NOTICE: This guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the guideline set forth herein for any particular application. The determination of the suitability of this guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. This guideline is subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI S5-93
SAFETY GUIDELINE FOR FLOW LIMITING DEVICES

NOTICE: This guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

1 Purpose

This safety guideline is intended to suggest a method to limit the rate of release of hazardous gases from the gas cylinder valve during transportation, storage, and use.

2 Scope

This guideline covers flow limiting devices for valves on cylinders containing hazardous gases. It covers uncontrolled releases of gases at or downstream of the valve outlet. It does not cover gas releases caused by failure of the cylinder, the valve connection to the cylinder, actuation of the cylinder pressure relief device, or failure of the valve.

3 Safety Warnings

3.1 *Installation* — Only the cylinder owner should install, remove, or otherwise service the flow limiting device. Special equipment and procedures may be required to perform any installation or service operation safely. No other person should install, remove, replace, clean, adjust, or otherwise alter the flow limiting device unless authorized by the cylinder owner.

3.2 *Purging* — The addition of a flow limiting device in the cylinder valve may restrict gas flow during purging. The purchaser must assure that adequate purging methods are used to prevent plugging the flow limiting device.

NOTE: The user should purge the valve after use with the same procedure used in the initial purge of the cylinder. This is important to prevent contamination of the valve and reduce the probability of creating a hazard at the cylinder supplier's plant.

4 Referenced Documents

4.1 *NFPA Documents*[1]

NFPA 704 — Standard System for the Identification of Fire Hazards of Materials

NFPA 49 — Hazardous Chemicals Data

5 Terminology

5.1 *Design Flow Rate* — The maximum flow rate exiting a gas cylinder valve when the valve is in a fully open position. All flow rates are given in standard liters per minute (slpm).

5.2 *Hazardous Gases* — Gases supplied in cylinders which are listed in NFPA 49 with a degree of hazard rating 3 or 4 in Health, Flammability, or Reactivity, or which would be so rated by experienced, technically competent persons when evaluated in accordance with the criteria set forth in NFPA 704.

5.3 *Flow Limiting Device* — A device installed in a valve that is designed to reduce the maximum flow from the valve under full flow conditions.

6 Flow Limiting Device Requirements

6.1 The valves used for gas cylinders containing the hazardous gases listed in Table 3 should be supplied with flow limiting devices. Table 3 lists those hazardous gases for which flow limiting devices can now be applied by reason of testing and experience. Annually, SEMI will consider modifying Table 3 as new information becomes available. SEMI will encourage testing by its members of hazardous gases not listed in Table 3.

6.2 The flow limiting device should be installed by the gas supplier or cylinder owner.

6.3 The flow limiting device will not allow equivalent air flows out of the valve outlet to exceed the design flow rates listed in Table 1, but will allow flow within the range indicated. The choice of design flow rate A, B, or C will be made by the purchaser.

The design flow rates in Table 1 are specified at 700 kiloPascals (kPa) (100 pounds per square inch gauge (psig)) of air. A purchaser should calculate, using the method specified in Paragraphs 6.3.1 and 6.3.2, the flow rate of the gas being purchased at various pressure to determine the proper flow limiting device for her application. The choice of the flow limiting device should be the smallest rate which satisfies the process requirements. Table 4 gives minimum flow rates for the gases listed in Table 3 at 700 kPa discharging to atmospheric pressure.

1 National Fire Protection Association, Batterymarch Park, Quincy, MA 02269

6.3.1 *Effect of Pressure*

$$Q = \frac{(P_{init} + P_{atm}) \times Q_D}{(P_D + P_{atm})} \qquad \text{(Equation 1)}$$

P_{init} is the initial gauge pressure in the gas cylinder for which the flow rate is being calculated.

Q is the maximum flow rate of the gas in slpm.

P_{atm} is standard atmospheric pressure (101 kPa or 14.7 psig) at sea level.

P_D is design final cylinder pressure for the cylinder (700 kPa or 100 psig).

Q_D is the design flow rate.

EXAMPLE: What is the maximum flow rate of air through a 4.5 slpm flow limiting device at 7000 kPa (1015 psig)?

$$Q = \frac{7000\,kPa + 101\,kPa}{700\,kPa + 101\,kPa} \times 4.5\,slpm$$

$$= 40\,slpm \text{ air}$$

NOTE: This formula is valid only for values of P_{init} and P_D greater than 101 kPa. Table 1 gives flow rates at 700 kPa. This formula corrects for pressure P.

Effect of Gas Specific Gravity

$$Q = \frac{Q_D}{\sqrt{specific\ gravity}} \qquad \text{(Equation 2)}$$

Specific gravity of the gas is relative to air. In case of mixtures, the specific gravity of the gas mixture should be used.

EXAMPLE: What is the flow range for silane at 700 kPa (100 psig) through a "C" flow limiting device?

$$Q = \frac{Q_D}{\sqrt{1.114}} =$$

$$= \frac{6.0\,slpm}{1.055} \text{ to } \frac{8.0\,slpm}{1.055}$$

Therefore, silane flow is 5.7 slpm to 7.6 slpm.

6.4 *Identification* — The preferred method of identifying the flow limiting devices or the valves, in the case of built-in devices, is by the letters A, B, or C as shown in Table 1. Other means of identification, requiring identification by the supplier as to the device installed, may be used if they are clear and unambiguous, except the single letters A-Z should not be used other than as defined herein.

6.5 *Materials* — The flow limiting device should be made of materials which are compatible with the gas in the cylinder.

6.6 *Service Life* — Removable flow limiting devices may be reused, but should be tested by the gas supplier or cylinder owner to assure that the flow rate is as listed in Table 1. Valves with non-removable flow limiting devices should be tested by the gas supplier or cylinder owner before each use to assure that the design flow is as specified in Table 1.

Table 1 Design Flow Rates for Flow Limiting Devices

Flow Limiting Device Size Designation	*Design Air Flow at 700 kPa (slpm)*	*Preferred Identification*
A	1.0–2.0	A
B	3.0–4.9	B
C	6.0–8.0	C

Table 2 Maximum Flow Rates of Air for Flow Limiting Devices

Flow Limiting	*Maximum Flows in slpm at 7000 kPa*	*Maximum Flows in slpm at 14000 kPa*
A	17.7	35.2
B	43.4	86.3
C	70.9	140.8

All flow rates and gas densities are referred to in Standard Liters per Minute at normal conditions (21.1°C, 101 kPa).

Table 3 Hazardous Gases for Use with Flow Limiting Devices

Arsine
Carbon Monoxide
Diborane
Germane

Air Flow Rate

SEMI S6-93
SAFETY GUIDELINE FOR VENTILATION

NOTICE: This guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

1 Introduction

The equipment supplier should design an internal equipment exhaust system that is efficient when connected to potential users' exhaust systems. Seldom, if ever, are users' systems designed for a specific piece of process equipment or set of process equipment. Most users' exhaust systems are designed and installed to industry-accepted exhaust principles.

2 Purpose

This document is intended to help the semiconductor equipment supplier design equipment exhaust systems to a common set of performance criteria as well as to provide assistance to both users and suppliers in the understanding of exhaust requirements for equipment systems. It is not intended to establish design specifications. The supplier will still own, and be responsible for, the information it specifies. This guideline has six concurrent performance-related objectives.

2.1 Ensure hazardous gases, fumes, and vapors are controlled (during normal operations of equipment and facilities services) such that concentrations present in the work room air should be less than 1.0% of the Threshold Limit Value (TLV), as established by the American Conference of Governmental Industrial Hygienists (ACGIH) or Permissible Exposure Limit (PEL) as published by the appropriate regulatory agency, whichever is lower.

2.2 Ensure exhaust is provided within specifications to support the proper operation of equipment.

2.3 Optimize the user's exhaust system(s).

2.4 Use the most cost effective methods to interface with user's exhaust systems.

2.5 Provide a platform for communicating "special case" exhaust requirements.

2.6 Establish guidelines for measurement and communication of equipment exhaust requirements.

3 Scope

This guideline applies to all semiconductor equipment that incorporates exhausted enclosures that are intended to be connected to user facilities' exhaust system(s). This document is written with the assumption that the users' exhaust distribution systems will be designed with central fans, ducting, and, where applicable, abatement equipment. Where users use other types of exhaust systems, equipment suppliers should acquire exhaust specifications from the users. Whether equipment is connected to a central exhaust system or to one which serves only that piece of equipment, this guideline should be applied.

4 Referenced Documents (see Appendix 2)

5 Terminology

5.1 *balancing* — Adjustments made after the ventilated equipment and the ventilation system are installed to assure that airflow to each piece of ventilated equipment is within design specifications.

5.2 *capture* — To entrain undesirable elements (gases, fumes, vapor, and particles) in the exhaust stream for removal.

5.3 *dilute* — To reduce the concentration of undesirable elements to acceptable levels. Dilution is a function of flow volume.

5.4 *flow velocity (V)* — The average speed at which the effluent stream travels through the exhaust duct. It is measured in meters per second (m/s) or feet per minute (fpm).

5.5 *flow volume (Q)* — The volumetric flow rate of the effluent stream passing a given location in the exhaust system per unit of time. It is measured in cubic meters per second (m^3/s) or cubic feet per minute (cfm).

5.6 *initiate motion* — To use an exhaust stream to start contaminants (or machine parts) moving from a rest position.

5.7 *long radius elbow* — An exhaust duct elbow that has a center line radius 1.5 or more times the duct diameter.

5.8 *set point tolerance* — The range (+/-) of static pressure within which an exhaust enclosure will perform efficiently and effectively.

5.9 *static pressure (SP)* — The measure of differential pressure across the duct wall to the ambient pressure (inside the duct). The unit of measure is pascals (Pa, Newtons per square meter (N/m^2)) or inches of water.

5.10 *traverse measurements* — Multiple air flow measurements taken at points of equal separation, in a matrix pattern, along the face plane of an exhaust duct or opening in an exhaust enclosure.

5.11 *vena contracta* — A point in a duct where the diameter of the air stream is smaller than the diameter of the duct.

6 Attributes of Typical Semiconductor Facilities' Exhaust Systems

6.1 A typical semiconductor facility's exhaust system has three measurable working elements: (1) flow velocity, (2) flow volume, and (3) pressure.

6.1.1 Flow Volume is related to the Flow Velocity by the equation Q = VA. In this equation, Q = volumetric flow rate, V = average velocity, and A = duct cross sectional area (m^2 or ft^2).

6.2 There are three duct pressure measurements possible: (1) static pressure, (2) velocity pressure, and (3) total pressure.

6.2.1 In exhaust distribution systems with central fans and abatement equipment (typical of semiconductor facilities), exhaust duct pressure (static) upstream of the fan is less than the ambient pressure outside of the duct.

6.2.2 While Velocity Pressure (VP) and Total Pressure (TP) provide a more reliable measure of Flow than Static Pressure, VP and TP are normally not specified for semiconductor facilities' exhaust systems; therefore, they will not be discussed in these guidelines. If more information is desired on VP or TP, it can be found in "Industrial Ventilation" (Appendix 2, Reference 1).

7 Exhaust Usage Typical of Semiconductor Operations

Semiconductor equipment typically uses exhaust to perform one or more of the following tasks:

7.1 *Capture* — Capture should occur as close to the source as practical to prevent exposure of personnel or products to the undesirable elements.

7.1.1 Capture is a function of Flow Velocity. Chapter 3 of "Industrial Ventilation," A Manual of Recommended Practice, 20th Edition, (Appendix 2, Reference 1) outlines the design principles and required velocity calculations for proper capture of process emissions.

7.2 *Moving* is also a function of Flow Velocity. The exhaust requirements specified by the equipment supplier should be adequate to maintain motion of undesirable elements once they are captured in the exhaust stream.

7.3 *Dilution* is a function of Flow Volume. Dilution may also provide reactive elements to undesirable elements entrained in the exhaust stream (for example, air and silane).

7.4 *Holding* — The movement of the exhaust stream is often used to activate and hold safety control devices, such as vane switches or differential pressure gauges in the active state. Such safety control devices should be used to sense adequate exhaust pressure or flow to ensure safe operation of the process equipment.

7.5 *Initiation of Motion* — The use of exhaust to intiate motion in the semiconductor industry is a special case application and should be resolved at the time of purchase. Most semiconductor-related gases, vapors, fumes, and fine particles (less than 20 microns in diameter) move with the air in which they are mixed.

8 Key Elements of Exhaust Specifications

8.1 SEMI S2 establishes specific requirements for exhaust enclosures of equipment that use hazardous materials. Access to enclosures serving hazardous materials requires special design. If there is a potential for exposure of personnel to hazardous materials when the access hatch is open, an average face velocity (measured at the hatch opening) sufficient to capture the hazardous materials should be maintained in the hatch opening. (SEMI S2 also has recommendations for exhaust monitoring and alarms. S2 should be fully understood before designing exhaust systems for hazardous materials.)

8.2 Properties of chemicals (density, vapor pressure, boiling point, flammability, etc.), the state of the materials within the exhausted enclosure (solid, liquid, or gas), and conditions such as temperature and concentration will determine the final design and exhaust specifications of the equipment enclosure. Equipment suppliers should use available reference books and Material Safety Data Sheets (MSDS) to obtain information on chemical properties. The equipment's process requirements will dictate the state and condition of the material.

8.3 When developing specifications for equipment exhaust systems to be given to the equipment user, equipment suppliers should incorporate all of the key elements that will provide clear and accurate information. These key elements are:

1. Point of measurement.
2. Duct size at the point of measurement.
3. Flow through the duct.

4. Air density.
5. Temperature of the exhaust stream when it enters the exhaust system.
6. Static pressure at the point of measurement.
7. Physical condition of the process equipment at the time of measurement.
8. Peak, normal, and special exhaust requirements.
9. Equipment environmental conditions anticipated (installed).
10. Stability and tolerance requirements of the specifications.
11. Priority of exhaust attributes when the system is balanced. (What is the primary intent of the exhaust, secondary, etc.?)
12. Instruments and practices used (and recommended) for taking measurements.
13. Design information on the complete equipment exhaust system (including materials of construction).
14. Constituents of the exhaust stream.

Each of these key elements is discussed in detail in Sections 8.3.1 through 8.3.14.

8.3.1 The point of measurement for the equipment exhaust duct should be clearly defined. Information given to locate the point of measurement should include a diagram of the exhaust connection with locations of the traverse points used.

8.3.1.1 Turbulence in the duct at the point of measurement should be minimized. The measurement point should be in a straight section of duct. It should be downstream in the connecting duct past the vena contracta from the last transition made in the equipment. It should be far enough from fittings, dampers, or sprinkler heads to minimize their interference with the measurements. Normal recommended practice is 7.5 duct diameters from any point of connection or fitting. See "HVAC Systems Testing, Adjusting, and Balancing," (Appendix 2, Reference 3).

8.3.1.2 Equipment users typically use a throttling damper for exhaust balancing where the equipment drop connects to the rest of the exhaust system. Balancing measurements should be taken on the equipment side of these balancing dampers. The supplier may elect to provide a damper, at or near the equipment connection point, to be used only as a trimming device over a narrow performance band around the equipment flow and pressure specifications. Features of this damper should be designed to prevent complete blockage of exhaust flow.

8.3.2 Duct size is the inside diameter of the exhaust connection from the equipment. The supplier should provide any other dimensions needed to design the connection of the exhaust system to the equipment.

8.3.2.1 The duct size of the equipment connection should fall in the low flow velocity range of the duct friction table. See "HVAC Systems Duct Design" (Appendix 2, Reference 2). Low flow velocity ducts will promote flexibility and ease of interface to exhaust systems serving multiple equipment. When particles are to be captured and removed, design the system for the minimum flow velocity that will ensure capture.

NOTE: Exhaust system designers should always keep in mind the difficulty that can be experienced in flow velocity measurements in unduly large ducts. Tool connections should be sized for accurate flow measurements.

8.3.2.2 The design of the equipment exhaust connection should allow for long radius connecting elbows at the point of connection. This will reduce friction losses. Additionally, the equipment supplier should avoid configurations that would require an angle of entrance into the user's branch ducts of greater than 30 degrees.

8.3.2.3 Duct connection configuration should be such that liquid spills or releases within the equipment enclosures will not enter the facility's exhaust system.

8.3.3 Flow through the equipment enclosure, and the duct at the point of connection, can be specified in velocity or volume. Normally, the balancing engineer will measure Flow Velocity and convert velocity to Flow Volume using the equation Q = VA. (See Section 6.1.1.)

8.3.3.1 Section 8.3.6 of this document shows the pressure guidelines for semiconductor exhaust systems. The equipment supplier should establish, through testing, the Flow Velocity and Volume required for efficient operation of its equipment's exhaust system. The user and the supplier should agree, before the purchase of the equipment, on the safety control devices to be used. Any safety control device requiring flows or pressures outside these ranges is a special case and should be resolved at the time of purchase.

8.3.4 Exhaust specifications should be stated in Standard Air Density (kg/m^3 or lb/ft^3), as defined in "Industrial Ventilation," (Appendix 2, Reference 1). If the measurements are of non-standard air, state the correction factor for density. Users should correct field balancing measurements taken above 600 meters (2000 feet) elevation before comparing them to suppliers' specified data. Additionally, the supplier-specified data must be corrected to sea level if it was measured above 600 meters elevation.

8.3.4.1 Flow measurements taken at other than standard air temperatures (21.1°C (70°F)) should be corrected to standard conditions.

8.3.4.2 Corrections for altitude and temperature should use the following relationship:

$M^3/s = (m^3/s)(294.3/T_K)(D)$

$CFM = (cfm)(530/T_R)(D)$

M^3/s = Standard cubic meters per second

m^3/s = Measured cubic meters per second

CFM = Standard cubic feet per minute

cfm = Measured cubic feet per minute

T_K = Measured temperature in degrees K ($T_K = T_C + 273.2$)

T_C = Measured temperature in degrees C

T_R = Measured temperature in degrees R ($T_R = T_F + 459.7$)

T_F = Measured temperature in degrees F

D = Altitude density correction factor

Altitude	*Density Correction Factor*
sea level	1.00
300 m (1000 ft)	0.96
600 m (2000 ft)	0.93
900 m (3000 ft)	0.89
1200 m (4000 ft)	0.86
1500 m (5000 ft)	0.83

8.3.5 The expected temperature of the exhaust stream (from the supplier's equipment) at the connection to the user's exhaust system should be included in the specifications. The connecting duct material should be compatible with this temperature. The normal operating and maximum high and minimum low temperatures should be specified.

8.3.6 Static pressure is measured at the same traverse point as discussed in Section 8.3.1. The equipment specifications should define the minimum Static Pressure, at the point of connection, required for proper equipment operation.

8.3.6.1 The target Static Pressure range at the point of connection to equipment is -125 to -250 Pa (-0.5 inches to -1.0 inches of water). This permits flexibility of equipment placement with minimal need for pressure boosting devices, such as booster fans.

8.3.6.2 For exhaust Static Pressure requirements lower than -1.0 inches of water, the equipment supplier must establish, with the user's concurrence, the specifications for a safe booster add-on device. A larger negative number is a lower exhaust pressure. Normally, users will install boosters only when their exhaust distribution system cannot reach the specified static pressure. As each user's facility is unique, booster add-on devices should be separate from the equipment's functional design and used only as a last resort.

8.3.7 The physical settings and configuration of the process equipment when specified flow and pressure measurements are made is critical to the repeatability of the measurements.

8.3.7.1 Exhaust enclosures, capture zones, and entry points in the equipment should isolate the area to be exhausted from adjacent areas. Internal ducts, partitions, and guide plates in the equipment should be leak tight to prevent the release of contamination from the exhaust stream.

8.3.7.2 To capture, move, or dilute contaminants effectively within the equipment's exhaust enclosure, there must be a continuous supply of make-up air. The enclosure should be designed such that the make-up air is drawn from a selected area through designed openings in the enclosure walls. Care should be taken to ensure the make-up air does not contain, or potentially contain, vapors or fumes that could be incompatible with the exhaust enclosures material of construction, components, or target materials being exhausted.

8.3.7.3 Minimize the volume of the enclosures where possible to reduce the load on the exhaust system and on its companion make-up air system.

8.3.7.4 Enclosures supplied with, or as part of, equipment should be designed so that exhaust properly sweeps all potential emission release points.

8.3.7.5 Aerodynamic "dead spots" inside the enclosure should be minimized.

8.3.7.6 Components that have no potential for release should be located outside the enclosure, when possible. Additionally, the handles for any valves located inside the exhausted enclosure should be positioned outside of the enclosure to reduce the need to open the enclosure.

8.3.7.7 Verification that the exhaust enclosure provides the desired capture of contaminants can be accomplished by using Sulfur Hexafluoride as a tracer gas (see SEMI F15). Verification that aerodynamic "dead spots" have been eliminated can be accomplished by use of “clean smoke” generated from a deionized water vapor generating system.

8.3.7.8 Once capture has been verified, measurements should be taken at specific openings (make-up air slots, access ports, or windows, etc.) to establish the minimum flow velocity necessary at these specific openings to achieve capture.

8.3.7.9 Record the position of covers, doors, dampers, valved openings, etc., and flow restrictions (such as fluid levels in vessels which exhaust air serves or flows through) at the time of the ventilation tests so that the test can be duplicated.

8.3.7.10 The supplier should specify how to duplicate these conditions at the time of field adjustment and balance. If the original conditions are not duplicated, the exhaust losses through the equipment may vary. The major risk is that the equipment exhaust level will be set as close to the suppliers’ specifications as possible and may not provide the safety level intended during actual equipment operation.

8.3.8 The equipment may require different exhaust flow or pressure during the process cycle than in standby or maintenance modes. The supplier should provide specifications for normal operating mode demands, peak demand, and any other demand level required for employee safety. The normal, peak, and other critical safety condition demands should be compensated for in both the system design and the field balance.

8.3.9 Equipment data used to establish exhaust specifications should reflect the equipment’s environmental conditions anticipated when installed (e.g., bulkhead mounted equipment is supplied with data for a bulkhead installation).

8.3.9.1 Typical user clean rooms are designed using the “bay” and “chase” concept. The bay is served with 100% ceiling-supplied, HEPA-filtered air. Vertical air flow below the ceiling is typically 0.5 m/s (100 FPM) across the entire bay. The chase section is the return air plenum for the bay air supply system. The typical pressure differential across the bay wall is 2.5 to 7.5 Pa (0.01 to 0.03 inches of water), with the lower pressure on the chase side.

8.3.9.2 Bulkhead or through-the-wall mounted equipment should tolerate this pressure differential.

8.3.9.3 Cabinet or enclosure exhaust applications should be designed so that back streaming into the clean bay or chase is prevented.

8.3.10 The set point tolerance at time of initial installation should be included in the specification. Performance stability over time for the exhaust flow and pressure requirements, needed to support equipment operations and safe working conditions, should also be specified.

8.3.10.1 The users’ exhaust distribution systems typically hold a balance setting ±10% of the set point(s) over time. Equipment which integrates high or low exhaust level alarms, requiring tighter stability control, are special cases and should be identified at the time of purchase.

8.3.10.2 The supplier-specified set points for Exhaust Flow, Volume, and Pressure should include a tolerance of -0% +10%. (This is the common acceptance range established for exhaust distribution system balance.)

8.3.11 The five methods of exhaust use discussed in Section 7 drive different priorities when establishing exhaust specifications.

8.3.11.1 The “initiate motion” and “hold” functions are either pressure or velocity driven, depending on the safety equipment selected by the supplier.

8.3.11.2 “Capturing” and “moving” are typically velocity-dependent.

8.3.11.3 “Dilution” is flow volume dependent.

8.3.11.4 The equipment exhaust specification should focus on the exhaust attribute (see Section 6) associated with the exhaust use (see Section 7). If multiple uses are being met, the supplier should prioritize Pressure, Flow, and Flow Volume for balancing.

8.3.12 The instruments and practices used for taking measurements to establish equipment specifications should be recommended in the specifications and used in field balance operations.

8.3.12.1 A hot wire anemometer is acceptable for velocities less than 150 m/s (500 FPM). A low range differential pressure gauge (0 to 60 Pa or 0.0 to 0.25 inches of water) is acceptable for velocities over 150 m/s (500 FPM).

8.3.12.2 An inclined/vertical manometer or high range differential pressure gauge is acceptable for measuring static pressure.

8.3.12.3 Conversion charts should be developed to indicate what flow volume is present at various points on the inclined/vertical manometer or differential pressure gauge.

8.3.12.4 Equipment suppliers should include recommendations in the equipment specifications for the proper selection of the pitot tube, static tip, etc., to use when measuring exhaust flow and pressure.

8.3.12.5 The description, operation, maintenance, and limitations of these and alternate instruments is covered

8.3.12.6 in Chapter 9 of "Industrial Ventilation," A Manual of Recommended Practice, 20th Edition, (Appendix 2, Reference 1). A companion reference is Chapter 5 of HVAC Systems Testing, Adjusting, and Balancing, (Appendix 2, Reference 3).

8.3.12.7 As with any test performed to establish or verify specifications, the measuring instruments used should be in good working condition and current calibration.

8.3.12.8 If an air balancing contractor is used, it should be certified by the Associated Air Balance Council (AABC) or the National Environmental Balancing Bureau (NEBB) as meeting their technical standards for membership.

8.3.12.9 For additional information, see National Standards for Field Measurement and Instrumentation - Total System Balance, Volume Two, No. 12173, (Appendix 2, Reference 6). Also see Procedural Standards for Testing of Cleanrooms, (Appendix 2, Reference 4).

8.3.13 The exhaust specification provided to the user by the supplier should include design information on the complete equipment exhaust system. A prototype exhaust data worksheet is shown in Appendix 1. The supplier should also provide:

8.3.13.1 A scaled drawing of the equipment exhaust system showing all connections, dampers, monitoring devices, etc.

8.3.13.2 A diagram of the exhaust connection with critical dimensions, established set point, and the location of the traverse point used to develop the specifications.

8.3.13.3 Any special case exceptions.

8.3.13.4 A list of materials used in the construction of the exhaust enclosure and materials for components of the exhaust system.

8.3.14 The supplier should provide the user with a list of constituents that could be expected in the exhaust stream when the equipment and the users' exhaust system are operating within design specifications. Information typically required is:

8.3.14.1 Percent by volume.

8.3.14.2 Percent by weight.

8.3.14.3 State of constituent (liquid, gas, or solid).

8.3.14.4 Temperature of the composite exhaust stream under normal operations.

8.3.14.5 Information should be based on a continuous twenty-four hour operation of the equipment. (Extrapolation is generally acceptable if the method used is well-documented and can be duplicated.)

APPENDIX 1
PROCESS EQUIPMENT EXHAUST REQUIREMENT SUMMARY

Page 1 of 2

NOTICE: This guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the guideline set forth herein for any particular application. The determination of the suitability of the guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. This guideline is subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI S7-96
SAFETY GUIDELINES FOR ENVIRONMENTAL, SAFETY, AND HEALTH (ESH) EVALUATION OF SEMICONDUCTOR MANUFACTURING EQUIPMENT

NOTICE: This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE: This entire document was revised in 1995.

1 Purpose

1.1 The purpose of this document is to provide guidance to the equipment manufacturer or supplier, the evaluator, and the user to define responsibilities and to ensure the objective evaluation of designs and equipment.

1.2 Preservation of employee safety and conformance to environmental regulations are important criteria when selecting semiconductor manufacturing equipment. A basic expectation is that the equipment manufacturer will design and build inherently safe (to the operator, facility, and environment) equipment and will provide documentation that the equipment has been evaluated against a specific set of criteria, verifying conformance thereto.

1.3 A safety evaluation is important for a variety of reasons, including: operator safety, equipment reliability, conformance to regulatory (e.g., OSHA, EPA, local fire and building codes) and insurance requirements. These are intended to ensure a safe and environmentally responsible workplace.

2 Scope

2.1 This document defines the requirements for ESH evaluation of equipment design and operation.

2.2 These guidelines include:

- Purpose
- Scope
- Referenced Documents
- Terminology
- Codes, Regulations, and Standards
- Requirements for Third Party Evaluators
- Contracting with an Evaluator
- Documentation Provided to the Evaluator by the Supplier
- Evaluation Methods
- Contents of Reports
- Provision of Reports to Potential Users

2.3 The evaluation program is designed to be used in addressing the ESH aspects of new, refurbished, or resold process tools prior to the tool being delivered to the user.

2.4 The evaluator may be within the supplier's organization. As some equipment suppliers do not maintain a comprehensive ESH equipment evaluation program in-house, third party contractor(s) may be used. In either case, the evaluator should meet the requirements listed in Section 6.

3 Referenced Documents

NOTE: All documents cited shall be the latest published versions.

3.1 *SEMI Document*

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

3.2 *ANSI Document*[1]

Z34.1 — Third Party Certification Program

4 Terminology

4.1 *supplier* — The party providing the equipment to, and communicating directly with, the user. It may be the manufacturer or an equipment representative or distributor. The supplier has the responsibilities of obtaining the required information from the manufacturer or other sources and of providing it to the evaluator.

4.2 *user* — The purchaser of semiconductor manufacturing who will use the equipment.

5 Codes, Regulations, and Standards

5.1 Semiconductor equipment should conform to the applicable codes, regulations, and standards. The

[1] American National Standards Institute, 1430 Broadway, New York, NY 10018

evaluation should include accordance with the codes, guidelines, and the local regulations of potential users. To assist in this, the supplier should provide the evaluator with a list of jurisdictions in which the supplier intends to market the equipment.

6 Requirements for Third Party Evaluators

6.1 The evaluator should have at least five years' experience in the semiconductor equipment or fabrication or similar industry and:

a. be established in accordance with ANSI Z34.1, Third Party Certification Program; or

b. consist of individual(s) who are registered or certified professional(s) in the discipline(s) in which the evaluations were performed; or

c. consist of individual(s) with baccalaureate or higher degrees in related technical discipline(s) (engineering or science).

NOTE: In the United States, the United Kingdom, and several other countries, the "baccalaureate" or "bachelor of science" degree is awarded upon completion of a technical course of study, typically of four years, at a college or university. It is the degree prerequisite for professional registration in most U.S. states and for study towards a master's degree or doctorate.

7 Contracting with an Evaluator

7.1 The supplier initiates the evaluation by providing a "scope of work" to the evaluator. This scope should define the services to be provided, including the standards and guidelines that will be used to evaluate the equipment and the responsibilities of each party.

7.2 The evaluator is responsible only to the supplier.

7.3 Changes made to the equipment to bring it into accord with codes, regulations, and guidelines are the responsibility of the supplier.

8 Documentation Provided to the Evaluator by the Supplier

8.1 Any previous evaluations of equipment related to the included documents, with all appropriate documentation.

8.2 Material Safety Data Sheets (MSDS's) for all chemicals used in the maintenance of the equipment and for those used in baseline and known, user-intended processes.

8.3 When information is known for user intended or baseline process(s), the evaluator should be provided the estimated consumption of raw materials and the amount(s) of by-products generated as described in Section 20.2.1 of SEMI S2.

8.4 Copies of the equipment's installation, maintenance, and operation manuals.

8.5 Copies of any hazard analysis or safety reviews of the subject equipment.

8.6 A list of all assemblies and sub-assemblies.

8.7 Design drawings and schematics.

9 Evaluation Methods

9.1 The evaluator should ensure the review of the supplier's documents (listed above) and the outlining of deficiencies with corrective and/or improvement recommendations.

9.2 The ESH testing and evaluation may proceed concurrently with the document review by agreement of the parties.

9.3 After the supplier has addressed all deficiencies noted in the third party report, the supplier should review the actions taken with the evaluator. If appropriate, the evaluator may re-evaluate some or all of the areas addressed.

10 Contents of Reports

10.1 An interim report should be provided to the supplier after evaluator has performed the agreed services. It should include an overview of the services performed, the standards, guidelines, and codes against which the equipment was evaluated, and the evaluator's findings. Items found in conformance with the documents should be documented as well as those found to be deficient.

10.2 The evaluator's final report should be provided after the supplier and the evaluator have agreed that the changes made have brought the equipment into conformance with the applicable documents. This report should be attached to the supplier's bid to a potential user.

10.3 If the evaluator and the supplier differ in their interpretation of requirements of the applicable documents, the creator of the document in question should be consulted for an interpretation. If the difference remains unresolved, the evaluator should include this and any other unresolved issues in its final report.

10.4 The final report should be signed by the evaluator and should contain at least the following sections:

10.4.1 *Management Summary* — A brief description of the evaluation, recommendations, and results. A statement that the equipment does or does not conform (with noted exceptions) with the ESH specifications, guidelines, and codes that were used for the evaluation.

10.4.2 *System Description* — Type of equipment evaluated and its function.

10.4.3 *Analysis and Test Methods* — Specific tests used to determine the compliance with the criteria. This should include a point-by-point evaluation of requirements listed in the pertinent specifications.

10.4.4 *Environmental, Safety, and Health Assessment* — The detailed results of the evaluation, including the point-by-point results, using SEMI S2 as an outline. If a section is not applicable, so state.

10.4.5 *Body* — The body of the report should describe the type of ESH evaluations, methods, and test equipment used, and results achieved. The methods used may include: fault testing, fault tree analysis, task analysis, industrial hygiene analysis, chemical mass balance, and ergonomics assessment.

10.4.6 *Recommendations* — Listings of recommendations made by the evaluator and statements that the recommendations were implemented, rejected, or otherwise addressed.

10.4.7 *Detailed Analysis and Test Worksheets* — Copies of the laboratory and field test data.

10.4.8 *Additional Information/Remarks* — Any information that may clarify tests performed, exceptions not specifically defined in the documents, precautions for certain applications of the equipment, or conditions of operation.

11 Provision of Reports to Potential Users

11.1 Whenever possible, copies of the evaluator's final report should be made available to potential users. If the supplier considers some information in the evaluator's report proprietary, the supplier should write an overview report that includes all environmental, safety, and health information with all proprietary information deleted.

11.2 Deficiencies that have been remedied and now meet the appropriate standards do not need to be listed in the report available to users.

11.3 This modified report should be signed by the evaluator.

SEMI S8-0701
SAFETY GUIDELINES FOR ERGONOMICS ENGINEERING OF SEMICONDUCTOR MANUFACTURING EQUIPMENT

These safety guidelines were technically approved by the Global Environmental Health & Safety Committee and are the direct responsibility of the North American Environmental Health & Safety Committee. Current edition approved by the North American Regional Standards Committee on March 22 and April 30, 2001. Initially available on www.semi.org May 2001; to be published July 2001. Originally published in 1995; previously published October 2000.

NOTE: The official values in this guideline are expressed in The International System of Units (SI). Values that:

— are expressed in inch-pound (also known as “US Customary” or “English”) units,

— are enclosed in parentheses, and

— directly follow values expressed in SI units

are not official, are provided for reference only, and might not be exact conversions of the SI values.

1 Purpose

1.1 These guidelines provide ergonomics design principles and considerations for semiconductor manufacturing equipment.

1.2 The purpose of these guidelines is to promote compatibility between the user and the equipment in the manufacturing environment. The following general principles are integral to the ergonomics design and evaluation of equipment:

1.2.1 The equipment should be designed to optimize safety by distributing tasks. Tasks should be distributed among hardware, software, and users to make the best use of their respective capabilities and to minimize limitations and hazards. Appropriate distribution of tasks will also optimize performance.

1.2.2 Equipment should be designed to minimize potential for errors and mishaps, by conforming to users’ expectations.

1.2.3 The equipment design should reduce fatigue and injury by fitting the equipment to the expected body size, strength, and range of motion characteristics of the user population. Such design will also facilitate task performance.

2 Scope

2.1 The guidelines address safety aspects of ergonomics engineering in the design of semiconductor manufacturing equipment. It should be noted that in order to ensure comprehensive coverage of potential safety hazards, some guidelines also address general design goals for effective human-machine performance. The guidelines apply to the design, operation, maintenance, and service of semiconductor manufacturing equipment, as well as, to a limited extent, equipment installation (see Section 7.3).

2.2 This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 International, national, and local standards, codes, and regulations must be consulted to ensure that equipment meets regulatory requirements**.**

3.2 Human factors data compiled in references and specifications are influenced by the population from which they were drawn and the reason they were collected. Human factors design criteria are sometimes based on studies using few subjects or are context-specific. Ergonomics experts should be consulted where data development or interpretation is required.

3.3 The equipment design should incorporate reasonable accommodations for users with special needs, such as left-handedness and color blindness. Where feasible the design should also accommodate users with hearing or vision impairments and/or physical disabilities. It should be understood that although designing for the target user population will accommodate some users with special needs, these guidelines cannot anticipate and fully accommodate all such users.

3.4 Existing models and subsystems that meet previous versions of SEMI S8 should continue to meet the guidelines of SEMI S8 in force at the time of design. Models with redesigns that significantly affect the ergonomic design of the equipment should include conformance to the latest version of SEMI S8 for the redesign.

NOTE 1: Conformance with this document is believed to be a suitable substitute for conformance with its predecessors.

3.5 Conformance with the guidelines in Appendix 1 (SESC) constitute conformance with SEMI S8.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E95 — Specification for Human Interface for Semiconductor Manufacturing Equipment

SEMI S1 — Safety Guideline for Visual Hazard Alerts

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

4.2 *CEN/CENELEC Standards*[1]

4.2.1 European Norm (EN) standards are listed herein for application to semiconductor manufacturing equipment to be used in the European Union (EU). As EN standards are intended for use with a broad range of industrial and consumer products, conflicts with SEMI safety guidelines are likely. Additionally, provisional EN (prEN) standards are subject to revision prior to adoption.

EN 894-2 — Safety/Ergonomics for Displays

EN 894-3 — Safety/Ergonomics for Control Actuators

4.5 *ISO Document*[4]

ISO 9241 — Ergonomic Requirements for Office Work with Visual Display Terminals

4.6 *Other Standards*

Humanscale, The MIT Press, Massachusetts Institute of Technology, Cambridge, MA 02142, 1974

ANSI/IES RP7[5] — Practice for industrial lighting

Waters, Thomas, et. al., *Application Manual for the Revised NIOSH Lifting Equation*, U.S. Department of Health and Human Services (NIOSH), Cincinnati, OH, 1994.

A. Mital, A.S. Nicholson, M.M. Ayoub: *A Guide to Manual Materials Handling*, Taylor and Francis, London, 1993.

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *MAWL* — Maximum Acceptable Weight of Lift

5.1.2 *MMH* — Manual Material Handling

5.1.3 *SESC* — Supplier Ergonomics Success Criteria (See Appendix 1.)

5.2 *Definitions*

5.2.1 *administrative controls* — administrative controls modify the way in which a job is performed without involving equipment design. They are non-engineering controls which include: job rotation, job enlargement, work-rest scheduling, micro-breaks, and stretching exercises. Engineering controls are preferred over administrative controls.

5.2.2 *anthropometric considerations* — design considerations based upon anthropometric (e.g., size and strength) limitations of user personnel.

5.2.3 *anthropometry* — description of the physical measurement of humans (e.g., size, strength).

5.2.4 *cognitive* — relating to human information processing, perception, and attention.

5.2.5 *critical controls and displays* — controls and displays which prevent the equipment from entering, or indicate that equipment is entering an unsafe condition in which hazards to personnel or damage to equipment may occur. Emergency Off (EMO) switches, interlock defeat indicators, and malfunction alarms are examples of critical controls and displays.

5.2.6 *cumulative trauma disorder* — a disorder which results from the accumulation of stresses (e.g., forces, repetitive movements, etc.) to a body part over a period of time.

5.2.7 *duration* — the length of time of a cycle or the entire task, which represents the time of exposure to single or multiple risk factors.

5 American National Standards Institute, 1430 Broadway, New York, NY 10018 USA

5.2.8 *emergency off (EMO)* — a control circuit which, when activated, places the equipment into a safe shutdown condition.

5.2.9 *engineering control* — a method to eliminate or mitigate a hazard through equipment design.

5.2.10 *ergonomic-related hazard* — an equipment or workplace condition that creates stress to the user that contributes to the risk of developing either an acute injury or a cumulative trauma disorder.

5.2.11 *ergonomic issues* — those issues dealing with the user's physical and cognitive needs, capabilities, and human performance limitations in relation to the design of machines, tasks, and other features of the human's working environment.

5.2.12 *ergonomics* — the study of human mental and physical capability in relation to the working environment and the equipment operated by the worker.

5.2.13 *excessive reach* — a reach which may result in biomechanical or other stress to the user.

5.2.14 *extended reach* — a reach which requires either stretching, stooping, crouching, bending forward at the waist greater than 20 degrees, or shoulder flexion or abduction greater than 45 degrees.

5.2.15 *force* — the mechanical effort to accomplish a specific movement or exertion. These include: static exertions, which produce no motion but have significant duration; dynamic exertions, which are motions including lifting, pushing, pulling; and contact stress, which is localized pressure exerted against the skin by an external force.

5.2.16 *frequency* — how often a task is performed over time.

5.2.17 *frequently used* — used in processing or job cycle at least once every hour. Multiple tool operation by a single operator should be considered.

5.2.18 *human error* — errors which include: failure to perform a required function; performing a function that has an undesirable consequence; failure to recognize and correct a hazardous condition; or inadequate or incorrect response to a contingency.

5.2.19 *inadvertent actuation* — accidental or unintentional activation or deactivation of a control.

5.2.20 *infrequently used* — used in processing or job cycle less frequently than once every hour. Multiple tool operation by a single operator should be considered.

5.2.21 *installation* — the activities performed after the equipment is received at a user site through preparation for initial service, including transportation, lifting, uncrating, placement, leveling, and facilities fit up.

5.2.22 *lateral pinch* — grip in which the object is held between the thumb and the side of the index finger (often referred to as key grip).

5.2.23 *maintenance* — planned or unplanned activities intended to keep equipment in good working order.

5.2.24 *mock up* — a full size physical model of the equipment, generally made of relatively inexpensive materials, used for human factors evaluation.

5.2.25 *neutral posture* — the position of the human body in which the joints are least stressed. Generally, the body in its neutral position is standing erect with the eyes looking forward, and the arms hanging by the sides.

5.2.26 *non-neutral (awkward) postures* — The position of a joint(s) away from its neutral, or least stressed, posture.

5.2.27 *normal line of sight* — the line extending from the eyes, perpendicular to the interoccular line and 15 degrees below the horizontal position of the eye.

5.2.28 *operation* — consists of functions by which the operator causes the equipment to perform its intended purpose; these may include loading product and setting or manipulating external controls.

5.2.29 *operator* — a user that interacts with the equipment only to the degree necessary for the equipment to perform its intended function.

5.2.30 *override* — to take precedence over the current control system state.

5.2.31 *palmar pinch* — grip where the fingers press against the palm of the hand, with the object held between the fingers and the palm. Thumb is not used (e.g., picking up a sheet of plywood).

5.2.32 *personal protective equipment (PPE)* — equipment and clothing worn to reduce potential for personal injury from hazards associated with the task to be performed (e.g., chemical gloves, respirators, safety glasses, etc.). In the context of this document, cleanroom attire (e.g., gloves, smocks, booties, hoods) is not considered personal protective equipment.

5.2.33 *power grip* — a grip in which the fingers and thumb wrap entirely around the handle such that the thumb contacts or overlaps the index finger.

5.2.34 *postural stress* — stress occurring when a body position places undue load on the muscles, tendons, nerves, and blood vessels, or produces pressure on a joint.

5.2.35 *primary viewing area* — the 30 degree cone around the normal line of site (15 degrees above, below, and to either side of the line of sight).

5.2.36 *problem tasks* — tasks which have been defined as presenting ergonomically incorrect conditions that are likely to cause biomechanical stresses or injury to personnel, misoperation, or damage to equipment or the product.

5.2.37 *risk factors* — those elements of the design which allow an increased potential for injury/illness to personnel, or for damage to equipment, environment, or product.

5.2.38 *semiconductor manufacturing equipment* — equipment used in the design, development, manufacture, assembly, measurement and test of semiconductors, and associated semiconductor support processes.

5.2.39 *service* — unplanned activities intended to return equipment, which has failed, to good working order.

5.2.40 *static posture* — a fixed position, with minimal movement of the particular body parts.

5.2.41 *stooping* — bending the head and shoulders, or the general body, forward and downward from an erect position.

5.2.42 *task* — a group of related job elements performed within the work cycle and directed toward a specific objective.

5.2.43 *task analysis* — an analytical process employed to determine the specific actions required of the user when operating, maintaining, or servicing equipment, or doing work on single or multiple tools. Within each task, steps are described in terms of the perception, decision-making, memory storage, posture, and biomechanical requirements, as well as the expected errors.

5.2.44 *tip pinch* — grip in which the object is held between the tips of the thumb and index finger.

5.2.45 *user* — person interacting with the equipment. Users may include operators, maintainers, service personnel, and others.

5.2.46 *user population* — a specific cross section of persons that may reasonably be expected to interact with the equipment to perform operation, maintenance, or service tasks.

5.2.47 *validation testing* — testing to confirm effectiveness of design. An item's "effectiveness" is viewed in terms of its functional design, specific to SEMI S8.

5.2.48 *WIP nest* — a storage structure for Work in Process (WIP).

5.2.49 *work environment* — the location where semiconductor devices and associated support processes are designed, developed, manufactured, assembled, measured, and tested.

5.2.50 *workplace layout* — the physical arrangement of equipment in the facility.

5.2.51 *workspace* — the available area where the user is expected to operate, maintain, and service the equipment.

5.2.52 *workstation* — the location where equipment controls and displays are found or the location of loading/unloading of material.

6 General Guidelines

6.1 *Ergonomics-Related Safety Issues* — Ergonomics-related safety issues may exist whenever equipment design, installation, operation, service, or maintenance factors result in task demands that exceed the information processing or physical capabilities of properly trained users. For example, ergonomics-related safety issues may result from:

6.1.1 Static or awkward postures,

6.1.2 Repetitive motion,

6.1.3 Poor access, inadequate clearance, and excessive reach,

6.1.4 Lifting of heavy or bulky components,

6.1.5 Displays that are difficult to read or understand,

6.1.6 Controls that are confusing to operate or require too much force, and

6.1.7 Use of non-specific warnings or faults to communicate machine problems.

6.2 Safety-related issues should be designed out or otherwise reduced to an acceptable level prior to production. Ergonomics-related safety issues are reduced by implementing sound ergonomics engineering principles in design, and structuring job requirements around human performance capabilities and limitations.

6.3 Equipment should be designed to reduce or eliminate the potential types of error caused by human-machine or human-task mismatch (e.g., inadvertent actuation, errors of omission, or commission).

6.4 Engineering controls are the preferred means to reduce hazards. Where an engineering approach to ergonomic hazard control is not feasible, the user should implement administrative controls to mitigate hazards by reducing the duration, frequency, or severity of exposure.

6.5 Highest priority should be placed on issues which have the potential of resulting in injury to personnel. Secondary priority should be placed on issues which have the potential of resulting in significant damage to equipment.

6.6 Information exchange between equipment suppliers and users regarding human-machine interface issues is encouraged during the development stage, as part of beta site testing, after equipment is in full production, and throughout the life cycle of the equipment.

6.7 Ergonomics evaluation should be performed throughout the conception, design, build, and install phases to determine whether ergonomics guidelines have been met. The examination should yield a completed SESC document (see Appendix 1).

6.7.1 Equipment evaluation should identify risk factors associated with equipment design that affect operation, training, installation, maintenance, or service tasks.

6.7.2 Use of mock-ups and simulations are beneficial to identify and resolve ergonomic issues before the design is finalized. Testing should be performed with individuals who are representative of the user population under anticipated working conditions.

6.7.3 The evaluation should include consideration of multiple pieces of equipment under the control of one individual, resulting in an operation being repeated several times sequentially. The supplier should state the criteria for this scenario and include it in the report.

6.8 The overall objective is to provide for equipment effectiveness and for worker safety, convenience, and comfort when operating and maintaining the equipment.

6.9 Damage or undue deterioration of required garments or PPE should not occur as a result of equipment operation. Controls, such as knobs and switches, should be designed to be compatible with gloves worn by users for contamination control or personal protection. For example, cleanroom gloves typically reduce grip strength by 15%. Equipment displays should consider the potential for impaired vision and hearing that may occur with the use of cleanroom hoods, chemical goggles, or face shields.

6.10 Technical documentation (e.g., manuals) and on-equipment instructions (e.g., labels, indicators and screen menus) should be consistent in action, terminology, symbols, and format.

6.11 Equipment customized to meet specific customer requirements should not increase the level of ergonomic risk.

6.12 For recommendations on human interface design, see SEMI E95.

NOTE 3: SEMI E95 provides information on human computer interface. It is not the intent of S8 to incorporate the requirements of SEMI E95 by reference.

7 Documentation

7.1 The supplier should provide an evaluation of the equipment to SEMI S8 using Appendix 1, “Supplier Ergonomic Success Criteria” for measurable criteria. The evaluation should include a determination of the level of risk associated with non-conformance items. Evaluation of risk should be compatible with the SEMI S10 severity categories; catastrophic, severe, moderate, and minor.

7.1.1 For each item in Appendix 1 which does not meet the criteria, the evaluation report should include the measured actual dimensions, and state any supporting rationale for non-compliance. Supporting rationale may include test data or documented engineering judgment. EXCEPTION: For Section 1, the manual material handling analysis, the evaluation report should provide documented calculations regardless of the outcome of the analysis.

7.1.2 The evaluation report should also include the following information: manufacturer’s model number, serial number of unit evaluated, date the equipment was evaluated, a list of all tasks which were evaluated as part of the analysis and the name of the person performing the evaluation.

7.2 Supplier provided documentation should include administrative controls intended by the supplier to mitigate ergonomic risks.

7.3 Supplier provided documentation should illustrate any installation requirement necessary to meet SEMI S8 guidelines (e.g., Diagram should show clearance area required for opening hinged panels, operator working area, allowable range of vertical foot adjustment to keep ergonomic measurements within SESC acceptable limits, etc.).

APPENDIX 1
SUPPLIER ERGONOMIC SUCCESS CRITERIA (SESC)

NOTE: The material in this appendix is an official part of SEMI S8 and was approved by full letter ballot procedures by the North American Regional Standards Committee.

Table A1-1 Supplier Ergonomic Success Criteria Checklist

Section	*Indicator*	*Acceptance Criteria Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
1	**Manual Material Handling**			
1.1	Potentially hazardous manual material handling tasks performed as part of operations, maintenance, or service are analyzed utilizing appropriate procedures. NOTE: Two hand lifting or lowering tasks should be analyzed: if the object being handled weighs more than 44.5 N (10 lbs.); OR, if the object weighs more than 22.2 N (5 lbs.) and the anticipated frequency is greater than 1 lift every 5 minutes. See Appendix 2 for further information.	Analysis and results documentation. Table A2-2, Appendix 2, or the equivalent, should be used to document 2 hand lift/lower analysis.		
2	**Product Loading in a Standing Posture** (Applicable to all media other than wafer cassettes including JEDEC trays, magazines, and reticle cassettes.			
2.1	Clearance provided for finger thickness.	minimum 38 mm (1.5 in.)		
2.2	Clearance provided for hand thickness.	minimum 76 mm (3.0 in.)		
2.3	Reach distance measured from the leading edge of the tool or obstruction to the hand/product coupling point(s).	maximum 330 mm (13 in.)		
2.4	Vertical coupling point of hand to product in load position	maximum 1010 mm (40 in.) minimum 890 mm (35 in.)		
3	**Wafer Cassette Loading**			
3.1	Wafer cassette loading should not require greater than 10 degrees cassette rotation in any axis. NOTE: Unless otherwise specified, you should assume that 200 mm or smaller wafers are transported in the vertical orientation and that 300 mm wafers are transported in the horizontal orientation.	less than 10 degrees rotation in any axis		
3.2	Load port height, vertical distance from standing surface (150–200 mm wafers).	maximum 960 mm (38 in.) minimum 890 mm (35 in.)		
3.3	Maximum lip height in front of cassette load port over which cassette is lifted (150–200 mm wafer cassettes only). Measure lip height from the load surface.	maximum 30 mm (1.2 in.)		
3.4	Reach distance from the leading edge of the tool or obstruction to the coupling point(s) on rotation device or the product grasp point.	maximum 330 mm (13 in.)		
3.5	Minimum hand clearance on either side of the cassette, measured from the side of the cassette to the nearest adjacent object.	minimum 76 mm (3.0 in.)		

Section	*Indicator*	*Acceptance Criteria* *Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
4	**Work in Process Storage** (specific to wafer cassettes)			
4.1	Integral wafer cassette/lot box storage shelf height (150 and 200 mm wafer cassette/lot boxes only)	maximum (1 box deep) 1520 mm (60 in.) maximum (2 boxes deep) 1220 mm (48 in.) minimum 460 mm (18 in.)		
5	**Manual Wafer Cassette Rotation Device Design**			
5.1	Handle height, couple point for hand(s) from standing surface.	maximum 1206 mm (47.5 in.) minimum 838 mm (33 in.)		
5.2	Hand grip(s) shall allow for a full "power grip" similar to grabbing a rung on a ladder or holding a pistol.	Allows for a full power grip in either pronated (palm facing down) or neutral (handshake position) posture.		
5.3	Single hand lift force	maximum 37.8 N (8.5 lb.) This value includes a 15% capacity reduction due to cleanroom glove use. Wrist deviation reduces further strength capacity by 15%.		
5.4	Two hand lift force	maximum 64.5 N (14.5 lb.) This value includes a 15% capacity reduction due to cleanroom glove use. Wrist deviation reduces further strength capacity by 15%.		
6	**Handle Design** (Handle dimensions are correct for use of bare hand or use of typical cleanroom gloves) NOTE: See Appendix 3 for depiction of handle types.			
6.1	Handle surface finish	all edges radiused		
6.2	Cylindrical handle			
6.2.1	Cylindrical handle diameter (D)	maximum 38 mm (1.5 in.) minimum 25 mm (1.0 in.)		
6.2.2	Cylindrical handle length (L)	minimum 127 mm (5.0 in.)		
6.3	Circular or triangular handle			
6.3.1	Circular or triangular handle diameter (D)	maximum 90 mm (3.5 in.) minimum 50 mm (2.0 in.)		
6.3.2	Circular or triangular handle height (thickness) (H)	maximum 25 mm (1.0 in.) minimum 19 mm (0.75 in.)		
6.4	Ball handle			
6.4.1	Ball handle diameter	maximum 63 mm (2.5 in.) minimum 38 mm (1.5 in.)		
6.5	Pliers handle			
6.5.1	Pliers handle grip span (S)	maximum 89 mm (3.5 in.) open minimum 38 mm (1.5 in.) closed		
6.5.2	Pliers handle length (L)	minimum 127 mm (5.0 in.)		
6.6	Pistol grip handle			
6.6.1	Pistol grip handle diameter (D)	maximum 63 mm (2.5 in.) minimum 38 mm (1.5 in.)		
6.6.2	Pistol grip handle length (L)	minimum 127 mm (5.0 in.)		

Section	*Indicator*	*Acceptance Criteria Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
6.7	Enclosed handles NOTE: Handle diameter refers to the surface of the handle presented to the inside of the curled fingers. Enclosed handles need not be made solely from cylindrical stock.			
6.7.1	Enclosed handle, full hand power grip (suitcase handle) Width (W) Depth (D) Diameter (d)	minimum 127 mm (5.0 in.) minimum 45 mm (1.75 in.) maximum 25 mm (1.0 in.)		
6.7.1.1	Diameter (d), requiring no greater than 71 N (16 lbf) force	minimum 6.3 mm (0.25 in.)		
6.7.1.2	Diameter (d), requiring no greater than 89 N (20 lbf) force	minimum 13 mm (0.5 in.)		
6.7.1.3	Diameter (d), requiring no greater than 200 N (40 lbf) force	minimum 19 mm (0.75 in.)		
6.7.2	Enclosed handle, three fingers Width (W) Depth (D) Diameter (d) Force	minimum 90 mm (3.5 in.) minimum 38 mm (1.5 in.) minimum 6.3 mm (0.25 in.) maximum 71 N (16 lbf)		
6.7.3	Enclosed handle, two fingers Width (W) Depth (D) Diameter (d) Force	minimum 60 mm (2.5 in.) minimum 38 mm (1.5 in.) minimum 6.3 mm (0.25 in.) maximum 51 N (11.5 lbf)		
6.7.4	Enclosed handle, one finger Width (W) Depth (D) Diameter (d) Force	minimum 38 mm (1.5 in.) minimum 38 mm (1.5 in.) minimum 3.2 mm (0.13 in.) maximum 27 N (6 lbf)		
6.8	Hook grasp handle			
6.8.1	Hook grasp handle (four fingers) Opening length (L) Opening width (W) Depth (d) Lip length (l)	minimum 90 mm (3.5 in.) minimum 38 mm (1.5 in.) minimum 50 mm (2.0 in.) minimum 50 mm (2.0 in.)		
6.8.2	Hook grasp handle pull force (four fingers)	maximum 80 N (18.0 lb.)		
6.9	Finger pull handle			
6.9.1	Finger pull handles (four fingers) Opening length (L) Opening width (W) Depth (d) Lip length (l)	minimum 90 mm (3.5 in.) minimum 25 mm (1.0 in.) minimum 19 mm (0.75 in.) minimum 19 mm (0.75 in.)		
6.9.2	Finger pull handles pull force (four fingers)	maximum 9.8 N (2.2 lb.)		
7	**Maintainability and Serviceability**			
7.1	Minimum lighting level in routine maintenance areas is required where the operator has to read information, use a hand tool, or make a connection. This provision can be met by providing integral lighting or portable lighting which can be temporarily attached such that it does not have to be hand held.	minimum 300 lux (30 fc)		

Section	Indicator	Acceptance Criteria Metric Units (US Customary Units)	Actual	Conforms/Does Not Conform/Not Applicable
7.2	Full Body Clearance NOTE: Clearances should be approached from a task analysis point of view. Clearances should be provided based on the nature of the tasks performed in the designated area.			
7.2.1	Any posture: upper body clearance (shoulder width)	minimum 610 mm (24 in.)		
7.2.2	Standing: overhead clearance, measured from the floor forward horizontal clearance (see NOTE 3)	 minimum 1980 mm (78 in.) minimum 690 mm (27 in.)		
7.2.3	Sitting-on-Floor: overhead clearance, measured from the floor forward horizontal clearance (see NOTE 3) working height	 minimum 1000 mm (39 in.) minimum 690 mm (27 in.) minimum 280 mm (11 in.)		
7.2.4	Squatting: overhead clearance, measured from the floor forward horizontal clearance (see NOTE 3) working height	 minimum 1220 mm (48 in.) minimum 790 mm (31 in.) minimum 460 mm (18.1 in.)		
7.2.5	Kneeling: overhead clearance, measured from the floor forward horizontal clearance (see NOTE 3) working height	 minimum 1450 mm (57 in.) minimum 1220 mm (48 in.) minimum 640 mm (25.2 in.)		
7.2.6	Kneeling Crawl: overhead clearance, measured from the floor forward horizontal clearance (see NOTE 3)	 minimum 740 mm (29 in.) minimum 1520 mm (60 in.)		
7.2.7	Stooping: overhead clearance, measured from the floor forward horizontal clearance (see NOTE 3) working height	 minimum 1450 mm (57 in.) minimum 1020 mm (40 in.) minimum 640 mm (25.2 in.)		
7.2.8	Supine (lying on back): height length	 minimum 430 mm (17 in.) minimum 1980 mm (78 in.)		
7.2.9	Prone or crawl space: height length	 minimum 510 mm (20 in.) minimum 2440 mm (96 in.)		
7.3	Hand/Arm Clearance (where appropriate to do so, dimensions have been adjusted for the use of cleanroom gloves)			
7.3.1	Clearance provided for finger access, round (dia) or square: one finger 2, 3, or 4 finger twist of small knob	 minimum 32 mm (1.25 in.) minimum object diameter + 58 mm (2.3 in.)		
7.3.2	Clearance provided for flat hand to wrist access: height, palm thickness width, palm width	 minimum 89 mm (3.5 in.) minimum 114 mm (4.5 in.)		
7.3.3	Clearance provided for fist to wrist access: height, palm thickness width, palm width	 minimum height 89 mm (3.5 in.) minimum width 127 mm (5.0 in.)		

Section	*Indicator*	*Acceptance Criteria* *Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
7.3.4	Clearance provided for two hands arm to shoulders access (does not ensure visual access): reach width height	 maximum 610 mm (24.0 in.) minimum 483 mm (19 in.) minimum 114 mm (4.5 in.)		
7.3.5	Clearance provided for two hands, hand to wrist access (does not ensure visual access): reach width height	 maximum 203 mm (8.0 in.) minimum 191 mm (7.5 in.) minimum 114 mm (4.5 in.)		
7.3.6	Clearance provided for one arm to shoulder access, diameter or square area (does not ensure visual access).	minimum 132 mm (5.2 in.)		
7.3.7	Clearance provided for one arm to elbow access, diameter or square area (does not ensure visual access).	minimum 119 mm (4.7 in.)		
7.4	Maintenance and Service Access			
7.4.1	Enclosures or covers must, unless fully removable, be self-supporting, in the open position, and not require manual support during maintenance. Exceptions may be allowed for self closing doors for fire safety or compliance reasons.	Supports present		
7.4.2	Access covers should be equipped with full-handed grasp areas or other means for opening them.	Handles present, refer to Section 6 for design criteria.		
7.4.3	Height of access cover handle over the entire range of motion required for operation or maintenance. There should be no greater than a 254 mm (10 in.) deep obstruction in front of the handle.	maximum 1700 mm (67 in.)		
7.5	Replaceable Components			
7.5.1	Serviceable components are replaceable as modular packages, and are configured for rapid removal and replacement.	Serviceable components configured as described.		
7.5.2	Serviceable components should not be stacked directly on one another (*i.e.*, a lower layer should not support an upper layer).	Serviceable components independently accessible.		
7.5.3	Heavy components (objects which have a lifting index of 0.5 or greater, see SESC, Section 1.0) or bulky components (greater than 36 inches in length) requiring frequent removal/installation should include guide/locating aids to assist in positioning.	Guide/locating pins present.		
7.5.4	Cables, connectors, plugs, and receptacles should be labeled, keyed, color coded, or otherwise configured to make connection easier and prevent cross connection. This feature is assessed only if a SEMI S2 assessment is not being conducted.	Identification present, keyed where needed.		
7.5.5	Circuit boards mounted in a card cage configuration should have gripping or ejecting aids for mounting and removal.	Finger access, gripping, or ejecting aids available.		
8	**Display Location**			

Section	*Indicator*	*Acceptance Criteria Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
8.1	Location for operator primary interface, standing station (see NOTE 1)			
8.1.1	Height of video display terminal (single monitor). Does not include touchscreens, measured from floor to center of screen.	maximum 1470 mm (58 in.) minimum 1320 mm (52 in.)		
8.1.2	Height of video display terminal (stacked monitors). Does not include touchscreens, measured from floor to top line of the top monitor.	maximum 1680 mm (66 in.) The primary monitor in a stacked configuration is the bottom monitor.		
8.1.3	Height of infrequently used video display terminal (viewed briefly less often than once per hour) measured to top line of monitor.	maximum 1680 mm (66 in.)		
8.1.4	Height of very infrequently used video display terminal (viewed briefly less often than once per day) measured to top line of monitor.	maximum 1880 mm (74 in.)		
8.1.5	Height of infrequently viewed visual signal measured to the top of the signal. This guideline does not apply to light towers.	maximum 2130 mm (84 in.)		
8.1.6	Height of touch screen monitor.	maximum 1370 mm (54 in.), measured from floor to uppermost active pad on screen minimum 910 mm (36 in.), measured from floor to lowest active pad on the screen See Section 9 for horizontal reach criteria.		
8.1.7	Tilt angle of touch screen monitor between 41 and 48 inches in height to top of screen.	Upward minimum 30 degrees		
8.1.8	Tilt angle of touch screen monitor less than 41 inches in height to top of screen.	Upward minimum 45 degrees		
8.2	Location for operator primary interface, seated station (see NOTE 2)			
8.2.1	Height of video display terminal (single monitor), does not include touchscreens, measured from floor to centerline of monitor.	maximum 1190 mm (47 in.) minimum 940 mm (37 in.)		
8.2.2	Height of video display terminal (stacked monitors), does not include touchscreens, measured from floor to top line of top monitor.	maximum 1400 mm (55 in.) minimum 940 mm (37 in.) The primary monitor in a stacked configuration is the bottom monitor.		
8.2.3	Tilt angle of video display terminal greater than 55 inches in height to top of screen. This line item becomes significant in the event that the maximum height criteria cannot be met.	Downward minimum 15 degrees		
8.2.4	Height of touch screen monitor.	maximum 1070 mm (42 in.) measured from floor to highest active pad on the screen minimum 760 mm (30 in.) measured from floor to lowest active pad on the screen See Section 9 for horizontal reach criteria.		
8.3	Display characteristics			

Section	*Indicator*	*Acceptance Criteria* *Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
8.3.1	Lateral distance from the centerline of the display to the centerline of the input device(s). See MIL-STD-1472 for a depiction of this.	maximum 320 mm (12.6 in.)		
8.3.2	Character height (Specific to Chinese, Korean, and Japanese characters.)	Character height is greater than or equal to the viewing distance divided by 143. Recommended viewing distance is between 457 mm (18 in.) and 762 mm (30 in.)		
8.3.3	Character height (All characters other than Chinese, Korean, and Japanese.)	Character height is greater than or equal to the viewing distance divided by 215. Recommended viewing distance is between 457 mm (18 in.) and 762 mm (30 in.)		
9	**Hand Control Location** (These criteria only apply to controls, tools, and materials accessed for routine production operation and maintenance.)			
9.1	Standing station (see NOTE 1)			
9.1.1	Vertical location of very infrequently used controls (controls used less often than once every 24 hours) measured from the standing surface to the centerline of the control.	maximum 1640 mm (64.5 in.) minimum 0 mm (0 in.)		
9.1.2	Location of infrequently used and/or critical controls. Maximum reaches are indicated for various heights. Reaches are measured from the leading edge of the equipment or obstacle. Controls should not be located above 1638 mm (64.5 in.) or below 838 mm (33 in.). Interpolate for intermediate values. Height of 1638 mm (64.5 in.) Height of 1524 mm (60 in.) Height of 1422 mm (56 in.) Height of 1321 mm (52 in.) Height of 1219 mm (48 in.) Height of 1118 mm (44 in.) Height of 1016 mm (40 in.) Height of 914 mm (36 in.) Height of 838 mm (33 in.)	reach 254 mm (10.0 in.) reach 368 mm (14.5 in.) reach 432 mm (17.0 in.) reach 470 mm (18.5 in.) reach 483 mm (19.0 in.) reach 470 mm (18.5 in.) reach 394 mm (15.5 in.) reach 292 mm (11.5 in.) reach 178 mm (7.0 in.)		
9.1.3	Location of frequently used controls. Maximum reaches are indicated for various heights. Reaches are measured from the leading edge of the equipment or obstacle. Controls should not be located above 1270 mm (50 in.) or below 940 mm (37 in.). Interpolate for intermediate values. Height of 1270 mm (50 in.) Height of 1219 mm (48 in.) Height of 1168 mm (46 in.) Height of 1118 mm (44 in.) Height of 1067 mm (42 in.) Height of 1016 mm (40 in.) Height of 940 mm (37 in.)	reach 292 mm (11.5 in.) reach 330 mm (13.0 in.) reach 368 mm (14.5 in.) reach 394 mm (15.5 in.) reach 406 mm (16.0 in.) reach 394 mm (15.5 in.) reach 318 mm (12.5 in.)		
9.2	Seated station (see NOTE 2)			

Section	*Indicator*	*Acceptance Criteria Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
9.2.1	Location of infrequently used and/or critical controls. Maximum reaches are indicated for various heights. Reaches are measured from the leading edge of the work surface or obstacle. Controls should not be located above 1397 mm (55 in.) or below 533 mm (21 in.). Interpolate for intermediate values. Height of 1397 mm (55 in.) Height of 1270 mm (50 in.) Height of 1168 mm (46 in.) Height of 1067 mm (42 in.) Height of 965 mm (38 in.) Height of 864 mm (34 in.) Height of 762 mm (30 in.) Height of 660 mm (26 in.) Height of 533 mm (21 in.)	reach 356 mm (14.5 in.) reach 432 mm (17.0 in.) reach 470 mm (18.5 in.) reach 483 mm (19.0 in.) reach 483 mm (19.0 in.) reach 470 mm (18.5 in.) reach 445 mm (17.5 in.) reach 381 mm (15.0 in.) reach 254 mm (10.0 in.)		
9.2.2	Location of frequently used controls. Maximum reaches are indicated for various heights. Reaches are measured from the leading edge of the work surface or obstacle. Controls should not be located above 1067 mm (42 in.) or below 762 mm (30 in.). Interpolate for intermediate values. Height of 1067 mm (42 in.) Height of 1016 mm (40 in.) Height of 965 mm (38 in.) Height of 914 mm (36 in.) Height of 864 mm (34 in.) Height of 813 mm (32 in.) Height of 762 mm (30 in.)	reach 330 mm (13.0 in.) reach 368 mm (14.5 in.) reach 394 mm (15.5 in.) reach 406 mm (16.0 in.) reach 419 mm (16.5 in.) reach 419 mm (16.5 in.) reach 419 mm (16.5 in.)		
10	**Workstation Design**			
10.1	Standing station (see NOTE 1)			
10.1.1	Work surface edge radius where the operator can assume a static posture in contact with the edge.	minimum 6.4 mm (0.25 in.) radius		
10.1.2	Height of keyboard, trackball, or mouse (to home row, top of ball/mouse). NOTE: In applications where input devices (keyboard, trackball, or mouse) are used more like machine controls (intermittent one finger entry on the keyboard, intermittent short term use of the mouse or trackball) than for standard typing (continuous use of keyboard for entry of long character strings, extended use of trackball or mouse in graphical environment), it is appropriate to use the height and reach locations described in Section 9, Hand Control Location (standing station).	maximum 1020 mm (40 in.) minimum 970 mm (38 in.)		
10.1.3	Height of microscope eyepieces. Must be adjustable.	maximum 1730 mm (68 in.) minimum 1270 mm (50 in.)		
10.2	Seated station (see NOTE 2)			

Section	*Indicator*	*Acceptance Criteria Metric Units (US Customary Units)*	*Actual*	*Conforms/Does Not Conform/Not Applicable*
10.2.1	Height of keyboard, trackball, or mouse. (to home row, top of ball/mouse). NOTE: In applications where input devices (keyboard, trackball, or mouse) are used more like machine controls (intermittent one finger entry on the keyboard, intermittent short term use of the mouse or trackball) than for standard typing (continuous use of keyboard for entry of long character strings, extended use of trackball or mouse in graphical environment), it is appropriate to use the height and reach locations described in Section 9, Hand Control Location (seated station).	maximum 760 mm (30 in.) minimum 710 mm (28 in.)		
10.2.2	Vertical leg clearance.	minimum 673 mm (26.5 in.)		
10.2.3	Horizontal leg clearance, depth at knee level.	minimum 508 mm (20 in.)		
10.2.4	Horizontal leg clearance, depth at foot level.	minimum 660 mm (26 in.) depth × 254 mm (10 in.) vertical foot clearance		
10.2.5	Horizontal leg clearance, width.	minimum 610 mm (24 in.)		
10.2.6	Height of microscope eyepiece. Must be adjustable.	maximum 1370 mm (54 in.) minimum 1220 mm (48 in.)		
10.2.7	Thickness of work surface.	maximum 51 mm (2.0 in.)		
10.2.8	Work surface edge radius where the operator can assume a static posture in contact with the edge.	minimum 6 mm (0.25 in.) radius		

NOTE 1: A standing station is one where the operator can assume a standing posture or a seated posture in a tall stool which places the operator at approximately the same stature.

NOTE 2: A seated station is one where a short cylinder office style chair is used.

NOTE 3: Distance measured away from the equipment or obstruction for body clearance in the given posture.

APPENDIX 2
LIFTING, STRENGTH, AND MATERIALS HANDLING

NOTE: The material in this appendix is an official part of SEMI S8 and was approved by full letter ballot procedures by the North American Regional Standards Committee.

A2-1 General Considerations

A2-1.1 For recommended guidelines regarding the percentage of a user's maximum grip strength to be exerted in execution of a task see Related Information 1, Table R1-3.

A2-1.2 Where standard product or containers are to be handled at equipment load and unload stations, mechanization should be considered for orientation and handling. Where manual handling is necessary, the design should reduce extended reaching, lifting, pulling, and awkward postures. Simultaneous lifting and twisting should be avoided. Load, unload, and lift over points should be located such that the floor to hand height is 84–107 cm (33–42 in.), optimal design target is 102 cm (40 in.).

A2-1.3 Handles or cutouts should be designed to facilitate use of the power grip (e.g., similar to that used to hold a pistol). Avoid handles that require pinch grips or awkward postures. Handles should allow carrying close to the body.

A2-1.4 Lifting and handling tasks performed in a stooping position should be avoided. Stooping occurs when the vertical material handling height is less than 84 cm (33 in.), or the horizontal reach distance is greater than 46 cm (18 in.) in front of body.

A2-1.5 For two handed push/pull activities the floor to hand height should be between 97 cm (38 in.) and 112 cm (44 in.).

A2-1.6 Consideration should be given to the standing surface to minimize the risk of slips and falls.

A2-1.7 Awkward postures should be avoided. Refer to Related Information 1, Table R1-2 for a list of recommended ranges of awkward postures to avoid.

A2-1.8 For a 2-person handling task, there should be adequate coupling locations and adequate body clearance for the activity. Analyses need to be performed and documented for each person lifting if any of the parameters (e.g., horizontal reach) are different.

A2-2 Selecting and Using the Appropriate MMH Analysis Tool(s)

A2-2.1 Three general MMH evaluation tools are identified in the following matrix. The three tools are the "Application manual for the Revised NIOSH Lifting Equation" lifting equation, biomechanical models, and psychophysical capacity tabular data. Table A2-1 was designed to assist in determining which analysis tools are appropriate for a particular task. For each unique characteristic of the task, a checkmark in the analysis tool column indicates that the analysis tool is appropriate. If there is any aspect of the task that does not show a check mark in a particular tools column, that analysis tool is not appropriate to evaluate the task. Note that in many situations multiple tools are appropriate. In situations where the 1991 NIOSH equation is appropriate, the assessor should use it, because it typically will provide the most conservative results. In other situations, the assessor may use any of the appropriate tools.

A2-2.2 Correct application of the 1991 NIOSH equation is described in Waters, Thomas, et. al., Application manual for the Revised NIOSH Lifting Equation, U.S. Department of Health and Human Services (NIOSH), Cincinnati, OH, 1994.

A2-2.3 There are many sources of psychophysical data. One such source is A. Mital, A.S. Nicholson, M.M. Ayoub, A Guide to Manual Materials Handling, Taylor and Francis, London, 1993.

A2-2.4 Biomechanical analysis can be completed using biomechanical modeling software.

Table A2-1 Criteria to Determine Appropriate MH Analysis Tool(s)

MH Type	*"If" Condition*	*NIOSH (1991)*	*Bio Model*	*Psycho Physical*
2 Hand Lift or Lower	F < 1 lift/5 minutes	✔	✔	✔
	F > 1 lift/5 minutes	✔		✔
	F > 9 lifts/minute	✔		
	Twisting Occurs	✔	✔ (3D)	✔
	Handle Design is an Issue	✔		✔
	Limited Headroom During Lift			✔
	Work Duration > 8 hours			✔
	Load Placement Clearance is an Issue	✔		✔
	Load Asymmetry is an Issue	✔	✔ (3D)	✔
	Length of Object Measured in Frontal Plane of Body > 26"		✔ (3D)	
	Exposure to Heat Stress			✔
1 Hand Lifts	Posture = Standing		✔	✔
	Posture = Kneeling or Seated			✔
1 or 2 Hand Carry	NOTE: Carry is Operationally Defined as Horizontal Movement of Load ≥ 7 feet			✔
1 or 2 Hand Push/Pull	Distance < 7 feet and F < 1 Push/Pull/5 minutes		✔	✔
	Distance ≥ 7 feet and F ≥ 1 Push/Pull/5 minutes			✔
	Push/Pull Task Requires Significant Sustained Forces (e.g., slide box along floor)			✔
Lift/Lower in Non-Standard Postures	Kneeling, Sitting, or Lying			✔

NOTE 1: Under Bio Model, 3D indicates that only a 3-dimensional biomechanical model is appropriate for the task condition.

Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

Table R1-1 Selected Body Dimensions for Females and Males (see Figures R1-1 and R1-2)

Criteria		*5th Percentile Female (Asian)*		*95th Percentile Male (U.S.)*	
Standing Dimensions		**cm**	**inch**	**cm**	**inch**
Stature	(A)	147.1	57.9	189.50	74.60
Eye Height	(B)	135.6	53.4	176.30	69.40
Shoulder height	(C)	120.6	47.5	157.20	61.90
Elbow height	(D)	89.4	35.2	121.40	47.80
Knuckle height	(E)	67.6	26.6	83.10	32.70
Seated Dimensions		**cm**	**inch**	**cm**	**inch**
Seated height	(F)	78.0	30.7	97.30	38.30
Eye height	(G)	66.0	26.0	84.30	33.20
Shoulder height	(H)	51.0	20.1	64.50	25.40
Elbow height	(I)	16.5	6.5	28.70	11.30
Buttock-knee length	(J)	47.0	18.5	65.00	25.60
Popliteal height	(K)	35.0	13.8	52.10	20.50
Knee height	(L)	43.4	17.1	63.20	24.90
Reach		**cm**	**inch**	**cm**	**inch**
Standing vertical grip reach	(M)	171.2	67.4	213.4	84.0
Sitting vertical grip reach	(N)	85.5	33.7	135.6	53.4
Forward grip reach	(O)	58.0	22.8	78.7	31.0

NOTE 1: Dimensions based on Pheasant (1988), MIL-STD-1472, and SAE J833 (1989).

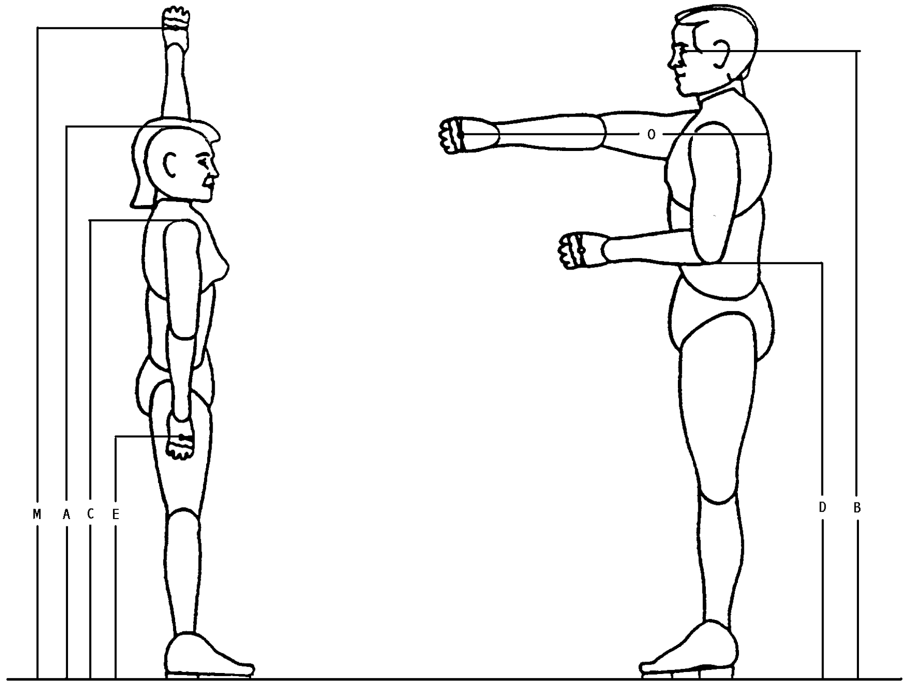

Figure R1-1
Selected 5th Percentile Female and 95th Percentile Male Standing Dimensions

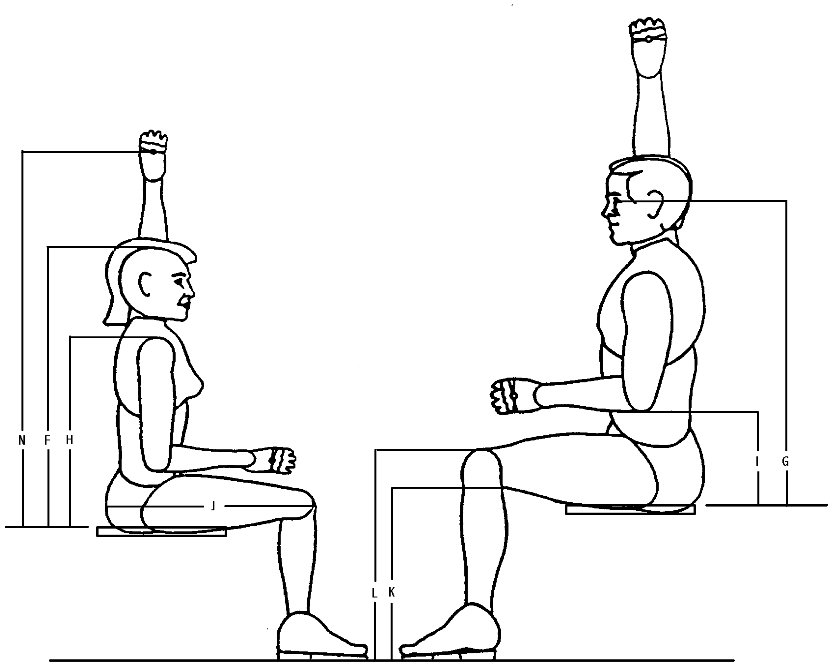

Figure R1-2
Selected 5th Percentile Female and 95th Percentile Male Seated Dimensions

Table R1-2 Awkward Postures

Body Part	*Awkward Posture (angle in degrees)*	*Comments*
Upper extremities		
Shoulder flexion (1)	> 45	Shoulder flexion is defined as reach in front of body mid-line.
Shoulder extension (2)	> 0	Shoulder extension is defined as reach behind body mid-line.
Shoulder abduction	> 45	NOT SHOWN. Abduction is movement of elbow away from body.
Forearm rotation	NA (See NOTE 3.)	NOT SHOWN. Forearm rotation is rotational movement at elbow (e.g., turning knob).
Forearm pronation	> 30	NOT SHOWN. Pronation is "palm facing down". Measured from neutral (handshake) position. Note that forearm pronation is less stressful than either rotation or supination.
Forearm supination (3)	> 30	Supination is "palm facing up". (Note that forearm is supinated in Figure R1-3.) Measured from neutral (handshake) position.
Wrist flexion (4)	> 10	Flexion is closing (reducing) the angle of the wrist.
Wrist extension (5)	> 15	Extension is opening (increasing) the angle of the wrist.
Wrist ulnar/radial deviation	> 10	Deviation is side to side movements of the wrist. Ulnar deviation is bending the wrist in the direction of the little finger. Radial deviation is bending the wrist in the direction of the thumb.
Neck flexion (6)	> 20	Neck flexion is bending the neck forward (e.g., looking downward).
Neck extension (7)	> 0	Neck extension is bending the neck back (e.g., looking up).
Neck rotation	> 45	Neck rotation is turning the neck (e.g., looking to the side).
Back (standing)		
Back bend, forward flexion (8)	> 20	Definition of "Awkward Posture" applies if posture is static.
Back twist	> 30	Measured from mid-sagittal plane of body. (See NOTE 2.)
Seated postures		
Elbow flexion (9)	< 90, OR > 120	A 90 elbow angle is defined as the theoretical "neutral" position.
Back trunk-thigh angle (10)	< 90	Increasing the trunk-thigh angle reduces pressure on the lower back.
Knee angle (11)	< 90	Increasing the angle at the knees reduces stress at the knees.

NOTE 1: Numbers in parentheses refer to numbers in Figure R1-3.

NOTE 2: Mid-sagittal plane is defined as a plane line drawn down the mid-line of the body, perpendicular to the back.

NOTE 3: Angle in degrees not available.

