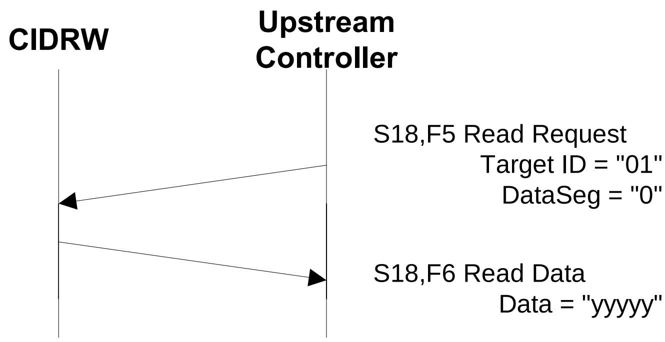

Figure R1-2
Read Data Scenario

R1-3 Write ID

R1-3.1 The CIDRW is in IDLE. The upstream controller requests the CIDRW change its operational status to MAINTENANCE.

R1-3.2 The CIDRW changes to MAINTENANCE and replies that it has changed state.

R1-3.3 The upstream controller sends a Write ID Request message to the CIDRW for Head 1. The CIDRW Head 1 reads the ID, and the CIDRW returns the ID to the upstream controller.

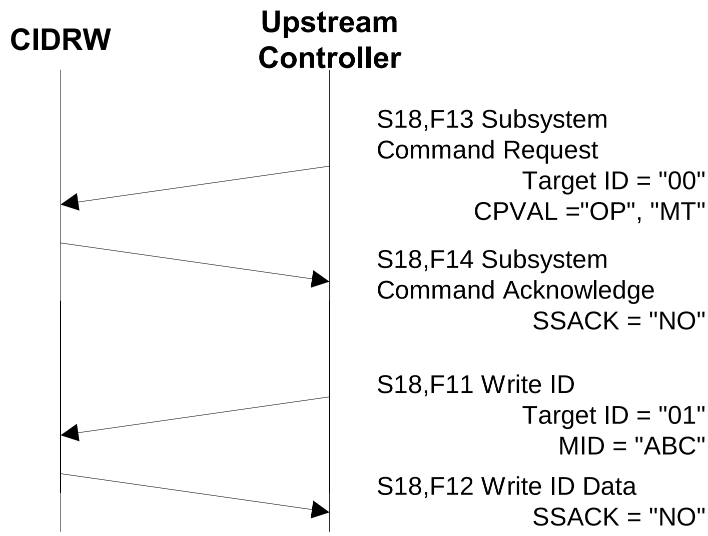

Figure R1-3
Write ID Data Scenario

R1-4 Write Data

R1-4.1 The upstream controller sends a Write Data Request message to the CIDRW for Head 1 and DataSeg 1. The CIDRW Head 1 writes the data, and the CIDRW returns the results to the upstream controller.

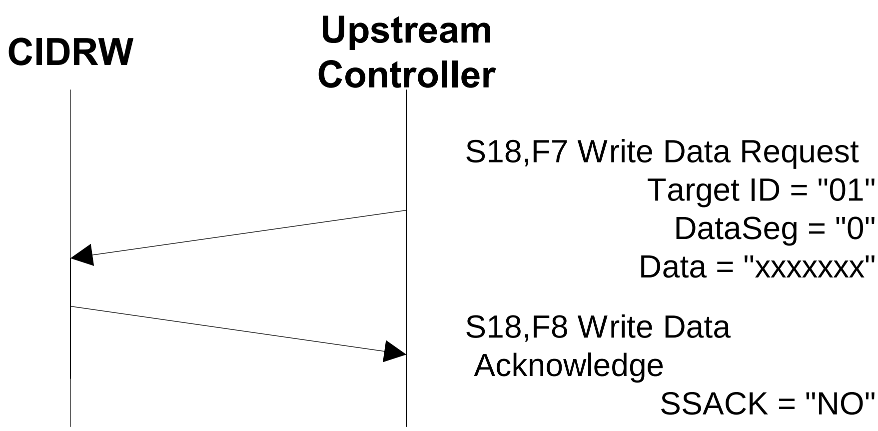

Figure R1-4
Write Data Scenario

SEMI E100-0302
SPECIFICATION FOR A RETICLE SMIF POD (RSP) USED TO TRANSPORT AND STORE 6 INCH OR 230 mm RETICLES

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the North American Physical Interfaces and Carriers Committee. Current edition approved by the North American Regional Standards Committee on October 14, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published February 2000, previously published November 2001.

1 Purpose

1.1 This standard specifies the Reticle SMIF Pod (RSP) used to transport and store 6 inch or 230 mm reticles in a reticle (photomask) or integrated circuit (IC) manufacturing facility.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and inter-changeability at all mechanical interfaces. Most of the requirements given in this specification are in the form of maximum or minimum dimensions with very few required surfaces. Only the physical interfaces for the RSP are specified; no materials requirements or micro-contamination limits are given in this specification.

2.2 The pellicle exclusion volumes of this specification accommodate pellicles which extend the full length of the reticles. The pellicle exclusion volume widths are limited to 151 mm for 230 mm reticles, and 129 mm for 6 inch reticles.

2.3 The RSP has the following components, sub-components, and other features. A "●" symbol indicates components or features which are *required* and a "◊" symbol indicates components or features which are *optional*.

- Top
  - ◊ robotic handling flange (optional)
- Interior
  - supports for one 6 inch or 230 mm reticle
  - reticle capture mechanism
  - end-effector exclusion volume
  - 2 safety rail exclusion volumes
  - pellicle exclusion volume
  - transverse pellicle exclusion volume
- Sides
  - ◊ 2 side handling flanges on the sides parallel to the bi-lateral reference plane (optional)
  - 1 carrier ID exclusion volume on the rear side
  - ◊ 2 side handling exclusion volumes
- Bottom
  - door compatible with SMIF as defined in SEMI E19.4
  - pod latch-pin holes
  - features which mate with kinematic coupling pins
  - carrier sensing pads as defined in SEMI E1.9
  - 4 info pads
  - ◊ 4 bottom conveyor rails

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *bilateral reference plane* — a vertical plane that bisects the reticle and is perpendicular to both the horizontal and facial reference planes. The bilateral reference plane is coplanar with the bilateral datum plane defined in SEMI E57.

4.2 *facial reference plane* — a vertical plane which bisects the reticle and is parallel to the front side of the pod (where reticles are removed or inserted). The facial reference plane passes through the center of the 200 mm SMIF as defined in SEMI E19.4. The facial reference plane is coplanar with the facial datum plane defined in SEMI E57.

4.3 *horizontal reference plane* — a horizontal plane coplanar with the top surface of the port door as defined in SEMI E19.4. The horizontal reference plane is coplanar with the horizontal datum plane defined in SEMI E57.

4.4 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

4.5 *nominal reticle center line* — the line that is defined by the intersection of the two vertical reference planes (facial and bilateral) and passes through the nominal center of the seated reticle (which must be horizontal when the carrier is placed on the SMIF as defined in SEMI E19.4).

4.6 *pellicle* — as defined in SEMI P5.

4.7 *reticle* — as defined in SEMI E30.1.

4.8 *Reticle SMIF Pod* (RSP) — a minienvironment compatible carrier capable of holding one 6 inch or one 230 mm reticle in a horizontal orientation during transport and storage and is compatible with a Standard Mechanical Interface (SMIF) per SEMI E19.4.

4.9 *robotic handling flanges* — horizontal projections on the top of the box for lifting and rotating the box (as defined in SEMI E47.1).

4.10 *side handling flanges* — horizontal projections on the sides of the pod (sides parallel to the bilateral reference plane) for manual or automated lifting, transportation or positioning of the pod.

5 Ordering Information

5.1 *Intended Use* — This standard is intended to specify reticle carriers over a reasonable lifetime of use, not just those in new condition. For this reason, the purchaser needs to specify a time period and the number and type of uses to which the carriers will be put. It is under these conditions that the carriers must remain in compliance with the requirements listed in Section 6.

5.2 *Reticle Size and Thickness* — The purchaser needs to specify the reticle size and thickness to be accommodated in the RSP.

5.3 *Optional Features* — The purchaser needs to specify whether optional components (identified in Section 2) are required.

5.4 *Temperature Ranges* — The purchaser needs to specify two sets of temperatures to which the RSPs might be exposed. An operating temperature range is the set of environmental temperatures in which the RSPs will remain in compliance with the requirements listed in Section 6. A temporary temperature range is the set of environmental temperatures to which the pods can be exposed such that when the RSPs return to the operating temperature range, the RSPs will be in compliance with the requirements listed in Section 6. Limits on exposure times to elevated temperatures should be specified.

5.5 *Electrostatic Dissipation* — The end user may require a continuous path to ground from the reticle to the carrier registration and handling features. The purchaser needs to specify whether electrostatic dissipation is required.

5.6 *Contamination Requirements* — The purchaser needs to specify their contamination requirements.

6 Requirements

6.1 *Symmetry* — Most of the dimensions of the RSP are determined with respect to the three orthogonal reference planes defined in this document: the facial reference plane, the horizontal reference plane and the bilateral reference plane. All dimensions are symmetric about the bilateral reference plane except the latch features. All dimensions are symmetric about the facial reference plane except the registration features, carrier sensing pads, info pads, and latch features.

6.2 *Door* — The pod door, and its frame on the bottom of the pod, must be compatible with a port which conforms to SEMI E19.4.

6.3 *Reticle Centering and Capture* — When the carrier is closed, the reticle must be secured in all degrees of freedom within the carrier to prevent movement during transport and must be centered with respect to the SMIF defined in SEMI E19.4. A bisecting plane through the reticle, parallel to the bilateral reference plane must be within x114 of the bilateral reference plane of the load port when the reticle is seated in the carrier. A bisecting plane through the reticle, parallel to the facial reference plane must be within y133 of the facial reference plane of the load port when the reticle is seated in the carrier. When the carrier is open, it must provide a horizontal reticle capture range of x135 and y135. This capture range must be provided at z162 above the horizontal reference plane.

6.4 *Exclusion Volumes* — The interior of the RSP must never intrude into the pellicle exclusion volumes, and must not intrude into the end-effector exclusion volumes or safety rail exclusion volumes when the carrier is open. Where the exclusion volumes overlap, the end-effector exclusion volume is reduced by the pellicle exclusion volume when handling pelliclized or chrome-down reticles.

6.4.1 *End-Effector Exclusion Volumes* — Volumes in an opened pod which must be free for the end-effector to enter and handle the reticle as defined by x116, x132, y136, x144, x146, y144, z159, and z160 for a 230 mm RSP, and by x118, x143, x145, y143, z159, and z160 for a 6 inch RSP. No obstructions should exist in the end-effector exclusion volume which extends in the direction normal to the facial reference plane.

6.4.2 *Pellicle Exclusion Volumes* — Volumes in the pod below the reticle which must remain free from intrusion to accommodate the pellicle mounted on the reticle. No obstructions should exist in the pellicle exclusion volume which extends in the direction normal to the facial reference plane as defined by x115, z159 and z161 for a 230 mm RSP, and by x119, z159 and z161 for a 6 inch RSP. No obstructions should exist in the transverse pellicle exclusion volume which extends in the direction normal to the bilateral reference plane as defined by y129, z159 and z163 for a 230 mm RSP, and by y130, z159 and z163 for a 6 inch RSP.

NOTE 2: The transverse pellicle exclusion volume is only intended to specify where the reticle supports in the pod cannot exist. Reticles with the pellicles transverse are typically handled with end-effectors which grip from above the reticle.

6.4.3 *Safety Rail Exclusion Volumes* — Volumes in an opened pod which must remain free from intrusion to accommodate safety rails which may be used on end-effectors to protect the edge of the reticle during handling. No obstructions should exist in the safety rail exclusion volumes which extend in the direction normal to the facial reference plane as defined by x137 and z167 for a 230 mm, and by x138 and z167 for a 6 inch RSP.

6.5 *External Dimensions* — Figures 1, 2 and 3 show, respectively, the external top view, a detail and the front view of the RSP. Table 2 defines all of the external dimensions of the RSP (equivalent for both the 6 inch and the 230 mm versions).

6.6 *Internal Dimensions* — Figures 4 through 8 show internal dimensions for the 6 inch and 230 mm versions of the RSP. Table 2 defines all internal dimensions which are common to the 6 inch and 230 mm RSP. Table 3 defines the internal dimensions which apply only to the 230 mm RSP. Table 4 defines the internal dimensions which apply only to the 6 inch RSP. The maximum height of the features which support the reticle are given by z164 for a 230 mm RSP and z165 for a 6 inch RSP.

NOTE 3: The maximum height of the reticle supports, plus the clearance between the reticle supports and reticle (chosen by the tool supplier) determine the height the reticle must be lifted before being extracted from, or inserted into the RSP.

6.7 *Robotic Handling Flange* — On the top of the pod is an optional handling flange for automated manipulation of the RSP. Figures 1, 3, and 5 show dimensions for the robotic handling flange. Table 2 defines the dimensions for the robotic handling flange.

6.8 *Side Handling Flanges* — On the sides of the pod parallel to the bilateral reference plane are optional handling flanges for automated manipulation of the RSP. Figures 1, 2, and 3 show dimensions for the side handling flanges. Table 2 defines the dimensions for the side handling flanges. No obstructions may exist in the side handling exclusion volumes which extend in the direction normal to the facial reference plane as defined by x136 and z166 when the side handling flanges are present.

6.9 *Kinematic Coupling* — The RSP door must have the capability of registering on the kinematic pins defined in SEMI E57. The features that mate with the pins must provide a lead-in capability that corrects an RSP misalignment no greater than r19 in any horizontal direction. However, it is recommended that robots placing RSPs on kinematic couplings use as little of this lead-in capability as possible to avoid wear.

6.10 *Carrier Sensing Pads* — The RSP door must have carrier sensing pads as defined in SEMI E1.9.

6.11 *Info Pads* — When the RSP is placed on a port, the info pads A, B, C, and D communicate information about the RSP configuration. Figures 6 and 8 show the dimensions of the info pads. Table 2 defines the info pad dimensions. A pad in the up position must be z26 above the horizontal reference plane. A pad in the down position must be z2 above the horizontal reference plane. Info pad assignments are shown in Table 1. Info pads that are “not defined” can be at either the up or down position unless specified by the end user. RSP configurations “to be assigned” may be assigned by the end user.

Table 1 Info Pad Assignments

RSP Configuration	*Info Pad*			
	A	*B*	*C*	*D*
230 mm reticle	not defined	not defined	up	down
6 inch reticle	not defined	not defined	down	down
to be assigned	not defined	not defined	up	up
to be assigned	not defined	not defined	down	up

6.12 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*65 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*66 to prevent small contact patches with large stresses that might cause wear and particles. Note that these limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the carrier supplier. Note also that this radius applies to every required feature unless another radius is called out specifically. Here a required feature is an area on the surface of the carrier specified by a dimension (or intersections of dimensions) that has a tolerance and not just a maximum or minimum (such as the edges of the robotic handling flange).

6.13 *Carrier ID Exclusion Volume* — Volume external to the pod which must remain free from intrusion to accommodate a carrier ID label or tag mounted on the pod. No obstructions should exist in the carrier ID exclusion volume as defined by x147, y137, y138, z180, and z181. Figures 1 and 3 show dimensions for the carrier ID exclusion volume. Table 2 defines the dimensions for the carrier ID exclusion volume. If a label is used, its surface must be at y139.

6.14 *Conveyor Rails* — Optional surfaces on the bottom for transporting the RSP on roller conveyors. The conveyor rail surfaces are bounded by x140, x141, x142, y140, y141 and y142 as shown in Figure 9. The height of the conveyor rail surface is defined by z171. Table 2 defines the dimensions for the conveyor rails.

APPENDIX 1
APPLICATION NOTES

NOTE: The material in this appendix is an official part of SEMI E100 and was approved by full letter ballot procedures on September 3 and December 15, 1999 by the North American Regional Standards Committee, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 Edge contact only with the photomask is preferred when handling, transporting, or storing.

A1-2 Skewness, warp, rock, and stiffness are implicitly defined in the geometric tolerances.

A1-3 A 6 inch reticle with a 140 mm wide pellicle can be accommodated in the RSP, but may require automation which approaches from above the reticle.

A1-4 Features on the RSP which enable stacking may be required by end users. It is preferred that these features allowing stacking in only one orientation.

A1-5 Features on the RSP which provide visual orientation of the RSP top and RSP door may be required by end users.

A1-6 In order to permit end-effectors, which can handle both 230 mm and 6 inch reticles, it is recommended to include the 230 mm end-effector exclusion volumes in RSPs configured for 6 inch reticles.

APPENDIX 2
ADDITIONAL INFORMATION

NOTE: The material in this appendix is an official part of SEMI E100 and was approved by full letter ballot procedures on September 3, 1999 by the North American Regional Standards Committee.

A2-1 Features on the RSP which enable stacking may be standardized in the future pending learning from first design approaches and standardization of reticle ID location.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copy-righted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E101-1000
PROVISIONAL GUIDE FOR EFEM FUNCTIONAL STRUCTURE MODEL

This guide was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces and Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on July 14, 2000. Initially available at www.semi.org September 2000, to be published October 2000. Originally published February 2000; previously published June 2000.

1 Purpose

1.1 Productivity improvement is the task with the highest priority in semiconductor factories of the 300 mm generation, and computer-integrated manufacturing or factory automation (CIM/FA) technologies become more and more important to accomplish it. The standardization of these technologies is also necessary to provide the CIM/FA infrastructure in a short period of time at a low cost. Since the standards will have to cover a wide range of production equipment, communication hardware, and software tools, it is very important that the standards have a high degree of compatibility. In order to improve the compatibility, this guide provides a functional structure model of an Equipment Front End Module (EFEM) that handles carriers and substrates at the interface between the factory material handling system and the process equipment.

1.2 The major purposes of this guide are as follows:

1) provide a common understanding of functions of EFEM (Equipment Front End Module) and associated interfaces between functional elements (components with particular function roles),

2) provide a common understanding of the hierarchical structure of functions and their interfaces in an EFEM,

3) provide a common understanding of possible units used for maintenance, adjustment, and control, and

4) provide a map between EFEM functional elements and existing standards.

2 Scope

2.1 *Model Structure and Functions*

2.1.1 This document recognizes EFEM as a component of semiconductor manufacturing equipment. It creates an EFEM functional structure model to clearly describe EFEM, its functional elements, and the functions of each functional element. The functional structure model includes the following:

1) definition of functional elements that constitute EFEM,

2) definition of functions of functional elements, and

3) hierarchical description of functional elements.

2.1.2 For clarity, Fixed Buffer Type EFEM and Internal Buffer Type EFEM (see Terminology) are represented as independent functional structure models in this document.

2.2 *Preconditions for Modeling*

2.2.1 The models are created under the following conditions:

1) Modeling should be restricted to SEMI E15.1, Option 1, Options 2 and 3, and Option 3 types. (See SEMI E15.1, Figure 2 (Load Port Options)).

2) The model supports handling of open cassette (OC), and Front Opening Unified Pod (FOUP) (see Terminology).