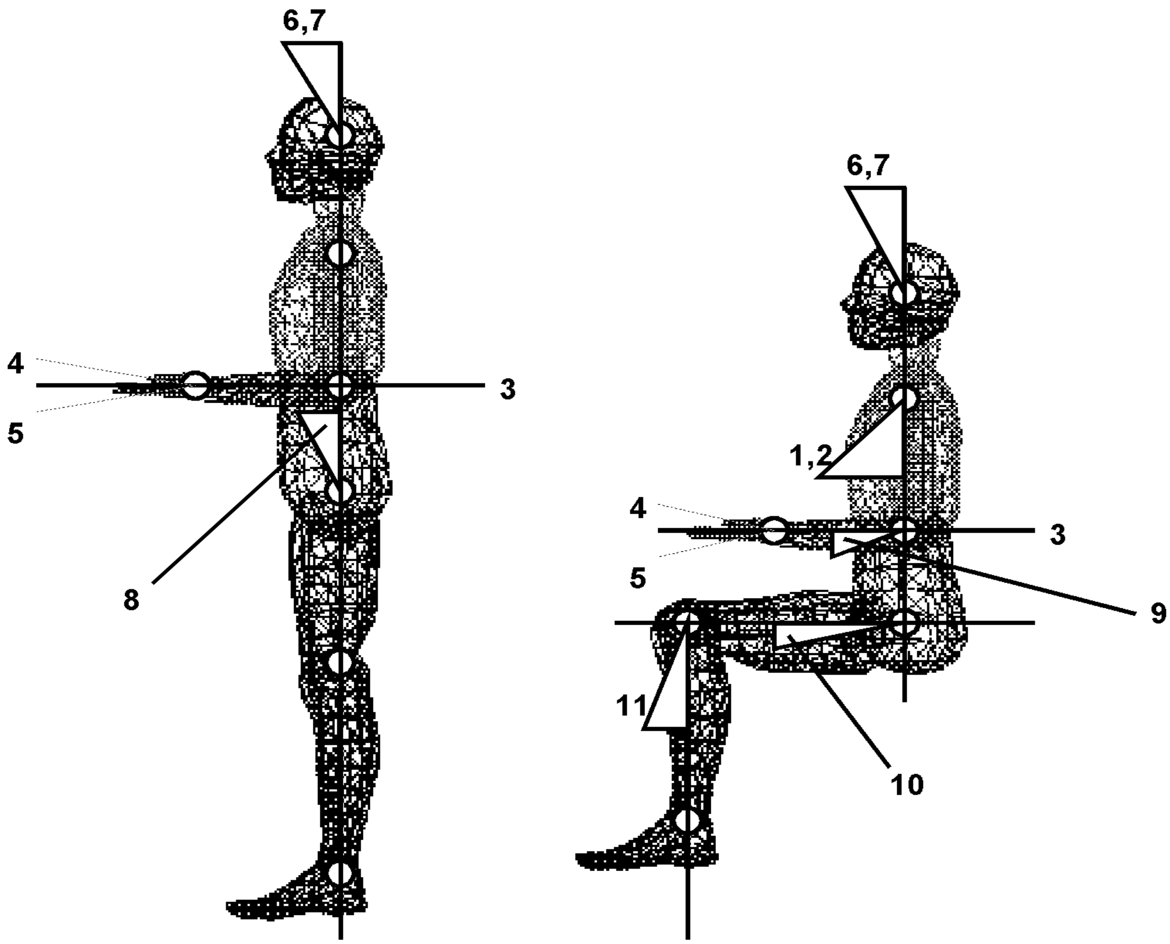

Figure R1-3
Postural Angles

Table R1-3 Maximum Grip Forces

Grip Type	*Glove Use*	*Maximum Force*		
		Infrequent Tasks	*Occasional Tasks*	*Static or Frequent Tasks*
Power Grip: The fingers of the hand wrap around the object, and the thumb overlaps the index finger (e.g., gripping a hammer).		137 N (30.9 lbf)	82 N (18.5 lbf)	41 N (9.4 lbf)
	with cleanroom gloves	116 N (26.3 lbf)	70 N (15.7 lbf)	35 N (8.0 lbf)
	with chemical gloves	111 N (25.0 lbf)	66 N (15.0 lbf)	33 N (7.6 lbf)
Lateral Pinch: Object is held between the thumb and the side of the index finger (often referred to as key grip).		35 N (7.9 lbf)	21.8 N (4.9 lbf)	10.7 N (2.4 lbf)
	with cleanroom gloves	30 N (6.7 lbf)	19 N (4.2 lbf)	9 N (2.0 lbf)
	with chemical gloves	28 N (6.4 lbf)	18 N (4.0 lbf)	9 N (1.9 lbf)
Tip Pinch: Object held between the tips of the thumb and index finger.		24.5 N (5.5 lbf)	14.7 N (3.3 lbf)	7.6 N (1.7 lbf)
	with cleanroom gloves	21 N (4.7 lbf)	13 N (2.8 lbf)	7 N (1.4 lbf)
	with chemical gloves	20 N (4.5 lbf)	12 N (2.7 lbf)	6 N (1.4 lbf)
Palmar Pinch: Fingers pressed against the palm of the hand, with the object held between the fingers and the palm. Thumb is not used (e.g., picking up a sheet of plywood).		36 N (8.2 lbf)	21.6 N (4.85 lbf)	11.1 N (2.5 lbf)
	with cleanroom gloves	31 N (7.0 lbf)	18 N (4.1 lbf)	9 N (2.1 lbf)
	with chemical gloves	29 N (6.6 lbf)	18 N (3.9 lbf)	9 N (2.0 lbf)

RELATED INFORMATION 2
ERGONOMIC RESOURCE DATA

NOTE: This related information is not an official part of SEMI S8 and is not intended to modify or supersede the official guidelines. It was derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

Table R2-1 Standing Workstation Recommendations

Criteria	*Fixed Dimension cm (in.)*	*Adjustable Dimension cm (in.)*
Standing workstation height. Assumes hands are located primarily at work surface height.	maximum 102 cm (40 in.) (See NOTE 2) minimum 96 cm (38 in.)	maximum 122 cm (48 in.) minimum 91 cm (36 in.)
Keyboard height/trackball/mouse (to home row, top of ball or mouse)	maximum 102 cm (40 in.) minimum 96 cm (38 in.)	maximum 122 cm (48 in.) minimum 91 cm (36 in.)
Microscope eyepiece height	Installation of fixed location standing microscope is not recommended	maximum 173 cm (68 in.) minimum 127 cm (50 in.)
Foot clearance height	minimum 15 cm (6.0 in.)	NA
Foot clearance depth	minimum 15 cm (6.0 in.)	NA
Foot clearance width	minimum 49 cm (19 in.)	NA
Work surface edge radius	minimum 0.64 cm (0.24 in.)	NA
Infrequently used hand control height measured from the floor to the midpoint of the control.	maximum 164 cm (64.5 in.) minimum 84 cm (33 in.)	NA
Infrequently used hand control reach measured from leading edge of tool or obstruction.	maximum 64 cm (19 in.)	NA
Frequently used hand control height measured from the floor to the midpoint of the control.	maximum 127 cm (50 in.) minimum 94 cm (37 in.)	NA
Frequently used hand control horizontal reach measured from leading edge of tool or obstruction.	maximum 48 cm (14 in.)	NA

NOTE 1: Data adapted from Advanced Ergonomics Inc., 1994; Ayoub, 1973.
NOTE 2: Standing platform may be required for shorter populations for fixed height designs.

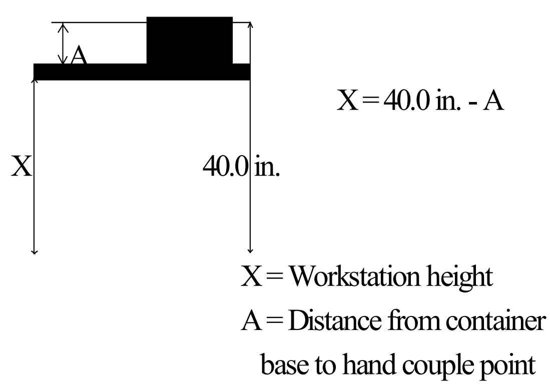

Figure R2-1
Formula for Determining Fixed Workstation Height

NOTE R1-1: For workstations where product handling is the primary task the fixed workstation height may need to be adjusted based on the product container size. The fixed height should allow the hand/container coupling point to be at 40.0 in. (101.6 cm) assuming normal light to moderate material handling/push/pull forces. Use the following formula to determine appropriate fixed heights. See Figure R2-1.

Table R2-2 Seated Workstation Recommendations

Criteria	*Fixed Dimension cm (in.)*	*Adjustable Dimension cm (in.)*
Sitting workstation height (D) (assumes hands are primarily at work surface level)	maximum 76 cm (30 in.) minimum 71 cm (28 in.)	maximum 84 cm (33 in.) minimum 58 cm (23 in.)
VDT Height (single monitor, measured to centerline)	maximum 119 cm (47 in.) minimum 94 cm (37 in.)	NA
VDT height (stacked monitors, measured to top line of top monitor)	maximum 140 cm (55 in.)	NA
Touch screen monitor height	maximum 107 cm (42 in.) (measured to uppermost active pad)	maximum 1214 mm (47.8 in.) minimum 894 mm (35.2 in.) (measured to center of screen)
Microscope eyepiece height (assumes a standard work surface height of 30")	NA	maximum 137 cm (54 in.) minimum 122 cm (48 in.)
Work surface thickness	minimum 5 cm (2 in.)	NA
Work surface edge radius	minimum 0.65 cm (0.25 in.)	NA
Vertical leg clearance	minimum 67 cm (26.5 in.)	NA
Horizontal leg clearance-depth at knee level	minimum 51 cm (20 in.)	NA
Horizontal leg clearance-depth at foot level	minimum 66 cm (26 in.) depth × 25 cm (10 in.) vertical clearance	NA
Horizontal leg width clearance	minimum 61 cm (24 in.)	NA

NOTE 1: Data adapted from ANSI/HFS 100; Ayoub 1973; Advanced Ergonomics Inc., 1994.
NOTE 2: Recommended dimensions are based on the assumption that a footrest and an adjustable chair are provided.

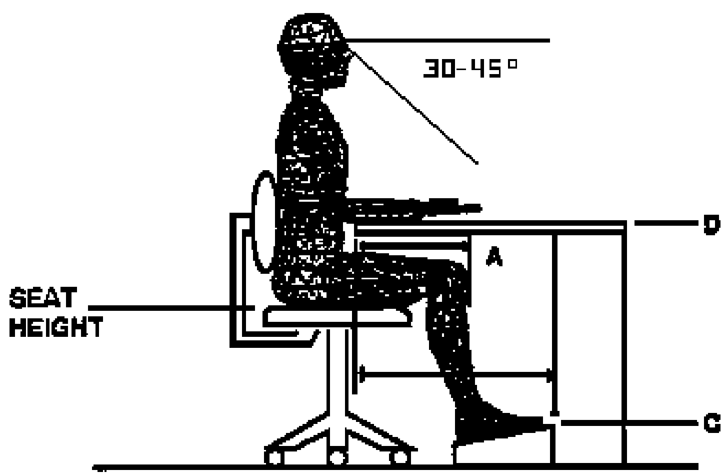

Figure R2-2
Seated Workstation Dimensions

Table R2-3 Sit/Stand Workstation Recommendations

Criteria	*Fixed Dimension cm (in.)*	*Adjustable Dimension cm (in.)*
Height of workstation above floor	minimum 96 cm (38 in.) maximum 102 cm (40 in.)	minimum 91 cm (36 in.) maximum 122 cm (48 in.)
Buttock support adjustment range	------	minimum 66 cm (26 in.) maximum 99 cm (39 in.)
Horizontal leg clearance (measured at knee level)	minimum 51 cm (20 in.)	NA
Horizontal leg clearance (measured at foot level)	minimum 66 cm (26 in.)	NA
Work surface angle		minimum 0 degrees maximum 45 degrees

NOTE 1: Data adapted from Grandjean, 1988; Humanscale, 1981.

RELATED INFORMATION 3
WORKSTATION DESIGN

NOTE: This related information is not an official part of SEMI S8 and is not intended to modify or supersede the official guidelines. It was derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

R3-1 General Considerations

R3-1.1 To enable good system performance, equipment and workspaces should be designed to accommodate the physical dimensions of greater than 90 percent of user population. For recommended anthropometric data see Related Information 1, Table R1-1, Figures R1-1 and R1-2.

R3-1.2 Where impairment of safety might result in danger to life, such as the inability to exit or escape under emergency conditions, wider percentile ranges should be used (e.g., 1st through 99th percentile range).

R3-1.3 Many anthropometric databases cite unclothed dimensions.

R3-1.4 For standing, sitting, and sit/stand work station design recommendations see Related Information 2.

R3-1.5 Critical and frequently used equipment, tools, and work items should be placed in the operator's primary viewing area.

R3-1.6 Provision for placement of required materials and informational items used during operation should be accommodated in the design. Examples of materials/items include product boxes, wafer boxes, maintenance manuals, and shop orders.

R3-2 Working Postures

R3-2.1 Workspace configurations that require static or frequent awkward postures (where the limbs or torso deviate from a neutral position) should be avoided. For ranges of posture to avoid see Related Information 1.

R3-2.2 Equipment should be designed to avoid unsupported awkward static postures for operational tasks lasting more than 20 seconds and unsupported awkward static postures for maintenance and service tasks lasting for more than 40 seconds.

R3-2.3 Where applicable to tasks performed, equipment should be designed to allow both sitting and standing operation.

R3-2.4 Controls, tools, and materials should be located so that the most frequent activities are performed from a neutral posture.

R3-2.5 To prevent users from bending at the waist, the design should place users close to the point of operation by providing adequate leg and foot clearance and keeping work materials at an appropriate height. See the "Supplier Ergonomics Success Criteria" in Appendix 1 for design criteria. For recommended dimensions refer to Related Information 2, Tables R2-1, R2-2, and R2-3.

R3-3 Standing Workstations

R3-3.1 See the "Supplier Ergonomics Success Criteria" in Appendix 1 for standing workstation design criteria. For standing workstation design recommendations see Related Information 2, Table R2-1.

R3-3.1.1 Display screens should be perpendicular to the normal line of sight and the angle of the screen should be adjustable or positioned to minimize glare.

R3-4 Sitting Workstations

R3-4.1 See the "Supplier Ergonomics Success Criteria" in Appendix 1 for seated workstation design criteria. For further design recommendations see Related Information 2, Table R2-2.

R3-4.2 Sit/stand workstations are workstations where the operator can assume a standing posture or a seated posture using a task stool.

R3-4.3 For sit/stand workstations design recommendations see Related Information 2, Table R2-3.

RELATED INFORMATION 4
DESIGN FOR MAINTAINABILITY AND SERVICEABILITY

NOTE: This related information is not an official part of SEMI S8 and is not intended to modify or supersede the official guidelines. It was derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

R4-1 General Considerations

R4-1.1 Equipment design should facilitate rapid and positive fault detection and isolation of defective items.

R4-1.2 Standard parts should be used whenever practicable. Where practical, components should be replaceable as modular packages and configured for rapid removal and replacement (e.g., use of a standard fastener throughout a design).

R4-1.3 Equipment requiring periodic calibration and adjustment should be readily accessible without disassembly.

R4-1.4 Use of cleanroom gloves reduces maximum allowable grip forces listed in Related Information 1, Table R1-3 by 15%.

R4-1.5 Use of cotton gloves reduces maximum allowable grip forces listed in Related Information 1, Table R1-3 by 26%.

R4-1.6 Use of chemical protective gloves reduces maximum allowable grip forces listed in Related Information 1, Table R1-3 by 19%.

R4-1.7 Component design should preclude improper mounting and installation of any component.

R4-1.8 Guides, tracks, or stops should be provided as necessary to facilitate handling and prevent damage to equipment or injury to personnel.

R4-1.9 Refer to ANSI/IES "Practice for Industrial Lighting" for recommended illumination based on task characteristics.

R4-1.10 Structural members or permanently installed equipment should not visually or physically prevent adjustment, servicing, removal of replaceable equipment, or other required maintenance tasks.

R4-1.11 Items which require rapid or frequent maintenance should be most accessible. Predicted or known high failure-rate items should be accessible for replacement with minimal removal of nearby or adjacent non-failed items. If it is necessary to remove non-failed items, then the total ergonomic impact must be assessed to determine conformance.

R4-1.12 Sufficient space should be provided for the use of standard test equipment and required maintenance tools without difficulty or hazard. Self-checking or built-in test features are recommended.

R4-2 Cables, Connectors, Plugs, Receptacles, and Circuit Boards

R4-2.1 Connectors which may need to be disconnected and reinstalled during the life of the tool that are mounted in close proximity should have clearance so that each one can be easily removed and reinstalled.

R4-3 Equipment Enclosures

R4-3.1 Equipment enclosures should be easily removable or sufficiently larger than the item they cover to facilitate installation and removal of components.

R4-3.2 Cover or shield holes should be large enough for fastener clearance without precise alignment.

R4-3.2.1 Access openings should be designed to permit unobstructed physical and visual operation. Size and shape of the access should allow for easy passage of equipment and body parts of a 95th percentile North American male with necessary PPE and tools, as appropriate.

R4-3.2.2 Unless prohibited from a microcontamination standpoint, access covers should be hinged or sliding. Lift off covers will require manual material handling analysis.

R4-3.3 The number and diversity of fasteners used should be minimized. Fasteners requiring non-standard tools should be avoided, except where access is to be restricted.

R4-3.3.1 Hinges, tongue-and-slot catches, and mounting pins should be used to minimize the number of fasteners required. Pin and hook arrangements are preferred to hinges for contamination control.

R4-3.3.2 Captive fasteners should be used where dropping or loss of such items could cause damage to equipment or create difficult or hazardous removal. Captive fasteners should also be provided for access covers requiring frequent removal.

R4-3.3.3 Fasteners should require the minimum number of turns compatible with mechanical stress, alignment, positioning, and load considerations. Items requiring removal for daily or more frequent inspection and servicing should use quick release fasteners.

RELATED INFORMATION 5
HAZARD ALERTS, LABELS, AND ALARMS

NOTE: This related information is not an official part of SEMI S8 and is not intended to modify or supersede the official guidelines. It was derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

R5-1 Hazard Alerts

R5-1.1 Potential hazards to the user, equipment, or product should be identified and documented. An evaluation should be made as to the appropriate method(s) of alert, alert content, and location. More than one method of hazard alert may be necessary. Refer to SEMI S1.

R5-1.2 Hazard alerts should be consistent with information provided in operator and maintenance manuals and other training information materials.

R5-1.3 Hazard alerts can be provided by labels, signs, placards, visual alerts, auditory alarms, status indicators, or hazard alert systems integral with the equipment's operating system (e.g., displayed through the video display).

R5-1.4 Hazard alerts and fault messages should be specific and communicate the consequences of engaging hazards.

R5-2 Labels

R5-2.1 Hazard alert labels should be located such that they are readily visible to the intended viewer and alert the viewer to the potential hazard in time to take appropriate action.

R5-3 Audible Alarms

R5-3.1 To avoid noise pollution, alarms should be reserved for situations requiring immediate intervention to prevent personal injury, equipment damage, process disruption, or product damage.

R5-3.2 Alarm design should take into account impairments that may be caused by clothing and hearing and eye protection.

R5-3.3 Users should be provided with an input device for acknowledging and canceling alarms without erasing information that accompanies the alarm. The capability to cancel alarms should be evaluated for its impact on safety.

R5-3.4 Alarm decibel levels will require a setpoint above the background noise levels sufficient to meet local regulations.

RELATED INFORMATION 6
CONTROLS AND DISPLAYS

NOTE: This related information is not an official part of SEMI S8 and is not intended to modify or supersede the official guidelines. It was derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

R6-1 General Considerations

R6-1.1 The selection and/or design of controls and displays should be based on careful analysis of equipment functionality requirements. This will determine what information the operator needs to make appropriate decisions and responses, thus reducing potential design-induced error.

R6-1.2 Potential errors due to inattention, stress, fatigue, sensory overload, etc., need to be considered during system design. This can be accomplished by ensuring that critical controls and displays attract the user's attention and that controls and displays are clearly labeled and arranged to reduce confusion. Whenever possible, functionally related controls and displays should be grouped together.

R6-1.3 Appropriate feedback should be provided for system status, mode of operation, operator input actions, and equipment malfunctions.

R6-1.4 Controls and displays should be clearly labeled/identified by function. Controls and displays can be coded by color, size, shape, or location to help discriminate between functions and identify critical information. Colors should be in accordance with NFPA 79 and EN 60204-1.

R6-1.5 Placement of labels should be consistent on pieces of equipment (e.g., either below or above controls and displays).

R6-1.6 To accommodate color blind users, color should be supplemental to other means of coding such as icons, words, flashing, shape, etc.

R6-2 Controls

In general, the design of controls should consider the following criteria:

R6-2.1 Control movement or activation should be compatible with users' expectations and provide positive evidence that an input has been accepted or that control action is being accomplished. Feedback can be visual, auditory, tactile, or a combination thereof.

R6-2.2 Controls should be designed and located to minimize awkward postures.

R6-2.3 Controls should be designed, positioned, or protected to prevent inadvertent actuation.

R6-2.4 The maximum width of frequently used control panels should be 68.6 cm (27 in.).

R6-2.5 Controls should be located away from chemical, thermal, radiation, electrical, or mechanical hazards. If such a location cannot be avoided, controls should be appropriately shielded and labeled.

R6-2.6 Control force requirements should be designed in accordance with HumanScale, NFPA 79, EN 60204-1, or another recognized standard.

R6-3 Visual Displays

R6-3.1 The type of visual display selected should depend on the nature of information conveyed and conditions of use. The effectiveness and utility of a visual display generally depends on visibility, legibility, and meaningfulness.

R6-3.2 Further information may be found in MIL-STD-1472 for non-VDT displays, and ISO 9241 for VDTs.

R6-3.3 The visibility of a display is determined by the viewing distance, the size of the display, the location, angle of view, local illumination characteristics, obstructions, or reflections.

R6-3.4 Critical and frequently used displays should be placed in the operator's primary viewing area.

R6-3.5 The display should be positioned so the user has a clear line of sight. Displays should not be located where they are obstructed (by controls, equipment, body parts, etc.) or subject to glare. Display viewing should not require awkward body postures.

R6-3.6 The legibility of a display is determined primarily by its visual angle and luminance contrast with the background.

R6-3.7 There should be sufficient contrast between the object, letters, or numbers on a display to separate them from the background, minimum ratio 3:1, preferred is 7:1 (ISO 9241). Too much contrast may result in glare.

R6-3.8 The ability of displayed information to communicate with the user clearly and precisely depends on the amount of information displayed. Display design should emphasize simplicity and usability to:

R6-3.8.1 Reduce error and decrease response time.

R6-3.8.2 Provide only the amount of information necessary and only at a level of precision required.

R6-3.8.3 Display content in a directly usable form with no transformation required.

R6-4 Auditory Displays

Auditory coding or signals may be used to alert a user to critical conditions or operations. Auditory coding should be supplementary to visual coding. Auditory displays can be used effectively when:

R6-4.1 Vision is overburdened or degraded,

R6-4.2 The message requires immediate action,

R6-4.3 The job requires the operator or maintainer to move around frequently,

R6-4.4 The message is simple and short,

R6-4.5 The message signals an event in time, or

R6-4.6 The message does not need to be referred to later.

R6-5 Control - Display Relationships

R6-5.1 The relationship between associated controls and displays (their organization and layout) is critical to optimizing system performance and minimizing operator error.

R6-5.2 Controls and displays should be organized into functional groups and positioned according to criticality, sequence of operation, and frequency of use.

R6-5.3 Control-display compatibility refers to the extent to which the relationship between a control operation and its effect is predictable by the user. Predictability is determined by individual and population cultural stereotypes (user expectations, previous experience, an idea of the way equipment works, etc.). Lack of compatibility degrades speed, accuracy of performance, and increases probability of error. Types of compatibility include sequential arrangement, spatial organization, and direction of movement. Technology transfer and utilization by a multi-cultural or multi-ethnic work force, as well as across global user populations should consider the impact of cultural and behavioral stereotypes.

R6-5.4 Display layout, control location, and operation should be similar throughout a particular type and/or model of equipment or system. Consistency is particularly important for color, shape, and size of controls, scale markings on displays, and labeling.

RELATED INFORMATION 7
USER COMPUTER INTERFACE

NOTE: This related information is not an official part of SEMI S8 and is not intended to modify or supersede the official guidelines. It was derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the user's responsibility.

R7-1 Operator Interaction

NOTE R7-1: Refer to ISO 9241 for detailed guidance.

R7-1.1 The dialogue should be suitable for the task.

NOTE R7-2: A dialogue is suitable for a task when it supports the user in the effective and efficient completion of the task.

R7-1.1.1 The dialogue should present the user only with information related to the completion of the task.

R7-1.1.2 The information displayed should be in a directly usable form to avoid the need to transpose, compute, interpolate, or translate.

R7-1.1.3 Help information should be task dependent.

R7-1.1.4 Any actions that can appropriately be allocated to the interface software for automatic execution should be carried out by the software without user involvement.

R7-1.1.5 When designing the dialogue, consideration should be given to the complexity of the task with respect to the users' skills and abilities.

R7-1.1.6 The format of input and output should be appropriate to the given task and user requirements.

R7-1.1.7 The dialogue should support the user when performing recurrent tasks.

R7-1.1.8 If default input capabilities exist for a given task (e.g., standard default values) it should not be necessary for the user to input such values. It should also be possible to replace default values with other values or other appropriate default values.

R7-1.1.9 During performance of a task in which data is changed, the original data should remain accessible if the task requires it.

R7-1.1.10 The dialogue should avoid forcing unnecessary task steps.

R7-1.2 The dialog should be self-descriptive.

NOTE R7-3: A dialogue is self-descriptive when each dialogue step is immediately comprehensible through feedback from the system or is explained to the user on request.

R7-1.2.1 After any user action, the dialogue should provide feedback, where appropriate. If severe consequences result from the user action, the system should provide explanation and request confirmation before carrying out the action.

R7-1.2.2 Feedback or explanations should be presented in consistent terminology, which is derived from the task environment, rather than from the dialogue system technology (e.g., when the user wants to input an order to load a cassette, LOAD should be the command rather than a code followed by pressing the ENTER key).

R7-1.2.3 Feedback or explanations should assist the user in gaining a general understanding of the dialogue system as a possible supplement to user training.

R7-1.2.4 Feedback or explanations should be based on the level of knowledge which the typical user may be expected to have.

R7-1.2.5 Feedback or explanations varying in types and length, based on user needs and characteristics, should be available for the user.

R7-1.2.6 To enhance their value for the user, feedback or explanations should strictly relate to the situation for which they are needed.

R7-1.2.7 The quality of feedback or explanations should minimize the need to consult user manuals and other external information, thus avoiding frequent media switches.

R7-1.2.8 If defaults exist for a given task they should be made available to the user.

R7-1.2.9 The user should be informed about changes in the dialog system status that are relevant to the task.

R7-1.2.10 When input is requested, the dialogue system should give information to the user about the expected input.

R7-1.2.11 The requirement to learn special program codes, long sequences, and special instructions should be avoided.

R7-1.3 The dialogue should be controllable.

NOTE R7-4: A dialogue is controllable when the user is able to initiate and control the direction and pace of the interaction until the point at which the goal has been met

R7-1.3.1 The speed of interaction should not be dictated by the operation of the system. It should always be under the control of the user according to the user's needs and characteristics.

R7-1.3.2 The dialogues should give the user control over how to continue with the dialogue. Exceptions may be made for critical alarms, fault situations, as well as process and safety reasons. User interrupt or abort options to terminate interactions should be provided.

R7-1.3.3 If the dialogue has been interrupted, the user should have the ability to determine the point of restart when the dialogue is resumed, if the task permits.

R7-1.3.4 If interactions are reversible and the task permits, it should be possible to undo at least the last dialogue step.

R7-1.3.5 Different user needs and characteristics require different levels and methods of interaction.

R7-1.3.6 The way that input/output data are represented (format and type) should be under the control of the user.

R7-1.3.7 Where alternative input/output devices exist, the user should have the option of which one to use.

R7-1.4 The dialogue should conform with user expectations.

NOTE R7-5: A dialogue conforms with user expectations when it is consistent and corresponds to the user characteristics, such as task knowledge, education, experience, and to commonly accepted conventions.

R7-1.4.1 Dialogue behavior and appearance within a dialogue system should be consistent.

R7-1.4.2 State change actions should be implemented consistently.

R7-1.4.3 Dialogues used for similar tasks should be similar so that the user can develop common task solving procedures.

R7-1.4.4 Immediate feedback on user input should be given where appropriate to user expectations. It should be based on the level of knowledge of the user.

R7-1.4.5 The cursor should be located where the input is wanted.

R7-1.4.6 If a response time is likely to deviate considerably from the expected response time, the user should be informed of this.

R7-1.5 The dialogue should be error tolerant.

NOTE R7-6: A dialogue is error tolerant if, despite evident errors in input, the intended result may be achieved with either no or minimal corrective action by the user.

R7-1.5.1 The application should assist the user in detecting and avoiding errors in input. The dialogue system should prevent any user input from causing undefined dialogue system states or dialogue system failures.

R7-1.5.2 Errors should be explained to help the user to correct them.

R7-1.5.3 Depending on the task, it may be desirable to apply special effort in presentation techniques to improve the recognition of error situations and their subsequent recovery.

R7-1.5.4 In cases where the dialogue system is able to correct errors automatically, it should advise the user of the execution of the corrections and provide the opportunity to override the corrections.

R7-1.5.5 User needs and characteristics may require that error situations are deferred, leaving the decision to the user when to handle them.

R7-1.5.6 Additional explanations should be provided during error correction on request.

R7-1.5.7 Validation/verification of data should take place before attempting to process the input.

R7-1.5.8 Additional controls should be provided for commands with serious consequences.

R7-1.5.9 Error correction should be possible without switching dialogue system states, where the task permits.

R7-1.6 The dialogue should be capable of individualization.

NOTE R7-7: A dialogue is capable of individualization when the interface software can be modified to suit the task needs, individual preferences, and skills of the user.

NOTE R7-8: Although, in many cases, providing users with customization capabilities is very desirable, it is not an acceptable substitute for ergonomically designed dialogues. In addition, customization capabilities should be provided only within certain limits such that modifications cannot cause users any potential discomfort (e.g., unacceptable noise levels with user configured auditory feedback).

R7-1.6.1 Mechanisms should be provided to allow the dialogue system to be adapted to the user's language and culture, individual knowledge and experience of task domain, perceptual, sensory-motor, and cognitive abilities.

R7-1.6.2 The amount of explanation (e.g., details in error messages, help information) should be modifiable according to the level of knowledge of the user.

R7-1.6.3 The user should be allowed to incorporate their own vocabulary to establish individual naming for objects and actions if it suits the contexts and tasks. It should also be possible for the user to add individualized commands.

R7-1.6.4 The user should be able to set up operational time parameters to match their individual needs.

R7-1.6.5 Users should be able to choose between different dialogue techniques for different tasks.

R7-1.6.6 Log in should be a separate procedure that is completed before a user may select an operational step. Passwords should be used to protect (limit access to) parts of the operating system which may be beyond the user's skill level to control safely.

R7-1.7 The dialogue should be suitable for learning.

NOTE R7-9: A dialogue is suitable for learning when it supports and guides the user in learning to use the system.

R7-1.7.1 Rules and underlying concepts which are useful should be made available to the users, thus allowing the users to build up their own grouping strategies and rules for memorizing activities.

R7-1.7.2 Relevant learning strategies, (e.g., comprehension oriented, learning by doing, learning by example) should be provided.

R7-1.7.3 Relearning facilities should be supported.

R7-1.7.4 A number of different means to help the user to become familiar with the dialogue elements should be provided.

R7-2 Video Display Terminals

NOTE R7-10: Refer to ISO 9241 and EN 894-2 for detailed guidelines.

R7-2.1 Display characteristics should be selected to suit the specific conditions of use. For example, the expected viewing distance, ambient levels of illumination, and lighting color (e.g., yellow illumination) in the work area should be considered.

R7-2.2 Displays should be perpendicular to the user's normal line of sight. The angle of the screen should be adjustable or positioned to minimize glare.

R7-2.3 Surfaces immediately adjacent to the display should have a matte finish to control glare.

R7-2.4 Areas coded by luminance only should differ in display luminance with respect to each other by ratio of at least 1.5:1.

R7-2.5 Where blink coding is used solely to attract attention, a single blink frequency of 1Hz to 5Hz with a duty cycle of 50% is recommended. Where readability is required during blinking, a single blink rate of 1/3Hz to 1Hz with a duty cycle of 70% is recommended. It should be possible to switch off the blinking of the cursor.

R7-2.6 The number of colors simultaneously presented on a display should be based on the performance requirements of the task. In general, the number of colors simultaneously presented should be minimized. For accurate identification, the default color set(s) should consist of no more than eleven colors in each set.

R7-3 Input Devices

NOTE R7-11: Refer to ISO 9241 and EN 894-3 for detailed guidelines.

R7-3.1 Input characteristics should be selected to suit the specific conditions of use. For example, the performed task, workstation arrangement, ambient levels of illumination in the work area, and related tasks should be considered.

R7-3.2 Keyboards should permit easy repositioning on the work surface. Other than for special applications with clearly defined tasks, the keyboard should be detachable. The keyboard should be stable during use (i.e., it should not slip or rock).

R7-3.3 Keyboard support surfaces should be adjustable to accommodate standing or seated operation where suitable.

SEMI S9-1101
SAFETY GUIDELINE FOR ELECTRICAL DESIGN VERIFICATION TESTS FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT

This guideline was technically approved by the Global Environmental Health and Safety Committee and is the direct responsibility of the North American Environmental Health and Safety Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1995.

NOTICE: This document as balloted is intended to replace SEMI S9-95 in its entirety.

NOTICE: Paragraphs entitled "NOTE" are not an official part of this document and are not intended to modify or supercede the official guideline. The task force has supplied them to clarify and to enhance usage of the guideline by equipment designers.

1 Purpose

1.1 The purpose of this document is to provide electrical design verification tests, test methods, and acceptance criteria for semiconductor manufacturing equipment. Some of these tests are used as part of the electrical safety evaluation in SEMI S2.

2 Scope

2.1 This safety guideline should be applied to one or more representative samples of the equipment (or parts of the equipment) used for the manufacturing, measurement, assembly, and testing of semiconductor products.

2.2 The following tests are discussed in this document:

- Leakage Current Test (Section 9.1)
- Grounding Continuity Test (Section 9.2)
- Starting Current Test (Section 9.3)
- Input Test (Section 9.4)
- Dielectric Test (Section 9.5)
- Strain Relief Test (Section 9.6)
- Transformer Output Short Circuit Test (Section 9.7)
- Power Supply Output Short Circuit Test (Section 9.8)
- Safety Circuit Function Test (Section 9.9)
- Safety Circuits Conductor Disconnection Test (Section 9.10)
- Capacitor Stored Energy Discharge Test (Section 9.11)
- Temperature Test (Section 9.12)

2.3 This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this safety guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document is not intended to be a comprehensive compilation of electrical tests specified in product safety standards. This document is also not intended to replace any test methods described in any appropriate national or international product safety standards.

3.2 It is not the intent of this guideline to require repetition of tests where the equipment has been certified or tested to other relevant electrical product safety standards. Any applicable test from this guideline that has been previously completed under an applicable product standard and which satisfies the intent of that test should be accepted, even if there are differences in test methods.

3.3 Engineering analysis, when based on sound engineering principles, may serve as an alternative to conducting a test.

3.4 If it is evident from the design and construction of the equipment that a particular test is not safety-relevant, the test need not be performed.

3.5 This document is not intended to address production line or routine testing.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI S2 — Environmental, Health, and Safety Guideline for Semiconductor Manufacturing Equipment

4.2 *IEC Standard* [1]

IEC 61010-1 — Safety Requirements for Electrical Equipment for Measurement, Control, and Laboratory Use, Part 1: General Requirements

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *1500 ohm impedance network* — a network consisting of a 1500 ohm resistor in parallel with a 0.15 μF capacitor.

5.2 *accessible* — capable of being contacted by an IEC accessibility probe (IEC standard test finger, as described in IEC 61010).

NOTE 2: The test finger is also known, in various IEC documents, as the "jointed test finger" and "jointed standard test finger".

5.3 *full load current* — current when the equipment is operated at the maximum manufacturer's specified operating conditions including all motors and heaters designed to operate simultaneously.

5.4 *hazardous energy* — energy of 20 J (Joules) or more, or an available power level of 240 V*A or more.

5.5 *least favorable condition* — the condition which is most likely to result in a test failure.

5.6 *permanently connected equipment* — Equipment that is intended to be electrically connected to a supply by means of connection which can be detached only by the use of tools.

5.7 *primary circuit* — an internal circuit which is directly connected to the external supply mains or other equivalent source (such as a motor-generator set) which supplies the electric power. It includes the primary windings of transformers, motors, other load devices and the means of connection to the supply mains.

5.8 *safe condition* — a condition in which all relevant hazardous energy sources are removed or suitably contained and all relevant hazardous production materials are removed or contained, unless this results in additional hazardous conditions.

5.9 *PE Terminal* — a terminal which is bonded to conductive parts of a piece of equipment for safety purposes and is intended to be connected to an external protective earthing system.

5.10 *standby condition* — condition in which equipment is energized and in its idle state.

5.11 *tool* — an external device used to aid a person in performing a mechanical function. As used in this document, *tool* includes devices such as keys.

5.12 *V*A* — Volt-ampere.

6 Safety Precautions

6.1 The tests outlined in this document are to be performed by trained and qualified personnel who have knowledge of the techniques and the test apparatus described herein.

7 Calibration and Standardization

7.1 All test equipment should be calibrated and traceable to a calibration standards organization (e.g., National Institute of Standards and Technology (NIST) in the United States or the National Metrology Institute in Japan).

7.2 The calibration interval for test equipment should not exceed one year.

8 Test Conditions

8.1 Except where noted otherwise, the equipment should be tested under the least favorable conditions within the manufacturer's operating specifications. These conditions include:

- supply potential
- supply frequency
- position of movable parts
- operating mode (e.g. full temperature conditions, motors in operation)
- adjustment of thermostats, regulating devices, or similar controls in operator-accessible areas

8.2 *Test Supply Potential* — To determine the least favorable supply potential for a test, consider:

- multiple-nominal rated potentials (e.g., 120/240 V)
- extremes of nominal rated potential ranges (e.g., 208–240 V)

8.2.1 Consideration of the tolerance on a nominal rated potential (e.g., 120 ± 5%) is not necessary.

NOTE 3: Some standards (e.g., IEC 61010-1 and IEC 60950) may specify 90% and 110% of any rated supply voltage.

8.3 *Test Supply Frequency* — To determine the least favorable supply frequency for a test, consider the nominal frequencies as specified (e.g., 50 Hz, 60 Hz, or 50/60 Hz).

1 International Electrotechnical Commission, 1, rue de Varembé, Case Postale 131, CH-1211 Geneva 20, Switzerland. Website: www.iec.ch

NOTE 4: Consideration of the tolerance on a nominal rated frequency (e.g., 50 ± 0.5 Hz) is not usually necessary.

8.4 As an alternative to carrying out tests on the complete equipment, tests may be conducted on circuits, components and sub-assemblies independent of the equipment, provided that the results of the tests would be representative of those performed as part of the assembled equipment.

EXCEPTION: The leakage current and grounding continuity tests identified in Sections 9.1 and 9.2 should be completed only on fully assembled equipment.

9 Electrical Tests

9.1 *Leakage Current Test for Cord-and-Plug Equipment*

9.1.1 *Test Equipment* — A 1500 ohm impedance network and a true RMS voltmeter with an accuracy of 1.0%. The impedance network can be a separate assembly or incorporated within a leakage current measuring instrument.

9.1.2 *Procedure* — For equipment connected to the facility branch circuit with a cord-and-plug (plug/socket combination), ensure that the equipment is isolated (e.g., by placing the equipment on a wooden or other isolating surface). Connect the equipment to its rated source of supply with the equipment grounding (PE) conductor disconnected and operate it at the least favorable conditions specified by the manufacturer. Connect the 1500 ohm impedance network between each accessible metal part and the supply equipment grounding (PE) conductor. In determining accessibility of live parts, remove all doors, panels, etc. that are to be removed by the operator during normal operation. Using a true RMS voltmeter, measure the voltage drop across the impedance network. Calculate the leakage current using the formula:

$$I_{leakage} = \frac{Voltage_{measured}}{1500\ ohms}$$

9.1.3 *Acceptable Results* — The maximum calculated leakage current does not exceed 3.5 mA.

9.2 Grounding Continuity Test

9.2.1 *Test Equipment* — Low range ohmmeter with a range to measure 0.10 ohm with an accuracy of 1.0%.

9.2.2 *Procedure* — Disconnect the equipment from the supply. For equipment installed with fixed wiring methods, disconnect the supply equipment grounding conductor (protective earthing conductor) from the main equipment grounding terminal (PE Terminal). Measure the resistance between the power supply equipment grounding terminal (PE Terminal) and each accessible metal part (handle, monitor, doors, etc.) on the equipment using a low-range ohm-meter. Upon test completion, reconnect the supply equipment grounding conductor (protective earthing conductor).

EXCEPTION: Grounding Continuity Test is not required to be measured where accessible metal surfaces are not likely to become energized in a single fault condition.

NOTE 5: Some standards (e.g., IEC 60204-1, IEC 61010-1) may specify this test to be performed using a current injection method.

9.2.3 *Acceptable Results* — The resistance between the grounding conductor terminal and each accessible part shall not exceed 0.1 ohm.

9.3 *Starting Current Test*

9.3.1 *Test Equipment* — None.

9.3.2 *Procedure* — Start the equipment in accordance with manufacturer's instructions three times from a completely stopped condition. Ensure that the time interval between successive starts is sufficient to allow the equipment return to ambient conditions.

9.3.3 *Acceptable Results* — None of the equipment's overload or overcurrent protections activates during this test.

NOTE 6: It is recommended that the peak inrush starting current be measured using an appropriate current measuring device and recorded in the test report.

9.4 *Input Test*

9.4.1 *Test Equipment* — True RMS current measuring equipment, with accuracy of 3.0%.

9.4.2 *Procedure* — Measure the input current to the equipment under the maximum normal operating load conditions (i.e., with all motors, heaters, etc. running at manufacturer's specified maximum loading conditions).

9.4.3 *Acceptable Results* — The measured current does not exceed 110% of the rated full load current value specified on the equipment nameplate.

9.5 *Dielectric Test*

9.5.1 *Test Equipment* — Timer with accuracy of ± 5 seconds. Dielectric Withstand Tester with means of indicating test potential, as well as an audible or visual indicator of electrical breakdown, or an automatic-reject feature for any unacceptable unit. In an alternating current test, the test equipment should include a transformer having sinusoidal output. This transformer should have a rating of 500 VA or greater unless it is provided with a voltmeter that directly measures the applied output potential.

9.5.2 *Procedure* — With the equipment disconnected from its supply, apply a dielectric withstand potential of 1500 Volts AC or 2121 Volts DC between live metal parts of primary circuit(s) and dead metal parts. Surge suppression components and devices, and electronic components certified by an accredited testing laboratory that may be damaged may be disconnected from the circuit for this test. For this test, the following conditions need to be set:

- The equipment should be at its maximum operating temperature
- Switches should be placed in the "on" position
- Circuits through contactors be completed by manually engaging the contacts or bypassing the contactor terminals.

9.5.2.1 Achieve the test potential gradually, starting from zero and holding at the maximum value for a period of one minute.

NOTE 7: A grounded circuit (neutral) conductor, if used in the circuit, is considered a live part.

NOTE 8: Where line-to-ground filter components are installed in the equipment, the DC dielectric potential specified above may be used as an equivalent.

9.5.3 *Acceptable Results* — The equipment does not have a dielectric breakdown as indicated by a puncture, flashover or sparkover.

NOTE 9: Breakdown is often indicated by an abrupt decrease or nonlinear advance of voltage as the voltage is increased. Similarly, a breakdown is often indicated by an abrupt increase in current. Partial discharge (corona) and similar phenomena are disregarded during application of the test voltage.

9.6 *Strain Relief Test*

9.6.1 *Test Equipment* — Timer with accuracy of ± 5 seconds. A calibrated weight to apply a force of 156 Newtons (35 lb) ± 1.56 Newtons (0.35 lb). A supporting surface to secure the equipment.

9.6.2 *Procedure* — For cord-and-plug connected equipment, strain relief is provided to prevent mechanical stress such as a pull or twist being transmitted to terminals, splices or interior wiring. Support the equipment on a surface so it will not move when the force is applied to the cord. Apply a direct pull of 156 N (35 pounds) to the equipment supply cord from the least favorable angle. If necessary use pulleys or other means to adjust the angle of force applied to the strain relief on the equipment. Apply the force gradually by slowly suspending the weight on the cord and maintain the applied force for a period of one minute.

9.6.3 *Acceptable Results* — The equipment supply cord does not displace to the extent that stress could be applied to the internal connections.

9.7 *Transformer Output Short Circuit Test*

9.7.1 *Test Equipment* — Timer with accuracy of ± 5 minutes. A substantial conductor suitable for carrying the short circuit current.

9.7.2 *Procedure* — With the equipment in its standby condition, short circuit the output of each power transformer.

NOTE 10: If overcurrent protection is connected to the output of the transformer under test, connect the short-circuit jumper after this protective device.

EXCEPTION 1: Where the overcurrent protective devices on the input or output of the transformer are rated at not more than 125% of the rated current of the transformer respectively and the overcurrent protective devices are certified by an accredited testing laboratory, the transformer need not be subjected to this test.

EXCEPTION 2: A thermally-protected or impedance-protected transformer that is certified by an accredited testing laboratory need not be subjected to this test.

9.7.3 *Acceptable Results* — A hazardous condition (e.g., smoke, fire, or molten material) does not exist within 8 hours or before activation of overcurrent protection, thermal protection, or other protective circuit/device whichever occurs first.

9.8 *Power Supply Output Short Circuit Test*

9.8.1 *Test Equipment* — Timer with accuracy of ± 5 minutes. A substantial conductor suitable for carrying the short circuit current.

9.8.2 *Procedure* — With the equipment in its standby condition, short circuit the output of each power supply, one at a time.

NOTE 11: If overcurrent protection is connected to the output of the power supply under test, connect the short circuit jumper after this protective device.

EXCEPTION: A power supply that is certified by an accredited testing laboratory and used in accordance with its certification and the manufacturer's instructions need not be subjected to this test.

9.8.3 *Acceptable Results* — A hazardous condition (e.g., smoke, fire, or molten material) does not exist within 8 hours or before activation of overcurrent protection, thermal protection, or other protective circuit/device whichever occurs first.

9.9 *Safety Circuit Function Test*

9.9.1 *Test Equipment* — Depends on safety devices being tested.

9.9.2 *Procedure* — Functionally test each safety circuit (e.g., EMO, Emergency Stop, End-of-travel sensors, loss of exhaust sensors, light curtains, and safety interlocks) by actuation and resetting.

9.9.3 *Acceptable Results* — The following sections provide the acceptable results for the applicable safety systems.

9.9.3.1 When the EMO is actuated, all hazardous voltage and all power greater than 240 volt-amps in the equipment beyond the main power enclosure should be de-energized, except where permitted by SEMI S2.

9.9.3.2 Actuation of the emergency stop and safety interlocks causes the equipment, or relevant parts of the equipment, to be automatically brought to a safe condition.

9.9.3.3 Resetting of the safety circuit should not cause the system to resume operation.

NOTE 12: This test documents the electrical functionality of the safety circuit(s). It is not intended to determine or document the appropriateness of the shutdown actions taken.

9.10 *Safety Circuit Conductor Disconnection Test*

9.10.1 Test Equipment — None.

9.10.2 *Procedure* — For each independent safety interlock (such as door interlock), EMO, and safety sensor (e.g., exhaust sensor, low fluid level sensor), disconnect each conductor, in turn, and each connector, in turn.

9.10.3 *Acceptable Results* — The following sections provide the acceptable results for the applicable safety circuits.

9.10.3.1 The opening of the safety circuit causes the equipment to be placed in a safe condition as if the safety device had been actuated

9.10.3.2 Reconnecting the conductor should not cause the system to resume operation.

9.11 *Capacitor Stored Energy Discharge Test*

9.11.1 *Test Equipment* — Timer with accuracy of ± 1 seconds. DC voltmeter with sensitivity of 1.0%.

9.11.2 *Procedure* — Test each capacitor which stores a hazardous energy (20 J or more). Monitor the voltage across the capacitor terminals continuously. Disconnect the equipment from the supply. Record the voltage across the capacitor terminals after 10 seconds.

9.11.3 *Acceptable Results* — The capacitor is discharged to less than 20 J within 10 seconds of equipment disconnection from the supply.

NOTE 13: The following formula is provided to calculate the energy.

$$J = \frac{1}{2} C V^2$$

where J is the energy in joules,

C is the capacitance in farads and

V is the potential in volts.

EXCEPTION: This criterion does not apply if a tool is necessary to remove a panel to reach the capacitor and the equipment is marked specifying the discharge time—5 minutes maximum—that is required for the capacitor to discharge to less than 20 J.

9.12 *Temperature Test*

9.12.1 T*est Equipment*— Timer with accuracy of ± 5 seconds. A thermometer with a full range resolution of 0.1°C.

9.12.2 *Procedure* — The equipment is to be operated at the manufacturer's maximum design load for 8 hours or until thermal equilibrium is reached (whichever occurs first). Measure and record the ambient room temperature. Measure and record the temperatures of the various components and devices for comparison with Table 1.

NOTE 14: Thermal equilibrium is considered to be attained when three successive readings taken at five minutes intervals indicate that there is no temperature change of the part exceeding 1.0 °C.

9.12.3 *Acceptable Results* — The measured temperatures do not exceed the values listed in Table 1.

Table 1 Maximum Temperature Limit

Parts of the Equipment	*Temperature Limit (°C)*
Knife switch blade and contact jaws	55
Fuse and fuse clip	110
Rubber and thermoplastic insulated conductors	See Note 1.
Field wiring terminals	--
Equipment marked for 60°C or 60/75°C supply wires	75
Equipment marked for 75°C supply wires	90
Buses and connecting straps or bars	125
Capacitors	See Note 2.
Power switching semiconductors	See Note 3.
Printed wiring boards	See Note 4.
Motors and Transformers	See Note 5.

NOTE 1: The temperature as marked on the conductor.
NOTE 2: The temperature marked on the capacitor.
NOTE 3: The case temperature for the applied power dissipation recommended by the semiconductor manufacturer.
NOTE 4: The operating temperature of the board as specified by the board manufacturer.
NOTE 5: The rated temperature of the motor or transformer as specified by the manufacturer, if provided. When not provided, use appropriate standards such as IEC 61010-1 for guidance.

10 Reporting Test Results

10.1 Include the following information on the test data form:

- Name, model, and serial number of the equipment
- Date of tests
- Name(s)/signature(s) of tester(s)
- Complete test methods and conditions
- Complete test results
- Complete test equipment information (type of test equipment, manufacturers' names, model numbers, serial numbers, and calibration information).

10.2 The general configuration and actual operating mode that was used for the test should be clearly documented. Where components are tested separately or only parts of the overall system are operational, this should be documented as a condition for the test results reported. This information can be on the test data form(s), or incorporated in the test report.

10.3 See Table 2 for a sample blank test data form.

SAFETY GUIDELINE FOR RISK ASSESSMENT

1 Purpose

1.1 This document provides a method for assessing the risk associated with any hazard and for ranking different hazards according to the risks they present. The method can be used to differentiate between those hazards which are acceptable and others which require further mitigation to reduce their risk to acceptable levels.

2 Scope

2.1 This method is applicable to hazards associated with semiconductor facilities, processes, and manufacturing equipment. It is used to evaluate the risks presented by identified hazards and provides consistent basis for prioritizing corrective action and allocating of limited resources according to the risks those hazards present.

3 Referenced Documents

None.

4 Terminology

4.1 *hazard* — A condition that is a prerequisite to a mishap.

4.2 *likelihood* — The expected frequency with which a mishap will occur. Usually expressed as a rate (e.g., events per year, per product, per wafer processed).

4.3 *mishap* — An unplanned event or series of events that results in death, injury, occupational illness, damage to or loss of equipment or property, or environmental damage.

4.4 *risk* — The expected losses from a mishap, expressed in terms of severity and likelihood.

4.5 *severity* — The extent of the worst credible loss from a mishap caused by a specific hazard.

5 Procedures

5.1 *Mishap Severity & Likelihood* — Risk assessment first requires evaluating the expected severity and likelihood of occurrence for the mishap that results from the hazard. Examples of mishap severity and likelihood groups are presented in Tables 1 and 2.

For example, the risk assessment for a hazard that can credibly result in disabling injury and may occur once a year would be 2C (Severe/Possible), while a moderate hazard that is likely to occur more than five times per year would have a risk assessment of 3A.

NOTE 1: No standardized criteria for severity or likelihood groupings exist; users should develop groupings that are consistent with their own organization’s hazard control objectives and safety policies.

NOTE 2: Likelihood and severity may vary, depending on the activity phase (e.g. operation, maintenance or service.)

5.2 *Risk Assessment Matrix* — Once a hazard’s risk is determined, decisions can be made about whether the risk is acceptable or whether further mitigation is necessary. The Risk Assessment Matrix (such as the example shown in Figure 1) is a tool for making this judgment in a consistent, repeatable way.

The risk assessment categories tend to group together hazards with similar loss potentials (e.g., rare catastrophic loss and a frequent minor loss). The contours shown in Figure 1 are not standardized and users should define the matrix to suit their specific risk assessment criteria.

Besides establishing the risk assessment category for a single hazard, the matrix can be used to compare and prioritize different risks. This makes it easier to identify and concentrate resources on hazards having the greatest risk. The matrix can also be used to determine the effectiveness of alternative risk reduction strategies so that cost effective hazard reduction can be implemented.

Table 1 Severity Grouping

Severity Group	*People**	*Equipment/Facility**	*Property**
1 - Catastrophic	One or more fatalities.	System or facility loss.	Chemical release with acute, lasting environmental or public health impact.
2 - Severe	Disabling injury/illness.	Major subsystem loss or facility damage.	Chemical release with temporary environmental or public health impact.
3 - Moderate	Medical treatment or restricted work activity (OSHA recordable).	Minor subsystem loss or facility damage.	Chemical release triggering external reporting requirements.
4 - Minor	First aid only.	Non-serious equipment or facility damage.	Chemical release requiring only routine cleanup without reporting.

Table 2 Likelihood Grouping

Likelihood Group	*Expected Rate of Occurrence**
A - Frequent	More than five times per year.
B - Likely	More than once per year, but no more than five times per year.
C - Possible	More than once in five years, but no more than once per year.
D - Rare	More than once in ten years, but no more than once in five years.
E - Unlikely	No more than once in ten years.

* These descriptions are for example only. Use measures that are appropriate for your specific application.

RELATED INFORMATION 1
EXAMPLE OF APPLICATION OF THIS METHOD

NOTE: This supplemental information is not an official part of SEMI S10 and is not intended to modify or supercede the document. It has been derived from practical application by task force members. Publication is authorized by full letter ballot. Determination of the suitability of this material is solely the responsibility of the user.

The severity and likelihood for each mishap have been determined and the resulting risk assessment assigned using the matrix in Figure 1.

Mishap Description	*Severity/*	*Likelihood*	*Risk Category*	*Priority*
I - Service personnel electrocuted due to accidental contact with exposed high voltage when main AC cabinet is opened.	1	B	Critical	1
II - Wafer handling blade breaks in slit valve during infrequentcalibration.	4	C	Low	3
III - Reactive chemicals mix in and destroy exhaust lines.	3	A	High	2

The “critical” and “high” risks presented in mishap descriptions I and III are likely considered unacceptable/undesirable and corrective action to reduce these risks will be indicated. However, the “low” risk of breaking a wafer handling blade during calibration may be considered allowable/acceptable without corrective action.

RELATED INFORMATION 2
EXPANDED HAZARD SEVERITY TABLE

NOTE: This supplemental information is not an official part of SEMI S10 and is not intended to modify or supercede the official document. It has been derived from practical application by task force members. Publication is authorized by full letter ballot. Determination of the suitability of this material is solely the responsibility of the user.

This table gives examples of human and equipment losses resulting from different hazard sources in each hazard severity category:

SEVERITY GROUPING	*HAZARD SOURCE*			
SEVERITY CATEGORY	*Electrical*	*Mechanical*	*Chemical*	*Radiation*
Catastrophic/Human	Death due to electrocution	Paralysis or death due to crushing	Death due to arsine release	Death due to exposure to X-ray source
Catastrophic/Equipment	Loss of tool due to electrical fire	Loss of system due to structural failure	Loss of fab due to pyrophoric release	Exhaust treatment system destroyed due to EMI induced switching failure
Severe/Human	Burn due to contact with exposed RF conductor	Loss of limb crushed by closing doors	Bone damage due to Hydrofluoric Acid exposure	Eye damage due to exposure to laser beam
Severe/Equipment	Heat Exchanger frame destruction due to electrical fire	Structural failure of ancillary equipment rack	Chamber/pump destruction due to incompatible chemicals	Magnetron destruction due to lack of plasma
Moderate/Human	Shock due to contact with exposed conductor	Strain/sprain due to heavy lifting	Burns due to acid spill	Skin burn due to unguarded UV source
Moderate/Equipment	Major PCB or transformer fire due to loose connector	RF generator destruction due to bracket failure	Gas line contamination due to cross connection	Broken susceptor due to EMI induced robot movement
Minor/Human	Startle due to contact with exposed conductor	Minor cut on extremity due to sharp edge	Skin irritation due to contact with solvents	Non-ionizing exposure at TLV
Minor/Equipment	Burned connector due to inadequate torque	Robot blade breakage due to slit valve closure	TEOS spill within secondary containment	EMI-induced CRT flutter

SEMI S11-1296
ENVIRONMENTAL, SAFETY, AND HEALTH GUIDELINES FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT MINIENVIRONMENTS

1 Purpose

1.1 These guidelines are intended as a minimum set of performance-based environmental, health, and safety considerations for minienvironments used in semiconductor manufacturing.

1.2 These guidelines are intended to be a supplement to SEMI S2 (see Section 3.1).

2 Scope

2.1 These guidelines apply to minienvironments used in the manufacturing, metrology, assembly, and testing of semiconductor products.

2.2 Equipment enclosed by, or used in conjunction with, the minienvironments is addressed separately by SEMI S2 (see Section 3.1). Examples are process tools and exhaust emissions abatement devices.

2.3 For "integrated minienvironments," only the minienvironment enclosure portion is addressed by these guidelines.

3 Referenced Documents

NOTE: Documents as listed or referenced shall be the latest available.

3.1 *SEMI Documents*

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

SEMI S8 — Safety Guidelines for Ergonomics/Human Factors Engineering of Semiconductor Manufacturing Equipment

3.2 *NFPA Documents*[1]

NFPA 255 — Standard Method of Test of Surface Burning Characteristics of Building Materials

NFPA 318 — Standard for the Protection of Cleanrooms

3.3 *Other Documents*

ACGIH — Industrial Ventilation - A Manual of Recommended Practice[2]

UL 181 — Standard for Safety Factory-Made Air Ducts and Air Connectors[3]

4 Terminology

4.1 *closed loop air supply* — A system in which air is recirculated from the minienvironment and returned to the minienvironment with minimal make-up air.

4.2 *emergency off (EMO)* — Control circuit which when activated, places the equipment into a safe shut down condition.

4.3 *integrated minienvironment* — The minienvironment that is an integral part of the tool.

4.4 *minienvironment* — A localized environment created by an enclosure to isolate the product from contamination and people.

4.5 *minienvironment end user* — The facility which uses a minienvironment for semiconductor fabrication.

4.6 *minienvironment supplier* — The party that builds, sells, or otherwise provides minienvironment enclosures.

4.7 *tool supplier* — The party that builds, sells, or otherwise provides the tools that are used together with the minienvironments.

5 General Requirements

5.1 *Safety and Health Design Requirements* — Minienvironment manufacturers should consider site-specific design requirements but must not compromise compliance with applicable regulatory requirements. The requirements covered in these guidelines are not all-inclusive. The minienvironment supplier should employ any additional applicable regulatory and industry standards that govern associated components. It is the minienvironment supplier's responsibility to work with the user and tool supplier to understand the local codes and variances.

2 American Conference of Governmental Industrial Hygienists, 6500 Glenway, Building D-7, Cincinnati, OH 45211-4438

3 Underwriters Laboratories Inc., 33 Pfingsten Road, North Brook, IL 60062

5.2 *Environmental Design Requirements*

5.2.1 In order to assess the environmental impact of minienvironments, the minienvironment supplier should provide a listing of materials of construction showing the compatibility with chemical and process materials typically used in the given minienvironment. In the case of “non-typical” chemical and process chemicals, the minienvironment supplier and minienvironment end-user will evaluate the particular materials involved to ensure compatibility. “Nonprocess” chemical wastes (i.e., wastes not in contact with the product such as oil filters, pump oils, etc.) that are generated by routine preventative maintenance should be included.

5.3 Materials of construction should be in conformance with SEMI S2, Section 19.

6 Enclosure Interlocks

6.1 Not all enclosure panels, doors, and hatches require interlocks. There may be cases where the customer requires ports for manual access for product load/unload or tool adjustment without process tool interrupt. The need for interlocks should be assessed. If the overall level of safety is not compromised, interlocks need not be provided.

6.2 Interlocks are required when the minienvironment replaces an interlocked door or panel on the process tool or where the minienvironment provides the primary barrier to operator exposure to chemical, electrical, mechanical, thermal, radiation or other recognized hazards.

7 Chemical and Physical Hazards

7.1 The addition of the minienvironment and its associated components should not compromise equipment safety and health considerations required for conformance with SEMI S2.

7.2 *Shut-off Valves* — Manual shut-off valves for hazardous materials should be clearly visible, labeled, and easily accessible. Access to these valves should not be restricted by any part of the minienvironment.

8 Noise

The addition of a minienvironment system should not cause the noise level to exceed conformance with SEMI S2, Section 9 (see Section 3.1).

9 Ventilation & Exhaust

9.1 Recirculating air ducts, connectors, and ventilation components within the minienvironment, should be constructed of noncombustible material of Class 0 or Class 1 materials as tested in accordance with UL 181, Standard for Safety Factory-Made Air Ducts and Air Connectors.

9.2 Recirculating air duct materials should be compatible with chemical processes used in the given minienvironment; the minienvironment supplier should provide a listing of materials of construction showing the compatibility with chemical and process materials typically used in the given minienvironment. In the case of “non-typical” chemical and process materials, the minienvironment supplier and minienvironment end-user will evaluate the particular materials involved to ensure compatibility.

9.3 Exhaust should not be altered in any fashion to accommodate a process where flammable liquids are used or flammable vapors present. Dampers, where required for balancing or control of the exhaust system, should be of the locking type.

9.4 Primary exhaust and monitoring of the equipment/process enclosed should be incorporated as defined in SEMI S2 (see Section 3.1).

9.5 Minienvironments with a closed loop air supply should control fugitive emissions in accordance with SEMI S2, to prevent the buildup of gases and vapors within the enclosure.

9.6 Ventilation of tools and areas in which hazardous materials are used, should comply with the ACGIH reference in Section 3.2.

10 Electrical

The addition of the minienvironment and associated equipment should be in compliance with SEMI S2 (see Section 3.1).

11 Emergency Shutdown

Emergency off (EMO) buttons should be relocated, or additional EMO buttons installed, if the original EMOs are out of reach or obstructed due to mini-environment installation.

12 Ergonomics/Human Factors

12.1 Ergonomics/human factors should comply with SEMI S8 (see Section 3.1).

12.2 Areas of particular concern for minienvironments include load/unload ports and maintenance accesses. The design should discourage extended reaching, lifting, pulling, and manual orientation of product and/or containers.

13 Seismic Event Design

Minienvironments and associated equipment should be designed in conformance with SEMI S2, Section 17 (see Section 3.1).

14 Fire Suppression

14.1 Whenever possible, non-combustible materials should be used in minienvironment design and construction. Fire detection/suppression should be incorporated based on evaluation of the minienvironment size, materials of construction, the process, equipment enclosed, the facility design, and interaction with the facility fire detection/suppression systems.

14.2 If fire sprinklers are used, they should be the "quick response" (QR) type.

14.3 If the minienvironment prevents personnel exposure to the tool and process, an automatic gaseous fire suppression system may be used as an alternative to sprinklers. Gaseous extinguishing systems should be actuated by optical detectors.

15 Maintenance & Servicing

15.1 *Maintenance and Service Preparation of Minienvironments with Chemical Process Tools* — Exhaust design at the tool should be adequate to prevent the concentration buildup of fugitive vapor emissions in the tool and minienvironment. The exhaust should be maintained during maintenance and service operations even though the enclosure doors are open.

15.2 Hazardous materials should be avoided for service and maintenance requirements.

15.3 Minienvironment panels, doors, and access ports removed for service or maintenance, should be stored in a secure manner that will not permit these parts to fall, obstruct passage ways, or otherwise cause tripping or handling hazards.

SEMI S12-0298
GUIDELINES FOR EQUIPMENT DECONTAMINATION

1 Purpose

1.1 This document establishes guidelines for decontaminating equipment which has been exposed to hazardous materials and which is intended for further productive use. Equipment intended for further productive use may include, but is not limited to, that being offered for reuse, resale, repair, refurbishment, or relocation.

1.2 These guidelines should be adapted at each site with proper consideration given to local, state, national, and international regulations and organization policies.

2 Scope

2.1 These guidelines apply to the preparation for transfer or relocation of equipment which has been exposed to hazardous or toxic materials and may pose a threat to human health or the environment. These activities may include, but are not limited to, shutdown, dismantling, removing, labeling, and packaging prior to transport.

2.2 These guidelines describe minimum requirements for documentation of decontamination and notification of residual hazards associated with decontamination.

2.3 The level of decontamination required for equipment designated for reuse in the same service in the same location may be assessed on a case-by-case basis by the site Environmental, Health, and Safety organization.

2.4 These guidelines are intended to be used to ensure that decontamination prior to transport occurs to the greatest extent possible, while acknowledging practical limitations which may exist in individual circumstances.

3 Referenced Documents

None.

4 Limitations

4.1 These guidelines are not intended to address decontamination requirements for the preparation of equipment for final “end-of-life” disposal.

4.2 These guidelines are not intended to supersede applicable international, governmental, site, or original equipment manufacturer requirements.

5 Terminology

5.1 *decontamination* — The removal of materials in or on equipment.

5.2 *equipment* — Process tools, chemical (liquid or gas) controls and delivery systems, ancillary support systems, structures, piping, ductwork, parts, and subassemblies (e.g., vacuum pumps, pump packages, effluent/exhaust treatment systems).

5.3 *hazardous material* — Any chemical, substance, or compound which is defined or interpreted to pose risks or hazards to human health or the environment by applicable international, national, regional, or local laws or regulations.

5.4 *health hazard* — A chemical for which there is statistically significant evidence based on at least one study conducted in accordance with established scientific principles that acute or chronic health effects may occur in exposed persons. Health hazards include chemicals which are carcinogens, toxic or highly toxic materials, reproductive toxins, irritants, corrosives, sensitizers, hepatotoxins, neurotoxins, agents which act on the hematopoietic system, and agents which damage the lungs, skin, eyes, or mucous membranes.

5.5 *transferor* — The party with physical custody of the equipment and responsibility for transfer.

5.6 *transferee* — The party who will receive physical custody of the equipment.

6 Responsibility

6.1 It is the responsibility of the equipment transferor to ensure the removal or minimization of all hazardous materials associated with the subject equipment prior to transfer or relocation. Hazards not addressed in the guideline may exist, including undissipated electrical charges or mechanical energy. It is recognized that, in many cases, complete chemical decontamination cannot be achieved without destruction of the equipment. The equipment transferor should ensure that *all* known remaining potential hazards are clearly identified to the transferee.

6.2 It is the responsibility of the equipment transferor to ensure residues, waste materials, and scrap parts/ equipment that are generated as part of the equipment decontamination process are safely handled and appropriately disposed of as per local, state, national, and international regulations or standards.

7 Personnel Safety

7.1 Assessment and decontamination procedures should be performed only by properly trained and equipped personnel.

7.2 Any specific procedures used to follow these guidelines should be pre-approved by the site environmental, health, and safety organization prior to decontamination activities.

7.3 Assessment and decontamination procedures should include requirements for appropriate personal protective equipment.

8 Equipment Assessment Prior to Decontamination

8.1 An assessment should be performed on all equipment prior to transfer. Assessment of equipment should initially consider history of the equipment and visual inspection. If initial assessment shows a potential for equipment to have contacted hazardous materials during the life of the equipment, further assessment needs to be performed. (See the flowchart in Figure 1.)

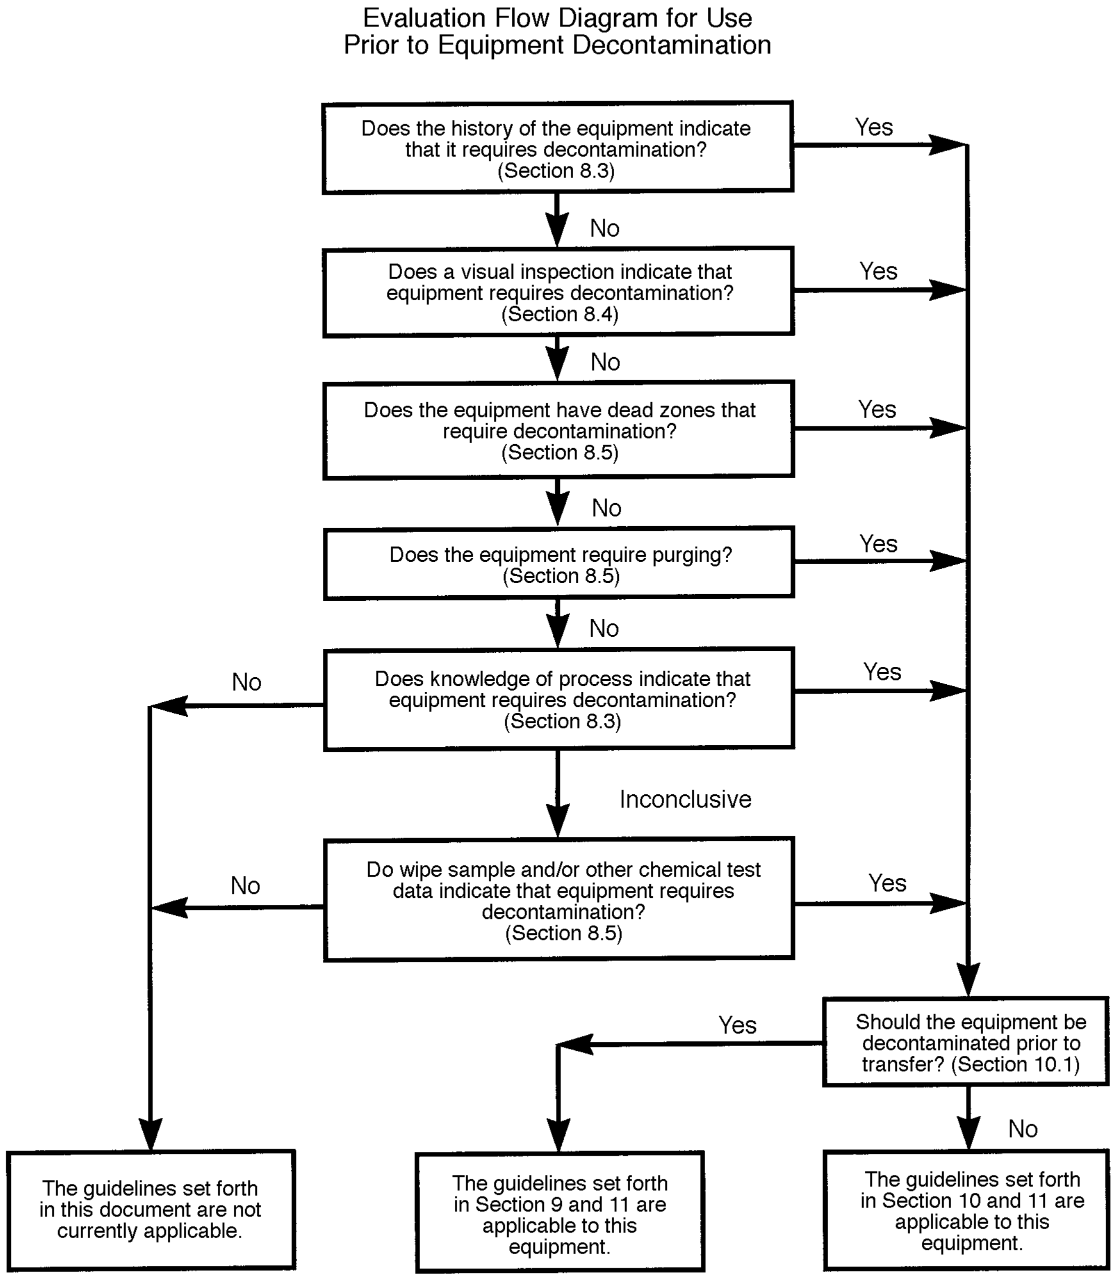

Figure 1
Equipment Assessment Flowchart

8.2 Prior to decontamination, the equipment should be evaluated for abnormalities or non-functionality that may affect the evaluation and decontamination efforts.

8.3 Decontamination should be performed on all areas of equipment which had potentially contacted hazardous materials during the life of the equipment, unless the areas are judged non-hazardous by the criteria set forth in this section. The areas to be decontaminated include external surfaces, internal areas which are accessible without disassembly, and areas accessible during normal operations. Normally inaccessible areas should be addressed on a case-by-case basis by the site Environmental, Health, and Safety organization. Normally removable parts may also require cleaning.

8.4 Visible residues on equipment surfaces, including liquids, powders, flakes, or films, potentially indicate the presence of hazardous materials. All visible indicators of hazardous materials should be assumed to be hazardous unless otherwise determined and documented by appropriate test, analysis, or evaluation.

8.5 Wipe sampling and chemical testing verifying the absence of materials posing physical and health hazards is recommended for all equipment that has been exposed to hazardous materials (regardless of the presence of visible residues).

8.5.1 It is recommended that professional guidance be used to determine the number, type, and location of samples that should be taken. *General guidance is available through air sampling strategy methodologies developed by NIOSH (Occupational Exposures Sampling Strategies) and through surface sampling strategies developed by the Nuclear Regulatory Commission (Manual for Conducting Radiological Surveys in Support of License Termination).*

8.6 If results of activities in Sections 8.2–8.5 indicate that equipment should be decontaminated prior to transfer, refer to Section 9 of this document. If results of activities in Sections 8.2–8.5 indicate that equipment requires decontamination but will not or cannot be decontaminated prior to transfer, see Section 10. If results of activities in Sections 8.2–8.5 indicate that equipment does not require decontamination prior to transfer, this guideline is not currently applicable to the equipment in its present state.

9 General Guidelines for Decontamination

9.1 All activity-specific safety and health procedures, including, but not limited to, hazardous energy control procedures, must be followed.

9.2 Equipment should be decontaminated before movement. If movement of the equipment is required prior to decontamination, precautions should be taken to remove potential sources of leakage, spillage, offgassing, or hazardous material emissions. These precautions may include draining, purging, and then the use of appropriate barriers, covers, or containment devices.

9.3 Chemical supply sources should be made safe prior to disconnecting or removal from the equipment and capped prior to the beginning of the cleaning process. Exhaust ventilation to control exposures to, and the spread of, airborne particulate should remain in service during equipment decontamination, or alternate exhaust provisions should be made.

9.4 Where equipment parts are routinely removed from the equipment for cleaning, such as those used in ion implanters, photoresist spinners/developers, and metal deposition chambers, these parts should be cleaned prior to equipment transfer.

9.5 Where equipment parts are routinely removed and replaced, such as filters, O-rings, or oil traps, these parts should be removed and replaced with clean parts or appropriate blanking device prior to equipment transfer. If any such parts are removed but not replaced, this fact should be noted on decontamination documentation (see Section 12 of this guideline).

9.6 All liquid and gas lines on the equipment should be appropriately purged, drained, protected against corrosion and process contamination, and securely sealed with blanking plugs, caps, or similar devices.

9.7 Thorough decontamination may not be achieved within component systems or equipment due to inaccessibility (i.e., “dead zone”) or to physical characteristics of materials. Equipment with such zones require additional cycle purges and/or disassembly for access and proper cleaning. If complete decontamination cannot be achieved, follow the guidelines outlined in Section 11.

9.8 While disconnecting equipment or removing components, gas leak monitoring and pH levels should be measured.

10 Requirements for Equipment Transfers without Complete Decontamination

10.1 It is recognized that, in some cases, complete chemical decontamination cannot or will not be desired or achieved for various reasons (e.g., it will destroy the equipment (i.e., pumps), there is a need for failure analysis). This section establishes guidelines for the transfer of equipment intended for further productive use which cannot or will not be completely decontaminated prior to transfer.

10.2 If the contaminated equipment is a sub-component or subassembly of a larger piece of equipment which will not be otherwise decontaminated, the contaminated sub-component or subassembly should be removed and transferred separately under the requirements of this section.

10.3 Prior to transfer, the transferor must ensure that any remaining potential hazards are clearly identified to persons handling, transporting, and receiving this equipment, as specified in Section 11. All requirements in Section 11 must be followed, with the exception of Section 11.3.2.

10.4 Prior approval must be obtained before transfer of contaminated equipment. Prior approval should consist of receipt of all documentation and certifications specified in Section 11 before shipment and a signed authorization from the receiver to accept the equipment.

10.5 Equipment which is not completely decontaminated is potentially a hazardous material. Transfer of this equipment, including transportation, must be in accordance with all applicable local, state, national, and international regulations and organization policies.

11 Documentation and Certifications

11.1 The documentation recommended by this guideline is in addition to that required by local, state, national, and international regulations.

11.2 Documentation and certifications should be securely attached in a clear, weatherproof bag and transported with the equipment.

11.3 The following documentation and certifications should be prepared prior to transfer of equipment:

11.3.1 A history of all hazardous materials used in the equipment and potential by-products, including concentrations, if known. At a minimum, list the hazardous materials used in the tool just prior to decontamination or transfer.

11.3.2 Documentation of the procedure used for decontaminating the equipment, including:

11.3.2.1 the cleaning procedures used (including chemicals used for cleaning),

11.3.2.2 liquid or gas purge procedure used,

11.3.2.3 testing procedure used to determine adequacy of decontamination,

11.3.2.4 results of tests, and

11.3.2.5 other significant information pertinent to the decontamination activities, including parts removed for separate decontamination.

11.3.3 When it is likely that hazardous material residues remain in or on the equipment, a warning must accompany the equipment. The warning should identify suspected hazards, state appropriate personal protective equipment that should be worn, and precautions that should be taken when handling the equipment.

11.3.4 Documentation should include the name and phone number of the responsible/knowledgeable parties in case of emergency or requirements for additional information.

11.3.5 A certification by a responsible site environmental, health, and safety representative that states the equipment has been prepared for transfer according to this guideline.

RELATED INFORMATION 1
EXAMPLES OF WIPE SAMPLING PROCEDURES

NOTE: This related information is not an official part of SEMI S12 and is not intended to modify or supersede the official standard. It has been derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

Wipe sampling should be conducted primarily on nonporous surfaces. "Wet" (swab or filter paper with solvent) or "dry" (swab or filter paper without solvent) wipe sampling techniques may be used. These procedures are based on those contained in the US EPA's "Guide for Decontaminating Buildings, Structures, and Equipment at Superfund Sites," EPA/600/2-85/028, March, 1985. The sample area has been decreased in the wet wipe sampling procedure from 0.25 m^2 to 100 cm^2 (0.01 m^2) due to the size of equipment and surfaces anticipated to be sampled for this SEMI Guideline. *Another relevant document on sampling for surface contamination is contained in the OSHA - Occupational Safety and Health Administration, U.S. Department of Labor, OSHA TECHNICAL MANUAL, CPL 2 - 2.20B, Chapter 2, Sampling for Surface Contamination, February 5, 1990*. Chemical-resistant gloves should be worn while performing these procedures. Gloves should be clean to avoid tainting the samples obtained and should be changed between the securing of samples to avoid cross-contamination.

R1-1 General Recommendations

R1-1.1 Assure that the marking method for the sample container and area to be wiped will not interfere with the intended analysis.

R1-1.2 Assure that the container will not absorb the material being sampled or add interfering material that will be detected during analyses.

R1-1.3 Assure that the wetting agent will not react with the material being sampled, interfere with the analysis, or degrade the shipping container.

R1-1.4 Should it become necessary to swipe an area other than 100 cm^2 (e.g., a lever or knob or other part of a tool), then record the estimated or, preferably, measured swipe area.

R1-1.5 Submit a blank with each batch of swipe samples. The blank is a sampling device (such as a swipe tab) of the same type and from the same batch as that used for the sampling and which is wetted and handled just like the samples, but which is not rubbed on a surface.

R1-1.6 Use appropriate personal protective equipment during sampling.

R1-1.7 Samples should be analyzed by a competent and appropriately certified laboratory for the hazardous materials being evaluated.

R1-1.8 The *sampling* and *analytical* methods used should be *appropriate for the agent in question, with the NIOSH Manual of Analytical Methods, EPA's Test Methods for Evaluation of Solid Wastes (EPA SW-846), and OSHA's Sampling and Analytical Methods being established methodologies*. *If new methods are to be* developed or reviewed, *they should be* approved by an industrial hygienist certified by the American Board of Industrial Hygiene or by another appropriately certified or registered professional.

R1-2 Wet Wipe Sampling Procedure

R1-2.1 Mark off a square area of approximately 100 cm^2 on the surface to be wiped, using a template which is cleaned between each sampling event. If a template is unavailable or the area to be wiped is less than 100 cm^2, note the exact dimensions and establish markings on the four outer corners of the area to be wiped.

R1-2.2 Label the appropriate wet sample container with the information listed in R1-1.5.

R1-2.3 Hold a filter paper with a clean, *impervious*, gloved hand or metal clamp, and saturate the wipe with either deionized water, isopropyl alcohol, *or other wetting* agent, depending on the *hazardous material* to be sampled.

R1-2.4 Wipe the sampling area starting at the outside edge and progressing toward the center, making concentric circles of decreasing size, applying moderate pressure. Fold the wipe sample with the exposed side in, and fold it over again.

R1-2.5 Carefully place the completed wipe sample in the container for storage and transportation, without allowing the sample to contact any other surfaces.

R1-3 Dry Wipe Sampling Procedure

R1-3.1 Label the appropriate dry sample container with the information listed in R1-1.5.

R1-3.2 Hold a filter paper wipe with a clean, impervious, gloved hand.

R1-3.3 Wipe the sampling area, starting at the outside edge and progressing toward the center, making concentric circles of decreasing size, applying maximum pressure. Fold the wipe sample with the exposed side in, and fold it over again.

R1-3.4 Label a glass-stoppered jar or zipper-closure plastic bag with the information listed in R1-1.5.

R1-3.5 Carefully place the completed wipe sample in the container for storage and transportation without allowing the sample to contact any other surfaces.

R1-4 Scrape and Bulk Sampling

NOTE: A scrape sample is one made by abrading material and collecting it in a container which is sent to a laboratory for analysis. Scrape sampling might be done to assure lead and hexavalent chromium are not present in paint on the exterior of a tool. Bulk sampling requires the collection of *adequate amounts of the suspected material to allow for meeting minimum detection limits of the sampling and analytical techniques being used. Close consultation is needed with the accredited laboratory performing the analysis.*

R1-5 Sample Control

R1-5.1 Label each sample container with the following information before sampling:

- Sample Number
- Sample Location (where was sample taken from)
- Sample Type *and Media Used*
- Date of Sample
- Name of Person Performing Sampling
- Areas Sampled (in cm^2)

R1-5.2 Record each sampling event in a log book. Include a rough sketch of the equipment, associated areas of concern, and exact sampling locations. Also include any other pertinent notes or details which may affect the interpretation of sample results.

R1-5.3 Follow the chain of custody procedures outlined in EPA SW-846.

R1-5.4 Analyze samples using standard methods, such as those specified by *NIOSH*, *OSHA* or *EPA* SW-846, whenever possible. (See Section R1-1.8 for additional details.)

RELATED INFORMATION 2
EXAMPLE OF METHOD FOR ESTABLISHING "NON-HAZARDOUS" LEVELS

NOTE: This related information is not an official part of SEMI S12 and is not intended to modify or supersede the official standard. It has been derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

This method was compiled from various sources. The applicability of this method and the validity of its assumptions in the application for which it is considered must be determined by an appropriate professional.

R2-1 Method 1

This method is designed to be protective of the health and safety of untrained and unprotected individuals. In this method, "non-hazardous" level is determined by assessment of the risk posed by potential exposure to the contaminant(s). (This method is based on the assumptions that 1) the exposed portions of a worker's body collect a single layer of the contaminant, with a density half that of the layer on the contaminated surface, in the course of a day and that 2) this contaminant is then incorporated, at the end of the day, into the body by either absorption or ingestion.) This method is, therefore, probably inappropriate for contaminants which are absorbed rapidly throughout the day.

R2-1.1 Toxicity criteria are determined for each of the chemicals identified as potentially leaving a residue. As an example, toxicity criteria used are reference doses (RfDs) for human uptake of chemicals (US EPA's Integrated Risk Information System, 1996), and no significant risk levels (NSRLs) defined under California's Safe Drinking Water and Toxic Enforcement Act of 1986 (Proposition 65). Daily exposures to the RfD (expressed in mg/kg-day) over a lifetime are not expected to cause adverse health effects (non-cancer effects). Daily exposure to the NSRL (μg/day) over a lifetime are considered to pose an insignificant (less than 1 in 100,000) increased cancer or reproductive risk.

R2-1.2 Oral and dermal exposures are considered. Dermal exposure is assumed to occur through direct contact with contaminated work *surfaces* (i.e., hands, arms, and face). Oral exposure is assumed to occur though *direct* contact with *contaminated work surfaces and* hands, and subsequent contact between hand and mouth.

R2-1.3 The equations used in this method to calculate the oral and dermal “Health-Based Cleanup Levels (HBCL’s)” are:

$$HBCL_{oral} = \frac{RfD \times BW}{SA_O \times MF \times CE \times AF_O \times EF}$$

$$HBCL_{dermal} = \frac{RfD \times BW \times ED}{SA_d \times CE \times AF_d \times EF}$$

Where :

$RfD =$ EPA RfD [mg/kg – day]

$BW =$ Body weight [70 kg]

$ED =$ Exposure duration [0.5 days]

$SA_O =$ Surface area of exposed hands [0.084 m^2]

$SA_d =$ Surface area of exposed hands, forearms, and head [0.316 m^2]

$MF =$ Fraction of exposed dermal are contacted by mouth [0.5/day]

$CE =$ Skin contact efficiency [0.5]

$AF_O =$ Gastro-intestinal absorption factor [1.0] (conservative)

$AF_d =$ Dermal absorption factor [0.01]

$EF =$ Exposure factor [12 hours/24 hours; 250 days/365 days; 40 years/70 years = 0.20]

Body weight and surface area factors are as suggested by EPA’s *Exposure Factors Handbook* (1989). The fraction of skin contaminant that will be ingested orally (MF) is conservatively assumed to be 50%. This is approximately equivalent to a person ingesting all of the chemical that contacts the palms of the hands, but not the backs. Contact efficiency (CE) refers to the fraction of chemical that is removed from the contaminated surface through contact with the skin. It is assumed that no more than 50% of the chemical contamination from equipment will rub off the surface and adhere to the skin. Oral and dermal absorption factors are chosen as the most conservative numbers due to limited available data.

The exposure factor (EF) represents the fraction of time that a person could be expected to be in contact with chemical contamination from exposed surfaces. Exposure to surfaces is assumed to follow an occupational exposure scenario. This scenario includes the following conservative assumptions:

- A person works at the facility for 40 years of a 70-year lifetime;
- Exposure occurs 250 days per year (365 days);
- The skin is in contact with the chemicals for 12 hours per day. This assumes that the chemicals are not removed from the skin until washed, and the skin is washed only once per day.

R2-1.4 The final HBCL for each chemical is then the lower of the levels for oral or dermal exposure routes.

NOTE: These HBCLs represent levels that are considered to be health-protective for a person who contacts equipment with residual contamination on a daily basis. These values are based on extremely conservative assumptions and are likely to provide an overestimate of a health-protective clean-up level.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI S13-0298
SAFETY GUIDELINES FOR OPERATION AND MAINTENANCE MANUALS USED WITH SEMICONDUCTOR MANUFACTURING EQUIPMENT

NOTICE: These safety guidelines do not purport to address all of the safety issues associated with their use. It is the responsibility of the user of these guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1 Purpose

1.1 These guidelines present considerations when drafting operation and maintenance manuals in order to help hazard reduction in operation and maintenance of equipment used in semiconductor manufacturing. These guidelines supplement Section 18 of SEMI S2.

2 Scope

2.1 These guidelines apply to the operation and maintenance manuals used with equipment that is used for production, measurement, assembling, and testing of semiconductor products. These guidelines contain the following items:

- Purpose
- Scope
- Referenced Documents
- Terminology
- Concept of Operation and Maintenance Manuals
- Hazards Inherent in Equipment
- Hazardous Energy Control Procedures
- Hardware Safety Interlocks
- Hazard Alerts
- Hazard Inherent in Equipment
- Material Safety Data Sheet (MSDS)
- Personal Protective Equipment (PPE)
- Inspection of System Equipment and Maintenance of Consumables
- Training Requirements
- Place of Supplier's Contact in Case of Emergency
- Laws and Regulations
- Related Documents

3 Referenced Documents

NOTE: All documents cited shall be the latest publications of adopted standards and guidelines.

3.1 *SEMI Documents*

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

SEMI S10 — Safety Guideline for Risk Assessment

3.2 *ANSI Documents*[1]

ANSI Z535.4 — American National Standard for Product Safety Signs and Labels

ANSI Z400.1 — American National Standard for Hazardous Industrial Chemicals - Material Safety Data Sheets - Preparation

ANSI Guide for Developing User Product Information

3.3 *Other Document*[2]

International Labor Convention No. 170 — Convention Concerning Safety in the Use of Chemicals at Work

4 Terminology

4.1 *caution* — Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices (ANSI Z535.4).

4.2 *danger* — Indicates an imminently hazardous situation which, if not avoided, will result in death or serious injury. This signal word is to be limited to the most extreme situations (ANSI Z535.4).

4.3 *equipment* — The system equipment, its component parts, and auxiliary or peripheral equipment.

4.4 *warning* — Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury (ANSI Z535.4).

NOTE: Danger or Warning should not be considered for property damage accidents unless personal injury risk appropriate to these levels is also involved. Caution is permitted for property-damage-only accidents (ANSI Z535.4).

1 American National Standards Institute, 1430 Broadway, New York, NY 10018

2 International Labour Organization, CH-1211, Geneva 22, Switzerland

NOTE: Additional terminology is given in SEMI S2 and SEMI S10.

5 Concept of Operation and Maintenance Manuals

5.1 Operation and maintenance manuals should provide sufficient information on proper operation methods and appropriate maintenance methods to enable safe operation and maintenance. Warnings of potential hazards and how to avoid or minimize hazards should be provided.

5.2 Operation and maintenance manuals should conform to the *ANSI Guide for Developing User Product Information*, or an equivalent, to ensure that they have easy-to-read and understandable contents.

5.3 The operation and maintenance manuals should be designed so that the user can readily understand the risk associated with each task.

5.4 Where contractually agreed upon, by request of the user, or where required by law, the operation and maintenance manuals should be provided in the primary language of the location in which the equipment is to be used. However, the language in which the manuals were created should be identified.

5.5 Safety measures provided in the equipment according to the equipment user's requisition or request may be described separately. The additional safety features can be provided with the manuals as a separate attachment.

6 Hazards Inherent in Equipment

6.1 The equipment supplier should use the result of a risk assessment of the equipment, of which method is provided in SEMI S10, to determine the risk of hazards inherent in equipment.

6.2 Hazards in the equipment should be summarized in a safety section of the manuals, including their location and safety procedures recommended by the supplier. Such hazards may be located, for example, within a plasma etcher, at the RF unit, vacuum pump, gas supply and exhaust unit, or chiller.

7 Hazardous Energy Control Procedures

7.1 Any source of electrical, chemical, thermal, or mechanical energy, radiation and compressed air, or liquid energy that exists in equipment which may be hazardous to workers maintaining the equipment should be described in the maintenance manual, along with the procedures for isolation and control of the hazardous energies.

8 Hardware Safety Interlocks

8.1 The equipment supplier should describe the hardware safety interlocks provided for the equipment and their operation in a list or similar format in the operation and maintenance manuals. The interlock list should include, but not be limited to, hazards protected, detection methods, and equipment conditions after the interlocks are activated.

8.2 The locations of hardware safety interlocks protecting personnel should be clearly indicated using a layout sketch.

9 Hazard Alerts

9.1 The equipment supplier should explain in the operation and maintenance manuals the meaning of hazard alerts on the equipment. Examples of hazard alerts include: visual alerts, auditory alarms, status indicators; or hazard alert systems integral with the equipment's operating system (e.g., displayed through the video display).

9.2 The equipment supplier should describe the location of each hazard alert label attached to the equipment.

10 Hazards Inherent in Tasks

10.1 In operation and maintenance manuals, hazards inherent in each task should be indicated using the signal words "Danger," "Warning," or "Caution." The recommended safety procedures should be followed to avoid the hazard and resulting potential injury. The signal word and the explanations for such a hazard should be enhanced by, for instance, enlarging the letters or surrounding them with a box.

10.2 The equipment supplier should include the definitions of "Danger," "Warning," and "Caution" in the operation and maintenance manuals.

11 Material Safety Data Sheet (MSDS)

11.1 The equipment supplier should attach, to the operation and maintenance manuals of the subject system, a material safety data sheet (MSDS) covering those chemical substances which are inherent in, and shipped with, the equipment, including those to which operators or workers may be exposed during operation, maintenance, or inspection of said equipment. For those chemical substances which are used for processing, the manual should state that the user must obtain the MSDS from their chemical supplier.

11.2 Adopted by the International Labor Convention No. 170 and ANSI Z400.1, the MSDS calls for the following points to be described:

11.2.1 The name of the business corporation compiling the particular MSDS.

11.2.2 The name of the substance and its chemical formula, constitutional formula, molecular weight, CAS No., UN No., etc.

11.2.3 Categorization of its hazards or toxicity.

11.2.4 First aid measures.

11.2.5 Measures to be taken in case of fire.

11.2.6 Measures to be taken when leakage occurs.

11.2.7 Handling and storage precautions.

11.2.8 Exposure prevention measures.

11.2.9 Physical and chemical properties.

11.2.10 Matters relevant to hazardousness.

11.2.11 Matters relevant to toxicity.

11.2.12 Matters relevant to ecological effect.

11.2.13 Cautions when disposing of the substance.

11.2.14 Cautions when transporting the substance.

11.2.15 Applicable laws and regulations.

11.2.16 Date of enactment, standards cited, etc.

12 Personal Protective Equipment (PPE)

12.1 Personal protective equipment (such as goggles, aprons, gloves, masks, safety shoes, and helmets) to be worn when operating or maintaining a system should be identified. The operation and maintenance manuals should clarify which of the personal protective equipment is needed for each task.

12.2 The equipment supplier should state in the manuals that the use of PPE should be in accordance with instruction manuals provided by the PPE suppliers, except where additional instructions by the equipment supplier are required for the specific use of PPE.

13 Inspection of System Equipment and Maintenance of Consumables

13.1 The equipment supplier should describe recommended methods of the daily check before the start and after the end of each day's work and periodic inspections in the operation and maintenance manuals.

13.2 The equipment supplier should provide a list of consumable parts and materials, with their replacement intervals, maintenance methods, and part/material number in the manuals.

13.3 The equipment supplier should provide information on the specific tools and PPE necessary for said inspections and maintenance in the manuals.

14 Training Requirements

14.1 The equipment supplier should describe the training required for safe operations and maintenance in the operation and maintenance manuals.

15 Place of Supplier's Contact in Case of Emergency

15.1 The equipment supplier should indicate, in the operation and maintenance manuals, or as a separate attachment, whom to contact in case of emergency or equipment failure.

15.2 When the contact is changed, the equipment supplier should promptly notify the user in writing and inform the user of the new contact.

16 Laws and Regulations

NOTE: The contents of this section should be addressed in the terms and conditions of sale and/or other contractual agreements between the supplier and user. When the supplier recognizes the necessity based on the local condition or custom, the following information may be included in the operation and maintenance manuals:

16.1 *Relevant Administrative Laws and Regulations* — These may include, but not be limited to, laws and regulations relevant to installation, operation, maintenance, and decommissioning of the equipment.

16.1.1 The supplier may describe, in the manual, the laws and regulations of the user's jurisdiction relevant to operation, maintenance, and supervision of the system.

16.1.2 The supplier may describe the measure of support by the supplier for the implementation of laws and regulations after delivery of the equipment.

NOTE: The supplier and user should jointly investigate the laws and regulations of the jurisdiction where the equipment is to be used, and they should incorporate these requirements into the purchase specification. In addition, the supplier should describe the laws and regulations considered, and means of compliance implemented, during the development and production of the equipment.

16.2 *Issues Regarding Product Liability (PL)*

16.2.1 The supplier should inform the user of the following to ensure better mutual understanding of the issues regarding product liability for the equipment:

16.2.1.1 How a field retrofit is announced and implemented.

16.2.1.2 When the equipment manufacturer discontinues production of the equipment and what repair and maintenance services are available after discontinuation of production of the equipment.

16.2.1.3 The extent of responsibility when equipment of another manufacturer is added to the equipment on user's own judgment.

16.2.1.4 How parts should be handled by the user for the transport for repair.

16.2.1.5 The extent of responsibility for repair or maintenance work to be carried out by personnel dispatched by the supplier or the manufacturer. (The equipment supplier should describe, in the manual, the possibility of not being able to carry out servicing for reasons of safety and health care of the dispatched personnel, if the equipment user refuses to disclose the names and contents of processing materials being used and/or processing piping, for reasons of confidentiality or trade secret protection.)

16.2.1.6 The extent of responsibility on the part of the equipment supplier when a user transports, reuses, resells, or modifies the equipment for his or her own use.

16.2.1.7 The extent of responsibility with regard to the supplied parts and parts designed by the user.

16.2.1.8 The extent of responsibility of the equipment supplier when the user fails to observe the provisions and/or cautions given in the manuals.

SEMI S14-0200E
SAFETY GUIDELINES FOR FIRE RISK ASSESSMENT AND MITIGATION FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT

These safety guidelines were technically approved by the Global Environmental Health and Safety Committee and are the direct responsibility of the North American Environmental Health and Safety Committee. Current edition approved by the North American Regional Standards Committee on September 3 and December 15, 1999. Initially available at www.semi.org February 2000; to be published February 2000.

E This document was modified in November 2000 to correct various errata. Changes were made to Section 7.7.5 and Note 21 (now Note 23).

1 Purpose

1.1 This document provides considerations to the manufacturers of semiconductor manufacturing equipment that will assist them in assessing and mitigating the risk to equipment and product associated with fire and combustion by-products.

1.2 Although these guidelines are written in the form of an assessment tool, they are intended for use throughout the design and development of semiconductor manufacturing equipment.

1.3 These guidelines may also be used by the users of such equipment and by other interested parties to assess and compare the described risks of various equipment designs or in the design and evaluation of ancillary equipment or modifications.

1.4 These guidelines are not intended to specify which techniques (e.g., selection of materials or detection systems) are to be used to mitigate fire risk. These guidelines do, however, recommend that the traditional risk management hierarchy of elimination, engineering controls, administrative controls, warning and work practices be followed.

1.5 The appropriate application of these guidelines will result in a report which identifies, analyzes and assesses residual fire risks.

2 Scope

2.1 These guidelines apply to equipment used to manufacture, measure, assemble, and test semiconductor products which is intended to be located in cleanrooms used for semiconductor manufacturing processes or areas within their recirculation airstream. They apply to all of the components of the equipment, as described herein.

NOTE 1: This document is not limited to the structural or large-area components of equipment.

2.2 This document applies to fire risks originating within the subject equipment that may result in damage to it, other equipment, products, or the facility.

2.3 This document identifies considerations for assessing the fire risk of semiconductor manufacturing equipment, means of categorizing the risks, and means of mitigating the risks.

2.4 These safety guidelines do not purport to address all of the safety issues associated with its use. It is the responsibility of the users of these safety guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 These guidelines do not establish acceptance criteria for residual risk.

3.2 This document recommends a hierarchy of approaches (e.g., elimination of a hazard is preferable to an engineering control) but neither prescribes which specific risk mitigation methods (e.g., change of material or elimination of an ignition source) are to be used nor ranks their relative merit.

3.3 These guidelines apply to the protection of property; they do not apply to the protection of personnel.

NOTE 2: Protection of personnel from fire risk is within the scope of SEMI S2.

3.4 This document applies to equipment in its scope when the equipment is used in the environment specified by the equipment supplier. Specifically, it does not apply to the behavior of equipment when it is subject to an external fire.

3.5 This document is not intended to be used to assess compliance with regulatory requirements, nor is it intended to be adopted as regulation.

3.6 Because of these limitations, it may be appropriate for purchasers of equipment to specify the applicable codes and standards and the acceptable level of residual risk.

NOTE 3: Applicable regional, and national codes, international regulations, and the equipment manufacturer's and user's requirements must also be considered. When a conflict exists, the regional and national codes take precedence.

5 Terminology

5.1 *abort switch* — a switch which, when activated, interrupts the activation sequence of a detection or suppression system.

5.2 *accredited testing laboratory* — an independent organization dedicated to the testing of components, devices, or systems; competent to perform evaluations based on established safety standards and recognized by a governmental or regulatory body.

5.3 *cleanroom* — a confined area in which the humidity, temperature, particulate matter, and contamination are precisely controlled within specified parameters (SEMI E70).

5.4 *combustible liquid* — a liquid that will burn and has a flash point at or above 37.8°C (100°F).

5.4.1 For the purpose of this guideline, a combustible liquid, when used by a system capable (under normal or single-fault conditions) of heating it above its flash point, is considered a flammable liquid.

5.5 *combustible material* — for the purpose of this document, a combustible material is any material which does not meet the definitions in this section for noncombustible materials.

NOTE 5: A list of criteria, guidelines and standards that may be used to evaluate the fire properties of materials is included in Appendix 2.

5.6 *flammable liquid* — a liquid having a flash point below 37.8°C (100°F).

5.7 *hazard* — a condition that is a prerequisite to a mishap.

5.8 *hazardous voltage* — unless otherwise defined by an appropriate international standard applicable to the equipment, voltages greater than 30 volts rms, 42.4 volts peak, 60 volts dc are defined in this document as hazardous voltage.

NOTE 6: The specified levels are based on normal conditions in a dry location environment.

5.9 *ignition energy* — sufficient energy to ignite a combustible material. The energy required depends on the form of the energy and the composition and form of the combustible material.

NOTE 7: The combustible material may be solid, liquid, or gas.

5.10 *likelihood* — the expected frequency with which a mishap will occur. Usually expressed as a rate (e.g., events per year, per product, per wafer processed).

5.11 *mishap* — an unplanned event or series of events that results in death, injury, occupational illness, damage to or loss of equipment or property, or environmental damage.

5.12 *noncombustible material* — a material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat. Typical noncombustible materials are metals, ceramics, and silica materials (e.g., glass and quartz).

5.13 *non-recycling deadman-type abort switch* — a type of abort switch that must be constantly held closed for the abort of the detection or suppression system. In addition, it does not restart or interrupt any time delay sequence for the detection or suppression system when it is activated.

5.14 *process chemicals* — solids, liquids, and gases used in the normal use of the equipment included in the scope of this document.

NOTE 8: Solids, liquids, and gases used in the maintenance procedures (e.g., isopropanol used as a cleaning agent) specified by the equipment supplier should be considered as well as those used in operation.

5.15 *pyrophoric material* — a chemical that will spontaneously ignite in air at or below a temperature of 54.4°C (130°F).

5.16 *residual risk* — that risk which remains after engineering, administrative, and work practice controls have been implemented.

5.17 *risk* — the expected losses from a mishap, expressed in terms of severity and likelihood.

5.18 *safe shutdown condition* — a condition in which all hazardous energy sources are removed and hazardous production materials are removed or contained, unless this results in additional hazardous conditions.

5.19 *semiconductor manufacturing process* — those manufacturing steps which are part of the creation of active or passive electrical devices on a semiconducting wafer, including the deposition of passivation layers after final metallization, but excluding testing and dicing.

5.20 *severity* — the extent of the worst credible loss from a mishap caused by a specific hazard.

5.21 *supervisory alarm* — an alarm indicating a supervisory condition.

5.22 *supervisory condition* — a condition in which action or maintenance is needed to restore or continue proper function.

5.23 *trouble alarm* — an alarm indicating a trouble condition.

5.24 *trouble condition* — a condition in which there is a fault in a system, subsystem or component that may interfere with proper function.

6 Fire Risk Assessment

6.1 *Overview*

6.1.1 This section provides criteria for evaluation of the risks associated with several types of fire hazards.

6.1.2 For each identified hazard described in Section 6, the evaluator should analyze the contributing, causal, and mitigating factors. The evaluator should also review any assessment of the material, component, or equipment as a whole by an accredited testing laboratory.

6.1.3 The risk assessment should include both normal operation and the consequence of reasonably foreseeable, single-point failures within the equipment. It should not include exposure to fire or external ignition sources not within the intended use environment.

6.1.4 Certifications by an accredited testing laboratory of materials, components, or the equipment as a whole may be used in the fire risk assessment. However, such certifications are valid only to the extent that the conditions of use for the certification correlate to the conditions of use for the equipment whose fire risk is being assessed.

NOTE 9: For example, a personal computer certified to IEC 60950 might be incorporated into equipment for use as a controller. The material flammability requirements of IEC 60950 may or may not be sufficient for this use of the personal computer, depending upon its exposure to oxidizers and external sources of ignition when incorporated into the equipment. Also, the levels of smoke tolerable in the environment for which a general industry standard was written may exceed those tolerable in semiconductor manufacturing cleanrooms. Furthermore, if the equipment is intended to be used in a potentially explosive atmosphere, the certification to IEC 60950 would not sufficiently control its risk of being a source of ignition.

6.1.5 The consequences and the probability of fire from each identified hazard should be assessed and rated, as described in SEMI S10. See Appendix 1 for the criteria used for the assignments of Severity, Likelihood and Risk in this document.

6.1.5.1 The assigned Severity and Likelihood and resulting Risk category should be recorded as part of the analysis.

6.1.5.2 For those hazards for which the Risk depends on the conditions of use or use environment, the equipment supplier should make and state appropriate assumptions. If the equipment supplier is unable to make appropriate assumptions as to the Likelihood because it depends predominantly on factors in the users' sole control (e.g., adherence to specified procedures), the supplier should state that and provide an estimate of the Severity.

NOTE 10: The facilities requirements on which the risk assessment depends are to be specified by the equipment supplier.

6.1.6 For fire to occur, there must be a fuel, an oxidizer and a source of ignition. Elimination of any of these factors eliminates the risk of fire. Similarly, the Severity, Likelihood and Risk of a fire can be reduced by reducing one or more of these elements appropriately.

6.1.7 It is important to remember that there are often implicit oxidizers (e.g., room air) and sources of ignition (e.g., room temperature for a pyrophoric material).

6.1.8 The fire risk assessment should include the judgement of a qualified (as described in SEMI S7) party to determine the level of detail of the assessment. That party may group similar hazards for assessment and reporting.

NOTE 11: Such grouping could include, for example, all of the knobs and buttons of similar materials into one group, the heated surfaces into a second, and the several flammable liquids with similar properties into a third.

6.2 *Fuels*

6.2.1 Fuels include all those materials capable of reacting with an oxidizer in a fire. The risks of both the materials of which the equipment is constructed and the process chemicals used in it should be assessed.

6.2.2 *Materials of Construction*

6.2.2.1 The risk assessment should include all of the materials of construction, regardless of quantity or application.

NOTE 12: This includes small parts, such as knobs, buttons, electrical contactors**,** terminal strips, circuit boards, signal wire and power wiring as well as large components, modules (such as mini-environments) and subassemblies.

NOTE 13: Some of the smallest components can create a high risk, as in the potential for ignition by adiabatic compression of fluoropolymer seats in high pressure oxygen valves.

NOTE 14: The assessment can be simplified by grouping similar items together. Example 1: wiring that has the same type of insulation. Example 2: knobs, switches, handles and latches made from similar polymers. Identified groups should include their approximate total mass.

6.2.2.2 In assessing the risk, the evaluator should consider:

- the size of each component,
- the total quantity and distribution of similar components,
- the inherent properties of the material, such as ignitability, flame spread, heat of combustion, and byproducts (see Appendix 2 for guidance on evaluation of these properties),
- the exposure to oxidizers, and
- the exposure to ignition sources.

NOTE 15: The specification control of materials used in approved electrical components should also be considered. Approvals may allow for substitution of many materials with equivalent flammability ratings.

NOTE 16: The inherent properties of materials affect two types of risk within the equipment: flame spread risk and contamination risk (i.e., smoke damage from combustion byproducts). In the case of electrical and electronic components used in assemblies and equipment that are constructed and used in accordance with applicable standards (e.g., IEC 61010-1, IEC 60204-1), flame spread risk may be adequately controlled by the standard, and detailed assessment of the material properties of such components that affect flame spread may not be warranted. However, a significant contamination risk could still remain (e.g., a standard may allow a component mounted on a printed circuit board to fail and burn, as long as the burning remains local to the printed circuit board) and warrant a detailed assessment of related material properties of the components. The level of detail of the assessment may also be affected by the mitigation method chosen (see Section 7).

6.2.3 *Process Chemicals*

6.2.3.1 This portion of the risk assessment should include all of the process chemicals expected (based on the equipment supplier's recommended or baseline processes) to be used in the equipment. It should also include flammable and combustible wastes generated or collected within the equipment and fluids in the equipment which are required for its operation but which do not participate chemically in the process (e.g., vacuum pump oil).

6.2.3.2 In assessing the risk, the evaluator should consider:

- the quantity, concentration, state, temperature, and pressure of each chemical in each container,
- for those chemicals supplied automatically by the facility, the available flow, pressure, and total quantity,
- the aggregate supplies and distribution of similar chemicals,

- the inherent properties of the chemicals, such as flammable limits, flash point, autoignition temperature, heat of combustion, and the products of combustion and decomposition (see the Material Safety Data Sheets for guidance on evaluation of these properties),
- the exposure to oxidizers, and
- the exposure to ignition sources.

NOTE 17: Chemicals with similar fire properties may be considered together for the purpose of this assessment.

6.3 *Sources of Ignition*

6.3.1 Sources of ignition can be broadly divided into those within the equipment and those external to it.

6.3.2 *Internal Sources*

6.3.2.1 Potential electrical ignition sources:

- devices or conditions that in normal operation can generate ignition energy (e.g., heaters, static electricity, lasers);
- devices or conditions that in reasonably foreseeable assembly, use and/or wear conditions can generate ignition energy (e.g., power connectors, terminal strips);
- devices that in reasonably foreseeable single point failure modes can generate ignition energy (e.g., transformers, electronic components); and
- short circuits.

6.3.2.2 Potential chemical ignition sources:

- exothermic process chemical reactions,
- exothermic reactions from inadvertent mixing of process chemicals,
- exothermic reactions between process chemicals and materials of construction, and
- release of pyrophoric or air-reactive chemicals from processing or maintenance.

6.3.2.3 Sudden changes in process conditions:

- rapid (sometimes called “adiabatic”) compression of gas mixtures, and
- rapid increases in temperature.

6.3.2.4 Mechanical friction

6.3.3 *External Sources*

6.3.3.1 External sources include expected and foreseen conditions of the equipment’s use. As these are factors normally outside the control of the equipment supplier, their risks are difficult to assess. They are outside the scope of this document.

6.4 *Oxidizers*

6.4.1 The most common oxidizer is air, which is present within and around most semiconductor manufacturing equipment. Unless specific measures are taken to exclude air (e.g., inert pressurizing of an electrical enclosure), it should be assumed to be available in infinite supply.

6.4.2 It is possible that some materials of construction will act as oxidizers or will yield oxidizers when subjected to heat.

6.4.3 Several common process chemicals (e.g., oxygen and hydrogen peroxide) are oxidizers. Their risks should be assessed in a manner similar to that described above for process chemicals that are fuels.

6.5 *Reporting*

6.5.1 Although these guidelines are intended for use throughout the design and development process, it is not the intent of these guidelines that the equipment supplier should make all of the information recorded during the development of the equipment available to others. The equipment supplier should document the fire risk assessment and mitigation in three forms: internal records, a final fire risk assessment report, and a summary report.

6.5.2 Relevant analyses, assessments, and design decisions should be documented in the equipment supplier's internal records. These records need not, however, be made available to other parties.

6.5.3 *Final Fire Risk Assessment Report*

6.5.3.1 This report should contain an itemized list of the residual risks identified in reviewing the final design, considering the risks described in the preceding subsections or otherwise known or foreseen by the evaluator. Only those risks meeting the criteria in Appendix 1 should be included. For each identified residual risk, the report should:

- explain the mechanism of loss or damage;
- identify aggravating or necessary contributing factors;
- identify the mitigating factors;
- state the assigned Severity for each type of loss and present the rationale for its assignment. A “type” is a column in Table A1-1, e.g., “Equipment Physical Damage”;
- state the assigned Likelihood and present the rationale for its assignment; and

- state the resulting Risk category.

NOTE 18: Criteria for risks may be found in Appendix 1, Sections A1-2.5 through A1-2.8.

6.5.3.2 This report should also describe the fire risk mitigation techniques included in the equipment design.

6.5.3.3 The final fire risk assessment report should be prepared or reviewed by a party qualified, as described in SEMI S7, to do such work.

NOTE 19: This party may be an employee of the equipment supplier or may be a third party.

6.5.3.4 When this guideline is being used as part of a SEMI S2 equipment evaluation, the manufacturer should make the final fire risk assessment report available to the party performing the SEMI S2 evaluation.

6.5.3.5 The equipment supplier may make the final fire risk assessment report available to other parties.

6.5.4 *Summary Report*

6.5.4.1 The summary report should be prepared from the final fire risk assessment report and contain:

- a list of the residual fire risks and their ratings, and
- brief descriptions of the fire risk mitigation techniques included in the equipment.

6.5.4.2 The equipment supplier should provide the summary report to users of the equipment and may provide it to other parties.

7 Fire Risk Mitigation

7.1 *Overview*

7.1.1 This section describes several means of mitigating the risks of fire. It first describes ways in which the equipment and its use can be designed to minimize the risks. It also describes the use of detection and suppression systems.

NOTE 20: The description of a mitigation technique in this section is not intended to imply that such technique should be used for each system. Therefore, the decision to include a particular mitigation technique, such as detection or suppression, should be based on the assessed risk.

7.1.2 In mitigating risks, the general hierarchy of elimination, engineering controls, administrative controls, warning and work practices should be followed. Following this hierarchy comprises using techniques which are highest in it if several techniques are equally applicable. Design and use constraints, as well as relative cost, however, may justify using techniques from generally less preferable categories. In any case, the residual risk should be assessed and reported.

7.2 *Fuels*

7.2.1 *Materials of Construction*

7.2.1.1 The lowest fire risk is posed by noncombustible materials of construction. Available noncombustible materials are not, however, suitable or desirable for all applications within semiconductor manufacturing equipment.

NOTE 21: The properties necessary to perform the intended function of system components and the properties necessary to satisfy component-level standards may also restrict the use of noncombustible materials.

7.2.1.2 When materials which are combustible are chosen, the fire risk may be mitigated by:

- selecting those materials with the least undesirable properties as described above; and
- minimizing the total mass and distribution of such materials.

7.2.2 *Process Chemicals*

7.2.2.1 It may be possible to reduce the fire risk by changing the quantities and species of the chemicals used in the intended processes.

7.2.3 The fire risks of combustible materials of construction and flammable and combustible process chemicals may also be reduced by limiting those factors described in Section 6.

7.3 *Sources of Ignition*

7.3.1 Potential sources of ignition should be considered in conjunction with the fuels and oxidizers they might ignite.

7.3.2 Risks due to sources of ignition can be mitigated by:

- limiting their number,
- limiting their energy, and
- separating them from combustible materials of construction and from flammable and combustible process chemicals. Separation may be by distance or by barriers.

7.4 *Oxidizers*

7.4.1 Reducing the quantities or pressures of oxidizing process chemicals may reduce the fire risk.

7.4.2 The fire risks of oxidizing process chemicals may also be reduced by limiting those factors described in Section 6.

7.5 *Exhaust, Enclosures and Barriers*

7.5.1 Mechanical exhaust may reduce the risk of damage to the facility, other equipment, or other portions of the same equipment by limiting the spread of combustion and decomposition products. The mechanical exhaust could be provided by the equipment or by the facility.

7.5.2 Enclosures and barriers within the equipment may reduce the fire risk by separating the fuels and oxidizers from each other and from potential sources of ignition.

7.5.3 These design features may also limit the spread of fire, reducing both the loss of equipment and the emission of combustion and decomposition products.

7.6 *Fire Detection, Alarm and Control*

7.6.1 The fire detection system, which includes detectors, alarms and their associated controls, should be accepted for the application by an accredited testing laboratory and installed in accordance with the terms of that acceptance. The components should be suitable for the environments in which they are to be used.

7.6.2 The fire detection, alarm and control system should be installed in accordance with an appropriate national or international standard.

NOTE 22: NFPA 72 is such a standard.

7.6.3 The fire detection system should be capable of interfacing with the facility's alarm system. It may be preferable for the equipment supplier to specify the location and performance of detectors, but not provide them, so that the user may better integrate the detection in the equipment with that in the facility. This alternative should be negotiated explicitly with the user.

NOTE 23: Such devices, used solely for internal equipment protection, as opposed to fire risk mitigation, may not require compliance with fire alarm standard or regulations or Subsections 7.6 and 7.7. Some local jurisdictions, however, require that all smoke detectors be connected to building systems.

7.6.4 Activation of the fire detection alarm should be annunciated audibly and visually at the equipment.

7.6.5 Activation of the trouble or supervisory alarm should:

- notify the operator;
- allow the completion of processing of the wafers in the equipment; and
- preclude starting processing of additional wafers until the trouble or supervisory condition is cleared.

NOTE 24: Some local jurisdictions require that such alarms signal the building/facility fire alarm systems.

7.6.6 The fire detection system should be capable of operating at all times, including when equipment is inoperable or in maintenance modes. For the purpose of this section, "inoperable" includes the equipment state after an EMO is activated, and after the equipment has had its hazardous energies isolated (i.e., has been "locked out"). Therefore, the detection system must not require hazardous voltages (e.g., line alternating current) to operate. A battery back-up power supply, capable of sustaining the detection system for 24 hours, should be included.

NOTE 25: The requirements for battery back-up vary among jurisdictions.

EXCEPTION: Maintenance of the fire detection system.

7.6.7 Activation of the fire detection system should shut down the equipment within the shortest time period which allows for safe equipment shutdown.

EXCEPTION: A non-recycling, deadman type abort switch is acceptable on detection systems which are used primarily for equipment shutdown, but not on those used for activation of a suppression system.

EXCEPTION: Activation of the fire detection system should not remove power from fire and appropriate safety systems.

7.7 *Fire Suppression*

7.7.1 The selection of the suppression agent should consider the effectiveness of the agent, amount and location of storage, method of delivery, and potential for environmental impact, both within the facility and to the community.

7.7.2 The fire suppression agent should be accepted for the application by an Accredited Testing Laboratory.

7.7.3 The fire suppression system should be installed in accordance with an appropriate national or international standard.

NOTE 26: NFPA 12, NFPA 13, and NFPA 2001 are such standards.

7.7.4 Activation of the fire suppression system should be annunciated audibly and visually at the equipment. This is not intended to be separate from the annunciation for detection.

7.7.5 The fire suppression system should be capable of operating at all times, including when equipment is inoperable and during equipment maintenance. For the purpose of this section, "inoperable" includes the equipment state after an EMO is activated. Some suppression systems comprise sources of hazardous energy which must be capable of being isolated to protect personnel.

EXCEPTION: Allowances can be made to provide for the deactivation of an automatic discharge of the suppression system when in the maintenance mode. Such deactivation switches should be supervised, i.e., if the suppression system is deactivated, there should be an indication to the user and the resumption of production in the tool should be precluded.

NOTE 27: Hazardous energies associated with the fire suppression system (e.g., release of a compressed suppression agent) may be isolated, using an energy isolation procedure, during equipment maintenance.

NOTE 28: The permissibility of deactivation of the suppression system varies among jurisdictions.

7.7.6 A battery back-up power supply, capable of sustaining the suppression system for 24 hours, should be included.

NOTE 29: The requirements for battery back-up vary among jurisdictions.

7.7.7 The fire suppression system should be capable of interfacing with the facility's alarm system.

7.7.8 It may be preferable for the equipment supplier to specify the location and performance of suppression system components, but not provide them, so that the user may better integrate the suppression in the equipment with that in the facility. This alternative should be negotiated explicitly with the user.

7.7.9 The fire suppression system should be capable of manual activation, which should shut down the equipment.

EXCEPTION: Activation of the fire suppression system should not remove power from fire and safety systems.

7.7.10 The entire fire protection system should be tested on a representative sample of the equipment. The test procedure should include a suppression agent discharge test, unless precluded for health or environmental reasons.

7.7.10.1 This test may be performed at the equipment supplier's or other, similar facility, but should be performed under conditions that adequately duplicate any factors (e.g., equipment exhaust) that may reduce the effectiveness of the suppression.

7.8 *Maintenance of Fire Detection and Suppression Systems*

7.8.1 The equipment supplier should provide detailed maintenance and testing procedures for the fire systems provided with each piece of equipment. These procedures should include testing frequency, as well as details of special equipment required for testing.

7.8.2 The maintenance testing procedure should include testing the facility interface and verifying that all the equipment fire protection systems are functional.

7.8.3 The detection and suppression systems should be designed so that preventive maintenance of components does not degrade their performance, e.g., by resulting in the displacement of sensors.

APPENDIX 1
RISK ASSESSMENT CRITERIA

NOTE: The material in this appendix is an official part of SEMI S14 and was approved by full letter ballot procedures on September 3, 1999 by the North American Regional Standards Committee.

A1-1 The risk assessment should be performed for each identified fire hazard using the method provided in SEMI S10 and the following definitions of Likelihood and Severity Groupings and Risk Categories.

NOTE A1-1: Unlike SEMI S10, in which the tables are provided only as examples, this document defines the Severity, Likelihood, and Risk to be used herein.

A1-2 *Severity*

A1-2.1 The Severity Groupings are given in Table A1-1.

Table A1-1 Severity Groupings

Severity Group	*Equipment Physical Damage*	*Equipment Loss of Use*	*Facility Loss of Use (Minimum Times)*	*Environmental and Real Property Contamination*
1 Catastrophic	Loss of entire piece of equipment	One year	One week	Lasting facility or environmental impact
2 Severe	Loss of major subsystem	One month	One day	Temporary facility or environmental impact
3 Moderate	Loss of minor subsystem	One week	One shift	Limited to the equipment, but requiring more than routine cleanup
4 Minor	Non-serious equipment loss	One day	Less than one shift	Requiring routine cleanup but not external reporting

A1-2.2 The Severity should be assigned for each of the columns for which information is available.

A1-2.3 The most severe Group assigned should be used in determining the risk.

A1-2.4 Each of the Severities should be reported.

A1-2.5 Contamination is by release of materials that were used in the equipment or by combustion or thermal degradation byproducts.

A1-2.6 To be included in the assessment, a foreseen occurrence must be unplanned and include a loss.

A1-2.7 Losses exclude the performance of the design function of protective devices, such as fuses.

A1-2.8 The scope of the assessment in this document is limited to the consequences of fire.

A1-3 *Likelihood*

A1-3.1 The Likelihood Groupings are given in Table A1-2.

Table A1-2 Likelihood Groupings

Likelihood Group	*Expected Frequency (% of Systems per Year)*
A Frequent	More than 1%
B Likely	More than 0.2% but not more than 1%
C Possible	More than 0.04%, but not more than 0.2%
D Rare	More than 0.02%, but not more than 0.04%
E Unlikely	Not more than 0.02%

A1-3.2 “System” refers to the equipment as configured and offered by the supplier.

A1-4 *Risk*

A1-4.1 The Risk should be calculated based on the Severity and Likelihood assigned above and the Risk Categories defined in Table A1-3.

Table A1-3 Risk Categories

	Likelihood				
Severity	*A*	*B*	*C*	*D*	*E*
1	Critical	Critical	High	Medium	Low
2	Critical	High	Medium	Low	Low
3	High	Medium	Low	Low	Slight
4	Medium	Low	Low	Slight	Slight

A1-4.2 The Risks are to be reported in total for the equipment as offered for sale. (e.g., if the equipment being evaluated is a cluster tool, the risks should be reported by the system integrator for the assembled tool, not the individual modules.)

NOTE A1-2: Although the risks for cluster tools should be reported for the assembled tool, the modules are not necessarily contiguous and this may bear on the risk.

NOTE A1-3: The Risks of components or subsystems may be increased or decreased by their integration into the equipment being assessed.

APPENDIX 2
ASSESSMENT OF THE FIRE PROPERTIES OF MATERIALS

NOTE: The material in this appendix is an official part of SEMI S14 and was approved by full letter ballot procedures on September 3, 1999 by the North American Regional Standards Committee.

A2-1 This Appendix describes the qualitative criteria for evaluating some of the relevant fire properties of materials. It also provides references to several standards which may be used in these evaluations. Each of the standards listed defines test methods and provides quantitative criteria for consideration.

A2-2 *Preferable Materials:*

A2-2.1 Require higher heat fluxes to be ignited.

A2-2.2 Once ignited may burn locally in the ignition area, but they will not propagate a fire beyond the ignition zone.

A2-2.3 Generate lower quantities of smoke and corrosive products or generate smoke and corrosive products that are less damaging.

A2-3 The following standards provide means of assessing the fire properties of materials. Each of these standards specifies the types of materials and uses of materials to which it applies and the fire properties that its application assesses. Therefore, each must not be used outside of the scope for which it was written. It may be appropriate to use different standards for assessing the materials used in different components in the equipment.

NOTE A2-1: There are many other standard methods available for characterizing the fire properties of materials and it is not the intent of the document to exclude methods other than those listed here, as long as the methods are applied appropriately.

RELATED INFORMATION 1
TEST PROTOCOL FOR WET BENCH MATERIALS PROCESS COMPATIBILITY

NOTE: This related information is not an official part of SEMI S14 and is not intended to modify or supersede the official guideline. It has been derived from the cited work. Publication is authorized by vote of the responsible committee. Determination of the suitability of this material is solely the responsibility of the user.

R1-1 SEMATECH has published the results of a study on testing of polymeric materials for use in wet benches. The Abstract and citation are provided as Related Information 1 to SEMI S14, Safety Guidelines for Fire Risk Assessment and Mitigation for Semiconductor Manufacturing Equipment as the responsible committee believes the information in this document may be of use in identifying materials that are appropriate for the described applications and consistent with appropriate management of fire risks.

R1-2 The report, SEMATECH Document ID #: 98123623A-ENG, entitled Process Compatibility Parameters for Wet Bench Plastic Materials, was written by Archibald Tewarson, Avtar S. Jassal, Latif Ahmed, and Mark Camenzind and published 30 December 1998.

R1-3 SEMATECH retains the copyright to the document, but has granted SEMI permission to include the Abstract and citation in this Safety Guideline. The complete document (90 pages) is available from SEMATECH's web site:

http://www.sematech.org/public/docubase/abstract/tech-5.htm.

R1-4 *Abstract*

R1-4.1 This report presents a test protocol of accepted analytical procedures to determine the process compatibility parameters for commonly used wet bench plastic materials (PP, FRPP, and PVC) and proposed plastic materials (CPVC, ECTFE, and PVDF) that may be used for wet bench construction. Three industry standard test methods were used to determine the outgassing, leaching, and extraction parameters, defined in combination as the process compatibility parameters. To supplement them, the presence of critical elements at the surface of the materials and the condition of the surface were examined before and after exposure to water and chemicals. Changes in the mass of plastic materials as a result of outgassing, leaching, and extraction were also used to supplement the parameters. The report includes details of the test procedures, data analysis, surface topography of the plastic materials, before and after exposure to water and chemicals, and discussion of the results.

SEMI S15-0200
SAFETY GUIDELINE FOR THE EVALUATION OF TOXIC AND FLAMMABLE GAS DETECTION SYSTEMS

This safety guideline was technically approved by the Global Environmental, Health, and Safety Committee and is the direct responsibility of the North American Environmental, Health, and Safety Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available on www.semi.org January 2000; to be published February 2000.

1 Purpose

1.1 This guideline provides considerations for the evaluation of fixed gas detection systems used to monitor for safety of plant personnel, product and materials, the local environment and community. It provides an evaluation guide and reference sources appropriate to facilities and equipment where toxic and flammable gases are used and stored in gaseous or liquid form.

2 Scope

2.1 This guideline applies to toxic and flammable gas detection and addresses performance characteristics of gas detection systems.

2.2 It also describes several technologies available for detection of such gases and their performance characteristics.

2.3 This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this safety guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guideline does not include applicable fire and safety code regulations.

3.2 The gases or liquids which should be monitored are not listed.

3.3 This guideline does not suggest the appropriate levels of detectability. Such levels may be determined by reviewing accepted government and non-governmental agency standards, such as those promulgated by ACGIH, USEPA, and USOSHA.

3.4 Process related issues and corrective actions in the case of gas leaks are not discussed in this guideline.

3.5 This guideline makes no recommendation of any specific technology or manufacturer, nor does it provide installation and operation recommendations.

3.6 This guideline provides neither a comprehensive list of all gases, nor recommended areas for monitoring of toxic and flammable gases.

3.7 Not all known analytical methodologies for monitoring of toxic and flammable gases are described in this guideline.

4 Referenced Standards

4.1 *SEMI Standard*

SEMI E33 — Specification for Semiconductor Manufacturing Facility Electromagnetic Compatibility

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *ACGIH* — American Conference of Governmental Industrial Hygienists

5.1.2 *EMI* — Electromagnetic interference

5.1.3 *EU* — European Union

5.1.4 *RFI* — Radio frequency interference

5.1.5 *USEPA* — United States Environmental Protection Agency

5.1.6 *USOSHA* — United States Occupational Safety and Health Administration

5.2 *Definitions*

5.2.1 *challenge gas* — a gas/chemical used to create a response in the gas detection system.

5.2.2 *conditioning* — the necessity to expose a gas/chemical sensor to the target gas/chemical to enable more rapid detection of that gas/chemical.

5.2.3 *fail-safe relay* — an alarm relay that is "fail-safe" returns to a safe operating condition when power is lost.

5.2.4 *filter lag* — relative to gas/chemical sensors, the time delay in the detection of a challenge gas/chemical due to the incorporation of a chemical, mechanical or electrical filter.

5.2.5 *latching* — relative to discrete alarm contacts, the alarm relay will not reset when the alarm condition ceases to exist. The alarm must be manually or remotely reset by operator interface.

5.2.6 *poisoning* — the interaction of a gas/chemical other than the target gas/chemical that temporarily or permanently disables the sensor from reliably detecting the presence of the target gas/chemical, or otherwise renders the device inoperable.

5.2.7 *span drift* — the percentage change in a known calibration point or span of a sensor or gas detection system over time.

5.2.8 *surrogate gas/chemical* — a substitute gas/chemical that is more benign than the gas/chemical it is replacing. This concept is used in the calibration of gas/chemical sensors when a highly toxic or corrosive challenge gas is undesirable. The surrogate gas/chemical will simulate the interaction with the sensor of the gas/chemical for which it is substituted.

5.2.9 *target gas* — the specific gas intended to be detected.

5.2.10 *zero drift* — the percentage change in the zero point or baseline of a sensor or gas detection system over time.

6 Performance Characteristics

6.1 The performance characteristics (the test results of which should be reliable and repeatable) are as identified below. These are factors one should consider in the evaluation of a gas detection system (from the point of detection through the output signal) for a specific application. A form for compiling a comparison table is provided as Appendix 1.

6.2 *Accuracy* — What is the stated accuracy of the system? Over what time period will that accuracy be valid (before calibration of the gas detection system is necessary)?

6.3 *Alarms* — What is the range for setting the alarms for each gas detection point? Are the alarms user-adjustable for set and reset time delays, latching or non-latching, normally open or closed, fail-safe or non fail-safe? How many alarm levels are available per detection point? Is there a fail alarm and what conditions will activate that alarm? Are the alarms dedicated to each detection point or are they common to a group of monitoring points?

6.4 *Calibration*

6.4.1 Is calibration required? If so, how often? How is it accomplished? Can it be done away from the point of detection or must it be done on site? What equipment is needed to perform the calibration? Can a surrogate gas be used for calibration? Can the calibration be accomplished by one individual? Is calibration accuracy affected by humidity?

6.4.2 During start-up, how much time must elapse before the gas detection system can be calibrated?

6.5 *Certifications and Classifications* — Does the gas detection system have the necessary performance or safety approvals for the specific application and location (e.g., UL, CE, SEMI S2)?

6.6 *Communications (serial)* — What types of serial communication are available from the gas detection system? What communication protocols are supported? Is it one-way or two-way communication?

6.7 *Conditioning Requirements* — Is the monitoring equipment always ready and able to detect a gas leak or must it be preconditioned on a periodic (regular) basis to ensure response times are achieved?

6.8 *Cost of Ownership* — What is the initial cost for the equipment and installation? What is the long-term cost of ownership of the system (consumables, calibration equipment, and labor)? What is the cost (hardware and installation) to expand the system (additional points of detection) and/or change the gas configuration?

6.9 *Data Archiving* — Are data documentation or data archiving system available as a part of the gas detection system?

6.10 *Diagnostics* — What system diagnostics are included? Can electrical or mechanical failures within the system be detected? Will a fault alarm be activated? Are diagnostics communicated over analog and/or digital outputs? Are faults archived by the gas detection system? Will an inoperative system be identified through a self-activated alarm (fail-safe)? Will the system alert the user that a calibration is required? Are communication outputs supervised?

6.11 *Display* — What local displays are available on the gas detection systems? Where is the display located? Does the display show gas concentration level with engineering units and identify active alarms with signal lights? Are other diagnostic and control functions displayed when activated? Is the display easy to read from a distance?

6.12 *Drift* — What is the zero and span drift over 30, 60, 90, and 180 days? Does the gas detection system compensate for drift?

6.13 *Environmental Conditions* — What are the temperature and relative humidity specifications for the gas detection system for normal operation as well as for storage of consumable parts? Could environmental changes such as quick humidity transients or temperature changes cause the gas detection system to spike or drift into an alarm condition?

6.14 *Equipment Failure* — Is the gas detection system capable of reporting all single point failures that disable detection? What failure mode disables both detection of gas and reporting failure?

6.15 *Expansion Flexibility* — Is the gas detection system capable of expansion to accommodate additional detection points? How easy is it to integrate into the user's system (hardware, installation, programming, etc.)?

6.16 *Extraction Detection Systems*

6.16.1 *Sampling Distance* — What is the maximum sampling distance for the gas detection system? Will all the gas entering the sample line at the point of detection reach the central monitor? What is the sample loss due to the challenge gas absorbing onto the sample tubing walls?

6.16.2 *Sample Cycle Time* — How frequently, if multiple points are sampled, is the same detection point surveyed by the extraction detection system, at the desired alarm level?

6.16.3 *Sample Contamination* — What, if any, is the potential for contamination of the sample line tubing and manifolding equipment when multiple gases are monitored within the same extraction system? What combination of gases should be avoided due to chemical interaction on wetted materials?

6.17 *Filter Lag* — Does the gas detection system use any mechanical, chemical or electronic filters (for cross sensitivity, particles, etc.) which could slow the sampling response? If so, what lag time is expected for each gas type?

6.18 *Installation - Wiring Configuration* — How many wires are required per detection point? Can the system be wired in a highway configuration (bus, ring, star, etc.)? Are special barriers or grounds required to ensure no earth loop faults exist?

6.19 *Isolation* — Does the gas detection system require any special electrical isolation or grounding?

6.20 *Limits of Detection*

6.20.1 *Lowest Alarm Level* — What is the lowest alarm level setting for the gas detection system which will not activate due to sensor drift or insufficient signal to noise ratio?

6.20.2 *Limit of Detection* — What is the absolute lowest value that a sensor can detect, for each gas?

6.20.3 *Upper Limit of Detection* — What is the highest level of gas that can be quantified reliably by the gas detection system?

6.21 *Linearity* — What is the linearity over the full measuring range of the gas detection system output?

6.22 *Maintenance Interval* — What is the manufacturer's recommended maintenance frequency? What is involved to perform this maintenance? What items potentially require maintenance or periodic replacement (pumps, sensors, tapes, etc.)?

6.23 *Other Utilities* — In addition to electrical power, what other utilities are required to operate the system (e.g., compressed air, hydrogen, oxygen, etc.)?

6.24 *Outputs* — Does the gas detection system have analog, digital, and relay outputs? How many are available per system?

6.25 *Physical Size* — What is the physical size of the gas detection system for both the detection head (or sampling point) and the control systems or central monitor, including the required floor space?

6.26 *Poisoning* — Is the gas detection system susceptible to gases or vapors which would reduce the performance (ability to detect gas) of the system or render it contaminated and inoperative?

6.27 *Position Effect (Attitude Sensitivity)* — Is there a specific orientation of the sensor, detector, or sampling point required for the gas detection system to function optimally?

6.28 *Power Outage* — When system power is lost, what happens to the gas detection system? Once power is restored, what is the time lag before the system is fully functional?

6.29 *Power Requirements* — What are the power requirements (i.e., AC, DC, voltage, and amperage) of the system? What is the power draw of the total gas detection system?

6.30 *Recovery Time* — What is the amount of time it takes the gas detection system, once exposed to challenge gas, to recover to 10% of the original target gas concentration value?

6.31 *Repeatability* — What is the ability of the gas detection system to produce the same detection results within a certain percentage, when repeatedly exposed to the same gas concentration?

6.32 *Reliability* — What is the expected life of the various portions of the gas detection system (including the main unit, detection sensors, and consumables)?

6.33 *Replacement/Replenishment* — Does the system contain consumable items? How frequently must they be replaced? Can they be replaced by the user or is a factory person required for servicing?

6.34 *Resolution* — What is the level of resolution for changes in gas concentration? That is, to what extent can the gas detection system detect a changing challenge gas concentration? Is this user selectable?

6.35 *Response Time* — From the point of release of the challenge gas, how long does it take the gas detection system to reach 90% of the challenge gas concentration?

6.36 *RFI/EMI Susceptibility* — Does the gas detection system meet the requirements for CE Marking for RFI/EMI immunity and per SEMI E33?

6.37 *Self-Test* — Does the gas detection system have an automatic or user initiated self-test routine? How is it accomplished? What is the interval for the self-test? Can the operator override the self-test? Is the self-test just an electrical check or is gas actually generated? Is the generated gas the target gas?

6.38 *Sensor Exchange* — Do sensors require on-site calibration only or can they be factory calibrated? Are additional adjustments or programming operations required when replacing a sensor? Is there a warm-up period for the sensors before they are functional (for calibration purposes)? If so, how long?

6.39 *Sensor Specificity* — Are gas specific sensors available for every gas that must be monitored? What are the known interferences to the gas detection system that could cause a false alarm or mask a real alarm?

6.40 *Service & Support* — What is the manufacturer's capabilities to service and support their equipment once it is has been installed? Does the manufacturer have a 24 hour/7 day service support program in place?

6.41 *Spare Parts Availability* — What is the availability of spare parts from the manufacturer? Are emergency spare parts always available?

6.42 *Special Handling Considerations* — Are there items that require special handling, storage, or disposal? If so, what are the considerations?

6.43 *Storage and Shelf-Life Requirements* — What are the storage (environmental) requirements for the consumable items (e.g., electrochemical sensors and paper tapes)? Do these items have a shelf-life and if so how long?

6.44 *System Check* — Does the gas detection system have a system check facility? If so, is this done on a continuous or interval basis? What is the interval?

6.45 *System Expandability & Flexibility* — Is the gas detection system universal, in the sense that the user can change from one gas sensor to another by only exchanging the sensing elements? How much modification is required? Can this be done in the field by the user or must the detection system be returned to the manufacturer for service?

6.46 *Wake Up Requirement* — Does the gas monitor's sensor require periodic doses of challenge gas or electrical charges to ensure the sensor will continually operate? If so, what is the interval required for each gas type or electrical challenge?

6.47 *Warm Up Period* — Upon installation or sensor replacement, how long does it take for the gas detection system's sensor to stabilize after power is applied?

6.48 *Warranty* — What is the warranty period of the gas detection system?

7 Gas Detection Technologies Available

7.1 Several gas detection technologies are described in the following paragraphs. As additional technologies become available, they should be considered, using the performance characteristics described above.

7.2 *Acoustic (Hydrogen Gas Measurement Only)* — Piezoelectric crystals send and receive pulsed ultrasound. These sound waves travel through two tubes of air, one tube filled with sample air, the other with reference air. The returned pulses are counted, normalized for temperature, and compared. Through mathematical calculations the result represents the concentration of hydrogen gas present in percent by volume or percent LEL.

7.3 *Catalytic* — Catalytic gas sensors measure flammable gases by comparison of the change in resistance across a Wheatstone bridge. The sensor contains two resistive elements (beads), one active which increases its resistance when exposed to gas, and the other which maintains a constant resistance. The sensor output is then conditioned by the gas detection system and generates a current output proportional to the gas concentration in percent of lower explosive limit (LEL).

7.4 *Electrochemical* — Electrochemical gas sensors measure toxic gases and contain components (electrodes and electrolyte) designed to react when exposed to a specific toxic gas or a family of gases; the reaction generates a current which is measured and conditioned by the gas detection system and represents an output which is proportional to the concentration of gas, measured in parts per million (ppm) or parts per billion (ppb).

7.5 *FTIR* — Fourier-transform infrared (FTIR) gas detection systems use spectrophotometric techniques to detect and measure gas. Infrared light is passed through a gas sample, and the resulting absorbency spectrum is analyzed to determine its constituents. A current output is generated which is proportional to the concentration of gas present.

7.6 *Infrared* — Monochromatic infrared gas detection systems measure the absorption of radiation (light) by a gas sample. The absorption is translated into a current output which is proportional to concentration. Each gas has a unique absorption wavelength which the system must be tuned to make an accurate measurement.

7.7 *Ion Detection* — Ion detection is useful for detecting SiO_2 particles which are created by the burning of certain gases such as silane, TEOS and TEOA. SiO_2 "smoke" is created when these gases are burned, and this can be detected with an ionization detector chamber, which operates similarly to a smoke detector. SiO_2 particles entering the chamber create a signal that is calibrated to represent the presence of a known concentration of the target gas. A gas detection system using this method is typically used in a sample draw system and can be used either by itself or in conjunction with a pyrolyzer to condition (burn) the gas entering the detection head.

7.8 *Molecular Emission Spectrometer* — Sample air is injected into a reaction chamber. In the reaction chamber, a flame, fed by hydrogen and sample air, is the activating reaction. When a sample gas enters the flame, reactions of the target gas result in additional light emissions. The resulting light passes through two optical filters and is converted to electronic signals in a dual photomultiplier tube. The signals are combined to produce a linear, quantitative output.

7.9 *Paper Tape* — Paper tape systems use the color change of a chemically impregnated tape to detect toxic gases. The tape changes color when exposed to a challenge gas; the color change is then detected by a photocell, analyzed, and converted into a concentration value (ppm or ppb).

7.10 *Solid State* — One type of solid state sensor is made of a metal oxide (typically tin-oxide) material that changes resistance in response to the presence of a toxic gas; the gas detection system measures this resistance change and converts it into a concentration value. Thin film semiconductor sensors absorb the target gas onto the semiconductor, resulting in a transfer of electrons which causes a measured change in the resistance of the semiconductor and reported as a ppm or ppb concentration.

NOTICE: SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of this guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. This guideline is subject to change without notice.

The user's attention is called to the possibility that compliance with this guideline may require use of copyrighted material or of an invention covered by patent rights. By publication of this guideline, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this guideline. Users of this guideline are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI S16-0600
ENVIRONMENTAL, HEALTH AND SAFETY GUIDELINES FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT DISPOSAL

These guidelines were technically approved by the Global Environmental, Health and Safety Committee and are the direct responsibility of the Japanese Environmental, Health and Safety Committee. Current edition approved by the Japanese Regional Standards Committee on April 28, 2000. Initially available on www.semi.org June 2000; to be published June 2000.

1 Purpose

1.1 This document provides guidelines to minimize hazards to workers and impacts to the environment during equipment and component disposal.

2 Scope

2.1 These guidelines apply to the disposal of semiconductor manufacturing equipment, its materials and components and equipment design consideration to facilitate disposal.

2.2 These guidelines are intended to be voluntary best practices for this industry. These guidelines apply to disposal parties, equipment designers, equipment manufacturers, equipment suppliers and equipment owners. The information should be provided to the disposal party by the equipment owner prior to contract negotiations.

2.3 These safety guidelines do not purport to address all of the safety issues associated with its use. It is the responsibility of the users of these guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitation

3.1 These guidelines are not intended to supersede the applicable codes and regulations of the region where the equipment is disposed.

3.2 Section 6 in these guidelines should be applied not to existing models and subsystems but to newly designed models and subsystems after publication of these guidelines.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI S1 — Safety Guidelines for Visual Hazard Alerts

SEMI S2 — Environmental, Health, and Safety Guideline for Semiconductor Manufacturing Equipment

SEMI S10 — Safety Guideline for Risk Assessment

SEMI S12 — Environment, Health and Safety Guidelines for Equipment Decontamination

SEMI S13 — Safety Guidelines for Operation and Maintenance Manuals Used with Semiconductor Manufacturing Equipment

4.2 *ISO Documents*[1]

ISO11469 — Plastics; Generic Identification and Marking of Plastic Products

ISO14001 — 1996 Environment Management Systems, Specifications with Guideline for Use

4.3 *CEN*[2] / *CENELEC*[3] *Document*

EN1050 — Safety of Machinery—Principles for Risk Assessment

4.4 *OSHA Document*[4]

29 CFR 1910. 1200 — Labor

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 Terminology defined in SEMI S1, S2, S12, and S13 should be referred to except if otherwise specified below.

5.1.1 *decontaminate* — to remove all known hazards from equipment, including chemical, physical, electrical, to a level that will not pose a threat or harm to humans or the environment. This level may be set by each country, state and local regulations or industry practice.

5.1.2 *decontamination* — the process required to remove hazards to an acceptable level of risk (see Section 5.1).

1 International Standards Organization, 1, rue de Varembe, Case postale 56, CH-1211 Geneve 20, Switzerland.

2 European Committee for Standardization, 36, rue de Stassart, B-1050 Brussels, Belgium

3 European Committee for Electrotechnical Standardization, Rue de Stassart, 35, B-1050 Brussels, Belgium

4 US Government Printing Office, Washington, D.C. 20402

5.1.3 *disposal* — to dispose of equipment and/or component/material based on legislation or industry/regional standard practices.

5.1.4 *disposal party* — a party who disposes of equipment and its components.

5.1.5 *EMAS* — Eco-Management and Audit Scheme which came into force in July, 1993 and operational in the EU Member States in April, 1995.

5.1.6 *equipment owner* — a party who surrenders equipment to a disposal party or disposals of potentially contaminated materials or components.

5.1.7 *hazardous energy* — energy with the potential to affect human health or the environment.

5.1.8 *hazardous material* — materials including chemicals (solid, liquid or gas) that pose a threat to the environment or human health as defined by international, each country and local regulations.

5.1.9 *Material Safety Data Sheet (MSDS)* — written or printed material concerning chemical elements and compounds, including hazardous materials, prepared in accordance with applicable standards such as the International Labor Convention (ILC) No. 170, provisions of USA government regulation 29 CFR 1910,1200, or Canadian WHMIS (Workplace Hazardous Material Information System).

6 Equipment Design for Disposal

6.1 The equipment design should comply with environment section of SEMI S2.

6.2 The equipment design should consider the following regarding disassembly prior to waste treatment:

6.2.1 The equipment design should encourage refurbishing, reuse or recycling.

6.2.1.1 The equipment design should enable disassembly down to the component or subassembly size to facilitate refurbishing or recycling.

6.2.1.2 The equipment design should provide for the ability to appropriately decontaminate all components.

6.2.2 The equipment design should consider enabling all hazardous energies in/on the equipment to be reduced to a non-hazardous level upon equipment disassembly. If a hazardous energy still remains, see Section 7 of this document.

6.2.2.1 This includes the ability to release or remove any trapped materials.

6.2.3 The equipment design should avoid mixing of incompatible chemicals upon equipment disassembly. If this is not feasible, an appropriate hazard alert label based on SEMI S1 should be affixed at each applicable position (see Section 7 of this document).

6.2.4 The equipment design should prevent release of hazardous materials to the environment upon equipment disassembly. If this is not feasible, see Section 7 of this document.

6.3 Chemicals used to maintain the equipment or chemicals used in the baseline process should comply with following sub-sections.

6.3.1 Materials for which special disposal procedures are required, such as batteries (lithium, ni-cad, mercury and silver), mercury and fluorescent lamps, and other potentially hazardous material should be accompanied by material safety data sheet (MSDS) or other document describing necessary information for disposal and instructions for safe handling and disposal.

6.3.2 Additional information on proper disposal of materials, designed into the equipment with the intent of being contaminated but disposable, but not hazardous themselves until contaminated, such as absorbents and adsorbents, should also be provided with disposal procedures which minimize environmental impact and personnel effect.

6.3.3 Equipment containing ionizing radiation sources subject to licensing by federal or local agencies should be constructed so as to allow the easy removal of ionizing radiation sources. Disposal of ionizing radiation sources must be in compliance with applicable each country, state and local regulations.

6.4 Construction materials and components of equipment should be selected by considering their environmental impacts based on the supplier's environment management program. Environment management programs should be constructed based on ISO14001, EMAS or other environment management system.

6.5 The hazardous and primary construction materials of equipment should be provided in document such as operation and/or maintenance manuals based on the supplier's environment management program.

6.5.1 Recycling category identification should be molded as part of the material or labeled on the material. This requirement should only be applied to non-metallic materials which are capable of being molded or labeled.

6.5.2 Identification and marking of plastics should comply with ISO11469 unless local regulations differ. This requirement should be applied to only materials which are able to be molded or labeled.

7 Information Provided by the Supplier

7.1 The supplier should provide the equipment owner with operation and/or maintenance manuals or similar documents drafted according to SEMI S13, which include the following information on the materials used in equipment, subassemblies and components upon the delivery of the equipment:

NOTE 2: The supplier may gather appropriate information at the time of design in conjunction with a disposal party.

7.1.1 Primary materials of appropriate disassemble-able unit in consideration with reuse, refurbishing, recycling and disposal of each component such as, chemicals (e.g., mercury), metals (e.g., stainless steel, steel, or copper), plastics (e.g., ABS - i.e., Acrylonitorile Butadiene Styrene plastics - or non-combustible ABS), glass, or ceramics.

7.1.2 Describe opportunities for reuse, refurbishing or material recycling of every component or recyclable subassembly. If there are no opportunities, a waste disposal method should be recommended based on assumption of usage with baseline process by the supplier. (e.g., ABS can be recycled after decontamination as class X plastic and mercury requires reclaim or hazardous waste disposal.)

7.1.3 *Disassembly Procedure*

7.1.3.1 A disassembly procedure should be recommended by the supplier to the level required to facilitate complete decontamination and material separation for waste disposal.

7.1.3.2 The disassembly procedure should include procedures to remove all hazardous energies.

7.1.3.3 The disassembly procedure should prevent the mixture of incompatible chemicals. If it is not feasible, administrative control procedures should be included.

7.1.3.4 If the chemicals/materials described from Sections 7.1.3.4.1 to 7.1.3.4.4 are hazardous, the disassembly procedure should prevent the release of them to the environment. The chemicals include:

7.1.3.4.1 Chemicals used to maintain the equipment (e.g., lubricant and coolant).

7.1.3.4.2 Other potentially hazardous items which are parts of the equipment, such as capacitors, batteries, lamps or mercury, which require special disposal procedures.

7.1.3.4.3 Chemicals used in the baseline process of the equipment manufacturer.

7.1.3.4.4 Anticipated byproducts of the baseline process.

NOTE 3: Byproducts are changeable according to several kinds of conditions such as exhaust diameter/length/volume, chamber volume/pressure/configuration, maintenance method/cycle, and evacuation frequency.

7.1.3.4.5 The disassembly procedure should address any hazards of ionizing radiation sources, if they are present, and address safe removal and storage procedures.

7.1.4 Disposal procedure should be a safer way based on the result of risk assessment such as SEMI S10 or EN 1050 and job hazard analysis.

8 Information Provided by the Equipment Owner

8.1 Prior to disposal, the equipment owner should provide the following information to the disposal party in order to reflect all residual waste hazards. This information should be provided to any party handling the waste regardless of intention to dispose or recycle the equipment unless the component in question is fully decontaminated.

8.1.1 Relevant information provided by the supplier per Section 7 of this document.

8.1.2 Chemicals used in the equipment owner specific process other than the baseline process and its byproducts.

8.1.3 Decontamination and waste disposal method for parts contaminated by an equipment owner specific process other than the baseline process.

8.1.4 The minimal information of necessary personal protective equipment (PPE) based on the equipment usage history.

NOTE 4: PPE and necessary training are to be specified by the employer of those personnel to be protected.

8.1.5 The details of the decontamination procedure and any remaining chemicals and their locations after the equipment owner has completed initial decontamination of the equipment.

9 Selection of the Disposal Party

9.1 The disposal party must comply with regional/national codes and regulations related to the receipt, transfer and disposal of equipment.

NOTE 5: A specially controlled industrial waste disposal license as well as a specially controlled waste collection and transfer license may be typically required by the relevant country's government.

9.2 The incident and compliance record of the waste disposal party should be considered at the time when a selection of the disposal party is made.

10 Equipment Disposal Procedure

10.1 The possibility of refurbishing the entire piece of equipment should be considered before disassembly and disposal is selected.

10.1.1 When refurbishing of the entire equipment is chosen, only the disposal parts which are not able to be refurbished at the time should be decontaminated or considered for disposal. This results in a significant reduction in waste.

10.2 *Equipment Decontamination and Packaging for Transfer* — Equipment being transferred should comply with SEMI S12 and all applicable hazardous materials shipping regulations. If the equipment has to be transported prior to decontamination, it should be ensured, that no contaminants may be released (e.g., by appropriate packaging).

10.3 *Disassembly and Decontamination* — The equipment owner or disposal party should follow all local regulations regarding disassembly and disposal.

10.3.1 If there is an equipment owner specific process, the specifics of that process and its hazards should be provided to the disposal party by the equipment owner.

10.4 *Material Separation* — Only materials that cannot be refurbished, recycled or reused should be categorized for other disposal methods (e.g., incineration and landfill) under this disposal assessment procedure.

10.4.1 First decontaminate any contaminated material which is capable of further decontamination.

10.4.2 Discard any materials incapable of decontamination by appropriate contaminated waste disposal categories or process (e.g., incineration, hazardous landfill, etc.).

10.4.3 Further separate materials into reusable components (e.g., pumps, motors, electronics, etc.).

10.4.3.1 This includes any components with a potential for refurbishing.

10.4.4 Separate recyclable materials by categories (e.g., metals, class of plastics, etc.).

10.4.5 Separate into reclamation categories (e.g., mercury recovery from lamps, lead recovery from batteries, etc.).

10.5 The equipment owner should confirm that the disposal party follows the procedures required by this document through checking manifest and/or implementing practical inspection periodically as well as applicable regional codes and regulations.

10.6 Ionizing radiation sources, if present, should be disposed of in accordance with each applicable country, state and local regulations. All applicable licensing and reporting requirements should be met.

11 Documentation and Records

11.1 Documentation should be prepared and maintained by the equipment owner according to applicable codes and regulations for the region or locality where disposal occurs.

11.2 Documentation showing final disposition of each class of material should be returned to the equipment owner by the disposal party.

SEMI S17-0701
SAFETY GUIDELINE FOR UNMANNED TRANSPORT VEHICLE (UTV) SYSTEMS

This safety guideline was technically approved by the Global Environmental Health and Safety Committee and is the direct responsibility of the Japanese Environmental Health and Safety Committee. Current edition approved by the Japanese Regional Standards Committee on February 1, 2001. Initially available at www.semi.org April 2001; to be published July 2001.

NOTICE: Paragraphs entitled "NOTE:" are not an official part of this document and are not intended to modify or supersede the official guideline.

1 Purpose

1.1 These guidelines are intended as a set of environmental, safety, and health considerations for unmanned transport vehicle (UTV) systems. UTV systems are used to automate the movement of material within semiconductor factories. Unmanned transport vehicle systems include both floor-traveling vehicle systems and space-traveling vehicle systems.

2 Scope

2.1 This guideline applies to UTV systems used in semiconductor manufacturing.

2.2 This guideline addresses both floor-traveling and space-traveling UTV systems. Floor-traveling vehicle systems include automatic guided vehicle (AGV) systems and rail guided vehicle (RGV) systems. Space-traveling vehicle systems include interbay overhead transport vehicle systems and intrabay overhead hoist transport vehicle (OHT) systems.

2.3 Evaluations for conformance to this document should include all equipment that is provided by the UTV system supplier including separate items such as rails, control panels, power panels, and any other type of equipment necessary for operation of the unmanned transport vehicles.

2.4 This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2.5 This document contains the following sections:

- Purpose
- Scope
- Limitations
- Referenced Standards
- Terminology
- Equipment Evaluation
- Clearances and Interfaces
- Emergency Shutdown
- Manual Operation
- Vehicle Travel
- Material Protection
- Load/Unload Operation
- Hazard Indicators
- Hazardous Materials
- Related Documents

3 Limitations

3.1 This safety guideline may have only limited application to vehicles without on-board power (direct or induced) such as primary-grounded linear–motor-driven overhead transport vehicle systems used for interbay transport. Determinations of applicability should be made by section when evaluating such systems.

3.2 This safety guideline does not address rail-guided or robotic mechanisms included as part of semiconductor processing equipment. This type of equipment should be evaluated as part of the processing equipment per SEMI S2.

3.3 Person Guided Vehicles (PGVs) are not unmanned vehicles, therefore PGVs are not addressed by this standard.

3.4 This document does not supersede international, national or local codes, regulations and laws, which may impose separate requirements for assessing the safety of installations.

NOTE 1: Users should provide information to UTV suppliers about regulations for the location of use.

4 Referenced Standards

NOTE 2: Unless otherwise indicated, all documents cited shall be the latest published versions.

4.1 *SEMI Standards*

SEMI E15.1 — Specification for 300 mm Tool Load Port

SEMI E23 — Specification for Cassette Transfer Parallel I/O Interface

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O Interface

SEMI S2 — Environmental, Health, and Safety Guideline for Semiconductor Manufacturing Equipment

SEMI S8 — Safety Guidelines for Ergonomics Engineering of Semiconductor Manufacturing Equipment

4.2 *ANSI Standard*[1]

ANSI/RIA R15.06 — Industrial Robots and Robot Systems - Safety Requirements

4.3 *CENELEC Standards*[1]

EN775 — Manipulating Industrial Robots – Safety

4.4 *ISO Standards*[2]

ISO 10218 — Manipulating Industrial Robots – Safety

5 Terminology

5.1 *automated operation* — system operation under full pre-programmed control of the computer controller.

5.2 *automatic guided vehicle (AGV)* — a floor based vehicle, with or without robotic manipulators, used for transporting loads and operating without the need for assistance by factory personnel. AGVs travel without mechanical guidance.

5.3 *bumper* — a shock absorber for a UTV. A bumper is typically equipped with a contact switch or sensor on it. And if the bumper switch or sensor is activated, the UTV will stop immediately.

5.4 *EMO* — an actuator (e.g., button) which, when activated, places the equipment into a safe shutdown condition, without generating any additional hazard to personnel or the facility.

5.5 *E-Stop* — emergency stop feature provided to stop all moving parts but not necessarily isolating or controlling all energy sources.

5.6 *end user customer* — as related to UTVs, the company operating the factory in which the UTVs are installed.

5.7 *fault-tolerant* — designed so that a reasonably foreseeable single point failure does not result in an unsafe condition.

5.8 *floor-traveling vehicle* — a vehicle that automatically travels on the factory floor to a specified station where a load/unload operation is performed automatically or manually. Floor-traveling vehicles include automatic guided vehicles (AGV) and rail guided vehicles (RGV).

5.9 *hoist* — the assembly on a space-traveling vehicle that performs the load/unload operation by transferring a load [e.g., carrier(s), pod(s)] to and from an overhead vehicle.

5.10 *interbay transport* — movement of loads [e.g., carrier(s), cassette(s), reticle(s)] between functional work areas or bays.

5.11 *intrabay transport* — movement of loads [e.g., carrier(s), cassette(s), reticle pod(s)] within a functional work area or bay.

5.12 *load* — load is the object to be transported by UTV. Load includes a carrier (cassette, box, pod, etc.) and its contents.

5.13 *load/unload operation* — the action necessary to move a load [e.g., carrier(s), cassette(s) reticle pod(s)] to and from a vehicle. This operation may involve hoisting, manual, or robotic manipulation to transfer loads between a vehicle and semiconductor manufacturing equipment (such as process equipment or stockers). See Figure 1.

5.14 *manual operation* — defined as any control outside of automated operation.

5.15 *overhead hoist transport (OHT)* — a rail guided vehicle and hoist used to transport material above the factory floor over the heads of factory personnel.

5.16 *rail guided vehicle (RGV)* — a floor-based vehicle, with or without robotic manipulators, used to transport loads and operating on a guide rail without the need for assistance by factory personnel.

5.17 *space-traveling vehicle* — a vehicle that automatically travels through space, such as in the region just below a factory ceiling, to a specified station where a load/unload operation is performed automatically or manually. Space-traveling vehicles include interbay overhead transport vehicles and intrabay overhead hoist transport vehicles (OHT).

1 American National Standards Institute, 11 West 42nd St., 13th Floor, New York, NY 10036

2 International Organization for Standardization (ISO), 1 rue de Varembe, Case postale 56, CH-1211 Geneve 20, Switzerland

5.18 *station* — the destination point where an unmanned transport vehicle is programmed to stop for load/unload operation (also known as a control point).

5.19 *travel* — the automated motion of a vehicle along a rail or programmed path from one station to another station. Travel does not include load/unload operation. See Figure 1.

5.20 *unmanned transport vehicle (UTV)* — a vehicle used to automate the movement of production material within semiconductor factories. There are two types of UTVs, floor-traveling vehicles and space-traveling vehicles.

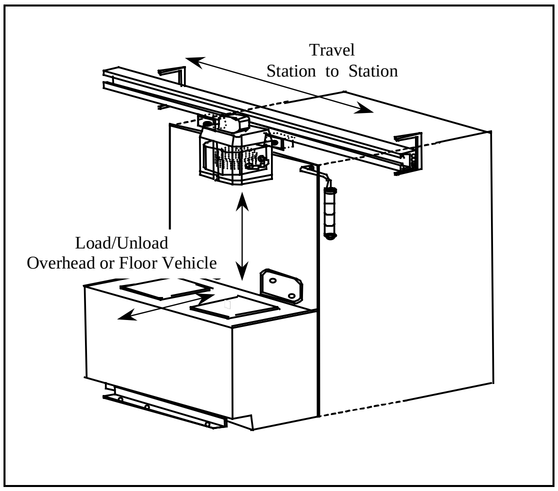

Figure 1
Delineation of Travel vs. Load/Unload

6 Equipment Evaluation

6.1 *Equipment Evaluation for both Floor-Traveling and Space-Traveling Vehicles* — All UTV equipment should be evaluated against the following referenced provisions.

6.2 All UTV equipment should be evaluated against appropriate sections of SEMI S2 for environmental, safety, and health considerations.

6.2.1 Evaluations to the provisions in the following sections of SEMI S2 are applicable to declare conformance to this document.

a) Electrical Design

b) Emergency Shutdown

c) Automated material handlers (This Automated material handlers section only applies to the robotics portion of UTV equipment, when provided.)

d) Hazard Warning Labels

e) Seismic Protection

f) Documents provided to User

6.2.2 At the discretion of the evaluator, additional provisions in SEMI S2 may be considered for evaluation based on the functionality of the UTV equipment.

6.3 All UTV equipment should be evaluated against SEMI S8 for ergonomic considerations.

6.4 All UTV equipment should be evaluated against the applicable Electro Magnetic Compatibility (EMC) regulations of the proposed installation site.

6.5 In addition to the provisions referenced in Section 6.1, UTV equipment should also be evaluated to the provisions contained in the following sections of this document.

7 Clearances and Interfaces

7.1 *Body Shape of both Floor-Traveling and Space-Traveling Vehicles* — The body of a UTV should be free of any dangerous parts such as sharp edges and protrusions. The UTV body surface should have a smooth finish.

7.2 *Minimum Clearance for Floor-Traveling Vehicles* — Where passageways are used for emergency egress, they should be provided on at least one side of the UTV. International, national or local codes, regulations, and laws should be used to determine passageway width.

7.3 *Minimum Clearance for Space-Traveling Vehicles* — The lowest part of the space-traveling vehicle, including the load, should maintain a minimum clearance of 2135 mm (7 feet) above the walking floor.

NOTE 3: Some end user customers may request a higher minimum clearance, or a minimum clearance between the space-traveling vehicle and the top of other equipment, to accommodate clearances specified by SEMI E15.1.

7.4 *Interfaces with Building Structures for both Floor-Traveling and Space-Traveling Vehicles* — UTV suppliers should provide for optional vehicle interfaces with building structures like doors, elevators, and walls.

7.4.1 If UTVs are required to operate in conjunction with building structures, such as automatic doors or elevators, UTVs should be capable of communicating with the facility to assure safe door opening/closing.

7.4.2 If it is necessary for a UTV to travel through a building firewall, the firewall pass through should be specified and/or designed to maintain the fire rating of the wall in the event of a fire.

8 Emergency Shutdown

8.1 *Emergency Shutdown for both Space-Traveling and Floor-Traveling Vehicles* — In addition to the emergency shutdown provisions of SEMI S2, UTV equipment should also conform to the following provisions.

8.1.1 The UTV should be equipped with an emergency off (EMO) circuit that, when activated, immediately stops the operation and motion of the UTV, including both travel and load/unload operation. The EMO circuit should be activated whenever the following actions occurs:

a) An EMO button on the UTV is pressed.

b) An EMO at a fixed floor location is pressed.

NOTE 4: See Section 9.2 for handheld remote control.

8.1.2 Once an EMO circuit has been activated, the UTV should not move under its own power until the cause of the emergency condition has been resolved and the system has been reset by a human operation. The system should not reset or restart automatically.

8.2 *Position of EMO Buttons on Floor-Traveling Vehicles* — Structure-mounted EMO buttons should be located for easy accessibility by factory personnel.

8.2.1 Vehicle-mounted EMO Buttons should be accessible and visible from all sides of the vehicle, typically on the four-corners of a floor-traveling vehicle.

8.3 *Position of EMO Buttons for Space-Traveling Vehicle Systems* — EMO buttons should be located for easy accessibility by factory personnel, for example:

- Near control panels or operator terminals including handheld vehicle remote controls.
- Near process equipment load ports or stations.
- On walls or other fixed locations in the factory area where space-traveling vehicles operate.

NOTE 5: Some end user customers may request EMO buttons included on the space-traveling vehicle.

8.3.1 Since space-traveling vehicle EMO buttons are typically remote from the vehicles, space-traveling systems should provide a method of determining the location of the activated EMO button. This will ensure that the emergency condition can be identified and resolved prior to resetting the system per Section 8.1.2.

9 Manual Operation

9.1 *Manual Movement of both Space Traveling and Floor-Traveling Vehicles* — When the EMO is activated, the UTV should be capable of brake release to allow for release of a potentially trapped person.

9.1.1 The UTV should be equipped with a manual movement function that permits a human operator to maneuver the vehicle in the event of a problem. In the event of a problem, manual movement of all vehicle functions including travel and load/unload should be allowed.

9.2 *Manual/Remote Operation of both Space-Traveling and Floor-Traveling Vehicles* — Except for EMO and E-Stop, any control of a vehicle outside of automated operation should be exclusive. Other devices should not override vehicle control or cause movement of more than one vehicle at a time.

EXCEPTION: Those controls that do not cause motion.

9.2.1 Manual control of a vehicle motion that could present a hazard if control is lost should be controlled with an enabling type switch, such that movement is enabled only when a switch is continuously held (pressed) by an operator.

9.2.1.1 Handheld remote controls should have an E-Stop or EMO function to allow operators to stop movement that could cause risk to themselves or others. If remote control is wireless, this function should not be marked or labeled as an EMO.

9.2.1.2 During handheld remote control operation, the UTV should stop any vehicle motion that could create a hazard if power or the communication signal is lost.

10 Vehicle Travel

10.1 *Collision Avoidance for both Space-Traveling and Floor-Traveling Vehicles* — UTVs should provide for protection of persons in the same traveling space from injury. Damage to property or equipment from traveling vehicles should also be prevented.

10.1.1 The UTV system supplier should provide documentation specifying safe practices for working within traveling space of the UTVs, to include documented administrative procedures necessary to work safely while performing maintenance on or near operating UTV systems.

10.1.2 UTVs should be equipped with non-contact approach sensing system so those vehicles do not inadvertently contact people or other obstacles during the traveling motion of the UTV. Non-contact approach sensing systems should consist of either electromechanical (preferred) or solid-state devices and components and be designed to be fault-tolerant.

10.1.2.1 If an overhead vehicle is provided with a fault-tolerant contact sensing system (such as a bumper switch), as primary safety protection for people, the circuitry of the secondary non-contact system is not limited to electromechanical or solid state devices and components.

10.1.2.2 Where solid-state devices and components are used in an approach sensing system circuit, the system and relevant parts of the system should be evaluated for suitability for use. Abnormal conditions such as overvoltage, undervoltage, power supply interruption, transient overvoltage, ramp voltage, electromagnetic susceptibility, electrostatic discharge, thermal cycling, humidity, dust, vibration, and jarring should be considered.

EXCEPTION: When the severity of a reasonably foreseeable mishap is deemed to be Minor per SEMI S10, a software based control may be considered suitable.

10.1.2.3 Upon request by the user customer, suppliers should provide a test piece or set of test pieces (appropriate to the sensor device provided) along with procedures for testing and calibration.

10.1.3 When a UTV detects a vehicle or obstacle, the UTV should decelerate and stop automatically before it touches that vehicle or obstacle. If the non-contact approach sensing device should be disabled (for example because the UTV is negotiating a sharp turn), the UTV should decelerate and issue a warning (see Hazard Alarms and Displays section of this document) to indicate that the sensing device has been disabled.

10.1.4 In an area where multiple UTVs are operating, the capability to prevent the collision of one vehicle with another should be provided and to satisfy Section 10.1.3, should consider the following conditions:

a) The distance between a given vehicle and the vehicle that follows it.

b) The timing at which one stream of vehicles merges with another.

c) The timing at which a vehicle branches out from a stream of vehicles to pass another vehicle moving toward it.

d) The distance that separates two vehicles when they pass each other.

10.2 *Collision Detection for Floor-Traveling Vehicles* — In addition to Section 10.1, floor-traveling vehicles should also be equipped with a contact sensing device (such as a bumper switch) capable of detecting collision in the direction in which motion can create a hazard.

10.2.1 The bumpers should have a shape and structure that does not pose a risk to personnel or to objects around the floor-traveling vehicle.

10.2.2 The bumpers should be equal to or larger than the width of the floor-traveling vehicle body, as measured perpendicular to the direction of its traveling motion.

10.2.3 The maximum allowable distance between a bumper and the floor is 15 mm (0.6 inch).

EXCEPTION: If this provision cannot be maintained, (such as when the floor-traveling vehicle enters an elevator, or changes in floor height) the distance should be explicitly stated in the operation manuals (and the specifications) as an alert or warning notice to appropriate personnel.

10.2.4 If an obstacle contacts a bumper, the floor-traveling vehicle should be able to stop within the bumper stroke, irrespective of the speed at which the vehicle is traveling. If this provision cannot be met for technical reasons, the floor-traveling vehicle supplier should clearly indicate the maximum speed at which the vehicle can stop within the bumper stroke.

10.2.5 There should not be any device that disables the functionality of the bumper switch or sensor on floor-traveling vehicles.

10.2.6 If a bumper switch or sensor has been activated by contact, a floor-traveling vehicle should not restart until the system has been reset by a human operation.

NOTE 6: Since space-traveling vehicles travel in dedicated space above the heads of factory personnel, criteria for space-traveling vehicle bumpers are not included.

10.3 *Protective Zones for Space-Traveling Vehicles* — Written administrative procedures for creating a protective zone around personnel, required to work overhead in the path of space-traveling vehicles, should be included in documentation provided by the UTV system supplier.

NOTE 7: Implementation of these administrative procedures is the responsibility of the end user customer.

10.4 *Travel Speed of Floor-Traveling Vehicles* — Floor-traveling vehicles, intended for use in areas where there are both operating vehicles and personnel present, should be equipped with a variable speed-setting mechanism.

10.4.1 The variable speed settings designed for use in areas with both operating vehicles and personnel should not exceed 60 meters/minute (196 feet/minute). Any variable speed settings exceeding 60 meters/minute (196 feet/minute) should be reserved for use in dedicated and unmanned areas for which personnel safety can be assured.

10.4.2 The variable speed setting mechanism of a floor-traveling vehicle should be designed so that only authorized personnel, following access control procedures, can change the vehicle's speed setting.

NOTE 8: Criteria for traveling speeds of space-traveling vehicles are not included in this sub-section.

11 Material Protection

11.1 *Material Protection for both Floor Traveling and Space-Traveling Vehicles* — UTVs should provide for protection of the load when the UTV is traveling and during load/unload operations until safe transfer has been confirmed. UTV's should have an appropriate communication interface (For example SEMI standards such as SEMI E23 or SEMI E84). The UTV system supplier should document the exact method of confirmation.

11.1.1 UTVs should be designed so a single point of failure of the UTV system does not allow a load to fall.

11.1.2 Vehicles should be designed to prevent any load/unload movement when in traveling mode.

11.1.3 UTV load holding mechanisms should have load-shift prevention mechanism (such as stoppers), so that if the vehicle stops suddenly, the load is securely held in place.

11.2 *Material Protection for Floor-Traveling Vehicles* — In addition to the load protection provisions in Section 11.1, the following should also be provided on floor-traveling vehicles.

11.2.1 The floor-traveling vehicle should be designed to prevent loads from being placed on the vehicle so that the load overhangs any edge (length or width) of the vehicle.

11.3 *Material Protection for Space-Traveling Vehicles* — In addition to the load protection provisions in Section 11.1, the following should also be provided on space-traveling vehicles:

11.3.1 If secondary protection is required to meet Section 11.1.2 or to prevent loads from falling, covers or shields should be provided along rails to protect personnel from injury from falling loads.

11.3.2 Inadvertent lowering or uncontrolled drops of the vehicles' hoist mechanisms or loads should also be prevented.

12 Load/Unload Operation

12.1 *Protection from Load/Unload Motion of both Floor-Traveling and Space-Traveling Vehicles* — UTVs should have protection functions during load/unload operation to insure safety of the vehicle, the load and the equipment, until load/unload is completed.

12.1.1 Safety of personnel entering the load/unload area should be provided by a method agreed upon by the UTV supplier and the user.

12.1.2 UTVs should have an appropriate communication interface in order to provide the following functions. Examples for such interfaces are SEMI E84 or E23.