3) The model is created for the maximum structure including options.

4) Functional elements that have interfaces with EFEM are also included in the model.

NOTE 1: Functional elements that don't belong to EFEM, but are important in defining interfaces among the functional elements, are represented in this model to clarify their functional positions and attributes in the entire equipment.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E57 — Provisional Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI E64 — Provisional Specification for 300 mm Cart to SEMI E15.1 Docking Interface Port

SEMI E75 — Provisional Mechanical Specification for Box/Pod Compatible Cassette Used to Transport and Store 300 mm Wafers

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O Interface

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *Abbreviations and Acronyms*

4.1.1 AGV — automatic guided vehicle (cart)

4.1.2 *OHT* — overhead transport system with hoist for lifting carriers between load port level and transport level.

4.1.3 *PGV* — person guided vehicle (cart).

4.1.4 *PI/O* — parallel input/output interface, for example, as specified in SEMI E23.

4.1.5 *RGV* — rail guided vehicle (moving on the floor).

4.2 *Definitions*

4.2.1 *BOLTS plane* — a plane parallel to the facial datum plane near the front of the tool where the box opener/loader is attached (as defined in SEMI E63).

4.2.2 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.2.3 *box opener/loader* — the equipment component that opens wafer carriers (if needed) and presents the carriers to the equipment's Substrate Handler for unloading and loading wafers.

4.2.4 *carrier* — any cassette, box, or pod that are used to transport substrates (as defined in SEMI E15).

4.2.5 *cart* — a floor-based carrier transfer vehicle.

4.2.6 *cassette* — an open structure that holds one or more wafer substrates (as defined in SEMI E44).

4.2.7 *docking* — the act of locating a floor-based carrier transport vehicle for carrier transfer to/from equipment.

4.2.8 *equipment front end module (EFEM)* — it consists of the carrier handler that receives carriers from the factory material handling system on one or more load ports (as specified in SEMI E15.1), opens the carriers (if needed), and may include a Substrate Handler for unloading and loading wafers from the carrier to the process part of equipment.

4.2.9 *fixed buffer* — EFEM configuration with carrier places only on load port units arranged in a load port group.

4.2.10 *front opening unified pod (FOUP)* — front opening type box/pod with non-removable cassettes (as defined in SEMI E47.1).

4.2.11 *internal buffer* — EFEM configuration with carrier places different from load port units.

4.2.12 *kinematic coupling* — the physical alignment mechanism on the bottom of the wafer carrier that consists of features that mate with three vertical pins on the load port (as defined in SEMI E57).

4.2.13 *load port* — the interface location on a tool where carriers are placed to allow the tool to process wafers (as defined in SEMI E15).

4.2.14 *open cassette (OC)* — a cassette (as defined in SEMI E1.9) without a protective barrier around it.

4.2.15 *transfer* — to either load or unload (as defined in SEMI E15).

5 Modeling Methodology (General Rules)

5.1 *Notation*

5.1.1 A functional element to be defined is represented by a rectangle.

5.1.2 The name of a functional element is written in the rectangle representing the element.

5.1.3 Numbers preceding the functional element name indicate the number of elements.

[0, 1] indicates the element may exist or may not exist.

[1+] indicates the element may exist one or more times.

5.2 *Rules of Notation Usage*

5.2.1 A functional element that is written on the border between adjacent layers indicates the element may belong to either of two functional elements in the adjacent layers.

5.2.2 Functional elements whose position in the Functional Structure Model diagram are similar in the two models of Fixed Buffer Type EFEM and Internal Buffer Type EFEM have the same name.

5.2.3 A functional element whose location is still undecided between two adjacent layers is located in between them.

6 Definition of Functional Elements

6.1 *Overall Structure*

6.1.1 Figures 1a, 1b and Figures 2a, 2b show conceptual structures of two types of Fixed Buffer Type EFEM model and two types of Internal Buffer Type EFEM model in overall structure of equipment. Two types of EFEM exist, when Substrate Handler is installed outside the Process Part, and when the Substrate Handler is included inside the Process Part.

6.1.2 *EFEM [1]* — This is a major module whose functions are to transfer carriers to and from the factory material handling system, to provide all carrier handling and storage functions for production equipment, and to load and unload substrates from the carrier for processing. It consists of a Carrier Handler and may contain a Substrate Handler.

6.1.3 *Carrier Handler [1]* — A Carrier Handler receives and passes the carriers from and/or to the external system (such as the factory material handling system). A Carrier Handler of the Internal Buffer Type has the functions of handling and storing the carriers. A carrier handler for FOUPs has the opener(s) for opening and closing FOUPs.

6.1.4 *Substrate Handler [0,1]* — A Substrate Handler transfers substrates between the carriers and the process part of the equipment.

6.1.5 *Load Port Group [1+]* — The load port group is where carriers are received and passed from or to the external system (such as the factory material handling system). Each equipment has at least one load port group. A load port group consists of one or more load ports.

6.1.5 *Internal Buffer [1+]* — This is a buffer that stores carriers inside equipment. It moves carriers from Load Port Group to Buffer and moves carriers from Buffer to Internal Substrate Port. It consists of a Carrier Transfer Robot that transfers the carriers to or from a Carrier Storage and a Carrier Storage where carriers are stored.

6.1.6 *Internal Substrate Port [0,1+]* — This is where substrates are loaded and unloaded from a carrier, and it contains any functionality required to present the carrier for substrate access.

6.2 *Definition of Functional Elements for EFEM Models*

6.2.1 *Model of Fixed Buffer Type EFEM (see Figure 3)*

6.2.1.1 *Load Port [1+]* — A load port is where an individual carrier is held for pickup and delivery with the factory material handling system. It consists of a Load Port Unit and may contain PI/O for OHT/AGV/RGV, Cart-to-Tool Docking Port Interface, and a Load Port Door.

6.2.1.2 *Load Port Unit [1]* — This physically receives carriers from/to external systems. It consists of a Carrier Opener/Loader, and it may contain a Carrier Operation Panel, a Carrier ID Reader/Writer, and a Carrier Slot Mapper.

6.2.1.3 *PI/O for AGV/RGV/OHT [0,1]* — This is a means of low-level communications that synchronizes the hand-off between Automated Material Handling equipment (such as AGV, RGV, OHT) and production equipment. One Parallel I/O may exist for each stop position of the AGV, RGV, or OHT. It may be a part of a Load Port or a Load Port Group depending on the number of ports that can be accessed from a single stop position.

6.2.1.4 *Cart-to-Tool Docking Port Interface [0,1]* — This is the mechanical interface allocated for installing the module to be used as a docking means for a person-guided vehicle (PGV) at the Load Port Group. One Cart-to-Tool Docking Port Interface may exists per Load Port Group or per Load Port.

6.2.1.5 *Load Port Door [0,1]* — This is the door that may be used to separate the space on a load port from the external environment, or to prevent the operator from interfering with the load port mechanism or OHT. This may be a part of a Load Port or a Load Port Group depending on the number of ports that can be accessed through a single Port Door.

6.2.1.6 *Carrier Operation Panel [0,1]* — This is an operation panel that may be used when manually loading or unloading a carrier to or from a Load Port. One operation panel may exist for each of SEMI E15.1's Load Port Option 1 and Option 3 types. No operation panel may exist for a Load Port of SEMI E15.1, Option 2 type.

6.2.1.7 *Manual Switches [0,1]* — These are the switches that may be used by an operator when manually loading or unloading a carrier. They are located on the Carrier Operation Panel.

6.2.1.8 *Carrier Indicators [0,1]* — These consist of a Carrier Presence Indicator (that indicates the presence of a carrier) and a Carrier Placement Indicator (that indicates whether the carrier is correctly seated). One set of Carrier Indicators may exist for each Load Port Unit. They are located on the Carrier Operation Panel.

6.2.1.9 *Carrier Opener/Loader [1]* — This is the unit that prepares a carrier for access for loading and unloading substrates and includes all mechanisms required for docking and undocking, purging, opening and closing FOUPs. In the case of an OC, it consists only of the Load Plate.

6.2.1.10 *Dock Plate [0,1]* — This is a mechanism that advances a FOUP up to the door opening/closing mechanism. It contains a Load Plate that a carrier is placed on, and it may contain the Dock/Undock mechanism that advances the carrier into the equipment, and/or a Carrier Purge Interface.

6.2.1.11 *Load Plate [1]* — This is the base plate on which carriers are placed. It consists of a Kinematic Coupling and may contain Carrier Sensors and/or Info Pad Sensors.

6.2.1.12 *Carrier Sensors [0,1]* — These are sensors to detect whether a carrier is present and/or a carrier is correctly placed.

6.2.1.13 *Info Pad Sensors [0,1]* — These are sensors to detect Info Pads as defined in SEMI E1.9.

6.2.1.14 *Carrier Purge Interface [0,1]* — This is a mechanical interface for injecting and withdrawing gasses.

6.2.1.15 *Dock/Undock Mechanism [0,1]* — This is the mechanism that advances a carrier to the FOUP opener and locks the carrier, or releases it from its locked state. In the FOUP-OC (as defined in SEMI E75) and OC (as defined in SEMI E1.9) case, this mechanism only moves carriers.

6.2.1.16 *FOUP Opener [0,1]* — This is the mechanism that opens and closes the FOUP door.

6.2.1.17 *Carrier Opener/Loader Maintenance Panel [0,1]* — This is a user interface for maintenance of the Carrier Opener/Loader.

6.2.1.18 *Carrier Slot Mapper [0,1]* — This is the mechanism that detects the presence or the absence of substrates and their positions in a carrier. It may be installed on the FOUP Opener, the Carrier Opener/Loader, the Load Port Unit, or the Substrate Handler.

6.2.1.19 *Carrier ID Reader/Writer [0,1]* — This is the unit that reads and/or writes to an ID tag attached to a carrier. At most, one Carrier ID Reader/Writer exists for each Load Port Unit.

6.2.1.20 *Status Indicator [0,1]* — This is a set of indicators which shows operating status of the Load Port Unit.

6.2.1.21 *Substrate ID Reader [0,1]* — This is the unit which reads the Identification Label on the Substrate.

6.2.1.22 *Aligner [0,1]* — This is the unit which aligns the angular orientation of substrates and may center the substrate.

6.2.1.23 *Substrate Transfer Robot [0,1+]* — This is the unit which transfers substrates between Carrier Handler, automation components (Aligner, Substrate ID Reader, etc.) and Process Part.

6.2.2 *Model of Internal Buffer Type EFEM (see Figure 4)*

6.2.2.1 This section defines functional elements that exist only in an Internal Buffer Type EFEM.

6.2.2.2 *Internal Buffer [1+]* — This is where an individual carrier is stored in an EFEM. It consists of a Carrier Transfer Robot that transfers carriers and a Carrier Storage where carriers are stored.

6.2.2.3 *Carrier Transfer Robot [1]* — This is a robot that handles carriers in Carrier Storage.

6.2.2.4 *Carrier Storage [1+]* — This is where an individual carrier is stored.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E103-1000
PROVISIONAL MECHANICAL SPECIFICATION FOR A 300 mm SINGLE-WAFER BOX SYSTEM THAT EMULATES A FOUP

This provisional specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on July 28, 2000. Initially available on SEMI OnLine August 2000; to be published October 2000. Originally published June 2000.

1 Purpose

1.1 This standard specifies the carrier side of the mechanical interface between load ports (or buffers) with FIMS interfaces on process or metrology equipment and a system that includes a box that holds only one wafer (such as a test wafer) and that fits onto an adapter mechanism called a single-wafer interface (SWIF). This system appears to the equipment to be a 300 mm FOUP (except that only the volume around the middle wafer may be accessible).

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at relevant mechanical interfaces. Only the mechanical interface between a load port with a FIMS interface and this system (of a single-wafer box and a SWIF) is specified here; the mechanical interface between the single-wafer box and the SWIF is not specified. Also not specified is the method by which the SWIF raises the carrier sensing pads when the single-wafer box is removed (see Section 5.3). This standard does not forbid the SWIF from holding more than just the single-wafer box mentioned in this standard.

2.2 This standard is provisional because the single-wafer box system is a new technology. Once interface testing is done, this standard should be modified and upgraded from provisional status.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E62 — Provisional Specification for 300 mm Front-Opening Interface Mechanical Standard (FIMS)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *Abbreviations & Acronyms*

4.1.1 *FOUP* — front-opening unified pod

4.1.2 *PGV* — person guided vehicle (cart)

4.1.3 *SWIF* — single-wafer interface

4.2 *Definitions*

4.2.1 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

4.2.2 *carrier capacity* — the number of substrates that a carrier holds (as defined in SEMI E1.9).

4.2.3 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

4.2.4 *front-opening unified pod* — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a FIMS port that complies with SEMI E62) (as defined in SEMI E47.1).

4.2.5 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

4.2.6 *single-wafer interface* — an adapter mechanism that holds a single-wafer box and that appears to the equipment to be a 300 mm FOUP (except that only the volume around the middle wafer may be accessible).

4.2.7 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

5 Requirements

5.1 *System Components* — A system that conforms to this standard must include a box that holds one wafer and that fits onto a SWIF.

5.2 *Relevant FOUP Dimensions* — The SWIF must have all of the required bottom and front features and be no larger than the maximum dimensions of a 13- or 25-wafer FOUP. However, this system (of single-wafer box and SWIF) must have info pad B in the down position (which ordinarily indicates that the carrier type is an open cassette). For example, the SWIF must comply with dimensions r67, x53, y50, y51, y52, y53, z41, z47 – z48, z47 + z49, and the upper limits on x50 and y40 (as specified in SEMI E47.1) and with dimension y33 (as specified in SEMI E62).

5.3 *Optional Automation Features* — Since the single-wafer box and/or SWIF will usually be delivered manually (possibly with a PGV), the SWIF is not required to have the other automation features of the FOUP such as the robotic handling flange on top or the fork-lift flanges on the side (although this standard does not forbid the SWIF from having such features).

5.4 *SWIF Door* — The SWIF must have a full FOUP-size door (which surrounds the door of the single-wafer box) that mates with a FIMS-compatible interface (as specified in SEMI E62) to avoid contaminating the environment on the equipment side of the FIMS interface.

5.5 *Wafer Position* — When the FIMS door is opened by the equipment, the end effector may only be able to access the middle wafer slot (wafer 7 for a SWIF that has info pad A in the down position indicating a 13-wafer carrier, and wafer 13 for a SWIF that has info pad A in the up position indicating a 25-wafer carrier), because a surface immediately behind the door may block access to the other wafer slots. Thus, batch wafer handlers will probably not work with this system.

5.6 *Wafer Clearances* — The clearance below the middle wafer must be the same as the clearance below the bottom wafer in an ordinary FOUP (z8 minus z6, both from SEMI E1.9), and the clearance above the middle wafer must be the same as the clearance above the top wafer in an ordinary FOUP (z15 from SEMI E1.9). These vertical clearances are defined in SEMI E1.9 and SEMI E47.1 and apply throughout the wafer set-down and extraction volumes for the middle wafer. The horizontal clearances shown in Figure 10 of SEMI E47.1 are also required. One possible example of such a system (of single-wafer box and SWIF) is shown in Figures 1 and 2 (with vertical clearances indicated).

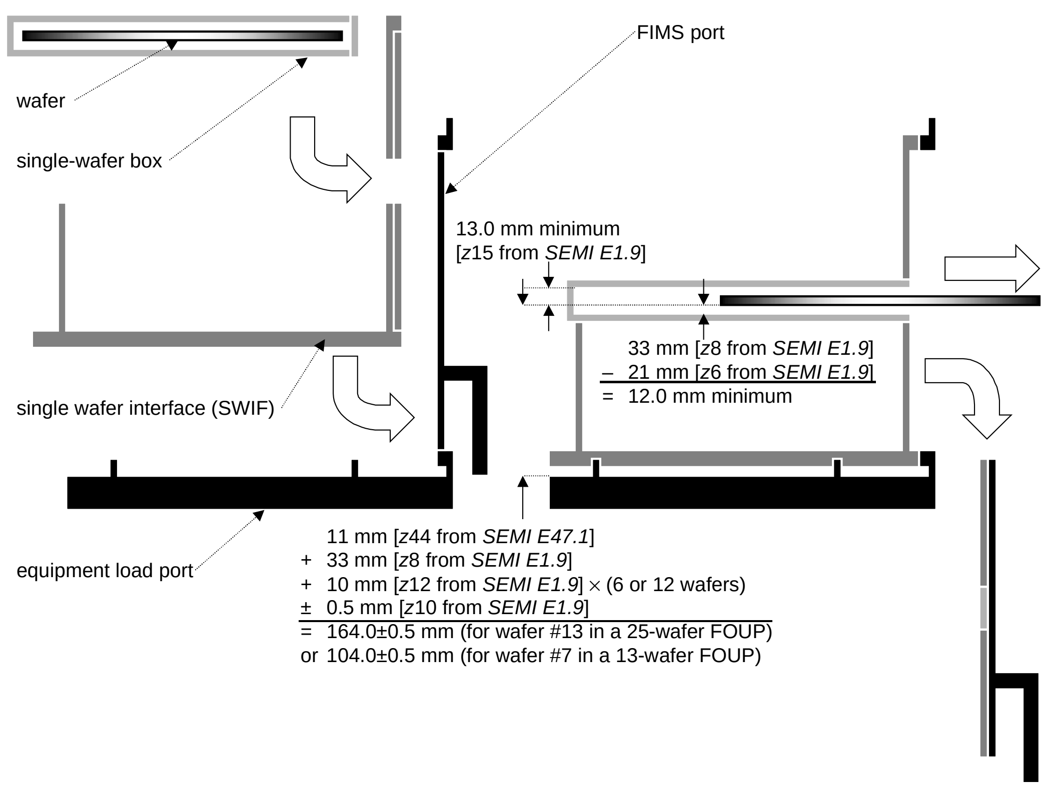

Figure 1
Side View of Example Single-Wafer Box and SWIF on a Load Port with a FIMS Interface

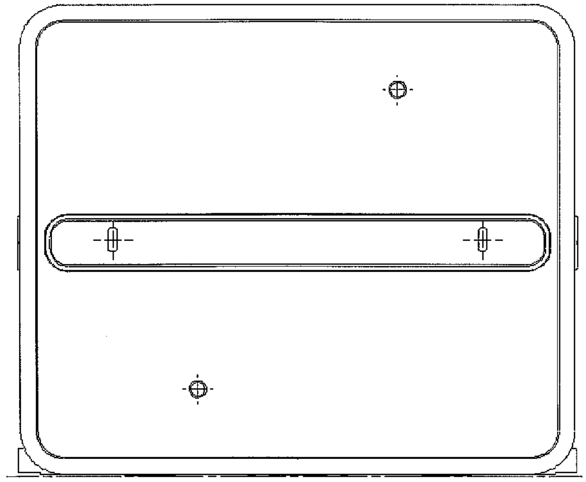

Figure 2
Front View of Example Single-Wafer Box and SWIF

5.7 *SWIF Sensing* — It is possible that the SWIF is not removed from the load port when single-wafer boxes are removed and replaced on the SWIF. However, when the single-wafer box is removed from the SWIF, all of the carrier sensing pads (defined in Section 6.6 of SEMI E1.9) on the bottom of the SWIF must be raised (so that the load port can sense a change of carriers by its carrier placement sensor, if any). However, in order to ensure that the SWIF triggers most optical carrier presence detectors on the load port, the SWIF (without a single-wafer box) must block any line of sight through a volume consisting of the smallest cylindrical section that contains all of the wafer pick-up volumes (defined in SEMI E1.9) of the corresponding FOUP (defined in SEMI E47.1). Note that this standard does not prevent the use of other kinds of carrier presence detectors (such as sensors that detect weight on the load port).