- confirm safe transfer of a load
- prevent transfer of loads prior to load port readiness
- notify affected factory personnel of abnormal load/unload conditions
- prevent transfer of loads when equipment is in manual delivery mode (PGV mode)
- prevent transfer of loads when equipment is at risk.

12.1.3 The UTV system supplier should provide to the end user customer documentation to ensure the UTV system interfaces properly with manufacturing equipment shields (if required), communications protocols, or other method necessary to prevent transfer of loads when equipment is at risk.

12.2 *Protection from Load/Unload Motion of Floor-Traveling Vehicles* — In addition to the load/unload provisions in Section 12.1, the following should also be provided on floor-traveling vehicles:

12.2.1 Load/unload mechanisms (transfer robots) on floor-based vehicles should be isolated or shielded as necessary to restrict contact with factory personnel. Measures should also be taken to prevent inadvertent motion of load/unload mechanisms.

12.2.2 If robotic manipulators are used on floor-traveling vehicles for load/unload operations, the robotic manipulator should meet requirements of the appropriate international or national standard (e.g., ISO 10218, EN775, or ANSI/RIA 15.06). If there are deviations from these general industry standards because of unique semiconductor applications, these deviations should be documented by the evaluator and assigned a risk factor according to a risk assessment.

13 Hazard Indicators

NOTE 9: The integrated design of any hazard indicator system or other safety system requires a coordinated effort among the UTV system supplier, the process equipment supplier, and the end user customer. The following are the minimum hazard indicators to be designed into UTV system equipment.

13.1 *Hazard Alarms and Lamps for both Floor-Traveling and Space-Traveling Vehicles* — The following indicators should be provided on all UTVs, but should be able to be configured to be compatible with the overall factory design for safety.

13.1.1 UTV suppliers should provide documentation of available configurations.

13.1.2 *Malfunction Alarm* — In the event of a malfunction, the UTV should both light a lamp(s) and generate an alarm sound to alert personnel.

NOTE 10: Malfunction alarms typically require the system to be reset by a human operation.

13.1.3 *Manual Operation Indicator* — The UTV should indicate if it is under manual operation, defined as any control of a vehicle outside of automated operation.

13.1.4 *Sensor Disabled Lamp* — The UTV should light a lamp(s) to indicate when the non-contact approach sensing device is disabled (for example, because the UTV is negotiating a sharp turn).

13.2 *Hazard Alarms and Lamps for Floor-Traveling Vehicles* — In addition to the indicators in Section 13.1, the following indicators should also be provided on floor-traveling vehicles:

13.2.1 *Startup Alarm* — When a floor-traveling vehicle restarts after stopping for 5 seconds or more, the vehicle should set off an audible alarm sound at least one second before it begins to move.

13.2.2 *Traveling Alarm* — When the floor-traveling vehicle is traveling, the vehicle should generate audible alarm sounds either continuously or intermittently as appropriate for the area in which the vehicle is operating.

13.2.3 *Turn Signal Lamps* — To indicate a floor-traveling vehicle is preparing to turn/spin-turn (right or left) and during the turn cycle, the vehicle should light turn signal lamp(s). Turn signal lamps should be clearly visible from the side in the direction of the turn.

13.2.4 *Automated Operation Indicator* — The floor-traveling vehicle should light lamp(s) to indicate it is in automated operation.

13.3 *Hazard Alarms and Lights for Space-Traveling Vehicles* — In addition to the indicators in Section 13.1, the following indicator should also be provided on space-traveling vehicles.

13.3.1 *Hoist Alarm* — The space-traveling vehicle and/or hoist should generate audible alarm sounds indicating that the hoisting mechanism is moving (raising or lowering).

NOTE 11: The same audible alarm device can be used to generate startup, traveling, hoist, or malfunction alarms, provided that different sounds are used to indicate each condition.

13.4 *Visual Hazard Alerts for both Floor-Traveling and Space-Traveling Vehicle Areas* — To assure personnel safety in the UTV operation area, information about the recommended system of safety measures should be provided by the UTV system supplier (including items such as alerts, signs, color coding, and safety poles for the vehicle operating area).

13.4.1 The UTV system supplier should provide information about style and placement of road signs, for posting along floor traveling vehicle paths and at load/unload or maintenance stations.

NOTE 12: End user customers may need to provide additional visual hazard alerts for posting on building structures (such as walls, columns, and doors) and/or equipment surrounding the UTV operation area.

13.5 *Visual Hazard Alerts on Floor-Traveling Vehicles* — In addition to the information about operational area visual hazard alerts (noted in Section 13.4), the floor-traveling vehicle supplier should provide all visual hazard alerts required for the floor-traveling vehicle. These visual hazard alerts should be clearly visible from all sides of the UTV.

13.6 *Visual Hazard Alerts for Space-Traveling Vehicles* — In addition to the operational area visual hazard alerts noted in Section 13.4, the following visual hazard alerts should also be provided by space-traveling vehicle suppliers.

13.6.1 The UTV system supplier should provide marking of maintenance station areas and their hazards, as well as a method of marking the floor location where maintenance descent occurs.

NOTE 13: End user customers may need to mark load/unload stations to identify the existence of the hazard. UTV system suppliers should suggest a method of marking these areas.

14 Hazardous Materials

14.1 *Batteries for Floor-Traveling and Space-Traveling Vehicles* — If the UTV requires the use of batteries, the following should be included in the documentation provided by the UTV supplier.

14.1.1 Specifications provided by the UTV system supplier for battery recharging, battery maintenance and battery storage areas should specify the following. This provision can be waived only if the batteries used are sealed with no possibility of gas emission.

- Requirements for eye-washing equipment.
- Requirements for ventilation.
- Restrictions on smoking and other sources of ignition.
- Personnel splash protection requirements during electrolyte handling.

14.1.2 The UTV system supplier should provide disposal requirements for batteries that constitute hazardous waste (such as lead, nickel cadmium or lithium).

NOTE 14: Disposal requirements should comply with national or local codes, regulations, and laws.

NOTE 15: Per SEMI S2 environmental guidelines, the UTV system supplier should provide information on the nature, volume, and risks of potential hazardous waste (such as lead or lithium).

NOTE 16: Battery charging stations may have to meet international, national, or local regulations (such as EU Directives or U. S. Department of Labor, Occupational, Safety and Health Act Regulations).

14.2 *Spill Prevention for Floor-Traveling and Space-Traveling Vehicles* — If the UTV requires the use of lubricants, the UTV supplier should meet the following spill and slip hazard provisions.

14.2.1 Any UTV with an internal oil-reservoir (such as a gearbox) should be structurally designed to prevent any oil from dripping out of the vehicle.

14.2.2 Space-traveling vehicle track lubricants should be restricted to those lubricant types and quantities that will not drip from the vehicle or create a slip hazard.

14.2.3 Rail guided vehicle or track lubricants should be restricted to those lubricant types and quantities that will not drip (e.g., onto sub-Fab floors). Neither should they create a slip hazard on the walking surfaces beside the rail or on the top of the rail itself.

RELATED INFORMATION 1
PROTECTIVE DEVICE OPTION CONSIDERATION FOR LOAD/UNLOAD OPERATIONS AT SEMICONDUCTOR MANUFACTURING EQUIPMENT LOAD STATIONS

NOTE: This Related Information is not an official balloted part of SEMI S17. It is included to assist the user of the document in making decisions about possible options.

R1-1 Purpose

R1-1.1 This Related Information should act as an application note for consideration and selection of safety devices that may be provided to protect load/unload operations where risks are generated by space traveling vehicles.

R1-1.2 Space traveling vehicle suppliers are not required to provide such devices, except as necessary to comply with local jurisdictional requirements.

NOTE R1-1: Refer to the main document for devices recommended for protecting equipment.

R1-2 Scope

R1-2.1 *Protective Devices* — As related to UTV equipment, devices designed to protect personnel or equipment from injury or damage during raising or lowering of loads into position.

R1-2.2 Protective devices should be considered when space-traveling vehicles with hoisting mechanisms are present.

R1-2.3 Protective devices function to warn of, or prevent transfer of, loads when personnel or equipment are at risk.

R1-2.3.1 This application note covers the following types of devices:

- Sensors
- Shields
- Alarms
- Signs and visual alerts
- Communication protocol

NOTE R1-2: This should not be considered a complete list there could be many other solutions.

R1-3 Limitations

R1-3.1 This Related Information is not intended to apply to situations where load ports are installed only in locations inaccessible to personnel walking on the factory floor (such as SEMI E15.1 Option 2 load ports).

R1-3.2 This Related Information does not apply to factories using only floor-traveling vehicles or PGVs.

R1-4 Considerations

R1-4.1 Protective devices should be considered for preventing transfer of loads when personnel or equipment are at risk.

R1-4.2 Protective device integration should be considered a coordinated effort between UTV supplier, manufacturing equipment supplier and the end user customer.

R1-5 Lookdown Sensors

R1-5.1 *Lookdown Sensors* — Such sensors surround the hoisting mechanism and look down to the loadport to determine if anything is within the path of descent.

R1-5.2 Lookdown sensors are one type of protective device that allows for the overhead vehicle to "see" if there is anything in the expected path of descent.

R1-5.3 Lookdown sensors can serve the function of protecting equipment from impact.

R1-5.4 Lookdown sensors should be capable of communicating the need for operator intervention back to a location that can notify the proper personnel.

R1-6 Shield Options

R1-6.1 *Shield Device* — Shield devices are physical shielding which is placed to block access to a hazard area.

R1-6.2 Shield devices, when selected, should be capable of fitting within the dimensional limitations of the load ports. (See SEMI E15.1 for dimensional requirements and exclusion zones for 300 mm load ports.)

R1-6.3 Shield device types include:

- Curtain Sensor
- Safety Guard
- Automatic Doors

R1-6.4 Shield devices, when chosen, should prevent simultaneous load/unload operation by a floor-traveling vehicle or person and a space-traveling vehicle.

R1-6.5 *Protective Device Interlocks* — These confirmation signals from shield devices are used to interrupt the transfer process if a shield is breached.

R1-6.5.1 In the case of UTV systems, protective device interlocks should communicate to the UTV equipment either directly or through the manufacturing equipment.

R1-6.5.2 Communication should be via a protected-path communications protocol that is fail safe.

R1-7 Alarms

R1-7.1 A*larms* — Alarms consist of audible and visual notices of hazards that may be approaching.

R1-7.2 Alarms may also be selected as protective devices.

R1-7.3 Alarms may be field configurable to allow for selection of type of audible or visual allowed, or to allow for selection of either audible or visual and elimination of the other type.

R1-8 Signs and Visual Alerts

R1-8.1 Signs such as “Caution”, “Warning”, or other sign appropriate to the potential hazard may be selected as a method of protection.

R1-8.2 Signs should be compatible with SEMI S1, or should be approved by the local jurisdictional authority.

R1-8.3 *Visual Alerts* — an indicator applied to floors or vertical surfaces surrounding a potential are of delivery, which indicates to persons present that a potential hazard exists in the area.

R1-8.4 Visual alerts may include:

- Striped tape on the floor
- Warning barriers
- Railings

NOTE R1-3: This should not be considered a complete list there could be many other solutions.

R1-9 Communication Protocol

R1-9.1 *Communication Protocol* — A method of communicating the status of the equipment to a centrally monitored location. This may be direct or through the equipment communication path.

R1-9.2 Protective devices offered should be capable of communicating with floor-traveling and space-traveling UTVs through some type of interface.

R1-10 Providing Information

R1-10.1 If protective devices are offered, the UTV supplier should provide documentation to the end user customer about protective devices available.

R1-10.2 Information should be provided to the user to explain the function of any protective devices that may be offered.

R1-10.3 Information may also be needed by suppliers of other equipment to insure adequate communication between equipment types.

SEMI INTERNATIONAL STANDARDS

FLAT PANEL DISPLAY

Semiconductor Equipment and Materials International

SEMI D3-91
QUALITY AREA SPECIFICATION FOR FLAT PANEL DISPLAY SUBSTRATES

1 Purpose

1.1 This document defines various areas on the pattern surface of a flat panel display substrate and describes their relationship. It assumes the existence of terminology and a banking convention described in other SEMI flat panel display documents.

2 Applicable Documents

2.1 *SEMI Documents*

SEMI D4 — Method for Referencing Flat Panel Display Substrates

Definitions for Flat Panel Display Substrates

3 Significance

The patterns placed on a flat panel display substrate are expected to occur only in a specified, central area, and certain requirements are applied in that area to both the substrate and pattern quality. The substrate peripheral area(s) outside this zone have different specified properties. Defining the terms to apply and the geometric relationship in these various areas will assist the suppliers and users of substrates and processing/inspection equipment.

4 Summary

4.1 A substrate edge length is defined in two dimensions, L_X and L_Y, with nominal and tolerance values for each.

4.2 A quality area is defined by two dimensions, QA_X and QA_Y, with nominal and tolerance values for each.

4.3 A fixed edge exclusion area is defined for the substrate edges to be placed against reference (also called "banking") pins.

4.4 Two variable edge exclusion areas result from combining the above three dimension sets.

5 Procedure

5.1 Locate the properties in Sections 5.2 – 5.4 relative to the substrate origin, using the nominal values assigned by the substrate specification.

5.2 Let L_X = the substrate edge length in the x-direction, and

L_Y = the substrate edge length in the y-direction. (See Figure 1.)

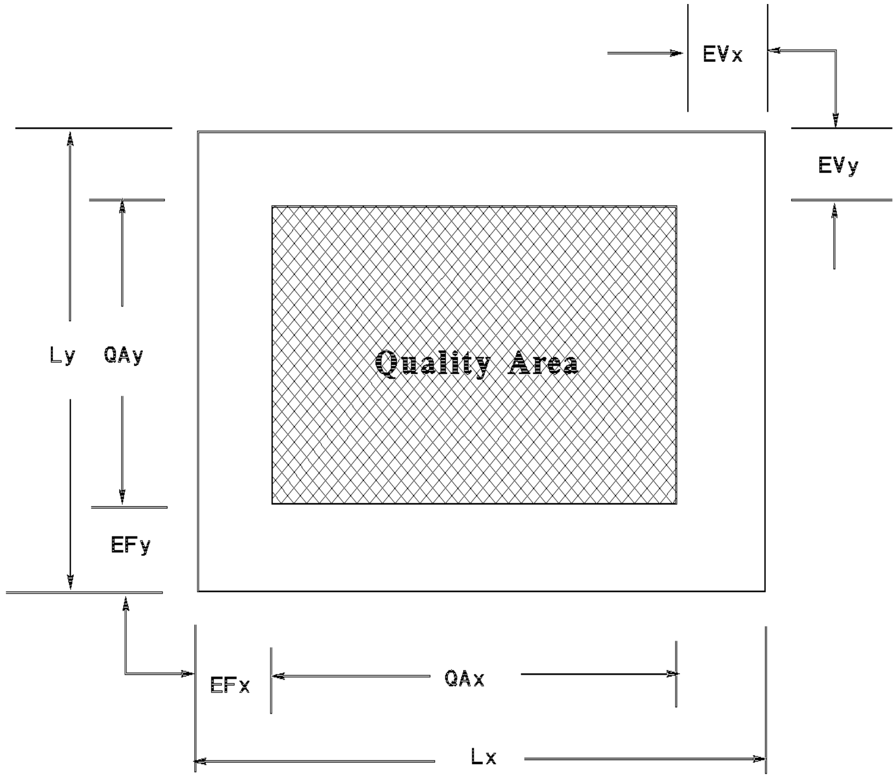
5.3 Let EF_X = the fixed edge exclusion area along the substrate's lower edge, and

EF_Y = the fixed edge exclusion area along the substrate's left edge.

5.4 Let QA_X = the quality area's edge length in the x direction, and

QA_Y = the quality area's edge length in the y direction.

5.5 Then EV_X and EV_Y, the variable edge exclusions, are not specified. They result from the interaction of substrate tolerance variations from nominal with the fixed location origin.



L_X, L_Y

QA_X, QA_Y are specified, nominal dimensions

EF_X, EF_Y

EV_X, EV_Y are not specified, but result from tolerance effects.

SEMI D5-94
STANDARD SIZE FOR FLAT PANEL DISPLAY SUBSTRATES

1 Purpose

This standard covers the specification of nominal edge length and thickness and related tolerances of a flat panel display substrate.

2 Scope

These dimensions apply to substrates that are principally used in fabricating AMLCD displays. These dimensions may also be applicable to substrates for other display types. The edge lengths specified range from 300 × 300 mm to 500 × 500 mm. A single thickness, 1.1 mm, applied to all substrates.

SEMI D6-1101
SPECIFICATION FOR EDGE LENGTH AND THICKNESS FOR LIQUID CRYSTAL DISPLAY (LCD) MASK SUBSTRATES

This specification was technically approved by the Global Flat Panel Display Materials and Components Committee and is the direct responsibility of the Japanese Flat Panel Display Materials and Components Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1992; previously published June 1999.

1 Purpose

1.1 This specification defines standard edge length and thickness dimensions and tolerances for substrates used to fabricate liquid crystal display masks.

2 Scope

2.1 These dimensions apply to photomasks that are principally used in fabricating liquid crystal displays. The edge lengths specified range from 202.8 × 202.8 mm to 700 × 800 mm.

2.2 Substrates with an edge length less than 200 mm follow the specifications for a semiconductor mask (see SEMI P1).

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

SEMI P1 — Specification for Hard Surface Photomask Substrates

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 None.

5 Ordering Information

5.1 Ordering information shall be discussed between suppliers and users.

6 Edge Length Specification

6.1 *Edge Length* — Units are in mm. See Tables 1A and 2A, 1B and 2B, 1C and 2C, and 1D and 2D for a combination of materials, edge length, and thickness.

6.2 *Edge Length Tolerance* — ± 0.4 mm. Applies to all groups.

6.3 *Thickness, Tolerance*

6.3.1 Thickness of substrates shall be specified by the edge length group and materials as shown in Tables 2A, 2B, and 2C.

6.3.2 *Tolerance* — For Groups A and B: –0.4 ~+ 0.2 mm. For Group C: See Table 2C. For Group D: See Table2D.

6.4 *Material* — See Section 7.

7 Material Specification

7.1 Substrate material shall be specified as high thermal expansion (HTE), medium thermal expansion (MTE), low thermal expansion (LTE), or ultra low thermal expansion (ULTE). Examples of HTE materials are soda lime glasses; of MTE materials are borosilicate and aluminosilicate glasses; of LTE materials are aluminosilicate glasses; and of ULTE materials are synthetic quartz glasses.

7.2 Substrate materials shall conform to thermal expansion and optical transmittance characteristics specified in SEMI P1.

7.3 Selected physical properties of HTE, MTE, LTE, and ULTE materials are provided for information in SEMI P1, Appendix 1.

JIS B0601-1982 — Definitions and Designation of Surface Roughness

4 Terminology

4.1 *stylus method surface roughness measuring instrument* — Instrument that traces on a section of a surface by a stylus, records irregularity on the surface in a enlarged form, and indicates its amplitude as roughness parameters.

The type of instrument in this standard is specified to an instrument which is sometimes called as a profiler for very thin films and steps.

4.2 *long wavelength cutoff* — Wavelength that the attenuation ratio of its amplitude becomes 75% when the traced profile is passed through the high-pass wavelength filter which eliminates waviness element.

4.3 *short wavelengh cutoff* — Wavelength that the attenuation ratio of its amplitude becomes 75% when the traced profile is passed through the low-pass wavelength filter which eliminates noise element.

5 Measurement Instrument

5.1 *Method* — Stylus method surface roughness measuring instrument defined in Sections 3.1 or 3.2, or an instrument which meets those conditions.

5.2 *Stylus*

Material — diamond
Shape — circular cone or rectangular cone
Tip Radius — 2 µm or less

5.3 *Measuring Force* — 0.1 mN (0.01gf) or above, 0.7 mN (0.07gf) or less.

5.4 *Sampling Interval* — 1 µm or less.

5.5 Vertical noise amplitude p-p value: 3 nm (=30 Å) or less.

6 Measurement Conditions

6.1 Long Wavelength Cutoff, λc — 0.08 mm or close.

6.1.1 Short Wavelength Cutoff, λs — 0.0025 mm or less.

6.1.2 Evaluation length, Le — 0.4 mm.

6.1.3 *Surface Roughness Parameter* — Maximum height of the profile Ry5(ISO4287/1-1984)(=Rz (DIN4768-1990)) or 10 point height of irregularities which is close to Ry5, Rz (JIS B0601-1982).

7 Test Specimen

7.1 A clean FPD glass substrate. No stains or oils should be seen by the naked eye.

8 Measurement Procedure

8.1 Contact the specimen on the stage of the instrument and leave for five minutes to condition the specimen to room temperature.

8.2 Put the stylus on the specimen, measure roughness by tracing the surface, and calculate the defined roughness parameter.

8.3 Change the measurement location to the location near the previous location and measure again.

8.4 Change the measurement location to the location defined in section 9 and repeat the above measurement.

9 Measurement Location

Describe the measurement location on the report, for example, measure the following two locations:

a. the center of the specimen
b. the point which is 20 mm inside from both edges of the orientation corner

10 Calculations or Interpretation of Results

Show the measurement results in nm (nanometers) and round fractions of .5 and over to the next highest whole numbers.

Table 1 Example: Measurement Results

Maximum Height: Ry5	n1	n2
The Center	**nm	**nm
The Corner	**nm	**nm

Measurement Conditions

Surface — The pattern surface
Instrument — (type of instrument and name of maker)
Stylus tip radius — 2 µm
Tracing speed — ** µm/sec
Measuring force — 0.* mN
Cutoff λc — 0.08 mm

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

SEMI D8-94
SPECIFICATION FOR OVERLAY CAPABILITIES OF FPD STEPPERS

1 Purpose

This specification provides a means for specifying the overlay performance of microlithographic stepping exposure systems used to expose resist–coated FPD display substrates (“FPD steppers”).

2 Scope

2.1 FPD substrates may contain a single–layer pattern in which separate sections are created by multiple reticles, unlike the patterns that are produced on semiconductor wafers by a single reticle. This specification defines the parameters required for specifying overlay performance of FPD steppers, for both single– and multiple–reticle applications. These parameters can be used for single–tool two–layer performance (e.g., layer 1 – layer 2) using two or more reticles. They can also be used for inter–tool performance of a single layer using two nominally identical reticles (e.g., layer 1 – layer 1).

2.2 This specification does not address the quality differences between different reticles used to qualify the tool(s). However, these differences must be quantified to validate the statistical derivation of performance measurements against this specification.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI Compilation of Terms

SEMI P18 — Specification for Overlay Capabilities of Wafer Steppers

3.2 *ASTM Document*

Standard 15D — Manual on the Presentation of Data and Control Chart Analysis[1]

3.3 *NIST Document*

Handbook 91 — Experimental Statistics, M G Natrella[2]

4 Terminology

alignment — Of an FPD substrate, the mechanical positioning of reference points on FPD substrates (“alignment marks” or “alignment targets”) to reference points on the reticle(s). The measure of alignment is the overlay at the positions on the FPD substrate where the alignment marks are placed. See *direct alignment* and *indirect alignment*.

overlay — Of an FPD substrate, a vector quantity defined at every point within the patterned area. It is the difference, O, between the vector position, P_1, of a substrate geometry, and the vector position of the corresponding point, P_2, in an overlaying pattern, which may consist of photoresist:

$$O = P_2 - P_1$$

The overlay value, O, may be decomposed into orthogonal components O_x and O_y along the directions of the stepper stage motions.

direct alignment — The mechanical positioning of alignment marks on the FPD substrate directly to the reference points on the reticle(s). Contrast with *indirect alignment*.

indirect alignment — The mechanical positioning of (a.) alignment marks on the FPD substrate to one set of reference points in the stepper, and (b.) alignment marks on the reticle(s) to a second set of reference points in the stepper. Contrast with *direct alignment*.

5 Ordering Information

5.1 Purchase orders of steppers furnished to this specification shall include the following items:

5.1.1 Total patterned area, A_T. For multiple reticle patterns, each unique reticle pattern on the substrate shall have a separate value A_{T1}, A_{T2}..A_{Tn}.

5.1.2 Overlay error for each specified area:

5.1.2.1 *O*, or

5.1.2.2 O_X and O_Y.

5.1.3 Number of data points with which each reticle pattern overlay is to be characterized, and method(s) of overlay calculation.

6 Test Methods

6.1 The test methods for overlay characterization shall be agreed upon between supplier and user.

SEMI D9-1101
TERMINOLOGY FOR FPD SUBSTRATES

This terminology was technically approved by the FPD Materials and Components Committee and is the direct responsibility of the Japanese FPD Materials and Components Committee. Current edition approved by the Japanese Regional Standards Committee on April 19, 2001. Initially available at www.semi.org August 2001; to be published November 2001. This document was originally published in 1994.

NOTE: This document was revised in its entirety in 2001.

1 Purpose

1.1 This document provides terms and definitions of materials and defects within and on the surface of flat panel display (FPD) substrates, and of dimensional, thermal, chemical, optical and mechanical properties of FPD substrates.

2 Scope

2.1 These terms and definitions are applicable to both front and back substrates used in FPD fabrication.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Definitions

4.1 *Internal Defects*

4.1.1 *bubble* — A gaseous inclusion.

4.1.2 *open bubble* — a gaseous inclusion which is so close to the surface that it is obviously open and/or one so close to the surface that it may be broken open with the point of a soft lead pencil.

4.1.3 *inclusion* — Opaque or partially melted particle of refractory or batch material embedded in glass. Its size is usually determined by the size of the distorted area.

4.1.4 *devitrification* — a crystalline area within the glass.

4.1.5 *knot* — an embedded glassy transparent lump having an irregular or tangled appearance. Its size is usually determined by the size of the distorted area.

4.2 *Material on the Surface*

4.2.1 *cullet* — small transparent glass particles that are adhered or fused to the glass substrate surface.

4.2.2 *particle* — a micron-size piece of foreign material on the glass surface.

4.2.3 *stain* — organic or inorganic material on the surface.

4.2.4 *blur* — any erosion of the surface; generally cloudy in appearance, it sometimes exhibits an apparent color.

4.3 *Surface Defects*

4.3.1 *scratch* — a surface fissure generally caused during handling.

4.3.2 *sleek* — a very shallow type of scratch on the polished surface that is sometimes invisible when the viewing angle is changed.

4.3.3 *latent scratch* — a scratch which is usually invisible but when subjected to an etching action by dipping into a detergent or a corrosive solution, such as an acid, the previously invisible scratch becomes visible due to the minor removal of surface glass.

4.3.4 *chip* — a region of material missing from the edge of the glass substrate, which is sometimes caused by processing or handling.

4.3.5 *pit/dig* — small indentation on the glass substrate surface.

4.3.6 *bump* — a small protuberance on the glass substrate.

4.3.7 *crack* — a fissure located at the sheet edge area or central area.

4.3.8 *streak* — a defect with a very small undulation on the glass substrate surface.

4.4 *Dimensional Properties*

4.4.1 *outsize dimension* — vertical and horizontal dimensions of the glass substrate.

4.4.2 *thickness* — the distance between the front surface and the back surface of a glass substrate at same single point.

4.4.3 *thickness variation* — any differences between maximum and minimum values within the thickness of a glass substrate.

4.4.4 *warp* — defined as the maximum distance from a reference plane to the guaranteed surface, this includes twists, partial rises or declines in the glass compared with the reference plane. Warp expression a condition of the whole glass (substrate).

4.4.5 *waviness* — the residual unevenness after the long wavelength component (warp) and the short wavelength component (surface roughness) have been eliminated. This is also called "FPD Waviness" when referring specifically to FPD substrates, as in SEMI D15.

4.4.6 *surface roughness* — the criterion for the smoothness of the sheet surface. Usually the randomly selected areas on the sheet surface are measured by a surface analyzer. Details are defined in SEMI D7.

4.4.7 *beveling* — grinding out or shaping substrate edges by lapping or grinding.

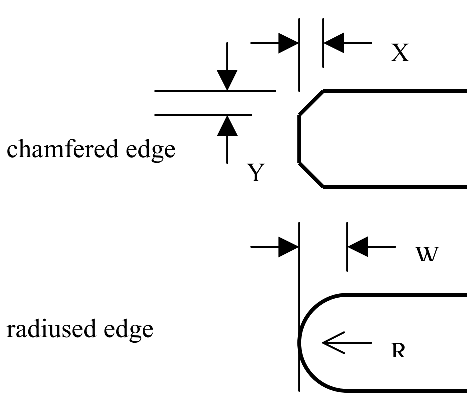

Figure 1
Beveling

4.4.7.1 *chamfered edge* — a beveled angle of approximately 45° in respect to the surface and cut edge surface. One characteristic is that part of the cut edge surface remains. For this reason, R-beveled edges have come to be used in conjunction with chamfered edges in liquid crystal applications. Chamfered edges with particularly small widths are also referred to as "string bevels". (See Figure 1.)

4.4.7.2 *R beveled edge* — a beveled shape of an arc in respect to the surface and cut edge surface. One characteristic is that the complete cut edge surface is ground with a wheel and processed into a frosted glass state. Generally, in TFT liquid crystals, R-beveled edges are used more often. (See Figure 1.)

4.4.8 *orientation corner* — the corner of a substrate which identifies the pattern surface and the rotational orientation. It is defined by the X and Y dimensions in the following figure. It is also commonly known as "orientation flat" or "orifra".

4.4.9 *corner cut* — removal of the corners of the substrate by either lapping or grinding. As with the orientation corner, this is defined by the X and Y dimensions, but generally, most corner cuts have a X and Y of the same length.

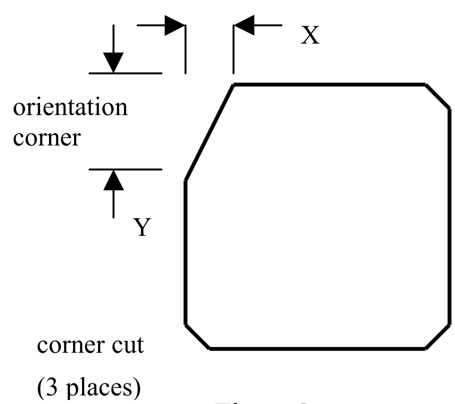

Figure 2
Orientation Corner and Corner Cut

4.4.10 *squareness* — deviation of the outline of the substrate from a true square or rectangle. Using the drawing below, it is defined as PS or PL, but must be recorded with a or b dimensions. Dimensions a and b can be decided voluntarily, but generally, most applications use a = S and b = L. (See Figure 3.)

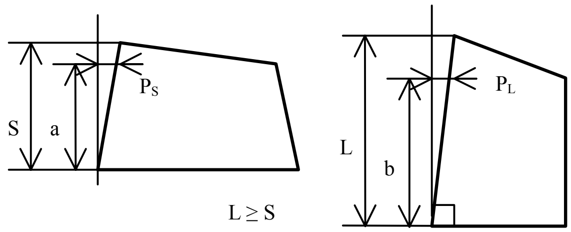

Figure 3
Squareness

4.5 *Thermal Properties*

4.5.1 *coefficient of thermal expansion* — expansion is the change in length per initial length caused by a thermal change. Concretely, it is shown as ΔL/L0, where ΔL = L2 – L1 and L0, L1, and L2 are the lengths of the material at the temperature T0, T1, T2 respectively. Usually, the coefficient of expansion (A), means the average coefficient of expansion over the temperature range T1 to T2. This is shown in the following equation.

$$\alpha = (\Delta L/\Delta T)/L_0 = [(L_2 - L_1)/(T_2 - T_1)]/L_0$$

4.5.2 *thermal shrinkage* — when the substrate is heat treated along a specific thermal profile, the relaxation of thermal stress, and the structure change occur in material and create the shrinkage of the substrate. Usually it is described with ΔL/L0, where, ΔL is the amount of change and shown as ΔL = L0 – L. L0 is the length of material before heat treatment and L is after heat treatment.

4.5.3 *strain point* — temperature of the glass when its viscosity is approximately $10^{14.5}$ Pa/sec. Strain point is defined by two methods in ASTM: Test Method C336 (Elongation of Glass Fibers) and Test Method C598 (Bending in Glass Beams). In practice, the strain point of glass is the maximum temperature at which glass can be processed without triggering unnecessary strain. Internal strain can be relieved by keeping (the glass) at this temperature for 4 hours.

4.5.4 *annealing point* — temperature of the glass when its viscosity is approximately 10^{13} Pa/sec. The annealing point is the temperature at which internal strain can be relieved in 15 minutes.

4.5.5 *softening point* — temperature of the glass when its viscosity is approximately $10^{7.6}$ Pa/sec. Softening point is defined in ASTM C338.

4.6 *Chemical Properties*

4.6.1 *chemical durability* — a measure of corrosion or attack of a glass surface when subjected to a specific reagent, such as acid, base, or water at a specific concentration for a specific time and temperature.

4.7 *Optical Properties*

4.7.1 *transmittance* — Percentage of incident light which permeates the glass. It is defined as I/Io, where Io is the strength of the incident light, and I is strength of the permeated light. Transmittance is effected by material composition, temperature, thickness and light wavelength.

4.7.2 *refractive index* — ratio of the speed of light in the material and in a vacuum at a specific wavelength. The refractive index of substrate glass is between approximately 1.50 and 1.53.

4.8 *Mechanical Properties*

4.8.1 *density* — mass per unit volume. Decided by the mass of the material's atomic composition and the volume (comparative capacity, mol capacity) which it occupies.

4.8.2 *Young's modulus* — a type of elasticity ratio, which shows the stretch (or compression) elasticity. When stretch (or compression) deformation stress σ and the strain ε resulting from the stress are proportionate, the proportionate constant E = σ/ ε is called Young's Modulus, a material characteristic.

4.8.3 *shear modulus* — a type of elasticity ratio which shows divergence elasticity. When divergent deformation stress τ and the strain Φ resulting from the stress are proportionate, the proportionate constant G = τ/Φ is called Shear Modulus, a material characteristic.

4.8.4 *Poisson's ratio* — the ratio between Young's modulus and shear modulus.

4.8.5 *Vickers hardness* — a type of pressure test. A diamond pyramid indentator with a face angle of 136° is pressed into the glass surface to find the degree of hardness by measuring trace indentation on the overall squareness.

4.9 *Electrical Properties*

4.9.1 *dielectric constant* — the proportionate dielectric constant which is the ratio between a vacuum dielectric constant and the material dielectric constant.

4.9.2 *dielectric loss* — the phenomenon, or volume, of (electricity) loss through heat when a dielectric is introduced to an alternating current.

4.9.3 *resistivity* — the reciprocal of electric conductivity.

4.10 *pattern surface* — the main area where device patterns can be formed, determined by the orientation corner, etc.

4.11 *quality area* — the center area to the substrate where specified substrate quality criteria (primarily internal defects, surface contamination, surface defects, waviness, and surface roughness) are applicable.

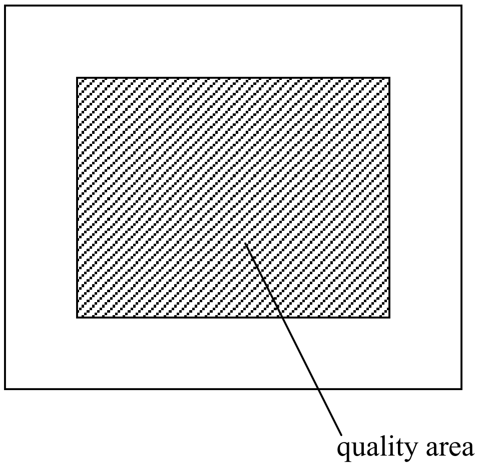

Figure 4
Quality Area

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D10-95
TEST METHOD FOR CHEMICAL DURABILITY OF FLAT PANEL DISPLAY GLASS SUBSTRATES

1 Purpose

1.1 This test procedure evaluates quantitatively the durability of flat panel display (FPD) glass substrates using reagents employed in FPD production processes.

2 Scope

2.1 This standard may be used by vendors and/or buyers of glass substrates for FPD.

2.2 This standard defines three methods for testing chemical durability of various flat panel display substrates: (Method A) Weight Loss, (Method B) Step Measurement Using Profilometry, and (Method C) Surface Haze. Each method provides a measure of the amount of material that is removed from a substrate during a controlled chemical reaction sequence. This sequence is nominally identical for each method.

3 Limitations

3.1 These tests are not applicable to calculating variations in chemical durability in local areas within a substrate.

3.2 The calculations assume that all edges are nominally straight. They do not include adjustments for corner cuts.

3.3 The chemicals used in these practices are potentially harmful and should be handled in a fume hood with the utmost care at all times. **Warning** - Hydro- fluoric acid solutions are particularly hazardous. **Precaution:** They should not be used by anyone who is not familiar with the specific preventive measures and first aid treatments given in the appropriate Material Safety Data Sheet.

5 Terminology

5.1 *haze* —A method to measure the degree of haze created on the FPD glass substrate surface by a chemical etch sequence.

5.2 *step measurement using profilometry* — A method to measure depths of etching by comparing the differences in heights between etched and non-etched parts of a specimen measured by profilometry or an equivalent method.

5.3 *weight loss method* — A method to calculate depths of etching by comparing differences in specimen weights before and after the etch sequence.

6 Apparatus

6.1 For all chemical reactions, the following apparatus shall be used.

6.1.1 *Reaction Vessel*

Material: Teflon or other suitably etch-resistant material.

Shape and Capacity: Cylindrical wide-mouthed sealable vessel, suitable for the size and quantity of samples to be tested.

6.1.2 *Thermostatically Controlled Shaker Bath or Equipment*

Shaking Stroke: 10 to 60 mm.

1 American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103

2 Japan Standards Association, 4-1-24, Minato-ku, Tokyo 107, Japan

3 American National Standards Institute, 11 W. 42nd St., New York, NY 10036

Shaking Frequency: 30 - 90/min., controllable to ± 10/min.

Operating Temperature Range: 20 to 150°C, controllable to ± 1°C.

6.1.3 *Oven* — Controllable to ± 10° over an operating range of 50 to 200°C.

6.1.4 *Desiccator* — Room temperature, with sufficient capacity and size for all samples to be tested.

6.1.5 *Caliper* — Per JIS B7507, or equivalent.

6.2 For the measurements, one of the following shall be used.

6.2.1 *Method A* — Balance per JIS B7601, or equivalent.

6.2.2 *Method B* — Profilometer per ISO 3274, JIS B0651, or equivalent.

6.2.3 *Method C* — Haze measurement equipment with integrating sphere per JIS K7105, or equivalent.

NOTE: It is ideal to use haze measurement equipment which automatically measures total transmittance, diffuse transmittance, and haze values.

7 Reagents and Materials

7.1 No specific requirement is defined for the reagents and materials. As long as the test conditions are reported with the result, any combination of chemical reagents with any concentration can be used for the test. The test conditions should reflect actual process conditions which are specific for the Flat Panel Display manufacturers. Some reagents suggested for the test are provided in Related Information 1 as a reference.

7.2 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsiblity of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

8 Sample Preparation

8.1 Prepare at least a specimen from a lot of the substrates to be tested. The specimen is a rectangular plate about 25 × 50 mm edge length for Methods A and B, or 40 × 40 mm edge length for Method C.

If they are not already chamfered, specimen edges and corners should be chamfered slightly to remove chips and prevent cracking. If repeated tests are expected, prepare an appropriate quantity of test specimens.

8.2 Measure edge lengths of the test specimens, and calculate total surface area, A:

$$A = (L \times W \times 2) + \{ L + W) \times T \times 2)\} \quad (1)$$

where

L = one edge length of test specimen in cm,

W = adjacent edge length of test specimen in cm,

T = thickness of test specimen in cm,

A = total surface area of test specimen in cm^2.

8.3 Clean all test specimens by a method appropriate for the history of the material. The cleaning method should not cause any corrosion. Clean the specimens by an appropriate neutral or alkali detergent for approximately 10 minutes using an ultrasonic bath.

8.3.1 Rinse them continuously in a stream of deionized water, having a conductivity of less than 1µ S/cm, for 1 minute using the ultrasonic bath. Finally, dry them.

8.4 Place all specimens on a clean heat resistant sample holder. Dry the specimens at 140 ± 10°C for 30 minutes.

8.5 Place all specimens in a desiccator containing silica gel or calcium sulfate and cool them, for a minimum of 1 hour, to room temperature.

8.6 If Method A will be used, weigh the test specimen to 0.1 mg or 0.01 mg as required using the balance.

8.7 If Method B will be used, coat about a half portion of each test specimen by an appropriate coating material durable to the test media and conditions. (Wax, varnish, epoxy resins, adhesive tape, etc., may be used.)

9 Procedure

9.1 *Test Specimen Processing*

9.1.1 Prepare cylindrical wide-mouthed sealable vessels, sample holders, etc., made of materials which do not react with the test medium under the test conditions. Use a reaction vessel in which the test specimen, while on the sample holder, is sufficiently immersed in the required volume of test reagent.

9.1.2 Place the test specimen on the sample holder with spacing of 1 to 2 cm between the test specimen and bottom of the empty vessel. When a part of the specimen is coated by protective material, position the sample so that its coated portion faces down. The test specimen may be leaned against the vessel wall if the test is to be done in relatively brief or slightly corrosive conditions, or in concentrated, extremely corrosive media.

9.1.3 Pour the test reagents into the reaction vessel. Volume of the test medium shall be 5 to 10 ml per cm^2 of specimen surface area. Preheat the test medium to the specified test temperature.

9.1.4 Place the reaction vessel in the preheated shaker bath with specified shaking stroke and frequency. Close the reaction vessel loosely, and expose the specimen at specified temperature for specified time.

9.1.5 At the completion of specified test time, immediately remove the reaction vessel from the shaker bath. Remove the test specimens from the reaction vessel using soft forceps, and rinse the specimens immediately by deionized water at appropriate temperature. When the specimen temperature is high following this process, rinse the specimens completely with water of gradually decreasing temperature. Finish it by deionized water at room temperature. Less caution is required when the reaction temperature is low. A synthetic rubber or plastic glove may be used instead of forceps if sufficient care is taken. In all cases, the surface of the test specimen shall not be scrubbed. Never dry the test specimen during this operation. Generation of cracks or chips due to thermal or mechanical shocks should be avoided.

9.1.6 For Method B samples, remove coating by appropriate non-corrosive method, and clean samples again. In this case, residue from the coating material should not contaminate the overall test specimen.

9.1.7 Place the test specimens on a clean heat-resistant sample holder, and dry them at 140 ± 10°C for 30 minutes.

9.1.8 Place the specimens in the desiccator and allow them to cool to room temperature.

9.2 *Measurement Method*

9.2.1 *Method A (Weight Change)*

9.2.1.1 Weigh the test specimen to 0.1 mg or 0.01 mg as required, using the balance.

9.2.1.2 Calculate the areal weight change with the following equation.

$$W_A = \frac{W_2 - W_1}{A} \qquad (2)$$

where

W_1 = the initial weight of the test specimen in mg,

W_2 = weight of the test specimen in mg after the test,

A = is surface area of test specimen in cm^2, as calculated in 8.2, and

W_A = the areal weight change, in mg• cm^{-2}.

NOTE: A negative result indicates areal weight loss, and a positive result indicates areal weight gain.

9.2.1.3 Calculate penetration depth of corrosion, P, of the test sample by the following equation.

$$P = \frac{10 W_A}{D} \qquad (3)$$

where

W_A = the areal weight change in mg• cm^{-2}

D = the density of the substrate material in mg• cm^{-3} (see 9.2.1.4) and

P = penetration depth in µm

NOTE: A negative result indicates loss of material, and a positive result indicates material gain.

9.2.1.4 When density of the materials is unknown, use the value measured by the method described in ASTM C729.

9.2.2 *Method B (Profilometry)*

9.2.2.1 Measure the height, H, in µm, of the step between the unetched (coated) section and the etched (uncoated) section by a calibrated surface profilometer. Trace length shall be between 2 and 4 mm, with the boundary between the two sections located near the center of the trace.

Repeat this measurement at least 3 times.

9.2.2.2 Calculate the average penetration depth P:

$$P = \frac{H_1 + H_2 + \bullet\bullet\bullet\bullet\bullet + H_N}{N} \qquad (4)$$

NOTE: A negative result indicates loss of material, and positive result indicates material gain.

9.2.3 *Method C (Surface Haze)*

9.2.3.1 Measure total transmittance, Tt, and diffuse transmittance, Td, and calculate the haze value from the following expression:

$$H = \frac{Td}{Tt} \times 100 \qquad (5)$$

where

Tt = total transmittance,

Td = diffuse transmittance, and

H = haze value in %.

10 Reporting Results

10.1 Report date and time of test, ambient temperature, test operator, test conditions (reagent and concentration, volume of the test medium, test temperature, test time, stroke length, and frequency of shaking), specimen size and total surface area, specimen cleaning method, and the following:

10.1.1 *Method A* — The areal weight change (W_A), the initial weight of the specimen (W_1), the density of the substrate material (D), and calculated depth of corrosion (P).

10.1.1.1 *Method B* —Penetration depth (P).

10.1.1.2 *Method C* — The average, maximum and minimum value of total transmittance (Tt), diffuse transmittance (Td), and haze value (H).

10.2 *Remarks* — In a typical test, one specimen is immersed in an unused medium of specified volume in a reaction vessel during a specified time. However, as long as various conditions are described in the report, even irregular methods may be allowed. Repetitive usage of a medium may not markedly affect the result when the test is done in relatively brief or slightly corrosive conditions, or in concentrated, extremely corrosive media.

11 Precision and Accuracy

11.1 Interlaboratory evaluation of these test methods is planned to verify their suitability and reliability. Until the results are established, use of this test method for commercial transactions is not recommended unless the parties to the test establish the degree of correlation that can be obtained.

11.2 No standards exist against which any bias of this test method can be evaluated.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI D10 and is not intended to modify or supercede the official standard. Publication was authorized by full letter ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

NOTICE: This related information does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this related information to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

A1-1 The following chemicals and test conditions are recommended when this test is applied to flat panel display glass substrates:

Buffered hydrofluoric acid (1:5) 49% HF, 49% NH_4F, at 40°C for 10 minutes.

Hydrofluoric acid nitric acid (1:5) 49% HF, 70% HNO_3, at 40°C for 10 minutes.

Hydrochloric acid (diluted) (1:1) 36% HCl, H_2O, at 50°C for 20 minutes.

Sodium hydroxide solution (10%) at 50°C for 20 minutes.

SEMI D11-95
SPECIFICATION FOR FLAT PANEL DISPLAY GLASS SUBSTRATE CASSETTES

1 Purpose

This document describes cassettes that are used with glass substrates in the fabrication and processing of subassemblies and masks for flat panel displays (FPD).

2 Scope

2.1 This document applies to cassettes that hold a quantity of rectangular FPD substrates. Selected terms and definitions and summary specifications are included. The specifications for single-substrate cassettes will be developed in other documents.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI E1 — Specification for 3", 100 mm, 125 mm, and 150 mm Plastic and Metal Wafer Carriers

SEMI D3 — Quality Area of FPD Substrates

SEMI D5 — Standard Size for FPD Substrates

SEMI D6 — Standard Size and Thickness for Flat Panel Display Mask Substrates

SEMI D20 — Defect Terminology for Flat Panel Display Masks

SEMI D21 — Definitions for Flat Panel Display Masks

4 Terminology

The following descriptions assume that the cassette orientation places the substrates in a horizontal plane.

4.1 *cassette bottom plate* — The bottom plate of the cassette. It is parallel to the substrate plane. It is physically different from the cassette top plate for purposes of machine interface and for mechanical positioning by operators.

4.2 *cassette front* — The area between top and bottom cassette plates through which substrates pass during loading and unloading.

4.3 *cassette plate opening* — An opening in the cassette top and bottom plate that provides access to the glass substrates for external roller driver mechanisms to move substrates into/from the cassette.

4.4 *cassette rear* — The area between top and bottom cassette plates opposite the cassette front.

4.5 *cassette top plate* — The upper plate of the cassette. It is parallel to the substrate plane. It is physically different from the cassette bottom plate for the purpose of machine interface and for mechanical positioning by operators.

4.6 *First mizo clearance* — The distance between the inside surface of the bottom plate and the centerline of the nearest mizo.

4.7 *First mizo dimension* — The distance between the outside surface of the bottom plate and the centerline of the nearest mizo.

4.8 *glass substrate cassette* — a container for holding glass substrates for processing, storage, and transportation during the fabrication of FPD.

4.9 *inner height* — The shortest distance between the inside surface of the bottom plate and the inside surface of the top plate.

4.10 *mizo* — A term (plural form = mizo) describing a family of rails that support the substrates. They may be smooth-sided, toothed symmetrically, or toothed non-symmetrically. Precise mizo contours are not described in this document.

4.11 *mizo base* — The innermost portion of a mizo.

4.12 *mizo centerline* — 1/2 the mizo clearance.

4.13 *mizo clearance* — The minimum dimensions between two adjacent mizo teeth, into which a substrate can be placed.

4.14 *mizo depth* — The distance between the base of the mizo and the top of the tooth. It is also called ‘tooth height.’

4.15 *mizo flat* — The distance along the mizo base between two adjacent mizo teeth.

4.16 *mizo opening width* — The distance between the extreme ends of two adjacent mizo teeth.

4.17 *mizo pitch* — The distance between adjacent mizo centerlines.

4.18 *mizo plate* — A plate that contains mizo for supporting glass substrates.

4.19 *mizo plate space* — The distance between adjacent mizo plates. It is used in the alignment of substrates after loading.

4.20 *mizo size* — The distance between opposite mizo bases.

4.21 *substrate clearance* — The difference between the substrate width and the mizo size.

4.22 *substrate load depth* — The shortest distance between the front surface of the cassette and the front surface of the substrate stops.

4.23 *substrate stop* — A portion of the cassette, located at the cassette rear, that provides a mechanical stop for substrates during their insertion.

4.24 *tooth* — The protrusion, on the inner surface of the mizo-pocket plate, that contains the mizo shape.

4.25 *tooth height* — See "mizo depth."

5 Cassette Specification

5.1 An FPD substrate cassette contains the following items:

5.1.1 One cassette bottom plate.

5.1.2 One cassette top plate.

5.1.3 One or more substate stops. A mizo plate may be used as a substrate stop.

5.1.4 Three or more mizo plates.

5.2 *Capacity* — Two or more substrates.

5.3 *Dimensions and Tolerances* — To be agreed upon between supplier and user. The following table and figures explain application of the above definitions and located related dimensions.

5.4 *Material* — To be agreed upon between supplier and user. Construction may be of one or more molded or machined parts.

Table 1 Cassette Designations

SEMI D12-95
SPECIFICATION FOR EDGE CONDITION OF FLAT PANEL DISPLAY (FPD) SUBSTRATES

1 Purpose

1.1 This document defines various aspects of the edges of a flat panel display substrate and describes their relationships. It assumes the existence of terminology described in other SEMI flat panel display documents. It applies to substrates whose nominal thickness specification is 1.1 mm.

2 Scope

2.1 *Significance* — The edges of a flat panel display substrate are important in both the specifications for and uses of the material. They effect the means for producing, handling, storing, and processing substrates. Defining the terminology and the geometric properties of these edges will assist both the producers and users of substrates and processing/inspection equipment.

3 Applicable Documents

3.1 *SEMI Documents*

SEMI D3 — Quality Area Specification for Flat Panel Display Substrates

SEMI D4 — Method for Referencing Flat Panel Display Substrates

4 Terminology

4.1 *corner* — of a substrate, any corner other than the orientation corner.

4.2 *edge length* — of a substrate, the nominal length of an edge, including that portion at the edge corner(s) from which material may have been removed for finishing purposes. It is "…defined by two dimensions X and Y, with nominal and tolerance values for each."

4.3 *orientation convention* — a means for denoting the rotational orientation of a substrate.

4.4 *orientation corner* — the corner of a substrate which identifies the pattern surface and rotational orientation.

5 Edge Condition

5.1 All edges shall be treated for purposes of operator safety and to minimize particulate generation. Edges shall be chamfered per Figure 1; other edge treatments are being developed as outlined in Related Information 1.

5.2 Other edge-related parameters shall be per Table 1.

6 Corner Condition

6.1 The orientation corner is asymmetrical for all substrates, with dimensions per Figure 2.

6.2 The edge condition within all corner areas shall meet the criteria of Section 5.

Table 1

Parameter	*Nominal*	*Tolerance*
Length	< 400 mm ≥ 400 mm	± 0.2 mm ± 0.3 mm
Squareness	≤ ± 1/1000 of longer edge for chamfered edge	

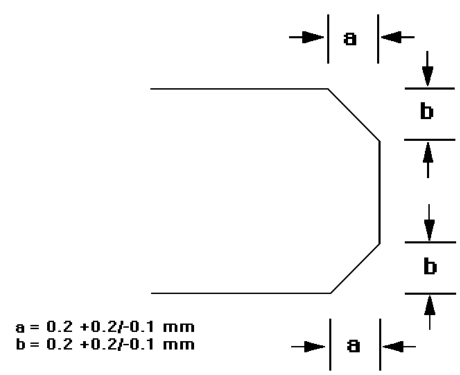

Figure 1
Chamfered Edge

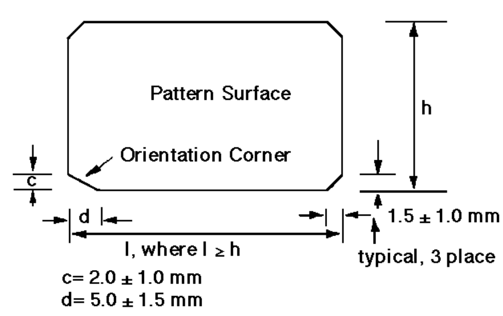

Figure 2
Substrate Corner Dimensions
(shown in 0,0 orientation)

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI D12 and is not intended to modify or supercede the official standard. Rather, this note describes methods for producing FPD substrate edges which may be under development. Publication was authorized by full letter ballot. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Current Practice

The edges of FPD substrates are modified during the substrate manufacturing process so that, in subsequent panel processing, operator safety is improved and particulate generation is minimized. Currently, a "chamfered edge" process is in general use. This modifies the two "corners" of each edge as shown in Figure 1.

R1-2 Future Developments

Other edge treatments may prove more efficient, and several alternate approaches are under development. Two of these are a "Radiused Edge" and "Rounded Edge," shown in Figures 3A and 3B. The radiused edge initially appears simple, but appropriate values of R, for various substrate thicknesses (T), are being examined for manufacturability. For cases where R > T, the proper "edge blend," where R intercepts the substrate pattern and back surfaces, may prove difficult to define and control.

Rounded Edge

SEMI D13-1101
TERMINOLOGY FOR FPD COLOR FILTER ASSEMBLIES

These specifications were technically approved by the Committee and are the direct responsibility of the Japanese FPD Materials and Components Committee. Current edition approved by the Japanese Regional Standards Committee on April 19, 2001. Initially available at www.semi.org August 2001; to be published November 2001. This document was originally published in 1995.

1 Purpose

1.1 These terms and definitions describe various elements and characteristics of FPD color filter (CF) assemblies. They are intended to assist in future CF standardization activity.

2 Scope

2.1 Color filters comprise the front plate assembly in a colored flat panel display. They consist of a number of material layers such as glass substrate, color filter layer, black matrix, overcoat layer, and Indium Tin Oxide (ITO) films. Each of these layers has various properties which may need to be specified, produced, controlled, and characterized. This document provides an overview of these layers, with terms and definitions for selected elements, and indicates the appearance of some color filter defects. This document may be useful in developing material specifications, inspection criteria, and test methods.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document does not contain detailed measuring and test methods. Such methods may be developed separately, and references to them may be incorporated into color filter specification documents where appropriate. The assembly of color filters into a flat panel display assembly is not covered herein.

4 Related Standards

4.1 *SEMI Standards*

SEMI D3 — Quality Area Specification for Flat Panel Display Substrates

SEMI D20 — Defect Terminology for Flat Panel Display Masks

SEMI D21 — Terminology for Flat Panel Display Masks

SEMI M21 — Specification for Assigning Addresses to Rectangular Elements in a Cartesian Array

5 Color Filter Elements (see Figure 1)

5.1 *alignment control projection* — a rib-shaped protrusion created within the display pixel on the color filter film surface for the purpose of controlling alignment direction of the liquid crystal.

5.2 *backside ITO film* — a thin film of Indium Tin Oxide formed on the glass surface on the back of the color filter substrate.

5.3 *black matrix (BM)* — layer which blocks light transmission. It provides a boundary between color filter pixels, preventing the transmitting light between adjacent pixels.

5.4 *color filter layer* — colored layer through which light is transmitted. It is deposited in three colors—red, green, and blue—which are patterned to produce an array of contiguous, rectangular, or square-shaped pixels.

5.5 *glass substrate* — the base material onto which black matrix and color filter layer are deposited. Also called the Front Plate. After assembly into a Display, its back surface faces the observer. See SEMI D3 and SEMI D21 for parameters, definitions, and dimensional specifications.

5.6 *ITO Film* — a thin film of Indium Tin Oxide.

5.7 *overcoat layer* — transparent material deposited over the color filter material. This provides a smooth surface and enough adhesion for subsequent ITO material deposition.

5.8 *post spacer* — a fixed pillar-shaped spacer formed outside of the pixel opening.

5.9 *reflective film* — a light-reflective layer created on the color filter substrate below the color filter layer.

6 Color Filter Pixel (RGB) Layout

6.1 The color filter pixels are arranged in one of several array patterns. The array is constructed from m vertical columns and n horizontal rows of identical pixels of dimensions a horizontally and b vertically. The number of pixels in different rows and columns may vary to suit the application. These are illustrated in Figure 2.

7 Color Filter Types and Fabrication Methods

7.1 *Fabrication Methods*

7.1.1 *photolithography* — Patterning method by using micro photolithograph machines and photopatternable materials. Precise patterns can be formed.

7.1.2 *color photoresist method* — Defined as color photoresist, it is possible to create a pattern through a direct exposure method using color pigment or dye dispersed on a photoresist.

7.1.3 *dyeing* — Dyeable photoresist materials are patterned by photolithographic image processing. These patterned materials are dyed by a special method. The various colors may be introduced sequentially.

7.1.4 *etching* — Dye or pigment-dispersed color material is coated on substrate, and it is patterned by photolithographic etching method.

7.1.5 *printing* — Pigment-dispersed color ink is placed and patterned on the substrate by printing method.

7.1.6 *electric deposition* — Micro cells capsulating pigment particles are dispersed in water solvent and deposited on the selected electrode on glass substrate.

7.1.6.1 *patterned ITO method* — Color filter layers are accumulated using a micell distribution liquid for each color of the ITO pattern formed according to the various RGB color filter layers.

7.1.6.2 *resist pattern method* — Color filter layers are accumulated on non-patterned ITO film by using a micell distribution liquid through openings (windows) in the photoresist according to the RGB pattern.

7.1.7 *multi-layer interference CF (Dichroic CF)* — Multiple layers of inorganic transparent thin films are patterned by photolithography method.

7.1.8 *ink jet method* — Color filter layers are formed by pigment or dye-colored ink blown out from an ink jet head nozzle onto the substrate pixels.

7.1.9 *others* — Fabrication methods other than those above.

7.2 *coloring materials* — Other than the multi-layer interference method, these are formed using pigments or dyes.

7.2.1 *pigment* — This can be pigment in fine powder form dispersed into plastic, or it can be pigment in fine powder form then capsulated in micell (microcell) and dispersed in a water solution.

7.2.2 *dye* — Patterned plastic or gelatin is colored using dye. Also, dyed plastic or gelatin can be patterned using photolithography.

7.2.3 *inorganic permeable thin film* — A clear thin film of inorganic material formed through methods such as vacuum deposition or sputtering.

7.2.4 *Other*

Table 1 Color Filter Fabrication Methods and Materials

Fabrication Method (main category)	*Fabrication Method (subcategory)*	*Material*
Photolithography	Color Resist Method	Pigment/Dye
	Dyeing Method	Dye
	Etching Method	Pigment/Dye
Printing		Pigment
Electric Disposition	Patterned-ITO Method	Pigment
	Resist Pattern Method	Pigment
Mulit-layer Interference	Vacuum Evaporation Method	Inorganic Material
	Sputtering Method	Inorganic Materials
Ink Jet Method		Pigment/Dye

8 Visible Defects

8.1 *black defect* — Black dot-shaped defect existing in the quality area that can be detected using transmitted light.

8.2 *white defect* — White dot-shaped defect existing in the quality area that can be detected using transmitted light.

8.3 *BM (Black Matrix) spot* — A dot-shaped defect caused by extraneous BM material deposited within the quality area, not related to the BM pattern.

8.4 *BM (Black Matrix) pin hole or pinhole* — A dot-shaped defect located within the BM pattern.

8.5 *decolorant* — The absence of a color element in a normally tri-colored pixel. This may occur in a partial area of one pixel.

8.6 *color non-uniformity* — Variation in brightness or chromaticity within the quality area.

8.7 *color spot* — A mixing or overlapping of color materials within an RGB pixel.

8.8 *reflectance non-uniformity* — Variation in reflectance of the surface of color filter within the quality area.

8.9 *hill* — A gently sloping projection smaller than the cell gap width. Will cause cell gap defect.

8.10 *stain* — A small-area spot, with no appreciable thickness, on the surface of some color filter material. It may be caused by introduction of foreign substances during processing.

8.11 *layer particle* — A three-dimensional substance adhered to the surface of some color filter layer material.

8.12 *protrusion* — A large, severe projection larger than the cell gap width. Will cause cell gap defect.

SEMI D14-96
SPECIFICATION FOR IMAGE FIELD STITCHING CAPABILITIES OF FPD STEPPERS

1 Purpose

1.1 This specification provides a means for specifying the image field stitching performance of microlithographic stepping exposure systems used to expose resist-coated FPD display substrates ("FPD steppers").

2 Scope

2.1 Patterns produced on FPD display substrates by FPD steppers are often composed of multiple interconnected fields, in contrast to conventional silicon-based semiconductors where exposure field patterns are generally isolated from each other. In FPD manufacturing, the ability to perform this inter-field alignment is an important characteristic of FPD stepper performance. This specification defines the parameters required to specify stitching performance of FPD steppers for both single- and multiple-reticle applications.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI D8 — Specification for Overlay Capabilities of FPD Steppers

SEMI Compilation of Terms

3.2 *ASTM*[1]

Standard 15D — Manual on the Presentation of Data and Control Chart Analysis

3.3 *NIST*[2]

Handbook 91 — Experimental Statistics, M G Natrella

4 Terminology

4.1 *butting error, on an FPD substrate* — See stitching error.

4.2 *photocomposition error on an FPD substrate* — See stitching error.

4.3 *stitching on an FPD substrate* — The process of aligning and exposing multiple adjacent interconnected fields using an FPD stepper.

4.4 *stitching error on an FPD substrate* — A vector quantity defined at every point along exposure field boundaries within the patterned area. (See also butting area and photocomposition error.) It is the difference, *O*, between the vector position, P_1, on one side of an exposure field boundary, and the vector position of the corresponding point, P_2, on the other side of the exposure field boundary. (see also butting area and photo compositon):

$$O = P_2 - P_1$$

The stitching error value, *O*, may be decomposed into orthogonal components O_x and O_y along the directions of the stepper stage motions.

The stitching error value, *O*, may also be decomposed into orthogonal components $O_{=}$, parallel to, and $O_{\perp}$, perpendicular to the directions of the exposure field boundaries.

NOTE: $O_{=}$ and $O_{\perp}$ are commonly referred to as "shear" stitching error and "overlap" stitching error.

5 Ordering Information

5.1 Purchase orders for steppers furnished to this specification shall include the following items:

5.1.1 *Permissible Stitching Error*

5.1.1.1 *O*, or

5.1.1.2 O_x and O_y, or

5.1.1.3 $O_{=}$ and $O_{\perp}$.

5.1.2 Number of data points to be analyzed and method(s) of overlay calculation.

6 Test Methods

6.1 The test methods for stitching error characterization shall be agreed upon between user and supplier.

SEMI D15-1296
FPD GLASS SUBSTRATE SURFACE WAVINESS MEASUREMENT METHOD

1 Purpose

1.1 This document covers the measurement of FPD glass substrate surface waviness by measuring instruments employing mechanical stylus, optical stylus, and optical interferometric measurement methods.

2 Scope

2.1 This test method is applicable to the documentation of waviness of all types of glass substrates used for flat panel displays.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI D3 — Quality Area Specification for Flat Panel Display Substrates

SEMI D4 — Method for Referencing Flat Panel Display Substrates

SEMI D9 — Definitions for Flat Panel Display Substrates

3.2 *ISO Documents*[1]

ISO 1101 - 1983 — Technical drawings — Geometrical Tolerances — Tolerances of Form, Orientation, Location and Run-Out — Generalities, definitions, symbols, indications on drawings.

ISO 3274 - 1975 — Instruments for the Measurement of Surface Roughness by the Profile Method — Contact (Stylus) Instruments of Consecutive Profile Transformation

4 Terminology

4.1 *bandpass filtered waviness profile* — A profile obtained by removing the long wavelength form components and short wavelength roughness components from a sampled real profile (see Figure 2).

4.2 *2CR filter* — A profile filter equivalent to a series of two CR filter circuits (see ISO 3274).

The standard transmission coefficients at cut-off wavelength are 75%.

4.3 *evaluation length, L_e* — The length of the profile used for assessing the waviness profile under evaluation. A traced length after deduction of both pre-travel and post-travel.

4.4 *FPD waviness, W_{fpd}* — Moving minimum zone method straightness of waviness. The maximum value of a minimum zone method straightness of a certain sampling length within an evaluation length. An approximation in Appendix 1 can be used as well.

DISCUSSION — In fact, it takes a long time to calculate W_{fpd} by the above method because of too large a number of sampling lengths which are all sampled data points within evaluation length minus the number of data points within a sampling length.

Therefore, is recommended that the computer approximation method described in Appendix 1 be used to save time.

Another manual evaluation method is the following:

1. Prepare the template which has a sampling length width window.
2. Scan the template with fitting properly on the recorded chart of bandpass-filtered waviness profile through the evaluation length.
3. Read out every straightness of the profile within the window of the template on every fitted position.
4. The maximum value of all of the readings is W_{fpd}.

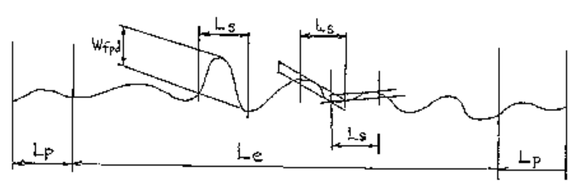

Figure 1
Explanation of L_e, L_p, L_s

4.5 *long wavelength cut-off, λ_L* — Wavelength that the attenuation ratio of its amplitude becomes a standard value when the traced profile is passed through the high-pass wavelength filter which eliminates form element.

4.6 *minimum zone method straightness* — The smallest distance between two parallel straight lines between which all of objective profile is included (see ISO 1101, Section 3.1).

1 American National Standards Institute, 11, W. 42nd St., New York, NY 10036

4.7 *optical interferometric flatness Measuring instrument* — instrument that analyzes the surface irregularities of a target, from the distribution of light intensity of laser interferometer between the target surface and datum flat.

4.8 *optical stylus method measuring instrument* — Instrument that uses the same profile method that a stylus method instrument uses. This instrument uses the displacement transducer to apply the spotlight to the target surface instead of using the stylus to apply the spotlight.

4.9 *phase correct filter* — A profile filter which does not cause phase shifts between total profile and filtered profile.

The standard transmission coefficients at cut-off wavelength are 50%.

4.10 *pre-travel (and post-travel),* L_p — Eliminated portions from a traced length for avoiding the profile distortion caused by transient response of the cut-off filter.

Recommended pre-travel with 2CR filter is double the long wavelength cut-off, λ_L, at the beginning of the traced length and no post-travel.

Recommended both pre-travel and post-travel with phase correct filter are the same as long wavelength cut-off, λ_L.

4.11 *real profile* — An intersection of a target surface with a plane perpendicular to the surface (see Figure 2).

4.12 *sampling length,* L_s — the length of the profile for calculations of waviness parameters in an evaluation length (L_e).

4.13 *short wavelength cut-off,* λ_c — Wavelength that the attenuation ratio of its amplitude becomes a standard value when the traced profile is passed through the low-pass wavelength filter which eliminates roughness element.

4.14 *streak* — A defect whose appearance is a transparent line on the glass substrate surface. It can either be caused by a micro surface discontinuity or a cord due to the heterogeneity of glass composition.

4.15 *stylus method measuring instrument* — Instrument that traces on a section of a surface by a stylus, records irregularity on the surface in an enlarged form, and indicates its amplitude as parameters (see ISO 3274).

4.16 *traced length* — Total traversing length of stylus or spotlight.

4.17 *waviness* — Components of surface irregularities with spatial wavelength intermediate between long wavelength (flatness) and short wavelength (roughness) (see Figure 2).

DISCUSSION — Especially on FPD substrates, those components cause visual irregularity of the shade of the panel due to deviations of the cell gap.

Waviness includes not only periodic waviness, but also streaks.

5 Measuring Instrument

5.1 *Method* — Stylus method measuring instrument, optical stylus instrument, or optical interferometric flatness measuring instrument.

5.2 *Stylus or Spotlight*

5.2.1 *Shape* — circular cone or sphere

5.2.2 *Tip radius* — from 2µm to 0.8 mm (0.03 inch)

5.2.3 *Spotlight* diameter of optical stylus method — 0.2 mm (0.0079 inch) or less

5.2.4 *Horizontal resolution of interferometer* — 0.2 mm (0.0079 inch) or less

5.3 *Measuring Force for Stylus Method* — 4 mN (0.4 gf) or less

5.4 *Sampling Interval* — 0.2 mm (0.0079 inch) or less

5.5 *Profile Filter* — 2CR filter or phase correct filter

DISCUSSION — The filtering method should be specified because the evaluated value of W_{fpd} with phase correct filter will be smaller than that with 2CR filter.

6 Measurement Conditions

6.1 *Target Surface* — The pattern surface (see SEMI D4, Section 5)

6.2 *Long Wavelength Cut-Off,* λ_L — 8 mm (0.3 inch) or 25 mm (1 inch)

6.3 *Short Wavelength Cut-Off,* λ_c — 0.8 mm (0.03 inch)

6.4 *Evaluation Length,* L_e — Is recommended to be Q_{ax} or Q_{ay}, total edge length of quality area of a substrate. If Q_{ax} or Q_{ay} is longer than (L_t - 2*λ_L), L_e is recommended to be (L_t – 2*λ_L).

If the measurable length of the instrument is shorter than the recommended length, then the overlapped section, which contains several traced profiles covering all of the recommended lengths, should be used to evaluate W_{fpd}.

6.5 *Sampling Length, L_s* — Is recommended to be 20 mm (0.79 inch) at λ_L = 8 mm (0.3 inch) or 25 mm (1 inch) at λ_L = 25 mm (1 inch).

7 Test Specimen

7.1 A clean FPD glass substrate. No strain or oils should be seen by the naked eye with fluorescent lamps or incandescent lamps.

8 Measurement Procedure

8.1 Put the specimen on the leveled stage of the instrument without bend and leave for five minutes or more to condition the specimen to room temperature.

8.2 Put the stylus on the specimen and measure a real profile parallel to the edge of substrate by tracing the surface.

8.3 Apply the bandpass profile filter to the real profile and get the bandpass-filtered waviness profile.

8.4 *Calculate the FPD Waviness* — W_{fpd} with manual template method or computer-aided method from the bandpass-filtered waviness profile.

9 Reporting Results

9.1 *Measurement Location and Direction* — Describe the measurement location and direction on the report; for example, measure along the following two directions:

a. the center line of the specimen parallel to the long edge

b. the center line of the specimen parallel to the short edge

9.2 *Interpretation of Results* — Show the measurement results in units of 0.01 µm (micron) and count fractions of 0.5 and over as a unit and cut away the rest.

Table 1 Example: Measurement Result

Direction	L_e	W_{lcd}
Long Edge	**mm	0. **µm
Short Edge	**mm	0. **µm

Measuring Condition

Surface — The pattern surface

Instrument — Stylus method (type of instrument)

Long cut-off, λ_L — 8 mm

Short cut-off, λ_c — 0.08 mm

Sampling length, L_s — 20 mm

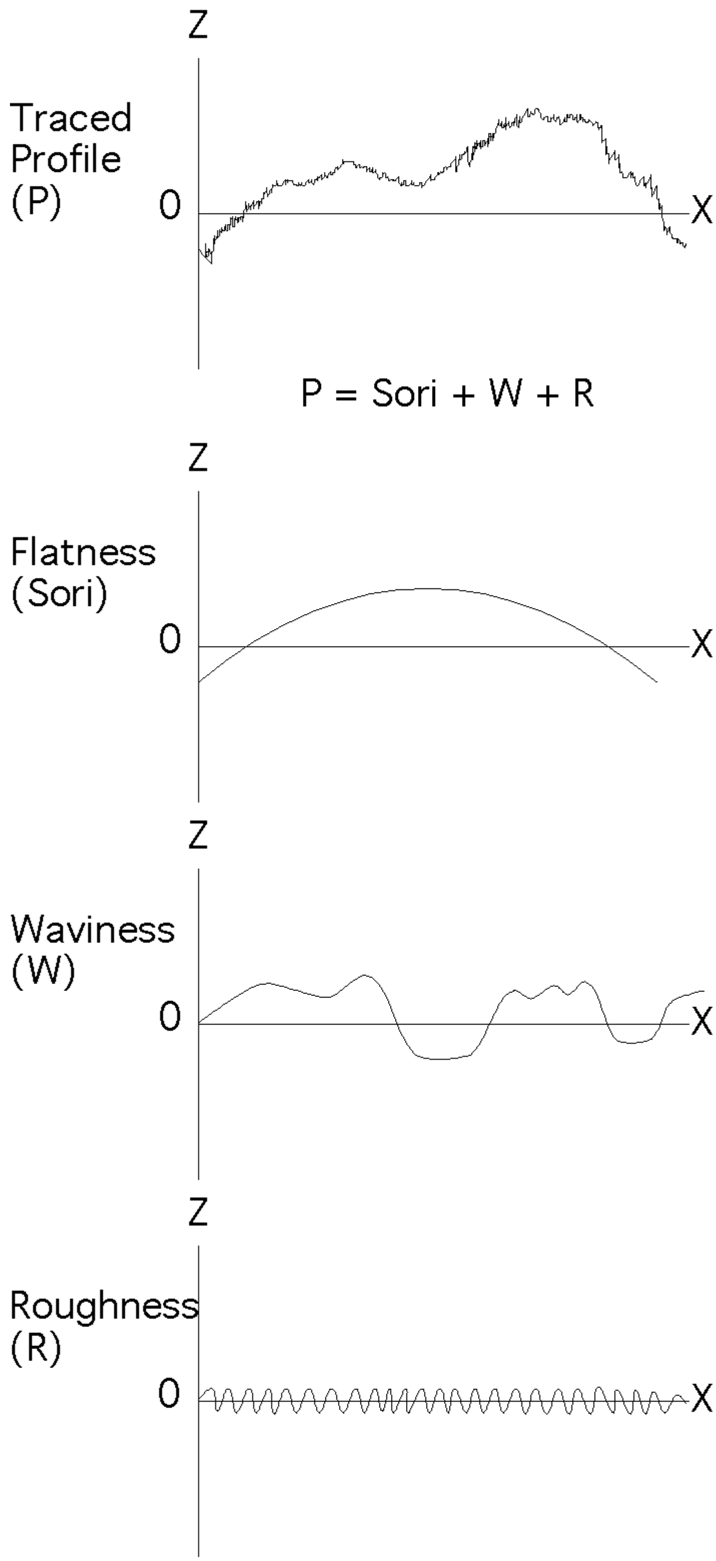

Figure 2
Explanation of Surface Profiles

APPENDIX 1

NOTE: This appendix was approved as an official part of SEMI D15 by full letter ballot procedure.

.A1-1 Purpose

A1-1.1 FPD waviness W_{fpd} requires a large amount of calculation on this standard.

A1-1.2 Therefore, the approximate calculation method shown below can be used instead.

A1-2 Terminology

A1-2.1 local peak of profile — The highest point of profile between two adjacent minima of the profile.

A1-2.2 local valley of profile — The lowest point of profile between two adjacent maxima of the profile.

A1-2.3 window — A sampling length for evaluation.

A1-3 Calculation Method

A1-3.1 Search all local peaks and local valleys within the evaluation length.

A1-3.2 Calculation of a waviness value based on a local peak.

A1-3.2.1 Calculation of a waviness value, W_{iL}, based in the left window of a local peak, P_i (position X_i).

1. Open the left window (L_1 - X_i) with L_s/2 width from the local peak, P_i.
2. Search the lowest point, V_L (position L_2), in the window (L_1 - X_i).
3. Find the point $L_3 = L_2 + L_s$ and open the window (X_i - L_3).
4. Search the lowest point, V_{LR}, in the window (X_i - L_3).
5. $W_{iL} = |Z_i - (V_L + V_{LR}) /2|$

A1-3.2.2 Calculation of a waviness value, Wi_R, based in the right window of a local peak, P_i.

1. Open the right window (X_i - R_1) with L_s/2 width from the local peak, P_i.
2. Search the lowest point, VR (position R_2), in the window (X_i - R_1).
3. Find the point $R_3 = R_2$ - Ls and open the window (R_3 - X_i).
4. Search the lowest point, V_{RL}, in the window (R_3 - X_i).
5. $W_{iR} = |Z_i - (V_R + V_{RL}) /2|$

A1-3.2.3 Calculate W_{iL} and W_{iR} on all local peaks, P_i, then calculate the maximum value, WP_{max}.

$WP_{max} = \max \{W_{iL}, W_{iR}\}$ (i = 1 to n)

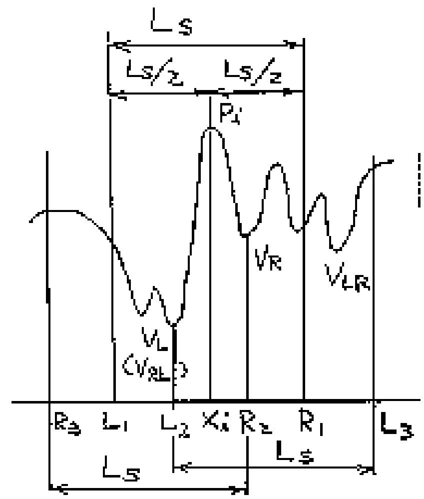

Figure A1-1
Calculation Points of a Local Peak

A1-3.3 Calculation of a waviness value based on a local valley.

A1-3.3.1 Calculation of a waviness value, W_{jL}, based in the left window of a local valley, V_j (position X_j).

1. Open the left window (L_1 - X_j) with L_s/2 width from the local valley, V_j.
2. Search the highest point, P_L (position L_2), in the window (L_1 - X_j).
3. Find the point $L_3 = L_2 + L_s$ and open the window (X_j - L_3).
4. Search the highest point, P_{LR}, in the window (X_j - L_3).
5. $W_{jL} = |Z_j - (P_L + P_{LR}) /2|$

A1-3.3.2 Calculation of a waviness value, W_{jR}, based in the right window of a local valley, V_j.

1. Open the right window (X_j - R_1) with L_s/2 width from the local valley, V_j.

2. Search the highest point, P_R (position R_2), in the window (X_j - R_1).

3. Find the point $R_3 = R_2 - L_s$ and open the window (R_3 - X_j).

4. Search the highest point, P_{RL}, in the window (R_3 - X_j).

5. $W_{jR} = |Z_j - (P_R + P_{RL}) /2|$

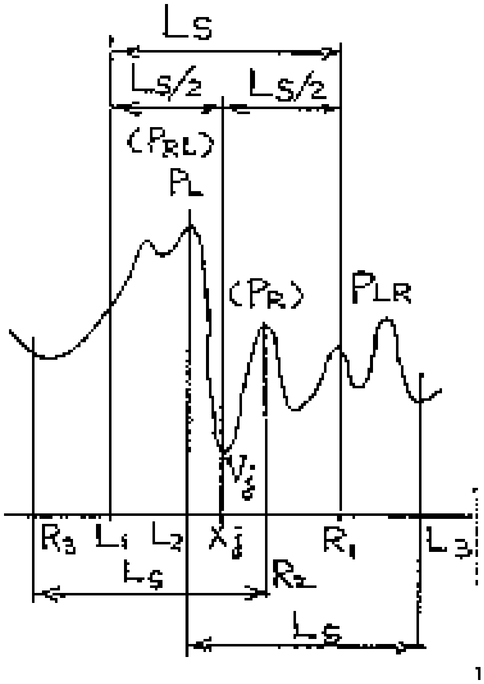

Figure A1-2
Calculating Points of a Local Valley

A1-3.3.3 Calculate W_{jL} and W_jR on all local valleys, V_j, then calculate the maximum value, WV_{max}.

$WV_{max} = \max \{W_{jL}, W_{jR}\}$ (j = 1 to n)

A1-3.4 *Calculation of FPD Waviness, W_{fpd}* — Calculate the maximum value among all maximum values calculated in Sections 3.2.3 and 3.3.3.

$W_{fpd} = \max \{WP_{max}, WV_{max}\}$

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D16-0998
SPECIFICATION FOR MECHANICAL INTERFACE BETWEEN FLAT PANEL DISPLAY MATERIAL HANDLING SYSTEM AND TOOL PORT

This specification was technically approved by the Flat Panel Display Equipment Committee and is the direct responsibility of the North American Flat Panel Display Committee. Current edition approved by the North American Regional Stadards Committee July 1998. Published on SEMI OnLine September 1998; print version published September 1998.

1 Purpose

1.1 This specification defines feature requirements on and about tool ports of process tools used in manufacturing of flat panel displays. These feature requirements facilitate the interfacing of transport equipment to the tool by standardizing the feature requirements. Such standards are intended to promote cost-effective interfacing while preserving freedom of choice in material handling equipment.

2 Scope

2.1 These standards define mechanical features on or about the process tool port, and in front of or on the tool face. Although these features are intended for specific functions, they do not set design requirements for any particular functionality. The interface requirements are meant to be universal and to avoid the promotion of any particular form of transport. Therefore, they are useful for the interfacing of continuous direct WIP transports, such as conveyors, or discrete vehicles of foreseeable future design, such as AGVs, to the process tool port. The dimensions incorporated in the standard apply to single panel handling as well as substrate carriers.

3 Limitations

3.1 Current display manufacturing utilizes several substrate sizes, many of them “non-standard.” This proposed interface specification includes dimensions for the substrate sizes of 550 × 650 mm, and 600 × 720 mm and anticipates the establishment of standard dimension in future substrate sizes. For these future substrate sizes, a universal dimensioning method based on substrate size may be possible.

4 Referenced Documents

4.1 *SEMI Standards*

SEMI D5 — Standard Size for Flat Panel Display Substrates

SEMI D11 — Specification for Flat Panel Display Glass Substrate Cassettes

5 Terminology

5.1 *Definitions*

5.1.1 *facial datum plane* — the plane coincident with the front face of the tool and perpendicular to the horizontal and vertical datum planes.

5.1.2 *horizontal datum plane* — the plane coincident with the top surface of the floor and perpendicular to the facial datum plane of the tool.

5.1.3 *vertical datum plane* — the plane that bisects the tool port and is perpendicular to the horizontal and facial datum planes.

5.2 *Functional Description of Dimensions*

5.2.1 *X1* — width of exclusion zone reserved for vertical material handling devices; maximum.

5.2.2 *X2* — width of the tool port at Z7 below tool load plane. This defines the horizontal limit of the tool port in the x-y plane at that level, beyond which space is reserved for transport equipment; maximum.

5.2.3 *Y1* — maximum tool port protrusion from the tool face. This dimension defines the limits of tool port attachments.

5.2.4 *Y2* — the centerline distance between substrate and tool face when the substrate is delivered to the tool port; ± 10 mm.

5.2.5 *Y3* — depth of the exclusion zone used for PGV cart alignment devices; maximum.

5.2.6 *Y4* — overhead exclusion zone for ceiling-hung material delivery systems; maximum.

5.2.7 *Y5* — maximum protrusion from tool port. May be used for mounting docking devices (mostly PGVs).

5.2.8 *Z1* — height of tool port; ± 10 mm (load plane of reference).

5.2.9 *Z2* — the lowest point on an overhead delivery system; minimum.

5.2.10 *Z3* — the maximum volume height of an overhead delivery system. This dimension extends the full width of the tool.

5.2.11 *Z4* — the height of the exclusion zone used for PGV cart alignment devices.

5.2.12 *Z5* — the maximum height of the protrusion used for docking devices.

5.2.13 *Z6* — the location for the bottom plane of the first substrate. This dimension is not specified in this document.

5.2.14 *Z7* — height of exclusion zones used by conveyor rails and fork lifts; maximum.

6 Requirements

6.1 Dimensions and tolerances of the required features are specified in Table 1 and Figures 1A and 1B.

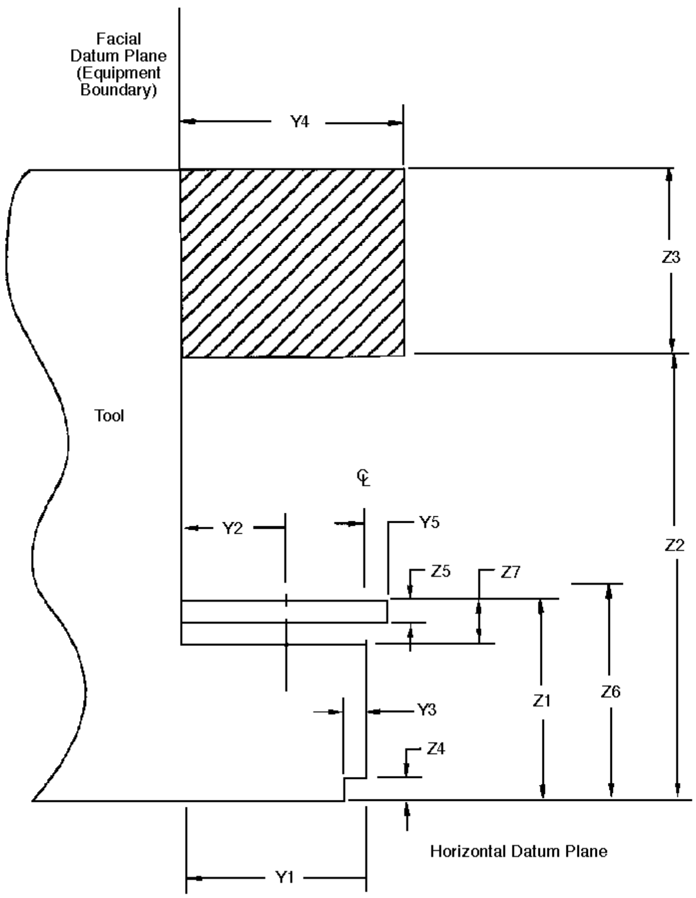

Figure 1A
Proposed Transport System to Tool Interface

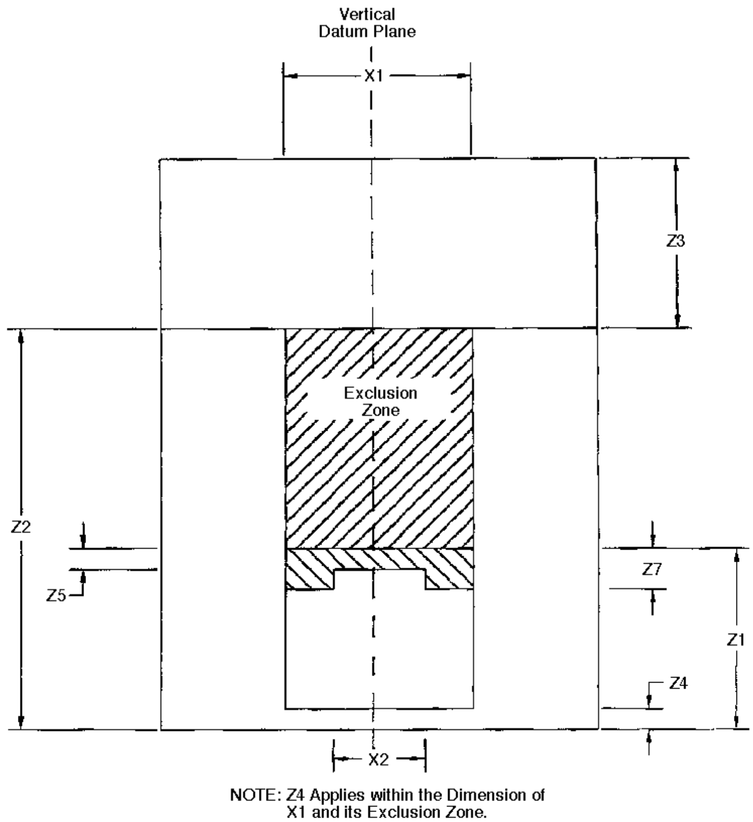

Figure 1B
Proposed Transport System to Tool Interface

6.2 Centerline location of the substrate, as it is delivered by the material handling equipment, with respect to the tool face may not coincide with the centerline location of the substrate when the latter is finally positioned on the tool port for substrate handling.