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E103 but was approved for publication by full letter ballot procedures on July 28, 2000.

R1-1 In fabs in which this system (of single-wafer box and SWIF) is used, equipment should have control software algorithms that prevent end effectors and wafer slot mappers from entering the carrier except in the clearances around the middle wafer (defined in section 5.2) when the presence of this system is detected. A variety of methods for differentiating the system from ordinary FOUPs are possible.

R1-2 Using sensors, equipment can differentiate the system (of single-wafer box and SWIF) from ordinary FOUPs. For example, sensors below the info pad B location on the load port and on the FIMS door (opposite the seal zones or the reserved spaces for vacuum application on the box door) could indicate that the carrier type is an open cassette but with a FOUP door, together implying the presence of this system (of a single-wafer box and SWIF). Note that such sensors on the load port are not currently specified in any SEMI standard.

R1-3 Carrier ID tags can inform the equipment that the load port holds this system (of single-wafer box and SWIF) instead of an ordinary FOUP.

R1-4 Messages from the host computer system can inform the equipment that the load port holds this system (of single-wafer box and SWIF) instead of an ordinary FOUP.

SEMI E104-0302
SPECIFICATION FOR INTEGRATION AND GUIDELINE FOR CALIBRATION OF LOW-PRESSURE PARTICLE MONITOR

This specification was technically approved by the Global Metrics Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on December 20, 2001. Initially available at www.semi.org January 2002; to be published March 2002. Originally published October 2000; previously published March 2001.

1 Purpose

1.1 The use of *in situ* particle monitoring (ISPM; particle measurements performed while the wafer resides inside the processing chamber) in low-pressure and vacuum applications provides a number of advantages for defect, process, and equipment management such as:

- Reduction of particle test wafers used for off-line tests and saving operator time,
- Optimization and real-time characterization of the process,
- Advanced process control,
- Advanced equipment control,
- Monitoring process chamber conditions, and
- Optimization of cleaning procedures and maintenance.

1.1.1 Therefore, ISPM achieves more equipment availability and faster ramp-up of the production, reduces cost of ownership, improves quality and yield. To reach these goals, ISPM needs to be easily integrated into new or existing process equipment and the acquisition as well as the analysis of the particle data needs to be automated. The ISPM sensor should not have any negative influence on the process and the measurement has to represent the main particle flow. The sensor should be designed to have a minimum negative impact on the parameters defined in SEMI E10 for the whole semiconductor process equipment, to achieve an advantage in capacity.

1.2 This standard is intended to stipulate operating conditions, mechanical, electrical, and communication interfaces for the use of Low-pressure Particle Detectors integrated in semiconductor process equipment. A guideline for a reference calibration of those sensors is intended to support correlation between measurements with different sensors.

2 Scope

2.1 This standard applies to particle measurement under low-pressure and vacuum conditions in semiconductor manufacturing equipment.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *SEMI Standards*

SEMI C6.5 — Particle Specification for Grade 10/0.2 Nitrogen (N_2) and Argon (Ar) Delivered as Pipeline Gas

SEMI C6.6 — Particle Specification for Grade 10/0.1 Nitrogen (N_2) and Argon (Ar) Delivered as Pipeline Gas

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E10 — Specification for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E33 — Specification for Semiconductor Manufacturing Facility Electromagnetic Compatibility

SEMI E37 — High-Speed SECS Message Services (HSMS) Generic Services

SEMI E54 — Sensor/Actuator Network Standard

SEMI E54.10 — Specification for Sensor/Actuator Network Specific Device Model for an In-Situ Particle Monitor Device

SEMI F6 — Guide for Secondary Containment of Hazardous Gas Piping Systems

3.2 *ASTM Standards*[1]

4 Terminology

4.1 *Abbreviations and Acronyms*

4.1.1 COV — Coefficient of Variation

4.1.2 HEPA — High-Efficiency Particulate Air

4.1.3 ISPM — In Situ Particle Monitor

4.1.4 LDL — Lower Detectable Limit

4.1.5 LPPD — Low-Pressure Particle Detector

4.1.6 PHA — Pulse Height Analyzer

4.1.7 RPC — Reference Particle Counter

4.1.8 ULPA — Ultra-Low Penetration Air

4.2 *Definitions*

4.2.1 *accuracy of size* — the closeness of agreement between the ascertained size of the detected particle and its real size.

4.2.2 *coefficient of variation (COV)* — the width of a distribution (in %), obtained by dividing the standard deviation of the distribution by the mean of the distribution.

4.2.3 *coincidence* — the presence of two or more particles in the detection area of the particle detector at the same time, causing the particle detector to interpret the combined signal erroneously as resulting from one larger particle.

4.2.4 *concentration* — the number of particles per unit volume, at ambient temperature T_A and pressure p.

4.2.5 *concentration limit* — the particle concentration specified by the manufacturer of the particle detector at which the error due to coincidence is 10% or less.

NOTE 2: Manufacturers may specify concentration limits at error levels other than 10%.

4.2.6 *counting efficiency* — the ratio (in %) of detected concentration divided by the actual concentration of particles of a given size or range of sizes (see appendix 2).

4.2.7 *detection area* — the area, defined through the light beam and the detection optics, in which the particles are detected. Often this area is much smaller than the cross-section of the pump line or the process chamber.

4.2.8 *high-efficiency particulate air (HEPA) filter* — filter with a minimum particle-collection efficiency of 99.97% on all particles larger than 0.3 micrometer.

4.2.9 *in situ* — refers to processing steps or tests that are done without moving the wafer. Latin for “in original position”.

4.2.10 *in situ particle monitor (ISPM)* — particle monitor used under atmospheric conditions or in low-pressure, vacuum or liquid applications to detect particles while a process is running.

4.2.11 *isokinetic sampling* — sampling of particles in a moving aerosol or fluid by matching the sample probe inlet velocity (flow speed and direction) to the velocity of the moving aerosol or fluid.

4.2.12 *lower detectable limit (LDL)* — in particle measurement: the smallest particle size that a particle detector can measure at a given flow rate with a signal-to-noise ratio of at least 3 dB and with a counting efficiency of 50% ± 10%.

NOTE 3: This is a general definition of LDL. Due to the special design of most of the LPPDs, a counting efficiency of 50% can not be achieved.

4.2.13 *low-pressure particle detector (LPPD)* — optical particle sensor for use under low-pressure and vacuum conditions to measure particles or particle levels in semiconductor process equipment.

4.2.14 *monodisperse calibration particles* — particles with known optical properties, a sizing accuracy of at least 95%, and a size distribution in which the coefficient of variation is 5% or less.

4.2.15 *optical equivalent size* — the diameter of a monodisperse calibration particle that produces the same detected scattering intensity as the localized light scatterer (LLS) under investigation under identical test conditions.

4.2.16 *particle size* — for applications, size is the optical equivalent diameter of a reference sphere with known properties as detected by a given light-scattering particle counter [as defined in SEMI C6.5 and SEMI C6.6]. For calibration, size is the mean diameter of the monodisperse sphere.

4.2.17 *resolution* — the capability of the particle detector to differentiate between particles of similar size.

NOTE 4: The procedure to define resolution is discussed in Section 9.2.3.5.

4.2.18 *sensitivity* — in particle measurement: the smallest standard particle size specified by the manufacturer that an instrument, method, or system is capable of measuring under specified conditions (with a counting efficiency of 50%; see Appendix 2). Also called minimum detectable particle size.

4.2.19 *ultrafine particle* — a particle with an equivalent diameter less than 0.1 µm [as defined in ISO 14644-1].

4.2.20 *ultra-low penetration air (ULPA) filter* — filter with a minimum particle-collection efficiency of 99.9995% on the most penetrating particle size.

4.2.21 *zero count* — the maximum particle count indicated by a particle counter, in a specified period of time, that is sampling particle-free air. This value is specified by the manufacturer, and is commonly also referred to as false call rate, false count, noise, or noise level.

4.2.22 *zero gas* — in determining contaminant contribution by gas distribution system components, a purified gas that has an insignificant particle concentration above the lower detectable limit (LDL) of the analytical instrument. This gas is used for both instrument calibration and component testing.

4.3 *Symbols*

4.3.1 A_L — the detection area (mm^2), defined through detector optics and light beam of the LPPD.

4.3.2 A_{RC} — the opening area (mm^2) of the probe inlet of the reference particle counter.

4.3.3 C_L — the number concentration (cm^{-3}) of particles in the line at the LPPD.

4.3.4 C_G — the number concentration (cm^{-3}) of particles generated from aerosol generator at given V'_G.

4.3.5 D_L — the diameter of the pump line (mm) at the LPPD.

4.3.6 d_p — the diameter of the spherical particle (µm).

4.3.7 D_{RC} — the diameter of the sample drawing line (mm) for the reference particle counter.

4.3.8 D_{VM} — the diameter of the pump line (mm) at the velocity meter.

4.3.9 p — the line pressure (torr or mbar).

4.3.10 RH — the relative humidity (%).

4.3.11 T_A — the ambient temperature (° C) around the measurement or calibration system.

4.3.12 T_G — the gas temperature (° C).

4.3.13 v_L — the velocity (m/s) of the aerosol at the LPPD.

4.3.14 $v_{L,\ min}$, $v_{L,\ max}$ — for applications, the velocity range (m/s) of the aerosol at the LPPD specified by the manufacturer.

4.3.15 V'_L — the volume flow rate (l/min) in the line at the LPPD.

4.3.16 V'_G — the volume flow rate (l/min) of the aerosol sample (measured directly behind the aerosol generator).

4.3.17 v_{VM} — the velocity (m/s) of the aerosol at the velocity meter.

4.3.18 V'_{ZG} — the volume flow rate (l/min) of the zero gas.

4.3.19 $\sigma_{V,LPPD}$ — the standard deviation of the voltage sensor signal.

4.3.20 $\sigma_{p,LPPD}$ — the standard deviation of the observed particle distribution

4.3.21 $\sigma_{d,p}$ — the standard deviation of the particles given by the particle supplier

5 Mechanical Interfaces

5.1 *Flanges*

5.1.1 One of the following vacuum flanges should be used for mounting an LPPD into a pump line or on process equipment:

ISO 2861-1 and ISO 2861-2 (ISO-KF/MF)

ISO 1609 (ISO-K and ISO-F)

ISO 3669 (ISO-K-CF)

5.2 *Space, Distances, and Installation*

5.2.1 The use of an LPPD should not have a negative impact on the process performance. The sensor location in the equipment shall ensure an optimum use of the sensor sensitivity in order to allow a measurement which is representative of the main particle flow. The influence of the process and the process equipment on the LPPD shall be minimized (thermal background radiation, vibrations etc.)

5.2.2 The standard does not specify where an LPPD should be located in original equipment, or where space should be allowed for retro-fitting. It is recognized that the location is dependent on factors including transport behavior of particles, thermal background radiation etc. The designers of semiconductor process equipment should resort to the experience of application engineers of the LPPD suppliers and the end users. However, in either case designers shall take into account access requirements for maintenance and re-calibration. In the case of retro-fitting, the design should facilitate sensor installation rather than hinder it.

6 Electrical Interfaces

6.1 *Sensor/Controller Communication*

6.1.1 Depending on the choice of the LPPD supplier and the semiconductor equipment manufacturer, one of the following interfaces for data exchange between the LPPD and process equipment controller should be used.

6.1.2 *Sensor/Actuator Network (SAN)*

6.1.2.1 The electrical interfaces of the Sensor/ Actuator Network are described in the suite of SEMI E54 standards.

6.1.3 *Serial Communication*

6.1.3.1 RS 232 C (V.24/V.28)

6.1.3.2 RS 485

6.1.4 *Others*

6.1.4.1 IEEE 488 or IEC 60625

6.2 *Others*

6.2.1 *Sensor calibration output (direct analog output)*

6.2.1.1 The analog output for access to the sensor signal used for calibration purpose should be supported.

7 Communication Interfaces

7.1 *Sensor Bus Communication*

7.1.1 It is recommended to use a Sensor/Actuator Network (SAN) for the intra-tool communication between the LPPD controller and the controller of the process equipment. This communication is based on a suite of SEMI standards including a network communication standard, several common device models (DeviceNet, SDS, Lonworks, ProfiBus etc.), and the specific device model for the sensor. The Network is described by the following suite of SEMI standards: SEMI E54. The specific device model for ISPM is described by SEMI E54.10.

7.2 *SEMI Equipment Communication (SECS)*

7.2.1 If LPPD controllers provide the collected particle data to the process equipment controller, factory automation system, or SPC system, the SECS tool-to-host communication could be used. SECS is described in the following standards:

- SEMI E5
- SEMI E4
- SEMI E37

7.3 *Attribute Definitions*

7.3.1 SEMI E54.10 addresses the minimum attributes, services and behavior an ISPM-device shall support. If any attributes and services are used by communication of the ISPM and the equipment controller via IEEE 488 (IEC 60625) or serial communication, they should be concurring.

8 Operating Conditions

8.1 To specify the operating conditions of an LPPD (temperature, humidity, electromagnetic compatibility, vibrations etc.) refer to the following standards:

- IEC 60654-1
- IEC 60654-2
- IEC 60654-3
- IEC 60654-4
- IEC 60801-1

8.2 *Temperature*

8.2.1 The LPPD should work correctly at an ambient temperature range T_A as specified in ISO 14644-5. If the use of an LPPD at an extended ambient temperature range is required, the specific LPPD should comply with these conditions.

8.2.2 The temperature T_G inside the pump line or inside the process equipment depends on the actual application. The application engineers shall check the use of LPPDs under these specific conditions. The temperature T_G is measured at the flange which the LPPD is mounted on.

8.3 *Humidity*

8.3.1 The LPPD should work correctly at an ambient humidity range RH as specified in ISO 14644-5. If the use of an LPPD at an extended ambient humidity range is required, the specific LPPD should comply with these conditions.

8.4 *Electromagnetic Compatibility*

8.4.1 The equipment should comply with SEMI E33.

8.4.2 Sensors will be incorporated into equipment either as original equipment or retro-fitted. In either case, the sensors or the equipment of which they are a part should comply with the current regulations covering EMC in the country or region where the equipment or sensor is used.

8.5 *Vibrations*

8.5.1 Process equipment designers are advised to consider the impact of vibration on the performance of the sensor while it is collecting data. Therefore, they should minimize vibrations. The designers of the LPPD sensors are also advised to consider the impact of vibrations on the equipment at a time the sensor is not collecting any data. It might be possible that these vibrations are stronger than those occurring while the sensor is collecting data.

9 Reference Calibration Procedure

9.1 The response of real contamination particles, typically with refractive indices and shapes different from calibration particles, will differ slightly from the results obtained by the procedures in this document. It is known that LPPDs with different optical design may not produce the same data from identical aerosol samples. This may happen even with similar LPPDs if calibration differences have occurred. Therefore, before the first use the sensor should be calibrated by the manufacturer. This calibration should be compliant with or should be reviewed with the following reference calibration equipment and procedure. This reference calibration allows the characterization of the performance of the LPPD under test. The LPPD should be recalibrated at regular intervals and also in case of unusual measurement readings to ensure correct results.

9.1.1 The parameters calibrated for LPPDs with sizing capability are:

- Sizing calibration,
- Resolution,
- Zero counting,
- Counting efficiency, and
- Sensitivity.

9.1.2 The parameters calibrated for LPPDs with non-sizing capability are:

- Zero counting, and
- Counting efficiency.

9.1.3 Field calibration may not necessarily require the calibration of all parameters performed by calibration at the sensor manufacturers site.

9.1.4 Due to the fact that different LPPDs might be working with different detection areas A_L, the number of counts should be printed out in counts per mm^2 detection area. Therefore, a comparison of the measurement results of different LPPDs is possible. The size of the detection area A_L shall be reported in the calibration report form. Any changes of calibration parameters or of the calibration setup shall be reported in the calibration report form. A copy of the calibration report form shall be delivered with the sensor.

9.2 *Apparatus*

9.2.1 *Materials*

9.2.1.1 *Particles*

9.2.1.1.1 Calibration particles are polymer spheres composed of polystyrene or a similar polymer, having a refractive index of 1.58-1.61+ 0i (absorption coefficient $\alpha = 0$), a sizing accuracy of at least 95%, and a size distribution in which the coefficient of variation is 5% or less. They should be traceable to a nationally or internationally recognized standard (e.g. NIST[9]).

9.2.1.1.2 The calibration particles are normally supplied in concentrations too high to be used directly in aerosol generators. The particles should be dispersed and diluted in either deionized, distilled water in accordance with ASTM D1193, Type 1, or Isopropanol. The diluent should be cleaned using a filter with a pore size no more than 10% of the size of the particles being used. The solution should be stored in a clean container. For generation and dilution of the suspension see Appendix 3. After generation the particles should be neutralized to avoid surface charge. For all tests described in this document, the concentration should be no more than 25% of the maximum recommended concentration limit specified by the manufacturer. For calibration a suitable set of particle sizes shall be used. This set should contain at least 5 sizes that cover the LDL size to at least 80% of the specified maximum size measurement capability of the LPPD.

NOTE 5: Most of the ISPM sensors are based on light scattering. The intensity of the scattered light detected by a photodetector depends on intensity, polarization state, and wavelength of the incident light beam, diameter, shape, and refractive index of the particle and the suspension fluid, as well as on the geometrical layout of the collection optics and detector. In the particle size range near the wavelength ($0.1\lambda < d_P < 10\lambda$), large oscillations can be seen in the intensity curve of the light scattered by spherical particles as a function of all these parameters. This phenomenon should be taken into account when selecting a suitable set of particle sizes for calibration. The used calibration particles should be within a monotonic response range of the LPPD response curve.

9.2.1.2 *Zero Gas*

9.2.1.2.1 Clean air or nitrogen filtered with a ULPA filter.

NOTE 6: The calibration will be executed under atmospheric pressure and zero gas. In semiconductor manufacturing, pressure and process gases will differ from the calibration conditions. This will affect the refractive index ratio of the particles and the process gas and consequently the scattering from the particles.

9 National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899-0001, USA

9.2.1.3 *Surfaces*

9.2.1.3.1 The materials of pump lines and other components should be conductive to minimize electrostatic interaction with the particles.

9.2.2 *Instrumentation (see Figure 1)* — Some LPPDs may require specialized equipment not generally available. Please contact the LPPD manufacturer.

9.2.2.1 *Fan System*

9.2.2.1.1 The fan or pump system should be adjustable to transport the aerosol and the zero gas within the stipulated velocity range $v_{L,\ min}$ ... $v_{L,max}$, specified by the manufacturer of the LPPD.

9.2.2.2 *Filter System*

9.2.2.2.1 The ULPA filter system is used for generation of zero gas. The filter system should be capable of removing particles at the minimum size detectable by the LPPD or the reference particle counter.

9.2.2.3 *Aerosol Generator*

9.2.2.3.1 An atomizer converts the monodisperse particle suspension to an aerosol by using compressed zero gas for generation and transportation of the particles. The aerosol generator should generate monodisperse particles as defined in Section 9.2.1.1 in constant and reproducible concentration C_G under constant and reproducible volume flow rate V'_G. The variation in particle concentration shall be no more than 10% as measured by the reference particle counter over a time period of 10 times or more of the sample measurement time. The generation should comply with the German VDI-Richtlinie 3491, or an equivalent standard in other countries.

9.2.2.4 *Aerosol dryer*

9.2.2.4.1 The monodisperse polymer spheres in the test aerosol shall be thoroughly dry to avoid that the particles have a water layer which would increase their size. A diffusion dryer, another appropriate instrument, or adequately dry dilution air should be used to dry the particles. The diffusion dryer uses silica gel desiccant to remove the moisture. The desiccant shall either be new or freshly regenerated. The design flow rate of the aerosol dryer shall at least match the output flow rate of the aerosol generator.

NOTE 7: Some diffusion dryers may precipitate polymer spheres and add other particles when the aerosol gets in direct contact with the silica gel.

9.2.2.5 *Neutralizer*

9.2.2.5.1 An aerosol neutralizer should be connected in line with the dryer to reduce electrostatic charges on the dry polymer spheres and to avoid electrostatic interaction with each other or the line wall. The design flow rate of the aerosol neutralizer shall at least match the output flow rate of the aerosol generator.

NOTE 8: Some electrostatic neutralizers may produce a large number of ultra-fine particles which will combine with the calibration aerosol.

9.2.2.6 *Aerosol Size Separator*

9.2.2.6.1 In the case of calibration with ultra-fine particles, a system should be used to separate single polymer spheres from the residual particles resulting from vaporization of solutions and aggregate particles consisting of several spheres. The size separation could be achieved with an electrostatic classifier or a diffusion battery.

9.2.2.7 *Aerosol Dilution*

9.2.2.7.1 If the particle concentration behind the aerosol generator is too high, the particle flow shall be diluted to achieve the required concentration and to avoid coincidence errors. The dilution should comply with the German VDI-Richtlinie 3491, or an equivalent standard in other countries.

9.2.2.8 *Aerosol Line System*

9.2.2.8.1 The system consisting of

- the aerosol generator,
- the aerosol dryer,
- the neutralizer,
- the particle size separator,
- the dilution stage, and
- tubing connecting the devices with each other and the filtered, dried and compressed zero gas.

9.2.2.8.2 The line system should be smooth, conductive, and electrically grounded to minimize electrostatic interaction of the particles with line walls and the particles themselves. The line should be as short and straight as possible with no bends with a radius of curvature less than 100 mm. Leak-free connections of the line and all devices should be ensured using appropriate fittings.

9.2.2.8.3 Figure 1 illustrates a recommended calibration aerosol generation system.

9.2.2.9 *Flow Control*

9.2.2.9.1 The velocity of aerosol and the zero gas should be within the stipulated range $v_{L,\ min}$ ... $v_{L,max}$, specified by the manufacturer of the LPPD. Dependent on the line diameter D_L, a stipulated aerosol flow is necessary. The velocity meter (e.g. thermoanemometer) or flow meter should be mounted in a line with known diameter D_{VM}.

NOTE 9: The aerosol drawn by the reference particle counter influences the velocity or flow measured by the velocity meter or flow meter if it is mounted behind the probe inlet. This is taken into account when calculating and adjusting the flow and velocity v_L at the LPPD. If the velocity meter or flow meter is mounted in front of the probe inlet of the reference particle counter, the device should have no influence on the particle size distribution measured by the reference particle counter.

9.2.2.10 *Calibration Line System*

9.2.2.10.1 The system consisting of

- a device to inject the particles into the zero gas,
- a device to mix the aerosol sample with the zero gas to obtain uniform particle concentration,
- a device to adapt the LPPD into the line (diameter D_L),
- a device to adapt the velocity meter or the flow meter,
- a device (diameter $D_{RC} = D_L$, same particle concentration as at the LPPD) to draw a defined, isokinetic sample from the line for the reference particle counter (the opening area of the probe inlet should be reported in the calibration report form), and
- tubing connecting the devices with each other and with the fan and filter system.

9.2.2.10.2 The line system should be smooth, conductive, and electrically grounded to minimize electrostatic interaction of the particles with line walls and the particles themselves. The line should be as short and straight as possible with no bends with a radius of curvature less than 100 mm. Leak-free connections of the line and all devices should be ensured using appropriate fittings.

9.2.2.10.3 Figure 1 illustrates a recommended LPPD calibration system.

NOTE 10: The distance between the device to adapt the LPPD under test and the device for sample acquisition for the reference particle counter should be as short as possible to minimize particle loss and to ensure comparable particle concentrations.

9.2.2.11 *Reference Particle Counter (RPC)*

9.2.2.11.1 The reference particle counter is required to measure the actual concentration of the monodisperse aerosol and the quality of the zero gas inside the line. Therefore, the counting efficiency of the reference particle counter is defined as 100% over the range of particle sizes used in the test. The resolution should be better than 10% at the lower detection limit of the LPPD under test. The values of the measurement should be printed out in counts per mm^2 opening area A_{RC} of the probe inlet. The sample transit line from the probe inlet and the reference particle counter should be as short and as straight as possible. Smooth, conductive, and electrically grounded materials should be used.

9.2.2.12 *Sensor Window Temperature*

9.2.2.12.1 Some LPPDs have the capability to heat their sensor windows to avoid coating of the window. A device to measure and to adjust the sensor window temperature within the operating range (measurable to 5%) should be installed in the calibration setup. The thermometer should be calibrated with an accuracy of 0.2° C.

9.2.2.13 *Pulse Height Analyzer (PHA)*

9.2.2.13.1 The external analyzer is connected with the analog sensor calibration output. The PHA should have at least 64 channels and a resolution of at least 1% of the average voltage that will be measured. The use of a PHA, which is built into the sensor electronics, is allowed if this PHA meets the criteria mentioned above. The required range and speed will depend on the performance of the LPPD under test. These parameters should be obtained by the LPPD manufacturer.

9.2.2.14 *Environmental Monitoring*

9.2.2.14.1 The environmental temperature T_A is measured by a thermometer calibrated with an accuracy of 0.2° C.

9.2.2.14.2 The environmental relative humidity RH is measured by a hygrometer.

9.2.2.14.3 The atmospheric pressure p is measured by a barometer calibrated with an accuracy of 133 Pa.

9.2.2.15 All instruments used for the reference calibration procedure shall have been checked for valid calibration in accordance with ISO 9000. Record all calibration data.

9.2.3 *Setup and Schematic*

9.2.3.1 See Figure 1.

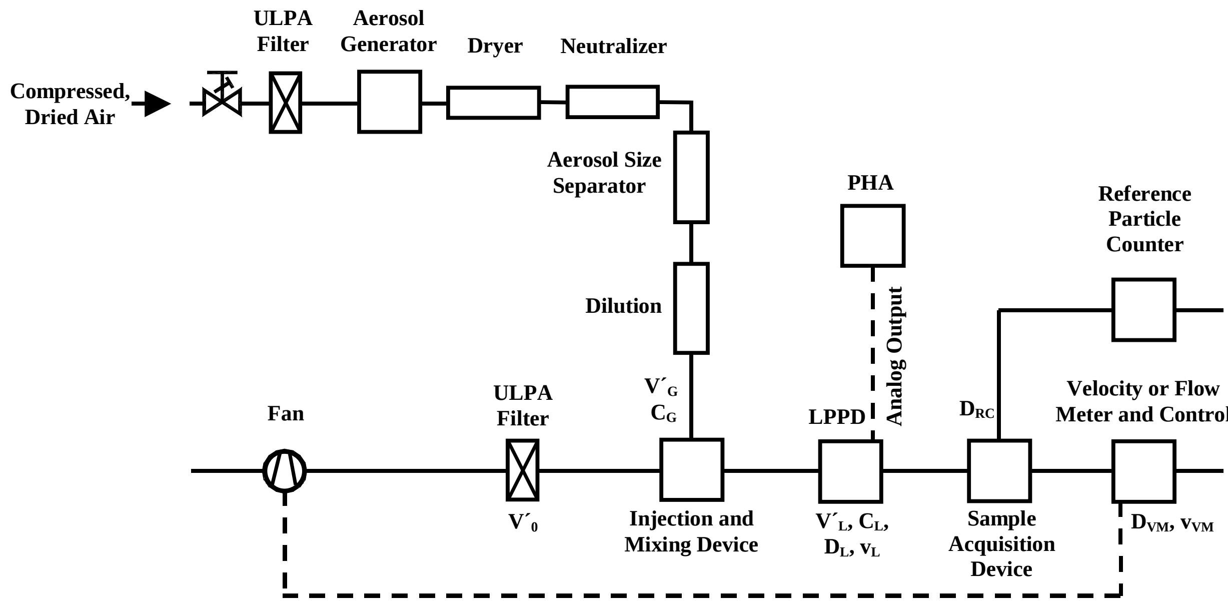

Figure 1
Calibration setup and schematic

9.3 *Calibration Procedure*

NOTE 11: Specific procedures for calibrating different LPPDs can vary considerably not only between manufacturers but between instrument models. For this reason, this document cannot provide detailed procedures for calibrating every LPPD. For detailed procedures for calibrating a specific LPPD, contact the manufacturer. The calibration should be performed by a skilled technician.

9.3.1 If the aerosol flow rate is varied, then particle residence time in the detection area A_L will also vary. This results in pulses of varying duration. Therefore, the particle velocity v_L at the LPPD should be constant and independent of the line diameter D_L. The fan has to be regulated so that the aerosol velocity at the velocity meter is $v_{VM} = v_L\ D^2_L\ /\ D^2_{VM}$. At a constant volume flow rate V'_G (depending on the pressure of the compressed air) and constant number concentration C_G the level of number concentration C_L reaches a value dependent on line diameter D_L at constant velocity v_L. With the known detection area A_L of the LPPD, the number of particles per time (counts per mm^2 detection area per time) is defined. The RPC monitors the number of particles C_L of the aerosol generator and the zero air inside the line.

9.3.2 If the response signal for the used particle size does not meet the expectations, the operator might use another particle size within the required size range.

9.3.3 *Calibration Parameters*

9.3.3.1 The sample measurement time for the calibration with each particle size should be at least 30 seconds to avoid statistical errors.

9.3.3.2 The calibration is to be performed at ambient atmospheric pressure in a controlled environment (temperature, humidity, vibrations).

9.3.3.3 The calibration of the LPPD is to be executed in a line diameter D_L in which the LPPD should be installed by the user.

9.3.3.4 Fixed particle concentration at the LPPD C_P to ensure that the coincidence error is always less than 10%.

9.3.3.5 Fixed velocity at the LPPD: v_L = 1 m/s (independent of line diameter at the LPPD).

9.3.3.5.1 Some LPPDs, e.g. a scanning LPPD for the use inside a process chamber, require a different velocity than 1 m/s for calibration. In such cases the used aerosol velocity at the location of the LPPD shall be reported in the calibration report form.

9.3.4 *Initial Setup*

9.3.4.1 Connect the aerosol generator to a supply of filtered, dried, and compressed zero gas (see Figure 1). Connect a dryer, neutralizer, and size separator (if necessary) to the aerosol outlet of the particle generator. If a dilution of the aerosol before the injection in the calibration line is necessary, install a dilution stage behind the size separator.

9.3.4.2 Connect the aerosol line to the calibration line. Mount the LPPD under test behind the injection and mixing device. Install the sample acquisition device and the velocity or flow meter into the calibration line.

9.3.4.3 Connect a PHA to the sensor calibration output if an appropriate built-in PHA is not available.

9.3.4.4 Before starting the following procedures, make sure all instruments are turned on and allow a certain time for warm-up and temperature stabilization.

9.3.4.5 Purge the aerosol line and the calibration line with filtered and dried air for a minimum of 30 minutes.

9.3.4.6 Check the quality of the zero gas and the condition of the calibration line using the RPC. Collect counts for three one-minute periods and determine the average number of particles reported in counts per minute. The volume flow of the zero gas shall be enough for correct operation of the RPC. Record the cumulative particle count reported for the zero gas for particles equal to and larger than the LDL of the LPPD under test.

9.3.4.7 Clean the aerosol generator liquid reservoir and fill it with clean diluent (particle-free deionized or destilled water or Isopropanol). Run the aerosol generator and adjust the pressure and flow rates as recommended by the aerosol generator manufacturer. Check the condition of the aerosol line using the RPC. Collect counts for three one-minute periods and determine the average number of particles reported per liter of air. If the number exceeds 1 particle per liter air, the diluent shall be refiltered before further use. The average number of particles (counts per minute) should be reported in the calibration report form.

9.3.4.8 Adjust the volume flow through the calibration line for the stipulated aerosol velocity at the LPPD under test.

9.3.4.9 Allow a certain time for stabilization of the adjusted calibration parameters before any test is performed.

9.3.5 *Sizing LPPD*

NOTE 12: For more information and background see Appendix 2.

9.3.5.1 *Size Calibration*

NOTE 13: To define the calibration settings either the mode or median of the voltage pulse distribution could be used. The use of the modal procedure is common. The calibration report form should identify the used method.

9.3.5.1.1 By running different monodisperse aerosols (with v_L and $V'_L = V'_0 + V'_G$), size calibration is performed. Begin with the largest particles for which a calibration value is required. Select the particle size range for which calibration is required. Be sure that the particle concentration is low enough that predominantly individual pulses are generated by the LPPD. Accumulate enough data to avoid statistical errors. The procedure is repeated for each particle size of interest. Determine the average LPPD pulse voltage amplitude with the PHA.

9.3.5.1.2 The mode of the voltage pulse distribution is determined by the highest point in the distribution. If the distribution is interfered with noise near the peak and the peak is not well defined, the data should be averaged and the peak of the averaged distribution should be used defining the mode.

9.3.5.1.3 The median voltage is determined by defining a “Region of Interest” (ROI) which includes the peak representing the voltage pulses from single polymer spheres. The PHA determines the total number of pulses under this peak. The median voltage is that voltage which devises the number of pulses in the region such that half are greater and half are less than the median.

NOTE 14: If the procedure is carried out for the smallest size of which the LPPD is specified, record the noise level of the LPPD. The average voltage for this size should be at least 10% higher than stated noise level voltage at which one noise pulse occurs in one minute.

9.3.5.1.4 The particle size and the average voltage should be reported in the calibration report form.

9.3.5.1.5 For calibration checks, a reference particle counter (RPC) with a good sizing capability could be used. The counting efficiency of the RPC is defined as 100% for the particle sizes used in test. The counts of the RPC and the LPPD under test in the corresponding channel should be normalized to a standard detection area (mm^2). The ratio of these counts (in %), the employed particle size and the threshold settings should be recorded in the calibration report form.

9.3.5.2 *Zero Counting*

NOTE 15: The intent of this procedure is not to adjust the thresholds for the zero count rate but to verify whether the LPPD is within its specification.

9.3.5.2.1 By running zero gas (with v_L and $V'_L = V'_0$) through the system the zero count rate, specified by the sensor manufacturer, is checked. The reference particle counter is used to check the quality of the zero gas. The minimum acceptable sample time is 10 minutes. The sampling time shall be long enough to provide adequate sampling statistics. The zero count rate (average counts per minute) should be recorded in the calibration report form.

9.3.5.3 *Counting Efficiency*

NOTE 16: The actual particle concentration is determined with a reference particle counter with a 100% counting efficiency for the employed particle size. It is important that there are no differences between the concentration within the detection area of the LPPD and the concentration monitored by the RPC.

9.3.5.3.1 By running a monodisperse aerosol (with v_L and $V'_L = V'_0 + V'_G$), the maximum of detected particles is counted. The ratio of the counts of the LPPD standardized per mm^2 to the counts of the reference particle counter per mm^2 detection area (in %) for each particle size should be recorded in the calibration report form.

9.3.5.4 *Sensitivity*

9.3.5.4.1 By running different monodisperse aerosols (with v_L and $V'_L = V'_0 + V'_G$) with particle sizes at the expected sensitivity where the counting efficiency is between 40% and 60%, the sensitivity is verified. The counts of the LPPD per mm^2 detection area compared to the counts of the reference particle counter per mm^2 detection area (in %) should be determined. The determined particle size shall have a counting efficiency between 40% and 60% and should be recorded in the calibration report form.

9.3.5.5 *Particle Size Resolution*

NOTE 17: The particle size shall be at least twice the lower counting limit to ensure measurement of the entire distribution and accurate characterization of the calibration response curve below the particle size of interest. The resolution is specified by the coefficient of variation (in %) obtained by dividing the portion of the standard deviation of the distribution σ_{LPPD} that is contributed by the LPPD by the mean size of the distribution d_p.

9.3.5.5.1 Record the size d_p and the standard deviation $\sigma_{d,p}$ of the used particles in the calibration report form. By running a monodisperse aerosol (with v_L and $V'_L = V'_0 + V'_G$), determine the standard deviation of the observed particle distribution $\sigma_{p,LPPD}$. To determine the standard deviation of the pure sensor signal $\sigma_{V,LPPD}$, a pulse height analyzer can measure the voltage peaks at the analog sensor calibration output. The portion of the standard deviation of the distribution σ_{LPPD} that is contributed by the LPPD is calculated by the following formula:

$$\sigma_{LPPD} = \sqrt{(\sigma_{p,LPPD})^2 - (\sigma_{d,p})^2}$$

9.3.5.5.2 The value of the standard deviation of the observed distribution $\sigma_{p,LPPD}$, the standard deviation of the sensor signal $\sigma_{V,LPPD}$, and the coefficient of variation (in %) should be recorded in the calibration report form.

9.3.6 *Non-Sizing LPPD*

NOTE 18: For more information and background see Appendix 2.

9.3.6.1 *Zero Counting*

9.3.6.1.1 See Section 9.3.5.2.

9.3.6.2 *Counting Efficiency*

NOTE 19: The actual particle concentration is determined with a reference particle counter with a 100% counting efficiency for the employed particle size. It is important that there are no differences between the concentration within the detection area of the LPPD and the concentration monitored by the RPC.

9.3.6.2.1 By running a monodisperse aerosol (using the smallest particles size which can be counted with v_L and $V'_L = V'_0 + V'_G$), the maximum of detected particles is counted. The counts of the LPPD per mm^2 detection area compared to the counts of the reference particle counter per mm^2 detection area (in %) and the employed particle size should be recorded in the calibration report form. These measurements should be executed for the defined set of particle sizes including one size no larger than 1.3 times the sensitivity limit as specified by the manufacturer.