6.3 Substrate delivery is to be horizontal, active (pattern) face up.

6.4 The single substrate or carrier is to have a horizontal loading orientation with shorter side parallel to the tool face plane.

6.5 Load height of the single substrate or carrier shall be adjustable on the material handling system within 20 (± 10) mm of the nominal height.

6.6 There should be no obstruction between the load port and the material delivery system within the defined adjustable range of the load port height.

6.7 Load and unload mechanisms must allow operator-assisted loading. This implies clearance space for the operator, as well as mechanisms that allow manual override.

Table 1 Substrate Edge Length, Interface Dimensions, and Tolerances (mm)

SEMI D17-0200
MECHANICAL SPECIFICATION FOR CASSETTES USED TO SHIP FLAT PANEL DISPLAY GLASS SUBSTRATES

This specification was technically approved by the Global Flat Panel Display – Equipment Committee and is the direct responsibility of the North American Flat Panel Display Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available on SEMI OnLine January 2000; to be published February 2000. Originally published September 1998.

1 Purpose

1.1 This standard specifies selected requirements of the cassettes used to ship flat panel substrates from the substrate finisher to the display maker and between process-added users.

1.2 This document incorporates pertinent dimensional data from SEMI D18, Specification for Cassettes Used for Horizontal Transport and Storage of Flat Panel Display Substrates.

2 Scope

2.1 This standard is intended to set levels of specification for a reusable cassette to ship clean glass substrates and process-added substrates between organizations without compromising substrate integrity. This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at common mechanical interfaces.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Substrate size and thickness are not specified so as not to cause constraints on supplier/customer relationships.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI D18 — Specification for Cassettes Used for Horizontal Transport and Storage of Flat Panel Display Substrates

SEMI E15 — Specification for Tool Load Port

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

See Figure 1 and Table 1.

5.1 *bilateral datum plane* — a vertical plane that equally bisects the substrate and that is perpendicular to both the horizontal and facial datum planes.

5.2 *carrier capacity* — the number of substrates that a carrier holds.

5.3 *cassette* — as defined in SEMI E44.

5.4 *cassette bottom domain* — volume (below z4 above the horizontal datum plane) that contains the bottom of the cassette.

5.5 *cassette front* — the area between the cassette top and bottom domains through which substrates pass during loading and unloading.

5.6 *cassette placement sensing pads* — surfaces on the bottom of the cassette for triggering optical or mechanical sensors.

5.7 *cassette rear* — the area between the cassette top and bottom domains opposite the cassette front.

5.8 *cassette rear domains* — volumes (from z4 above the horizontal datum plane to z9 above the top substrate) that contain rear columns which prevent the substrates from exiting the cassette rear.

5.9 *cassette side domains* — volumes (from z4 above the horizontal datum plane to z9 above the top substrate) that contain the mizo teeth and mizo plates that support the substrates.

5.10 *cassette top domain* — volume (higher than z9 above the top substrate) that contains the top of the cassette.

5.11 *conveyor rails* — features on the bottom of the cassette for supporting the cassette on roller conveyors.

5.12 *conveying surface* — entire bottom surface of cassette (z15 above the horizontal datum plane), excluding the v-rail, v-groove, and float roller zones, for supporting the cassette on roller conveyors.

5.13 *facial datum plane* — a vertical plane that equally bisects the substrates when the centers of the substrates are aligned and that is parallel to the front side of the carrier (where substrates are removed or inserted) and is perpendicular to the bilateral datum plane. On tool load ports, it is also parallel to the load face plane (as defined in SEMI E15) on the side of the tool where the carrier is loaded and unloaded.

5.14 *first nominal substrate height* — the distance (z5) from the horizontal datum plane to the first nominal substrate seating plane.

5.15 *first substrate end-effector clearance* — the distance (dimension z9) between the top of the cassette bottom domain and the first nominal substrate seating plane.

5.16 *horizontal datum plane* — load height as defined in SEMI E15.

5.17 *mizo plate* — a plate that contains mizo teeth and may provide structure to the cassette.

5.18 *mizo teeth* — elements that support the substrates in the cassette.

5.19 *nominal center line* — the intersection of the facial and bilateral datum planes.

5.20 *nominal substrate seating plane* — a horizontal plane that contains the nominal bottom surface of the substrate as it rests on the mizo teeth.

5.21 *optical substrate sensing paths* — lines of sight for optically sensing the positions of the substrates.

5.22 *polystyrene latex sphere (PSL)* — Reference material used to calibrate surface inspection systems.

5.23 *robotic handling flanges* — projections on the cassette for handling of the cassette.

5.24 *substrate extraction volume* — the open space for extracting a substrate from the cassette.

5.25 *substrate pick-up zone* — the space that includes the volume in which the substrate bottom may be found.

5.26 *substrate pitch* — the distance between adjacent nominal substrate seating planes.

6 Requirements

6.1 *Physical Protection of Substrate*

6.1.1 No chipping, scratching, or other damage shall occur under normal handling and shipping conditions.

6.1.2 Substrates shall be contained to prevent excess movement during shipment.

6.2 *Provisions for Tracking and Identification* — Provision for a printed label should be made.

6.3 *Thermal Requirements* — Construction materials shall withstand cleaning temperatures of 90ºC, following which the cassette shall meet the dimensional and other requirements of this specification.

6.4 *Loading/Unloading of Substrates*

6.4.1 Cassettes furnished to this specification must be compatible with manual and automated loading/ unloading systems, while minimizing cassette volume.

6.4.2 Such cassettes must also facilitate transfer of substrates to and from, a Transportation/Automation Cassette.

6.5 *Cassette Physical Alignment Interface* — The cassette should be registered to the tool interface by one of the three following registration types, A, B, or C. The locations of the registration features have been chosen such that all three types may coexist on the same cassette.

6.5.1 *Cassette Physical Alignment Interface Type A* — This interface consists of three features (not specified, but recommended to be inverted V-shaped grooves) placed on the bottom of the cassette that mate with three coupling pins located on the tool interface. The coupling pins are located by dimensions x14 and y13 relative to the bilateral and facial datum planes respectively.

6.5.1.1 *Coupling Pin Shapes* — The physical alignment mechanism on the bottom of the wafer carrier consists of features (not specified in this standard) that mate with three pins underneath. As shown in Figure 5 and defined in Table 3, each pin is radially symmetric about the vertical center axis line and can be seen as the intersection of a cylinder of diameter d1 and a sphere of radius r3 (which might contact a flat plate). An additional rounding radius r5 provides contact with angled mating surfaces, and blend radii r4 and r6 smooth the resulting edges. The final roughness height of the overall surface finish must be less than or equal to r7. Dimensions r2 and z13 have zero tolerance because they only give a distance to another toleranced dimension. (Dimensions in parenthesis are not part of the requirements in this standard but are intended to clarify the preparation of manufacturing instructions.)

6.5.1.2 The three features on the bottom of the cassette that mate with the coupling pins must provide a lead-in capability that corrects a cassette misalignment of up to 10 mm (0.4 in.) in any horizontal direction, although 15 mm (0.6 in.) is recommended. The exclusion zones for the three coupling features on the cassette are shown in Figure 3 and Table 1 and specified by dimensions x14, z9 and r1.

6.5.2 *Cassette Physical Alignment Interface Type B* — This interface consists of three features, a v-rail, float surface, and facial datum plane v-groove. The v-rail and float surface are located on the bottom of the cassette and mate with the two v-rail rollers and one float surface roller, respectively, mounted on the tool interface. The facial datum plane v-groove is located about the facial datum plane through the bottom surface of the cassette and mates with the facial datum plane lock pin located on the tool interface shown in Figure 3. The v-rail roller and the float surface roller are located by dimensions x15 and x16 relative to the bilateral datum plane, respectively, shown in Figure 6. The dimensiona relative to the facial datum plane for the v-rail rollers are not specified but recommended to be located furthest from and symmetrical about the facial datum plane as shown in Figures 3 and 6. The float surface roller revolute axis must lie on the facial datum plane.

6.5.2.1 The v-rail and float surface rollers are defined in Figure 7 and Table 4. Each roller is radially symmetric about the revolute axis. The rollers are circumferentially radiused of dimension r8. The diameter of the rollers is not specified, but the tangential surface created by dimension r8 must lie on the horizontal datum plane. The facial datum plane lock pin radius is equal to r8 and must be positioned into the facial datum plane v-groove to fully constrain the cassette to the facial datum plane. The facial datum plane lock pin is translated out of the facial datum plane v-groove to allow the cassette to be rolled in and out of the tool interface. Although only three rollers are specified, it is recommended to increase the total number of rollers so that the cassette is fully supported while being loaded and unloaded to the tool interface. All rollers, except for the v-rail and float roller, must be positioned so that the tangent of the r8 dimension lies below the horizontal datum plane.

6.5.2.2 The three features on the bottom of the cassette that mate with the rollers and lock pin must provide a lead-in capability that corrects a cassette misalignment of up to 10 mm (0.4 in.) in any horizontal direction, although 15 mm (0.6 in.) is recommended. The v-rail and facial datum plane v-groove are not specified but recommended to be inverted v-shaped grooves. The v-rail is recommended to extend the full length of the cassette from the cassette front to the cassette rear. The float surface is not specified but recommended to be a flat surface extending the full length of the cassette from the cassette front to the cassette rear. The exclusion zones for these features are shown in Figures 3 and 6 and specified by dimensions x15 and x16 through x22.

6.5.3 *Cassette Physical Alignment Interface Type C* — To be developed.

6.6 *Conveyor Rails* — If the cassette is to be transported on roller conveyors, each conveyor rail should extend the maximum distance from front to back. The exclusion zones for conveyor rails are shown in Figures 3 and 6 and specified by dimensions x13 and x22 and extend to the outer boundary of the cassette.

6.7 *Conveying Surface* — If the cassette is to be transported on roller conveyors that support the entire bottom of the cassette, the bottom surface excluding the v-rail, v-groove, and float roller zones is to be used. The location of this surface with respect to the horizontal datum plane is specified by dimension z3.

6.8 *Substrate Orientation* — The substrates must be horizontal when the carrier is placed on the coupling.

6.9 *Cassette Sides and Rear* — Figure 2 shows a top view of the boundaries of the cassette side domains (which contain the parts of the cassette higher than z4 above the horizontal datum plane and lower than z9 above the top substrate). Table 1 defines the dimensions shown in this and following figures.

6.10 *Cassette Top* — The boundaries of the cassette top domain contain any part of the cassette hither than z9 above the top substrate.

6.11 *Cassette Bottom* — Figure 3 shows a bottom view of the boundaries of the cassette bottom domain (which contains any part of the cassette lower than z4 above the horizontal datum plane). When the cassette is fully down, the cassette placement sensing pads must be z2 above the horizontal datum plane.

6.12 *Vertical Dimensions*

6.12.1 Figure 4 shows the vertical dimensions of the left half of the cassette as viewed from the rear. Note that z5 (the height of the bottom nominal substrate seating plane above the horizontal datum plane) and z8 (the distance between adjacent nominal substrate seating planes) are given as reference dimensions with no tolerance. This means that the sum of actual height variations in the cassette from the horizontal datum plane to the mizo tooth or slot holding each substrate must be contained within the tolerance of z6 with no further stack-up at each higher substrate.

6.12.2 The open space for the substrate extraction volume is indicated by dimensions x6 and y7 and is symmetric about the bilateral and facial datum planes, respectively. The top of the extraction volume is z7 above the nominal substrate seating plane and its bottom is half of the minimum z7 dimension above the nominal substrate seating plane. The cassette must give extra horizontal clearance once the substrate is picked up from wherever it ends up (within the bounds of the substrate pick-up volume) after transport in the cassette.

6.12.3 The open space for the substrate set-down volume is indicated by dimensions x5 and y6 and is symmetric about the bilateral and facial datum planes, respectively. The top of this volume is half of z7 above the nominal substrate seating plane and its bottom is z6 above the nominal substrate seating plane. The substrate should be placed within the bounds of the substrate set-down volume to avoid touching the edge of the substrate to the side of the cassette.

6.12.4 The substrate pickup zone is defined by an area indicated by dimensions x5 and y5 and is symmetric about the bilateral and facial datum planes, respectively. Its top and bottom are the upper and lower tolerance of z6 around the nominal substrate seating plane. If a substrate is placed in the substrate set-down volume and is then pushed to the rear of the cassette, then the entire bottom of the substrate must be contained in the substrate pick-up zone.

6.13 *Particle Generation* — The cassette will not add more than 0.05 particles/cm^2 of a size ≥ 0.5 µm (PSL equivalent) per substrate pass per shipping cycle. The shipping cycle is to be defined by the customer.

6.14 *Inner and Outer Radii* — All concave features may have as much as a 1 mm (0.04 in.) radius to allow for cleaning and to prevent contaminant build-up. All required convex features (such as the robotic handling flanges and the corners of the cassette top and bottom domains) must also have a minimum radius of 1 mm (0.04 in.) to prevent large stress contacts of the cassette that might cause wear and particles.

6.15 *Dimensional Tolerances* — Width (W), Length (L), and Height (H): ± 5 mm

6.16 *Special Design Features*

6.16.1 Compatible with automated cleaning tools.

6.16.2 External features that are compatible with material handling systems such as, but not limited to, Guided Vehicles, Stocker, and Conveyors.

Table 1 Cassette Registration Type A Coupling Pin Dimensions

Symbol Used	*Shown In*	*Dimensions Description*	*Algebraic Relation or Value*
d1	Figure 5	diameter of pin centered on the center axis line	= 12 ± 0.05 mm (0.4724 ± 0.002 in.)

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI D17 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee. Determination of the suitability of the material herein is solely the responsibility of the user.

A1-1 Application Notes

A1-1.1 The shape of the teeth holding the substrates is not specified in this standard. The tooth surface that touches the substrate should have a large radius to minimize stress on the substrate and tooth.

A1-1.2 Extra clearance (larger than the pitch) has been added below the bottom substrate (for non-random sequential access to the substrates with a faster or less precise robot). To increase the stability of Type A Cassettes, the points on the cassette bottom that are the most distant from the lines connecting each pair of coupling pins should be made as close as practical to the horizontal datum plane so that the cassette cannot tip very far off of the kinematic coupling.

SEMI D18-0299^E
SPECIFICATION FOR CASSETTES USED FOR HORIZONTAL TRANSPORT AND STORAGE OF FLAT PANEL DISPLAY SUBSTRATES

This specification was technically approved by the Flat Panel Display Equipment Committee and is the direct responsibility of the North American Flat Panel Display Committee. Current edition approved by the North American Regional Standards Committee on August 15, 1998. Initially available at www.semi.org September 1998; to be published February 1999.

E This document was editorially modified in October 2000 to correct a formatting error. Changes were made to Figure 5.

1 Purpose

1.1 This standard specifies the cassettes used to horizontally transport and store glass substrates 0.7 mm-1.1 mm thick (max) in a flat panel display (FPD) manufacturing facility.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Most of the requirements given in this specification are in the form of algebraic expressions defining maximum or minimum dimensions referenced from the length and width of the intended substrate with very few required surfaces. Only the mechanical interfaces for cassettes are specified; no materials requirements or microcontamination limits are given. However, this standard has been written so that cassettes of various designs and materials can be manufactured in conformance with it.

3 Referenced Standards

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *SEMI Standards*

SEMI D3 — Quality Area Specification for Flat Panel Display Substrates

SEMI D5 — Standard Size for Flat Panel Display Substrates

SEMI D6 — Standard Edge Length and Thickness for Flat Panel Display Mask Substrates

SEMI D9 —Definitions for Flat Panel Display Substrates

SEMI D11 — Specification for Flat Panel Display Glass Substrate Cassettes

SEMI D21 — Terminology for Flat Panel Display Masks

SEMI E15 — Specification for Tool Load Port

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

4 Terminology

4.1 *bilateral datum plane* — a vertical plane that equally bisects the substrate and that is perpendicular to both the horizontal and facial datum planes.

4.2 *carrier capacity* — the number of substrates that a carrier holds.

4.3 *cassette* — (as defined in SEMI E44)

4.4 *cassette bottom domain* — volume (below *z*4 above the horizontal datum plane) that contains the bottom of the cassette.

4.5 *cassette bottom opening* — an opening through the cassette bottom domain that provides access to the glass substrates for external roller drive mechanisms to move substrates into/from the cassette.

4.6 *cassette front* — the area between the cassette top and bottom domains through which substrates pass during loading and unloading.

4.7 *cassette rear* — the area between the cassette top and bottom domains opposite the cassette front.

4.8 *cassette rear domains* — volumes (from *z*4 above the horizontal datum plane to *z*9 above the top substrate) that contain rear columns which prevent the substrates from exiting the cassette rear.

4.9 *cassette placement sensing pads* — surfaces on the bottom of the cassette for triggering optical or mechanical sensors.

4.10 *cassette side domains* — volumes (from *z*4 above the horizontal datum plane to *z*9 above the top substrate) that contain the mizo teeth and mizo plates that support the substrates.

4.11 *cassette top domain* — volume (higher than *z*9 above the top substrate) that contains the top of the cassette.

4.12 *conveyor rails* — features on the bottom of the cassette for supporting the cassette on roller conveyors.

4.13 *conveying surface* — entire bottom surface of cassette (*z*15 above the horizontal datum plane), excluding the V-rail, V-groove, and float roller zones, for supporting the cassette on roller conveyors

4.14 *facial datum plane* — a vertical plane that equally bisects the substrates when the centers of the substrates are aligned and that is parallel to the front side of the carrier (where substrates are removed or inserted) and is perpendicular to the bilateral datum plane. On tool load ports, it is also parallel to the load face plane (as defined in SEMI E15) on the side of the tool where the carrier is loaded and unloaded.

4.15 *first substrate end-effector clearance* — the distance (dimension *z*9) between the top of the cassette bottom domain and the first nominal substrate seating plane.

4.16 *first nominal substrate height* — the distance (dimension *z*5) from the horizontal datum plane to the first nominal substrate seating plane.

4.17 *horizontal datum plane* — load height as defined in SEMI E15.

4.18 *mizo plate* — a plate that contains mizo teeth and may provide structure to the cassette.

4.19 *mizo teeth* — elements that support the substrates in the cassette.

4.20 *nominal center line* — the intersection of the facial and bilateral datum planes.

4.21 *nominal substrate seating plane* — a horizontal plane that contains the nominal bottom surface of the substrate as it rests on the mizo teeth.

4.22 *optical substrate sensing paths* — lines of sight for optically sensing the positions of the substrates.

4.23 *robotic handling flanges* — projections on the cassette for handling of the cassette.

4.24 *substrate extraction volume* — the open space for extracting a substrate from the cassette.

4.25 *substrate pitch* — the distance between adjacent nominal substrate seating planes.

4.26 *substrate set-down volume* — the open space for inserting and setting down a substrate in the cassette.

4.27 *substrate pick-up volume* — the space that contains entire bottom of a substrate if the wafer is pushed to the rear of the cassette.

5 Ordering Information

5.1 *Intended Use* — This standard is intended to specify cassettes over a reasonable lifetime of use, not just those in new condition. The purchaser needs to specify the time period, the number of cycles and any special conditions to which the cassettes will be exposed. It is under these conditions that the cassettes must remain in compliance with the requirements listed in Section 6.

5.2 *Temperature Ranges* — The purchase of the cassettes needs to specify three sets of temperatures to which the cassettes might be exposed. An operating temperature range is the set of environmental temperatures in which the cassettes will remain in compliance with the requirements listed in Section 6 (e.g. 23°C ± 5°C). A temporary temperature range is the set of environmental temperatures to which the cassettes can be exposed such that when the cassettes return to the operating temperature range, the cassettes will be in compliance with the requirements listed in Section 6 (e.g. 90°C maximum during cleaning of the cassette). Also, the purchaser needs to specify a range of temperatures for the substrates that might be inserted in the cassettes.

5.3 *Pitch and Capacity Options* — The purchaser needs to specify the pitch and capacity of the cassettes. Table 2 provides two options of pitch and capacity. Additional pitch and capacity options are not yet defined, but should be specified in the same manner.

5.4 *Material* — To be agreed upon between supplier and user. Construction may be of one or more molded or machines parts.

6 Requirements

6.1 *Dimensions* — Most of the dimensions of the cassette are determined with respect to the three orthogonal datum planes defined in that standard: the horizontal datum plane, the facial datum plane, and the bilateral datum plane (see Figure 1).

6.2 *Cassette Physical Alignment Interface* — The cassette should be registered to the tool interface by one of the three following types of registrations (Type A, B or C). The locations of the registration features have been chosen such that all three types may coexist on the same cassette

6.2.1 *Cassette Physical Alignment Interface-Type A* — This registration consists of three features (not specified, but recommended to be inverted V-shaped grooves) placed on the bottom of the cassette that mate with three coupling pins located on the tool interface. The coupling pins are located by dimensions *x*14 and *y*13 relative to the bilateral and facial datum planes respectively.

6.2.1.1 *Coupling Pin Shapes* — The physical alignment mechanism on the bottom of the wafer carrier consists of features (not specified in this standard) that mate with three pins underneath. As shown in Figure 5 and defined in Table 3, each pin is radially symmetric about the vertical center axis line and can be seen as the intersection of a cylinder of diameter *d*1 and a sphere of radius *r*3 (which might contact a flat plate). An additional rounding radius *r*5 provides contact with angled mating surfaces, and blend radii *r*4 and *r*6 smooth the resulting edges. The final roughness height of the over-all surface finish must be less than or equal to *r*7. Dimensions *r*2 and *z*13 have zero tolerance because they only give a distance to another toleranced dimension. (Dimensions in parenthesis are not part of the requirements in this standard but are intended to clarify the preparation of manufacturing instructions.)

6.2.1.2 The three features on the bottom of the cassette that mate with the coupling pins must provide a lead-in capability that corrects a cassette misalignment of up to 10 mm (0.4 in.) in any horizontal direction, although 15 mm (0.6 in.) is recommended. The exclusion zones for the three coupling features on the cassette is shown in Figure 3 and Table 1 and specified by dimensions *x*14, *z*9 and *r*1.

6.2.2 *Cassette Physical Alignment Interface-Type B* — Consists of three features, a V-rail, float surface, and facial datum plane V-groove. The V-rail and float surface are located on the bottom of the cassette and mate with the two V-rail rollers and one float surface roller, respectively, mounted on the tool interface. The facial datum plane V-groove is located about the facial datum plane through the bottom surface of the cassette and mates with the facial datum plane lock pin located on the tool interface shown in Figure 3. The V-rail roller and the float surface roller are located by dimensions *x*15 and *x*16 relative to the bilateral datum plane respectively shown in Figure 6. The dimension relative to the facial datum plane for the V-rail rollers are not specified but recommended to be located furthest from and symmetrical about the facial datum plane as shown in Figure 3 and 6. The float surface roller revolute axis must lie on the facial datum plane.

6.2.2.1 The V-rail and float surface rollers are defined in Figure 7 and Table 4. Each roller is radially symmetric about the revolute axis. The rollers are circumferentially radiused of dimension *r*8. The diameter of the rollers is not specified but the tangential surface created by dimension *r*8 must lie on the horizontal datum plane. The facial datum plane lock pin radius is equal to *r*8 and must be positioned into the facial datum plane V-groove to fully constrain the cassette to the facial datum plane. The facial datum plane lock pin is translated out of the facial datum plane V-groove to allow the cassette to be rolled in and out of the tool interface. Although only three rollers are specified it is recommended to increase the total number of rollers so that the cassette is fully supported while being loaded and unloaded to the tool interface. All rollers except for the V-rail and float roller must be positioned so that the tangent of the *r*8 dimension lies below the horizontal datum plane.

6.2.2.2 The three features on the bottom of the cassette that mate with the rollers and lock pin must provide a lead-in capability that corrects a cassette misalignment of up to 10 mm (0.4 in.) in any horizontal direction, although 15 mm (0.6 in.) is recommended. The V-rail and facial datum plane V-groove are not specified but recommended to be inverted V-shaped grooves. The V-rail is recommended to extend the full length of the cassette from the cassette front to the cassette rear. The float surface is not specified but recommended to be a flat surface extending the full length of the cassette from the cassette front to the cassette rear. The exclusion zones for these features are shown in Figure 3 and 6 and specified by dimensions *x*15, *x*16 through *x*22.

6.2.3 *Cassette Physical Alignment Interface-Type C* — to be developed.

6.3 *Conveyor Rails* — If the cassette is to be used on roller conveyors, each conveyor rail should extend the maximum distance from front to back. The exclusion zones for conveyor rails are shown in Figure 3 and 6 and specified by dimensions *x*13 and *x*22 and extends to the outer boundary of the cassette.

6.4 *Conveying Surface*—If the cassette is to be transported on roller conveyors that support the entire bottom of the cassette, the bottom surface excluding the V-rail, V-groove, and float roller zones is to be used. The location of this surface with respect to the horizontal datum plane is specified by dimension *z*3.

6.5 *Substrate Orientation and Numbering* — The substrates must be horizontal when the carrier is placed on the coupling, and the substrates are numbered in increasing order from bottom to top (so the bottom substrate is substrate number 1, the next substrate up is substrate number 2, etc.)

6.6 *Cassette Sides and Rear* — Figure 2 shows a top view of the boundaries of the cassette side domains (which contain the parts of the cassette higher than *z*4 above the horizontal datum plane and lower than *z*9 above the top substrate). Table 1 defines the dimensions shown in this and following figures.

6.7 *Cassette Top* — The boundaries of the cassette top domain contain any part of the cassette higher than *z*9 above the top substrate.

6.8 *Cassette Bottom* — Figure 3 shows a bottom view of the boundaries of the cassette bottom domain (which contains any part of the cassette lower than *z*4 above the horizontal datum plane). When the cassette is fully down, the cassette placement sensing pads must be *z*2 above the horizontal datum plane.

6.9 *Vertical Dimensions* — Figure 4 shows the vertical dimensions of the left half of the cassette as viewed from the rear. Note that *z*5 (the height of the bottom nominal substrate seating plane above the horizontal datum plane) and *z*8 (the distance between adjacent nominal substrate seating planes) are given as reference dimensions with no tolerance. This means that the sum of actual height variations in the cassette from the horizontal datum plane to the mizo tooth or slot holding each substrate must be contained within the tolerance of *z*6 with no further stack-up at each higher substrate.

6.9.1 The open space for the substrate extraction volume is indicated by dimensions *x*6 and *y*7 and is symmetric about the bilateral and facial datum planes, respectively. The top of the extraction volume is *z*7 above the nominal substrate seating plane and its bottom is half of the minimum *z*7 dimension above the nominal substrate seating plane. The cassette must give extra horizontal clearance once the substrate is picked up from wherever it ends up (within the bounds of the substrate pick-up volume) after transport in the cassette.

6.9.2 The open space for the substrate set-down volume is indicated by dimensions *x*5 and *y*6 and is symmetric about the bilateral and facial datum planes, respectively. The top of this volume is half of *z*7 above the nominal substrate seating plane and its bottom is *z*6 above the nominal substrate seating plane. The substrate should be placed within the bounds of the substrate set-down volume to avoid touching the edge of the substrate to the side of the cassette.

6.9.3 The substrate pick-up volume is defined by an area indicated by dimensions *x*5 and *y*5 and is symmetric about the bilateral and facial datum planes, respectively. Its top and bottom are the upper and lower tolerance of *z*6 around the nominal substrate seating plane. If a substrate is placed in the substrate set-down volume and is then pushed to the rear of the cassette, then the entire bottom of the substrate must be contained in the substrate pick-up volume.

6.10 *Pitch and Capacity* — Table 2 shows the different options with regard to the substrate pitch (spacing) and the cassette capacity.

6.11 *Inner and Outer Radii* — All concave features may have as much as a 1 mm (0.04 in.) radius to allow for cleaning and to prevent contaminant build-up. All required convex features (such as the robotic handling flanges, and the corners of the cassette top and bottom domains) must also have a minimum radius of 1 mm (0.04 in.) to prevent small contact patches with large stresses that might cause wear and particles.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI D18 and was approved by full letter ballot procedures on August 15, 1998.

A1-1 Application Notes

A1-1.1 The shape of the teeth holding the substrates is not specified in this standard. The tooth surface that touches the substrate should have a large radius to minimize stress on the substrate and tooth.

A1-1.2 Extra clearance (larger than the pitch) has been added below the bottom substrate (for non-random sequential access to the substrates with a faster or less precise robot). To increase the stability of Type A Cassettes the points on the cassette bottom that are the most distant from the lines connecting each pair of coupling pins should be made as close as practical to the horizontal datum plane so that the cassette cannot tip very far off of the kinematic coupling.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D19-0299[E]
TEST METHOD FOR THE DETERMINATION OF CHEMICAL RESISTANCE OF FLAT PANEL DISPLAY COLOR FILTERS

This test method was technically approved by the Global Flat Panel Display - Materials and Components Committee and is the direct responsibility of the Japanese Flat Panel Display - Color Filter Committee. Current edition approved by the Japanese Regional Standards Committee on September 18, 1998. Initially available on SEMI OnLine February 1999; to be published February 1999.

[E] This document was editorially modified in March 2000 to correct a formatting error. Changes were made to Section 11.4.

1 Purpose

1.1 This standard establishes two methods for evaluating the chemical resistance of FPD color filters. One of these methods is qualitative, the other is quantitative.

2 Scope

2.1 These methods may be used by suppliers and users of color filters for FPD applications, for use in judging quality of production and developing samples.

2.2 These methods test the chemical resistance of color filters by utilizing chemicals and conditions typically employed in FPD manufacturing.

2.3 These methods are destructive.

3 Limitations

3.1 This standard specifies only the methods for testing and evaluating chemical resistance of FPD color filters; however, it does not specify the criteria against which the test results are compared.

3.2 This standard specifies only items for color filters, but not for flat panel displays incorporating color filters.

4 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *JIS Standards*[1] *(available in Japanese only)*

JIS Z8113 — Glossary of Lighting Terms

JIS Z8120 — Glossary of Optical Terms

JIS Z8722 — Methods of Measurement of Color of Reflecting

JIS Z8730 — Method for Specification of Color Difference for Opaque Materials

4.2 *Others*[2]

IEC Publication 50 (845) — International Electrochemical Vocabulary (IEV)

5 Terminology

5.1 *color illuminator* — A light source having a uniform illumination plane which radiates diffuse light onto the back surface of a sample to permit direct observation of the sample.

5.2 Definitions of additional terms used in this document may be found in JIS Z8113, JIS Z8122 and IEC Publication 50 (845).

6 Summary of Method

6.1 A sample is placed in a suitable test container at controlled temperature for a specified period of time.

6.2 The sample is removed from the bath and residual chemicals removed.

6.3 The sample is examined visually for qualitative changes in appearance.

6.4 The sample is examined by microscope and/or surface profiler (stylus type) for material swelling.

6.5 The sample is measured per color layer for spectra transmittance.

6.6 The color difference for each color layer is calculated in one of two systems.

7 Apparatus

7.1 *Test Container* — A clean container shall be used with a sufficient size and depth to accommodate the sample and appropriate chemicals. The container material must be chosen which will not be affected by tests executed under this method. Note that chemicals should not change in quality by test container.

7.2 *Instrumentation*

7.2.1 *Color Illuminator* — This light source shall have chromaticity, color rendering, luminance and intensity uniformity, diffusion, and a sufficient illumination area for observation of the samples to be measured.

7.2.2 *Floodlight* — This light shall have luminance uniformity and an illumination area sufficient for the samples to be measured.

1 Japanese Standards Association, 1-24, Akasaka 4 Chome, Minato-ku, Tokyo 107, Japan

2 International Electrotechnical Commission, 3 rue de Varembe, CH 1211 Geneva 20, Switzerland

7.2.3 *Microscope* — The microscope used shall have appropriate magnification, normally 50×–400×.

7.2.4 *Spectrophotometer* — The spectrophotometer shall be in conformance with JIS Z8722 or an equivalent standard.

7.2.5 *Surface Profiler* — The equipment which can measure the thickness with X-Y stage.

8 Reagents and Test Conditions

8.1 No specific requirements are described for the reagents. As long as the test conditions are reported with the test result, any combination of chemical reagents with any condition can be used for the test. The test conditions should reflect actual process conditions, which are specific for the selected FPD manufacturer. Some reagents suggested for the test are given in Table 1.

Table 1 Chemicals Used for Chemical Resistance Tests and Related Conditions

Chemical[1]	*Liquid Temperature (C)*	*Soak Time (minutes)*
N-methyl-2 pyrolidone (NMP)	23 ± 2	30
γ-butyrolactone	23 ± 2	30
2-propanol (IPA)	23 ± 2	30
2-ethoxyethyl-acetate (ECA)	23 ± 2	30
2-methoxyethanol	23 ± 2	30
2.38% tetramethyl-ammoniumhydroxide (TMAH)	23 ± 2	30
18% HCl	23 ± 2	30
18% HCl	40 ± 5	10
5% NaOH	23 ± 2	10
5% KOH	23 ± 2	10

[1] % = % by weight

8.2 This standard may involve hazardous materials, operations and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determines the applicability of regulatory limitations prior to use.

9 Samples

9.1 FPD color filters are used as samples. For HCl resistance tests, color filters without ITO should be used.

NOTE 1: The test report shall identify whether or not ITO is present on the sample.

10 Procedure

10.1 Pour the selected chemicals into a test container.

10.2 Adjust the temperature of the chemicals to a predetermined value.

10.3 Place the sample, film side up, into the chemicals and cover the test container to prevent chemical evaporation.

10.4 Leave the sample in the chemicals for a predetermined period of time.

10.5 Remove the sample from the chemical bath. Completely remove all chemicals remaining on the sample.

NOTE 2: For chemicals, temperature and soaking time, refer to Section 8, *Reagents and Test Conditions.*

10.6 Evaluate the sample condition according to the following criteria:

10.6.1 *Change of Appearance* — During each test, observe any change of appearance, e.g., wrinkles, cracks, change of surface conditions due to swelling, film peeling, and discoloration. The sample is compared with untreated sample. Various observation techniques can be employed, including the following which is included for reference only:

10.6.1.1 Visual observation of transmission of the color filter by use of a color illuminator (Figure 1).

10.6.1.2 Visual observation of reflectance of the film side of the color filter by use of a floodlight.

10.6.1.3 Microscope observation or transmission of a color filter by use of transmitted illumination.

10.6.1.4 Microscope observation of reflectance of the color filter by use of reflected illumination.

10.6.1.5 A surface profiler (stylus type) is used in order to measure the changes of film thickness of the color filter.

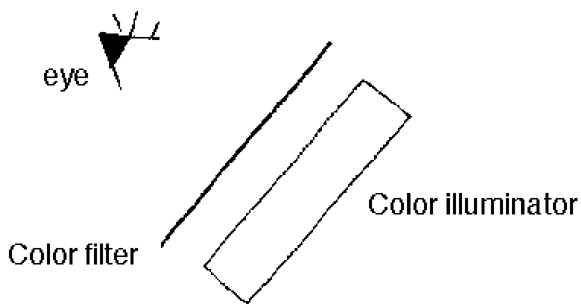

Figure 1
Visual Observation of Transmission of a Color Filter by Use of a Color Illuminator

10.6.2 *Color Differences*

10.6.2.1 Measure transmitted spectra of each colored layer of the color filter at any location. The center area of the sample is recommended.

10.6.2.2 Calculate tri-stimulus values of each colored layer of the color filter in accordance with JIS Z8730.

10.6.2.3 Repeat 10.6.2.1 and 10.6.2.2 on the same location of the sample.

10.6.2.4 Calculate color difference for each colored layer in the L*a*b* color system or the L*u*v* color specification system from the tri-stimulus values measured before and after this test, according to the method specified in JIS Z8730. Calculate either the difference)E*ab or)E*uv as the amount of color change of the color filter.

NOTE 3: Both the L*a*b* and L*u*v* color specification system can be used to evaluate the color change.

11 Report

Report the following:

11.1 Report date

11.2 Test date

11.3 Ambient temperature, in C

11.4 Conditions of the sample (construction of FPD color filter) – presence or absence of ITO film

11.5 Test conditions (name of chemicals, concentration, temperature and volume of chemicals, soaking time)

11.6 Observed changes in sample appearance between, before, and after the test.

11.7 The calculated color differences, for measurement location on each sample, and the color system used for these calculations.

12 Precision and Accuracy

No test data currently exists on which to base these statements. Tests are planned to develop such data for both single-laboratory repeatability and multi-laboratory reproducibility, on samples of the same nominal characteristics, and across a range of nominal characteristics.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. SEMI D20-1000
DEFECT TERMINOLOGY FOR FLAT PANEL DISPLAY MASKS

This terminology was technically approved by the Global Flat Panel Display Committee and is the direct responsibility of the Japanese Flat Panel Display Materials and Components Committee. Current edition approved by the Japanese Regional Standards Committee on July 28, 2000. Initially available on SEMI OnLine September 2000; to be published October 2000. Originally published in 1993.

1 Purpose

1.1 This document defines defect terminology for FPD masks. By this standard, it is intended that the concepts of terms which should be used at the technical conferences, business discussion, etc are clarified and that standardization as to masks will be promoted.

2 Scope

2.1 These terms apply to photomasks that are principally used in fabricating flat panel display.

2.2 These definitions do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these definitions to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the definitions set forth herein for any particular application. The determination of the suitability of the definitions is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These definitions are subject to change without notice.

3 Referenced Documents

None.

4 Terminology

4.1 *pin hole* — a small hole-shaped opening defect on the chrome-pattern.

4.2 *intrusion* — an absence of chrome extending inward from boundary.

4.3 *pattern disconnect* — an intrusion which completely separates the continuity of the chrome-pattern.

4.4 *missing pattern image* — complete disappearance of the designed chrome-pattern.

4.5 *spot* — isolated chrome residue on the etched area.

4.6 *protrusion* — an extension of chrome beyond the desired boundary.

4.7 *bridge* — an extension of chrome which connects completely and continuously from an edge to another edge.

4.8 *edge roughness* — subtle roughness and/or jagged zone on the pattern edge.

4.9 *round of corner* — unintended round on the pattern corner.

4.10 *flaw*

4.10.1 *scratch* — relatively thick and deep linear friction defect on the surface of the glass.

4.10.2 *sleek* — extremely thin and light linear friction defect on the surface of the glass.

4.10.3 *pit* — small dot-shaped depression on the surface of the glass.

4.11 *chipping* — chipping of edge of the glass caused by cutting or treatment.

4.12 *bubble* — void in the interior of the glass substrate.

4.13 *foreign substance*

4.13.1 *particle* — relatively high foreign substance attached on the surface of the substrate.

4.13.2 *contamination* — cluster of relatively small substances attached on the surface of the substrate in the shape of thin film.

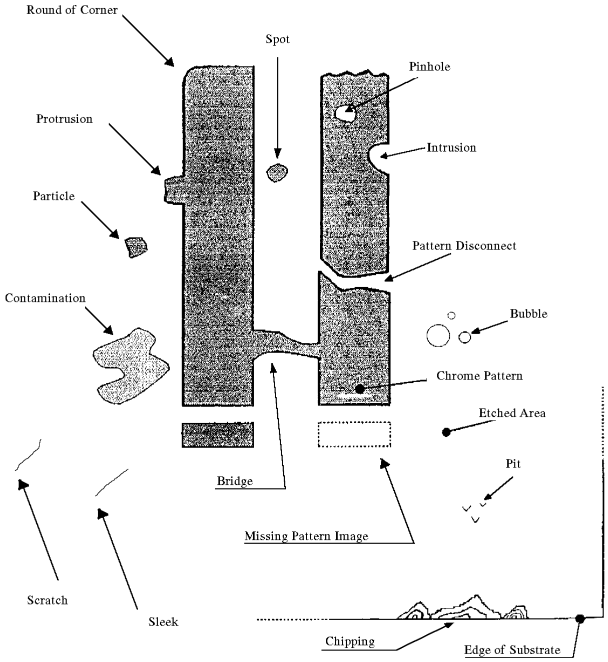

Figure 1
Image of Defects for FPD Mask

Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These definitions are subject to change without notice.

3 Referenced Documents

None.

4 Pattern Dimension

4.1 *Long Dimension Accuracy*

4.1.1 *Long Dimension* — The distances in the X and Y directions between the outermost elements of a pattern on the mask.

4.1.1.1 *Long Dimension Error* — The difference (ΔD) between the measured value (DM) and designed value (DD) of the long distance.

$\Delta D = DM - DD$

4.1.2 *Rectangularity* — Rectangularity of array pattern. Generally, it is indicated as deviation between X coordinate 3 and 4 , when Y coordinate of 1 and 2 are coincident.

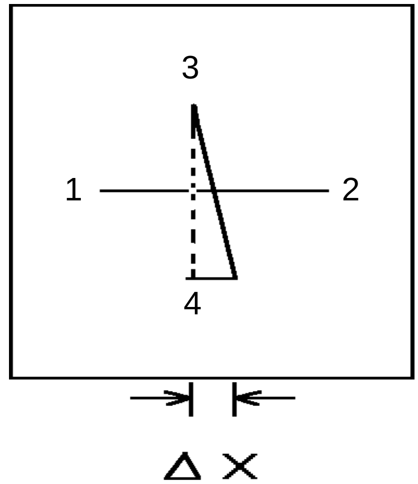

Figure 1
Rectangularity

4.2 *Overlay Accuracy* — Deviation between two or more masks in the direction of the long dimension X, Y. Generally, the two methods are as follows:

- Deviation is measured by comparing the two masks.
- Deviation is measured by comparing measured data of each long dimension of the two masks.

4.3 *Element Dimension Accuracy* — Dimension accuracy of element (line or space).

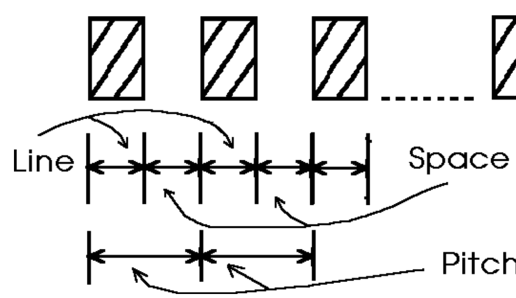

Figure 2
Element Dimension Accuracy

4.4 *Repeat Pitch Accuracy* — Deviation of measured pitch length from designed value.

4.5 *Stitching Error* — Joint accuracy of a pattern when a pattern is composed in a mask (e.g., pattern composition by a stepper). Usually, it is deviation as shown in the following figure.

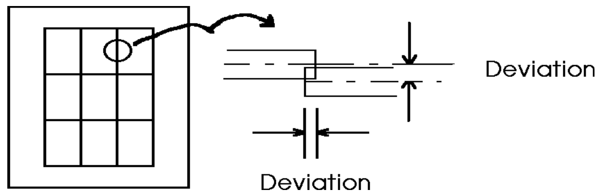

Figure 3
Stitching Error

5 Pattern Positioning Accuracy

5.1 *Pattern Positioning Accuracy* — Relation between the actual and desired locations of a printed pattern on a glass substrate.

5.2 *End Plane Reference* — Positioning accuracy of the printed pattern measured from the reference edge of a glass mask.

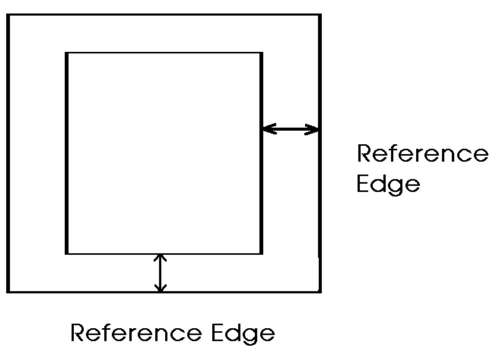

Figure 4
Pattern Positioning Accuracy

5.2.1 Reference Edge: Two adjacent edges are considered as the reference edge.

5.3 *Pattern Rotation* — Deviation of a printed pattern on a glass mask caused by rotation. Usually, it is expressed by the difference between two measured distances at separated points within one side as shown in the figure.

$\theta = (D_1 - D_2)/C_1$

Usually fix the value of C_1 and use the value of $D_1 - D_2$.

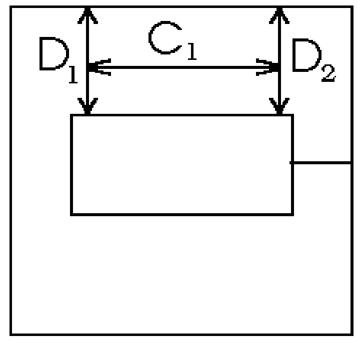

Figure 5
Pattern Rotation

5.4 *Cell Rotation in Multiimages* — Cell's slant rotation against axis of light in case of exposure by stepper and similar equipment. (Generally, it is measured by vernier outside of cells.)

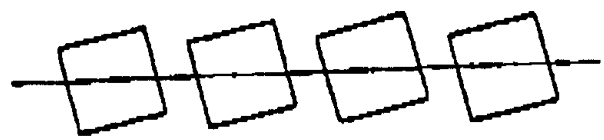

Figure 6
Cell Rotation in Multiimages

5.5 *Gaps of Cells in Multiimages* — X and Y directions' gaps of cells against designed grating which should be exposed primarily by stepper and similar equipment. (Generally, it is measured by gaps between cells which are next to each other with vernier outside of cells.)

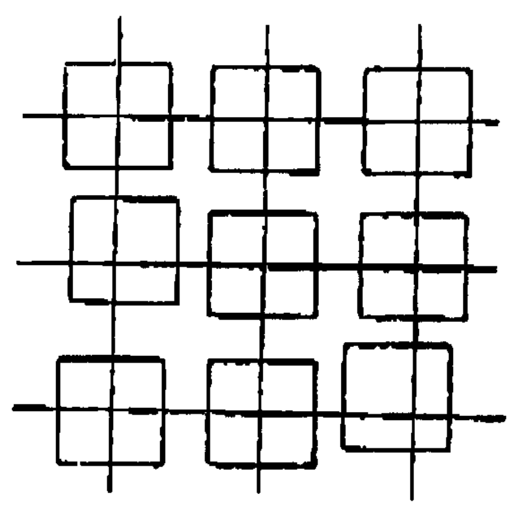

Figure 7
Gaps of Cells in Multiimages

NOTICE: The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D22-0999
TEST METHOD FOR THE DETERMINATION OF COLOR, TRANSMITTANCE OF FPD COLOR FILTER ASSEMBLIES

This test method was technically approved by the Global Flat Panel Display Committee and is the direct responsibility of the Japanese Flat Panel Display Committee. Current edition approved by the Japanese Regional Standards Committee on June 1, 1999. Initially available on SEMI OnLine August 1999; to be published September 1999.

1 Purpose

1.1 This standard establishes practices for measuring selected characteristics of FPD color filters. These methods are applicable to manufacturing, quality control, and development operations.

2 Scope

2.1 This document defines means to measure.

2.2 Transmittance and chromaticity of color filter elements by measuring the characteristics of flux passed through a subpixel.

2.3 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicablity of regulatory limitations prior to use.

CIE 1976 (L*,a*,b*) — Color Space (Recommendations on Uniform Color Spaces

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

None.

5 Summary of Method

5.1 The measurement equipment is set to appropriate illumination wavelength, incident beam angle, and spot size.

5.2 For measurements of chromaticity and spectral transmittance.

5.2.1 The sample to be measured is placed on the stage and the illumination spot is located on an area free of color filter or other coating material for a reference sample.

5.2.2 Reference data is taken and only the other coating material for the reference is removed.

5.2.3 The sample is repositioned to place the illumination spot on the desired target area and the sample data is taken.

5.3 Measurement data for both reference and color filter are recorded.

5.4 A graph of the resulting data is prepared.

6 Apparatus

6.1 Measurement equipment shall have the following capabilities:

6.1.1 Optical wavelength: variable between 380 and 780 mm, in increments of ≤ 10 nm.

---

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshocken, PA 19428-2959, tel. 610.832.9585, fax 610.832.9555

2 ISO Central Secretariat, 1, rue de Valembé, Case Postable 56, CH-1211, Geneva 20, Switzerland

3 CIE International Commission on Illumination, Kegelgasse 27, A-1030 Vienna, Austria

6.1.2 Measurement spot size of incident beam at sample surface: adjustable from 2 µm to 50 µm.

6.1.3 Incident beam angle, relative to sample normal.

6.1.3.1 For transmittance measurements: 0° ± 5°.

6.1.4 Sample stage: sufficient mechanical travel to permit measurements within the color filter area and in the transparent area of the substrate outside the color filter material.

7 Reference Material

7.1 For transmittance measurements, use the sample to be measured and measure transmittance in a portion of the surface that is clear of color filter material. This establishes the level against which transmittance of the area containing the color filter material is compared.

8 Calibration

8.1 Calibrate the equipment in accordance with manufacturer's instructions.

8.2 Record characteristics of the instrument observed during this calibration, e.g., linearity, phase shift, etc.

9 Measurement Procedure

9.1 Place the sample(s) on the stage of the measurement equipment.

9.1.1 Set equipment properties for desired values as follows:

9.1.1.1 Wavelength,

9.1.1.2 Spot size,

9.1.1.3 Incident beam angle,

9.1.2 Measure reference surface and record results, and

9.1.3 Measure color filter area at desired locations and record results.

10 Report

10.1 Data and time of test; operator ID.

10.2 Equipment manufacturer, model, serial number and software revision.

10.3 Reference material used.

10.4 Equipment set-up (wavelength, spot size, beam angle).

10.5 Direction of beam relative to orientation of the sample pattern.

10.6 Measured parameter and value, at each measurement location.

10.7 Sketch of measurement location.

10.8 For transmittance measurement, generate a graph with:

X-axis = wavelength, and

Y-axis = measured transmittance.

10.9 For chromaticity measurements, generate a graph in accordance with:

10.9.1 CIE 1931 – x, y graph

10.9.2 CIE 1976 – (L*, a*, b*) or (L*, u*, v*).

11 Precision and Accuracy

11.1 No test data currently exists on which to base these statements. Tests are planned to develop such data for both single-laboratory repeatability and multi-laboratory reproducibility, on samples of the same nominal characteristics, and across a range of nominal characteristics.

SEMI D23-0999
GUIDE FOR COST OF EQUIPMENT OWNERSHIP (CEO) CALCULATION FOR FPD EQUIPMENT

This guide was technically approved by the Global Flat Panel Display Equipment Committee and is the direct responsibility of the Japanese Flat Panel Display Equipment Committee. Current edition approved by the Japanese Regional Standards Committee on June 1, 1999. Initially available on SEMI OnLine August 1999; to be published September 1999.

1 Purpose

1.1 The purpose of this document is to provide a standard, simple CEO calculation method for evaluating FPD manufacturing equipment. With this document, the following merits can be expected:

1.1.1 Both panel and equipment manufacturers, as well as material manufacturers can work from the same standard with regard to cost.

1.1.2 Panel manufacturers' basis for equipment comparison will become clear, which will, in turn, help in equipment selection.

1.1.3 The document will serve to clarify cost reduction items as well as benchmark cost reduction activities.

1.1.4 Direction for improvement for equipment manufacturers will become clear.

1.1.5 By doing a separate analysis, comparison, and evaluation of lines, equipment for different substrate sizes will become simpler.

2 Scope

2.1 This standard focuses on each equipment in the FPD production line. It is used to define the calculation method for cost of installing/operating that equipment, to define the calculation method for productivity of that equipment, and to quantify CEO of that equipment.

2.2 It is necessary to clarify the substrate sizes that can be handled by this equipment. However, this standard does not deal with the equipment process performance. It takes the point of view that each panel manufacturer should evaluate each equipment's process performance, including yield, based on their own process requirements.

2.3 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicablity of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not attempt to include all elements necessary for equipment evaluation, and may be seen as incomplete from certain perspectives. However, it is believed that it will serve as the foundation for comparative evaluations.

4 Referenced Standards

None.

5 Terminology

5.1 Definitions for each of the items are listed in the following table.

6 CEO (Cost of Equipment Ownership) Table

6.1 Units in the document are for illustration only.

	Item	*Unit*	*Value*	*Definition & Formula*	*Notes*
A. Equipment Cost					
	(1) Base Cost	($)		Main Equipment Purchase Price	
	(2) Cost of Options	($)		Price of items which can be categorized as options separate from main equipment.	
	(3) Other Parts/Tools	($)		Price of tools and accessories (not included in main equipment or options price).	Enter maintenance-related consumables in D48 (Consumables).
	(4) Installation Cost	($)		Costs incurred in the installation of the equipment.	
	(5) Inspection Cost	($)		Costs incurred in inspection of the equipment.	
	(6) Shipping Cost	($)		Cost of shipping equipment to the installation location.	
	(7) Training Cost	($)		Cost of training in operation, maintenance, etc.	
	(8) Manual Cost	($)		Cost of manuals necessary for maintenance and operation.	
	(9) Other Costs	($)		Other necessary costs not included in above items.	
	(10) Subtotal	($)		Sum of (1) through (9).	If it is difficult to specify (1) through (9), it is possible to just enter (10).
	(11) Monthly Cost	($/month)		Monthly costs associated with equipment (10)/60 months.	Salvage value after 5 years is arbitrarily set here at 0. Adjust to real value as necessary.
B. Hook-Up Costs					
	(12) Materials (pipes, etc.)	($)		Costs for piping and other materials necessary to operate equipment.	
	(13) Power Connection	($)		Costs for connecting electricity, water, gas, air, etc. supplied by the factory to the equipment.	
	(14) Other	($)		Other installation costs not included in above items.	
	(15) Subtotal	($)		Sum of (12) through (14).	
	(16) Monthly Cost	($/month)		Monthly incidental installation costs (15)/60 months.	Salvage value after 5 years is arbitrarily set here at 0. Adjust to real value as necessary.
C. Clean Room Costs				For each area, if the shape is complex, use the square surface area.	Categorize clean area, gray area, and other dedicated areas according to the real situation of each factory.

	Item	*Unit*	*Value*	*Definition & Formula*	*Notes*
Clean Areas				Area for handling substrates and having the highest level of cleanliness.	
	(17) Main Equipment Dimensions (W*D)	(m^2)		Installed dimensions of the main equipment within the clean area.	
	(18) Accessory Dimensions (W*D)	(m^2)		Installed dimensions of pumps, power source, and other equipment outside of the main equipment within the clean area.	
	(19) Maintenance Area (W*D)	(m^2)		Dimensions of space in clean area necessary for maintenance of the equipment and accessories.	
	(20) Subtotal Area (W*D)	(m^2)		Subtotal of dimensions in clean area from above items (17) through (19).	
	(21) Floor Space (Unit Cost)	$\$/m^2$ • month		Monthly floor maintenance cost in clean area (by area unit).	
	(22) Monthly Dedicated Floor Cost	$/month		Monthly cost for clean area (20) $\times$ (21).	
Gray Area				Area with lower cleanliness level than above clean area.	
	(23) Main Equipment Dimensions (W*D)	(m^2)		Installed dimensions of the main equipment within the gray area.	
	(24) Accessory Dimensions (W*D)	(m^2)		Installed dimensions of pumps, power source, and other equipment outside of the main equipment within the gray area.	
	(25) Maintenance Area (W*D)	(m^2)		Dimensions of space in gray area necessary for maintenance of the equipment and accessories.	
	(26) Subtotal Area (W*D)	(m^2)		Subtotal of dimensions in gray area from above items (23) through (25).	
	(27) Floor Space (Unit Cost)	$\$/m^2$ • month		Monthly floor maintenance cost in gray area (by area unit).	
	(28) Monthly Dedicated Floor Cost	($/month)		Monthly costs for gray area (26) $\times$ (27).	
Other Dedicated Floor Area				Area with the lowest level of cleanliness (i.e., sub-floor, etc.).	
	(29) Dedicated Dimensions (W*D)	(m^2)		Installed dimensions of the main equipment in other dedicated floor area.	
	(30) Floor Space (Unit Cost)	$\$/m^2$ • month		Monthly floor maintenance cost in other dedicated floor area (by area unit).	
	(31) Monthly Dedicated Floor Cost	($/month)		Monthly costs for other dedicated floor area (29) $\times$ (30).	
D. Running Costs					

	Item	*Unit*	*Value*	*Definition & Formula*	*Notes*	
Power/ Utilities					Normal use and maximum use values entered by equipment manufacturer.	
					Normal Use [Unit]	Maximum Use [Unit]
	(32) Electricity	($/month)		Monthly cost of electricity necessary to operate equipment.	[ ]	[ ]
	(33) Cooling Water	($/month)		Monthly cost of cooling water necessary to operate equipment.	[ ]	[ ]
	(34) Air	($/month)		Monthly cost of air conditioning necessary to operate equipment.	[ ]	[ ]
	(35) Gas Exhaust Processing	($/month)		Monthly cost of gas exhaust processing necessary to operate equipment.	[ ]	[ ]
	(36) Liquid Waste Processing	($/month)		Monthly cost of liquid waste processing necessary to operate equipment.	[ ]	[ ]
	(37) Vacuum Line	($/month)		Monthly cost of vacuum volume necessary to operate equipment.	[ ]	[ ]
	(38) Nitrogen Gas	($/month)		Monthly cost of nitrogen gas necessary to operate equipment.	[ ]	[ ]
	(39) Dry Gas	($/month)		Monthly cost of dry gas necessary to operate equipment.	[ ]	[ ]
	(40) Other	($/month)		Other monthly power & utilities costs necessary to operate equipment.		
	(41) Power/Utilities Subtotal	($/month)		Subtotal of monthly power & utilities costs necessary to operate equipment; sum of (32) through (40).		
Process Materials Costs				Cost of materials necessary for processing.	Example: Resist, chemicals, process gases, cleaning gas, sputter target, etc. Enter by equipment in (42) to (46).	
	(42)	($/month)		Monthly cost	For the item name, enter each item necessary for the equipment.	
	(43)	($/month)		Monthly cost	For the item name, enter each item necessary for the equipment.	
	(44)	($/month)		Monthly cost	For the item name, enter each item necessary for the equipment.	
	(45)	($/month)		Monthly cost	For the item name, enter each item necessary for the equipment.	
	(46)	($/month)		Monthly cost	For the item name, enter each item necessary for the equipment.	
	(47) Process Materials Subtotal	($/month)		Subtotal of monthly costs for process materials; sum of (42) through (46).		

	Item	*Unit*	*Value*	*Definition & Formula*	*Notes*
Maintenance Costs				Expenditures (to external) for maintenance.	
	(48) Consumables	($/month)		Monthly cost for scheduled replacement parts.	
	(49) Scheduled Maintenance	($/month)		Monthly cost for scheduled maintenance.	Forecast maintenance
	(50) Other	($/month)		Monthly maintenance costs not included in above items.	
	(51) Maintenance Subtotal	($/month)		Subtotal of monthly expenditures (to external) for maintenance; sum of (48) through (50).	
	(52) Running Cost Subtotal	($/month)		Monthly running cost total: (41) + (47) + (51).	
E. Labor Costs				In-house labor costs	
	(53) Operator	($/month)		Equipment operator monthly labor cost	
	(54) In-house maintenance	($/month)		Equipment maintenance monthly labor cost	
	(55) Labor Cost Subtotal	($/month)		Subtotal of above costs (53) + (54).	Managers and engineers not included.
F. Cost Total					
	(56) Cost	($/month)		Total monthly costs necessary for operation of equipment: (11) + (16) + (22) + (28) + (31) + (52) + (55).	
G. Runtime					
	(57) Operating time	(hr/month)		Hours per month of factory operation	
	(58) 1-Item process time	(hr/ process)		Process recipe exchange time	
	(59) Number of processes/month	(process/ month)		Number of process recipe exchanges per month	
	(60) Process time	(hr/month)		Hour per month of process recipe exchange (58) $\times$ (59)	
	(61) Scheduled maintenance time	(hr/month)		Monthly scheduled maintenance time	
	(62) Start-up inspection time	(hr/month)		Time necessary, per month, for start-up.	
	(63) Down time (mc failure)	(hr/month)		Down time, per month, for machine failure.	
	(64) Other down time	(hr/month)		Down time, per month, not included in above items.	Product wait time not included.
	(65) Run time	(hr/month)		Monthly operation time (57) – [Σ (60) through (64)].	
H. Process Capacity					
	(66) Sheets/hour	(sheets/hr)		Number of sheets processed per hour	
	(67) Process capacity	(sheets/ month)		Number of sheets processed per month (65) $\times$ (66)

SEMI D24-0200
SPECIFICATION FOR GLASS SUBSTRATES USED TO MANUFACTURE FLAT PANEL DISPLAYS

This specification was technically approved by the Global Flat Panel Display – Material and Components Committee and is the direct responsibility of the North American Flat Panel Display Committee. Current edition approved by the North American Regional Standards Committee on September 3, 1999. Initially available on SEMI OnLine November 1999; to be published February 2000.

1 Purpose

1.1 This standard specifies selected geometrical requirements of glass substrates used to manufacture flat panel displays.

2 Scope

2.1 This standard is intended to set levels of specification for glass substrates to insure repeatable manufacture of flat panel displays and uniformity of substrates from all vendors. This standard will also insure inter-changeability at all mechanical interfaces within process tools as well as with Transportation and Automation Cassettes.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Substrate size (edge length and width) and thickness are **not** specified so as not to infringe on supplier/customer relationships. Wherever possible, tolerances are specified independent of substrate size. Additional documents will be developed to specify the standard method of measuring each dimension.

SEMI D9 — Definitions for Flat Panel Display Substrates

SEMI D12 — Specification for Edge Condition of Flat Panel Display (FPD) Substrates

SEMI D15 — FPD Glass Substrate Surface Waviness Measurement Method

4.2 *ISO Standard*[1]

ISO 1101 — Technical drawings — Geometrical Tolerances — Tolerances of Form, Orientation, Location and Run-Out — Generalities, definitions, symbols, indications on drawings

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *FPD Waviness* W_{fpd} — surface profile calculated by a moving minimum zone method. It is expressed as the maximum value of a minimum zone method straightness of a certain sampling within an evaluation length. An approximation in Appendix 1 of SEMI D15 can be used as well.

NOTE 2: It is recommended that the computer approximation method described in Appendix 1 of SEMI D15 be used.

5.2 *minimum zone method straightness* — the smallest distance between two parallel straight lines between which all of objective profile is included (see ISO 1101, Section 3.1).

5.3 *reference edges* — the two edges adjacent to the orientation corner.

5.4 *squareness* — the total variation of the position of the short sides of a substrate relative to straight lines drawn between the ends of, and perpendicular to, the long reference edge of the substrate.

5.5 *warp* — the gap between a) the bottom surface of an FPD substrate and b) the reference plate on which the substrate rests.

NOTE 3: Warp in other applications has traditionally been the TIR, or peak-to-valley of a surface (top, or bottom or median surface) of a substrate, measured with respect to a reference plane.

---

1 ISO Central Secretariat, C.P. 56, CH-1211 Geneve 20, Switzerland; available in the U.S. from American National Standards Institute, 11 West 42nd Street, 13th Floor, New York, NY 10036

6 Test Methods

NOTE 4: The methods described below are approximations, except where they are followed by a reference such as SEMI D7. Formal test methods supporting the parameters in this document will be developed where needed; these will be published as separate documents. References to them will then be added to this document.

6.1 *Thickness* — Measure with differential (2-probe) gage using optical, non-contact, or contact sensors.

6.2 *Edge Squareness* — measure per Figure 2.

6.3 *Edge Conditions* — to be determined.

6.4 *Edge Straightness* — measure per Figure 2.

6.5 *Total Thickness Variation* — to be determined.

6.6 *Flatness, medium sheet* — to be determined.

6.7 *Roughness* — SEMI D7 roughness measurement method (contact stylus method, tip radium ≤ 2 μm).

6.8 *Warp* — Feeler gage with thickness equal to the specified maximum warp value, inserted between substrate bottom edge and surface plate, at any point or at specified points along the edges (formal test method/description to be developed).

6.9 *Waviness* — see SEMI D15.

7 Requirements

See Table 1.

8 Ordering Information

8.1 Purchase orders for substrates furnished to this specification shall include the following items:

8.1.1 Edge length

8.1.1.1 Long reference edge

8.1.1.2 Short reference edge

8.1.2 Orientation corner dimensions, from Table 1

8.1.3 Quality edge area exclusion

8.1.4 Thickness

8.1.4.1 Nominal

8.1.4.2 Tolerance

8.1.5 Warp

8.1.6 Straightness

Warp[7]	≤ 0.60 mm		≤ 1.0 mm		
Roughness, R_a	≤ 20 nm		≤ 20 nm		SEMI D7 – Roughness Measurement
Straightness[8]	± 0.4 mm		± 0.4 mm		

NOTES:

1 For dimensional tolerance and squareness the long edge typically has the maximum tolerance. See Figures 1 and 2.

2 An asymmetric orientation corner is specified for purposes of mechanical orientation and operator's visual confirmation of orientation within a cassette. Optical means of identifying orientation is under investigation. See Figure 5.

3 Quality Area is that area in which the specified criteria apply.

4 Total thickness variation is the peak to valley (TIR) of the entire substrate front surface relative to a reference plane when the substrate back surface is constrained against a vacuum chuck. This scale is typically important for some film deposition and lithography processes. See Figure 6.

5 Local thickness variation is the absolute value of the maximum deviation of the substrate from a plane constructed in any 100–130 mm square area, within the Quality Area, when the substrate back surface is constrained against a vacuum chuck. This scale is typically important for lithographic stepper processes.

6 Waviness is the rms (root mean square) surface profile, within the quality area, over 0.8–8 mm spatial wavelengths.

7 See Figure 3.

8 See Figure 2.

9 See Figure 4.

10 This table applies to the indicated edge length ranges and thicknesses.

11 Example: For an 800 × 950 mm substrate, the effective process area, which excludes portions not processable for physical reasons, would be ≥ 760 × ≥ 910 mm.

SEMI D25-0600
SPECIFICATION FOR FLAT PANEL DISPLAY SUBSTRATE SHIPPING CASE

This specification was technically approved by the Global Flat Panel Display Committee and is the direct responsibility of the Japanese Flat Panel Display Committee. Current edition approved by the Japanese Regional Standards Committee on April 21, 2000. Initially available on SEMI OnLine May 2000; to be published June 2000.

1 Purpose

1.1 This document provides the packing and shipping specifications and/or guides for FPD glass substrates, which are called fourth generation substrates ($800 \times 950 \times 0.7$ mm or $800 \times 950 \times 1.1$ mm).

1.2 The objective of this document is to provide cost-effective packing and shipping in terms of packing materials, storage, and shipping, while making sure that packing meets the quality and automation requirements.

2 Scope

2.1 This document defines a specification for a full box type shipping case (see Figure 2) to be used for packing and shipping of 4^{th} generation FPD glass substrates from the manufacturer of the glass substrate to the user.

2.2 The application of this packing specification is limited to the following four FPD glass substrates:

2.2.1 Bare glass substrates which can be used as array substrates, and do not have film deposition.

2.2.2 Bare glass substrates which can be used as facing substrates and color filter substrates, and do not have film deposition.

2.2.3 Array substrates which do have film deposition.

2.2.4 Facing substrates and color filter substrates which do have film deposition.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Prerequisites and Limitations

3.1 This specification does not apply to:

3.1.1 cassettes used for intra/inter bay transfer inside the user's plant;

3.1.2 the semi-separating type the contact type packi-ng method (see Figure 4) or the full corner supporter type and the double side supporter type (see Figure 3)

3.2 The premise for glass substrates for this packing specification is as follows.

3.2.1 *Size*

W (mm):	Short Edge
L (mm):	Long Edge
t (mm):	Thickness

W = 800 mm W tolerance: see SEMI D24
L = 950 mm L tolerance: see SEMI D24
t = 1.1 t tolerance = see SEMI D24
t = 0.7 t tolerance = see SEMI D24

3.2.2 *Squareness* — see SEMI D24 *Beveling* — R beveling

3.2.3 *Orientation Corner* — see SEMI D24

3.2.4 *Corner Cut* — see SEMI D24

3.2.5 *Edge Exclusion Area* — see SEMI D24

3.2.6 *Sag* — In the event of the glass substrate being placed horizontally on the support as shown in Figure 1, sag is defined by h2 (two sides supported), and h4 (four sides supported) (Unit = mm) (see Figure 1).

3.2.7 *Density* — Less than 2.8 g/cm^3

3.3 When the glass substrates are shipped, they shall be loaded vertically.

3.4 When the glass substrates are shipped, a standard sized pallet shall be used for efficient loading on the truck platform or the floor of the container (see Appendices 1 and 2). The standard size used here is less than $1,100 \times 1,100$ mm^2 or, at the outside, $1,100 \times 1,200$ mm^2.

3.5 When the glass substrates are shipped, the loading should be as efficient as possible utilizing the available space, in line with:

- The smallest height for truck platforms and containers is 2,300 mm (see Appendices 1 and 2).
- Taking into consideration the head clearance when loading and unloading by forklift, as well as the height of the shipping case, the maximum height of the load is approximately 2,000 mm. If more efficient loading can be achieved, multiple boxes can be stacked.

4.3 *ISO Documents*[2]

ISO 668 — Series 1, Freight Container – Classification, Dimensions and Ratings

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

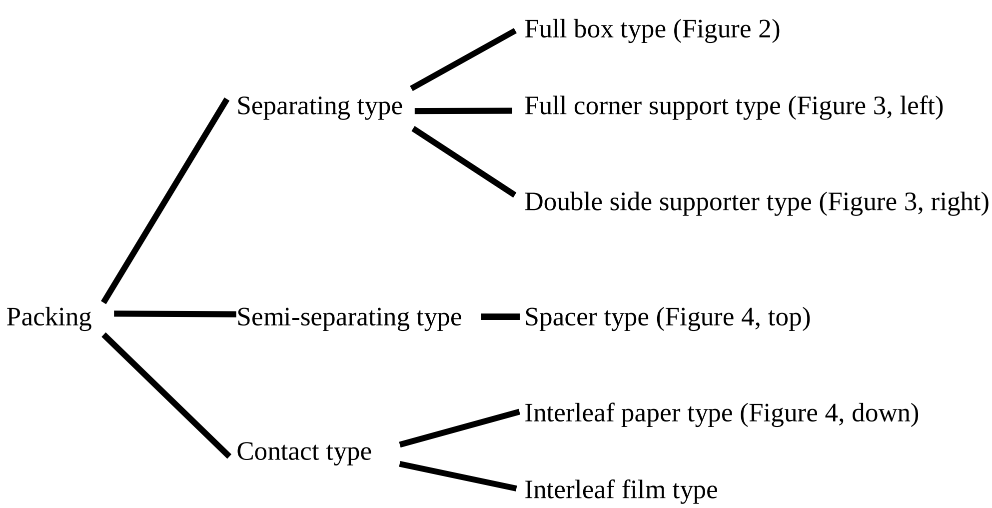
5 Terminology

5.1 *Size of exposed portion* — The length of the glass substrate exposed from the packing box (full box type) when the lid of the packing box is open.

6 Packing

6.1 *Classification*

6.1.1 Classification of packing is as follows:



6.2 *Packing Box Dimensions* — Figure 5 shows the key dimensions and tolerances of the packing box for the full box type.

6.2.1 *Packing Box Loading and Unloading*

6.2.1.1 Vertical loading shall be used to load and unload the glass substrates to and from the packing box (see Figure 6).

6.2.1.2 Vertical loading requires a tall loader/unloader because of the height of the loading direction. The ceiling height of the room where the loading equipment is installed has to be designed accordingly.

1 Japan Standards Association, 4-2-24, Minato-ku, Tokyo 107, Japan

2 ISO Central Secretariat, C.P. 56, CH-1211 Geneve 20, Switzerland

6.2.1.3 A suggested method for loading/unloading substrates from the shipping case with an automatic vertical loader/unloader is to tilt the box as shown in Figure 7. Align the substrates on one side of the clearance of the mizo and proceed with loading/unloading.

6.2.1.4 An alternative method for loading/unloading would be to rotate the packing box 90°, as shown in Figure 8.

6.2.1.5 Loading and unloading the substrates also can be done manually without using an automatic loader/unloader.

6.2.2 *Packing Box Size*

6.2.2.1 The shorter side of the substrate (side W, or the 800 mm side) as the vertical direction (direction z in Figure 5) during shipping. This way, the size of the substrate determines the inside measurements of the packing box, H: 800 mm (direction z), W: 950 mm (direction x).

6.2.2.2 The outside measurements of the packing box shall be H: 980 mm × W: 1,200 mm × L: ≤ 1100mm (Figure 5). It is important to note that the height of 980 mm indicates that it is possible to stack up the packing boxes, i.e. 980 mm × 2 = 1,960 mm, and still be less than the possible maximum height (2,000 mm) of the truck load.

6.2.2.3 The length of the packing box is determined by the calculated product of the pitch size between the substrates times the number of substrates stored in the box. the length (L in Figure 5) of the packing box cannot exceed 1,100 mm

6.2.3 *Packing Box Lid*

6.2.3.1 The packing box must prevent the substrates from getting contaminated as well as to give pressure to the substrates for securing them from both top and bottom. The lid must securely seal and be able to latch closed to the packing box by a lock. The latching mechanism must allow easy automatic lock and unlock as well.

6.2.3.2 The lid shall also have automatic and manual opening/closing capability. The inside of the lid is covered with a shock absorber that functions to secure the glass substrates by pressing them from the top and bottom.

6.2.4 *Mizo Pitch and Capacity of Packing Boxes*

6.2.4.1 The sag, h4 = 20 mm will be for the substrates of the size 800 × 950 × 0.7 mm as shown in Appendix 3, when a sudden turn, acceleration, or braking during shipping forces a 1G acceleration against the substrates. From this point of view, the pitch required here is a little bit larger than 20 mm. However, since all the substrates in the box are affected by the acceleration at the same time and in the same direction, the distance between the substrates will remain constant which means the substrates should not touch each other.

6.2.4.2 The mizo pitch, must be standardized by each shipping case supplier, but must range from a minimum of 9 mm to a maximum of 22 mm ± 0.2 mm. Table 1 shows possible number of substrates per shipping case at a given pitch.

Table 1 Pitch and Number of Substrates

Pitch (mm)	*Number of Substrates (pc)*
22	40
18	50
15	60
11	80
9	100

6.2.4.3 The first mizo clearance (see Figure 9) is to be more than 40.0 mm at the center of the groove. The distance from the reference plane to the first mizo is the sum of the first mizo clearance and the thickness of the side of the box which is the reference plane, and its allowance is ± 1.0 mm. The allowance of cumulative pitch distance is less than ± 2.0 mm, and that of each pitch is less than ± 1.0 mm.

6.2.4.4 Mizo clearance shall be designed to store the glass substrate of a thickness ranging from 0.7 mm to 1.1 mm.

6.2.5 *Size of Exposed Portion*

6.2.5.1 In this document, the size of f1 in Figure 10 is called “the size of the exposed portion” which is set as f1 = 100 mm. Size h in Figure 10 is the shorter side of the substrate at 800 mm. The size of f2 is 700 mm which means one eighth of the whole substrate is exposed.

6.2.6 *Reference Plane*

6.2.6.1 The reference plane needs to be determined as follows from three directions, x, y, and z in Figure 5 for automatic transferring:

x: Both sides or center position
y: Both sides or center position
z: Bottom surface of the box (not the bottom of the skid described later)

6.2.6.2 Specifically use the small area as a reference surface in Figure 11. The detail of the position and size of the reference surfaces shall be standardized to use a compatible reference for two different design boxes. Also the center line of substrate is automatically defined by symmetrical location between substrate and reference plane of case.

6.2.7 *Transfer and Lift Method for Packing Boxes*

6.2.7.1 It is expected that not only boxes containing glass substrates but also empty boxes are fairly heavy. At least, they probably cannot be carried by hand. Therefore, it is assumed that whether the box contains glass substrates or not and whether the box is in a regular room or a clean room, it shall be lifted by a forklift and transferred mechanically. To accommodate a mechanical transfer and lift, skids must be installed at the bottom of the box so that the forklift can insert its tongues underneath the box (see Figure 5). The height of the skids shall be standardized for each shipping case supplier, but not exceed 150 mm.

6.2.7.2 Assuming lifting of the box and short distance, transfer is done using a balancer; the packing box is required to have handles, as shown in Figure 12, on the sides of the box. The structure of the handles shall be designed in such a way that it does not hinder the reference plane.

6.2.8 *Packing Box Strength*

6.2.8.1 The weight of the contents of the box, with the prescribed number of substrates, can be calculated from the density of substrates. The packing box has to be strong enough to bear that weight. Moreover, it has to be strong enough to hold another full box on top of itself (need to specify less than or equal to weight).

6.2.8.2 Stacking three boxes with glass substrates is prohibited. Therefore there is no need for the packing box strength to hold two boxes on top of one box. However, empty boxes may be stacked three high, but the box has to be designed to bear the weight of two empty boxes.

6.2.8.3 The handles shall be strong enough to hold the weight when the box is filled with glass substrates as well as a full box on top or two empty boxes on top.

6.2.9 *Packing Box Material*

6.2.9.1 Because of this, packing box material is not covered in this document. Neither carcinogen nor de-gasification is covered. For the purpose of cleaning, cleanliness, and particle reduction, the material of the box has to be washable and solvent-resistant. The addition of draining holes is acceptable. Material must meet cleanliness, mechanical strength, and durability in line with specifications of this document.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI D25 and was approved by full letter ballot procedures on April 21, 2000 by the Japanese Regional Standards Committee.

A1-1 Truck Platform Dimensions

NOTE: This data only applies in Japan.

Reference: JIS D4002 Internal Dimensions for Rear Body of Motor Trucks

A1-1.1 *Dimensions* — The platform inner dimensions are categorized by width and length and listed in the table below. These dimensions shall be selected on the basis of their feasibility with regard to the functions of the chassis and the shape, use and special equipment of the platform. The dimensions represent the minimum dimensions for each category.

Table A1-1 Platform Inner Dimensions (mm)

Width Category	Symbol	A	B
	Ordinary Platform	2340	2120
	Van Body	2370	2150
Length Category		9600	
		9000	
		8400	
		7800	
		7200	7200
		6600	6600
		6000	6000
		5400	5400
		4800	4800
		4200	4200
Note		5-12 tons	4 ton wide 5-6 ton narrow

A1-1.2 *Dimension Naming* — Naming of the inner dimensions of the platform is accomplished by using the type (either Ordinary Platform or Van Body), the symbol for the width category and the length category in meters. Example:

Ordinary A – 8. 4

Van B - 6. 6

Length Category

Width Category

Van Body

At present, it seems that generally 10 ton-class trucks use A, and 4 ton trucks use B. The following information was gathered from one transport company:

10 Ton – W=2330	L=9560	H=2280
4 Ton – W=2100	L=6700	H=2300

(Unit = mm)

Measurements may differ depending on the manufacturer and model.

A1-2 Shipping Model

A1-2.1 The shipping model (Figure A1-15) shows the storing of fourth generation flat panel display glass substrates in the packing box as described in this specification, a glass substrate manufacturer transporting substrates to a user, and the user returning the box.

A1-2.2 For covering the outside of the packing box, a plastic bag over the top is recommended. If the contamination of the bottom part of the box is a concern, prevention is not limited. In any case, the goal of this shipping model is to make it as simple as possible and to reduce the cost and investment.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D26-1000
PROVISIONAL SPECIFICATION FOR LARGE AREA MASKS FOR FLAT PANEL DISPLAYS (NORTH AMERICA)

This specification was technically approved by the Global Flat Panel Display Committee and is the direct responsibility of the North American Flat Panel Display Committee. Current edition approved by the North American Regional Standards Committee on July 14, 2000. Initially available on SEMI OnLine August 2000; to be published October 2000.

1 Purpose

1.1 This specification establishes a set of standards to assist in specifying and ordering large area masks for the Flat Panel Display industry. A major objective is to improve the cycle time, order process efficiency and reduce the overall cost of manufacturing for both the mask maker and the customer.

1.2 This specification is intended for use in North America as an emerging market. However, the applicability of this specification is not restricted or limited to this region alone. This standard was developed to address a North American need for a common set of requirements for specifying, manufacturing, and ordering large area masks.

2 Scope

2.1 The following areas are covered by this document:

2.1.1 Registration and Accuracy

2.1.2 Critical Dimensions

2.1.3 Centrality

2.1.4 Pellicles

2.1.5 Edge Length and Thickness

2.1.6 Symbology

2.1.7 Data Formats

2.1.8 Auto Inspection Artifacts

2.1.9 Product Labeling

2.2 This specification is being issued so that the industry may evaluate the concept covered before its adoption as a full standard. It is expected that initial application will occur mostly in North America, however, nothing in this standard limits its use to this market region.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The document does not seek to be comprehensive. Instead, the areas listed are meant to help move the current industry towards an agreed upon set of standards that are useful in reducing the overall cost of supplying masks for use by FPD manufacturers. The document only describes 1X full field masks up to 620 × 720 mm for all display types except for Plasma, TN and STN LCD technologies.

4 Referenced Standards

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI D6 — Specification for Edge Length and Thickness for Flat Panel Display Mask Substrates

SEMI P1 — Specification for Hard Surface Photomask Substrates

SEMI P5 — Specification for Pellicles

SEMI P6 — Specification for Registration Marks for Photomasks

SEMI T8 — Specification for Marking of Glass Flat Panel Display Substrates with a Two-Dimensional Matrix Code Symbol

4.2 *AIM International Technical Specifications*[1]

AIM International Symbology Specification – Data Matrix

5 Terminology

Each section of the document defines the terms used in that section, with the exception of:

5.1 *alignment bar, of a data matrix symbol* — A solid line of contiguous filled cells abutting a line of alternatively filled and empty cells (AIM International Symbology Specification Data Matrix)

1 AIM International Inc., 11860 Sunrise Valley Drive, Suite 100, Reston, VA 20191, tel y703.391.7621, fax 703.391.7624

5.2 *border column* — The outermost column of a data matrix code symbol. This column is a portion of the finder pattern.

5.3 *border row* — The outermost row of a data matrix code symbol. This row is a portion of the finder pattern.

5.4 *cell, of a data matrix code symbol* — The area within which a dot may be placed to indicate a binary value.

6 Ordering Information

6.1 Purchase orders for substrates furnished to this specification shall include the following items:

Checklist:

6.2 Edge length

6.3 Long reference edge

6.4 Short reference edge

6.5 Orientation corner dimensions

6.6 Quality edge area exclusion

6.7 Thickness

6.8 Tolerance for all specified dimensions

6.9 Warp

6.10 Marking

6.10.1 Marking message characters

6.10.1.1 Quantity (46 to *mm*, where mm = 72)

6.10.1.2 Content of message characters related to Customer Specification Number, and message characters 47 and up, if present.

6.10.1.3 Location of mark, if different from Section 9.5.5

7 Requirements

7.1 *Materials Specification* — Substrate material shall be specified as high thermal expansion (HTE), medium thermal expansion (MTE), low thermal expansion (LTE), or ultra low thermal expansion (ULTE). Examples of HTE materials are soda lime glasses; examples of ULTE materials are synthetic quartz glasses. Substrate materials shall conform to thermal expansion and optical transmittance characteristics specified in SEMI P1. Selected physical properties of HTE, MTE, LTE, and ULTE materials are provided for information in SEMI P1.

7.2 *Overlay* — Overlay refers to alignment of the printed pattern of one mask to another of the same set. Overlay error shall not exceed ± 6.0 µm for soda lime plates and ± 2.0 µm for quartz plates when plate temperature is maintained within ± 1°C. Alignment or registration marks per SEMI P6 may be used to facilitate measurements.

7.3 *Positional Accuracy* — Relation between actual and desired locations of a printed feature on a glass substrate. This is a tolerance to be agreed upon by the end user and mask designer. The following guidelines should be used, with measurements being taken in a temperature and humidity controlled environment:

- ± 0.0157 µm/mm/ °C for soda lime masks
- ± 0.00394 µm/mm/ °C for quartz masks

Dimensioning from a central reference point shall be used.

7.4 *Critical Dimensions (CD)* — The gauging or measurement process is fundamental to manufacturing of masks. The purpose of this section is to define standard CD patterns to provide consistent evaluation and testing of micropatterning equipment, metrology instruments and processes used in large area mask photomask manufacturing.

7.4.1 Figures 1 and 2 are intended to illustrate the proper layout of each pattern cell and to define appropriate design elements used within each basic cell. The user will determine all appropriate dimensions for the feature as they apply to specific processing/ equipment situations.

7.4.2 *L-bar cell (see Figure 1)* — The L-bar cell is designed to be a measurement site for isolated features as well as line and space groups in orthogonal axes. The basic cell consists of one or more groups of nested L-shaped lines at a specific pitch. The pitch is defined as twice the nominal feature width. The center L-bar of each group shall extend beyond the ends of the other L-bars by at least 10µm. This implies that the number of bars is odd.

7.4.3 *Contact array cell (see Figure 2)* — The contact array cell is designed to provide resolution and proximity effect information over a wide range of contact sizes. The design elements will consist of a 5 × 5 contact array and an isolated contact. The 5 × 5 array will produce the maximal proximity for the center contact.

7.4.4 A label to indicate the nominal feature width must be placed near each basic cell. The labels must be of a clearly printable size. The details of the pattern cells, such as the orientation, magnitude, range of line widths and polarity of tone (clearfield vs. darkfield) shall be defined by the user.

7.4.4.1 The target CD should closely represent the size of the most critical feature in the end user's process, not necessarily the minimum feature. A reasonable tolerance is ± 10% of the target CD.

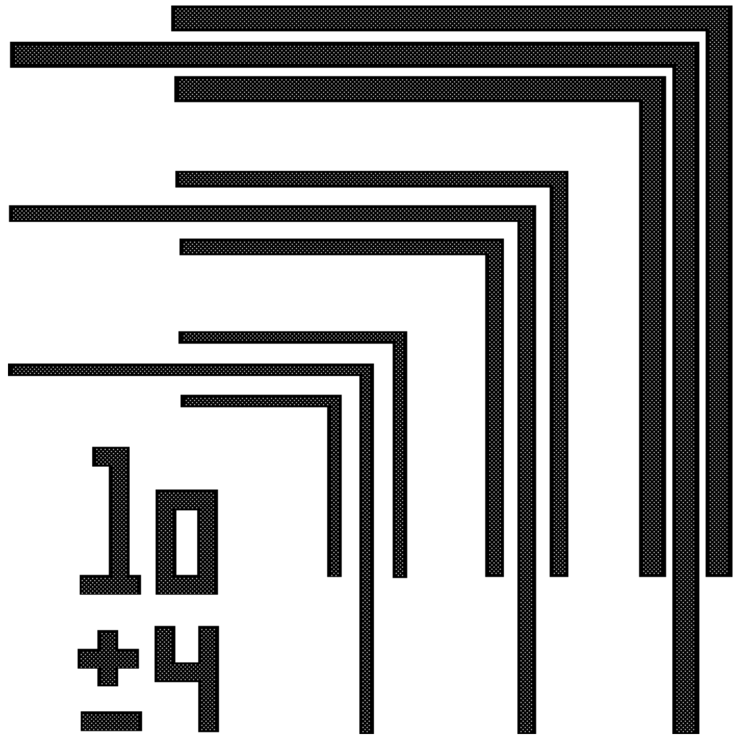

Figure 1
L-Bar Cell

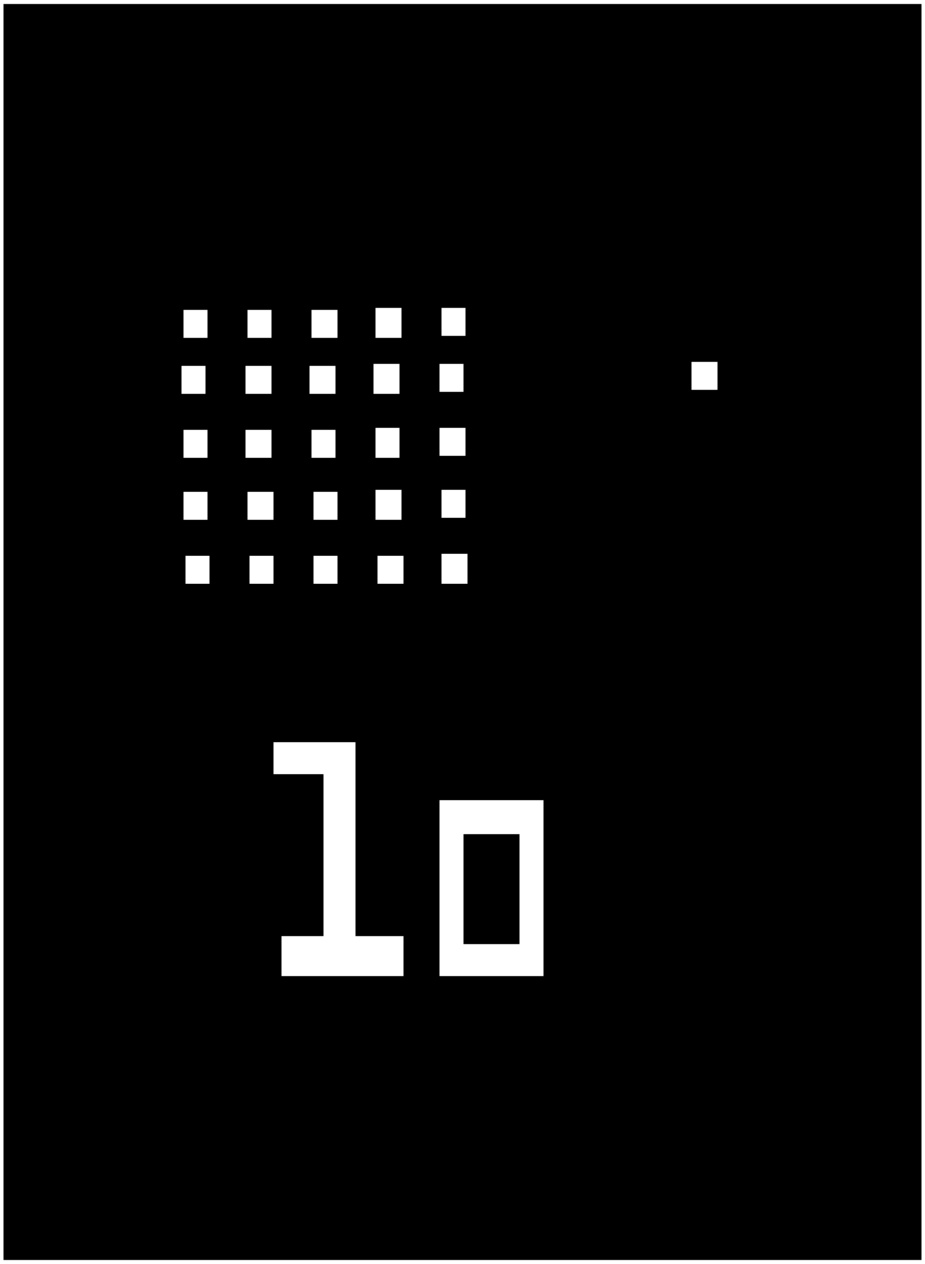

Figure 2
Contact Array Cell

7.5 *Centrality* — This section defines the placement of a patterned photo image onto a Mask Substrate relative to known reference points. It is defined as the physical (datum) position of a specific point on a photo pattern relative to a separate point on the substrate designated to be the photomask center.

7.5.1 *Requirements* — Pattern Placement Tolerance ± 400μm in x and y relative to coordinates on the photomask designated as center when referenced to the 0.000, 0.000 datum (see Figure 3).

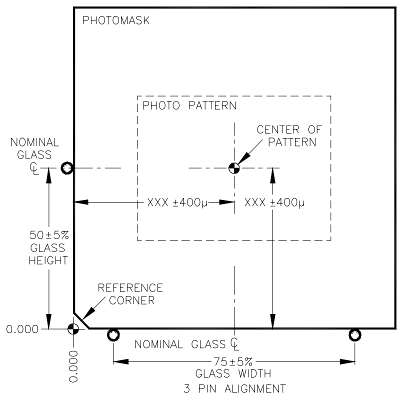

Figure 3
Pattern Placement Tolerance

7.5.2 *Reference 0.000, 0.000* — A datum identified as a point on the extension of a line drawn between the mask contact points on the bottom 2 pins, which is directly below the mask contact point on the third pin (see Figure 4).

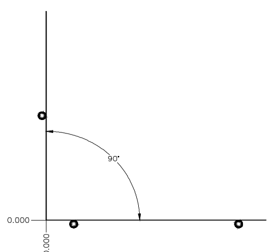

Figure 4
Reference Datum

7.6 *Pellicles (see SEMI P5)*

7.6.1 For Polychromatic exposure systems: Shape, Size, and Standoff of Pellicle

7.6.1.1 *Shape* — This is determined by agreement between the user and supplier.

7.6.1.2 *Size* — This is determined by agreement between the user and supplier, but expression of tolerance is as follows:

7.6.1.3 Outer diameter tolerance — + 0, -x

7.6.1.4 Inner diameter tolerance — + x, -0

7.6.1.5 *Standoff* — This is determined by agreement between the user and supplier. But expression of tolerance is as follows:

7.6.1.6 *Tolerance* — + 0, -x

Film Characteristics Polymer Films — Type - AR-coated or non AR-coated (see Table 1)

7.6.1.7 *Exposure Range* — 360 nm - 440 nm.

7.6.1.8 *Optical Transmission Rate* — There are the following two types depending on optical transmission rate at an incident angle of 90° from surface of pellicle.

Table 1 Film Characteristics Polymer Films

Type	*Average*	*Minimum*
AR-Coated	≥ 94%	88%
Non-AR-Coated	≥ 91%	82%

7.6.1.9 *Thickness* — This is determined by agreement between the user and supplier.

7.6.1.10 *Thickness Conformity* — This is determined by agreement between the user and supplier.

7.6.1.11 *Thickness Uniformity* — This is determined by agreement between the user and supplier.

7.6.1.12 *Film Thickness* — This is determined by agreement between the user and supplier

7.6.1.13 *Mechanical Strength* — The requirements for air blow are determined within ranges shown below:

- The air blow gun should be used; air pressure: ≤ 2.1 kgf/cm^2 (at input of the air blow gun);
- Nozzle diameter of the air blow gun: ≤ 2 mm. Distance between the nozzle tip and the film: ≥ 25 mm

7.6.2 *Defect Limits* — Maximum defect limits based on the pellicle standoff and the numerical aperture of the given type of exposure system are given in Table 1. Any departure from these defect limits shall be agreed to between supplier and user. Maximum defect limits are given in Table 2.

7.6.2.1 *Adhesives*

7.6.2.1.1 *Film Adhesive* — Film must be sealed on the entire top of the frame, with a minimum of 50% of the frame width at any location.

7.6.2.1.2 *Frame Adhesive* — Frame adhesive must be continuous and allow no gaps between pellicle frame and adhesive and between adhesive and photomask after attachment. No part of the frame adhesive may extend beyond the frame wall, and its edges must be free of visually detectable stringers (and particles). Adhesive should form a complete seal between the frame and the mask over a minimum of 40% of the width of the frame.

7.6.2.2 *Frame* — Pellicle frame must have no visually detectable machining burrs, discontinuities in anodization, or particles.

7.6.2.3 *Light Resistance* — This is expressed by total exposure energy value (mJ/cm^2 or J/cm^2) on pellicle film resulting in a 1% loss of transmission at any wavelength in the range 360 nm–440 nm. Also the test conditions (special characteristics of exposure wavelength, exposure energy between 360 nm–440 nm, exposure conditions, and others) must be clearly stated.

Table 2 Maximum Defect Limits

Characteristics	*Max. # Allowable*	*Size counted for Max. # Allowable*
Non-removable		
Particles	None	≥ 50 µm
Pinholes	None	> limit of detection
Scratches	None	Width ≥ 50 µm
Dirt	None	> limit of detection

7.6.3 *Pellicles for g, h and i Exposure Systems* — This specification includes the characteristics of pellicles for use in "g" (436 nm), "h" (405 nm), and "i" (365 nm) line exposure systems.

7.6.3.1 *Shape, Size, and Standoff of Pellicle*

7.6.3.1.1 *Shape* — This is determined by agreement between the user and supplier.

7.6.3.1.2 *Size* — This is determined by agreement between the user and supplier, but expression of tolerance is as follows:

- Outer diameter tolerance: +0, -x
- Inner diameter tolerance: +x, -0

7.6.3.1.3 *Standoff* — 6.3 mm and 4.0 mm should be standard.

7.6.3.1.3.1 Tolerance — + 0, -x

7.6.3.2 *Film Characteristics Polymer Films* — Type: AR-coated or non AR-coated.

7.6.3.3 *Exposure Wavelength* — "g", "h", and/or "i" lines.

7.6.3.4 *Optical Transmission Rate* — There are the following two types depending on optical transmission rate at incident angle of 90° from surface of pellicle at the specified wavelength(s).

Table 3 Film Characteristics Polymer Films

Type	*Minimum*
AR Coated	99 %
Non AR Coated	98 %

7.6.3.5 *Thickness* — This is determined by agreement between the user and supplier.

7.6.3.6 *Thickness Conformity* — This is determined by agreement between the user and supplier.

7.6.3.7 *Thickness Uniformity* — This is determined by agreement between the user and supplier.

7.6.3.8 *Film Thickness* — This is determined by agreement between the user and supplier.

7.6.3.9 *Mechanical Strength* — The requirements for air blow are determined within ranges shown below:

7.6.3.9.1 The air blow gun should be used. Air pressure: ≤ 2.1 kgf/cm^2 (at input of the air blow gun). Nozzle diameter of the air blow gun: ≤ 2 mm.

7.6.3.9.2 Distance between the nozzle tip and the film: ≥ 25 mm.

7.6.3.10 *Defect Limits* — Maximum defect limits based on the pellicle standoff and the numerical aperture of the given type of exposure system are given in Table 4. Any departure from these defect limits shall be agreed to between the user and supplier.

7.6.3.11 *Frame* — Pellicle frame must have no visually detectable machining burrs, discontinuities in anodization, or particles.

7.6.3.12 *Light Resistance* — This is expressed by total exposure energy value (mJ/cm^2 or J/cm^2) of specified wavelength on pellicle film resulting in a 0.5% loss of transmission at any wavelength in the range 360–440 nm. Also, the test conditions (half bandwidth of exposure specified wavelength, energy of exposure specified wavelength, exposure conditions, and others) must be clearly specified.

Table 4 Maximum Defect Limits

Characteristics	*Max. No. Allowable*	*Size Counted for Max. No. Allowable*
Non-removable		
Particles	None	> 20 µm
Pinholes	None	> limit of detection
Scratches	None	Width > 20 µm
Dirt	None	> limit of detection

7.7 *Edge Length and Thickness* — These dimensions apply to photomasks that are principally used in fabricating flat panel display. The edge lengths specified range from 202.8 mm × 202.8 mm to 620 mm × 720 mm. Substrates with an edge length less than 200 mm follow the specification for a semiconductor mask (see SEMI P1and SEMI D6).

7.7.1 *Edge Length and Tolerance* — Units are in mm. See Table A1 and A2 and Table B1 and B2 and Table C1 and C2 for a combination of materials, edge length, and thickness.

7.7.1.1 *Edge Length Tolerance* — + 0.4 mm. Applies to all groups.

7.7.2 *Thickness Center Point* — Thickness of substrates at center point shall be specified by the edge length group and materials as shown in Tables A2, B2 and C2.

7.7.2.1 *Tolerance* — ≤ 5 mm ± 0.2 mm, 8 mm + 0.2 mm, - 0.4 mm.

Table A-1 Edge Length (mm) (Group A)

202.8 × 202.8				
200 × 250	250 × 250			
	250 × 300	300 × 300

7.7.2.2 The active area is defined as area within the plate that is within 20 mm from the edge of the plate (See Figure 5).

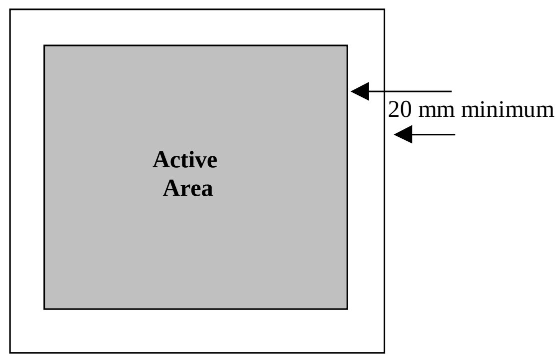

Figure 5
Defined Active Area

7.8 *Data Formats*

7.8.1 *Data Transfer Standards* — CAD data for mask generation can be designed with and delivered to the vendor in several different standardized data transfer formats. Among these are DXF, Gerber and its variants (274-D, 274-X, F9XXX, and BARCO DPF), GDSII, EDIF, IGES, and IPC-D-350.

7.8.2 *Non-Recommended Practices* — The following is a summary of some design practices and CAD entities that *should be avoided* when using DXF and Gerber data formats, since their use can have at best unintended results.

7.8.2.1 *DXF*

- Commands regarding 3D CAD.
- Parameters which control the view only, such as 3DFACE, VIEWPORT, STYLE, VIEW, DIMSTYLE, UCS, APPID, ATTRIB, ATTDEF, and POINT
- HATCH

- Outlines constructed with ARC and LINE that do not match exactly at the corners
- Duplicated entities
- Self-intersecting poly-lines
- VERTEX flags options
- TAPERED POLYLINE entities (different start and end width), straight or arced
- SHAPE entities
- ELLIPSE entities
- "Stretched" BLOCK entities – blocks with different X- and Y-scale factor
- Rotated BLOCK entities
- POINT entities
- Any of the "Curve-fitted" POLYLINE entities, such as "SPLINE" shapes
- "Paint & Scratch" LAYER entities without a specific identification of which layers should be opaque and which should be clear, and in which order.
- TEXT entities without the appropriate font files.
- TEXT entities with special attributes (mirror, rotate, slant, etc.).
- XREF BLOCK entities.
- Non-decimal linear and angular coordinates.
- Radian angular units.

7.8.2.2 *Gerber*

- Self-intersecting entities (line draws, outlines, "butterfly targets", etc.).
- Arrayed arrays (nested).
- Drawn apertures using shapes other than round (square apertures may be used only if drawn parallel to either axis).

7.8.3 *Recommended Practices* — The following is a summary of some recommended design practices DXF and Gerber data formats.

7.8.3.1 *DXF*

- SOLID entities
- TRACE entities
- CIRCLE entities
- BLOCKS, with a minimum level of nesting as required by the design
- Closed, zero width POLYLINE or LWPOLYLINE entities to describe complex CAD feature outlines
- TEXT objects that are exploded and exported as POLYLINE entities, either as closed zero width, or POLYLINE entities with width
- Decimal units for inches, mils, millimeters, microns, or degrees.

7.8.4 *Gerber*

- Subfigure or SR codes.
- POEX/POIN or G36/G37 codes.
- Complex apertures and aperture macros.
- Embedded apertures and parameters.

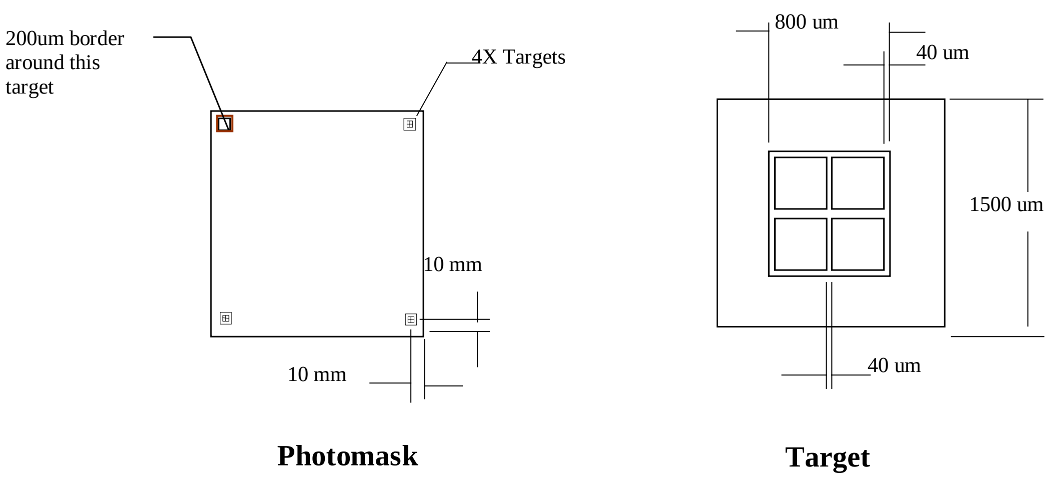

Figure 6
Location and Pattern

7.8.5 *Design Rules* — A comprehensive and well-presented set of design rules is an invaluable communication tool between the customer and supplier. For the manufacture of large area precision glass and quartz substrate photomasks having geometry's in the low to sub-micron range, design rules are an essential component of any successful program designed to minimize the risks of introducing errors and delays into the process.

7.8.5.1 The best match occurs when there is a commonality between the customer's design capabilities and vendor's requirements.

7.8.5.2 Design rule documents are usually unique to each Large Area Mask supplier, and the details depend mainly upon the vendor's software repertoire and their ability to process certain types of data.

7.8.5.3 The type of Computer Aided Design software package used by the customer to design their product must be capable of either exporting data in a format that the vendor can readily use, or the vendor must be capable of using data in the native format of the customer's design package.

8 Test Methods

8.1 *Auto Inspection Artifacts* — To perform any automated inspection of a photomask, the inspection equipment and photomask pattern must be precisely located. This is done with four alignment targets on the photomask. The alignment targets are part of the photomask pattern and are located near each corner of the photomask. The target in the upper left corner will also have a 200 micron border around it with a 10 micron space between the target and the border. When appropriate, this additional border will also be used as a closure test by exposing the targets first and then the border at the end of the plate exposure.

8.1.1 4 Alignment targets provide optimum alignment accuracy.

8.1.2 Greater distance between the targets provides greater alignment accuracy.

8.1.3 The target locations near the edge of the glass provide the maximum product image area.

8.1.4 The target pattern can be easily located visually on the photomask.

8.1.5 The target can be clear on dark or dark on clear.

9 Product Labeling

9.1 *General* — Large Area Masks used in FPD manufacturing are valuable, fragile and prone to contamination prior to use. The content of a LAM is difficult to discern unless each unit contains a unique ID that can be read by various tools. To simplify AMHS and process/metrology tool operations, this ID needs to be consistently readable on the bare mask, with and without resist coating; ideally it would be readable through the plastic container in which the mask is shipped. See Figures 7–10.

9.2 *Summary* — The labeling specified herein consists of a rectangular two-dimensional (2-D), machine-readable, binary Data Matrix symbology located on the pattern surface of LAMs, within the edge region and near the orientation corner. The specification defines a 46-character default message that is included in all mark fields, and option for up to 26 additional characters, for a total of 72 message characters (see SEMI T8).

9.3 *Field Construction* — While this specification does not specify the marking techniques that may be employed when complying with its requirements, it is assumed the symbol may be obtained through lithographic techniques, for instance during the mask exposure sequence.

9.4 *Shape and Size of the Data Matrix Code Symbol*

9.4.1 *Data Matrix Code Symbol Dimensions*

9.4.1.1 Each rectangular matrix code symbol shall be composed of an array of 16 rows and 36 or 48 columns as defined in AIM International Symbology Specification – Data Matrix. It may contain an alignment bar.

9.4.1.2 Cell spacing shall be 25 µm, center to center.

9.4.1.3 Matrix code symbol nominal dimensions are:

a. 4 × 9 mm, for a 16 row × 36 column field, or
b. 4 × 12 mm, for a 16 row × 48 column field.

9.4.2 *Dot Size* — The nominal shape of the dot produced in the matrix may be circular or square. Its diameter or edge length shall be 250 ± 10 µm.

9.4.3 *Border Rows and Columns (see Figure 9)*

9.4.3.1 One border row and one border column shall contain a dot in each cell. There are identified as the primary border row and the primary border column. These are used by the code reader to determine the orientation of the matrix.

9.4.3.2 The opposing (secondary) border row and column shall contain dots in alternating cells.

9.4.3.3 For these rectangular matrix code symbols, the reference point of the symbol shall be the physical center point of the cell common to the primary border row and the primary border column.

9.5 *Content of the Data Matrix Code Symbol*

9.5.1 Each rectangular matrix code symbol shall contain between 46 message characters (for 16 rows × 36 columns) and 72 message characters (for 16 rows × 48 columns), encoded in accordance with AIM International Symbology Specification – Data Matrix.

9.5.2 The message characters may include any of those designated as “mostly upper case” Annex K of AIM International Symbology Specification – Data Matrix. 8-bit characters may also be encoded with reduced field capacity. The first 20 characters shall contain two elements:

a. a vendor-assigned 15-character mask identification code, followed by

b. a 1-character field concatenation symbol (+) and 2-character field ID (per ANSI MH 10.8)

9.5.3 The next 26 message characters shall contain two elements:

a. a customer-assigned 13-character part #, followed by

b. a 1-character field concatenation symbol (+) followed by a 2-character field ID and

c. a 12-character customer-assigned part revision number.

9.5.4 The remaining message characters, if any, shall contain information as agreed between the vendor and the user. This may require field identifiers and field concatenation.

9.5.4.1 Field identifiers listed in ANSI MH 10.8.2 include:

a. Customer part number revision: 2P

b. Customer specification number: 20P

c. Customer specification revision: 21P

d. Customer drawing number: 12P

e. Customer drawing number revision: 22P

9.5.5 *Location of the Data Matrix Code Symbol*

9.5.5.1 With the substrate positioned front surface up and with the orientation corner toward the operator and to the operator’s left, the reference point of the data matrix code symbol shall be placed toward the orientation corner and

8 ± 1 mm from the substrate’s y-edge; this provides clearance for corner cuts or other elements adjacent to the corner, and

3 ± 1 mm from the substrate’s x-edge; this approximately centers the field between the x-edge and the FQA boundary.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D27-1000
GUIDE FOR FLAT PANEL DISPLAY EQUIPMENT COMMUNICATION INTERFACES

This guide was technically approved by the Global Flat Panel Display Committee and is the direct responsibility of the North American Flat Panel Display Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available at www.semi.org August 2000; to be published October 2000.

1 Purpose

1.1 This is a guide for implementing equipment communication features for successful integration and automation in a flat panel display manufacturing facility.

2 Scope

2.1 This guide includes references to other SEMI standards. It also includes definitions and explanations specific to FPD equipment automation.

2.2 The scope of this guide is limited to equipment communication features that interface with factory automation systems.

2.3 This guide does not reference physical or electrical interfaces, except to the extent necessary to implement the features described. For example, a serial data cable connector could be specified to have 9 pins or 25 pins.

2.4 This guide may not be applicable to all types of FPD equipment. It only applies to those for which a direct data communication interface will be implemented between the equipment and the factory automation systems.

2.5 This guide does not address all software standards that may be applicable, but addresses a subset that is necessary for effective integration and automation.

2.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The other SEMI standards referred to in this document have been carefully reviewed for applicability to FPD manufacturing. However, when referring to other SEMI standards used in this specification, the reader should allow for some editorial exceptions in order to apply the specification to FPD equipment. For example, if another SEMI specification referenced here uses the term "wafer", the reader can assume that this also applies to FPD substrates, and likewise with "silicon" and glass or plastic. These minor differences in no way impact the interpretation or implementation of those standards in FPD manufacturing equipment and factory systems.

3.2 This guide is not an all-inclusive list of applicable standards, but is a starting point for defining requirements of these equipment automation functions, and a guideline for implementation.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E23 — Specification for Cassette Transfer Parallel I/O Interface

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E37 — High-Speed SECS Message Services (HSMS), Generic Services

SEMI E37.1 — High-Speed SECS Message Services, Single-Session Mode (HSMS-SS)

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O

5 Terminology

5.1 The following define some descriptive terms that can be used to refer to systems that meet the requirements of the standards referenced herein.

5.1.1 *SECS Compliant* — This term is often used to describe systems which comply completely with both the SEMI E4 (SECS-I) and SEMI E5 (SECS-II) standards. However, it is more appropriate to identify the system as "SECS-I Compliant" and/or "SECS-II" compliant. This distinction is important because SECS-II can be implemented independently from SECS-I. The term "SECS Compliant" is ambiguous, but commonly used. It is suggested that the following terms be used instead to describe the equipment and host communication interface.

5.1.2 *SECS-I Compliant* — This term is used to identify a system that complies completely with SEMI E4.

5.1.3 *SECS-II Compliant* — This term is used to identify a system that complies completely with SEMI E5.

5.1.4 *HSMS Compliant* — This term is used to describe systems which comply with SEMI E37 (HSMS) and either SEMI E37.1 (HSMS-SS) or SEMI E37.2 (HSMS-GS) or both. However, it is more appropriate to identify the system as either “HSMS-SS Compliant” or “HSMS-GS Compliant”, since they both imply compliance with SEMI E37, and the user must know exactly which of the two is supported. The term “HSMS Compliant” is ambiguous, but commonly used.

5.1.5 *HSMS-SS Compliant* — This term is used to identify a system that complies completely with SEMI E37 and SEMI E37.1. This protocol has been adopted for use in FPD.

5.1.6 *HSMS-GS Compliant* — This term is used to identify a system that complies completely with SEMI E37 and SEMI E37.2.

5.1.7 *GEM* — Generic Equipment Model as defined in SEMI E30.

5.1.8 *GEM Compliant* — This term is defined in SEMI E30.

5.1.9 *Fully GEM Capable* — This term is defined in SEMI E30.

5.1.10 *System* — Either manufacturing equipment or factory host.

6 Data Transfer

6.1 For optimum compatibility, systems supporting the automation capabilities described herein should support all requirements defined for at least one of the following SEMI protocol standards:

6.1.1 SEMI E4 (SECS-I)

6.1.2 SEMI E37.1 (HSMS-SS). Note that this requires implementation of SEMI E37.

6.1.2.1 HSMS-SS compliant interfaces are preferred for FPD manufacturing because of its performance and logistical advantages, and because it allows other protocols to operate on the same connection simultaneously.

6.1.2.2 However, SECS-I interfaces are acceptable in systems where the performance of a serial interface is sufficient. Since many off-the-shelf component software implementations support both protocols, it is relatively easy to design systems which can be configured to support either.

7 Data Format

7.1 The system should support all minimum requirements of SEMI E5 (SECS-II). Although more modern data communication specifications are available (e.g. HTML), SECS-II has unique aspects which are valuable in microelectronics manufacturing. Also, there are many available “off-the-shelf” software packages which provide the SECS-II feature set.

7.2 Furthermore, for maximum compatibility and reliability, the implementation of any optional SEMI E5 objects (data items, variable items, messages, etc.) on the system should meet the requirements of SEMI E5. For example, if an FPD system implements the S7,F3 message, it must do so in compliance with SEMI E5 to be considered “SECS-II Compliant”. It is possible to implement “user-defined” SECS-II messages, and it is allowed by SEMI E5.

7.3 However, it is usually unnecessary to use such custom SECS-II messages. Complicated scenarios such as production sequence control, inline production, consumable management, and material handling can all be implemented using standard SECS-II messages. Many SECS-II messages are designed to be very generic and very flexible such as the Remote Command message (S2F41 or S2F49) which can contain any number of parameters of any type in any format. Many of the basic SECS-II data items such as variables can also take on any type of value in any format.

7.4 User-defined data items and messages are more difficult to integrate into FPD factory automation systems and should be avoided.

8 GEM and SEM

8.1 *Generic Equipment Model (GEM)*

8.1.1 Any reference to the term “GEM” (Generic Equipment Model) with respect to FPD manufacturing equipment will be construed as a reference to SEMI E30. The system provider should ensure that this term is used only for those systems which rigidly adhere to SEMI E30. End-users will make certain assumptions about the capabilities of “GEM” systems based on the requirements of SEMI E30.

8.1.2 SEMI E30 is applicable to FPD manufacturing equipment. FPD equipment suppliers may choose to implement GEM. In order for FPD equipment to be “GEM Compliant” or “Fully GEM Capable”, it must meet the requirements of SEMI E30 without exception. However, it may not be necessary to implement certain optional GEM capabilities for effective FPD automation.

8.1.3 The implementation of SEMI E30, or lack thereof, is usually a point of much negotiation between equipment supplier and end-user. SEMI E30 provides a useful template for identifying which capabilities are to be provided and which are not. The "GEM Compliance Statement" document should be provided by the equipment supplier to describe the capabilities of the interface, whether or not the system is GEM Compliant.

8.1.4 GEM is not applicable to host systems, but host systems must implement a compatible set of features to work effectively with GEM equipment.

8.2 *Specific Equipment Model (SEM)*

8.2.1 The concept of a Specific Equipment Model, which requires compliance with SEMI E30 (GEM), could be applied to FPD equipment as well. This document does not address SEMs. The user may wish to review the published SEM standards and determine their applicability in an FPD implementation.

9 Interfaces to Material Transfer Systems

9.1 *Carrier Transfer Parallel I/O Interfaces*

9.1.1 Material handling systems are critical for many FPD manufacturing operations. But, not all equipment support the automated transfer of material to and from the equipment. This section only applies to systems, which support automated carrier transfer.

9.1.2 For compatibility with many automated material handling systems on the factory floor, FPD equipment should support all requirements for at least one of the following SEMI carrier transfer parallel I/O standards:

9.1.2.1 *SEMI E23 (Cassette Transfer Parallel I/O Interface)* — Note that the diagram in SEMI E23 showing placement of the photo-coupled I/O interface with respect to the carrier stage (CS) shows specific CS size measurements. However, this is just an example and not a requirement of SEMI E23. The requirement is that the photo sensor must be on the front edge of the CS and its center aligned with the center of the CS. This applies to a CS of any size.

9.1.2.2 *SEMI E84 (Enhanced Carrier Handoff Parallel I/O Interface)* — Note that SEMI E84 references SEMI E1.9, SEMI E15, SEMI E15.1, SEMI E47.1, and SEMI E64 which are semiconductor specific standards and not applicable to FPD. However, none of the requirements in these documents are prerequisites for implementing SEMI E84. SEMI E84 is applicable to FPD and can be implemented independently.

SEMI D28-1101
SPECIFICATION FOR MECHANICAL INTERFACE BETWEEN FLAT PANEL DISPLAY MATERIAL HANDLING EQUIPMENT AND TOOL PORT, USING AUTOMATED GUIDED VEHICLE (AGV), RAIL GUIDED VEHICLE (RGV), AND MANUAL GUIDED VEHICLE (MGV)

This specification was technically approved by the Global Flat Panel Display Material Handling Committee and is the direct responsibility of the Japanese Flat Panel Display Material Handling Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This specification defines a common set of feature requirements on and about tool ports of process tools used in manufacturing of flat panel displays. These standardized feature requirements are intended to facilitate the interfacing of AGV, RGV, and MGV equipment to the process tool. Such standards are intended to promote cost-effective interfacing while preserving freedom of choice in material handling equipment, using AGV, RGV, and MGV.

2 Scope

2.1 This specification defines mechanical features on or about the tool port, and in front of or on the tool face. Although these features are intended for specific functions of AGV, RGV, and MGV, the interface requirements are meant to avoid the promotion of any particular form of transport.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Current display manufacturing utilizes several substrate sizes, many of them “non-standard.” This specification includes dimensions for the substrate sizes of 550 × 650 mm, 600 × 720 mm, 680 × 880 mm, 730 × 920 mm, and 800 × 950 mm and anticipates the establishment of standard dimensions in future substrate sizes.

4 Referenced Standards

4.1 None.

5 Ordering Information

5.1 Since this document is not a product specification but an interface specification, ordering information is not applicable.

6 Terminology

6.1 *Definitions*

6.1.1 *cassette loading position* — center point at under-surface of a cassette after loading by transport equipment.

6.1.2 *facial datum plane* — a plane that is parallel to the tool face and vertical to both vertical and horizontal datum planes at the cassette loading position.

6.1.3 *horizontal datum plane* — a plane that is parallel to the floor surface at the cassette loading position.

6.1.4 *vertical datum plane* — a plane that is vertical to both facial and horizontal datum planes at the cassette loading position.

6.2 *Dimensional Functions*

6.2.1 *X1* — width of the exclusion zone above the horizontal datum plane, which is needed by the transport equipment in loading cassettes.

6.2.2 *X2* — width of the exclusion fork zone below the horizontal datum plane, which is needed by the transport equipment in loading cassettes.

6.2.3 *X3* — width of the exclusion zone required for MGV cart alignment equipment.

6.2.4 *Y1* — dimension between the facial datum plane and the front of the tool port.

6.2.5 *Y2* — dimension between the facial datum plane and the tool face, which is the exclusion zone needed by the transport equipment in loading cassettes.

6.2.6 *Y3* — depth of exclusion zone required for MGV cart alignment equipment.

6.2.7 *Z1* — height between the horizontal datum plane and the floor surface.

6.2.8 *Z2* — height of exclusion zone above the horizontal datum plane, which is needed by the transport equipment in loading cassettes.

6.2.9 *Z4* — height of exclusion zone required for MGV cart alignment equipment.

6.2.10 *Z5* — height of exclusion fork zone below the horizontal datum plane, which is needed by the transport equipment in loading cassettes.

7 Requirements

7.1 Dimensions and tolerances of the required characteristics are shown in Table 1 as well as Figures 1A and 1B.

7.2 The cassette is stored horizontally with the shorter side parallel to the tool face and horizontal datum plane.

RELATED INFORMATION 1
ASSUMED DIMENSIONS FOR SUBSTRATE EDGE AND CASSETTE SIZE

NOTE: This related information is not an official part of SEMI D28 and was derived from work of the originating committee. This related information was approved for publication by full letter ballot procedures on August 3, 2001.

Table R1-1 Cassette Size

Substrate Edge length [mm]	*Cassette size [mm] Width×Length×Height*
550 × 650	591 × 682 × 524
600 × 720	642 × 755 × 695
680 × 880	736 × 923 × 706
730 × 920	792 × 978 × 770
800 × 950	870 × 1010 × 810

NOTE 1: 550 × 650, 600 × 720, 680 × 880, and 730 × 920 are the sizes which are actually adopted at the manufacturing sites. As for 800 × 950, please refer to SEMI PCS-FPD-Phase III Report.
NOTE 2: Cassette sizes in Table R1-1 were used only hypothetically as assumption to prescribe dimensions in Table 1.

SEMI D29-1101
TEST METHOD FOR HEAT RESISTANCE IN FLAT PANEL DISPLAY (FPD) COLOR FILTERS

This test method was technically approved by the Global Flat Panel Display Materials and Components Committee and is the direct responsibility of the Japanese Flat Panel Display Materials and Components Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 The purpose of this document is to standardize the method for measurement of heat resistance in color filters used for flat panel displays (FPD).

2 Scope

2.1 This method is to be used by suppliers and users of FPD color filters to measure quality in products as well as items under development.

2.2 This method is used in general FPD production to test the resistance of color filters to heat.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determines the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI D19 — Test Method for the Determination of Chemical Resistance of Flat Panel Display Color Filter

SEMI D22 — Test Method for the Determination of Color, Transmittance of Flat Panel Display Color Filter Assemblies

3.2 *ISO Standards*[1]

ISO 7724 [2,3] — Paints and varnishes -- Colorimetry

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *atomic force microscope (AFM)* — a device which precisely measures surface shape by gauging the reciprocal active force between atoms through use of a probe.

4.2 *clean oven* — a device that heats a specimen through circulation of heated air through an air filter.

4.3 *confocal scanning laser microscope* — a microscope which is able to create an image of just the focal point by concentrating light on a specimen using a confocal laser. This device can also measure surface shape by recording height information, which matches the focal point of each scans line image.

5 Summary of Method

5.1 Measure spectral transmittance, chromaticity, and surface shape of specimen.

5.2 Place specimen in heating device and leave at specified temperature for specified length of time.

5.3 Remove specimen from heating device and cool them.

5.4 Observe visually and by microscope to see if any exterior changes have occurred in the specimen.

5.5 Measure spectral transmittance, chromaticity, and surface shape of specimen.

6 Apparatus

6.1 *Heating Device and Holders*

6.1.1 *Heating Device* — Use a clean oven. The heating device being used must have the accuracy of temperature verified. Also, the device should have enough capacity to be able to heat the specimen evenly to the target temperature promptly. For example, there are devices where it is necessary to place a metal block inside to increase the heating capacity to the specimen.

6.1.2 *Holder* — First the holder should be raised to the specified temperature and then the specimen should be set in the holder.

1 International Organization for Standards(ISO), 1, rue de Varembe, Case, postale 56 CH-1211 Geneva 20, Switzerland. Tel: +41-22-749-01-11, E-mail: central@iso.ch, http://www.iso.ch

2 Available in Japanese as JIS Z8730 — Method for Specification of Color Differences for Opaque Material. Japanese Standards Association, 1-24, Akasaka 4 Chome, Minato-ku, Tokyo, 107-8440 Japan. Tel: +81-3-3583-8000, E-mail: webmaster@jsa.or.jp, http://www.jsa.or.jp

3 The expression method of its color differences is equal to the method defined in Publication of CIE No. 87 (1990) Parametric Effects in Color – Difference Evaluation. Commission Internationale de l'Eclairage, Kegelgasse 27, A-1030 Vienna, Austria. Tel: +43-1-714-31-87-0

6.2 *Measurement Devices*

6.2.1 *3-dimensional Profile Measurement Device* — Use a Stylus type surface roughness measurement device, AFM or laser microscope.

6.2.2 *Color Illuminator* — See SEMI D19.

6.2.3 *Floodlight* — See SEMI D19.

6.2.4 *Microscope* — See SEMI D19.

6.2.5 *Spectrophotometer* — Use a device in conformance with SEMI D22.

7 Test Conditions

7.1 As long as the test condition should be written in the test result, any combination of temperature and heating time can be acceptable in the conditions. The test conditions used should reflect actual conditions in the manufacturing process of flat panel displays. Table 1 contains a reference for test temperature, maintain time and atmosphere.

Table 1 Test Conditions

Item	*Device Condition*	*Test Temperature*	*Maintain time*
1	Room Air	180°C (± 2°C) 200°C (± 2°C) 230°C (± 2°C)	1 hour (± 5%)
2	Nitrogen Gas	180°C (± 2°C) 200°C (± 2°C) 230°C (± 2°C)	1 hour (± 5%)

8 Test Specimen

8.1 Use FPD color filters for specimens. In the test report, note the existence or non-existence of Transparent Conductive Film (ITO etc.).

9 Procedure

9.1 Adjust the temperature on the heating device and make sure of the furnace temperature.

9.2 Measure the spectral transmittance, chromaticity. Observe the surface of each color layer of the specimen. (The measurement method is described in Sections 9.6 and 9.7.)

9.3 Mount the specimen in the heating device.

9.4 After the temperature returns to the specified temperature, keep the specimen for the prescribed length of time.

9.5 Remove the specimen from the heating device and cool them to room temperature.

9.6 Inspect change of the outlook and the profile of the specimen according to the following procedures.

9.6.1 Observe the existence of peculiar changes in exterior appearance before and after each test (e.g. wrinkles, cracks, color “mura” etc.). It is possible for the users of this standard to use various appropriate methods of observation.

9.6.2 Visual observation by color illuminator from backside.

9.6.2.1 Visual observation by a floodlight from front side.

9.6.2.2 Microscope observation with transmitted illumination.

9.6.2.3 Microscope observation with reflected illumination.

9.6.2.4 Surface roughness measurement using a stylus-type surface roughness measurement device, AFM or laser microscope.

9.7 Measure the color changes according to the following procedures.

9.7.1 Measure the spectral transmittance and chromaticity of each color layer after heating using the method described in SEMI D22. (Measurements must be taken at the same location as before heating.)

9.7.2 Before and after the test, calculate the color difference ΔE^*ab or ΔE^*uv, in each color layer, according to ISO 7724, from the chromaticity of each color layer.

10 Reporting Results

10.1 Report the following items:

10.1.1 report date,

10.1.2 test date,

10.1.3 heating device type and conditions of use,

10.1.4 condition of specimen (with/without Transparent Conductive Film (ITO etc.), size, etc.),

10.1.5 conditions of test (temperature, length of time),

10.1.6 existence of change in outward appearance,

10.1.7 chromaticity, spectral transmittance of each color layer before and after thermal treatment (number of measuring points, position),

10.1.8 color difference of each color layer before and after thermal treatment, and

10.1.9 change in spectral transmittance at specified wavelength (e.g. back-light peak wavelength, etc.).

SEMI D13 — Terminology for FPD Color Filter Assemblies

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI D30-1101
TEST METHOD FOR LIGHT RESISTANCE IN FLAT PANEL DISPLAY (FPD) COLOR FILTERS

This test method was technically approved by the Global Flat Panel Display Materials and Components Committee and is the direct responsibility of the Japanese Flat Panel Display Materials and Components Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 The purpose of this document is to standardize the method for measurement of light resistance in color filters used for flat panel displays (FPD).

2 Scope

2.1 This method is to be used by suppliers and users of FPD color filters to measure quality in products as well as items under development.

2.2 This method shall be used in general FPD production to test the resistance of color filters to light.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determines the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI D19 — Test Method for Chemical Resistance of FPD Color Filter

SEMI D22 — Test Method for the Determination of Color, Transmittance of FPD Color Filter Assemblies

3.2 *JIS Standards (available in Japanese only)*[1]

JIS B7751 — Light-exposure and light-and-water-exposure apparatus (Enclosed carbon-arc type)

3.3 *ISO Standards*[2]

ISO 4892 — Methods of exposure to laboratory light sources

ISO 7724 [3,4] — Paints and varnishes -- Colorimetry

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *atomic force microscope (AFM)* — a device which precisely measures surface shape by gauging the reciprocal active force between atoms through use of a probe.

4.2 *fade meter* — a device which tests for the existence of external change or characteristics in materials by long term irradiation using fixed brilliance from a prescribed light source.

5 Summary of Method

5.1 Measure spectral transmittance, chromaticity, and surface shape of specimen.

5.2 Place specimen in light exposure apparatus and irradiate for specified length of time.

5.3 Remove specimen from light exposure apparatus.

5.4 Observe visually and by microscope to see if any exterior changes have occurred in the specimen.

5.5 Measure spectral transmittance, chromaticity, and surface shape of specimen.

6 Apparatus

6.1 *Light Exposure Apparatus* — Choose a test device to use from the following devices and specify which device was used in the report.

6.1.1 Carbon-arc Fade Meter

6.1.2 Sunshine Carbon-arc Fade Meter

6.1.3 Xenon-arc Fade Meter

3 Available in Japanese as JIS Z8730 — Method for Specification of Color Differences for Opaque Material.

4 The expression method of its colour differences is equal to the method defined in Publication of CIE No. 87 (1990) Parametric Effects in Color – Difference Evaluation. Commission Internationale de l'Eclairage, Kegelgasse 27, A-1030 Vienna, Austria. Tel: +43-1-714-31-87-0

6.2 *Measuring and Inspection Devices*

6.2.1 *Color Illuminator* — This light source shall have chromaticity, color rendering, luminance and intensity uniformity, diffusion, and a sufficient illumination area for observation of the specimen to be measured (See SEMI D19).

6.2.2 *Floodlight* — This light shall have luminance uniformity and an illumination area sufficient for the specimens to be measured (See SEMI D19).

6.2.3 *Microscope* — Use a microscope which has either transmitted illumination or reflected illumination, or both, and has a sufficient magnification ratio (See SEMI D19).

6.2.4 *Spectrophotometer* — The spectrophotometer shall be in conformance with SEMI D22.

6.2.5 *Surface Shape Measurement Device* — Use a Stylus-type surface roughness measurement (film thickness measurement) device, AFM or laser microscope.

7 Test Conditions

7.1 The principle test conditions are described in Table 1. In the case where tests are performed under conditions in addition to these, clearly state those conditions.

Table 1 Test Conditions

Item	*Device*	*Test Interval*	*Color Filter Condition*	*Evaluation Item*	*Reference Standard*
1	Carbon-arc Fade Meter	100 hrs. ± 5%	With/Without ITO	1. External Change	JIS B7751
2	Sunshine Carbon-arc Fade Meter	100 hrs. ± 5%	Glass Surface Irradiation	2. Color Difference ΔE*ab or ΔE*uv	ISO 4892
3	Xenon-arc Fade Meter	500 hrs. ± 5%	With UV-cut Filter	3.Transmittance Change	ISO 7724

8 Test Specimen

8.1 Use FPD color filters for specimens. In the test results, note the existence or non-existence of Transparent Conductive Film (ITO etc.). Specimen used in the test are cut to an appropriate size for the specified holder of the equipment above, and fastened at the specified distance from the light source. At this time, in order to test in conditions close to actual use, an UV-cut filter is attached to the glass surface, and light is radiated from UV-cut filter side.

9 Procedure

9.1 Turn on the light source of the light exposure apparatus and stabilize it.

9.2 Measure the spectral transmittance, chromaticity, and surface shape of each color layer of the specimen. (The measurement method is described in Sections 9.6 and 9.7.)

9.3 Mount the specimen in the light expose apparatus.

9.4 Radiate light on the specimen for the prescribed length of time. In order to keep the brilliance of the light source uniform over this period of time, control the light source according to the procedures accompanying your inspection device.

9.5 Remove the specimen from the light exposure device.

9.6 Inspect the change of the outlook and the profile of the specimen according to the following procedures.

9.6.1 Observe the existence of peculiar changes in exterior appearance before and after each test (e.g. wrinkles, cracks, color “mura” etc.).

9.6.1.1 Visual observation by a color illuminator from backside.

9.6.1.2 Visual observation by a floodlight from front side.

9.6.1.3 Microscope observation of color filter with transmitted illumination.

9.6.1.4 Microscope observation of color filter with reflected illumination.

9.6.1.5 Surface roughness measurement using a stylus-type surface roughness measurement device, AFM or laser microscope.

9.7 Measure the color changes according to the following procedures.

9.7.1 Measure the spectral transmittance and chromaticity of each color layer after the light resistance test using the method described in SEMI D22. (Measurements must be taken at the same location as before the test.)

9.7.2 Before and after the test, calculate the color difference ΔE*ab or ΔE*uv, in each color layer, according to ISO 7724, from the chromaticity of each color layer.

10 Reporting Results

10.1 Report the following items:

10.1.1 report date,

10.1.2 test date,

10.1.3 light exposure apparatus type and conditions of use,

10.1.4 condition of specimens (with/without Transparent Conductive Film (ITO etc.), size, etc.),

10.1.5 conditions of test (light source, brilliance, length of time, etc.),

10.1.6 existence of change in outward appearance,

10.1.7 chromaticity of each color layer before and after thermal treatment (number of measuring points),

10.1.8 color difference of each color layer before and after thermal treatment, and

10.1.9 change in spectral transmittance at specified wavelength (e.g. back-light peak wavelength, etc.).

SEMI INTERNATIONAL STANDARDS

GASES

Semiconductor Equipment and Materials International

SEMI C3-0699
SPECIFICATIONS FOR GASES

IMPORTANT NOTICE: This specification is incomplete. The incomplete sections are noted as "To Be Determined." The Gases Committee has agreed to publish this section prior to completion as a service to the Semiconductor Industry.

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1986; previously published in 1995.

1 Preface

1.1 Recognizing the importance of impurity content of gases in the manufacture of semiconductors, suppliers responded by introducing products with improved analytical characterization, notably for trace impurities.

1.2 The SEMI Gases Committee began its efforts in the spring of 1979. With this publication, the Committee establishes the definitions, general procedures, specifications, and analytical procedures for the gases listed in the index.

1.3 Products which meet all of the requirements may be described as "meeting SEMI specifications."

1.4 Where an analytical procedure different from that provided is substituted by a supplier or user, the burden of proof is on said supplier or user to confirm the equivalency. It should be noted that the following list of criteria was considered when determining the specified analytical method.

Reliability

Ease of Use

Maintenance

Precision

Accuracy

Sensitivity

Versatility

Availability of Equipment

1.5 The specifications provided by this work are intended to serve for gases to be used in the manufacture and processing of semiconductors and advanced electronic devices and circuits. The specifications and the associated test procedures are guidelines based on the experience of suppliers and users. The function of the specifications is to establish desired standards of quality.

1.6 Where feasible, a specification of content shall be expressed as a numerical limit in units of mole per mole (mole/mole).

1.7 For a major component, the value (assay or purity) shall be expressed as a minimum permissible limit. For an impurity, the value shall be expressed as a maximum permissible limit.

1.8 A gas conforming to the specifications will commonly contain more of the major component than the minimum permissible limit or contain less of an impurity (or several impurities) than the SEMI C3 maximum permissible limit. In neither case shall the gas be considered as of higher quality than that defined by the specification.

1.9 It is not practical to consider every impurity or contaminant that might be present. For certain applications, it is recognized that more stringent or additional specifications and procedures might be required. The intent of these specifications and the associated procedures is, on one hand, to assure that a gas is suitable for the common uses to which it may be put in the manufacture and processing of semiconductor devices and, on the other hand, to be consistent with contemporary manufacturing processes for that gas.

1.10 The Committee is continuing work on improvement of specifications and procedures and addition of other gases and systems such as mixed gases. The Committee welcomes comments, suggestions, and recommendations.

2 Definitions

2.1 *Abbreviations and Symbols* — In this work, abbreviations and symbols used shall be restricted to those listed in Table 1.

Table 1 Abbreviations and Symbols

Abbreviation or Symbol	*Explanation*
ASTM	American Society for Testing and Materials
atm	atmosphere
BP	Boiling point
°C	temperature, degrees Celsius

Abbreviation or Symbol	*Explanation*
cc	cubic centimeter(s)
CGA	Compressed Gas Association
cm	centimeter
DOT	Department of Transportation (U.S.)
°F	temperature, degrees Fahrenheit
ft	foot, feet
g	gram(s)
L	liter(s)
lb	pound(s)
max	maximum
min	minimum
mL	milliliter(s)
mm	millimeter(s)
MP	melting point
mw	molecular weight (g/mole)
ohm-cm	ohm - centimeter
ppm	mole/mole x 10^6
ppb	mole/mole x 10^9
ppba	mole/mole x 10^9 atomic
ppbw	weight/weight x 10^9
psia	pounds per square inch absolute
psig	pounds per square inch gauge
SCF	standard cubic foot (feet)
temp.	temperature
vol	volume
vol/vol	volume/volume
wt.	weight
w/v	weight/volume
ww	weight/weight

2.2 *accuracy* — (To Be Determined)

2.3 *assay* — determination of the content of a specific component with no evaluation of other components.

2.4 *comparison of analytical results with specific limits* — in the comparison of an analytical result for a test with the numerical limit associated with that specification, the result shall be rounded to the number of significant figures indicated for that limit. (See Rounding Numbers, SEMI C3, Section 2.22).

2.4.1 Consequently, a specification stated as 96% minimum will be met by a result as small as 95.5%, and that stated as 96.0% minimum will be met by a result as small as 95.95%. A specification of 0.1% maximum will be met as large as 0.14%, and that of 0.10% maximum by a result as large as 0.104%.

2.5 *cryogenic liquid* — liquid with a normal boiling point below –150°C.

2.6 *cylinder pressure* — pressure contained in a gas cylinder prior to regulation.

2.7 *cylinder tare weight* — containers which are stamped to denote the weight of the container or the weight of the container and the valve less the product. The weight does not include the weight of any protective cylinder cap.

2.8 *density* — weight per unit volume (w/v) is expressed as grams per liter for gases at zero degrees Celsius, one atmosphere.

2.9 *detection limit* — the detection limit for all the analytical methods that appear in this section of the BOSS must be established for each impurity defined. The detection limit must be stated as well as the statistical method used to establish that detection limit. The analytical method should be chosen such that the detection limit is at or below the specification.

2.10 *dewpoint* — the temperature at which liquid first condenses when vapor is cooled.

2.11 *expression of content and concentration* — unless otherwise stated, a specification limit and the analytical result related to it shall be expressed in units of mole per mole (mole/mole).

2.12 *filtration* — (To Be Determined)

2.13 *Gas Purity Guideline* — A Gas Purity Guideline is a proposed specification recommended by one or more users as needed in the future for the production of semiconductor devices. They reflect future needs in which test methods are not generally available at the time of proposal. These guidelines are approved by the Gases Committee for publication in the Standards Book. Products meeting these guidelines are not necessarily commercially available.

2.14 *heavy metals* — (To Be Determined)

2.15 *liquified compressed gas* — a gas which under the charged pressure is partially liquid at a temperature of 21.1°C (70°F).

2.16 *metals* — (To Be Determined)

2.17 *molecular weight* — the sum of the atomic weights of all the atoms in the molecule.

2.18 *nonliquified compressed gas* — a gas, other than a gas in solution, which under the charging pressure is entirely gaseous at a temperature of 21.1°C (70°F).

2.19 *physical properties* — physical properties shall not usually be employed for specification purposes; for information, however, representative values for a particular gas, as supplied, may be included as an item in the monograph for that gas.

2.20 *quality* — the quality is determined by subtracting the sum of the maximum acceptable gas phase impurity levels, expressed in percent, from 100. The result is truncated after the first significant figure which is not a nine. The quality does not represent an assay.

2.21 *rare gas* — any of the six gases, all noble, comprising the extreme right-hand group of the Periodic Table; namely helium, neon, argon, krypton, xenon, and radon.

2.22 *rounding numbers* — the following rules for rounding of measured or calculated values shall be employed:

2.22.1 When the figure next beyond the last place to be retained is less than 5, leave unchanged the figure in the last place retained.

2.22.2 When the figure next beyond the last place to be retained is greater than 5, increase by 1 the figure in the last place retained.

2.22.3 When the figure next beyond the last place to be retained is 5 and there are no figures beyond this 5 or only zeroes, (a) increase by 1 the figure in the last place retained if it is odd, or (b) leave the figure unchanged if it is even.

2.22.4 When the figure next beyond the last place to be retained is 5 and there are figures other than zeroes beyond this 5, increase by 1 the figure in the last place retained.

2.22.5 Obtain the rounded value in one step by direct rounding and not in two or more steps of successive rounding.

2.23 *specific gravity* — the ratio of the mass of a gas to the mass of an equal volume of air at a specified temperature. For liquids, it is the ratio of the mass of the liquid to the mass of an equal volume of water.

2.24 *specification and specification limits* — the specification limit should fall above or in the range of the result and its uncertainty.

2.25 *temperature* — temperature values shall be expressed in degrees Celsius.

2.26 *tolerances in measurements* — use the following guidelines for mixture tolerances:

2.26.1 Mixtures should be specified by the major component and the concentration of the desired minor component(s).

2.26.2 All component gases shall adhere to the appropriate SEMI specification, if available.

2.26.3 The impurity levels in the mixture shall not exceed the algebraic sum of the impurities specified for the designated components.

2.26.4 Mixtures shall be prepared according to the following mixing tolerances:

Concentration of Minor Component	*Preparation Tolerance Level*
10 - 99 ppm	± A 20%
100 - 999 ppm	± A 10%
0.1 - 50%	± A 5%

2.26.5 Standards used to verify mixing tolerance (henceforward called Certified Standards) shall meet the following requirements:

Range	*Preparation Tolerance of Each Minor Component*	*Analytical Accuracy of Each Minor Component*
0 - 9.9 ppm	To Be Determined	To Be Determined
10 - 99 ppm	± A 10%	± A 3%
100 - 999 ppm	± A 5%	± A 2%
0.1% - 50%	± A 4%	± A 2%

2.27 *Calibration Standards* — Calibration standards shall be as close as practical to specification and may not exceed ten times (10×) the specification unless specifically excepted in procedure.

3 Samples

3.1 *Sample Size* — The quantity of gas/liquid in a single sample container shall be sufficient to perform the analysis for all the listed specifications. If a single sample does not contain a sufficient quantity of gas/liquid to perform all of the required analyses, additional samples from the same source shall be taken under similar conditions.

3.2 *Gaseous Samples* — Gaseous samples shall be representative of the gaseous supply. Sampling shall be performed in accordance with one of the following:

3.2.1 By withdrawing a sample from the supply container through a suitable connection into the sample container. (For safety reasons, the sample container and sampling system must have a rated service pressure at least equal to the pressure in the supply container.)

3.2.2 By connecting the container being sampled directly to the analytical equipment.

3.2.3 By selecting a representative cylinder from the cylinders in the lot.

3.3 *Liquid Sampling (Vaporized)* — Vaporized liquid samples shall be representative of the liquid supply. Sampling shall be in accordance with one of the following:

3.3.1 By vaporizing liquid from the supply container in the sample tubing.

3.3.2 By flowing liquid from the supply container into, or through, a suitable container in which a representative sample is collected and then vaporized.

3.4 *Liquid Samples (Liquified Compressed Gases)* — A direct connection between the liquid phase of liquified compressed gas containers and the analytical equipment can be achieved, provided suitable flash vaporization is obtained.

3.5 *Lot Acceptance Tests* — These are analyses performed on the gas/liquid in the shipping container, or a sample thereof, which is representative of the lot. (The terms "lot" and "batch" may be used interchangeably.)

3.6 *Lots* — One of the following is to be used:

3.6.1 No specific quantity or any quantity of product agreed upon between the supplier and the customer.

3.6.2 All of the product supplied during the contract period.

3.6.3 All of the product supplied or containers filled during a calendar month.

3.6.4 All of the product supplied or containers filled during seven consecutive days.

3.6.5 All of the product supplied or containers filled during a consecutive 24-hour period.

3.6.6 All of the product supplied or containers filled during one eight-hour shift.

3.6.7 All of the product supplied in one shipment.

3.6.8 All of the product supplied in one shipping container.

3.6.9 All of the product supplied in the container(s) filled on one manifold at the same time.

3.7 *Number of Samples Per Lot* — The number of samples per lot shall be in accordance with one of the following:

3.7.1 One sample per lot.

3.7.2 Any number of samples agreed upon by the supplier and the customer.

4 Sampling

4.1 For gases provided in cylinders, a sample can be taken directly for analysis. For gases provided in bulk quantities or cylinders where direct sampling is not appropriate, a sample may be taken per SEMI sampling procedures.

4.2 *Sampling Procedures*

4.2.1 *Cryogenic Liquid Sample* — Liquid Samples for Oxygen, Nitrogen, and Argon, using the TTU-131/E sampler.

WARNING: DO NOT USE THIS PROCEDURE FOR THE SAMPLING OF LIQUID HYDROGEN.

4.2.2 *Applicable Document* — Military Specification MIL-S-27626D 16 August 1979, Amendment 1, 24 April 1981.

4.2.3 *General Description* — The TTU-131/E cryogenic sampler is a small, portable pressure vessel used to receive, vaporize, and contain a representative sample of cryogenic liquid from a supply source. The vaporized sample is withdrawn as a gas for analytical purposes.

4.2.4 *Theory* — The sampler is used to isolate a small but representative quantity of cryogenic liquid and vaporize the major component and all volatile impurities to form a homogeneous gas sample suitable for analysis. The cryogenic liquid is used to cool a shielding space and sampling cup prior to admitting the liquid to the sampling cup. The purpose of pre-cooling the sampling cup is to prevent concentrating impurities which could result when the warm cup causes the liquid to vaporize, leaving behind impurities with higher boiling points.

4.2.4.1 When the cup is adequately cooled, the sampling valve is opened, allowing liquid to fill the cup. When the sampling valve is closed, the liquid is trapped in the cup and will vaporize as a result of atmospheric heating. Once the sample is trapped, the flow of liquid is stopped.

4.2.5 *Preparation for Sampling*

4.2.5.1 The sample should be kept in the same product service to avoid sample contamination. If a product change is required, always thoroughly purge the sampler or evacuate to 100 microns prior to taking the sample.

4.2.5.2 When taking the sample, the sampler is to remain secured to the bottom half of the case and MUST be in an upright position.

4.2.5.3 Inspect the sampler vessel for any obvious physical defects, such as dents, gouges, bent fittings, etc. Since the sampler is a pressurized vessel, it should be removed from service if any damage is apparent.

4.2.6 *Sampling Procedure*

4.2.6.1 Remove cover.

4.2.6.2 Loosen inlet and outlet fittings dust caps located on side of the vessel.

CAUTION: SAFETY GLASSES AND PROTECTIVE GLOVES ARE REQUIRED WHEN OPERATING THIS EQUIPMENT. SAMPLING SHOULD BE DONE ONLY IN WELL VENTILATED AREAS.

4.2.6.3 Relieve pressure in vessel through vents in dust caps by cautiously opening inlet sampling valve.

4.2.6.4 When gauge indicates atmospheric pressure and flow ceases, close inlet sampling valve and remove dust caps.

4.2.6.5 Connect fill hose to supply tank and inlet fittings of sampler.

4.2.6.6 Open supply tank outlet valve. Gas and liquid will begin to flow from the sampler outlet.

CAUTION: WHEN OXYGEN IS SAMPLED, SOME ADDITIONAL PRECAUTIONS MUST BE OBSERVED. IF THERE IS NO FACILITY SUCH AS A CLEAN CONCRETE PAD ON WHICH THE LIQUID OXYGEN CAN EVAPORATE SAFELY, IT WILL BE NECESSARY TO CATCH THE LIQUID OXYGEN IN A CLEAN, PREFERABLY SEAMLESS ALUMINUM BUCKET. USE A LINE WITH MINIMUM INSIDE DIAMETER OF ONE-HALF INCH TO DIRECT THE LIQUID OXYGEN INTO THE BUCKET. FURTHERMORE, IT IS IMPORTANT THAT THERE IS NO RESTRICTION IN THIS LINE BECAUSE THE BACK PRESSURE DEVELOPED MAY BE SUFFICIENT TO CAUSE THE LIQUID IN THE CUP TO OVERFLOW INTO THE LARGE CHAMBER. ON WARMUP, THE PRESSURE IN THE SAMPLER COULD BECOME EXCESSIVE, PARTICULARLY IF THE SAMPLE WERE SUBCOOLED, NECESSITATING THE REPLACEMENT OF THE SAFETY RELIEF DEVICE.

4.2.6.7 Allow sampler to cool until a steady flow of liquid appears at outlet.

CAUTION: AVOID CONTACT WITH THE FLOW OF CRYOGENIC LIQUID. THE EXTREMELY LOW TEMPERATURE CAN CAUSE PAINFUL INJURIES.

4.2.6.8 Open inlet sampling valve completely to allow liquid to enter sampling cup.

4.2.6.9 After 30 seconds, close sampling valve.

4.2.6.10 Close supply tank outlet valve.

4.2.6.11 Disconnect fill hose.

4.2.6.12 Invert sampler for five minutes to allow sampling cup to empty and provide vaporization of liquid.

4.2.6.13 At ambient temperature the sampler should be at 400-500 psig, indicating that a good sample was obtained. A lower pressure would indicate a leak in the sampler or that the cup was not filled with liquid. If there is any doubt, release gas from sampler and take another sample.

4.2.6.14 Re-install inlet and outlet fitting caps. Do not tighten.

4.2.6.15 Affix a tag identifying the product to the inlet sampling valve handwheel.

4.2.6.16 Install cover.

4.3 *Gas Phase Sample* — (To Be Determined)

4.4 *Liquid Sample* — (To Be Determined)

4.5 *Delivery to Analytical Instruments* — (To Be Determined)

5 Quantification (To Be Determined)

5.1 *Linear Response*

5.1.1 Direct Comparison

5.1.2 Calibration Curve

5.2 *Non-Linear Response*

5.2.1 Direct Comparison

5.2.2 Calibration Curve

6 Gas Chromatography

6.1 The analysis of many gaseous impurities in bulk and specialty gases is done by means of a gas chromatography separation of impurities from the gas matrix and quantification using a broad range of sensitive and sometimes selective detectors. This section will provide a guide for the format and representation of such a procedure. Figure 1 is designed to represent the format for submission of such methodology.

6.2 *Sample Introduction* — By its nature, gas chromatography implies the use of carrier gases into which the gaseous sample is injected and carried into the separation medium, either solid or liquid in nature.

The introduction of a gaseous sample into a carrier gas stream is accomplished by means of a sample injection valve. Valves for this purpose can be any of several types, although the most commonly used are either rotary or diaphragm valves using loops of stainless steel tubing of a known volume. It is not necessary to diagram such sample introduction systems for a procedure unless the introduction system is unique to the application by way of special conditions for safety or other reasons critical to the accuracy of the sampling technique.

6.3 *Separations* — It is an acceptable and common practice to quantitate several gaseous impurities with a single gas chromatographic separation. Occasionally a single injected sample volume will undergo "multidimensional" separation to achieve the necessary analysis. Rotary valves, diaphragm valves or Dean's pressure switching again are used to move impurities from one separation medium to another, or from one column to another. Where multidimensional techniques are used, they should be accompanied by flowpath diagrams which clearly indicate valving and their appropriate positions. The valving sequences used should have adequate explanation to clarify the separations.

6.4 *Columns* — Columns used are generally of 3.2 mm (1/8 in.) o.d. and 2.2 mm (0.085 in.) i.d. stainless steel of varying lengths and packed with one of many solid supports. Columns may be specified by length and packing material if these standard dimensions apply. If another dimension or material is used for the column itself, it should be specified by material type, and by o.d. and i.d. in mm. Packing materials should be specified by material, % coating and coating type if applicable, and mesh size. Capillary columns are assumed to be fused silica unless otherwise specified and should be specified by i.d. in mm, film thickness in µm, and length in meters. Column temperatures and applicable program rates should be given for each independently heated zone in degrees Celsius.

6.5 *Carrier and Support Gases* — Carrier and support gas flow rates for all separations should be specified. Carrier and support gases used should fall into the general purity requirements in Table 2 and purity need not be specified unless the analysis has specific purity requirements for safety, accuracy, or component lifetime. Flows should be specified in mL/min or L/min, or as linear velocity for open tubular capillary columns.

6.6 *Detectors* — Detector technology should be specified, and alternative detection may be assumed equivalent for detectors of like selectivity and sensitivity. Table 2 gives a reference of relative detector sensitivity and is provided as a guideline only. Detector parameters are less likely to be easily formatted since detector technologies vary widely in their specific parameters. All elements critical to achieving like sensitivity must be included, such as temperature, make-up gases and their flows, flame, combustion or reaction gas ratios or flows, voltages, currents, or any additional settings as outlined by the detector manufacturer.

6.6.1 Detection limits must be specified for each impurity for the actual methodology used. Because the lower detection limit can be greatly influenced by retention time for any impurity, it is important that the detection limit be derived for the impurity within the context of the method, and not solely on the detectability of the detector. Detection limits are assumed to be calculated on a mole/mole basis.

6.7 *Operating Procedures* — The standard procedure assumed for the gas chromatographic analysis of most gases is as follows:

1. Inject the calibration standard onto the column using a gas sampling valve. Record the retention time(s) and peak area(s) for all impurities detected.
2. Analyze the sample to be tested in the same manner as the calibration standard.
3. Repeat 1.
4. Compare the average peak area of the calibration standard with that of the sample being tested. (See Calculation of Concentration, in Section 6.9.)

6.7.1 The method should specify any additional valve switching or special parameters which are necessary for the successful analysis of the impurities specified for the procedure. It must also specify the order of elution if multiple impurities are detected.

6.8 *Calibration* — Calibration for these analytical procedures is generally by external, single point calibration. Calibration gas mixtures should be specified and are assumed to be within the range specified in Section 2.26. Calibration standards are assumed to be made in a balance of gas representative of the sample unless otherwise specified. If calibration techniques other than external, point calibrations are used, they must be described.

6.9 *Calculation of Concentration* — The calculation of the concentration of impurity within the sample is based on a comparison of the average peak area of the impurity in the calibration standard, to the average peak area of the impurity within the sample, based on the formula:

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

It is assumed that the results of such a calculation must not exceed the specification for the product being analyzed.

6.10 *Notes* — Any special requirements for any section within gas method may be included here. Notes should reflect the minimum requirements to successfully achieve the desired detection limits with the equipment specified.

7 Special Analyses

7.1 *Resistivity Measurement* — The American Society of Testing and Materials (ASTM) is developing a method to measure resistivity in substrates. This method may be referenced when it is finalized.

7.2 *Metal Analysis of Gaseous Silicon Compounds*

7.2.1 Because of the importance of trace elemental impurities impacting silicon device characteristics, there is an increasing need for the detection and quantitative analysis of low-level impurities in the silicon materials used in device fabrication. Some of these materials are gaseous silicon-containing compounds, such as silane and the chlorosilanes. For elemental analysis by FTIR or PLS, a compound must first be converted to a solid form such as a single crystalline rod or disc. For the quantitative determination of metals and some non-metallic elements, the gases can be passed through a series of bubblers containing high-purity DI water or dilute acids. The aqueous media can be concentrated and analyzed by suitable techniques such as ICP or AA spectroscopy. In both cases, the recovery is assumed to be 100% efficient or, in other words, there is no loss of any impurity from the silicon source.

7.2.2 FTIR (Fourier Transform Infrared) Spectroscopy, PLS (Photoluminescence Spectroscopy) and NAA (Neutron Activation Analysis) are probably the most useful tools for the detection and analysis of trace quantities of elemental impurities in solid silicon materials. NAA requires special silicon material specimens to be submitted to neutron irradiation in a nuclear reactor and the analysis facility to be approved by the Nuclear Regulatory Commission (NRC) and other government agencies. In contrast, FTIR and PLS do not require special governmental regulations, and the instrumentation is available on the open market.

7.2.3 An FTIR spectrometer is an infrared spectrometer in which a Michelson Interferometer is used in place of a grating or prism. The simplicity of the Michelson Interferometer, with only one moving part, an oscillating mirror, along with a He-Ne laser as a reference, provides nearly absolute frequency accuracy. This translates into a high spectral resolution. FTIR has greater detection efficiency since the energy-wasting slits required for dispersive spectrometers are not used. With a microcomputer to control the functions and to perform data processing, signal averaging is used to improve the signal-to-noise ratio. All these features lead to good reproducibility and rapid measurement results compared with conventional IR techniques.

7.2.3.1 As FTIR is a transmission method, it requires a single crystalline silicon specimen with flat, parallel, mirror-polished surfaces. For oxygen in silicon, the absorption peak at 9 microns is used for quantitative analyses. For carbon in silicon, the absorption band at 16 microns is used. Both measurements may be performed at room temperature. (The carbon determination has strong interference from the silicon phonon band, but can be resolved with high purity, carbon-free standards.) For the determination of shallow donors and acceptors, FTIR measurements must be made at liquid helium temperatures, but the through-put is low. Although the operation of today's FTIR instrument is relatively simple, the interpretation of the results through software and associated problems/solutions is not. Quantitative analysis is based upon the measured percent transmission at the characteristic wavelength and compared to standards. Detection limits at about 10-12°K are in the 10^{11} to 10^{13} atoms/cc for shallow donors and acceptors, 3.1×10^{14} atoms/cc for oxygen, and 2×10^{15} atoms/cc for carbon.

Table 2 Carrier Gases for GC Instruments

Detector	*Gas*	*Detection Level*					
		0 - 100 ppt	*100 ppt - 100 ppb*	*100 ppb - 100 ppm*	*100 ppm - 1%*	*1% - 10%*	*10% - 100%*

*this does not represent detector capability; rather those analytes analyzed by current SEMI procedures

**used as combustion gases

7.2.4 Photoluminescence Spectroscopy (PLS) of single crystalline silicon specimens at liquid helium temperatures exhibits sharp emission lines. Electron hole pairs called excitons are formed by incident radiation (514.5 nm line from argon laser). The decay of these "exciton or multi-exciton" states yields the lines characteristic of the impurity atoms. For elemental detection, the observed emission lines must be assigned as being extrinsic (due to impurities) or intrinsic (due to silicon). The luminescence process itself appears too complex to attain precision or accuracy from basic calculations. The PLS emissions are analyzed as a function of wavelength, suggested to be 1077 to 1139 nm, for the elemental determination of shallow donors and acceptors in silicon. Quantitative measurements of impurities are based on the extrinsic-to-intrinsic intensity ratio and compared to standards. The PLS emissions are analyzed using a monochromator and detected by a photomultiplier. Sensitivity in the range of 5×10^{10} to 5×10^{11} atoms/cc has been claimed for B, Al, P, and As.

7.2.4.1 In order to obtain reliable measurements, the silicon specimens must be in single crystalline form with a mirrored surface. Epitaxial wafers with layers of thickness greater than 10 microns are suitable, since the sample's depth appears to be less than 5 microns. However, it is still in the development stage, and very few laboratories have such capability. A number of questions remain unanswered, including the following:

1. What is the effect of compensating impurities?

2. What is the effect of deep levels and intracenter transitions on the intensity ratios?
3. What is the effect of crystallographic defects? Of point defects? And of surface defects?
4. Interference from other shallow impurities may mask the detection of very low-level impurities. For instance, PLS signal of Al at 1078.5 nm may be affected by strong signals from As at 1079.0 nm or at 1078.2 nm.

7.2.4.2 CVD-deposited films in single crystalline form can be used for elemental detection of donors and acceptors for gaseous silicon compounds. However, PLS does not detect carbon, oxygen, or nitrogen. It is also not useful for metallic impurities. That is, in general, PLS is useful only for a very limited number of impurities.

7.2.5 Based on this analysis, it was recommended that the SEMI Gases Analytical Procedures Subcommittee should wait for further development of innovative and improved analytical techniques for the quantitative determination of low-level elemental impurities based on FTIR and PLS. Meanwhile, techniques such as ICP, AA, and Ion Chromatography may be applicable to a very large number of impurities of interest to the silicon semiconductor industry. Development and adaptation of these technologies should be encouraged.

7.2.6 AA (Atomic Absorption Spectrophotometry), ICP (Inductively Coupled Plasma Emission Spectrometry), and IC (Ion Chromatography) are probably the most valuable instrumental techniques for the detection and analysis of trace elemental impurities in aqueous media. These techniques usually require that the elements be dissolved in an aqueous medium. Due to this fact, and the fact that the elemental impurities are typically present in silane and the chlorosilanes at the ppb and sub-ppb levels (which is beyond the detection limits for these techniques for most elements) it is usually necessary to concentrate the impurities prior to analysis, such as by passing the gas through a series of impingers (i.e., gas bubblers) containing either DI water or, more commonly, acidic solutions. From analyses of the impinger solutions together with knowledge concerning impinger solution volume(s) and both the flow rate and period of flow of the gas, the concentration of the respective elements in the original gas should be readily calculated to a fairly high degree of accuracy.

7.2.6.1 Atomic Absorption Spectrophotometry can be used for elemental analyses for a multitude of elements in the periodic table at detection limits ranging from ppm to ppb, depending both on the exact configuration or setup and the element being analyzed. The principle of the technique involves conversion of an incoming aerosol into an atomic vapor which can absorb light from a primary light source, usually a hollow cathode lamp or an electrodeless discharge lamp (EDL), the latter providing improved sensitivity and lower detection limits for certain elements. In addition, a flameless (i.e., graphite furnace) technique can be used to increase sensitivities and detection limits 50 to 100 times better.

7.2.6.2 Complementary to Atomic Absorption Spectrophotometry is Flame Emission Spectrophotometry, which differs in the absence of a primary light source. Again, a flame is utilized to convert an incoming aerosol into an atomic vapor. However, the flame also thermally elevates the atoms to an excited electronic state, and, when the atoms return to the ground state, they emit light detectable by a photomultiplier. This technique is ideal for the analysis of Li, Ha, and K at ppm and sub-ppm levels.

7.2.6.3 Inductively Coupled Plasma Emission Spectrometry (ICP) is rapidly replacing Atomic Absorption Spectrophotometry for elemental analyses of liquids, since approximately 70% of the elements in the periodic table can be determined with better precision and equal or better sensitivity with minimal sample preparation. Detection limits, in fact, for this technique range from ppm to sub-ppb levels, depending both on instrumental and/or experimental conditions and the element being analyzed. ICP involves nebulizing liquid samples either directly or in diluted form into a spray chamber where a stream of argon gas carries the smaller sample droplets into the axial channel of an argon plasma which reaches temperatures of 4000-8000°K. The common technique employs an optical system for detection. Newer techniques are being investigated using a mass spectrometer as a detection system coupled to an ICP excitation source. This is referred to as ICP/MS.

7.2.6.4 Ion Chromatography (IC) uses the principle of ion exchange to separate anionic and cationic species at detection limits ranging from ppm to ppb, depending again both on the instrumental and experimental conditions and on the element being analyzed.

7.2.6.5 Detection of ionic species in IC is most commonly accomplished by an electrical conductivity detector capable of measuring most non-transition metal cations and anions to sub-ppm levels. An electrochemical detector (for amperometric detection) is available for measuring any electroactive species having an oxidation/reduction potential near the applied electrochemical cell potential. This latter detector is capable of measuring many ionic species at ppb levels (e.g., Br^-, CN^-, S^-, etc.).

7.2.6.6 Of the three aforementioned techniques, Atomic Absorption Spectrophotometry, Inductively Coupled Plasma Emission Spectrometry, and Ion Chromatography, the most sensitive method of analyzing for a multitude of elements is, without doubt, graphite furnace (i.e., flameless) Atomic Absorption Spectrophotometry. However, this instrumental technique suffers the disadvantage of being slow and tedious. Consequently, Inductively Coupled Plasma Emission Spectrometry is rapidly replacing Atomic Absorption Spectrophotometry for elemental analyses of liquids since it is a reasonably fast technique requiring minimal sample preparation with practical detection limits being superior to those of standard (i.e., flame) Atomic Absorption Spectrophotometry for most elements and approaching those of graphite furnace Atomic Absorption Spectrophotometry for many of the elements. An added attractive feature of Inductively Coupled Plasma Emission Spectrometry is that eventually it may be used to analyze for elements directly in gases. Preliminary work, in fact, is currently being conducted in this area by several research groups. Although Ion Chromatography can be used to analyze for a multitude of non-transition metal cations (e.g., Li^{+}, Na^{+}, K^{+}, Rb^{+}, Cs^{+} Ba^{+2}, Mg^{+2}, Ca^{+2}, Sr^{+2}, etc.) it is limited by the fact that currently only a few transition metals (e.g., Ni^{+2}, Cu^{+2}, Co^{+2}, Zn^{+2}, Fe^{+2}, Fe^{+3}, Cd^{+2}, etc.) can be analyzed by this instrumental technique. IC, however, has the advantage in that it can be used for analyzing for complex cationic and especially anionic species directly (e.g., NH_4^{+} , NO_2^{+}, NO_3^{-}, SO_3^{-}, SO_4^{-2}, PO_4^{-3}, $OC1^{-}$, SCN^{-}, CN^{-}, CO_3^{-2}, etc.) and for different oxidation states for certain elements (e.g., Fe^{+2} and Fe^{+3}), unlike the other techniques, which are strictly limited to elemental analyses only. Furthermore, IC is extremely valuable for analyzing ionic species, particularly anions (e.g., F^{-}, Cl^{-}, etc.) of many common elements which otherwise cannot be analyzed directly by either Atomic Absorption Spectrophotometry or Inductively Coupled Plasma Emission Spectrometry.

8 Standards

8.1 Certified Standards shall be made by weight traceable to the National Institute of Standards and Technology.

9 Determination of Precision

9.1 To Be Determined.

10 Safety

10.1 Because of the continuing evolution of safety precautions, it is impossible for this publication to provide definite statements related to the safe handling of individual chemicals. The user is referred to product labels, product data sheets, government regulations, and other relevant literature.

NOTE 1: This table is intended to identify various gases described in the SEMI standards and the typical uses for those gases in semiconductor processes. It is not all-inclusive. As other uses arise, they should be brought to the attention of the Gases Committee so that revisions can be made to this table as needed.

NOTE 2: Performance of a gas in an application may vary depending on the impurities in the gas. It is the responsibility of the user to determine the appropriate gas quality for any specific application.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.12-94
STANDARD FOR AMMONIA (NH_3) IN CYLINDERS, 99.998% QUALITY

1 Description

Ammonia is a colorless, alkaline gas having a pungent odor. Ammonia dissolves readily in water. It is shipped as a liquified gas under its own vapor pressure. It is combustible.

2 Specifications

QUALITY: 99.998% (See Note 1)

Impurities	*Maximum Acceptable Level (ppm)**
Carbon monoxide (CO)	1
Hydrocarbons $C_1 – C_3$	1
Nitrogen (N_2)	5
Oxygen (O_2)	2
Water (H_2O) (v/v)	3
TOTAL IMPURITIES	12

*An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	17.031	17.031
Boiling point at 1 atm	-33.4°C	-28.2°F
Density of gas at 0°C (32°F) and 1 atm	0.771 kg/m^3	0.0481 lb/ft^3
Specific gravity of gas at 0°C and 1 atm (air = 1)	0.597	0.597
Density of liquid at 21.1°C (70°F)	608.7 kg/m^3	38.00 lb/ft^3

4 Analytical Procedures (See Notes 2, 3, 4, 5)

4.1 *Carbon Monoxide, Oxygen and Nitrogen* — This procedure is for the determination of carbon monoxide, oxygen and nitrogen in ammonia using a gas chromatograph with a helium ionization detector. (See Note 6.)

4.1.1 *Detection Limits* — 25 ppb (mole/mole) carbon monoxide, 30 ppb (mole/mole) oxygen, 50 ppb (mole/mole) nitrogen.

4.1.2 *Instrument Parameters*

4.1.3 Columns:

Column 1:	HayeSep A or equivalent, 100/120 mesh, 32.8 m (10 ft) by 3.2 mm (1/8 in) 0.085 ID.
Column 2:	HayeSep A or equivalent, 100/120 mesh, 32.8 m by 3.2 mm 0.085 ID.

4.1.3.1 Carrier Flow: 30 mL/min helium, minimum of 99.9999% purity having a maximum of 40 ppb carbon dioxide.

4.1.3.2 Sample Volume: 1.0 mL.

4.1.3.3 Temperatures:

Detector	125°C
Columns	27°C

4.1.3.4 Determine the breakdown voltage of the detector. Set operating voltage at 10 volts below breakdown.

4.1.4 *Calibration Standards* — 1–2 ppm (mole/mole) carbon monoxide, 2–3 ppm (mole/mole) oxygen, 5-6 ppm (mole/mole) nitrogen, balance helium (having a total of other impurities of less than 1 ppm).

4.1.5 *Operating Procedure*

4.1.5.1 Set timing interval on sample select valve to 10 seconds.

4.1.5.2 Set timing interval on gas sampling valve to 3:30 minutes.

4.1.5.3 Set timing interval #3 to 4:20 minutes.

4.1.5.4 Do not change the initial sample flow setting once established.

4.1.5.5 Obtain a continuous flow of the calibration standard using a clean stainless steel line (0.02 in ID).

4.1.5.6 Inject the calibration standard onto the precolumn with the gas sampling valve. Record the retention times and peak areas. Order of elution is nitrogen, oxygen, and carbon monoxide.

4.1.5.7 Repeat step 4.1.4.6 until reproducibility of the reading is better than 1% of full scale.

4.1.5.8 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

4.1.5.9 Repeat 4.1.4.6.

4.1.5.10 Compare the average peak areas of the calibration standard to that of the ammonia sample being tested. Calculate the concentrations of carbon monoxide, oxygen and nitrogen, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

4.2 *Hydrocarbons $C_1 - C_3$* — This procedure is for the determination of hydrocarbons C_1 – C_3 in ammonia. The sample shall be gas phase and analyzed using a gas chromatograph with a flame ionization detector. (See Notes 7, 8, 9, 10, 11, and 12)

4.2.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.2.2 *Instrument Parameters*

4.2.2.1 Columns:

Column 1: 13X molecular sieve, 3.2 mm (1/8 in) by 3.2 mm (1/8 in) ss, or equivalent.

Column 2: Silica gel (saturated) 4.6 m (15 ft) by 3.2 mm ss, or equivalent.