9.3.7 *Interim Procedure*

9.3.7.1 Between the settings of the separate thresholds or the runs with different particle sizes, the system should be purged with zero gas for a sufficient time. The aerosol generator should be rinsed with clean diluent for a sufficient time before adding new suspension of particles with other size.

10 Calibration Report Form

10.1 The calibration report form shall contain the following information:

10.1.1 General part:

- Date and time of calibration
- Name of the operator
- Manufacturer of the LPPD
- Model and serial number of the LPPD to be calibrated (if sensor and counter are separate, model and serial number for each)
- Size of the detection area (if detection area is dependent on the particle size, all established values)
- Model, serial number, manufacturer, and date of last calibration of the reference particle counter
- Performance of the reference particle counter (volume flow, sensitivity, zero count rate)
- Environmental conditions: temperature T_A, relative humidity RH, pressure p
- Quality of zero gas as measured with the reference particle counter (counts per minute)
- Specifications of the particles used for calibration (manufacturer, certified size and tolerance, standard deviation $\sigma_{d,p}$, coefficient of variation, refractive index, lot number)
- Calibration parameters: particle concentration C_L, particle velocity v_L at the location of the LPPD, line diameter D_L, opening area A_{RC} of the probe inlet for each particle size
- Calibration procedure: sizing or non-sizing

10.1.2 For sizing LPPD:

- Size calibration: value of the average voltage of the different particle sizes, employed particle sizes, mode or median method
- Size calibration check: values of the thresholds, employed particle sizes, ratio of the normalized counts in the corresponding channel (in %)
- Zero counting: value of the zero count rate (average counts per minute), sampling time
- Particle size resolution: value of coefficient of variation, value of standard deviation of the observed distribution, mean size of the distribution, value of standard deviation of the sensor signal, employed particle sizes
- Counting efficiency: value of the counting efficiency (in %), employed particle sizes

10.1.3 For non-sizing LPPD:

- Zero counting: value of the zero count rate (average counts per minute), sampling time
- Counting efficiency: value of the counting efficiency (in %), employed particle sizes

10.2 Report significant variations from data reported from the previous calibration.

PERFORMANCE TESTING

NOTE: The material in this appendix is an official part of SEMI E104 and was approved by full letter ballot procedures on July 28, 2000 by the European Regional Standards Committee.

A1-1 The definitions of parameters and measurement of the terms described in SEMI E10 applies also to LPPDs and combined LPPD/process equipment.

APPENDIX 2
CALIBRATION NOTES

NOTE: The material in this appendix is an official part of SEMI E104 and was approved by full letter ballot procedures on July 28, 2000 by the European Regional Standards Committee.

A2-1 Size Calibration

A2-1.1 Size calibration is performed with monodisperse particles with known sizes and known optical properties. The procedure establishes the voltage response of the LPPD for these particles. The reported size for unknown particles is the same size of the monodisperse particle whose voltage response is the voltage pulse produced by the unknown particle (called Optical Equivalent Size).

A2-1.2 If an LPPD is able to detect all of the distribution (see counting efficiency) generated by a monodisperse aerosol and the size of the particle standard is known, the calibrating of an LPPD without a reference particle counter is possible. Ideally, the data collected by the LPPD observing a monodisperse aerosol would describe a Gaussian particle size distribution. However, the reported voltage pulse height distribution is often not symmetric. Therefore, the mode and modal values of the pulse height distribution are not equal. The thresholds for different particle sizes are set as the mode or median value of the observed distribution. The modal voltage method is commonly used.

A2-1.3 The intensity of the scattered light detected by a photodetector depends on intensity, polarization state, and wavelength of the incident light beam, diameter, shape, and refractive index of the particle, as well as on the geometrical layout of the collection optics and detector. In the particle size range near the wavelength ($0.1\lambda < d_P < 10\lambda$), large oscillations can be seen in the intensity curve of the light scattered by spherical particles as a function of all these parameters. Therefore, the response curve might not be monotonic. Particles of more than one size will produce the same voltage output signal. The calibration particles should be chosen so that their response is not included in such reversals of the calibration curves.

A2-1.4 For calibration checks, a reference particle counter (RPC) with a good sizing capability could be used. The counting efficiency of the RPC shall be 100% for the particle sizes used in test. The counts of the RPC and the LPPD under test in the corresponding channel should be normalized to a standard detection area (mm^2).

A2-2 Particle Size Resolution

A2-2.1 Particle size resolution of a particle detector describes its capability to differentiate between particles of nearly the same size, or it is a measure of the range of sizes which the counter would assign to a particular particle if its size was determined repeatedly. The resolution is specified by the coefficient of variation (in %) obtained by dividing the portion of the standard deviation of the distribution σ_{LPPD} that is contributed by the LPPD by the mean particle size.

A2-2.2 The employed particle size should be at least 2 times larger than the lower detection limit of the instrument and is within a monotonic response range of the LPPD response curve. The size d_p and the standard deviation $\sigma_{d,p}$ of the used particles is necessary to calculate the resolution.

A2-2.3 To determine the resolution, the standard deviation of the observed particle distribution $\sigma_{p,LPPD}$ is calculated. The quality of the photodetector is checked by determining the standard deviation of the pure sensor signal $\sigma_{V,LPPD}$ at the analog calibration output with a pulse height analyzer. The σ_{LPPD} is calculated by the following formula:

$$\sigma_{LPPD} = \sqrt{(\sigma_{p,LPPD})^2 - (\sigma_{d,p})^2}$$

A2-3 Zero Counting

A2-3.1 The intent of this procedure is not to adjust the thresholds for the zero count rate but to verify whether the LPPD is within its specification. It is assumed that the zero count level of a correct operating LPPD is sufficiently better than its specification. Failure of the verification test is due to a physical failure within the LPPD and not to statistical variation in the measurement.

A2-3.2 The output of a photodetector and the electronic circuits of the particle detector is afflicted with noise. The zero count rate verification is carried out to ensure that data, especially near the detection limit of the LPPD, is generated by particles rather than by noise. To achieve this goal, the basic thresholds for the LDL are to be set so that a signal-to-noise ratio of at least 3 dB is ensured. The sampling time shall be long enough to provide adequate sampling statistics.

A2-4 Counting Efficiency

A2-4.1 The counting efficiency for a specific particle size is defined as the ratio of the detected concentration of particles to the concentration actually present. The determination of the counting efficiency of an LPPD requires particles of known size and concentration in the aerosol. The counting efficiency is affected by several factors.

- First, the counting efficiency is dependent on a specific particle size.
- The effect of particle concentration is addressed under zero counting and coincidence.
- Due to inhomogeneous light intensity within the detection area of the particle counter, not all small particles near the lower detection limit of the instrument are detected.
- If the sampling flow is not completely contained within the defined detection area, then some portions of the aerosol will not be counted.

A2-4.2 Ideally, the counting efficiency of a particle counter covering 100% of the line cross-section area as detection area would consist of a step function at the point of the LDL. Real particle detectors have a gradual transition (efficiency curve) instead of a step function. The point with 50% detection probability of all particles of a given size moving through the detection area is often used as a reference point. The corresponding particle size is called the minimum detectable particle size (see sensitivity). If the slope of the efficiency curve for two detectors with the same specified 50% efficiency point is different, the two detectors may show different particle counts for the same polydisperse aerosol. To define an efficiency curve, more than one particle size, e.g. 5 particle sizes around the LDL covering 0% to 100% efficiency, should be used. Acceptable counting efficiency for single particle counting instruments is 50% ± 20% at the minimum detection size and 100% ± 10% for all particles larger than 1.5 times the minimum size.

A2-4.3 The detection area of most LPPDs comprises only a small portions of the cross-section area of the line. Therefore, it is not possible to specify a 50% efficiency point. For this, the commonly used definition for sensitivity could not be used for such instruments.

A2-4.4 The actual particle concentration is determined with a reference particle counter with a 100% counting efficiency for the employed particle size. It is important that there are no differences between the concentration within the detection area of the LPPD and the concentration monitored by the RPC.

A2-5 Sensitivity

A2-5.1 The particle size corresponding to the point with 50% counting efficiency of the particles of a given size is defined as the minimum detectable particle size. This is valid only for particle counters capable to reach 100% counting efficiency for a specific particle size. This does not apply to most LPPDs.

A2-6 Particle Concentration Effects

A2-6.1 All optical particle detectors are able to operate accurately only within a limited range of particle concentration. It is not the scope of this document to define how this limit is measured or how to verify the specification.

A2-6.2 *High Concentration Effects*

A2-6.2.1 The upper limitation of the particle concentration is chiefly based on coincidence effects.

A2-6.2.2 One effect is optical coincidence. If the particle concentration is too high, more than one particle is present within the detection area of the instrument. The reported particle concentration will be less than the true value, and the reported particle size distribution will be shifted towards the indication of larger particles than in reality.

A2-6.2.3 The other effect is electronic coincidence. It is defined as the inability of the electronic pulse processing system to detect and size individual pulses that are too closely spaced. If there are so many pulses that they cannot completely return to the baseline, they become superimposed. Electronic saturation occurs. Electronic coincidence introduces errors in both particle size and counts as well. Normally, this problem is not critical for modern electronic systems. Optical coincidence can become a problem at particle levels well below the point where electronic saturation occurs.

A2-6.2.4 Another error can occur when high concentrations of particles just smaller than the lower detection limit of the instrument are present. Even though no single one of these particles will be detected, scattering-light levels from these particles can increase the background optical noise level. So, errors might be produced in particle count data in the lower particle size ranges reported by the counter.

A2-6.3 *Low Concentration Effects*

A2-6.3.1 It is obvious that it is necessary to collect sufficient data to determine number and size of particles within an acceptable confidence limit.

APPENDIX 3
AEROSOL GENERATION AND AEROSOL DILUTION

NOTE: The material in this appendix is an official part of SEMI E104 and was approved by full letter ballot procedures on July 28, 2000 by the European Regional Standards Committee.

A3-1 Monodisperse Particle Suspension

A3-1.1 Monodisperse suspensions of particles (PSL) are available in sizes from 0.02 µm. These particles are grown by emulsion polymerization and are stabilized in aqueous suspensions with an anionic surfactant. They carry a negative charge which contributes to their stability. The suspension normally contains 10% solids and 2% dissolved, highly viscous stabilizer. The solid contains up to 8% emulsifier and inorganics.

A3-1.2 After evaporation, these solids and the stabilizer will both increase the diameter of the single particle and generate a residual nucleus out of an empty droplet. These residual particles are called secondary aerosol. The diameter of residual nucleus could be up to 0.25 µm according to the PSL size and dilution of the suspension. Most of these secondary aerosol particles might be too small to be detectable with commonly used particle detectors, but they will have an influence on the noise level because of there high number.

A3-1.3 Out of a high-concentration suspension it is not possible to aerosolize only individual particles. Droplets containing more than one of the suspended particles will become undesirable agglomerates upon evaporation.

A3-1.4 For this, an adequate dilution of the suspension is necessary to avoid the formation of aggregates and the enlargement of the particles.

A3-2 Generation and Dilution of PSL Suspension

A3-2.1 A diluted PSL suspension for particle generation in an aerosol generator can be created by the following procedure:

- Shaking and/or ultrasonic treatment of the PSL bottle distributed by the PSL manufacturer.
- Placing one drop of PSL in one liter of deionized or destilled water or Isopropanol. The water could be cleaned using a filter with a pore size no more than 10% of the size of the particles being used.
- Shaking and/or ultrasonic treatment of the suspension to disperse the particles.

A3-2.2 The suspension will probably need to be diluted further to provide a required particle concentration. This is necessary to avoid the formation of agglomerates and to restrict the size of the secondary aerosol particles. An equation to calculate the required particle concentration is given in “The Generation of Aerosols of Fine Particles” by O. Raabe (see Section 11).

A3-2.3 The particle suspensions distributed by the PSL manufacturer shows no detectable variation in particle characteristics when they are stored in a cool place over the years. Diluted suspensions for atomization feature an aging process. Diluted suspensions of polymer spheres smaller than 1 µm should not be stored for more than one week.

NOTE A3-1: Care should be taken to avoid contamination of the polymer spheres and the suspension.

A3-3 Aerosol Generation

A3-3.1 The diluted suspension is nebulized in the aerosol generator. Great account is taken of concentration and size distribution of the generated droplets and of the volume flow rate V'_G. To achieve a constant aerosol production, the volume flow rate and the droplet size distribution should be constant and independent of the supplies of suspension in the reservoir. The variation in particle concentration should be no more than 10% as measured by the reference particle counter over a time period of 15 minutes or more.

NOTE A3-2: Care should be taken to avoid contamination of the aerosol generator.

A3-4 Aerosol Drying

A3-4.1 The water of the generated droplets will completely evaporate when the relative humidity of the aerosol flow behind the nebulizer is lower than 70%. The volume flow of the suspension in the nozzle increases the humidity of the filtered compressed air which has a relative humidity of 10%–15% in spite of predrying. The use of a diffusion dryer or another appropriate instrument allows a higher relative humidity of the aerosol flow behind the aerosol generator. The diffusion dryer uses silica gel desiccant to remove the moisture. The desiccant shall either be new or freshly regenerated. It is not wise to get the aerosol in direct contact with the desiccant. Polymer spheres will be precipitated and additional particles out of the desiccant will change the particle size distribution of the aerosol.

A3-5 Aerosol Neutralization

A3-5.1 When dispersing the suspension, the particles are charged. This surface charge should be removed after drying the aerosol flow to avoid electrostatic interactions with each other or the line walls. With the help of the discharging distance of an electrostatic neutralizer, the aerosol is exposed to a bipolar ion source. Some electrostatic neutralizers may produce a large number of ultra-fine particles which will combine with the calibration aerosol and affects the signal-to-noise-ratio of the LPPD and the reference particle counter.

A3-6 Aerosol Size Separation

A3-6.1 When calibrating with ultra-fine particles, a particle size separation might be necessary to remove the residue particles and agglomerates. An electrostatic classifier is most effective for particle sizes less than 1 μm. This instrument electrically charges the incoming aerosol. With electrostatic deflection, it separates selected particles of one mobility. The residue particles and the larger aggregate particles would be stripped out of the particle stream consisting of the desired polymer particles. To charge the aerosol, the electrostatic classifier uses a radioactive neutralizer. The aerosol exiting the instrument will contain singly charged particles. This low charge level makes the use of an additional aerosol neutralizer unnecessary. Nevertheless, conductive tubing should be used between the aerosol generator and the LPPD and reference particle counter to minimize electrostatic particle loss.

A3-7 Aerosol Dilution

A3-7.1 The particle concentration of the aerosol generated by the nebulizer might be too high. The aerosol should be further diluted to achieve the required concentration and to avoid coincidence errors. The dilution could be executed with a mixing chamber in which the aerosol is mixed with zero gas. The internal chamber pressure should be stable and very close to ambient atmospheric pressure at operational flow rates. The spatial particle distribution in the exiting aerosol should be as homogenous as possible.

APPENDIX 4
AEROSOL TRANSPORT AND AEROSOL SAMPLING

NOTE: The material in this appendix is an official part of SEMI E104 and was approved by full letter ballot procedures on July 28, 2000 by the European Regional Standards Committee.

A4-1 Aerosol Transport

A4-1.1 Aerosol loss in lines occurs both for small and larger particles. Larger particles (approximately 5 µm and larger) are lost as a result of gravitational settling in horizontal lines and inertial effects in all lines. Smaller particles are lost to the line walls by diffusion and by electrostatic charge effects.

A4-1.2 A limitation of particle loss could be achieved with tubing as short and as straight as possible with no bends with a radius of curvature less than 100 mm. The tubing of the calibration setup should be smooth, conductive, and electrically grounded. Stainless, polished steel for rigid lines and Polyurethane or polyvinyl chloride for flexible lines is found acceptable for handling most aerosols with low electrostatic particle loss. If long transit lines are required, they should be sized to permit a Reynolds number in the range of 5,000 to 25,000 at the sample flow rate to minimize particle residence time in the tubing without causing excessive turbulence at high flow rates.

A4-2 Aerosol Sample Acquisition

A4-2.1 The term isokinetic sampling often is used in aerosol measurement and characterization. Isokinetic sampling of particles in a moving aerosol is performed by matching the sample probe inlet velocity (flow speed and direction) to the velocity of the moving aerosol. At velocities less than 15 m/s, anisokinetic sampling errors are negligible for most particles smaller than approximately 5 µm. Losses of larger particles might be significant. The larger the particle, the larger the loss due to inertial effects. Isokinetic sampling is not possible in environmental conditions with varying velocity, motionless air, and turbulent, random, or non-unidirectional flow. For better sampling inlet efficiency, isokinetic or at least isoaxial sampling is recommended at calibration.

SEMI E106-0301
PROVISIONAL OVERVIEW GUIDE TO SEMI STANDARDS FOR PHYSICAL INTERFACES AND CARRIERS FOR 300 mm WAFERS

This guide was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on October 19, 2000. Initially available at www.semi.org November 2000; to be published March 2001. Originally published October 2000. This document replaces SEMI PR6-0200 in its entirety.

1 Purpose

1.1 This document is intended to help users and suppliers of 300 mm carriers and production equipment to understand the complex interdependencies among the SEMI standards for 300 mm physical interfaces and carriers and to determine which standards apply to which products. As shown in Figure 1, these standards are highly inter-related, have many complex dependencies, and inherit a numbering system (from legacy 200 mm standards) that is non-intuitive.

2 Scope

2.1 This document describes how the SEMI standards for 300 mm physical interfaces and carriers work together. This document also clarifies the requirements (direct and indirect) on suppliers of each product, and suggests how users see these standards and options.

2.2 This document is provisional because the SEMI standards for 300 mm physical interfaces and carriers are not complete. Once all of the relevant standards have passed the balloting process, this document should be modified and upgraded from provisional status. Standards under development include documents that specify:

- carriers for thinned wafers
- load ports for frame cassettes at backend processes
- manual handoff operation interfaces at load ports

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

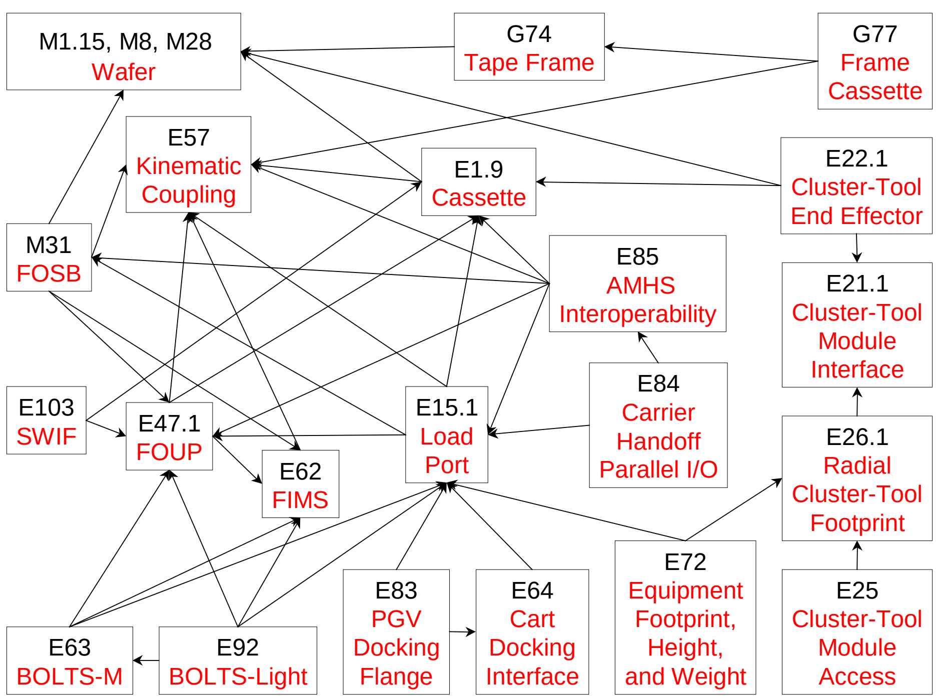

Figure 1
Complex Relationships and Dependencies Among 300 mm Standards

3 Limitations

3.1 *300 mm Only* — This document only covers SEMI standards that are specific to 300 mm, even though other standards may apply to 300 mm equipment. For example, standards not described here include:

- metrics documents such as SEMI E10;
- minienvironment documents such as SEMI E44, SEMI E45, and SEMI E46;
- facilities documents such as SEMI E70;
- reticle handling documents such as SEMI E100 which specifies a reticle SMIF pod for 6-inch or 230 mm reticles based on SEMI E19.4; or
- safety documents such as SEMI S2, SEMI S8, SEMI S11 and an upcoming Safety Guideline for Unmanned Transport Vehicle (UTV) Systems.