4.2.2.2 Carrier Flow: 50 mL/min helium.

4.2.2.3 Sample Volume: 5 mL.

4.2.2.4 Column Temperature: 40°C

4.2.2.5 Sample Flow: 150 mL/min.

4.2.2.6 Air Pressure and Flow: As specified by the instrument manufacturer's instructions.

4.2.2.7 Hydrogen Pressure and Flow: As specified by the instrument manufacturer's instructions.

4.2.3 *Calibration Standards* — 5–10 ppm (mole/mole) methane in nitrogen, 5–10 ppm (mole/mole) ethane, 5–10 ppm (mole/mole) propane in nitrogen.

4.2.4 *Operating Procedure*

4.2.4.1 Install the column switching as shown in Figure 1. Place the dual column switching valve in the molecular sieve column position for methane analysis. Use the silica gel column position for the analysis of C_2 – C_3 compounds.

4.2.4.2 Ignite the burner following the instrument manufacturer's instructions. Allow the system to stabilize for 15 minutes. (This is also indicated by a stable signal output.)

4.2.4.3 Inject the methane in nitrogen standard onto the molecular sieve column to determine the retention time for methane.

4.2.4.4 Inject the ethane and propane in nitrogen standard onto the silica gel column to determine the retention times for these compounds.

4.2.4.5 Inject the calibration standard onto the desired column to determine the peak area for the compound of interest. Record the retention times and peak areas.

4.2.4.6 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.7 Repeat 4.2.4.5.

4.2.4.8 Compare the average peak areas for at least three runs each of the calibration standard to that of the ammonia sample being tested. Calculate the concentration of hydrocarbons C_1 – C_3, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

4.3 *Water* — The method for the determination of water in ammonia is based on its decomposition by the reaction $2NH_3 \rightarrow N_2 + 3H_2$, which occurs completely and irreversibly when ammonia is passed over a nickel catalyst at 1000°C. Water passes through the catalyst unchanged. Therefore, the water content of ammonia may be determined by measuring the dewpoint of the stream of hydrogen and nitrogen produced by decomposition of ammonia. (See Notes 13 and 14)

4.3.1 *Apparatus* (shown in Figure 2)

4.3.1.1 The nitrogen and ammonia are connected to a tee with 3.2 mm (1/8 in) OD stainless steel tubing, keeping the lines as short as is practical.

4.3.1.2 The nitrogen may be fed from a regulator.

4.3.1.3 The ammonia should be fed through a stainless steel needle valve.

4.3.1.4 The furnace is a Lindberg Model 54032 or equivalent, with an Inconel reaction tube. The reaction tube is 0.6 m (24 in) long by 25 cm (1 in) OD and terminates in 1/8 in swaged tubing connectors.

4.3.1.5 The reaction tube is filled with nickel lumps, MCB Catalog number NX305 or equivalent.

4.3.1.6 The outlet of the furnace is connected by a 1.2 m (4 ft) by 3.2 mm (1/8 in) OD stainless steel tubing to a moisture analyzer suitable for determining the concentration of water is a mixture of hydrogen and nitrogen at the specified concentration. This length of tubing is required to permit adequate cooling of the gas between the furnace and the moisture analyzer.

4.3.1.7 The outlet of the moisture analyzer is connected to the inlet of a 0-10 CFH flowmeter.

4.3.1.8 The outlet of the flow meter is connected to an appropriate vent for the disposal of ammonia, nitrogen and hydrogen.

4.3.2 *Operating Procedure*

4.3.2.1 Start a nitrogen purge flow of approximately 5 CFH.

4.3.2.2 Set furnace to 950°C and allow to equilibrate (approximately 1.5 to 2 hours).

4.3.2.3 With the ammonia cylinder valve closed, disconnect the tubing from the cylinder outlet and open the ammonia inlet needle valve to allow the ammonia sample line to purge with nitrogen. Reconnect the tubing to the cylinder outlet and close the needle valve.

4.3.2.4 Shut off the nitrogen flow.

4.3.2.5 Open the ammonia cylinder valve and adjust the needle valve to obtain a flow of approximately 5 CFH.

4.3.2.6 Gradually increase the furnace temperature, periodically testing the gas for the presence of ammonia by placing a piece of wet red litmus paper in the vent stream. If ammonia is present, the paper will turn blue. When ammonia is no longer found, the appropriate catalyst temperature has been reached.

4.3.2.7 Measure the concentration of water in the nitrogen and hydrogen stream, following the instructions of the moisture analyzer manufacturer. Periodically test the vent stream for the presence of ammonia, as described in 4.3.2.6, and adjust the furnace temperature as necessary.

4.3.3 *Reporting of Measurement*

4.3.3.1 Double the water concentration obtained in 4.3.2.7 to correct for the doubling of gas volume by the decomposition of the ammonia.

4.3.3.2 Subtract twice the concentration of oxygen (as measured by the procedure specified in Section 4.1) in the sample from the concentration of water calculated in 4.3.3.1. This is necessary because oxygen in the ammonia reacts with the hydrogen formed by decomposition to produce additional water.

4.3.3.3 The concentration of water calculated in 4.3.3.2 in the ammonia may not exceed the limit specified in Section 3.

4.4 *Notes*

Note 1: This specification applies to the gas phase of the cylinder as delivered.

Note 2: Observe proper safety procedures for handling and venting the ammonia sample.

Note 3: Introduce the calibration standard as many times as necessary to achieve the desired precision.

Note 4: All the gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

Note 5: All carrier lines, carrier pressure regulators and sample containers are to be constructed of stainless steel and cleaned. The systems must be assembled without pipe threads, PTFE tape or polymeric seal materials.

Note 6: Due to the extreme sensitivity of the helium ionization detector, the system is to be helium leak tested to a maximum of 10^{-7} atm-cc/sec.

Note 7: It is good practice to keep carrier gas flowing through the instrument. This prevents the back-diffusion of moisture and carbon dioxide in the air from contaminating the column.

Note 8: When not analyzing samples, the dual column switching valve should be set at the molecular sieve position to prevent the silica gel column from drying out.

Note 9: The silica gel column will, after repeated use, tend to dry out. This will manifest itself by the peaks of each component becoming separated farther and farther apart. Overall sensitivity will drop as the peak areas decrease due to the peaks spreading out more and more.

Note 10: The condition of the silica gel column is restored by allowing the carrier gas to pass through the water-saturated silica gel trap that has been provided. (Normally the carrier gas bypasses this trap.)

Note 11: The flame should be extinguished when not in use; also the air and hydrogen is shut off; and the helium flow reduced.

Note 12: Until one is completely familiar with all sampling techniques, and interpretation of results, three consecutive determinations of the sample gas should be made. If results agree, then the analysis may be considered valid.

Note 13: The system should be checked for leaks prior to use to preclude atmospheric contamination of the sample.

Note 14: The moisture analyzer must be calibrated according to the manufacturer's specified method prior to use.

Electronic Ammonia Water Measurement

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.1-93 (Reapproved 1101)
STANDARD FOR ARGON (Ar), BULK LIQUID, 99.998% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1978; previously published in 1993.

1 Description

1.1 Argon is the most abundant member of the rare gas family. It is monatomic and is characterized by its extreme chemical inactivity. Argon is a colorless, odorless and tasteless gas somewhat soluble in water. It is normally delivered and stored as a cryogenic liquid.

2 Specifications

QUALITY: 99.998%

Impurities	*Maximum Acceptable Level (ppm)**
Carbon monoxide and carbon dioxide ($CO + CO_2$)	0.5
Hydrogen (H_2)	1
Nitrogen (N_2)	10
Oxygen (O_2)	2
Particles	**
Total Hydrocarbons expressed as Methane (THC)	0.5
Water (H_2O) (v/v)	1
TOTAL LISTED IMPURITIES	15

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.
** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	39.948	39.948
Boiling point at 1 atm	-185.9°C	-302.6°F
Density of gas at 21.1°C (70°F) and 1 atm	1.656 kg/m^3	0.1034 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	1.38	1.38
Density of liquid at boiling point	139 kg/m^3	8.698 lb/ft^3

4 Analytical Procedures (See Notes 1 and 2.)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in argon using a gas chromatograph with a flame ionization detector and methanizer.

4.1.1 *Detection Limit* — 100 ppb.

4.1.2 *Instrument Parameters*

4.1.2.1 Column: Porapak T or Q, 3 m (9.8 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or

Chromosorb 102, 2 m (6.6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 0.5 to 2.0 mL.

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standard* — 1–5 ppm carbon monoxide, 1–5 ppm carbon dioxide, balance argon.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

4.1.4.4 Compare the average peak area of the calibration standard to that of the argon sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.2 *Hydrogen and Nitrogen* — This procedure is for the determination of hydrogen and nitrogen in argon using a gas chromatograph with a helium ionization detector.

4.2.1 *Detection Limit* — 0.5 ppm.

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 5A molecular sieve, 65.6 m (20 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 1.0 to 3.0 mL.

4.2.2.4 Temperatures:

Detector	125°C
Column Oven	25°C

4.2.3 *Calibration Standard* — 1–5 ppm hydrogen in argon, 10–30 ppm nitrogen in argon.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.3 Repeat 4.2.4.1. (See NOTE 1.)

4.2.4.4 Compare the average peak area of the calibration standard to that of the argon sample being tested. Calculate the concentrations of hydrogen and nitrogen, using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in argon using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb.

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 3–15 ppm oxygen in argon or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the sample flow setting once established.

4.3.4.2 Introduce argon sample and record oxygen reading. The result may not exceed the specification in Section 2 of this standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in argon using a continuous flow flame ionization detector equipped with a total hydrocarbon analyzer. (See Notes 3, 4, and 5.)

4.4.1 *Detection Limit* — 0.1 ppm.

4.4.2 *Flow Requirements*

4.4.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen: 35–40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75–80 mL/min.

4.4.2.2 Dry, hydrocarbon-free (less than 0.1 ppm) air: 350-400 mL/min.

4.4.2.3 Set sample flow rates in accordance with instrument manufacturer's instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Zero argon with known quantity of hydrocarbons at 0.1 ppm level.

4.4.3.2 The upper level span gas not exceeding 5 times the concentration of the specification.

4.4.4 *Operating Procedure*

4.4.4.1 Do not change the flow settings for hydrogen, air and sample, once established.

4.4.4.2 Introduce the zero argon with known quantity of hydrocarbons and, using the 0–10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

NOTE 3: The 0–1 range can be used provided that zero and span gas standards in argon with known levels of hydrocarbons between 0–1 ppm are used in the calibration of the analyzer.

4.4.4.3 Introduce the span gas standard in argon and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

NOTE 4: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

4.4.4.4 Introduce argon sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

NOTE 5: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the common hydrocarbon impurities in argon can be totaled accurately and compared to methane.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in argon using a continuous flowing piezoelectric hygrometer.

4.5.1 *Detection Limit* — 0.1 ppm (vol/vol) or –90°C (–130°F).

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

NOTE 6: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently by another analytical method.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the argon sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this standard.

SEMI C3.14-94 (Withdrawn 0701)
STANDARD FOR ARGON (Ar) IN CYLINDERS, 99.998% QUALITY

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Argon is the most abundant member of the rare gas family. It is monatomic and is characterized by its extreme chemical inactivity. Argon is a colorless, odorless and tasteless gas somewhat soluble in water, normally delivered and stored as a cryogenic liquid.

SEMI C3.46-93
STANDARD FOR ARGON (Ar), BULK LIQUID, 99.9992% QUALITY

4 Analytical Procedures (See Notes 1, 2)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in argon using a gas chromatograph with a flame ionization detector and methanizer.

4.1.1 *Detection Limit* — 100 ppb (mole/mole).

4.1.2 *Instrument Parameters*

4.1.2.1 Column:

Porapak T or Q, 3 m (9.8 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or

Chromosorb 102, 2 m (6.6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 0.5 to 2.0 mL.

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standard* — 0.2–1 ppm (mole/mole) carbon monoxide, 0.2–1 ppm (mole/mole) carbon dioxide, balance argon.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak area of the calibration standard to that of the argon sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.2 *Hydrogen and Nitrogen* — This procedure is for the determination of hydrogen and nitrogen in argon using a gas chromatograph with a helium ionization detector.

4.2.1 *Detection Limit* — 0.5 ppm (mole/mole).

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 5A molecular sieve, 65.6 m (20 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 1.0 to 3.0 mL.

4.2.2.4 Temperatures:

Detector	125°C
Column Oven	25°C

4.2.3 *Calibration Standard* — 1–5 ppm (mole/mole) hydrogen in argon, 5–25 ppm (mole/mole) nitrogen in argon.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the argon sample being tested. Calculate the concentrations of hydrogen and nitrogen, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in argon using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb (mole/mole).

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 0.5–2.5 ppm (mole/mole) oxygen in argon or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce argon sample and record oxygen reading. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in argon using a continuous flow flame ionization detector equipped with a total hydrocarbon analyzer. (See Notes 3, 4, 5)

4.4.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.4.2 *Flow Requirements*

4.4.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen: 35–40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75–80 mL/min.

4.4.2.2 Dry, hydrocarbon-free (less than 0.1 ppm) air: 350–400 mL/min.

4.4.2.3 Set sample flow rates in accordance with instrument manufacturer's instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Zero argon with known quantity of hydrocarbons at 0.1 ppm level.

4.4.3.2 The upper level span gas not exceeding 5 times the concentration of the specification.

4.4.4 *Operating Procedure*

4.4.4.1 Do not change the flow settings for hydrogen, air and sample, once established.

4.4.4.2 Introduce the zero argon with known quantity of hydrocarbons and, using the 0–10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.4.4.3 Introduce the span gas standard in argon and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.4.4.4 Introduce argon sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in argon using a continuous flowing piezoelectric hygrometer. (See Note 6)

4.5.1 *Detection Limit* — 0.1 ppm (vol/vol) or -90°C (-130°F).

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the

range of interest. Verify the standards employed independently by another analytical method.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the argon sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this Standard.

4.6 *Notes*

Note 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

Note 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

Note 3: The 0–1 range can be used provided that zero and span gas standards in argon with known levels of hydrocarbons between 0–1 ppm are used in the calibration of the analyzer.

Note 4: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

Note 5: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the common hydrocarbon impurities in argon can be totaled accurately and compared to methane.

Note 6: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

Oxygen (O_2) + Argon (Ar)	5
Phosphine (PH_3)	10
Water (H_2O)	4
TOTAL LISTED IMPURITIES	533

Metals — See NOTE 2.

Particles — See NOTE 2.

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

NOTE 2: To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	77.946	77.946
Boiling point at 1 atm	-62.48°C	-80.46°F
Density of gas at 20°C (68°F) and 1 atm	3.243 kg/m^3	0.202 lb/ft^3
Specific gravity of gas at 21.1°C (70°F) and 1 atm (air = 1)	2.695	2.695
Density of liquid at B.P.	1653 kg/m^3	103.96 lb/ft^3

4 Analytical Procedures

4.1 *Carbon Monoxide, Carbon Dioxide, and Hydrocarbons (methane, ethane, ethylene, acetylene)* — This procedure is for the determination of carbon monoxide, carbon dioxide, and hydrocarbons in arsine using a gas chromatograph with a methanizer and a flame ionization detector. (See Note 1 and Figure 1.)

4.1.1 *Detection Limit* — 0.1 ppm each impurity.

4.1.2 *Instrument Parameters*

4.1.2.1 Column: Porapak QS, 3.5 m (12 ft) by 2 mm ID (1/8 in OD) ss or equivalent.

4.1.2.2 Carrier Flow: 35 mL/min helium.

4.1.2.3 Support Gases: Set the flow rates as specified by the instrument manufacturer.

Hydrogen:	30 mL/min added to the carrier gas between the column outlet and the methanizer inlet.
Air:	500 mL/min.

4.1.2.4 Temperatures:

Detector	110°C
Injector	40°C
Oven	40°C
Methanizer	370–400°C

4.1.2.5 Sample Volume: 3 mL.

4.1.3 *Calibration Standards* — 1–10 ppm each: carbon monoxide, carbon dioxide, methane, ethane, ethylene, and acetylene; balance helium.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. Order of elution is carbon monoxide, methane, carbon dioxide, acetylene, ethylene, ethane.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Vent the arsine after the ethane peak. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to those of the arsine sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

4.2 *Phosphine* — This procedure is for the determination of phosphine in arsine using a gas chromatograph with a thermal conductivity detector.

4.2.1 *Detection Limit* — 5 ppm (mol/mol).

4.2.2 *Instrument Parameters*

4.2.2.1 Column: Porapak QS, 3.5 m (12 ft) by 2 mm ID (1/8 in OD) ss or equivalent.

4.2.2.2 Carrier Flow: 35 mL/min helium.

4.2.2.3 Temperatures:

Detector	80°C
Injector	40°C
Oven	40°C

4.2.2.4 Sample Volume: 3 mL.

4.2.3 *Calibration Standard* — 10–50 ppm (mol/mol) phosphine, balance helium.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample being tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the arsine sample being tested. Calculate the concentration of phosphine, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

4.3 *Hydrogen, Nitrogen and Oxygen + Argon* — This procedure is for the determination of hydrogen, nitrogen, oxygen + argon in arsine using a gas chromatograph with a helium ionization detector.

4.3.1 *Detection Limits* — 100 ppb (mol/mol) hydrogen, 100 ppb oxygen + argon, 500 ppb nitrogen.

4.3.2 *Instrument Parameters*

4.3.2.1 Columns:

Column 1:	Porapak QS, 2.5 m (8 ft) by 3.2 mm (1/8 in) ID ss or equivalent
Column 2:	Molecular Sieve 5A, 3 m (10 ft) by 3.2 mm ID ss or equivalent.

4.3.2.2 Carrier Flow: 25 mL/min helium.

4.3.2.3 Temperatures:

Detector	10°C
Injector	30°C
Oven	30°C

4.3.2.4 Sample Volume: 3 mL.

4.3.3 *Calibration Standard* — 1–10 ppm nitrogen, 1–10 ppm oxygen, 1–10 ppm argon, 10–100 ppm hydrogen, balance helium.

4.3.4 *Operating Procedure*

4.3.4.1 Determination of the backflush time: Inject a methane sample (1–1000 ppm, balance helium) using a 10 port gas valve and backflush at different times. Select the backflush time so that the methane peak is split by the backflush.

4.3.4.2 Inject the calibration standard into the column using the same gas valve. Backflush at the time determined in 4.3.4.1 and record retention times and peak areas. Order of elution is hydrogen, oxygen + argon and nitrogen.

4.3.4.3 Inject the sample being tested in same manner as the calibration standard. Record the retention times and peak areas.

4.3.4.4 Repeat 4.3.4.2.

4.3.4.5 Compare the average peak areas of the calibration standard to those of the arsine sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

4.4 *Hydrogen Sulfide* — This procedure is for the determination of hydrogen sulfide in arsine using gas a chromatograph with a flame photometric detector.

4.4.1 *Detection Limit* — 0.1 ppm (mol/mol).

4.4.2 *Instrument Parameters*

4.4.2.1 Column: Porapak QS 3.5 m (12 ft) by 2 mm ID (1/8 in OD) ss or equivalent.

4.4.2.2 Carrier Flow: 35 mL/min helium. Set the flow rates as specified by the instrument manufacturer.

4.4.2.3 Support Gases:

Hydrogen:	30 – 40 mL/min.
Air:	300 – 400 mL/min.

4.4.2.4 Temperatures:

Detector	75°C
Injector	40°C
Oven	40°C

4.4.2.5 Sample Volume: 1.5 mL.

4.4.3 *Calibration Standard* — 1–10 ppm hydrogen sulfide, balance helium.

4.4.4 *Operating Procedure*

4.4.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention time and peak area.

4.4.4.2 Inject the sample being tested in the same manner as the calibration standard. Vent before arsine peak is eluted using same configuration as in Figure 1.

4.4.4.3 Repeat 4.4.4.1

4.4.4.4 Compare the average peak area of the calibration standard to those of the arsine sample being tested. Calculate the concentration of the hydrogen sulfide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.5 *Water* — This procedure is for the determination of moisture in arsine using continuous flow electrolysis of water in a phosphorus pentoxide (P_2O_5) cell.

4.5.1 *Detection Limit* — 1 ppm (vol/vol).

4.5.2 *Instrument Parameters*

4.5.2.1 *Flow Requirements* — Set the sample flow rate and pressure in accordance with manufacturer's instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently on a condensation dewpoint/frostpoint hygrometer.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain representative sample of gas to be analyzed and direct to unit as with the standards.

4.5.4.2 Determine the moisture content in the sample gas by comparing the indicated concentration with the calibration curve constructed in 4.5.3. The result may not exceed the specification in Section 2 of this Standard.

NOTE 1: Carrier gases should contain less than 0.1 ppm (mol/mol) carbon monoxide and less than 0.1 ppm (mol/mol) carbon dioxide.

SEMI C3.51-1101
SPECIFICATION FOR BORON TRICHLORIDE (BCl_3), 99.98% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1995.

1 Purpose

1.1 To define the specification and analytical methods and validate the specifications for BCl_3.

2 Scope

2.1 This specification relates to a geometry of 0.5 μ or less (0.35 to 0.5 range) and describes analytical techniques using gas phase analysis.

3 Description

3.1 Boron trichloride is a colorless toxic and corrosive gas at room temperature and atmospheric pressure which fumes in the presence of moist air. It has a choking odor.

4 Referenced Standards

4.1 *ISO Standards*[1]

ISO 6145-1 — Preparation of calibration gas mixtures – Dynamic volumetric methods – Part 1: Methods of calibration

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Specifications

Quality: 99.98% vapor phase

Impurities	*Maximum Acceptable Level (ppm)**
Nitrogen (N_2)	5
Carbon Dioxide (CO_2)	2
Chlorine (Cl_2)	10
Hydrogen Chloride (HCl)	100
Phosgene ($COCl_2$)	1
Silicon Tetrachloride ($SiCl_4$)	2
* TOTAL LISTED IMPURITIES (excluding metals)	120
Iron (Fe)	0.5 wt.
Nickel (Ni)	0.5 wt.

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and precision of the provided procedure.

6 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	117.17	117.17
Boiling point at atm	12.4°C	54.3°F
Density of gas at 20°C and 1 atm	5.326 kg/m^3	0.3325 lb/ft^3
Specific gravity	4.12	4.12
Density of liquid at –18°C	1372.8 kg/m^3	85.76 lb/ft^3

7 Analytical Procedures

NOTE 2: The boiling point of boron trichloride is 12.4°C. It is recommended that, prior to the sampling operation, the cylinder should be allowed to reach room temperature to prevent the possibility of any suck-back.

7.1 *Nitrogen* — This procedure is for the determination of nitrogen in boron trichloride using a gas chromatograph fitted with a backflush valve and a thermal conductivity detector.

7.1.1 *Detection Limits* — 0.5 ppm nitrogen.

7.1.2 *Instrument Parameters*

7.1.2.1 Columns:

Column 1:	Porapak QS 60/80 mesh 2 m (6 ft) × 3.2 mm (1/8") OD SS or equivalent.
Column 2:	Molecular sieve 5A 60/80 mesh 2 m (6 ft) × 3.2 mm (1/8") OD SS or equivalent.

7.1.2.2 *Carrier Gas Flow* — Helium N6.0 Flow 25 mL/min

NOTE 3: The helium carrier gas should contain less than 10 ppb of the impurities it is desired to measure. This is best achieved by using a commercial helium gas purifier.

7.1.2.3 *Sample Volume* — 2.5 mL.

1 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

7.1.2.4 *Temperatures*:

Column Temperature	100°C
Detector Temperature	100°C

7.1.2.5 *Bridge Current* — 200 mA.

7.1.3 *Calibration Standard* — 1–10 ppm nitrogen in helium.

7.1.3.1 *Calibration* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

7.1.4 *Operating Procedure*

7.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Adjust the backflush valve operation sequence to present the nitrogen. Record the retention time and peak area. A sample chromatogram is shown in Figure 1.

NOTE 4: Introduce the calibration standard as many times as necessary to achieve the desired precision.

7.1.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention time and peak areas (see Note 2).

7.1.4.3 Repeat Section 7.1.4.1.

7.1.4.4 Compare the average peak areas of the nitrogen in the calibration standard to that of the boron trichloride sample being tested. Calculate the concentration of nitrogen using the formula below. The results may not exceed the specification in Section 5 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

7.2 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in boron trichloride using a gas chromatograph fitted with a backflush and a thermal conductivity detector.

7.2.1 *Detection Limits* — 0.5 ppm carbon dioxide.

7.2.2 *Instrument Parameters*

7.2.2.1 *Columns*:

Column 1	Porapak QS 60/80 mesh 3m (10 ft.) by 3.2 mm (1/8") OD SS or equivalent
Column 2	Porapak QS 60/80 mesh 2.5 m (8 ft.) by 3.2 mm (1/8") OD SS or equivalent

7.2.2.2 *Carrier Gas Flow* — Helium N6.0 flow 25 mL/mm (See Note 3.)

7.2.3 *Sample Volume* — 2.5 mL.

7.2.4 *Temperatures*:

Column Temperature	60°C
Detector Temperature	110°C

7.2.5 *Bridge Current* — 200 mA.

7.2.6 *Calibration Standard* — 1–5 ppm carbon dioxide in helium.

7.2.6.1 *Calibration* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

7.2.7 *Operating Procedure*

7.2.7.1 Inject the calibration standard into the column using a gas sampling valve. Adjust the backflush valve operation sequence to present the carbon dioxide peak. Record the retention time and peak area. A sample chromatogram is shown in Figure 2 (see Note 4).

7.2.7.2 Inject the sample to be tested in the same manner as the calibration standard (see Note 2). Record the retention time and peak areas.

7.2.7.3 Repeat Section 7.2.7.1.

7.2.7.4 Compare the average peak areas of the carbon dioxide in the calibration standard to that in the boron trichloride sample being tested. Calculate the concentration of carbon dioxide using the formula below.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

7.3 *Chlorine* — This procedure is for the analysis of chlorine in boron trichloride using a gas chromatograph with a thermal conductivity detector.

7.3.1 *Detection Limits* — 5 ppm chlorine.

7.3.2 *Instrument Parameters*

7.3.2.1 Column 60 m (200 ft.) 0.53 mm (1/32") ID Dimethyl silicone megabore capillary column (Ristek RTxi)

7.3.2.2 *Carrier Gas* — Helium: N6.0 25–30 mL/min (See Note 3.)

7.3.2.3 *Sample Volume* — 2.0 mL.

7.3.2.4 *Temperatures*:

Column Temperature	100°C
Detector Temperature	110°C

7.3.2.5 *Bridge Current* — 200 mA.

7.3.3 *Calibration Standard* — 5–10 ppm chlorine in helium.

7.3.3.1 *Calibration* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

7.3.4 *Operating Procedure*

7.3.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area. A sample chromatogram is shown in Figure 3 (see Note 4).

7.3.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention time and peak areas (see Note 2).

7.3.4.3 Repeat Section 7.3.4.1.

7.3.4.4 Compare the average peak areas of the chlorine in the calibration standard with that obtained in the boron trichloride sample being tested. Calculate the concentration of chlorine using the formula below. The results may not exceed the specification in Section 5 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

7.4 *Hydrogen Chloride, Phosgene, and Silicon Tetrachloride* — This procedure is for the determination of hydrogen chloride, phosgene, and silicon tetrachloride using a Fourier transform infra red (FTIR) analyzer.

7.4.1 *Detection Limits*

10 ppm hydrogen chloride

1 ppm phosgene

0.5 ppm silicon tetrachloride

7.4.2 *Instrument Parameters*

7.4.2.1 *Cell Path Length* — 16 cm × 16 mm ID K Br windows

7.4.2.2 *Wavenumbers*:

Hydrogen Chloride	2970–2990 (cm^{-1})
Phosgene	855–865 (cm^{-1})
Silicon Tetrachloride	610–630 (cm^{-1})

7.4.2.3 The associated sampling system must be equipped with inert gas purging and evacuation capabilities.

7.4.3 *Calibration Standards* — Prepare calibration standards for 10–100 ppm hydrogen chloride, 1–5 ppm phosgene, and 0.5–5 ppm silicon tetrachloride in boron trichloride.

NOTE 5: To ensure stability, the hydrogen chloride calibration standard should be prepared dynamically using a method defined in ISO 6145/part 1.1986. Phosgene and silicon tetrachloride standards may be prepared by syringe additions to liquid boron trichloride in the cooled sealed container.

7.4.4 *Operating Procedures*

7.4.4.1 Evacuate and purge the sampling system leading to the cell and purge the cell with dry nitrogen for 30 minutes. Fill the cell with calibration standard. Record the absorbance of hydrogen chloride, phosgene, and silicon tetrachloride. A sample spectrum is shown in Figures 4A, 4B, and 4C.

7.4.4.2 Fill the sample into the cell following the same procedures used in Section 7.4.4.1 above. Record the absorbance at the same wave number as the calibration standard. Calculate the concentrations of hydrogen chloride, phosgene, and silicon tetrachloride. The results should not exceed the amount specified in Section 3 of this specification.

$$\frac{\begin{matrix}\text{Measured}\\ \text{Absorbance of}\\ \text{the Sample}\end{matrix}}{\begin{matrix}\text{Measured}\\ \text{Absorbance of}\\ \text{the Standard}\end{matrix}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

NOTE 6: The following method should be adopted for cleaning metallic parts used for sampling hydrogen chloride gas:

a. Clean in a bath with methanol or isopropanol.

b. Ultrasonic clean in an appropriate solvent.

c. Rinse with isopropanol under Class 100 bench.

This cleaning method should be applied when a new cylinder has to be connected and repeated after ten samplings, or if a new cylinder has to be connected.

NOTE 7: Low-pressure plastic parts should be cleaned as follows using 18 MΩcm water:

a. Fill sampling lines with the following solutions for 30 minutes: NH_4OH 25%: H_2O_2 35%: H_2O = 1 to 1 to 5 parts by vol.

b. Wash sampling lines 5 times with water.

c. Fill sampling lines with the following solutions for 30 minutes: HCl 37%: H_2O_2 35%; H_2O = 1 to 1 to 5 parts by vol.

d. Wash sampling lines a minimum of 5 times with water. Terminate if the resistivity of the wash water from the lines is more than 18 MΩcm.

Cleaning of lines, flow meters and valves shall be completed before a new cylinder has to be analyzed and shall be repeated after 10 samplings, or if a new cylinder has to analyzed. The impingers must be rinsed with water after each sampling. Before a new cylinder has to be analyzed and after five samplings, the impingers must be cleaned using the above described procedures. Drying of the impingers is not recommended (contamination risks).

NOTE 8: Cleaning of cylinder valve.

Clean outside (visible parts, threads) with wipe. Clean the interior parts of the valve-outlet with methanol or isopropanol using a syringe, followed by a purge with filtered gas.

7.5 *Iron and Nickel* — This procedure is for the determination of iron and nickel in gas phase boron trichloride using atomic absorption or inductive coupled plasma methods.

7.5.1 *Detection Limits*

7.5.2 *Instrument Parameters* — Operate the designated analytical instruments according to the manufacturer's instructions.

7.5.3 *Sampling Procedure*

7.5.3.1 Clean all metallic and plastic components according to the procedures described in Notes 6 and 7. Use 18 MΩcm water.

7.5.3.2 Connect all components of the sampling system.

NOTE 9: The apparatus is charged with sufficient water to just cover the rim of the funnel (approximately 100 ml). A magnetic stirrer is introduced and the apparatus closed.

7.5.3.3 Connect the sampling system to the sample boron trichloride cylinder (see Note 8).

7.5.3.4 Purge with filtered argon (< 0.01 µ) at approximately 1 L/min. for 15 minutes prior to sampling. During this period, the apparatus is inclined so as to allow a higher flow rate without excessive agitation of the water.

NOTE 10: Due to the design of the apparatus, suck-back should be prevented, but this must be guarded against. A bubble rate of about one per second should be set.

7.5.3.5 While observing the sampling apparatus, operate the needle valve to admit sample slowly to the sampling apparatus. Initial absorption will be fast.

7.5.3.6 The sample flow is halted when no further absorption seems to be taking place (i.e., when bubble rate increases at the vent).

7.5.3.7 The argon purge is re-established for a further 15 minutes.

7.5.3.8 The apparatus is allowed to cool and the contents quantitatively transferred to a 250 ml polypropylene flask.

NOTE 11: The solution prepared above will contain some crystals of boric acid which have come out of solution during cooling. For the purpose of analysis, the concentration of boric acid must be reduced. Also the amount of BCl_3 samples need to be determined.

7.5.3.9 A 5 ml aliquot of the solution is titrated against 1 M NaOH using methyl red as an indicator. The quantity of sample boron trichloride taken is then calculated.

7.5.3.10 A sample of the solution is diluted × 10 with water. The aliquot is taken from the supernatant liquid.

7.5.3.11 Analysis is carried out in a suitable analyzer capable of meeting the required detection limits. A blank solution of 1% hydrochloric acid is used. Yttrium is used as an internal standard at a level of 0.2 ppm added to all analysis solutions.

7.5.3.12 Calibration curves are prepared using standard solutions covering the elements required. Traceable standards can be obtained from national and international bodies.

7.5.3.13 Calculate the concentration of iron and nickel content using the calibration curve and the volume of boron trichloride sampled.

SEMI C3.27-94
STANDARD FOR BORON TRIFLUORIDE (BF_3) IN CYLINDERS,99.0% QUALITY

1 Description

Boron trifluoride is a colorless gas. It fumes in moist air and has a pungent odor. Boron trifluoride is nonflammable and does not support combustion.

2 Specifications

QUALITY: 99.0%

Impurities	*Maximum Acceptable Level (ppm)**
Gases not soluble in water	0.94%
Particles	**
Silicon Tetrafluoride (SiF_4)	200
Sulfur Dioxide (SO_2)	21
Total Sulfates (SO_4^{-2})	7
TOTAL IMPURITIES	9628

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	67.81	67.81
Boiling point at 1 atm	-100.4°C	-149.0°F
Density of gas at 70°C (21.1°F) and 1 atm	3.076 g/L	0.192 lb/ft^3
Specific gravity of gas	2.7	2.7
Critical pressure	49.2 atm	723 psia
Critical Temperature	-12.25°C	9.95°F

4 Analytical Procedures

4.1 *Sampling Procedures* — Boron trifluoride is sampled separately for water-soluble gases and water-insoluble gases. The water-soluble components are collected in a plastic bottle which contains chopped ice. After the ice melts, weighed aliquots of the solution are taken for individual determinations. The water-insoluble components are collected in a modified gas collection tube.

4.1.1 *Apparatus*

4.1.1.1 Balance, l000-g capacity, capable of weighing to 0.01 g.

4.1.1.2 Polyethylene bottles (wide mouth, 1-L capacity) with caps.

4.1.1.3 Tygon[R] tubing, 6 mm (1/4 in).

4.1.1.4 PTFE tubing, 6 mm (1/4 in).

4.1.1.5 Valve assembly consisting of a needle valve with a stainless steel needle, a steel bushing and steel coupling with a steel gas cylinder connection; a gas take-off consisting of a steel sleeve from the valve with steel pipe leading to a 61 cm Tygon delivery tube. The delivery tube is a temporary connection and is replaced as needed (see Figure 1).

4.1.1.6 Trap: 1-liter polyethylene bottle fitted with a 2-hole Neoprene stopper and two 4-inch pieces of 1/4" PTFE tubing which do not extend below the stopper by more than 1 inch. The Tygon delivery tube is attached to one of the PTFE tubes in the stopper (Inlet to Trap). A 61 cm length of Tygon tubing is attached to the second piece of PTFE tubing in the stopper (Outlet from Trap). The trap is supported with a clamp and ring stand.

4.1.1.7 Modified gas collecting tube (see Figure 2); 250-mL Pyrex sampling tube (modified with a graduated scale on one end).

4.1.2 *Reagents*

4.1.2.1 Distilled-water ice, cracked.

4.1.2.2 Nitrogen, dry; 35 ppm water, or less.

4.1.3 *Operating Procedure* — Water-Insoluble Components

CAUTION: Perform all work in a hood.

4.1.3.1 Prepare the gas-collecting tube by washing with distilled water, rinsing with acetone, then drying in an air oven at 100–125°C. Flush with dry nitrogen for about one minute. Leave filled with dry nitrogen; close the stopcocks.

4.1.3.2 Connect the needle valve assembly apparatus to the cylinder to be tested.

4.1.3.3 Attach the gas-collecting tube to the valve nipple with a short piece of dry Tygon tubing.

4.1.3.4 Open the cylinder valve, open the gas collecting tube stopcocks, and very carefully crack open the needle valve.

4.1.3.5 Purge the tube for 5 minutes with a slow stream of BF_3 gas.

4.1.3.6 Close the needle valve, close the gas-collecting tube stopcocks, and then close the cylinder valve.

4.1.3.7 Proceed with the analysis, after removing the gas-collecting tube from the valve nipple.

4.1.4 *Operating Procedure* — Water Soluble Components

CAUTION: Perform all work in a hood.

4.1.4.1 Before attaching the Tygon delivery tube, purge the sampling valve system for 1 minute with a slow stream of boron trifluoride from the cylinder. Use a separate piece of tubing when purging.

4.1.4.2 Weigh an empty 1-L polyethylene bottle with cap to the nearest 0.01 g. Record this weight as A.

4.1.4.3 Fill the bottle with about 400 g of cracked, distilled-water ice. Re-weigh the bottle with cap to the nearest 0.01 g; record as weight B.

4.1.4.4 A sampling line is used to transfer BF_3 gas from the cylinder to the sample bottle.

4.1.4.5 Connect the Tygon delivery tube from the sampling valve apparatus to the trap. Support the Tygon tubing from the trap outlet; then open the needle valve and adjust until a steady flow of BF_3 is obtained. Insert this Tygon tubing (from the trap outlet) into the polyethylene sample bottle, extending down to the bottom of the bottle. Carefully introduce the BF_3 into the ice until most of the ice is melted, then close the needle valve and remove the Tygon tubing. Remove the sample bottle and cap it. Re-weigh the bottle, cap and contents to the nearest 0.01 g. Record this weight as C.

4.1.4.6 Mix thoroughly by careful inversion until all of the ice melts, being certain to keep the plastic bottle tightly capped so that none of the liquid is lost.

4.1.4.7 Proceed with the determination of water-soluble components, being sure to do the sulfur dioxide first, since opening the bottle repeatedly may result in a considerable loss of sulfur dioxide.

4.1.4.8 Calculations for sample size:

B-A = Grams of Ice (H_2O)

C-A = Weight of Solution (BF_3 Solution)

C-B = Weight of Water-soluble Material (grams of BF_3 gas)

$$\frac{\text{Grams of } BF_3 \text{ Gas}}{\text{Grams of Solution}} = \frac{C - B}{C - A} = F$$

$$\frac{\text{Grams } BF_3 \text{ needed for Method}}{F} = \frac{\text{Grams Solution}}{\text{Needed for Method}}$$

4.2 *Air* — This procedure describes the determination of insoluble gases in boron trifluoride gas. A known volume of boron trifluoride gas is absorbed in sodium chloride solution, then any undissolved gases remaining are measured and calculated as % air.

4.2.1 *Method Capabilities* — The range of this method is 0.05% to 2.3% (mole/mole).

4.2.2 *Apparatus*

4.2.2.1 The modified gas collecting tube shown in Section 4.1.1.7, Figure 2.

4.2.2.2 Separatory funnel, 2000-mL Pyrex (with 61-cm Tygon[R] tubing and pinch clamp attached to stopcock end).

4.2.2.3 Tygon tubing, 1/4 inch.

4.2.2.4 Balance, capable of weighing 1000 grams to 0.01 gram.

4.2.3 *Reagents* — All reagents used are reagent grade unless otherwise indicated.

4.2.3.1 Water. All water used in the preparation of reagents and in the procedure is either distilled or deionized.

4.2.3.2 Sodium chloride solution. Dissolve 300 g of sodium chloride in 1 liter of water.

4.2.4 *Calibration* — Gas Collecting Tube

4.2.4.1 Weigh the gas collecting tube to the nearest 0.1 g; weight - A, then clamp the tube securely on a ringstand with the calibrated stem up.

4.2.4.2 Fill the tube with distilled water and allow it to stand with the top stopcock open until it has reached room temperature.

4.2.4.3 Record the room temperature to the nearest 0.01°C; temperature - °C.

4.2.4.4 Close the top stopcock. Drain and dry both of the outer stems. Weigh the water-filled collecting tube to the nearest 0.1 g; weight - B.

4.2.4.5 The net weight of the water in the tube (B-A) in grams is equal to the volume of the tube in milliliters, corrected for the density of water at temperature °C. Determine this volume as follows:

$$\text{Volume in mL } - \frac{(B - A)}{D - E}$$

where D - Density (g/mL) of water at temperature °C (from Table 1).

Table 1 Density vs T°C for Water

Temp. °C	*Density g/mL*
20	0.99823
21	0.99802
22	780
23	756
24	732
25	0.99707
26	681
27	654
28	626
29	597
30	567

4.2.5 *Procedure*

4.2.5.1 Obtain the sample of BF_3 gas in the gas collecting tube. See Section 4.1.3 for sampling details.

4.2.5.2 Fill the separatory funnel with sodium chloride solution. Attach Tygon tubing and a pinch clamp to the funnel.

4.2.5.3 With a small dropper, fill the glass tubing leading to the stopcock opposite the calibrated end of the gas collecting tube with the salt solution. (Note: the gas collecting tube is inverted at this point.)

4.2.5.4 Open the separatory funnel stopcock and the pinch clamp on the Tygon tubing. Hold the tubing upright and when it completely fills with NaCl solution, slip the tubing onto the end of the gas collecting tube which was previously filled in step 4.2.5.3. (See Note 1.)

4.2.5.5 Hold the gas collecting tube vertical, with the calibrated end up and the entire collecting tube below the liquid level of the separatory funnel.

4.2.5.6 Open the lower stopcock of the gas collecting tube carefully and shake the tube to aid in dissolving of the BF_3 gas in the salt solution.

4.2.5.7 Bring the liquid level in the gas collecting tube equal to the liquid level in the separatory funnel.

4.2.5.8 Read and record the volume of undissolved gas in the upper calibrated end of the gas collecting tube and record this volume, to the nearest one-tenth of a milliliter; mL - F. Record the room temperature.

4.2.6 *Calculations*

4.2.6.1 F = Total milliliters of undissolved gas (from Section 4.2.5.8).

4.2.6.2 E = Total volume of gas collecting tube in mL; see Calibration — Gas Collecting Tube.

4.2.6.3

$$\frac{F}{E} \times 100 = \%air$$

Report to the nearest 0.01%.

4.3 *Sulfur Dioxide* — This procedure describes the determination of sulfur dioxide in boron trifluoride gas. A sample of the solution prepared in Section 4.1.4 is titrated with standard iodine solution to a starch end-point (blue). The sulfur dioxide is determined from the equivalents of iodine used in the titration.

4.3.1 Method Capabilities: The range of this method is 5 ppm to 1500 ppm (mole/mole).

4.3.2 *Apparatus*

4.3.2.1 Burette, 10 mL, graduated in units of 0.05 mL.

4.3.2.2 Beaker, 250-mL.

4.3.3 *Reagents* — All reagents used are reagent grade unless otherwise specified.

4.3.3.1 Water. All water used in the preparation of reagents and in the procedure is either distilled or deionized.

4.3.3.2 Iodine solution, 0.01 N. Prepare fresh daily and standardize.

4.3.3.3 Starch indicator solution, 10 g/L. Prepare a thin paste of 1 g of soluble starch with water. Pour the paste with constant stirring, into 100 mL of boiling water. Boil for one minute. Allow the solution to cool and add 2.5 g of potassium iodide. Keep the solution in a glass-stoppered bottle. Prepare fresh when the color obtained for end points is violet or red instead of blue. Alternatively, Thyodene dry indicator powder may be used.

4.3.4 *Operating Procedure*

4.3.4.1 Calculate the amount of sample (prepared in Section 4.1.4 that contains about 20 grams of BF_3 gas, rounding off to the nearest milliliter. Calculate the grams of BF_3 gas in this volume to the nearest 0.01 g, using the “F” factor in Section 4.1.4.8. Transfer this amount to a 250-mL beaker and add 5 drops of starch indicator.

4.3.4.2 Using a 10-mL burette graduated in 0.05 mL, titrate with iodine to a starch end-point (blue). Stir constantly with a Teflon stir-bar or equivalent. Record the volume of the iodine solution to the nearest 0.01 mL.

4.3.5 *Calculations*

$$\frac{\text{mL } I_2 \times \text{Normality of } I_2 \times 0.032 \times 1 \times 10^6}{\text{Grams of Water-Soluble Material}} = \text{ppm } SO_2$$

where : 0.032 the milliequivalent weight of SO_2;
1×10^6 is factor for conversion to ppm.

4.4 *Silicon Tetrafluoride* — This procedure describes the determination of silicon tetrafluoride in boron trifluoride gas. This method is based on the reaction of soluble silica with molybdate ion to form a greenish-yellow complex, B-silicomolybdic acid. This complex is then reduced to a blue complex by 1-amino-2-naphthol-4-sulfonic acid. The absorbance is measured at 650 nm and the amount of silicon tetrafluoride present is obtained from a calibration curve.

4.4.1 *Method Capabilities* — The range of this method is 45–450 ppm (mole/mole).

4.4.2 *Apparatus*

4.4.2.1 Photometer: One of the folowing is required, with preference in the order given. (See Note 2.)

a. Spectrophotometer, suitable for measurements at 650 nm.

b. Filter photometer, for measurements from 640 to 700 nm, if less sensitivity is preferred.

c. Fisher Electrophotometer, with a red filter and 23-mm cells.

4.4.2.2 Absorption cells, 1.0-cm light path (for use with a or b above).

4.4.2.3 Plastic beakers, 150-mL capacity.

4.4.2.4 Polyethylene weighing bottle with cap, 250-mL.

4.4.2.5 Plastic volumetric flasks, 100-mL.

4.4.2.6 Plastic pipets, 0, 1.0, 2.0, 3.0, 4.0, 6.0, 8.0 and 10.0-mL sizes.

4.4.3 *Reagents* — All reagents are reagent grade unless otherwise specified.

4.4.3.1 Water. All water used in this method is either distilled or deionized and must be silica-free.

4.4.3.2 Boric acid solution, saturated. Dissolve 70 g of boric acid, H_3BO_3, in 800 mL of hot water. Dilute to 1000 mL and mix. Store in a plastic bottle.

4.4.3.3 Ammonium molybdate solution, 10%. Dissolve 50 g of ammonium molybdate, $(NH_4)_6MO_7O_{24}4H_2O$, in water and dilute to 500 mL. Store in a plastic bottle. Prepare fresh weekly.

4.4.3.4 Sulfuric acid, 5N, H_2SO_4. Carefully pour 35 mL of concentrated sulfuric acid into about 150 mL of water in an ice bath. Cool to room temperature, dilute to 250 mL and mix. Store in a plastic bottle.

4.4.3.5 Tartaric acid solution, 40%. Dissolve 80 g of tartaric acid in 140 mL of water. Dilute to 200 mL and mix. Store in a plastic bottle. Prepare fresh weekly.

4.4.3.6 l-Amino-2-naphthol-4 sulfonic acid solution, 2.5 g/L. Dissolve 30 g of sodium bisulfite in 100 mL of water in a 250-mL beaker. In a 100-mL beaker, dissolve 1 g of sodium sulfite in 25 mL of water and add 0.5 g of 1-amino-2-naphthol-4-sulfonic acid. Mix the two solutions and dilute to 200 mL. Store in a plastic bottle and filter before using. Prepare fresh weekly.

4.4.3.7 Sodium silicate standard solution, 1 mL = 10 micrograms Si. Dissolve 1.012 g sodium silicate (meta), Na_2SiO_3 $9H_2O$, in water in a 100-mL plastic volumetric flask and dilute to volume. Pipet 10.00 mL of this solution, using a polyethylene pipet, into a 1-liter plastic volumetric flask and dilute to volume. One mL of this dilution contains the equivalent of 10 micrograms Si.

4.4.4 *Calibration*

4.4.4.1 To a series of nine 150-mL plastic beakers, pipet 0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, and 10.0 mL of sodium silicate standard solution. These additions correspond to 0, 10, 20, 30, 40, 50, 60, 80, and 100 micrograms of Si.

4.4.4.2 Into each beaker, pipet 25.0 mL of boric acid solution. Dilute to about 60 mL with water and mix.

4.4.4.3 Continue with Procedure Sections 4.4.5.3 – 4.4.5.9. Measure the absorption of each standard and then return to Calibration, Section 4.4.4.4.

4.4.4.4 Subtract the absorbance of the 0 microgram standard from each of the other standard absorbances and plot the net absorbance versus the corresponding micrograms of Si. Draw the best smooth line fitting the points and passing through the origin.

4.4.5 *Procedure* (To be run in triplicate)

4.4.5.1 Calculate the amount of sample prepared in Section 4.1.4 that contains about 0.5 g of BF_3 gas. Transfer this amount to a polyethylene bottle and weigh to the nearest 0.0001 g.

4.4.5.2 Wash this solution into a 150-mL plastic beaker. Add 25 mL of boric acid solution. Dilute to about 60 mL and mix.

4.4.5.3 Add 5 mL of ammonium molybdate solution and mix.

4.4.5.4 Adjust the pH to 1.1 to 1.5 with 5N sulfuric acid. Allow to stand 10 minutes.

4.4.5.5 Transfer the solution to a 100-mL plastic volumetric flask and add 10 mL of tartaric acid solution. Mix well.

4.4.5.6 Add 1 mL of 1-amino-2-naphthol-4-sulfonic acid solution. Dilute to 100 mL and mix. Allow to stand 30 minutes.

4.4.5.7 Prepare a reagent blank by treating a 50-mL aliquot of water as directed in Sections 4.4.5.2 through 4.4.5.6.

4.4.5.8 Set the wavelength of the spectrophotometer to 650 nm.

a. *Single Beam Spectrophotometer* — Rinse and then fill a 1-cm absorption cell with water. Place the cell into the cell holder and adjust the instrument to zero absorbance.

b. *Double Beam Spectrophotometer* — Rinse and then fill two matched 1-cm absorption cells with water and zero the instrument with water in both beams. Keep water in the reference beam and use the other matched cell for the blank, standards and samples.

4.4.5.9 Rinse a second matched 1-cm absorption cell with the blank solution and measure its absorbance. Then, using the same cell, measure the absorbance of each sample solution. Be sure to rinse the cell completely with the solution to be measured before each measurement. Recheck the instrument zero before each measurement.

4.4.5.10 Subtract the blank absorbance from the absorbance of the sample. Determine the corresponding micrograms of Si from the standard curve.

4.4.6 *Calculations*

$$\text{ppm SiF}_4 = \frac{\text{Micrograms of Si} \times 3.706 \times 1,000,000}{\text{Weight of sample} \times 1,000,000}$$

where :

3.706 converts Si to SiF_4

1,000,000 converts ug to g

1,000,000 converts to ppm.

4.5 *Sulfate* — This procedure describes the determination of sulfate in boron trifluoride gas. Sulfate ion is converted to a barium sulfate suspension under controlled conditions in such a manner as to form barium sulfate crystals of uniform size. Solutions are added to stabilize the suspension and minimize interferences. The resulting turbidity is determined by a turbidimeter, filter photometer or spectrophotometer and compared to a curve prepared from standard sulfate solutions.

4.5.1 *Method Capabilities* — The range of the method is 7 to 70 ppm (mole/mole). (See Note 3.)

4.5.2 *Apparatus*

4.5.2.1 Platinum dish, 100-mL capacity.

4.5.2.2 Steam bath (or Argand burner, if available).

4.5.2.3 Photometer: One of the following is required, with preference in the order given:

a. Turbidimeter

b. Spectrophotometer, for use at 420 nm, providing a light path of 4 to 5 centimeters.

c. Filter photometer, equipped with a violet filter having a maximum transmittance near 420 nm and providing a light path of 4 to 5 centimeters.

d. Fisher Electrophotometer, using a #525 Green Filter and 23-mm cells.

4.5.2.4 Stopwatch.

4.5.3 *Reagents* — All reagents used are reagent grade unless otherwise specified.

4.5.3.1 Water. All water used in the preparation of reagents and in the procedure is either distilled or deionized.

4.5.3.2 Sodium carbonate, Na_2CO_3.

4.5.3.3 Hydrochloric acid, concentrated, HC_l.

4.5.3.4 Barium chloride, $BaCl_2$ $2H_2O$.

4.5.3.5 Sodium chloride solution, 10% in water. Dissolve 10 grams sodium chloride in 100 mL water.

4.5.3.6 Gum Arabic Solution. Dissolve 0.5 gram gum arabic (acacia) in 100 mL of water, heat if necessary to dissolve, filter before using. Conditioning Reagent (may be used in place of gum arabic solution): Mix 50 mL glycerol with a solution containing 30 mL concentrated hydrochloric acid, 300 mL water, 100 mL 95% ethyl alcohol or isopropyl alcohol and 75 grams sodium chloride.

4.5.3.7 Standard sulfate solution, 1.00 mL = 0.100 mg SO_4^{-2}. Dissolve 0.1479 grams anhydrous sodium sulfate in 4 water and dilute to 1 L.

4.5.3.8 Sodium hydroxide, 1N, NaOH; dissolve 40 g of sodium hydroxide pellets in water and dilute to 1 L.

4.5.3.9 Nitric acid, concentrated, HNO_3.

4.5.4 *Calibration*

4.5.4.1 Calibrate the photometer according to the manufacturer's instructions.

4.5.4.2 Pipet 0, 1.0, 3.0, 3.0, 4.0, 5.0, 10.0 and 20.0 mL of the 0.100 mg SO_4^{-2} standard into each of eight separate 150-mL beakers. These additions correspond to 0, 0.1, 0.2, 0.3, 0.4, 0.5, 1.0, and 2.0 mg SO_4^{-2}.

4.5.4.3 Follow the Procedure described in Sections 4.5.5.5 through 4.5.5.7.

4.5.4.4 Plot, on linear graph paper, the sulfate ion in grams against the corresponding photometer reading and draw the best smooth line through the points. (See Note 4.)

4.5.5 *Procedure*

4.5.5.1 Weigh a clean platinum dish to 0.0001 g; weight - A.

4.5.5.2 Calculate the amount of sample prepared in Section 4.1.4 that contains about 50 grams of BF_3 gas; transfer this amount to the platinum dish, then weigh the dish to the nearest 0.0001 g; weight - B.

4.5.5.3 Add about 0.1 gram of sodium carbonate and 10 mL of hydrochloric acid to the dish. Evaporate to dryness over a steam bath or an Argand burner. Repeat the evaporation 4 more times with 10-mL portions of hydrochloric acid.

4.5.5.4 Add 1 mL of hydrochloric acid and 5 mL of water to the dish; warm to dissolve any residue. Filter through Fisher G4 or equivalent filter paper in a 55-mm Buchner funnel, then transfer the filtrate to a 150-mL beaker. Wash the filter with water and transfer washings to the same 150-mL beaker.

4.5.5.5 Dilute to approximately 90 mL. Add 1 mL of 10% sodium chloride solution, 1.5 mL of freshly filtered gum arabic solution and mix. Adjust the pH to 1.75 with 1:10 hydrochloric acid or sodium hydroxide (1N). Dilute to 100 mL. (See Note 5.)

4.5.5.6 Place the beaker on a magnetic stirrer and while the solution is being stirred add 1 gram of barium chloride ($BaCl_2$ $2H_2O$) crystals. Begin timing immediately and stir for exactly 1 minute at a constant speed. (See Note 6.)

4.5.5.7 Immediately after the stirring is completed, pour some of the solution into the absorption cell of the photometer. Record the measured turbidity after 4 minutes. (See Note 7.)

4.5.5.8 Prepare a sample blank using the same quantities of all reagents except the barium chloride, which is withheld. Read the blank and obtain the correction.

4.5.5.9 After proper correction for the blank, determine the mg of sulfate from the calibration curve.

4.5.6 *Calculations*

$$\frac{\text{mg } SO_4^{-} \times 1 \times 10^6}{1000\,(B - A) \times F} = \text{ppm } SO_4^{-2}$$

where : F is from Section 4.1.4.8

4.6 *Notes*

Note 1: There should be no air bubbles in the connections between the gas collecting tube and the separatory funnel. A trace of a wetting agent such as Ultrawet (Atlantic Refining Co.) in the salt solution assists in freeing small air bubbles from the walls of connecting tubes.

Note 2: If the photometer being used measures in units other than absorbance, the appropriate conversion to absorbance must be made before calculating any results.

Note: 3 Color or suspended matter in large amounts may interfere with this procedure.

Note 4: A specific calibration curve must be prepared for each photometer. A new curve must be prepared if the instruments cell, lamp, or filter are changed, or if any other significant change in instrument or reagents is made.

Note 5: The conditioning reagent may be substituted for the gum arabic solution. In this case Procedure, Step 4.5.5.5 reads: Add 5.0 mL of conditioning reagent, then dilute to 100 mL with water. Proceed to Step 4.5.5.6.

Note 6: It is recommended that a timer be used to permit the magnetic stirrer to operate exactly one minute with a constant stirring speed. The important point is the speed of stirring and time should be constant for the standards and the samples.

Note 7: If the reading is off the calibration curve, prepare a new curve with standards in the required range, or take a smaller portion of sample.

SEMI C3.57-0600
SPECIFICATION FOR CARBON DIOXIDE, CO_2, ELECTRONIC GRADE IN CYLINDERS

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the European Gases Committee. Current edition approved by the European Regional Standards Committee on April 4, 2000. Initially available at www.semi.org May 2000; to be published June 2000.

1 Description

1.1 Carbon dioxide is a non-flammable, colorless, odorless, slightly acidic gas which is stable under normal conditions.

2 Specifications

Purity: 99.999%

Impurities	*Maximum Acceptable Level*
Nitrogen	4 ppm
Oxygen	1 ppm
Methane	0.5 ppm
Moisture	2 ppm

3 Referenced Standards

3.1 *DIN Standard*[1]

DIN 50457-1

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Physical Constants (for information only)

Formula	CO_2
Molecular weight	44
Melting point	-56.6°C
Boiling point	-78.5(s)°C
Critical temperature	30°C
Relative density, gas	1.52 (air=1)
Relative density, liquid	0.82 (water=1)
Vapor pressure 20°C	57.3 bar
Appearance/Color	Colorless gas
Odor	none

5 Analytical Procedures

5.1 *Nitrogen, oxygen and methane* — This procedure is for the determination of nitrogen, oxygen and methane using a gas chromatograph with discharge ionization detector and heartcut column switching.

5.1.1 *Detection Limit* — 100 ppb.

1 Deutches Institut für Normung e.V., BeuthVerlag GmbH, burggrafenstrasse 4-10, D10787 Berlin, Germany, www.din.de

5.1.2 *Instrument Parameters*

5.1.2.1 *Columns*

Column 1: Hayesep Q, 2 meters by 3 mm (Stainless-steel or nickel rich alloy).

Column 2: Molecular sieve 5A, 3 meters by 3 mm (Stainless-steel or nickel rich alloy) 80/100 mesh or equivalent.

5.1.2.2 *Carrier Flow*: 25 mL/minute helium.

5.1.2.3 *Sample Volume*: 2 mL.

5.1.2.4 Temperatures:

Detector	110°C
Column Oven	50°C
Injector	Ambient

5.1.3 *Calibration Standard* — 1–10 ppm (mole/mole) nitrogen, oxygen and methane, balance helium.

5.1.4 *Operating Procedure*

5.1.4.1 Inject the calibration standard into the gas chromatograph via the gas sampling valve. Record the retention times and peak areas for the components within the standard. The order of elution is: oxygen, nitrogen, methane.

5.1.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas. The carbon dioxide matrix gas is vented via the heartcut.

5.1.4.3 Repeat 5.1.4.1.

5.1.4.4 Compare the average peak areas of the calibration standard to that of the unknown carbon dioxide sample being tested. Calculate the concentrations of oxygen, nitrogen and methane using the formula below. The results shall not exceed the values specified in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\\text{Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\\text{Sample}\end{matrix}$$

5.2 *Moisture* — This procedure is for the determination of moisture in carbon dioxide using a direct readout moisture analyzer with a phosphorus pentoxide electrolytic cell.

5.2.1 *Detection Limit* — 100 ppb.

5.2.2 *Instrument Parameters*

5.2.2.1 *Flow requirements* — Zero and span the analyzer in accordance with the instrument manufacturers instructions. Set the sample gas flow to the rate specified by the manufacturer.

5.2.3 *Calibration standard* — The analyzer shall be calibrated at the time of use by reference to a standard gas calibration mixture containing a certified moisture content close to the expected value of the gas under test. If the analyzer indicates the certified moisture content, within the overall measurement uncertainties stated by the instrument and gas manufacturers, it may be used without further adjustment or calibration.

NOTE 2: Further Experimental detail may be found in DIN 50450-1.

5.2.4 *Sample system*

5.2.4.1 Use insulated stainless steel sample lines to prevent frosting during sampling.

5.2.4.2 Keep sample lines to a minimum length.

5.2.5 *Operating Procedure*

5.2.5.1 Follow the procedures specified in the instrument manufacturer's manual.

5.2.5.2 Allow the system to run until a stable reading is obtained for 5 minutes.

5.2.5.3 Read and record the concentration of moisture, in ppm, indicated on the moisture analyzer. The result obtained shall not exceed the value specified in Section 2 of this standard.

NOTE 3: This specification applies to gaseous phase product from a cylinder supply.

NOTE 4: It is recommended that the user discontinue use of the cylinder prior to the complete consumption of the liquid phase contents. The contents of cylinders containing liquefied product should be determined by weight and not pressure.

NOTE 5: Adopt a replicate sampling protocol for both calibration standard and unknown to achieve the required measurement uncertainty.

SEMI C3.21-90 (Withdrawn 1000)
STANDARD FOR CARBON TETRAFLUORIDE (CF_4) IN CYLINDERS (PROVISIONAL)

This document was balloted and approved for withdrawal in 2000.

1 Description

Carbon tetrafluoride is an inert, colorless, nonflammable gas. It is shipped in steel cylinders as a nonliquified gas.

SEMI C3.40-1000
STANDARD FOR CARBON TETRAFLUORIDE (CF_4), VLSI GRADE

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on July 11, 2000. Initially available at www.semi.org September 2000; to be published October 2000. Originally published in 1989; previously published in 1992.

1 Description

1.1 Carbon tetrafluoride is an odorless, colorless, nonflammable gas. It is a simple asphyxiant. It is also known as tetrafluoromethane.

2 Specifications

QUALITY: 99.997%

Impurities	*Maximum Acceptable Level (ppm) **
Carbon Dioxide (CO_2)	1
Carbon Monoxide (CO)	1
Nitrogen (N_2)	20
Other Halocarbons (CF_3Cl, CF_2Cl_2,CF_3H)	1
Oxygen (O_2)	5
Sulfur Hexafluoride (SF_6)	1
Water (H_2O) (v/v)	1
TOTAL IMPURITIES	30

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Chemical Specification

Total Hydrolyzable Fluorides as HF	1 ppm max.

4 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	88.005	88.005
Boiling point at 1 atm	-128.0°C	-198.4°F
Density of gas at 0°C (32°F) and 1 atm	3.946 kg/m^3	0.246 lb/ft^3
Specific gravity of gas at 0°C and 1 atm	3.05	3.05
Density of liquid at -80°C	1317 kg/m^3	82.22 lb/ft^3

5 Analytical Procedures (See Notes 1 and 2, and Figures 1 and 2.)

5.1 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in carbon tetrafluoride using a gas chromatograph with an ultrasonic detector.

5.1.1 *Detection Limit* — 0.5 ppm (mole/mole).

5.1.2 *Instrument Parameters*

5.1.2.1 Columns:

Column 1:	Haysep D, 100/120 mesh, 4.6 m (15 ft) by 3.2 mm (1/8 in) OD ss or equivalent.
Column 2:	Porapak QS, 100/120 mesh, 2.1 m (7 ft) by 3.2 mm OD ss or equivalent.

5.1.2.2 Carrier Flow: 16 mL/min helium.

5.1.2.3 Temperatures:

Detector	120°C
Column	50°C
Valve	90°C

5.1.2.4 Sample Volume: 1.0 mL

5.1.2.5 *Time Table* — Determine the times for valve switching and signal changes, and enter into the run table.

An example of a run table follows.

Valve	On	Off
1	0.01	*
2	9.20	*
3	0.01	12.00

* Valve left on until end of run.

5.1.3 *Calibration Standard* — 1–5 ppm carbon dioxide and balance helium.

5.1.4 *Operating Procedure*

5.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. The retention time for carbon dioxide is approximately 16 minutes.

5.1.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

5.1.4.3 Repeat 5.1.4.1.

5.1.4.4 Compare the average peak areas of the calibration standard to those of the carbon tetrafluoride sample being tested. Calculate the concentration of carbon dioxide in the sample, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.2 *Oxygen, Nitrogen and Carbon Monoxide* — This procedure is for the determination of oxygen, nitrogen, and carbon monoxide in carbon tetrafluoride using a gas chromatograph with an ultrasonic detector.

5.2.1 *Detection Limits* — 0.5 ppm (mole/mole) for each impurity.

5.2.2 *Instrument Parameters*

5.2.2.1 Columns:

Column 3:	Porapak QS, 100/120 mesh, 3.6 m (12 ft) by 3.2 mm (1/8 in) OD ss or equivalent.
Column 4:	Haysep D, 100/120 mesh, 4.6 m (15 ft) by 3.2 mm OD ss or equivalent.
Column 5:	Molecular Sieve 13X, 45/60 mesh, 2.1 m (7 ft) by 3.2 mm OD ss or equivalent.

5.2.2.2 Carrier Flow: 16 mL/min helium.

5.2.2.3 Temperatures:

Detector	120°C
Column	50°C
Valve	90°C

5.2.2.4 Sample Volume: 2.0 mL

5.2.2.5 *Time Table* — Determine the times for valve switching and signal changes, and enter into the run table.

An example of a run table follows.

Valve	On	Off
1	0.01	*
2	9.20	*
3	0.01	12.00

* Valve left on until end of run.

5.2.3 *Calibration Standard* — 1–5 ppm (mole/mole) each nitrogen, oxygen and carbon monoxide, balance helium.

5.2.4 *Operating Procedure*

5.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. The approximate retention times are: oxygen 11.1 minutes, nitrogen 11.6 minutes, carbon monoxide 14.5 minutes.

5.2.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

5.2.4.3 Repeat 5.2.4.1.

5.2.4.4 Compare the average peak areas of the calibration standard to those of the carbon tetrafluoride sample being tested. Calculate the concentrations of oxygen, nitrogen and carbon monoxide in the sample, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.3 *Fluorocarbon and Chlorofluorocarbon Impurities* — This procedure is for the determination of the volatile organic impurities in carbon tetrafluoride using a gas chromatograph with a flame ionization detector.

5.3.1 *Detection Limits* — 0.5 ppm (mole/mole) for each impurity.

5.3.2 *Instrument Parameters*

5.3.2.1 Column: 1% SP-1000 on Carbopak B (60/80), 7.3 m (24 ft) by 3.2 mm (1/8 in) OD ss or equivalent.

5.3.2.2 Carrier Flow: 40 mL/min helium.

5.3.2.3 Support Gases: Set the flow rates as specified by the instrument manufacturer.

5.3.2.4 Temperatures:

Injection Port	200°C
Detector	250°C
Initial Oven	35°C
Pre-Program Hold	7 min
Temperature Rise	10°C/min
Final Oven	150°C
Final Hold	10 min

5.3.2.5 Sample Volume: 2 mL.

5.3.3 *Calibration Standard* — 1–10 ppm (by volume) desired impurities in helium. Practical impurities may be trifluoromethane (CHF_3), hexafluoroethane (C_2F_6), dichlorodifluoromethane (CCl_2F_2), and chlorotrifluoromethane ($CClF_3$).

5.3.4 *Operating Procedure*

5.3.4.1 Attach a stainless steel diaphragm two-stage regulator to the standard cylinder. Connect the regulator to the 6 port chromatographic sampling valve.

5.3.4.2 Purge the sampling lines with the standard for at least one minute.

5.3.4.3 Pressurize the sampling lines to 5 psig.

5.3.4.4 Inject the standard into the gas chromatograph, and start the scan. Record the retention times and peak areas. Order of elution for the above mentioned standard is carbon tetrafluoride, trifluoromethane, hexafluoroethane, chlorotrifluoromethane, and dichlorodifluoromethane.

5.3.4.5 Inject the sample to be tested in the same manner as the calibration standard.

5.3.4.6 Repeat 5.3.4.1–5.3.4.4.

5.3.4.7 Compare the average peak areas of the calibration standard to those of the carbon tetrafluoride sample being tested. Calculate the concentration of each of the impurities using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.4 *Sulfur Hexafluoride* — This procedure is for the determination of sulfur hexafluoride in carbon tetrafluoride using a gas chromatograph with a thermal conductivity detector. (See Figure 2.)

5.4.1 Detection Limit — 0.5 ppm.

5.4.2 *Instrument Parameters*

5.4.2.1 Column: Super Q, 80/100 mesh, 4.9 m (16 ft) by 1.75 mm (1/16 in) ID, 3.2 mm (1/8 in) OD, ss or equivalent.

5.4.2.2 Carrier Flow: 19 mL/min helium.

5.4.2.3 Temperatures:

Detector	100°C
Oven	70°C
Gas sampling valve	70°C

5.4.2.4 Sample Volume: 1 mL.

5.4.3 *Calibration Standard* — 1 ppm sulfur hexafluoride, balance helium.

5.4.4 *Operating Procedures*

5.4.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention time and peak area.

5.4.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

5.4.4.3 Repeat 5.4.4.1.

5.4.4.4 Compare the average peak areas of the calibration standard to those of the carbon tetrafluoride sample being tested. Calculate the concentration of sulfur hexafluoride using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.5 *Water* — This procedure is for the determination of trace moisture (water) in carbon tetrafluoride using a continuous flowing electrolytic hygrometer.

5.5.1 *Detection Limit* — 1.0 ppm (vol/vol) or -76°C (-105°F).

5.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

5.5.3 *Operation Check* — Check the electrolytic hygrometer periodically. A gas, containing a known amount of water, should be passed through the hygrometer. Agreement between the electrolytic hygrometer and the moisture standard should be within their relative accuracies.

5.5.4 *Operating Procedure*

5.5.4.1 Obtain a continuous flow sample of gas, from the CF_4 source, using a clean, passivated stainless steel line which has been purged dry after exposure to ambient moisture. (See Notes 3 and 4.)

5.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the electrolytic moisture analyzer until a stable reading is obtained. The result may not exceed the specification in Section 2 of this standard.

5.6 *Hydrolyzable Fluorides as HF* — This procedure is for the determination of hydrolyzable fluorides in carbon tetrafluoride using fluoride ion selective electrode.

5.6.1 *Detection Limit* — Detection limits should be checked for any new implementation of a method. Detection limits below 0.1 ppm have been determined with this method. Detection limits can be improved by increasing the volume of gas sampled.

5.6.2 *Equipment*

5.6.2.1 mV meter (0.1 mV scale)

5.6.2.2 Reference electrode (single junction type)

5.6.2.3 Fluoride ion selective electrode

5.6.2.4 Magnetic stir bars (PTFE coated)

5.6.2.5 Magnetic stirrer

5.6.2.6 Plastic beakers (See note 5)

5.6.2.7 PTFE bubblers

5.6.2.8 1000 ml and 100 ml plastic volumetric flasks (See note 5)

5.6.2.9 0.2 ml and 1 ml plastic volumetric pipettes (See note 5)

5.6.2.10 Flow controller or flowmeter (0-1000 sccm CF_4)

5.6.3 Reagents

5.6.3.1 Distilled or deionized water

5.6.3.2 5 N sodium hydroxide

5.6.3.3 0.2 N sodium hydroxide

5.6.3.4 Glacial acetic acid

5.6.3.5 *Buffer Solution* — To 500 ml distilled or deionized water in a 1000 ml volumetric flask, add 57 ml glacial acetic acid and 58 g of sodium chloride. Adjust the pH to between 5.0–5.5 with 5 M sodium hydroxide. Cool to room temperature. Dilute to one liter with distilled or deionized water.

5.6.4 *Calibration Standard* — Sodium fluoride standard (10^{-3} M F^- in water, freshly prepared)

5.6.5 *Operating Procedure*

5.6.5.1 Prepare working standard by adding 100 ml 10^{-3} M F^- to 100 ml buffer solution.

5.6.5.2 Prepare a blank containing 50.0 ml 0.2 N NaOH and 50.0 ml buffer solution in a plastic beaker.

5.6.5.3 While stirring blank gently, record mV reading from the blank once reading is stable.

5.6.5.4 Successively add increments of working standard to the blank to generate a calibration curve. Record stable mV reading after each addition. Table 1 shows recommended increments and resultant concentrations.

Table 1 Calibration Concentrations

Added volume of Working Standard (ml)	*Total Volume (ml)*	*Resulting F- Concentration (M)*
0.2	100.2	1.0×10^{-6}
0.2	100.4	2.0×10^{-6}
0.4	100.8	4.0×10^{-6}
0.4	101.2	5.9×10^{-6}
0.8	102.0	9.8×10^{-6}
1.0	103.0	1.5×10^{-5}
2.0	105.0	2.4×10^{-5}

5.6.5.5 Put 50 ml 0.2 N NaOH into each of two bubblers connected in series

5.6.5.6 Establish a flow of < 1000 sccm of CF_4 through the bubblers using a suitable flow controller or flowmeter.

5.6.5.7 Sample approximately 15 liters of CF_4. Record flowrate and time of sampling to determine total volume sampled (flowrate x time). A wet test meter can also be used to measure total volume. The amount of gas sample must be the volume at STP. If the flowmeter or wet test meter is not reference to 0º and 760 torr, use the formula below to correct sample volume.

$$\text{Liters at STP} = \text{Measured Liters} \times \frac{760\,\text{Torr}}{P} \times \frac{T + 273}{273\,K}$$

P: Pressure of sampled gas (mm Hg)

T: Temperature of sampled gas or reference temperature of the flow controller or meter in ºC.

5.6.5.8 Transfer contents of each bubbler to individual 100 ml volumetric flasks and add 50 ml Buffer solution to each. Then, if necessary, add deionized or distilled water to bring the volume up to 100 ml.

5.6.5.9 Transfer contents to a plastic beaker

5.6.5.10 While stirring, measure and record mV readings for each sample.

5.6.5.11 Determine F^- concentration in solution using calibration curve generated in section 5.6.5.4.

5.6.5.12 Calculate gas phase hydrolyzable fluoride concentration using the equation below. Note: the equation assumes the hydrolyzable fluoride is hydrogen fluoride.

$$\text{Gas Phase HF}\,(\text{ppm}_y) = C \times 0.11 \times \frac{22.4\,\text{l/mole}}{Vs} \times 10^6$$

C: Measured hydrolyzable fluoride concentration (M) determined in section 5.6.5.11

Vs: Volume of CF_4 sampled (liters at STP)

5.6.5.13 The HF concentration of the second bubbler should be insignificant compared to the first bubbler. If significant HF levels are found in the second bubbler, resample with a lower flowrate.

5.7 *Notes*

Note 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

Note 2: All gases used in the analysis of the sample should not contain more than 10% of the specified value of the component of interest, unless otherwise stated.

Note 3: A passivation procedure is described in the Metals Handbook, 10th ed., Vol. 2, American Society for Metals, Metals Park, OH.

Note 4: The sampling system and hygrometer must be designed to operate at the sample pressure, or the sample pressure must be reduced, by a regulator with a diaphragm of stainless steel or other suitable material, to accommodate the pressure restrictions of the hygrometer.

Note 5: Polytetrafluoroethlyene, polymethylpentene and polypropylene are suitable plastic materials.

SEMI C3.32-0301
SPECIFICATION FOR CHLORINE (Cl_2), 99.996% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on October 17, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published in 1987; previously published in 1995.

1 Description

1.1 Gaseous chlorine is greenish-yellow and about 2.5 times as heavy as air. Chlorine has a disagreeable and suffocating odor.

2 Specifications

QUALITY: 99.996%

Impurities	*Maximum Acceptable Level (ppm) (See NOTE 1.)*
Carbon dioxide (CO_2)	10
Carbon monoxide (CO)	1
Hydrocarbons ($C_1 – C_2$)	1
Nitrogen (N_2)	20
Oxygen (O_2)	4
Water (H_2O) (v/v)	(See NOTE 2.)
TOTAL LISTED IMPURITIES (excluding chromium, iron, nickel, and sodium)	36

	Maximum Acceptable Level (ppm) (See NOTE 1.)
Chromium (Cr)	0.2 by wt. Liquid Phase
Iron (Fe)	0.2 by wt. Liquid Phase
Nickel	0.2 by wt. Liquid Phase
Sodium	1 by wt. Liquid Phase

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and on the precision of the provided procedure.

NOTE 2: It is not known whether H_2O remains as H_2O in Cl_2 or reacts to other species. For this reason, interpretation of H_2O measurement data is questionable. Test and acceptance criteria shall be determined between user and supplier. Possible methods include: a) determination of HCl by Fourier transform infrared spectrometry (FTIR), mass spectrometry, or gas chromatography; b) measurement of water by electrolysis in a P_2O_5 cell (reported in terms of H_2O equivalents); c) determination of water by FTIR.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	70.9	70.9
Boiling point at 1 atm	-34.05°C	-29.3°F
Density gas at 20°C (68°F) and 1 atm	2.980 kg/m^3	0.1860 lb/ft^3
Specific gravity	2.473	2.473
Density liquid at -118°C (-180.8°F)	1574.8 kg/m^3	98.26 lb/ft^3

4 Analytical Procedures

4.1 *Carbon Monoxide, Carbon Dioxide, and Hydrocarbons (CH_4, C_2H_2, C_2H_4, C_2H_6)* — This procedure is for the determination of carbon monoxide, carbon dioxide, and C_1–C_2 hydrocarbons in chlorine. The sample shall be vapor phase and analyzed using a gas chromatograph with a flame ionization detector/ methanizer combination. (See Figure 1 and Notes 1, 2, and 3.)

4.1.1 *Detection Limit* — 0.1 ppm (mol/mol).

4.1.2 *Instrument Parameters*

4.1.2.1 *Injection Valve* — 10 port corrosion-resistant.

4.1.2.2 *Sample Volume* — 2 mL.

4.1.2.3 Columns:

Column 1:	Porapak P, 3.1 m (10 ft) by 3.2 mm (1/8 in) OD ss or equivalent.
Column 2:	Porapak P, 3.1 m by 3.2 mm OD ss or equivalent.

4.1.2.4 *Carrier Flow* — 20 mL/min nitrogen.

4.1.2.5 *Column Temperature* — 40°C.

4.1.2.6 Air and Hydrogen Pressure and Flow — As specified by the instrument manufacturer.

4.1.3 *Calibration Standard* — 1–5 ppm (mol/mol) each component in nitrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Place the 10 port valve in the sample load position.

4.1.4.2 Turn on the methanizer heater and establish hydrogen flow. Allow unit to heat to operating temperature (as specified by the manufacturer).

4.1.4.3 Establish air flow and ignite burner following the instrument manufacturer's instructions. Allow the system to stabilize for 15 minutes.

4.1.4.4 Determine the time at which ethane elutes from the first column and absorbs onto the second column so one can vent the chlorine. Inject the calibration ethane standard and record the retention time of ethane obtained without returning the valve to the load position. Multiply this time by 0.6. The result will be the time during the analysis at which the injection valve should be returned to the load position, backflushing the chlorine to vent.

Repeat the injection of the ethane calibration standard, including the backflush, to ensure that enough time has passed to allow elution of ethane onto the second column.

4.1.4.5 Inject the remaining standards using the backflush technique. Record the retention times and peak areas.

4.1.4.6 Analyze the chlorine sample to be tested in the same manner as in 4.1.4.5. Repeat the sample injection until peak areas of the impurity of interest agree within 5%.

4.1.4.7 Analyze each of the calibration standards again as in 4.1.4.5.

4.1.4.8 Compare the average peak areas of the calibration standards to those of the chlorine sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Oxygen and Nitrogen* — This procedure is for the determination of oxygen and nitrogen in chlorine. The sample shall be vapor phase and analyzed using a gas chromatograph with a thermal conductivity detector. (See Figure 2 and Notes 1 and 2.)

4.2.1 *Detection Limits* — 2 ppm (v/v) oxygen, 5 ppm (v/v) nitrogen.

4.2.2 *Instrument Parameters*

4.2.2.1 *Injection Valve* — 10 port corrosion-resistant.

4.2.2.2 *Sample Volume* — 2 mL.

4.2.2.3 Columns:

Column 1:	Porapak Q, 1.8 m (6 ft) by 3.2 mm (1/8 in) OD ss or equivalent.
Column 2:	Molecular sieve 13×, 3.1 m (10ft) by 3.2 mm OD ss or equivalent.

4.2.2.4 *Carrier Flow* — 20 mL/min helium.

4.2.2.5 *Temperature:*

Column	30°C
Detector	50°C

4.2.3 *Calibration Standard* — 10–40 ppm (v/v) each component in helium.

4.2.4 *Operating Procedure*

4.2.4.1 Place the 10 port valve in the sample load position.

4.2.4.2 Inject the standard, wait one minute, then return the valve to the sample load position to backflush the principal gas to vent while allowing the oxygen and nitrogen to pass to the analytical column. Record the retention times and peak areas.

4.2.4.3 Inject the standard at least three times. All peak areas for a specific impurity should agree within 5%.

4.2.4.4 Inject the chlorine sample to be tested in the same manner as in 4.2.4.2 and 4.2.4.3. Record the retention times and peak areas.

4.2.4.5 Repeat 4.2.4.2 and 4.2.4.3.

4.2.4.6 Compare the average peak areas of calibration standards with that of the chlorine sample being tested. Calculate the concentrations of oxygen and nitrogen, using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Trace Elements* — This procedure gives instructions for the determination of trace elements in liquid phase chlorine using inductively coupled plasma mass spectrometry (ICP-MS). (See Note 4.)

4.3.1 *Detection Limit* — (See Note 4.)

4.3.2 *Instrument Parameters* — (See Note 4.)

4.3.3 *Calibration Standards* — (See Note 4.) All instrument calibration standards should be prepared from NIST-traceable reference standards.

4.3.4 *Sample Collection Apparatus* — (See Notes 5 and 6 and Figures 3 and 4.)

4.3.4.1 *Cylinder Connector* — Stainless steel, or other suitable material, dependent on the cylinder valve used.

4.3.4.2 *Fluorocarbon Tubing* — 6.4 mm (1/4") and 3.2 mm (1/8") outer diameters required, lengths dependent on construction of apparatus.

4.3.4.3 *Fluorocarbon Needle Valve* — Two 6.4 mm (1/4") needle valves (designated as V1 and V2). (See Figure 3.)

4.3.4.4 *Fluorocarbon Ball Valve* — One 6.4 mm (1/4") ball valve and one 3.2 mm (1/8") ball valve (designated as V3 and V4, respectively). (See Figure 3.)

4.3.4.5 *Fluorocarbon T-Joint* — One 6.4 mm (1/4") T-joint.

4.3.4.6 *Fluorocarbon Cylinder Union* — One 6.4 mm (1/4") to 15.9 mm (5/8") iron pipe size female pipe thread adapter to attach to the stainless steel cylinder connector.

4.3.4.7 *Fluorocarbon Reducer* — One 6.4 mm (1/4") to 3.2 mm (1/8") reducing union.

4.3.4.8 *Flask Connector* — One Plasmatech #16F424 flask connector, or similar, attached to a cap for the 100 mL sampling flask.

4.3.4.9 *Sampling Flasks* — 100 mL polypropylene volumetric flask.

4.3.4.10 *Nitrogen Source* — A source of high-purity nitrogen to purge the sampling system prior to and after sampling and for evaporation.

4.3.4.11 *Scrubber Source* — A caustic scrubber source to neutralize chlorine from the sampling process. The scrubber is connected to an eductor tube, with the vacuum created by an N_2 source regulated at 20 psi.

4.3.5 *Operating Procedure*

4.3.5.1 Assemble the system according to Figures 3 and 4, ensuring that the connections are leak tight.

4.3.5.2 Wrap Teflon tape around the threads of a 100 mL volumetric flask to ensure a good seal. Connect the 100 mL polypropylene flask to the flask connector as shown in Figure 3. All 100 mL volumetric flasks used for sample collection should be prepared in a similar manner.

4.3.5.3 Clean the exterior of the cylinder CGA by rinsing it with (in succession) 10% HNO_3/DI H_2O, isopropanol/DI H_2O, and DI H_2O. The CGA must be free of residue. The CGA is then cleaned and dried with a cotton swab. Dry the exterior of the CGA with the high-purity N_2. Repeat the process for the nut and gland. The cylinder CGA must be completely dry prior to connecting the nut and gland.

4.3.5.4 Invert the cylinder with a cylinder inverter and connect the cylinder CGA to the nut and gland.

4.3.5.5 Purge the system by opening V1 and V2 and allowing high purity N_2 to flow through the system at 5–10 psig for a minimum of three minutes. The ball valves (V3 and V4) remain in the open position.

4.3.5.6 Close V1 and V2. To condition the sampling system, open the cylinder valve, then slowly open V2 to allow Cl_2 to flow into the sample flask. After collecting 70–100 mL of Cl_2, close the cylinder valve and open V1 to purge the system.

4.3.5.7 Discard the initial Cl_2 sample by passing it through to the scrubber, remove the flask and replace it with a labeled sample flask. Continue to purge the system for at least two minutes. Close V1 and V2. Open the cylinder valve, then slowly open V2.

4.3.5.8 Allow 100 g of sample to be introduced into the sample flask. Once this is completed, close V2, then close the cylinder valve. Open V1 and V2 to allow for purging of the Cl_2 in the sample flask with high purity N_2 flowing through the system at 5 psig. This will purge the Cl_2 at a rate of 7–10 gms per minute.

4.3.5.9 When the sample has been flushed, replace the sample flask with another flask. Loosely cap the sample flask to allow for any residual Cl_2 to evaporate. If additional samples from the same cylinder are desired, repeat Steps 4.3.5.5 through 4.3.4.9.

4.3.5.10 Close V1 and disconnect the cylinder valve connector from the cylinder valve. Return the cylinder to the upright position. Rinse the cylinder CGA and nut, gland with DI H_2O, and dry with N_2. Remove the cylinder from the cylinder inverter.

4.3.5.11 Repeat Steps 4.3.5.3 to 4.3.5.10 for additional cylinders.

4.3.5.12 After obtaining all samples of interest, hand dry the connector and place it into an oven to prevent corrosion and build-up of condensation. Clean the tubing and valve system with a 10% HNO_3/DI H_2O solution and store in a 25% HNO_3/DI H_2O solution.