3.2 *Physical Interfaces and Carriers Only* — This document also does not cover standards that were generated by committees other than the SEMI Physical Interfaces and Carriers Committee, even though such standards may be specific to 300 mm. For example, standards not described here include:

- Information and Control documents such as SEMI E82; and
- Silicon documents such as SEMI M1.15, SEMI M8, and SEMI M28 (Developmental Wafers).

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E1.9 — Provisional Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Specification for 300 mm Tool Load Port

SEMI E19 — Standard Mechanical Interface (SMIF)

SEMI E19.4 — 200 mm Standard Mechanical Interface (SMIF)

SEMI E19.5 — Specification for 300 mm Bottom-Opening Standard Mechanical Interface (SMIF)

SEMI E21.1 — Cluster Tool Module Interface 300 mm: Mechanical Interface and Wafer Transport Standard

SEMI E22.1 — Cluster Tool Module Interface 300 mm: Transport Module End Effector Exclusion Volume Standard

SEMI E23 — Specification for Cassette Transfer Parallel I/O Interface

SEMI E25 — Cluster Tool Module Interface: Module Access Guideline

SEMI E26.1 — Radial Cluster Tool Footprint 300 mm Standard

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

SEMI E45 — Test Method for the Determination of Inorganic Contamination from Minienvironments

SEMI E46 — Test Method for the Determination of Organic Contamination from Minienvironments

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E57 — Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI E62 — Provisional Specification for 300 mm Front-Opening Interface Mechanical Standard (FIMS)

SEMI E63 — Mechanical Specification for 300 mm Box Opener/Loader to Tool Standard (BOLTS-M) Interface

SEMI E64 — Specification for 300 mm Cart to SEMI E15.1 Docking Interface Port

SEMI E70 — Guide for Tool Accommodation Process

SEMI E72 — Specification and Guide for 300 mm Equipment Footprint, Height, and Weight

SEMI E75 — Provisional Mechanical Specification for Box/Pod Compatible Cassettes Used to Transport and Store 300 mm Wafers

SEMI E82 — Specification for Interbay/Intrabay AMHS SEM (IBSEM)

SEMI E83 — Specification for 300 mm PGV Mechanical Docking Flange

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O Interface

SEMI E85 — Provisional Specification for Physical AMHS Stocker to Interbay Transport System Interoperability

SEMI E92 — Provisional Specification for 300 mm Light Weight and Compact Box Opener/Loader to Tool-Interoperability Standard (BOLTS-Light))

SEMI E99 — The Carrier ID Reader/Writer Functional Standard: Specification of Concepts, Behavior, and Services

SEMI E99.1 — Specification for SECS-I and SECS-II Protocol for Carrier ID Reader/Writer Functional Standard

SEMI E100 — Specification for a Reticle SMIF Pod (RSP) Used to Transport and Store 6 Inch or 230 mm Reticles

SEMI E101 — Provisional Guide for EFEM Functional Structure Model

SEMI E103 — Provisional Mechanical Specification for a 300 mm Single-Wafer Box System that Emulates a FOUP

SEMI G74 — Specification for Tape Frame for 300 mm Wafers

SEMI G77 — Specification for Frame Cassette for 300 mm Wafers

SEMI M1.15 — Standard for 300 mm Polished Monocrystalline Silicon Wafers (Notched)

SEMI M8 — Specification for Polished Monocrystalline Silicon Test Wafers

SEMI M28 — Specifications for Developmental 300 mm Diameter Polished Single Crystal Silicon Wafers

SEMI M29 — Specification for 300 mm Shipping Box

SEMI M31 — Provisional Mechanical Specification for Front-Opening Shipping Box Used to Transport and Ship 300 mm Wafers

SEMI S2 — Environmental, Health, and Safety Guideline for Semiconductor Manufacturing Equipment

SEMI S8 — Safety Guidelines for Ergonomics Engineering of Semiconductor Manufacturing Equipment

SEMI S11 — Environmental, Safety, and Health Guidelines for Semiconductor Manufacturing Equipment Minienvironments

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AGV* — automatic guided vehicle (as defined in SEMI E101).

5.1.2 *PGV* — person guided vehicle (cart) (as defined in SEMI E101).

5.1.3 *RGV* — rail guided vehicle (moving on the floor) (as defined in SEMI E101).

5.2 *Definitions*

5.2.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

5.2.2 *BOLTS plane* — a plane parallel to the facial datum plane near the front of the tool where the box opener/loader is attached (as defined in SEMI E63).

5.2.3 *box* — a protective portable container for a cassette and/or substrate(s) (as defined in SEMI E44).

5.2.4 *box opener/loader* or *BOLTS unit* — the equipment component that opens wafer carriers (if needed) and presents the carriers to the equipment's wafer handler for unloading and loading wafers (as defined in SEMI E63).

5.2.5 *carrier handler* — receives and passes the carriers from and/or to the external system (such as the factory material handling system). A carrier handler of the internal buffer type has the functions of handling and storing the carriers. A carrier handler for FOUPs has the opener(s) for opening and closing FOUPs.

5.2.6 *cart* — a floor-based carrier transfer vehicle (as defined in SEMI E101).

5.2.7 *cassette* — an open structure that holds one or more substrates (as defined in SEMI E44).

5.2.8 *docking* — the act of locating a floor-based carrier transport vehicle for carrier transfer to/from equipment (as defined in SEMI E101).

5.2.9 *equipment front end module (EFEM)* — consists of the carrier handler that receives carriers from the factory material handling system on one or more load ports (as specified in *SEMI E15.1*), opens the carriers (if needed), and may include a substrate handler for unloading and loading wafers from the carrier to the process part of the equipment (as defined in SEMI E101).

5.2.10 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

5.2.11 *fixed buffer* – EFEM configuration with carrier places only on load port units arranged in a load port group (as defined in SEMI E101).

5.2.12 *front-opening unified pod (FOUP)* — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a

FIMS port that complies with SEMI E62) (as defined in SEMI E47.1).

5.2.13 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

5.2.14 *internal buffer* — EFEM configuration with carrier places different from load port units (as defined in SEMI E101).

5.2.15 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

5.2.16 *OHT* — overhead transport system with hoist for lifting carriers between load port level and transport level (as defined in SEMI E101).

5.2.17 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19 (as defined in SEMI E44).

5.2.18 *substrate handler* — transfers substrates between carriers and the process part of the equipment (as defined in SEMI E101).

5.2.19 *wafer carrier* — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

6 Description of the Standards

6.1 *Overview* — Figure 2 shows roughly what most of the SEMI standards for 300 mm physical interfaces and carriers specify. However, this picture is greatly over-simplified. For example, a front-opening shipping box (FOSB) compliant with SEMI M31 (with its thicker door) generally cannot be opened by equipment load ports that are compliant with SEMI E63. Also, a wire link to an OHT for the carrier handoff parallel I/O can also be located at the top of the equipment. Furthermore, the atmospheric wafer handler for emptying the carrier will generally be different from the wafer handler used in the vacuum environment of the central handler module of a cluster tool.

6.2 *Kinematic Coupling* — The foundational document of the SEMI standards for 300 mm physical interfaces and carriers is SEMI E57 which specifies the mechanical couplings used to ergonomically align and precisely support 300 mm wafer carriers. The kinematic coupling consists of three pins that mate with grooves on the bottom of the wafer carrier (which are not specified) for physical alignment and support. Most of the dimensions in the SEMI standards for 300 mm physical interfaces and carriers are determined with respect to the three orthogonal datum planes defined in SEMI E57: the horizontal datum plane, the facial datum plane, and the bilateral datum plane. Such a kinematic coupling can be used at several interfaces, including:

- between a FOUP or cassette and an equipment load port or vehicle nest,
- between a transport cassette and a box, and
- between a process cassette or quartz boat and the floor of a process chamber.

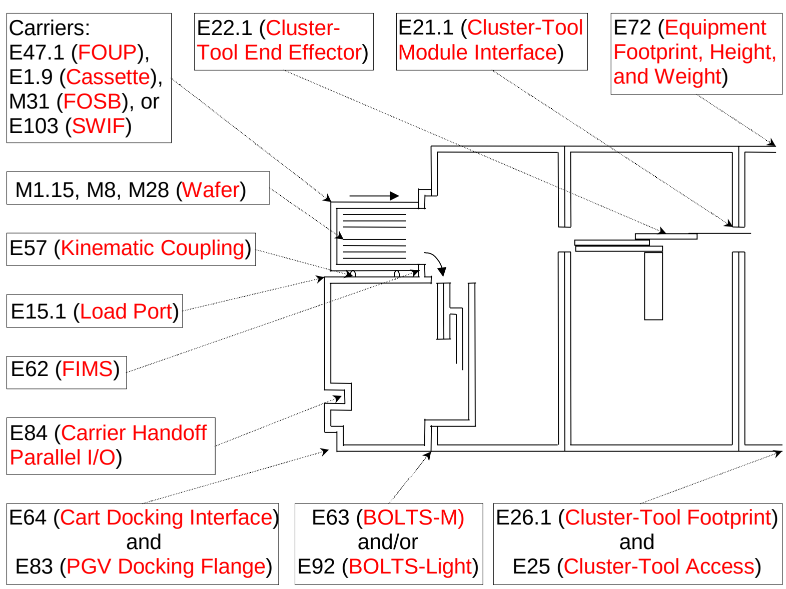

Figure 2
Key Standards for 300 mm Equipment

6.3 *Wafer Carriers* — SEMI E1.9 and SEMI E47.1 specify the carriers used to transport and store 300 mm wafers in an IC manufacturing facility. SEMI E47.1 specifies the outside features of the front-opening unified pod (FOUP). The inside features of the FOUP are specified in SEMI E1.9, which also specifies the open cassette. Both standards specify carriers that hold either 13 or 25 wafers. SEMI M31 specifies the front-opening shipping box (FOSB) used to transport and ship 300 mm wafers. SEMI E103 specifies a system that includes a box that holds only one wafer and that fits onto an adapter mechanism called a single-wafer interface (SWIF). This system appears to the equipment to be a 300 mm FOUP (except that only the volume around the middle wafer may be accessible).

6.4 *Equipment Load Ports* — SEMI E15.1 specifies the carrier load ports at the front of 300 mm process or metrology equipment (or stockers). In addition, the substrate port that opens a FOUP door is specified in SEMI E62 (FIMS). At the floor below each load port is a cart docking interface exclusion volume specified in SEMI E64; this volume can contain a PGV docking flange as specified in SEMI E83. SEMI E63 (BOLTS-M) or SEMI E92 (BOLTS-Light) or both standards specify the mechanical interface between the main part of a process or metrology tool and the box opener/loader unit that opens FOUPs and presents them to the tool wafer handler for unloading and loading 300 mm wafers. Also associated with each load port is a wire or optical link (from the equipment to the AMHS carrier delivery system) specified in SEMI E84 which is the 300 mm version of SEMI E23. SEMI E99 and SEMI E99.1 specify the electronics and communication interface between a carrier ID reader/writer and the equipment controller. SEMI E101 specifies the functional structure model and component behavior for the entire equipment front-end module (EFEM).

6.5 *Cluster-Tools* — SEMI standards for 300 mm cluster tools include SEMI E22.1, SEMI E21.1, SEMI E26.1, and SEMI E25.

6.6 *AMHS* — SEMI standards for automated material handling systems (AMHS) include SEMI E85.

6.7 *Equipment Volume and Weight* — SEMI E72 specifies limits on the footprint, height, and weight of equipment for 300 mm fabs. Separate limits are given for the parts of the equipment in the main fab and in the sub-fab. Separate limits are also given for the equipment after it is installed and for the components of the equipment as it is moved into the fab.

6.8 *Back-End Standards* — SEMI G74 specifies the tape frames used for 300 mm wafers between the dicing process and the die-bonding process. SEMI G77 specifies the mechanical features of a metal or plastic frame cassette used for framed 300 mm wafers between the wafer mounting process and the die-bonding process. Future standards may also specify the carrier for thinned 300 mm wafers and the load port for back-end process or metrology equipment.

6.9 *Standards of Uncertain Use* — Some SEMI 300 mm standards that passed balloting have a scope of application or extent of use that is yet to be fully determined. Such standards include SEMI E19.5 which specifies the bottom-opening standard mechanical interface (SMIF), SEMI E75 which specifies FOUP-compatible cassettes, and SEMI M29 which specifies a manually-opening shipping box for 300 mm wafers. In the other SEMI 300 mm standards are also some options of uncertain use such as bottom-opening pods and pods with removable cassettes.

7 Application of Standards to Products

7.1 *One-Sided Interface Specifications* — The SEMI standards for 300 mm physical interfaces and carriers are intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and inter-changeability between different types of products. To accomplish this, only one side of each mechanical interface (between different types of products) is specified, leaving the supplier of the product on the other side of the interface more freedom to improve their product. For example, only the bottom half of the kinematic coupling (the pin) is specified by SEMI E57 so that suppliers can be flexible in designing wafer carrier grooves that can mate with it. Table 1 shows which standards apply to each type of product and shows which side of the interface is specified:

- "D" indicates if the standard directly specifies that type of product (by specifying that product's side of the relevant interface).
- "I" indicates if the standard indirectly specifies that type of product (by specifying the other side of the relevant interface).

7.2 *Carriers* — A FOUP is directly specified by SEMI E47.1 (for its outside features not including the door) and by SEMI E1.9 (for its inside features). The FOUP is indirectly specified by SEMI E57 (for its kinematic coupling grooves) and by SEMI E62 (for its FIMS door interface). Thus, if a FOUP door fails to open or close correctly on any load port that complies with SEMI E57 and SEMI E62, that FOUP is in violation of the standards. The wafer support function of all of the 300 mm carriers is specified directly (by specifying where the wafers must be located rather than specifying the shape and location of the supports), so the 300 mm wafer standards indirectly specify the carriers.

7.3 *Stockers* — A carrier stocker is directly specified by SEMI E57 (for the kinematic coupling pins on its shelves, if any, and on its manual/AGV/RGV and interbay load ports), by SEMI E15.1 (for its manual/AGV/RGV load ports), by SEMI E85 (for its interbay load ports), by SEMI E84 (for its carrier handoff parallel I/O at either kind of load port) and by SEMI E64 (for the cart docking interface exclusion volume below each manual/AGV/RGV load port). The carrier stocker is indirectly specified by the carrier standards (for the volume required to store and transfer the carriers).

7.4 *Carrier ID* — A carrier ID reader/writer unit is directly specified by a future standard that specifies the electronics and communication interface between a carrier ID reader/writer and the equipment controller. The carrier ID reader/writer unit is indirectly specified by the carrier standards (which specify reserved areas for carrier ID tags) and by SEMI E15.1 (for its exclusion volume in each load port).

7.5 *Load Port and Carrier Handler Modules* — A box opener/loader (the module on a piece of equipment that includes load ports and carrier handling) is directly specified by SEMI E57 (for the kinematic coupling pins on the load port and on its shelves if it includes an internal buffer in addition to its fixed buffer), by SEMI E15.1 (for its load ports), by SEMI E62 (for its FIMS door interface), by SEMI E84 (for its carrier handoff parallel I/O), by SEMI E64 (for the cart docking interface exclusion volume below each load port), and by SEMI E72 (for its limits on footprint, height, and weight). The module is indirectly specified by the carrier standards (for the volume required to store and transfer the carriers) and by SEMI E63 and/or SEMI E92 (for the mechanical interface to the main part of the process or metrology equipment that contains the substrate handler).

7.6 *Main Part of Process or Metrology Equipment* — The main part of process or metrology equipment (including the substrate handler) is directly specified by SEMI E63 and/or SEMI E92 (for the mechanical interface to the module that includes load ports and carrier handling) and by SEMI E72 (for its limits on footprint, height, and weight). The substrate handler is indirectly specified by SEMI E1.9 (for the features inside most carriers) and it is recommended to follow the direct specifications in SEMI E22.1 (which specifies cluster-tool end effectors).

7.7 *Material Handling Systems* — A carrier transport vehicle is directly specified by SEMI E57 (for the kinematic coupling pins on the carrier nest, if any) and by SEMI E84 (for its carrier handoff parallel I/O, if any). The AMHS system is indirectly specified by the carrier standards (for the volume required to hold and transfer the carriers), by SEMI E15.1 (for equipment load ports), by SEMI E85 (for stocker load ports, if it is an OHT), by SEMI E72 (to allow for equipment height, if it is an OHT), and by SEMI E64 and SEMI E83 (for the cart docking interface exclusion volume and the PGV docking flange, respectively, below each equipment load port, if it is a floor based vehicle).

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E106 and is not meant to modify or supersede it in any way. Rather, these notes are provided primarily as a source of information to aid in the application of the standard. As such, they are to be considered as reference material only. The standard should be referred to in all cases.

R1-1 *Standards Endorsed by Users* — Section 8 lists documents in which the members of I300I and/or J300E have endorsed SEMI 300 mm standards or have specified methods for testing compliance with those standards.

SEMI E108-0301
TEST METHOD FOR THE ASSESSMENT OF OUTGASSING ORGANIC CONTAMINATION FROM MINIENVIRONMENTS USING GAS CHROMATOGRAPHY/MASS SPECTROSCOPY

This test method was technically approved by the Global Metrics Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on December 20, 2000. Initially available at www.semi.org February 2001; to be published March 2001.

1 Purpose

1.1 The purpose of this standard is to define a test method for the determination of the outgassing organic contamination from minienvironments used for storage and transport of wafers using gas chromatography/mass spectroscopy (GC/MS).

1.2 This test method is intended as an alternative to SEMI E46. The main difference between SEMI E46 and this document is that SEMI E46 defines a test method which is based on ion mobility spectroscopy (IMS) as the measurement technique while this standard is based on gas chromatography/mass spectroscopy in combination with thermal desorption. Additionally, this test method provides a procedure for testing the outgassing of organic compounds in a complete minienvironment. The results of SEMI E46 and this document are given in different units.

2 Scope

2.1 The test method provided in this document is applicable to the assessment of the outgassing of organic contamination from minienvironments.

2.2 Gas chromatography/mass spectroscopy is chosen as the method to determine organic contamination because it is commonly used for characterization and quantification of organic compounds. In combination with thermal desorption, it provides a method for the identification of organic compounds in the atmosphere (i.e., inside the minienvironment) as well as directly from source materials, and transferred contaminants. This method can also be used to evaluate materials and processes used in semiconductor industry.

2.3 This test method is based on ASTM F1982.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 The test methodologies, metrics and applications provided in this standard are limited by the following constraints:

3.1.1 The specific recovery of compounds by the proposed standard method strongly depends on the setup of the apparatus used. This has been taken into account by the use of the "reference-cocktail", see Section 9.2.

3.2 Identification of the source of organic compounds inside the minienvironment is out of the scope of this test method. For a procedure for the analysis of outgassing organic compounds from individual materials using gas chromatography/mass spectroscopy, see IDEMA M11-99.

3.3 This test method does not provide a procedure how to use the obtained data for assessing the risks that come from individual compounds.

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *analytical environment* — environment where all analytical measurements are taking place.

5.2 *headspace sampling* — in this standard defined as: collecting volatile organic compounds in an enclosed volume by means of a silicon wafer or silicon wafer chips.

5.3 *minienvironment* — A localized environment for transport and storage created by an enclosure to isolate the product from contamination and people.

5.4 *sample* — wafer or wafer chips used for the headspace sampling of organic contaminants.

5.5 *static storage conditions* — conditions excluding any active movement of test specimens.

5.6 *thermal desorption tube* — Analytical equipment capable of collecting organic compounds of interest (i.e., adsorbent filled glass tube).

5.7 *wafer* — Object made of semiconducting material to be processed, handled or stored in the minienvironment to be tested (i.e., prime or processed silicon wafer).

6 Summary of Method

6.1 This test method comprises storage tests of wafers in minienvironments under static storage conditions. The contamination is directly measured from the silicon wafer surface. Three important aspects are covered:

a) Contamination due to the minienvironment alone,

b) Contamination from the use of minienvironments for wafer processing, and

c) Contamination from future materials to be used in semiconductor technology.

6.2 The setup for each test comprises an analytical equipment in the analytical environment as well as a test equipment in the test environment. Each environment has to fulfill the following requirements:

6.2.1 *Analytical Environment* — shall be clean enough with respect to airborne organic contamination: recommendation is less than 100 pptM for organic compounds with boiling points > 150°C (Class MC-100, according to SEMI F21).

6.2.2 *Test Environment* — shall equal the environment in which the test specimen will be used.

6.3 Silicon wafers are placed in the minienvironment or used for headspace sampling experiments. These wafer samples are then analyzed by gas chromatography/mass spectrometry to determine the amount of contaminants.

6.4 The wafers or wafer chips to be used for the test method are decontaminated as described in ASTM F1982 for bare silicon wafers. The surface condition of the wafer (hydrophobic or hydrophilic) has to be adjusted in a reproducible way and has to be the same for all comparative measurements.

6.5 The wafer or the wafer chips are placed in the minienvironment and are left there under static conditions for the chosen static storage time (depending on the intended use of the minienvironment to be tested, a time between 1 h and 28 d may be used). When loaded into the minienvironment the wafer may have a temperature which reflects production circumstances (i.e., 80°C when unloading from furnace processes). In some situations wafers may be exposed to severe thermal conditions. The minienvironment should be evaluated under the conditions exposed to. Be sure that the material to be tested does not undergo phase transitions under the chosen temperature conditions.

6.6 After the static storage test period, the wafer is returned to the analytical equipment and the organic contamination on the wafer is measured immediately.

6.7 The quantitative value for the total amount of outgassed and adsorbed organics from the minienvironment is calculated as the difference between the detected amount of contamination on a blank sample vs. the amount on the exposed sample.

7 Interferences

7.1 The presence of organic contamination in the atmosphere of the test environment may lead to a significant contribution to the detected total amount of organic compounds on the test wafers or wafer chips. Care has to be taken when subtracting the blank value from the test value. Transport times from test environment to analytical environment have to be as short as possible.

8 Apparatus

8.1 For the analysis of organic compounds on wafers a gas chromatography/mass spectroscopy apparatus with thermal desorption unit is required: A gas chromatography (GC) instrument, which utilizes a capillary column to separate a wide variety of organic compounds, combined with mass spectrometer (MS). A thermal desorption unit is used to desorb organics from sample thermal desorption tubes and collect them in a trap. Two types of trapping may be used:

a) cooling the trap down to a minimum of -150°C does not require any adsorbent (glass wool may be used) or

b) a Tenax® filled trap has to be cooled down to a minimum of -25°C.

8.1.1 The thermal desorption unit is coupled to the gas chromatography instrument via a heated transfer line. This apparatus may be used directly for the desorption from wafer chips which are put in empty glass (or stainless steel) thermo desorption tubes (method A).

8.1.2 A desorption unit for complete wafers is specified in ASTM F1982. In this case sample thermal desorption tubes packed with adsorbent have to be used to trap compounds desorbed from the wafer. These thermal desorption tubes are analyzed within the thermal desorption unit (method B).

8.2 The analysis of outgassing organic contamination from minienvironments requires an extremely sensitive analytical equipment. Recovery and limit of detection for the different classes of compounds must be evaluated carefully in order to ensure reliable results.

9 Reagents and Materials

9.1 For the materials used for handling and transport of wafers clean, decontaminated equipment has to be used, e.g. tweezers heated in a propane flame. Refer to the reagent and materials described in SEMI E46 and ASTM F1982.

9.2 *Test Mixture* — For the calibration of equipment and the quantification of the amount of contamination a test mixture (”cocktail”) is used. This mixture was chosen in order to give an ”average” over typical substance classes present in semiconductor production lines, which have high sticking factors to the wafer surface. The response factor of the MS-detection for organics varies significantly. As this is true for all contaminants, the method gives a realistic trustworthy quantitative correlation to a ”typical average compound mixture” of contaminants on wafer surfaces.

9.3 *Preparation of Test Mixture*

9.3.1 The mixture consists of triethyl phosphate, ε-caprolactam, palmitic acid and diethylhexyl phthalate each 0.5 µg/µl in isooctane (as solvent). The preparation has to be done according to SEMI E46.

NOTE 2: A similar test mixture is suggested by the working group *WG 031* of the *Institute for Environmental Science and Technology* (IEST)

10 Safety Precautions

10.1 All preparation and analytical work has to be done according to local safety regulations.

11 Preparation of Minienvironment and Sample

11.1 *Minienvironment* — The minienvironment to be tested has to be used as received from the supplier. A cleaning step can be added but there must be no contribution from the cleaning procedure to the outgassing of organic compounds from the minienvironment. The cleaning method has to be defined by the supplier or agreed upon between supplier and user of the tested minienvironment.

11.2 *Sample* — The wafers shall be made organic-free before using them to monitor organic contamination. The surface condition of the wafer (hydrophobic or hydrophilic) has to be adjusted in a reproducible way and has to be the same for comparative measurements. Refer to SEMI E46 and ASTM F1982.

12 Procedure

12.1 The procedure described below is used for obtaining the baseline value of the method (method blank) as well as the test value for outgassing organic compounds of the minienvironment within a defined static storage time (storage time t_S = 1 h - 28 d).

12.1.1 Choose that static storage time according to the intended use of the minienvironment (i.e., if the maximum sit time of wafers in a process where the minienvironment is to be used is 4 h then choose a static storage time of 4 h). If no static storage time related to processes can be defined, a recommended value for the first static storage time is 1 day.

NOTE 3: Composition of adsorbed compounds may vary with static storage time.

12.2 For transport store the wafers or wafer chips used for testing in decontaminated, organic-free petri-dishes wrapped in organic-free aluminum foil. Refer to SEMI E46.

12.3 *Loading Procedure*

12.3.1 *For tests at room temperature:* open a minienvironment to be tested and load it with a decontaminated wafer using decontaminated handling tools (i.e., tweezers). Default storage location is the center slot of the minienvironment. Close the minienvironment. Leave the minienvironment closed for the chosen static storage time.

12.3.2 *For tests at elevated temperatures using a wafer furnace:* place the decontaminated wafers in a clean furnace used for production processes and heat the wafers under inert gas to a temperature > 120°C. Turn off the heating. When the temperature of the furnace has reached (90±10)°C open the minienvironment to be tested and fully load it with the hot wafers from the furnace. Close the minienvironment. Leave it closed for the chosen static storage time. For analysis use only one wafer. Default wafer is the one in the center slot.

12.3.3 *For tests at elevated temperatures using a heating chamber*: open the minienvironment to be tested and load it with a decontaminated wafer using decontaminated handling tools (i.e., tweezers). Default location is the center slot. Close the minienvironment. Wrap the minienvironment with decontaminated aluminum foil. Place the minienvironment in an inert and clean heating chamber heated to 70°C. Leave it for 1 h and then remove it from the heating chamber and place it at the test minienvironment. Leave it there closed for the chosen static storage time.

NOTE 4: The purpose of the aluminum foil is to prevent direct contact between the recirculating hot air inside the heating chamber and the minienvironment.

12.4 *Unloading Procedure* — Open the minienvironment and unload the wafer using decontaminated handling tools into decontaminated petri-dishes and wrap them into organic-free aluminum foil. Transport the wafer immediately to the measurement equipment and analyze the organic contamination on the wafer according to the standard ASTM F1982.

12.5 *Method Blank* — Perform the test sequence using a container made completely of glass or quartz instead of the minienvironment. Use the same static storage time for the method blank but perform this blank test at room temperature. The container has to be decontaminated with respect to organics inside by heat treatment (refer to SEMI E46). With this blank method the baseline contribution from the cleanroom air on the adsorption of organic contamination on the silicon wafer surface is determined.

12.6 *Analyzing Procedure* — Put the wafer or wafer chips in the precleaned desorption unit or thermal desorption tube and heat it for 10 min to a minimum of 275°C (but 400°C is better). The desorbed contaminants have to be trapped directly with the cold trap of the thermodesorption unit (method A) or first by adsorbent filled desorption tubes and then by the cold trap (method B). Desorption parameters for adsorbent filled desorption tube and cold trap may be taken from ASTM F1982 (see also Section 12.6.1).

12.6.1 The substances desorbed should be separated by an appropriate column temperature program. A recommended temperature program for standard analysis uses a polydimethylsiloxane/polydiphenylsiloxane (95/5) coated column (30 m × 0.25 mm × 0.25 µm), heated from 50°C to 250°C at a rate of 10°C/min followed by a temperature hold at 250°C for 10 min. Column flow should be about 1 ml/min He at constant flow.

12.6.2 All parameters (thermo desorption unit, gas chromatograph, mass spectrometer) should be set to yield the recommended detection limits and recovery rates (see Calibration Procedure Section 13.2).

12.7 *Materials Testing* — Materials testing can be done, using the sample preparation described in SEMI E46, but using gas chromatography/mass spectroscopy instead of IMS for the analysis of contaminants on the test wafers or wafer chips.

12.8 Perform the procedure for calibration, method blank and test (including sample preparation) in triplicate in order to obtain mean value and standard deviation for the analysis.

13 Calibration and System Performance

13.1 *Calibration* — The test mixture (2 µl liquid, equals 1 µg of each substance; see Section 9.3) is applied to the wafer or wafer chips as described in SEMI E46. The so produced reference wafer or wafer chips are handled in the same way as the samples. That means, they are put in the precleaned desorption unit or thermal desorption tube and heated for 10 min to minimum 275°C (but 400°C is better) and so on as described in Section 12.6.

13.2 *System Performance* — All parameters (thermodesorption unit, gas chromatograph, mass spectrometer) should be set to yield the specified detection limits and recovery rates (method B) for the components of the reference mixture. The limit of detection (3σ) must equal or be better than 250 ng for each of the four reference substances. The standard deviation (inaccuracy) of the calibration must be ≤ 10%. Sample measurements are not allowed, unless these requirements are fulfilled. For sample measurements the same parameters as for the calibration measurements have to be used.

14 Quantification

14.1 *Integration* — After the analysis measure the surface area (A_s) of the tested wafer or wafer chips. Summing up all the peak areas from gas chromatography/mass spectroscopy chromatogram of the wafer or wafer chips gives the total integral (I_s). Determine the total integral (I_b) of the blank wafer and the total integral of the four peaks of the gas chromatography/mass spectroscopy chromatogram of the test mixture (I_r) with the same technique.

14.2 *Calculation*

$$T_c = \left(\frac{I_s}{A_s} - \frac{I_b}{A_b} \right) \times \frac{W_r}{I_r}$$

where

$\mathbf{T_c}$	=	total of organic contaminants, [ng test mixture equivalent/cm^2]
$\mathbf{I_s}$	=	total integral from gas chromatography/mass spectroscopy chromatogram of the sample
$\mathbf{I_b}$	=	total integral from gas chromatography/mass spectroscopy chromatogram of the method blank
$\mathbf{I_r}$	=	total integral from gas chromatography/mass spectroscopy chromatogram of the peaks of the test mixture
$\mathbf{W_r}$	=	total weight amount of test mixture compounds applied to wafer [ng] { = 4000 ng}
$\mathbf{A_s}$	=	total area (cm^2) of the sample investigated (wafer or wafer chips)
$\mathbf{A_b}$	=	total area (cm^2) of the method blank (wafer or wafer chips)

15 Reporting Results

15.1 The essential results of carrying out the procedure are to be summarized in a data sheet for each experiment. The data sheet has to comprise the following information:

General data:

- Date
- Operator

Environmental data:

- Cleanroom class of analytical environment (cf. SEMI F21)
- Cleanroom class of test environment

Data concerning minienvironment:

- Type
- Manufacturer
- ID
- pretreatment (cleaning, etc.)

Data concerning sample:

- Manufacturer
- Type (resistivity, dopant)
- Surface condition (hydrophilic, hydrophobic)
- Decontamination procedure

Data concerning *analytical equipment (gas chromatography/mass spectroscopy, thermal desorption, wafer furnace or heating chamber)*:

- Manufacturer
- Type
- Limit of detection and standard deviation of calibration procedure

Data concerning *static storage test*:

- Storage temperature [°C]
- Storage relaive humidity [%]
- Time of static storage test [h]
- Wafer furnace or heating chamber used (if applicable)

Data concerning *storage test result*:

- Slot location of wafer
- Total of organic contaminants T_c
- Standard deviation of measurement (if applicable)

SEMI E110-1101[E]

GUIDELINE FOR INDICATOR PLACEMENT ZONE AND SWITCH PLACEMENT VOLUME OF LOAD PORT OPERATION INTERFACE FOR 300 mm LOAD PORTS

This guideline was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces and Carriers Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

[E] This document was modified in December 2001 to reflect proposed changes in ballot 3342A that was not made in the previous cycle. Changes were made to Table 3.

1 Purpose

1.1 This guideline defines the zones and volumes in which load port status indicators and load port operation switches should be placed. The purpose of this guideline is to give a similarity in the placement of them on a 300 mm load port. This guideline only defines the zones and volumes for them and the exact placement of them within these zone and volumes are at the direction of the load port suppliers.

1.2 The zones or volumes may be defined more precisely by standardization improvement on load port design and good unification of load port operation among device manufactures. This guideline may be improved to be a specification after this effort.

2 Scope

2.1 This guideline defines following recommended specifications for 300 mm load port.

- Indicator placement zone in which load port status indicators should be placed.
- Switch placement volume in which load port operation switch should be placed.

2.2 This guideline covers the specifications for both fixed buffer equipment and internal buffer equipment.

2.3 This guideline is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and inter-changeability at all mechanical interfaces. Only the physical interfaces for the load port are specified; no materials requirements, micro-contamination limits, use of or logic associated with the defined physical features are given in this specification.

2.4 This guideline does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *bilateral datum plane* — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

4.2 *facial datum plane* — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

4.3 *fixed buffer equipment* — production equipment that has only fixed load ports and no internal buffer for carrier storage. Substrates are loaded and unloaded directly from the carrier at the load port for processing (as defined in SEMI E87).

4.4 *horizontal datum plane* — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

4.5 *indicator placement zone* — a zone in which load port status indicators are placed.

4.6 *internal buffer equipment* — equipment that uses an internal buffer (as defined in SEMI E87).

4.7 *load port operation interface* — any indicator (e.g. lamp, LED) to visualize status information of a load port to an operator and/or any switch to be used for manual handoff operation.

4.8 *load port operation switch* — any switch to be used for manual handoff operation.

4.9 *load port status indicator* — any indicator (e.g. lamp, LED) to visualize status information of a load port to an operator.

4.10 *switch placement volume* — a volume in which load port operation switch is placed.

5 Requirements

5.1 *Indicator placement zone*

5.1.1 *Indicator Placement Zone for a Load Port per SEMI E15.1 Option 1* — It is recommended that load port status indicators should be positioned within a zone given by x400, z400, and z401. The exact placement of them within this zone is at the direction of the load port supplier. They may be located at or behind (away from the operator) the equipment boundary. Clearances required by SEMI E15.1 cannot be violated.

NOTE 2: The indicator placement zone is not an exclusion zone. No assumption can be made that this zone needs to be kept empty by the load port supplier. Furthermore, no assumption can be made that a load port must have a physical surface representing the indicator placement zone.

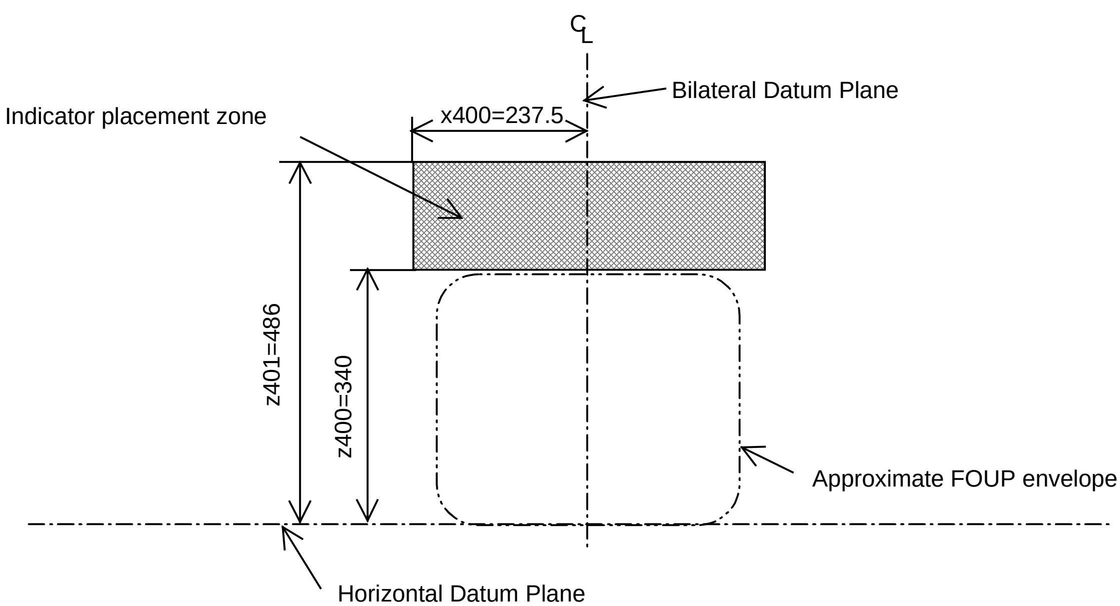

Figure 1
Indicator placement zone for a load port per SEMI E15.1 Option 1

Table 1 Dimensions of indicator placement zone for a load port per SEMI E15.1 Option1

Symbol Used	*Figure*	*Value Specified*	*Reference Measured From*
x400	1	237.5 mm (9.35 in.)	bilateral datum plane
z400	1	340 mm (13.39 in.)	horizontal datum plane
z401	1	486 mm (19.13 in.)	horizontal datum plane

5.1.2 *Indicator placement zone for a load port per SEMI E15.1 Option 3* — It is recommended that load port status indicators should be positioned within a zone given by x401, x402, z402 and z403. The exact placement of them within this zone is at the direction of the load port supplier. They may be located at or behind (away from the operator) the equipment boundary. Clearances required by SEMI E15.1 cannot be violated.

NOTE 3: The indicator placement zone is not an exclusion zone. No assumption can be made that this zone needs to be kept empty by the load port supplier. Furthermore, no assumption can be made that a load port must have a physical surface representing the indicator placement zone.

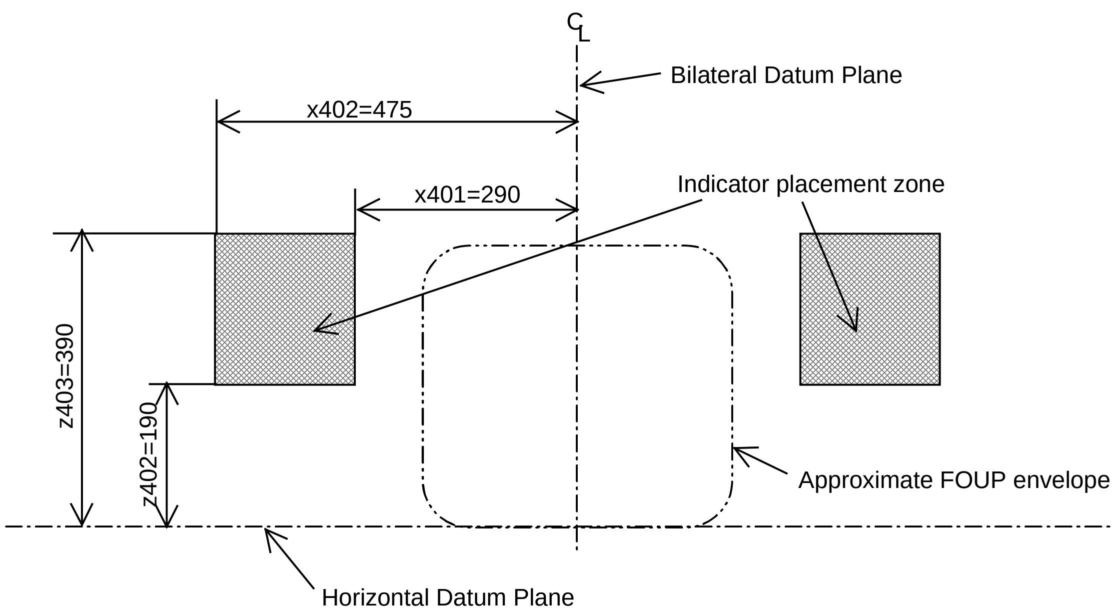

Figure 2
Indicator placement zone for a load port per SEMI E15.1 Option 3

Table 2 Dimensions of indicator placement zone for a load port per SEMI E15.1 Option3

Symbol Used	*Figure*	*Value Specified*	*Reference Measured From*
x401	2	290 mm (11.42 in.)	bilateral datum plane
x402	2	475 mm (18.79 in.)	bilateral datum plane
z402	2	190 mm (7.48 in.)	horizontal datum plane
z403	2	390 mm (15.35 in.)	horizontal datum plane

5.2 *Switch Placement Volume* — For a load port according to option 1 and 3 per SEMI E15.1, it is recommended that load port operation switches should be positioned in a way, that the surface of the switch is within a volume given by x403, x404, r400, y402 (equal to the maximum values of r67 and y53 defined in SEMI E47.1 respectively), y400, y401 (equal to the maximum value of D defined in SEMI E15.1), z404, and z405. The exact placement of the switches within this volume is at the discretion of the load port supplier.

NOTE 4: The switch placement volume is not an exclusion volume. No assumption can be made that this volume needs to be kept empty by the load port supplier. Furthermore, no assumption can be made that a load port must have a physical surface representing the switch placement volume.

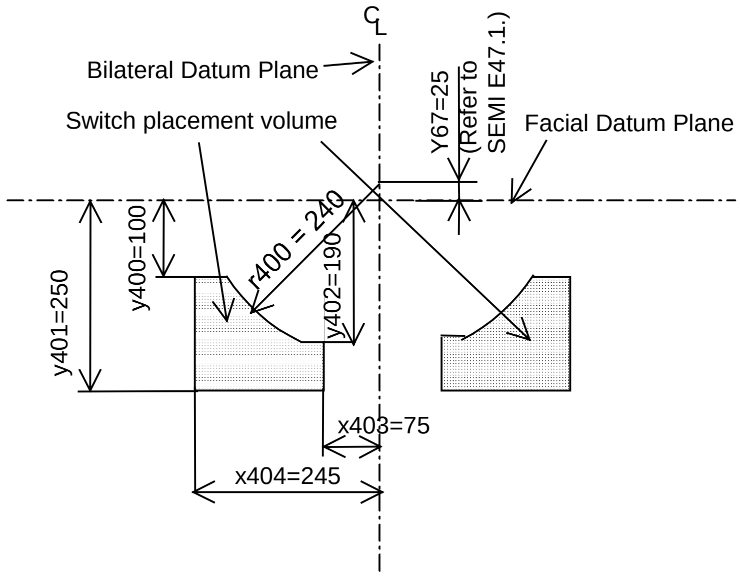

Figure 3
Top view of switch placement volume

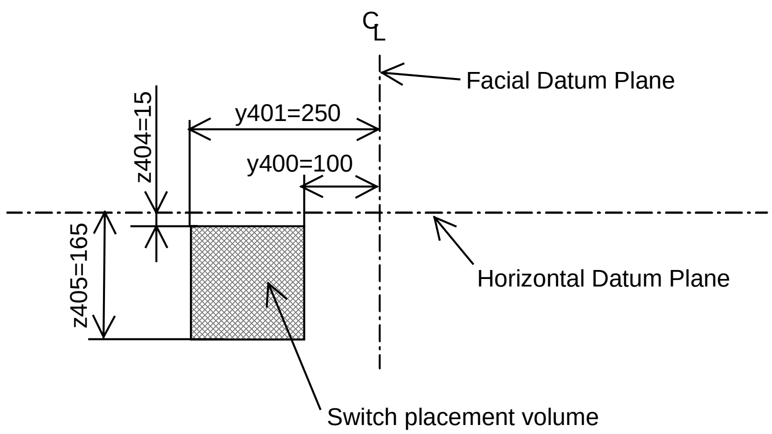

Figure 4
Side view of switch placement volume

Table 3 Dimensions of Switch Placement Volume

Symbol Used	*Figure*	*Value Specified*	*Reference Measured From*	*Remarks*
r400	3	240 mm (9.45 in)	y67 in front of nominal wafer center line	Equal to the maximum value of r67 defined in SEMI E47.1
x403	3	75 mm (2.95 in.)	bilateral datum plane	-
x404	3	245 mm (9.65 in.)	bilateral datum plane	-
y400	3,4	100 mm (3.94 in)	facial datum plane (as shown in Figure 1 of SEMI E15.1)	-
y401	3,4	250 mm(9.843 in)	facial datum plane (as shown in Figure 1 of SEMI E15.1)	Equal to the maximum value of D defined in SEMI E15.1
y402	3	190 mm (7.48 in)	facial datum plane (as shown in Figure 1 of SEMI E15.1)	Equal to the maximum value of y53 defined in SEMI E47.1
z404	4	15 mm (0.59 in.)	horizontal datum plane	-
z405	4	165 mm (6.50 in.)	horizontal datum plane	-

SEMI E111-0302
PROVISIONAL MECHANICAL SPECIFICATION FOR A 150 mm RETICLE SMIF POD (RSP150) USED TO TRANSPORT AND STORE A 6 INCH RETICLE

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the North American Physical Interfaces and Carriers Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published November 2001.

1 Purpose

1.1 This standard specifies the 150 mm Reticle SMIF Pod (RSP150) used to transport and store a 6 inch reticle in an integrated circuit (IC) manufacturing facility.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and inter-changeability at all mechanical interfaces. Most of the requirements given in this specification are in the form of maximum or minimum dimensions with very few required surfaces. Only the physical interfaces for the RSP150 are specified; no materials requirements or micro-contamination limits are given in this specification.

2.2 The pellicle exclusion volume of this specification accommodates pellicles which extend the full length of the reticle and up to a maximum pellicle width of 124 mm.

2.3 The RSP150 has the following components, sub-components, and other features. A "●" symbol indicates components or features which are *required* and a "◊" symbol indicates components or features which are *optional*.

- Top
    - ◊ robotic handling flange
- Interior
    - supports for one 6 inch reticle
    - reticle capture
    - reticle contact surfaces
    - end-effector exclusion volumes
    - 2 safety rail exclusion volumes
    - pellicle exclusion volumes
    - lateral constraints
    - 2 reticle backstops
- Sides
    - ◊ 2 side handling flanges on the sides parallel to the bi-lateral reference plane
    - 2 side handling exclusion volumes
- Bottom
    - door compatible with SMIF as defined in SEMI E19.3
    - pod latch-pin holes
    - 2 conveyor rails on the sides parallel to the bi-lateral reference plane

2.4 This standard is provisional because of the issues detailed in the related information section. Once investigation of issues in the Related Information section has been completed, this standard should be upgraded from provisional status.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

SEMI E19.3 — 150 mm Standard Mechanical Interface (SMIF)

SEMI E30.1 — Inspection and Review Specific Equipment Model (ISEM)

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI P5 — Specification for Pellicles

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *150 mm Reticle SMIF Pod* (RSP150) — a minienvironment compatible carrier capable of holding a 6 inch reticle in a horizontal orientation during transport and storage and is compatible with a Standard Mechanical Interface (SMIF) per SEMI E19.3.

4.2 *bilateral reference plane* — a vertical plane which bisects the RSP150 and is perpendicular to both the horizontal and facial reference planes and passes through the center of the 150 mm SMIF as defined in SEMI E19.3.

4.3 *facial reference plane* — a vertical plane which bisects the RSP150 and is parallel to the front side of the pod (where reticles are removed or inserted) and passes through the center of the 150 mm SMIF as defined in SEMI E19.3.

4.4 *horizontal reference plane* — a horizontal plane coplanar with the top surface of the port door as defined in SEMI E19.3.

4.5 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

4.6 *nominal reticle center line* — the line that is defined by the intersection of two perpendicular vertical planes each of which bisect the reticle at the mid-point of a side.

4.7 *pellicle* — as defined in SEMI P5.

4.8 *reticle* — as defined in SEMI E30.1.

4.9 *robotic handling flanges* — horizontal projections on the top of the box for lifting and rotating the box (as defined in SEMI E47.1).

4.10 *side handling flanges* — horizontal projections on the sides of the pod (sides parallel to the bilateral reference plane) for lifting, transportation or positioning of the pod.

5 Ordering Information

5.1 *Intended Use* — This standard is intended to specify reticle carriers over a reasonable lifetime of use, not just those in new condition. For this reason, the purchaser should specify a time period and the number and type of uses to which the carriers will be put. It is under these conditions that the carriers must remain in compliance with the requirements listed in Section 6.

5.2 *Reticle Thickness* — The purchaser needs to specify the reticle thickness to be accommodated in the RSP150.

5.3 *Optional Features* — The purchaser needs to specify whether optional components (identified in Section 2) are required.

5.4 *Temperature Ranges* — The purchaser needs to specify two sets of temperatures to which the RSP150s might be exposed. An operating temperature range is the set of environmental temperatures in which the RSP150s will remain in compliance with the requirements listed in Section 6. A temporary temperature range is the set of environmental temperatures to which the pods can be exposed such that when the RSP150s return to the operating temperature range, the RSP150s will be in compliance with the requirements listed in Section 6. Limits on exposure times to elevated temperatures should be specified.

5.5 *Electrostatic Dissipation* — The end user may require a continuous path to ground from the reticle to the carrier registration and handling features. The purchaser needs to specify whether electrostatic dissipation is required.

5.6 *Contamination Requirements* — The purchaser needs to specify their contamination requirements.

6 Requirements

6.1 *Symmetry* — Most of the dimensions of the RSP150 are determined with respect to the three orthogonal reference planes defined in this document: the facial reference plane, the horizontal reference plane and the bilateral reference plane. All dimensions are symmetric about the bilateral reference plane.

6.2 *Door* — The pod door, and its frame on the bottom of the pod, must be compatible with a port which conforms to SEMI E19.3.

6.3 *Positioning* — The nominal reticle seating plane is defined by z291, as shown in Figure 4 and Table 1. The entire bottom surface of a reticle must lie within the z276 dimension of its nominal seating plane shown in Figure 6 and Table 1.

6.4 *Reticle Capture* — When the carrier is closed, a bisecting plane through the reticle, parallel to the bilateral reference plane must be constrained by the carrier within x114 of the bilateral reference plane of the load port when the reticle is seated in the carrier. A bisecting plane through the reticle, parallel to the facial reference plane must be constrained by the carrier within y228 of the facial reference plane of the load port when the reticle is seated in the carrier.

6.5 *Reticle Contact Surfaces* — The reticle contact surfaces are the only 4 locations where the RSP150 may contact the pellicle side of the reticle. These surfaces are shown in Figures 9 and 10 with dimensions given in Table 1. The contact surfaces are defined by x245, x246, y233, y234 and y235.

6.6 *Exclusion Volumes* — The interior of the RSP150 must never intrude into the pellicle exclusion volume, and must not intrude into the end-effector exclusion volumes, lift clearance exclusion volume or safety rail exclusion volumes when the carrier is open.

6.6.1 *End-Effector Exclusion Volumes* — Volumes in an opened pod which must be free for the end-effector to enter and handle the reticle as defined by x238, x239, x240, y227, y232, y237, y238, z297, z299 and z302. No obstructions should exist in the end-effector exclusion volumes which extend in the y direction (normal to the facial reference plane.) Table 1 defines the dimensions for the end-effector exclusion volumes shown in Figures 4, 6, 7 and 9.

6.6.2 *Pellicle Exclusion Volume* — Volume in the pod below the reticle which must remain free from intrusion to accommodate the pellicle mounted on the reticle. No obstructions should exist in the pellicle exclusion volume as defined by x119 and z290 which extends in the y direction (normal to the facial reference plane). The pellicle exclusion volume is defined in Table 1 and shown in Figure 4.

6.6.3 *Reticle Lift Clearance Exclusion Volume* — Volume in an opened pod which must be free above the reticle to allow the end-effector to lift and handle the reticles, having a width defined by x243 as shown in Table 1 and Figure 4. No obstructions should exist in the reticle lift clearance exclusion volumes which extend in the y direction (normal to the facial reference plane.)

6.6.4 *Safety Rail Exclusion Volumes* — Volumes in an opened pod which must remain free from intrusion to accommodate safety rails which may be used on end-effectors to protect the edge of the reticle during handling. No obstructions should exist in the safety rail exclusion volumes which extend in the y direction (normal to the facial reference plane) as defined by x241 and z301 in Table 1 and shown in Figure 4.

6.6.5 *Rear Retainer Volume* — Volume in an opened pod in which any reticle rear retainer must exist. The volume is defined by x242, y231 and z312 as shown in Figure 7 and Figure 8 and Table 1.

NOTE 2: This volume is never to be accessed by an end-effector.

6.6.6 *Reticle Backstops* — The interior of the RSP150 shall have a reticle backstop which may be used by end-effectors to position the reticle when being removed from the RSP150.

NOTE 3: These are the minimum required backstops, the backstops may be larger than this minimum specification, occupying any part of the rear retainer volume. The dimensions are defined by x249, x250, y239 and z313 as shown in Table 1 and in Figure 7.

6.7 *External Dimensions* — Figures 1, 2, 3, 5 and 11 show, respectively, the external top view, a detail, the rear view, the robotic handling flange and the conveyor rails of the RSP150. Table 1 defines the external dimensions of the RSP150.

6.8 *Internal Dimensions* — Figures 4, 6, 7, 8, 9 and 10 show internal dimensions of the RSP150. Table 1 defines the internal dimensions of the RSP150.

6.9 *Robotic Handling Flange* — On the top of the pod is an optional robotic handling flange for automated manipulation of the RSP150. Figures 1, 3 and 5 show dimensions for the robotic handling flange. Table 1 defines the dimensions for the robotic handling flange.

6.10 *Recess* — Surface on the top of the pod defined by dimensions x100, y106 and z303. Figures 1 and 3 show dimension for the recess. The recess provides clearance for use of robotic handling flange.

NOTE 4: The raised surface around the recess is not required.

6.11 *Side Handling Flanges* — On the sides of the pod parallel to the bilateral reference plane are optional handling flanges for automated manipulation of the RSP150. Figures 1, 2 and 3 show dimensions for the side handling flanges. Table 1 defines the dimensions for the side handling flanges. No obstructions may exist in the side handling exclusion volumes which extend in the y direction (normal to the facial reference plane) as defined by x236 and z308.

6.12 *Conveyor Rails* — Surfaces on the bottom of the RSP150 used to transport the RSP on conveyors. The rails consist of smooth portions of the bottom periphery, parallel with each other, on two opposite sides, and extending at least y236 from the facial reference plane (optionally the full length) on those sides. Surfaces on these portions of the bottom periphery should be uninterrupted (i.e. no notches in the surface along the bottom or the side). No other feature of the carrier may extend below the plane defined by the surfaces of the conveyor rails. The conveyor rail surfaces are bounded by x247, x248 and y236 as shown in Figure 11. Table 1 defines the dimensions for the conveyor rails.

6.13 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*65 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*66 to prevent small contact patches with large stresses that might cause wear and particles.

NOTE 5: These limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the carrier supplier.

NOTE 6: This radius applies to every required feature unless another radius is called out specifically. Here a required feature is an area on the surface of the carrier specified by a dimension (or intersections of dimensions) that has a tolerance and not just a maximum or minimum (such as the edges of the robotic handling flange).