4.3.5.13 Fill each sample flask with a solution of 5% ultrapure HNO_3/DI H_2O spiked with 25 ppb of an internal standard (such as indium) up to the graduation mark. Allow the samples to digest in the solution in the flasks for a minimum of one hour. (See Note 7.)

4.4 *Water* — This procedure is for the determination of moisture in gas phase chlorine using a continuous flow electrolysis of water in a phosphorous pentoxide (P_2O_5) cell. (See Notes 2 and 8.)

4.4.1 *Detection Limit* — 1 ppm (vol/vol).

4.4.2 *Flow Rate* — Set the sample flow rate and pressure in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards* — Construct a calibration curve which contains at least two points covering the range of interest.

4.4.4 *Operating Procedure*

4.4.4.1 Leak check the entire system using helium and a helium leak detector prior to use.

4.4.4.2 Pre-purge through the regulator/cross-purge assembly with a dry gas of known moisture content until the moisture content is measured below 1 ppm (vol/vol).

4.4.4.3 Direct samples of two standards, independently verified with a dewpoint/frostpoint hygrometer, spanning the range of moisture content of interest to the analyzer. After a stable reading is obtained, record the instrument's response to each standard.

4.4.4.4 Obtain a representative sample of the gas to be analyzed and direct it to the unit as with the standards. After a stable reading is obtained, record the instrument’s response.

4.4.4.5 Construct a calibration curve from the standard data and determine the moisture content in the sample gas. The result may not exceed the specification in Section 2 of this standard.

4.5 *Notes*

NOTE 1: Sample system should be constructed entirely of stainless steel or other suitable material due to the corrosive nature of the product.

NOTE 2: Sample must be appropriately vented for health and safety of operating personnel.

NOTE 3: Individual standards are required for accuracy and identification by retention time.

NOTE 4: Other accepted instrumental techniques are also appropriate for this analysis. In addition, operating procedures for ICP-MS instruments vary, depending on the manufacturer. In all cases, refer to individual instrument vendor instructions.

NOTE 5: All sampling flasks are leached with a 25% HNO_3/H_2O solution for at least 24 hours, rinsed thoroughly with DI H_2O, and filled with DI H_2O for at least 24 hours prior to use. On the day of sampling, flasks are rinsed thoroughly with DI H_2O and dried with N_2 prior to system setup.

NOTE 6: The tubing and Fluorocarbon valves are soaked in a 25% HNO_3/DI H_2O solution prior to use (either apart or pre-assembled). The tubing and valves are rinsed thoroughly with DI H_2O and dried with high-purity N_2 prior to system setup.

NOTE 7: A different digestion solution may be used, depending on possible interferences with a given analysis technique.

NOTE 8: All wetted surfaces, including P_2O_5 hygrometer and sample system, are to be of 316 stainless steel or other suitable material.

NOTICE: This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the specification set forth herein for any particular application. The determination of the suitability of the specification is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials or equipment mentioned herein. This specification are subject to change without notice.

The user's attention is called to the possibility that compliance with this specification may require use of copyrighted material or of an invention covered by patent rights. By publication of this specification, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.44-91 (Withdrawn 0701)
STANDARD FOR DIBORANE (B_2H_6) (PROVISIONAL)

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Diborane is toxic, flammable, colorless gas. It has a sickly sweet odor.

SEMI C3.56-0600
SPECIFICATION FOR DIBORANE MIXTURES

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the European Gases Committee. Current edition approved by the European Regional Standards Committee on April 4, 2000. Initially available at www.semi.org May 2000; to be published June 2000.

1 Purpose

1.1 To define the specification and analytical methods and validate the specifications for diborane mixtures.

2 Scope

2.1 Diborane is not used as a pure gas but as a mixture with balance gases of N_2, H_2, Ar, He, or SiH_4.

2.2 The quality of the mixture is affected by a number of factors which include:

- the purity of the gases used for mixture preparation;
- component filling precision;
- the cylinder preparation process and *in-situ* reactions of diborane with the internal surface of the cylinder.

2.2.1 Furthermore, the elapsed time after filling is important due to the chemical instability, and hence decomposition, of the diborane (see Appendix 1).

2.2.2 All component gases shall adhere to the appropriate SEMI specification, if available.

2.3 The quality of the final mixture can be checked after manufacturing by analyzing each cylinder for the concentration of diborane and for key impurities (tracers), namely H_2, N_2, O_2.

2.4 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *DIN Standard*[1]

DIN 50457-1

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Specifications

4.1 *Mixing Tolerances*

Concentration of Diborane	*Preparation Tolerance Level*
10–999 ppm	± 20%
0.1–10%	± 5%

4.2 *Analytical precision: Determination of Diborane Content*

Concentration of Diborane	*Analytical Precision*
10–99 ppm	± 3%
100–999 ppm	± 2%
0.1–10%	± 2%

N.B. Analytical precision is based on at least 6 replicate determinations

4.3 *Impurities*

4.3.1 In the final mixture the concentration of impurities should fulfill the following condition:

$$c_i(mix) = \left[\frac{x_{(diborane)}}{100} \bullet c_i(diborane)\right] + \left[\frac{x_{(main)}}{100} \bullet c_i(main)\right]$$

$c_i(mix)$ — concentration of impurity i in the mixture (ppm)

$c_i(diborane)$ — maximum concentration of impurity i in diborane (ppm)

$c_i(main)$ — maximum concentration of impurity i in the balance gas (ppm)

$x_{(diborane)}$ — concentration of diborane in the mixture (%)

$x_{(main)}$ — concentration of balance gas in the mixture (%)

5 Analytical Procedure for the Determination of Diborane Concentration

NOTE 2: This procedure is for the determination of the diborane content using a Fourier Transform Infrared analyzer.

5.1 *Detection limit* — 2 ppm (mole/mole)

1 Deutches Institut für Normung e.V., BeuthVerlag GmbH, burggrafenstrasse 4-10, D10787 Berlin, Germany, www.din.de

5.2 *Instrument parameters*

5.2.1 *Cell path length*

5.2.1.1 10 cm (mixtures 100 ppm to 10%)

5.2.1.2 10 m (mixtures up to 100 ppm)

Wavenumber — 2444–2739 cm^{-1}

Resolution — 4 cm^{-1}

5.2.2 *Sample Flow*

5.2.2.1 20 l/h at 10 cm path length

5.2.2.2 40 l/h at 10 m path length

5.3 *Calibration standard* — diborane in hydrogen

NOTE 3: Depending on the concentration of diborane and the storage temperature the standard can be unstable (Section 5). It is recommended to use an appropriate standard with a diborane concentration as low as possible and to store it at low temperature. If there are doubts about the stability of the standard the diborane concentration can be verified by wet chemical methods. (See DIN 50457-1.)

5.4 *Operating Procedures*

5.4.1 Purge the sampling system leading to the cell and the cell with dry nitrogen for 15 minutes and until a zero absorbance is obtained between 2444–2739 cm^{-1}. Then purge the cell with the calibration standard and record the absorption of diborane. When a steady absorbance reading is obtained, after approximately 5–10 minutes, the true concentration of the standard shall be recorded. Record the pressure in the gas cell using a calibrated pressure-measuring device.

5.4.2 To determine the concentration of diborane in the mixture set the sample flow through the cell following the same procedures as detailed above. Record the absorption at the same wave number as the calibration standard. Ensure that gas cell pressures are equal during calibration and the determination. Calculate the concentration of diborane. The result must conform to the specification in Section 4 of this standard.

APPENDIX 1
STABILITY OF DIBORANE MIXTURES (FOR INFORMATION ONLY)

NOTE: The material in this appendix is an official part of SEMI C3.56 and was approved by full letter ballot procedures on April 4, 2000 by the European Regional Standards Committee.

A1-1 The stability of diborane mixtures in N_2, Ar, or He depends on the concentration of diborane and on the storage temperature. At ambient temperature best stability is found for mixtures of diborane in hydrogen. No difference in stability could be found for different cylinder materials (steel, stainless steel, aluminum).

A1-2 The following values were measured for different concentrations of diborane at two different storage temperatures:

Storage Temperature	*Diborane Concentration (%) in Nitrogen after*				
	2	17	45	100	160 Days
8 °C	0.549	0.547	0.547	0.543	0.542
22 °C	0.549	0.544	0.539	0.530	0.526
8 °C	5.05	4.91	4.87	4.85	4.78
22 °C	5.05	4.92	4.83	4.72	4.49
8 °C	10.51	10.45	10.43	10.19	10.00
22 °C	10.59	10.30	10.08	9.44	8.85

A1-3 Based on these results it is recommended to keep mixtures at low temperature.

NOTICE: SEMI makes no warranties or representations as to the suitability of the specification set forth herein for any particular application. The determination of the suitability of the specification is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These specifications are subject to change without notice.

The user's attention is called to the possibility that compliance with this specification may require use of copyrighted material or of an invention covered by patent rights. By publication of this specification, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.18-94
STANDARD FOR DICHLOROSILANE (H_2SiCl_2) IN CYLINDERS, 97% QUALITY

1 Description

Dichlorosilane is a flammable, corrosive, colorless liquid which hydrolizes in the presence of moisture. It oxidizes readily and rapidly to release hydrogen chloride. It is easily ignited in the presence of air.

2 Specifications

QUALITY: 97% (liquid) (See Notes 1, 2, 3, and 4)

Impurities	*Maximum Acceptable Levels**
All Other Chlorosilanes (Monochlorosilane, Silicon Tetrachloride, Trichlorosilane)	3% (liquid phase)
Aluminum	1 ppbw (vapor phase derived)
Arsenic	0.5 ppbw (vapor phase derived)
Boron	0.3 ppbw (vapor phase derived)
Carbon	10 ppmw (vapor phase derived)
Iron	50 ppbw (liquid phase)
Phosphorus	0.3 ppbw (vapor phase derived)

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Electrical Specification

Resistivity*	greater than 50 ohm-cm (n-type) **

* The resistivity measurement technique is to be determined between supplier and user.

** Monocrystalline silicon formed from this material, not the material itself.

4 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	100.99	100.99
Boiling point at 1 atm	8.2°C	46.8°F
Density of gas at 25°C (77°F) and 1 atm	4.168 kg/m^3	0.260 lb/ft^3
Specific gravity of gas at 21.1°C (70°F) and 1 atm (air = 1)	3.48	3.48
Density of liquid at 25°C (77°F)	122 kg/m^3	7.62 lb/ft^3

5 Analytical Procedures (See Note 5)

5.1 *Other Chlorosilanes* — This procedure is for the determination of other chlorosilanes (monochlorosilane, trichlorosilane and silicon tetrachloride) in dichlorosilane using a gas chromatograph with a thermal conductivity detector.

5.1.1 *Detection Limit* — 10 ppm (mole/mole).

5.1.2 *Instrument Parameters*

5.1.2.1 Column: 3.05 m (10 ft) by 3.2 mm (1/8 in) stainless steel tubing packed with 20% OV-101 on 80/100 Chromosorb W-HP or equivalent.

5.1.2.2 Carrier Flow: 20 mL/min helium.

5.1.2.3 Sample Volume: 0.5 to 1.0 mL.

5.1.2.4 Temperatures:

Detector	350°C
Column	60°C ramped to 325°C at 10°C/min
Inlet	300°C

5.1.3 *Operating Procedure*

5.1.3.1 Inject a known sample of monochlorosilane, trichlorosilane and silicon tetrachloride in dichorosilane into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is monochlorosilane, dichlorosilane, trichlorosilane, silicon tetrachloride.

5.1.3.2 Inject the sample to be tested in the same manner as in 5.1.3.1. Record the areas of the peaks which have the same retention times as those in 5.1.3.1.

5.1.3.3 Repeat 5.1.3.1.

5.1.3.4 Calculate the purity of dichlorosilane in the sample, using the equations stated below. The result may not exceed the specification in Section 2 of this Standard.

5.1.4 *Calculations*

5.1.4.1 Determine the total area of the chlorosilane peaks (A_T) by adding the areas of the four peaks.

5.1.4.2 Divide the area of the dichlorosilane peak by A_T. Multiply the result by 100% to obtain the purity of the dichlorosilane.

5.2 *Notes*

Note 1: This specification applies to the appropriate phase of the cylinder as delivered.

Note 2: The liquid phase purity is to be based on the chlorosilane determination. In addition, argon + helium are to be controlled in the vapor phase to less than 0.5%. This argon + helium determination will not affect the percent purity determination.

Note 3: Initial purging of the vapor phase is recommended to reduce inert gas content used in the cylinder fill procedure.

Note 4: Analytical procedures for the doping elements, metals and selected impurities are to be determined between the user and supplier at the present time.

Note 5: The sample is extremely flammable and corrosive. Test for leaks before sampling. Ensure good electrical grounding.

SEMI C3.31-94
STANDARD FOR DICHLOROSILANE (H_2SiCl_2) IN CYLINDERS, 99% QUALITY (PROVISIONAL)

1 Description

Dichlorosilane is a flammable, corrosive, colorless liquid which hydrolizes in the presence of moisture. It oxidizes readily and rapidly to release hydrogen chloride. It is easily ignited in the presence of air.

2 Specifications

QUALITY: 99% (Liquid) (See Notes 1, 2, 3, 4.)

Impurities	*Maximum Acceptable Levels **
All other Chlorosilanes (Monochlorosilane not to exceed 0.5%)	1% (liquid phase)
Aluminum (Al)	1.0 ppbw (vapor phase derived)
Arsenic (As)	0.2 ppbw (vapor phase derived)
Boron (B)	0.1 ppbw (vapor phase derived)
Carbon (C)	1 ppmw (vapor phase derived)
Iron (Fe)	50 ppbw (liquid phase)
Phosphorus (P)	0.3 ppbw (vapor phase derived)

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Electrical Specification

Resistivity*	Greater than 150 ohm-cm (n-type)**

* The resistivity measurement is to be determined between supplier and user.

** Monocrystalline silicon formed from this material, not the material itself.

4 Analytical Procedures (see Note 5)

4.1 *Other Chlorosilanes* — This procedure is for the determination of other chlorosilanes (monochlorosilane, trichlorosilane and silicon tetrachloride) in dichlorosilane using a gas chromatograph with a thermal conductivity detector.

4.1.1 *Detection Limit* — 10 ppm (mole/mole).

4.1.2 *Instrument Parameters*

4.1.2.1 Column: 3.05 m (10 ft) by 3.2 mm (1/8 in) stainless steel tubing packed with 20% OV-101 on 80/100 Chromosorb W-HP or equivalent.

4.1.2.2 Column Flow: 20 mL/min helium.

4.1.2.3 Sample Volume: 0.5 to 1.0 mL.

4.1.2.4 Temperatures:

Detector	350°C
Column	60°C ramped to 325°C at 10°C/min.
Inlet	300°C

4.1.3 *Operating Procedure*

4.1.3.1 Inject a known sample of monochlorosilane, trichlorosilane and silicon tetrachloride in dichlorosilane into the column using a gas sampling valve. Record retention times and peak areas. The order of elution is monochlorosilane, dichlorosilane, trichlorosilane, silicon tetrachloride.

4.1.3.2 Inject dichlorosilane sample to be tested in the same manner as in 4.1.3.1. Record the areas of the peaks which have the same retention times as those in 4.1.3.1.

4.1.3.3 Calculate the purity of dichlorosilane in the sample, using the formula below. The result may not be less than the specification in Section 2 of this Standard.

4.1.3.4 Calculate the percentage the monochlorosilane in the sample using the equation stated below. The result may not be more than the specification in Section 2 of this Standard.

4.1.4 *Calculations*

4.1.4.1 Determine the total area of the chlorosilane peaks (A_T) by adding the areas of the four peaks.

4.1.4.2 Divide the area of the dichlorsilane peak by A_T. Multiply the result by 100% to obtain the purity of the dichlorosilane.

4.1.4.3 Divide the area of the monochlorosilane peak by A_T. Multiply the result by 100% to obtain the percentage of monochlorosilane.

4.2 *Notes*

Note 1: This specification applies to the appropriate phase of the cylinder as delivered.

Note 2: The liquid phase purity is to be based on the chlorosilane determination. In addition, argon + helium are to be controlled in the vapor phase to less than 0.5%. This argon + helium determination will not affect the percent purity determination.

Note 3: Initial purging of the vapor phase is recommended to reduce inert gas content used in the cylinder fill procedure.

Note 4: Analytical procedures for the doping elements, metals and selected impurities are to be determined between the user and supplier at the present time.

Note 5: The sample is extremely flammable and corrosive. Test for leaks before sampling. Ensure good electrical grounding.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.34-92
STANDARD FOR DISILANE (Si_2H_6)

1 Description

Disilane is a pyrophoric, highly flammable, noncorrosive, colorless gas. It is toxic and a powerful irritant.

2 Specifications

QUALITY: 97% (See Note 1.)

Impurities	*Maximum Acceptable Level (ppm)**
Argon (Ar) + Oxygen (O_2)	1
Carbon dioxide (CO_2)	1
Carbon monoxide (CO)	1
Chlorosilanes (Total hydrolizable chlorides, reported as (Cl-))	5
Chromium (Cr)	**
Disiloxane ($H_3SiOSiH_3$)	5
Hydrogen (H_2)	500
Iron (Fe)	**
Monoethylsilane	50
Nickel (Ni)	**
Nitrogen (N_2)	10
Silane (SiH_4)	2.5%
Total methane, ethane, propane	10
Total trisilane and tetrasilane	500
Water (H_2O)	1
TOTAL SPECIFIED IMPURITIES (excluding chloride, chromium, iron and nickel)	2.6082%

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

Note 1: This specification applies to the gas phase of the cylinder as received.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	62.22	62.22
Boiling point at 1 atm	-14.8°C	5.4°C
Freezing point	-132.5°C	-206.5°C
Vapor density (air = 1)	2.38	2.38

4 Analytical Procedures

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in disilane using a gas chromatograph with a methanizer and a flame ionization detector. (See Figure 1, Notes 1 and 2.)

4.1.1 *Detection Limit* — 0.1 ppm for each impurity.

4.1.2 *Instrument Parameters*

4.1.2.1 Column: Porapak QS 3 m (10 ft) by 1.6 mm (1/16 in) ID ss or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 1.5 mL.

4.1.2.4 Support Gases: As specified by the instrument manufacturer.

Hydrogen: 20–30 mL per min added to the carrier gas between the column outlet and the methanizer inlet.

Air: 500 mL/min.

4.1.2.5 Temperatures:

Detector	110°C
Injector	60°C
Oven	60°C
Methanizer	370° – 400°C

4.1.3 *Calibration Standards* — 1–10 ppm carbon monoxide, 1–10 ppm carbon dioxide, balance helium.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is carbon monoxide, carbon dioxide. Repeat this operation.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard and vent after elution of carbon dioxide is completed, in case any silane is present. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1

4.1.4.4 Compare the average peak areas of the calibration standard to that of the disilane sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.2 *Methane, Ethane, Propane, and Silane* — This procedure is for the determination of hydrocarbons (methane, ethane, and propane) and silane in disilane using a gas chromatograph with a thermal conductivity detector.

4.2.1 *Detection Limit* — 3 ppm for each impurity.

4.2.2 *Instrument Parameters*

4.2.2.1 Column: Porapak QS 3 m (10 ft) by 1.6 mm (1/16 in) ID ss or equivalent.

4.2.2.2 Carrier Flow: 25 mL/min. Helium.

4.2.2.3 Sample Volume: 1 mL.

4.2.2.4 Temperatures:

Detector	80°C
Injector	60°C
Oven	60°C

4.2.3 *Calibration Standards* — 10–50 ppm methane, 5–10 ppm ethane, 5–10 ppm propane, 0.1 – 1% silane, balance helium.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is methane, silane, ethane, propane.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak areas of the calibration standard to that of the disilane sample being tested. Calculate the concentrations of methane, silane, ethane, and propane, using the formula below. The results may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.3 *Hydrogen, Nitrogen, and Argon* — This procedure is for the determination hydrogen, nitrogen, and argon in disilane using a gas chromatograph with a helium ionization detector.

4.3.1 *Detection Limit* — 100 ppb for hydrogen and argon, 500 ppb for nitrogen.

4.3.2 *Instrument Parameters*

4.3.2.1 Columns:

Column 1:	Porapak QS 2.5 m (8 ft) by 3.2 mm (1/8 in) OD ss or equivalent.
Column 2:	5A Molecular sieve, 3 m (10 ft) by 3.2 mm OD ss or equivalent.

4.3.2.2 Carrier Flow: 25 mL/min helium.

4.3.2.3 Sample Volume: 3 mL.

4.3.2.4 Temperatures:

Detector	100°C
Injector	30°C
Oven	30°C

4.3.3 *Calibration Standards* — 1–10 ppm nitrogen, 1–10 ppm argon, 10–100 ppm hydrogen, balance helium.

4.3.4 *Operating Procedure*

4.3.4.1 Determination of the backflush time: Inject a methane sample (1–1000 ppm, balance helium) using a 10 port gas valve and backflush at different times. Select the backflush time so that the methane peak is split by the backflush.

4.3.4.2 Inject the calibration standard into the column using a gas sampling valve. Backflush at the time determined in 4.3.4.1. Record retention times and peak areas. Order of elution is hydrogen, argon, nitrogen.

4.3.4.3 Inject the sample to be tested in same manner as the calibration standard. Backflush at the time determined in 4.3.4.1. Record the retention times and peak areas.

4.3.4.4 Repeat 4.3.4.2.

4.3.4.5 Compare the average peak areas of the calibration standard to that of the disilane sample being tested. Calculate the concentrations of hydrogen, nitrogen and argon using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.4 *Disiloxane, Monoethylsilane, Trisilane, and Tetrasilanes* — This procedure is for the determination of disiloxane, monoethylsilane, trisilane, and tetrasilanes in disilane using a gas chromatograph with a thermal conductivity detector.

4.4.1 *Detection Limits* — 5 ppm for disiloxane and 10 ppm for each of the other impurities.

4.4.2 *Instrument Parameters*

4.4.2.1 Column: 30% DC 200 on Chromosorb P, 80/100 mesh, 10 m (33 ft) by 3.2 mm (1/8 in) ss or equivalent.

4.4.2.2 Carrier Flow: 20 mL/min helium.

4.4.2.3 Sample Volume: 1 mL.

4.4.2.4 Temperatures:

Detector	120°C
Injector	60°C
Oven	60°C for 25 min then 10°C/min to 120°C

4.4.3 *Calibration Standard* — 100 ppm (mole/mole) each of trisilane, i-tetrasilane, and n-tetrasilane, and 10 ppm each disiloxane and monoethylsilane in helium. If one or several components cannot be obtained, use a 100 ppm monosilane standard and apply the following correction factors using the formula below (See Reference 1).

Trisilane CF = 0.54

i-tetrasilane CF = 0.42

n-tetrasilane CF = 0.41

Correction factors for disiloxane and monoethylsilane are not available. Use the same as disilane CF = 0.69. concentration of impurity = calculated concentration, using silane standard, × CF.

4.4.4 *Operating Procedure*

4.4.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. Order of elution is disiloxane, disilane, monoethylsilane, trisilane, i-tetrasilane, and n-tetrasilane.

4.4.4.2 Inject the sample to be tested in same manner as calibration standard. Record the retention times and peak areas.

4.4.4.3 Repeat 4.4.4.1.

4.4.4.4 Compare the average peak areas of the calibration standard to that of the disilane sample being tested. Calculate the concentrations of disiloxane, disilane, monoethylsilane, trisilane, i-tetrasilane, and n-tetrasilane, using the formula below. If necessary, correct the results using the specified correction factors in 4.4.3. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.5 *Water* — This procedure is for the determination of moisture in disilane using a continuous flow electrolysis of water in a phosphorus pentoxide (P_2O_5) cell. (See Note 3.)

4.5.1 *Detection Limit* — 1 ppm (volume/volume).

4.5.2 *Flow Requirement* — Set the sample flow rate and pressure in accordance with manufacturer's instructions.

4.5.3 *Operating Procedure*

4.5.3.1 Direct samples of three standards, independently verified with a dewpoint/frostpoint hygrometer, spanning the range of moisture content of interest to the analyzer. After a stable reading is obtained, record the instrument's response to each standard.

4.5.3.2 Obtain a representative sample of the gas to be analyzed and direct it to the unit as with the standards. After a stable reading is obtained, record the instrument's response.

4.5.3.3 Construct calibration curve from the standard data and determine the moisture content in sample gas. The result may not exceed the specification in Section 2 of this Standard.

4.6 *Total Chlorides* — This procedure is for the determination of total hydrolyzable chlorides in disilane by titration of a hydrolyzed sample of disilane. (See Figure 2.)

4.6.1 *Detection Limit* — 0.5 ppm.

4.6.2 *Instrument Parameters*

4.6.2.1 *Equipment*

1. Safety purge regulator with proper fittings.
2. Flow meter capable of measuring 0.25 standard liters per minute (0.5 SCF/hour) (Brooks or equivalent).
3. One cylinder of nitrogen with regulator.
4. One ice bath.
5. Three magnetic stirring bars.
6. Two 2000 mL heavy-duty sidearm flasks (Fisher Cat. No. 10-181G or equivalent).
7. One #9 one-hole rubber stopper.
8. One #9 two-hole rubber stopper.
9. Two borosilicate glass tubes with fritted cylinders (Fisher Cat. No. 11.138B or equivalent).
10. One gas washing bottle with fritted cylinder, 125 mL cap. (Fisher Cat. No. 03-040A or equivalent).
11. One buret, 50 mL capacity with PTFE stopcock (Fisher Cat. No. 03-700-22C or equivalent).

12. One buret stand (Fisher Cat. No. 14-688 or equivalent).
13. Miscellaneous clamps, support stands, and rubber hose.
14. Two 250 mL Erlenmeyer flasks.

4.6.3 *Reagents*

1. Potassium hydroxide flakes, technical (Fisher Cat. No. P-246 or equivalent).
2. Mercuric nitrate crystal (Fisher Cat. No. M-168 or equivalent).
3. Sodium chloride crystal (Fisher Cat. No. S-271 or equivalent).
4. Diphenyl carbazone (Fisher Cat. No. D-86 or equivalent).
5. Bromophenol blue (Fisher Cat. No. B-392 or equivalent).
6. Nitric acid (Fisher Cat. No. AA-200 or equivalent).
7. Ethanol, denatured (Fisher Cat. No. AA-407 or equivalent).

4.6.4 *Operating Procedure*

4.6.4.1 Fill each 2000 mL sidearm flask with about 1700 mL of 15% potassium hydroxide solution (15 g KOH per each 100 mL water).

4.6.4.2 Fill the gas washing bottle with about 75 mL of deionized water that has been degassed.

4.6.4.3 Assemble apparatus as shown in Diagram A and purge entire system with nitrogen for 30 minnutes.

4.6.4.4 Pass 30 liters (approximately one cubic foot) of disilane through the system at a rate of 0.25 liters per minute. Record the volume the disilane sample.

4.6.4.5 Stop disilane flow and purge system for 30 minutes.

4.6.4.6 Remove gas washing bottle from system and transfer contents quantitatively and with the aid of three 25 mL deionized water washings, to a 250 mL Erlenmeyer flask.

4.6.4.7 Add a few drops of indicator solution (5 g diphenyl carbazone plus 0.5 g bromophenol blue dissolved in 750 mL ethanol, plus 250 mL deionized water).

4.6.4.8 Add, in a drop-wise fashion, sufficient 0.2*N* HNO_3 (13 mL conc. HNO_3, diluted to 1 L in deionized water) in order to just turn the solution to yellow from purple.

4.6.4.9 Titrate with a solution of 5 g. mercuric nitrate $Hg(NO_3)_2$, (diluted to 1000 mL in deionized water; then 50 mL diluted to 500 mL in deionized water) which has been previously standardized to 5.0 mL of a sodium chloride solution (approximately 165 ng NaCl, accurately weighed, dissolved in 100 mL deionized water).

4.6.5 *Calibration*

4.6.5.1 Run titration blank consisting of 150 mL deionized water.

4.6.5.2 Calculate the concentration of chloride, using the formula below. The result may not exceed the specification in Section 3 of this Standard.

$$\frac{\text{mL sample - mL blank}}{\text{mL standard - mL blank}} \times \frac{\text{wt. of NaCl(g)}}{\text{100.0 mL}} \times$$

$$\frac{60.66\%\ Cl^-}{100\%\ NaCl} \times \frac{1000\ mL}{1\ L} \times \frac{.005\ L}{35.453\ g/mole} \times$$

$$\frac{0.082\ \text{atm L/mole K}}{1\ \text{atm}} \times \frac{294.26\ \ K}{\text{volume of gas samples}} \times$$

$$1 \times 10^6\ \text{ppm} = \text{ppm}\ Cl^-$$

4.6.6 *Final Calculation* — Convert the results from ppm (mole/mole) to ppm-wt using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\text{ppm - wt} = \text{ppm (mole/mole)} \times \frac{35.45}{62.22}$$

4.7 *Reference*

R.J. Bogaert, R.E. Rocheleau and B.N. Baron "Gas Chromatographic Determination of Silanes" J. of Chrom. Science Vol. 24, March 86.

4.8 *Notes*

Note 1: An optional temperature ramping during vent will shorten the analysis time.

Note 2: Carrier gases should contain less than 0.1 ppm (mole/mole) carbon monoxide and less than 0.1 ppm (mole/mole) carbon dioxide.

Note 3: Direct gases for moisture measurment to the analyzer with stainless steel lines which have been purged.

SEMI C3.20-92 (Reapproved 0999)
STANDARD FOR HELIUM (He), IN CYLINDERS, 99.9995% QUALITY

This standard was technically reapproved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1982; previously published in 1992.

1 Description

1.1 Helium is a rare gas or cryogenic liquid that is inert, colorless, odorless, and tasteless.

2 Specifications

QUALITY: 99.9995%

Impurities	*Maximum Acceptable Level (ppm)**
Carbon monoxide and carbon dioxide ($CO + CO_2$)	1
Nitrogen (N_2)	2
Oxygen (O_2)	0.5
Total Hydrocarbons expressed as Methane (THC)	0.5
Water (H_2O) (v/v)	0.5
TOTAL SPECIFIED IMPURITIES	4.5

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	4.003	4.003
Boiling point at 1 atm	-268.9°C	-452.0°F
Density of gas at 21.1°C (70°F) and 1 atm	0.1656 kg/m3	0.01034 lb/ft3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	0.138	0.138
Density of liquid at boiling point	124.9 kg/m3	7.798 lb/ft3

4 Analytical Procedures (See Notes 1, 2)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in helium using a gas chromatograph with a flame ionization detector and methanizer.

4.1.1 *Detection Limit* — 100 ppb (mole/mole).

4.1.2 *Instrument Parameters*

4.1.2.1 Column:

Porapak T or Q, 3 m (9.8 ft) by 3 mm (1/8 in) ss;

or

Chromosorb 102, 2 m (6.6 ft) by 3 mm ss;

or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 0.5 to 2.0 mL.

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standards* — 1-10 ppm (mole/mole) carbon monoxide, 1-10 ppm (mole/mole) carbon dioxide, balance helium.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to that of the helium sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{array}{c}\text{Concentration}\\ \text{of Standard}\end{array} = \begin{array}{c}\text{Concentration}\\ \text{of Sample}\end{array}$$

4.2 *Nitrogen* — This procedure is for the determination of nitrogen in helium using a gas chromatograph with a helium ionization detector.

4.2.1 Detection Limit — 500 ppb.

4.2.2 Instrument Parameters

4.2.2.1 Column: 5A molecular sieve, 1.9 m (6 ft) by 3.2 mm (1/8 in) ss, or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 3.0 mL.

4.2.2.4 Temperatures:

Detector	125°C
Column Temperature	65°C

4.2.3 *Calibration Standard* — 5-15 ppm nitrogen in helium.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the helium sample being tested. Calculate the concentration of nitrogen, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in helium using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb (mole/mole).

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 1-10 ppm (mole/mole) oxygen in helium or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce helium sample and record oxygen reading. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Water* — This procedure is for the determination of trace moisture (water) in helium using a continuous flowing piezoelectric hygrometer. (See Note 3.)

4.4.1 *Detection Limit* — 0.1 ppm (vol / vol) or -90°C (-130°F).

4.4.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently by another analytical method.

4.4.4 *Operating Procedure*

4.4.4.1 Obtain a continuous flow of sample gas from the source using a clean and passivated 316 stainless steel line which has been purged dry after exposure to ambient moisture.

4.4.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric hygrometer until a stable reading is obtained. Determine the concentration of moisture by comparing the reading to the calibration curve obtained in 4.4.3. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in helium using a continuous flow flame ionization detector-equipped total hydrocarbon analyzer. (See Notes 4, 5, 6.)

4.5.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.5.2 Flow Requirements

4.5.2.1 High purity, hydrocarbon-free (less than 1.0 ppm) hydrogen: 35-40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75-80 mL/min.

4.5.2.2 Dry, hydrocarbon-free (less than 1.0 ppm) air: 350-400 mL/min.

4.5.2.3 Set sample flow rates in accordance with instrument manufacturer's instructions.

4.5.3 *Calibration Standards*

4.5.3.1 Helium with known quantity of hydrocarbons at 0.5 ppm level.

4.5.3.2 The span gas not exceeding 5 times the concentration of the specification.

4.5.4 *Operating Procedure*

4.5.4.1 Do not change the initial flow settings for hydrogen, air and sample once established.

4.5.4.2 Introduce the zero helium with known quantity of hydrocarbons and, using the 0-10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.5.4.3 Introduce the span gas standard in helium and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.5.4.4 Introduce helium sample into the analyzer and read the quantity of hydrocarbons on the analyzer. The result may not exceed the specification in Section 2 of this Standard.

4.6 *Notes*

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

NOTE 3: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

NOTE 4: The 0-1 range may be used provided that zero and span gas standards in helium with known levels of hydrocarbons between 0-1 ppm are used in the calibration of the analyzer.

NOTE 5: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero gas matrices must coincide with that of the sample gas.

NOTE 6: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the most common hydrocarbon impurities in helium can be accurately totaled and compared to methane.

SEMI C3.45-92 (Withdrawn 0701)
STANDARD FOR HEXAFLUOROETHANE (C_2F_6), 99.996% QUALITY (PROVISIONAL)

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Hexafluoroethane is one of the most stable of all organic compounds. It is inert, colorless, nonflammable, odorless and tasteless.

SEMI C3.37-0701
SPECIFICATION FOR HEXAFLUOROETHANE (C_2F_6), 99.97% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001. Originally published in 1989; previously published in 1993.

1 Description

1.1 Hexafluoroethane is one of the most stable of all organic compounds. It is inert, colorless, nonflammable, odorless and tasteless.

2 Specifications

QUALITY: 99.97%

Impurities	*Maximum Impurities Acceptable (ppm)**
Carbon Dioxide (CO_2)	1
Carbon Monoxide (CO)	1
Nitrogen (N_2)	100
Other Halogenated Hydrocarbons (CF_3Cl, CF_3H, CF_2HCl, C_2F_5Cl)	50
Oxygen (O_2)	25
Water (H_2O) (v/v)	40
TOTAL LISTED IMPURITIES	217

*An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Chemical Specification

Total Acidity	0.1 ppmw max.

4 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	138.01	138.01
Boiling point at 1 atm	-78.2°C	-108.8°F
Density of gas at 24°C (75°F) and 1 atm	5.734 kg/m^3	0.357 lb/ft^3
Specific gravity of gas at 24°C and 1 atm	4.823	4.823
Density of liquid at -80.0°C	1611 kg/m^3	100.6 lb/ft^3

5 Analytical Procedures (See Notes 1, 2, 3, and Figure 1)

5.1 *Oxygen, Nitrogen, Carbon Monoxide, and Carbon Dioxide* — This procedure is for the determination of oxygen, nitrogen, carbon monoxide, and carbon dioxide in hexafluoroethane using a gas chromatograph with an ultrasonic detector.

5.1.1 *Detection Limit* — 0.5 ppm (mol/mol) for each impurity.

5.1.2 *Instrument Parameters*

5.1.2.1 *Columns:*

Column 1:	Haysep D, 100/120 mesh, 4.6 m (15 ft) by 3.2 mm (1/8 in) OD ss, or equivalent.
Column 2:	Porapak QS, 100/120 mesh, 2.1 m (7 ft) by 3.2 mm (1/8 in) OD ss, or equivalent.
Column 3:	Porapak QS, 100/120 mesh, 3.6 m (2 ft) by 3.2 mm (1/8 in) OD ss, or equivalent.
Column 4:	Haysep D, 100/120 mesh, 4.6 m (15 ft) by 3.2 mm (1/8 in) OD ss, or equivalent.
Column 5:	Molecular Sieve 13×, 45/60 menh, 2.1 m (7 ft) by 3.2 mm (1/8 in) OD ss, or equivalent.

5.1.2.2 Carrier Flow: 16 mL/min helium

5.1.2.3 Sample Volume: 1.0 and 2.0 mL

5.1.2.4 *Temperatures:*

Detector	120°C
Column 1, 2 and 5	50°C
Column 3 and 4	90°C
Valve	90°C

5.1.2.5 *Time Table* — Determine the times for valve switching and signal changes, and enter into the run table.

An example run table follows:

Valve	*On*	*Off*
1	0.01	*
2	9.20	*
3	0.01	12.00

* Valve left on until end of run.

5.1.3 *Calibration Standard* — 1–5 ppm (mol/mol) each carbon dioxide, nitrogen, oxygen and carbon monoxide, balance helium.

5.1.4 *Operating Procedure*

5.1.4.1 Inject a sample of the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. The approximate retention times are: oxygen 11.1 minutes, nitrogen 11.6

minutes, carbon monoxide 14.5 minutes and carbon dioxide 15.9 minutes.

5.1.4.2 Analyze the hexafluoroethane sample to be tested in the same manner as in 5.1.4.1

5.1.4.3 Repeat 5.1.4.1.

5.1.4.4 Calculate the concentration of oxygen, nitrogen, carbon monoxide and carbon dioxide in the sample, using the formula below. The result may not exceed specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

5.2 *Halogenated Hydrocarbons* — This procedure is for the determination of halogenated hydrocarbons in hexafluoroethane using a gas chromatograph with a flame ionization detector.

5.2.1 *Detection Limit* — 0.5 ppm (mol/mol).

5.2.2 *Instrument Parameters*

5.2.2.1 Column: 1% SP-1000 on Carbopak B, 60/80 mesh, 7.3 m (24 ft) by 3.2 mm (1/8 in) OD ss, or equivalent.

5.2.2.2 Carrier Flow: 40 mL/min helium

5.2.2.3 Support Gases: Set the flow rates as specified by the instrument manufacturer.

5.2.2.4 Sample Volume: 2.0 mL

5.2.2.5 Temperatures:

Detector	250°C
Initial Oven	35°C
Pre-Program Hold	7 min
Temperature Rise	10°C/min
Final Oven	150°C

5.2.3 *Calibration Standard* — 5 ppm (mol/mol) each CF_3H, C_2F_6, CF_3Cl, CF_2HCl, C_2F5Cl balance helium.

5.2.4 *Operating Procedure*

5.2.4.1 Inject a sample of the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. The order of elution is CF_3H, C_2F_6, CF_3Cl, CF_2HCl, C_2F_5Cl.

5.2.4.2 Analyze the hexafluoroethane sample to be tested in the same manner as in 5.2.4.1.

5.2.4.3 Repeat 5.2.4.1.

5.2.4.4 Calculate the concentration of each impurity in the sample using the formula below. Total the amounts of chlorofluorocarbons and hydrofluorocarbons. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \frac{\text{Concentration}}{\text{of Standard}} = \frac{\text{Concentration}}{\text{of Sample}}$$

5.3 *Water (See Note 4)* — This procedure is for the determination of trace moisture (water) in hexafluoroethane, using a continuous flowing electrolytic hygrometer.

5.3.1 *Detection Limit* — 1.0 ppm (ppmw). This is equivalent to a frostpoint of -76°C (-105°F).

5.3.2 *Sample Pressure and Flow* — Set in accordance with instrument manufacturer's instructions.

5.3.3 *Operation Check* — The instrument should be checked periodically for correct operation. A gas containing a known amount of moisture should be passed through the instrument. Agreement between the hygrometer and the standard should be within their relative accuracies.

5.3.4 *Operating Procedure*

5.3.4.1 Obtain a continuous flow sample of the hexafluoroethane source, using a clean, electropolished or passivated (see Note 5) stainless steel line which has been purged dry after exposure to ambient moisture.

5.3.4.2 After purging with a dry gas, allow the sample gas to flow through the sampling system and hygrometer until a stable reading is obtained. The reading may not exceed specification in Section 2 of this Standard.

5.4 *Notes*

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should not contain more than 10% of the specified value of the component of interest, unless otherwise stated.

NOTE 3: Samples of hexafluoroethane should be equilibrated at no less than 22°C (72°F) for at least 24 hours prior to analysis to ensure that the material, whose critical temperature is 20°C (68°F), is single phase.

NOTE 4: The sampling system and hygrometer must be designed to operate at the sample pressure, or the sample pressure must be reduced (by a regulator with a stainless steel diaphragm) to accommodate the pressure restrictions of the hygrometer.

NOTE 5: A passivation procedure is described in Metals Handbook, Eighth Edition, Volume 2, ASM International, Metals Park, Ohio.

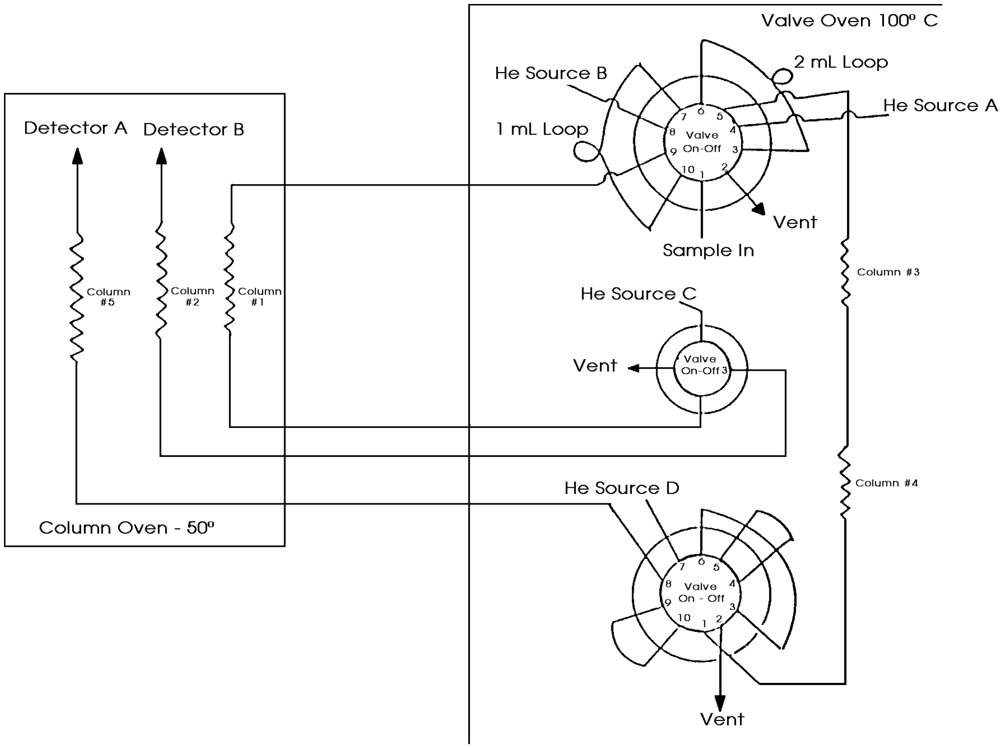

Figure 1
Configuration for the Analysis of O_2, N_2O_2 in C_2F_6

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.19-0200
STANDARD FOR HYDROGEN (H_2), 99.9995% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org January 2000, to be published February 2000. Originally published in 1982; previously in 1996.

1 Description

1.1 Hydrogen is a colorless gas. Its vapors are highly flammable, colorless, tasteless, and nontoxic. It is the lightest gas known.

2 Specifications

QUALITY: 99.9995%

Impurities	*Maximum Acceptable Level (ppm) (See NOTE 1.)*
Carbon Dioxide (CO_2)	0.5
Carbon Monoxide (CO)	0.5
Nitrogen (N_2)	2
Oxygen (O_2)	0.5
Particles	(See NOTE 2.)
Total Hydrocarbons expressed as Methane (THC)	0.5
Water (H_2O) (v/v)	0.5
TOTAL SPECIFIED IMPURITIES	4.5

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

NOTE 2: To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	2.016	2.016
Boiling point at 1 atm	–252.7°C	–423.0°F
Density of gas at 21.1°C (70°F) and 1 atm	0.0834401 kg/m^3	0.005209 lb/ft^3
Specific gravity of gas at 0°C (32°F) and 1 atm (air = 1)	0.06950	0.06950
Density of liquid at boiling point	68.6 kg/m^3	4.28 lb/ft^3

4 Analytical Procedures (See NOTES 1 and 2)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in hydrogen using a gas chromatograph with a flame ionization detector and methanizer.

4.1.1 *Detection Limit* — 100 ppb (mole/mole)

4.1.2 *Instrument Parameters*

4.1.2.1 *Column* — Porapak T or Q, 3 m (9.8 ft) by 3 mm (1/8 in) ID by 2.2 mm (0.085 in) OD stainless steel;

or

Chromosorb 102, 2 m (6.6 ft) by 3 mm stainless steel;

or equivalent.

4.1.2.2 *Carrier Flow* — 30 mL/min helium

4.1.2.3 *Sample Volume* — 0.5 to 2.0 mL

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standard* — 0.5–2.5 ppm (mole/mole) carbon monoxide, 0.5–2.5 ppm (mole/mole) carbon dioxide, balance hydrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat Section 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to that of the hydrogen sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Nitrogen* — This procedure is for the determination of nitrogen in hydrogen using a gas chromatograph with a helium ionization detector.

4.2.1 *Detection Limit* — 500 ppb (mole/mole)

4.2.2 *Instrument Parameters*

4.2.2.1 *Column* — 5A molecular sieve 1.9 m (6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID by stainless steel or equivalent.

4.2.2.2 *Carrier Flow* — 30 mL/min helium

4.2.2.3 *Sample Volume* — 3.0 mL

4.2.2.4 Temperatures:

Detector	125°C
Column Temperature	65°C

4.2.3 *Calibration Standard* — 0.5–2.5 ppm, (mole/mole) nitrogen in hydrogen.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.3 Repeat Section 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the hydrogen sample being tested. Calculate the concentration of nitrogen, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in hydrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb (mole/mole)

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer’s instructions.

4.3.3 *Calibration Standard* — 0.5–2.5 ppm (mole/mole) oxygen in hydrogen or in accordance with the instrument manufacturer’s instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce hydrogen sample and record oxygen reading. The result may not exceed the specification in Section 2 of this standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in hydrogen using a continuous flow flame ionization detector-equipped total hydrocarbon analyzer. (See NOTES 3, 4, and 5.)

4.4.1 *Detection Limit* — 0.1 ppm (mole/mole)

4.4.2 *Flow Requirements*

4.4.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen: 35–40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75–80 mL/min.

4.4.2.2 Dry, hydrocarbon-free (less than 0.1 ppm) air: 350–400 mL/min.

4.4.2.3 Set sample flow rates in accordance with instrument manufacturer’s instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Zero hydrogen with known quantity of hydrocarbons at 0.1 ppm level.

4.4.3.2 The upper level span gas not exceeding five times the concentration of the specification.

4.4.4 *Operating Procedure*

4.4.4.1 Do not change the initial flow settings for hydrogen, air and sample once established.

4.4.4.2 Introduce the zero hydrogen with known quantity of hydrocarbons and using the 0–10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.4.4.3 Introduce the span gas standard in hydrogen and using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.4.4.4 Repeat Sections 4.4.4.2 and 4.4.4.3 until reproducibility of readings is better than 1% full scale.

4.4.4.5 Introduce hydrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in hydrogen using a continuous flowing piezoelectric hygrometer. (See NOTE 6.)

4.5.1 *Detection Limit* — 0.1 ppm (vol/vol) or –90°C (–130°F)

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer’s instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently by another analytical method.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the hydrogen sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this standard.

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

NOTE 3: The 0-1 range can be used provided that zero and span gas standards in hydrogen with known levels of hydrocarbons between 0 and 1 ppm are used in the calibration of the analyzer.

NOTE 4: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero gas matrices must coincide with that of the sample gas.

NOTE 5: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the common hydrocarbon impurities in nitrogen can be accurately totaled and compared to methane.

NOTE 6: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

SEMI C3.30-96 (Reapproved 0999)
STANDARD FOR HYDROGEN (H_2), BULK, 99.9997% QUALITY

This standard was technically reapproved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1986; previously published in 1996.

1 Description

1.1 Hydrogen is a colorless gas. Its vapors are highly flammable, colorless, tasteless, and nontoxic. It is the lightest gas known.

2 Specifications

QUALITY: 99.9997% (see Note 1)

Impurities	*Maximum Acceptable Level (ppm)**
Carbon monoxide andcarbon dioxide ($CO + CO_2$)	0.2
Nitrogen (N_2)	2.0
Oxygen (O_2)	0.2
Particles	**
Total Hydrocarbons expressed as Methane (THC)	0.2
Water (H_2O) (v/v)	0.2
TOTAL IMPURITIES	2.8

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	2.016	2.016
Boiling point at 1 atm	-252.7°C	-423.0°F
Density of gas at 21.1°C (70°F) and 1 atm	0.0834401kg/m^3	0.005209 lb/ft^3
Specific gravity of gas at 0°C (32°F) and 1 atm (air = 1)	0.06950	0.06950
Density of liquid at boiling point	68.6 kg/m^3	4.28 lb/ft^3

4 Analytical Procedures

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in hydrogen using a gas chromatograph with a flame ionization detector and methanizer.

4.1.1 *Detection Limit* — 50 ppb (mole/mole).

4.1.2 *Instrument Parameters*

4.1.2.1 Column:

Porapak T or Z, 3 m (9.8 ft) by 3.2 mm (1/8 in) ss;

or

Chromosorb 102, 2 m (6.6 ft) by 3.2 mm ss;

or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 0.5 to 2.0 mL.

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standard* — 1-5 ppm (mole/mole) carbon monoxide, 1-5 ppm (mole/mole) carbon dioxide, balance hydrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to that of the hydrogen sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed specifications in Section 2 of this standard.

4.2 *Nitrogen* — This procedure is for the determination of nitrogen in hydrogen using a gas chromatograph with a helium ionization detector (see Notes 2, 3, 4, 5, 6, and Figures 1 and 2).

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.2.1 Detection Limit — 12 ppb.

4.2.2 Instrument Parameters

4.2.2.1 Columns:

Column 1 (Pre-Column):	Molecular sieve 5A, 60/80 Mesh, 2.4 m (8 ft) by 3.2 mm (1/8 in), ss, or equivalent.
Column 2 (Analytical Column):	Molecular sieve 5A, 60-80 Mesh, 2.4 m by 3.2 mm, ss, or equivalent.

4.2.2.2 Carrier Flow: 40 mL/min helium.

4.2.2.3 Sample Volume: 1.0 mL.

4.2.2.4 Temperatures:

Detector	100°C
Column	50°C
Hydrogen Purifier	300°C

4.2.2.5 Determine the breakdown voltage of the detector. Set operating voltage at 10 volts below breakdown.

4.2.3 *Calibration Standard* — 2 ppm (mole/mole) nitrogen, balance hydrogen (99.9999% purity).

4.2.4 *Operating Procedure*

4.2.4.1 Set timing interval on sample select valve to 10 sec.

4.2.4.2 Set timing interval on gas sampling valve to 3 minutes.

4.2.4.3 Set timing interval #3 to 5 minutes.

4.2.4.4 Do not change the initial sample flow setting once established.

4.2.4.5 Obtain a continuous flow of the calibration standard using a clean stainless steel line (0.5 mm (.02 in.) ID).

4.2.4.6 Inject the calibration standard onto the column with the gas sampling valve. Record the retention times and peak areas.

4.2.4.7 Repeat 4.2.4.6 until reproducibility of reading is better than 1% of full scale.

4.2.4.8 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.9 Compare the average peak area of the hydrogen sample being tested to that of the calibration standard. Calculate the concentration of nitrogen, using the formula below. The result may not exceed the specification in Section 2 of this standard.

4.3 *Oxygen* — This procedure is for the determination of oxygen in hydrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 50 ppb (mole/mole).

4.3.2 *Instrument Parameters* — Set the sample pressure and flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 1-10 ppm (mole/mole) oxygen in hydrogen or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce hydrogen containing less than 2 ppm oxygen through a deoxygenation catalyst to verify that there is no leakage of air into the system and to demonstrate that the detection limit can be achieved.

4.3.4.3 Introduce the calibration standard. Using the span adjust knob, set the needle (or output reading) to match the level oxygen in the calibration gas.

4.3.4.4 Introduce hydrogen sample and record the oxygen reading. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.4 *Water* — This procedure is for the determination of trace moisture (water) in hydrogen using a continuous flowing piezoelectric hygrometer (see Note 7).

4.4.1 *Detection Limit* — 0.1 ppm (vol/vol) or -90°C (-130°F).

4.4.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently by another analytical method.

4.4.4 *Operating Procedure*

4.4.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.4.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.4.4.3 Determine the moisture content of the hydrogen sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this standard.

4.5 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in hydrogen using a continuous flow flame ionization detector equipped total hydrocarbon analyzer. (See Note 8.)

4.5.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.5.2 *Flow Requirements*

4.5.2.1 High-purity, hydrocarbon-free (less than 1.0 ppm) hydrogen: 35-40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75-80 mL/min.

4.5.2.2 Dry, hydrocarbon-free (less than 1.0 ppm) air: 350-400 mL/min.

4.5.2.3 Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards*

4.5.3.1 Zero hydrogen with known quantity of hydrocarbons at 0.1 ppm level.

4.5.3.2 *Span Gas* — Hydrogen with known quantity (1-10 ppm) hydrocarbons.

4.5.4 *Operating Procedure*

4.5.4.1 Do not change the initial flow setting for hydrogen, air and sample once established.

4.5.4.2 Introduce the zero hydrogen with known quantity of hydrocarbons and, using the 0-10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.5.4.3 Introduce the span gas standard in hydrogen and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.5.4.4 Repeat steps 4.5.4.2 and 4.5.4.3 until reproducibility of readings is better than 1% of full scale.

4.5.4.5 Introduce hydrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

4.6 *Notes*

NOTE 1: A purifier is allowed to be used to meet this specification.

NOTE 2: All carrier lines must be cleaned stainless steel.

NOTE 3: The carrier gas must be 99.9998% purity helium with less than 40 ppb carbon dioxide.

NOTE 4: Use a stainless steel pressure regulator with no pipe threads, PTFE thread sealant or other plastic seal components for the carrier gas.

NOTE 5: Due to the extreme sensitivity of the helium ionization detector, it is imperative that the system be leak tested to 1 X 10^{-7} atm. cc/sec (helium) or lower with a helium leak detector.

NOTE 6: The hydrogen separator is the palladium tube type where the sample flows through a heated palladium tube through which the hydrogen selectively diffuses separating it from the impurities which are carried to the column by the helium carrier gas.

NOTE 7: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced, by a regulator with a diaphragm of stainless steel or other suitable material, to accommodate the pressure restrictions of the analytical hygrometer.

NOTE 8: The 0-1 ppm range can be used provided that zero and span gas standards in hydrogen with known levels of hydrocarbons between 0-1 ppm are used in the calibration of the analyzer.

SEMI

SEMI C3.47-1101
SPECIFICATION FOR HYDROGEN BROMIDE (HBr), 99.98% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1993; previously published in 1995.

1 Description

1.1 Hydrogen Bromide is an irritating and corrosive gas with a sharp, penetrating, suffocating odor. It is colorless and nonflammable, but fumes in moist air.

2 Specifications

QUALITY: 99.98%, ASSAY (Total Acidity): 98% min

Impurities	*Maximum Impurities Acceptable (ppm)**
Carbon Dioxide (CO_2)	50
Carbon Monoxide (CO)	5
Hydrogen Chloride (HCl)	**
Methane (CH_4)	15
Oxygen (O_2) + Nitrogen (N_2)	50
Water (H_2O) (v/v)	5
TOTAL LISTED IMPURITIES (excluding metals)	125

Impurities	*Maximum Impurities Acceptable (ppm)**
Iron (Fe)	1 (by weight, vapor phase)

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.
** To be analyzed and reported (typically 500 ppm).

3 Physical Constants (for information only)

	Metric Units	*U.S. Units*
Molecular Weight	80.92	80.92
Boiling Point at 1 atm	-66.7°C	-88.1°F
Density of gas at 70°F (21.1°C) and 1 atm	3.333 g/L	0.208 lb/ft^3
Specific gravity of gas	2.7	2.7
Critical Pressure	85.16 bar	1234.8 psia
Critical Temperature	90°C	193.6°F

4 Analytical Procedures

4.1 *Nitrogen, Oxygen, Carbon Monoxide, Methane, and Carbon Dioxide* — This procedure is for the determination of nitrogen, oxygen + argon, carbon monoxide, methane, and carbon dioxide using a gas chromatograph with a discharge ionization detector.

4.1.1 *Detection Limits*

- N_2 < 10 ppb
- O_2 + Ar < 20 ppb
- CO < 20 ppb
- CH_4 < 10 ppb
- CO_2 < 10 ppb

4.1.2 *Instrument Parameters* — All components are analyzed using two columns and two detectors with a single injection. (See Figure 1.)

4.1.2.1 *Columns*:

- HayeSep Db 2.0 m (6 ft.) by 3.2 mm (1/8") O.D. by 2.2 mm (0.085") I.D.
- Molecular Sieve 5A 2.0 m (6 ft) by 3.2 mm (1/8") O.D by 2.2 mm (0.085") I.D. ss or equivalent (60/80 mesh)

4.1.2.2 *Carrier Flow* — 40 mL/min He

4.1.2.3 *Sample Volume* — 1.0 mL

4.1.2.4 Temperatures:

Detector	100°C
Column 1	40°C
Column 2	100°C

4.1.3 *Calibration Standards* — 5 ppm of each compound of interest including nitrogen, oxygen, carbon monoxide, methane, and carbon dioxide in helium.

4.1.4 *Operating Procedures*

4.1.4.1 Inject a sample of the calibration standard into the HayeSep column using a gas sample valve. Allow the effluent of HayeSep column to enter the Molecular Sieve column until after CO has eluted. Switch the switching valve to allow the methane and CO_2 to elute directly into detector A while oxygen, nitrogen, and CO separate on the molecular sieve column and elute into detector B. Record retention times and peak areas for all peaks. The order of elution from the HayeSep column to detector A is methane and CO_2. The order of elution on the molecular sieve column to detector B is oxygen, nitrogen, and CO.

4.1.4.2 Analyze the HBr sample to be tested in the same manner.

4.1.4.3 Analyze the calibration standard again.

4.1.4.4 Compare the average peak area of the calibration standard to that of the HBr sample being tested. Calculate the concentration of impurities, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Water* — This procedure is for the determination of trace moisture (water) in hydrogen bromide gas using a continuous flowing, cooled surface condensation point hygrometer.

NOTE 1: The National Institute of Standards and Technology (NIST) provides calibration services for the thermometer used in condensation point hygrometers.

NOTE 2: This method is not applicable if other constituents in the gas will condense before the moisture condensation i.e., excessive carbon dioxide and/or oil contamination.

NOTE 3: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced to accommodate the pressure restrictions of the analytical hygrometer using a regulator with a stainless steel diaphragm.

4.2.1 *Detection Limit* — 2.0 ppm.

4.2.2 *Flow Requirements:*

4.2.2.1 Sample flow rate and pressure will be set in accordance with the instrument manufacturer’s instructions.

4.2.2.2 Gas must flow past the chilled mirror where optic means are provided to detect the deposit (condensation) and to read the thermometer measuring the temperature of the mirror.

4.2.3 *Calibration*

4.2.3.1 A calibration thermometer designed to indicate temperatures in the –89°C (–121°F) range is required.

4.2.3.2 A calibration curve representing water added to dried hydrogen bromide vs condensation point is required. This can be obtained by preparing a standard of water balance nitrogen and mixing it with dry hydrogen bromide using a dynamic gas blender with mass flow controllers or calibrated flow meters. The hydrogen bromide gas can be dried by passing it over an activated molecular sieve (5A) or magnesium perchlorate.

4.2.4 *Operating Procedures*

4.2.4.1 Obtain a continuous flow of sample gas from the source using a clean stainless steel sampling line which has been purged dry after exposure to ambient moisture.

4.2.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the condensation point hygrometer for one-quarter hour to two hours to allow the entire system to reach equilibrium with regard to moisture content.

4.2.4.3 After equilibrium has been reached, cool the mirror to determine the actual condensation point of the sample. Follow the manufacturer’s recommendations to create the temperatures needed.

4.2.4.4 Continue to verify the condensation point for at least 30 minutes after a stable reading has been confirmed.

4.2.4.5 Correct the condensation point reading from the measured pressure to 1 atm of pressure. The result may not exceed the specification in Section 2 of this standard.

4.3 *Iron* — This procedure is for the determination of iron in gaseous hydrogen bromide and analyzed by inductively coupled plasma.

4.3.1 *Sampling Apparatus*

- 3 Teflon diaphragm valves (1/4" FNPT) (Fluoroware 201-10 or equivalent)
- 2 Teflon tees (1/4") (Fluoroware UT4FN-1 or equivalent)
- 50 ft. Teflon tubing (1/4") (Fluoroware AT250-047 or equivalent)
- Teflon flow meter (1/4" FNPT calibrated for HBr flow) (Fluoroware FM-4N-1P or equivalent)
- 8 Teflon connectors (1/4" tube to 1/4" MNPT (Fluoroware C4-CFN-1 or equivalent)
- 9 gas washing bottles (375 mL) (Savillex #507 or equivalent with 501-4-2 cap)
- Tee purge assembly (Matheson 4756-330 or equivalent)
- Manual control valve (Matheson 55A-330 or equivalent)
- Cylinder scale that can measure the mass of the cylinder to ± 1 g accuracy.

4.3.2 *Water* — 18 megaohm-cm DI water is used for all dilution blanks and washings.

4.3.3 *Reagents* — All reagents are of the highest purity available minimizing background metal contamination.

4.3.4 *Sampling Gaseous Hydrogen Bromide*

4.3.4.1 Assemble sampling apparatus in laboratory hood for safety.

4.3.4.2 Fill gas washing bottles (scrubbers) with 75 mL 18 megaohm-cm DI water.

4.3.4.3 Start nitrogen purge to remove air from system and to check for leaks.

4.3.4.4 Close V4 and nitrogen purge.

4.3.4.5 Close V2.

4.3.4.6 Open V1 and V3.

4.3.4.7 Open V2 and controlling flow rate at 1 L/min taking care not to over-pressurize system.

4.3.4.8 Continue flow through scrubber train #1 until scale shows that approximately 100 grams of HBr have been purged.

4.3.4.9 Open V4 and close V3. Record the weight of HBr cylinder.

4.3.4.10 Collect 100 grams of HBr in scrubber train #2. Close V1 and record weight of HBr sampled.

4.3.4.11 Open nitrogen purge and purge lines, scrubber train #1 and scrubber train #2, before disconnecting scrubbers.

4.3.5 *Sample Preparation*

4.3.5.1 For each scrubber train, quantitatively wash with DI water and add to 250 mL volumetric.

4.3.5.2 Wash associated tubing of each scrubber train with DI water and add to the 250 mL volumetric.

4.3.5.3 Make up reagent blank of water from the same lot of DI water used in the sampling.

4.3.6 *Calibration* — Make calibration standards by serial dilution of standard iron solution which is matrix matched traceable to NIST.

4.3.7 *Instrument Parameters* — Perform analysis on an inductively coupled plasma spectrometer or equivalent technique employing operating procedures suggested by manufacturer. Correct result to ppm (ppmw) basis on HBr used.

4.4 *Chloride Ion* — This procedure is for the determination of chloride ion in gaseous hydrogen bromide using ion chromatography.

4.4.1 *Detection Limit* — 5 ppb wt/vol.

4.4.2 Sample was prepared as in Section 4.3.5. The 250 mL aqueous sample was diluted further 500 to 1, by diluting one milliliter of 250 mL aqueous sample with DI water in a 500 mL volumetric flask.

4.4.3 *Instrument Parameters*

4.4.3.1 *Flow*:

- Eluent l0 mM NaOH at 1 cc/min.
- Regenerate 25 mM H_2SO_4 at 7 psi.

4.4.3.2 *Column* — AS5A with AG5A guard column

4.4.3.3 *Sample Size* — 25 microliters.

4.4.3.4 *Program* — Boost eluent concentration to 100 mM NaOH after elution of chloride peak (4.3 min). Continue 100 mM eluent flow for 7 minutes to elute bromide peak. Return to 10 mM NaOH at 12 minutes. Allow to equilibrate for 6 minutes.

4.4.4 *Calibration* — A multi-point calibration curve is constructed in the range of 10 ppb to 250 ppb (wt/vol) employing standards traceable to NIST.

4.4.5 Use procedures provided by manufacturer of ion chromatograph. Correct results and calculate them to pure HBr on a weight/weight basis.

Iron Analysis Sampling Apparatus

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.36-94 (Withdrawn 0701)
STANDARD FOR HYDROGEN CHLORIDE (HCl), 99.994% QUALITY (PROVISIONAL)

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Hydrogen chloride is a colorless, pungent, corrosive gas having a suffocating odor. Hydrogen chloride is heavier than air and fumes strongly in moist air. It is very soluble in water and alcohol, and also soluble in ether. Hydrogen chloride is shipped as a liquified compressed gas stored under its own vapor pressure. As long as liquid is present in the cylinder, the pressure will remain fairly constant. When the liquid phase is exhausted, the cylinder pressure will drop rather rapidly.

SEMI C3.35-1101
SPECIFICATION FOR HYDROGEN CHLORIDE (HCl), 99.997% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1988; previously published in 1995.

1 Description

1.1 Hydrogen chloride is a colorless, pungent, corrosive gas having a suffocating odor. Hydrogen chloride is heavier than air and fumes strongly in moist air. It is very soluble in water and alcohol, and also soluble in ether. While in the cylinder under pressure, hydrogen chloride is in the form of a gas over liquid. As long as liquid is present in the cylinder, the pressure will remain fairly constant. When the liquid phase is exhausted, the cylinder pressure will drop rather rapidly.

2 Specifications

QUALITY: 99.997% (See Notes 1, 2, and 3.)

Impurities	*Maximum Acceptable Level (ppm)**
Carbon dioxide (CO_2)	10
Hydrogen (H_2)	5
Nitrogen (N_2)	10
Oxygen (O_2) + Argon (Ar)	1
Methane and Acetylene	1
Water (H_2O) (v/v)	1
TOTAL LISTED IMPURITIES (excluding metals)	28

	*Maximum Acceptable Level (ppm)**
Iron (Fe)	1 wt. vapor phase

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the procedure provided.

NOTE 1: Due to the reactive nature of the material and the impurities, this product should be used within a period which may be specified by the supplier.

NOTE 2: It is recommended that the user discontinue the use of a cylinder prior to complete consumption of the liquid phase. The content of cylinders should be determined by weight, not pressure.

NOTE 3: This specification applies to the gas phase of the cylinder as received.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	36.465	36.465
Boiling point at 1 atm	–85.°C	–121.°F
Density of gas at 21.1°C (70°F) and 1 atm	1.522 kg/m^3	0.095 lb/ft^3
Specific gravity of gas at 0°C (32°F) and 1 atm	1.268	1.268

4 Analytical Procedures

4.1 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in hydrogen chloride using a gas chromatograph with a thermal conductivity detector. A backflush is used to keep the main component from reaching the detector.

4.1.1 *Detection Limit* — 2 ppm.

4.1.2 *Instrument Parameters*

4.1.2.1 Column: Porapak Q, 2.4 m (8 ft) by 6.4 mm (1/4 in) OD ss or equivalent.

4.1.2.2 Carrier Flow: 40 mL/min helium.

4.1.2.3 *Temperatures*:

Detector	50°C
Column Oven	40°C

4.1.2.4 Sample Volume: 10 mL.

4.1.3 *Calibration Standard* — 100 ppm carbon dioxide in helium.

4.1.4 *Operating Procedure*

4.1.4.1 To determine the backflush time, inject the calibration standard, using a gas sampling valve. Record the retention time for carbon dioxide. Choose the backflush time so that the complete carbon dioxide peak is eluted.

4.1.4.2 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Backflush at the time determined in Section 4.1.4.1.

4.1.4.3 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas. Backflush the main component at the time determined in Section 4.1.4.1.

4.1.4.4 Repeat Section 4.1.4.2.

4.1.4.5 Compare the average peak area of the calibration standard to that of the hydrogen chloride sample being tested. Calculate the concentration of carbon dioxide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Hydrogen* — This procedure is for the determination of hydrogen in hydrogen chloride using a gas chromatograph with a thermal conductivity detector.

4.2.1 *Detection Limit* — 3 ppm.

4.2.2 *Instrument Parameters*

4.2.2.1 *Columns*:

Column 1:	Ascarite, 0.3 m (1 ft) by 9.6 mm (3/8 in) OD ss or equivalent.
Column 2:	Molecular Sieve 5A, 2.4 m (8 ft) by 6.4 mm (1/4 in) OD ss or equivalent.

4.2.2.2 Carrier Flow: 40 mL/min nitrogen.

4.2.2.3 *Temperatures*:

Detector	50°C
Column Oven	40°C

4.2.2.4 Sample Volume: 10 mL.

4.2.3 *Calibration Standard* — 50 ppm hydrogen in nitrogen.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard with that of the hydrogen chloride sample being tested. Calculate the concentration of hydrogen using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Iron* — This procedure is for the determination of iron sampled from gaseous hydrogen chloride and analyzed by inductively coupled plasma.

4.3.1 *Sampling Apparatus*

- 3 Teflon diaphragm valves (1/4" FNPT) (Fluoroware 201-10 or equivalent).
- 2 Teflon tees (1/4") (Fluoroware UT4FN-1 or equivalent).
- 50 ft. Teflon tubing (1/4") (Fluoroware AT250-047 or equivalent).
- Teflon flow meter (1/4" FNPT calibrated for HCl flow) (Fluoroware FM-4N-1P or equivalent).
- 8 Teflon connectors (1/4" tube to 1/4" MNPT (Fluoroware C4-CFN-1 or equivalent).
- 9 gas washing bottles (375 mL) (Savillex #507 or equivalent with 501-4-2 cap).
- Tee purge assembly (Matheson 4756-330 or equivalent).
- Manual control valve (Matheson 55A-330 or equivalent).
- Cylinder scale that can measure the mass of the cylinder to ± 1 g accuracy.

4.3.2 *Water* — 18 megohm-cm DI water is used for all dilution blanks and washings.

4.3.3 *Reagents* — All reagents are of the highest purity available minimizing background metal contamination.

4.3.4 *Sampling Gaseous Hydrogen Chloride*

4.3.4.1 Assemble entire sampling apparatus (see Figure 1) in laboratory hood for safety.

4.3.4.2 Fill gas washing bottles (scrubbers) with 75 mL 18 mega-ohm DI water.

4.3.4.3 Start nitrogen purge to remove air from system and to check for leaks.

4.3.4.4 Close V4 and close nitrogen purge.

4.3.4.5 Close V2.

4.3.4.6 Open V1 and V3.

4.3.4.7 Open V2, and, controlling flow rate at 1 L/min., take care not to over-pressurize system.

4.3.4.8 Continue flow through scrubber train #1 until scale shows that approximately 100 grams of HCl have been purged.

4.3.4.9 Open V4 and close V3. Record the weight of HCl cylinder.

4.3.4.10 Collect 100 grams of HCl in scrubber train #2. Close V1 and record weight of HCl sampled.

4.3.4.11 Open nitrogen purge and purge lines, scrubber train #1 and scrubber train #2, before disconnecting scrubbers.

4.3.5 *Sample Preparation*

4.3.5.1 For each scrubber train, quantitatively wash both scrubbers with DI water and add to 250 mL volumetric flask.

4.3.5.2 Wash associated tubing of each scrubber train with DI water and add to 250 mL volumetric flask.

4.3.5.3 Make up reagent blank of water from the same lot of DI water used in the sampling.

4.3.6 *Calibration* — Make calibration standards by serial dilution of standard iron solution traceable to NIST.

4.3.7 *Instrument Parameters* — Perform analysis on an inductively coupled plasma spectrometer employing operating procedures suggested by manufacturer. Correct result to ppm (wt/wt) basis on HCl used.

4.4 *Nitrogen* — This procedure is for the determination of nitrogen in hydrogen chloride using a gas chromatograph with a thermal conductivity detector.

4.4.1 *Detection Limit* — 1 ppm.

4.4.2 *Instrument Parameters*

4.4.2.1 *Columns*:

Column 1:	Ascarite, 0.3 m (1 ft) by 9.6 mm (3/8 in) OD ss or equivalent.
Column 2:	Molecular Sieve 5A, 2.4 m (8 ft) by 6.4 mm (1/4 in) OD ss or equivalent.

4.4.2.2 Carrier Flow: 40 mL/min helium.

4.4.2.3 *Temperatures*:

Detector	50°C
Column Oven	40°C

4.4.2.4 Sample Volume: 10 mL.

4.4.3 *Calibration Standard* — 100 ppm nitrogen in helium.

4.4.4 *Operating Procedure*

4.4.4.1 Inject the calibration standard using a gas sampling valve. Record the retention time and peak area.

4.4.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.4.4.3 Repeat Section 4.4.4.1.

4.4.4.4 Compare the average peak area of the calibration standard with that of the hydrogen chloride sample being tested. Calculate the concentration of nitrogen, using the formula below. The results may not exceed the specification in Section 2 of this Standard.

4.5 *Oxygen + Argon* — This procedure is for the determination of oxygen + argon in hydrogen chloride using a gas chromatograph with a thermal conductivity detector.

4.5.1 *Detection Limit* — 1 ppm. The oxygen and argon elute simultaneously and are therefore quantified as a sum.

4.5.2 *Instrument Parameters*

4.5.2.1 *Columns*:

Column 1:	Ascarite, 0.3 m (1 ft) by 9.6 mm (3/8 in) OD or equivalent.
Column 2:	Molecular Sieve 5A, 2.4 m (8 ft) by 6.4 mm (1/4 in) OD ss or equivalent

4.5.2.2 Carrier Flow: 40 mL/min helium.

4.5.2.3 *Temperatures*

: Detector	50°C
Column Oven	40°C

4.5.2.4 Sample Volume: 10 mL.

4.5.3 *Calibration Standard* — 1–5 ppm oxygen in helium.

4.5.4 *Operating Procedure*

4.5.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.5.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

4.5.4.3 Repeat Section 4.5.4.1.

4.5.4.4 Compare the average peak area of the calibration standard with that of the hydrogen chloride sample being tested. Calculate the total concentration of oxygen + argon, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.6 *Methane and Acetylene* — This procedure is for the determination of methane and acetylene in hydrogen chloride. Samples from gas phase are analyzed by a gas chromatograph with a flame ionization detector. A backflush is used to keep the main component from the detector. (See Figure 2.)

4.6.1 *Detection Limit* — 0.1 ppm for each impurity.

4.6.2 *Instrument Parameters*

4.6.2.1 *Column*:

Alumina-GC, 60-80 mesh, Chromopack, 1.5 m (5 ft) by 2 mm ID (1/8 in OD) ss;

or

Alumina-GC, 60-80 mesh, Chromopack, 2 m (6.7 ft) by 2 mm ID (1/8 in OD) ss;

or equivalent.

4.6.2.2 Detector Sensitivity: 0.012 coulombs/gram.

4.6.2.3 Carrier Flows (1 and 2): 30 mL/min helium.

4.6.2.4 Set the following rates as specified by the instrument manufacturer.

Support Gases:

Hydrogen Flow:	30 mL/min.
Air Flow:	450 mL/min.

4.6.2.5 *Temperatures*:

Detector	200°C
Column Oven	100°C

4.6.2.6 Sample Volume: 0.5 mL.

4.6.2.7 Sample Flow: 200 mL/min.

4.6.3 *Calibration Standard* — 5 to 10 ppm each methane and acetylene in nitrogen.

4.6.4 *Operating Procedure*

4.6.4.1 Install switching valve and columns.

4.6.4.2 Adjust carrier gas flows:

Switching valve in injection position

- Set a flow rate of 30 mL/min, with the regulator T1 measured at the FID outlet.

Switching valve in backflush position

- Set a flow rate of 30 mL/min, with the regulator T2 measured at the FID outlet.
- Set a flow rate of 30 mL/min, with the metering valve, measured at the pre-column outlet.

A last adjustment between the injection and backflush position may be carried out by the FID signal. For this, the baseline is recorded in the injection and backflush position. With the regulator T2, the flow rate is changed so far as there is no offset in the baseline while switching.

4.6.4.3 Adjust hydrogen and air flows and ignite the burner, following the instrument manufacturer's instructions. Allow the system to stabilize for at least 30 minutes.

4.6.4.4 *Determine backflush time* — Inject calibration standard and leave the switching valve in inject position until all components have been eluted. Determine retention times for methane and acetylene. Choose backflush time so that the acetylene peak is completely registered.

4.6.4.5 Inject the calibration standard. Backflush at the time determined in Section 4.6.4.4. Record the retention times and peak areas.

4.6.4.6 Inject the sample to be tested in the same manner as the calibration standard. Backflush at the time determined in Section 4.6.4.4. Record the retention times and peak areas.

4.6.4.7 Repeat Section 4.6.4.5.

4.6.4.8 Compare the average peak areas of the calibration standard with those of the hydrogen chloride sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed the specifications in Section 3 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.7 *Water* — This procedure is for the determination of trace moisture (water) in hydrogen chloride gas using a continuous flowing, cooled-surface condensation point hygrometer.

4.7.1 *Detection Limit* — 1.0 ppm.

4.7.2 *Flow Requirements*

4.7.2.1 Set the sample flow rate and pressure in accordance with the instrument manufacturer’s instructions.

4.7.3 *Calibration Standards*

4.7.3.1 A calibration thermometer designed to indicate temperatures in the –89°C (–121°F) range is required.

NOTE 4: The National Institute of Standards and Technology (NIST) provides calibration services for the thermometers used in condensation point hygrometers.

4.7.3.2 A calibration curve representing water added to dried hydrogen chloride vs. condensation point is required. This can be obtained by preparing a standard of water balance nitrogen and mixing it with dry hydrogen chloride using a dynamic gas blender with mass flow controllers or calibrated flowmeters. The hydrogen chloride gas can be dried by passing it over activated molecular sieve (5A) or magnesium perchlorate.

NOTE 5: This method is not applicable if other constituents in the gas will condense before the moisture condensation, e.g., carbon dioxide or oil.

4.7.4 *Operating Procedure*

4.7.4.1 Obtain a continuous flow of sample gas from the source using a clean stainless steel sampling line which has been purged dry after exposure to ambient moisture.

NOTE 6: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced to accommodate the pressure restrictions of the analytical hygrometer using a regulator with a diaphragm of stainless steel or other suitable material.

4.7.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the condensation point hygrometer for one-quarter hour to two hours to allow the entire system to reach equilibrium with regards to moisture content.

4.7.4.3 After equilibrium has been reached, cool the mirror to determine the actual condensation point of the sample.

4.7.4.4 Continue to verify the condensation point for at least 30 minutes after a stable reading has been confirmed.

4.7.4.5 Correct the condensation point reading from the measured pressure to 1 atm of pressure. The result may not exceed the specification in Section 2 of this standard.

SEMI C3.43-90 (Withdrawn 0701)
STANDARD FOR HYDROGEN FLUORIDE (HF), ANHYDROUS (PROVISIONAL)

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Hydrogen fluoride is a highly toxic, irritating and corrosive gas with a sharp, pungent odor. It is colorless and nonflammable, but reacts violently with most organic materials.

SEMI C3.5-93 (Reapproved 0999)
STANDARD FOR NITROGEN (N_2), BULK LIQUID, 99.998% QUALITY

This specification was technically reapproved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1981; previously published in 1993.

1 Description

Nitrogen is an odorless, tasteless, diatomic gas comprising approximately 78% of the earth's atmosphere; colorless liquid. Noncombustible; a cryogenic gas derived from liquid air by fractional distillation.

2 Specifications

QUALITY: 99.998%

Impurities	*Maximum Acceptable Level (ppm)**
Carbon dioxide (CO2)	1
Carbon monoxide (CO)	5
Hydrogen (H_2)	2
Oxygen (O_2)	3
Particles	**
Total Hydrocarbons expressed as Methane (THC)	1
Water (H_2O) (v/v)	1
TOTAL SPECIFIED IMPURITIES	13

*An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

Density of liquid at boiling point	808.8 kg/m^3	50.49 lb/ft^3

4 Analytical Procedures (See Notes 1, 2)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in nitrogen using a gas chromatograph with a flame ionization detector and methanizer. (See Note 3.)

4.1.1 *Detection Limit* — 100 ppb (mole/mole).

4.1.2 Instrument Parameters

4.1.2.1 Column:

Porapak T or Q, 3 m (9.8 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or

Chromosorb 102, 2 m (6.6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 0.5 to 2.0 mL.

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standards* — 1-5 ppm (mole/mole) carbon monoxide, 1-5 ppm (mole/mole) carbon dioxide, balance nitrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Hydrogen* — This procedure is for the determination of hydrogen in nitrogen using a gas chromatograph with a helium ionization detector.

4.2.1 *Detection Limit* — 500 ppb (mole/mole).

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 5A molecular sieve, 1.9m (6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ss or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 3.0 mL

4.2.2.4 Temperatures:

Detector	125°C
Column Temperature	65°C

4.2.3 *Calibration Standard* — 1-5 ppm (mole/mole) hydrogen in nitrogen.

4.2.4 Operating Procedure

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentration of hydrogen, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\\text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\\text{of Sample}\end{matrix}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in nitrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb (mole/mole).

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 3-15 ppm (mole/mole) oxygen in nitrogen or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the sample flow setting once established.

4.3.4.2 Introduce nitrogen sample and record oxygen reading. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in nitrogen using a continuous flow flame ionization detector equipped total hydrocarbon analyzer. See Notes 4, 5, 6.)

4.4.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.4.2 *Flow Requirements*

4.4.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen: 35-40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75-80 mL/min.

4.4.2.2 Dry, hydrocarbon-free (less than 0.1ppm) air: 350-400 mL/min.

4.4.2.3 Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Nitrogen with known quantity of hydrocarbons at 0.5 ppm level.

4.4.3.2 The upper level span gas not exceeding 5 times the concentration of the specification.

4.4.4 *Operating Procedure*

4.4.4.1 Do not change the flow settings for hydrogen, air and sample once established.

4.4.4.2 Introduce the nitrogen with known quantity of hydrocarbons and, using the 0-10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.4.4.3 Introduce the span gas standard in nitrogen and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.4.4.4 Introduce nitrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in nitrogen using a continuous flowing piezoelectric hygrometer. (See Note 7.)

4.5.1 *Detection Limit* — 0.1 ppm (vol/vol) or -90°C (-30°F).

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the

range of interest. Verify the standards employed independently by another analytical method.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the nitrogen sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this Standard.

4.6 *Notes*

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

NOTE 3: Carrier gases should contain less than 0.1 ppm (mole/mole) carbon monoxide and less than 0.1 ppm (mole/mole) carbon dioxide.

NOTE 4: The 0-1 range can be used provided that zero and span gas standards in nitrogen with known levels of hydrocarbons between 0-1 ppm are used in the calibration of the analyzer.

NOTE 5: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

NOTE 6: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the common hydrocarbon impurities in nitrogen can be accurately totaled and compared to methane.

NOTE 7: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

SEMI C3.15-93 (Reapproved 0999)
STANDARD FOR NITROGEN (N_2), IN CYLINDERS, 99.9992% QUALITY

This standard was technically reapproved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1982; previously published in 1993.

1 Description

1.1 Nitrogen is an odorless, tasteless, diatomic gas comprising approximately 78% of the earth's atmosphere; colorless gas. Noncombustible; an asphyxiant gas; cryogenic. Derived from liquid air by fractional distillation.

2 Specifications

QUALITY: 99.9992%

Impurities	*Maximum Acceptable Level (ppm)**
Carbon dioxide (CO_2)	1
Carbon monoxide (CO)	2
Hydrogen (H_2)	2
Oxygen (O_2)	1
Particles	**
Total Hydrocarbons expressed as Methane (THC)	1
Water (H_2O) (v/v)	1
TOTAL SPECIFIED IMPURITIES	8

* Analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	28.013	28.013
Boiling point at 1 atm	-195.8°C	-320.4°F
Density of gas at 21.1°C (70°F) and 1 atm	1.1605 kg/m^3	0.07245 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	0.967	0.967
Density of liquid at boiling point	808.8 kg/m^3	50.49 lb/ft^3

4 Analytical Procedures (See Notes 1, 2)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in nitrogen using a gas chromatograph with a flame ionization detector and methanizer. (See Note 3.)

4.1.1 *Detection Limit* — 100 ppb (mole/mole).

4.1.2 *Instrument Parameters*

Column:

Porapak T or Q, 3 m (9.8 ft) by 3 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss;

or

Chromosorb 102, 2 m (6.6 ft) by 3 mm OD by 2.2 mm (0.085 in) ID ss;

or equivalent.

4.1.2.1 Carrier Flow: 30 mL/min helium.

4.1.2.2 Sample Volume: 0.5 to 2.0 mL.

4.1.2.3 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standards* — 1-5 ppm (mole/mole) carbon monoxide, 1-5 ppm (mole/mole) carbon dioxide, balance nitrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to that of the nitrogen sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Hydrogen* — This procedure is for the determination of hydrogen in nitrogen using a gas chromatograph with a helium ionization detector.

4.2.1 *Detection Limit* — 500 ppb (mole/mole).

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 5A molecular sieve, 1.9 m (6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss, or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 3.0 mL.

4.2.2.4 Temperatures:

Detector	125°C
Column Temperature	65°C

4.2.3 *Calibration Standard* — 1-5 ppm (mole/mole) hydrogen in nitrogen.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentration of hydrogen, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in nitrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb (mole/mole).

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 1-5 ppm (mole/mole) oxygen in nitrogen or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce nitrogen sample and record oxygen reading. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in nitrogen using a continuous flow flame ionization detector-equipped total hydrocarbon analyzer. (See Notes 4, 5, 6.)

4.4.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.4.2 *Flow Requirements*

4.4.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen: 35-40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75-80 mL/min.

4.4.2.2 Dry, hydrocarbon-free (less than 0.1 ppm) air: 350-400 mL/min.

4.4.2.3 Set sample flow rates in accordance with instrument manufacturer's instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Zero nitrogen with known quantity of hydrocarbons at 0.1 ppm level.

4.4.3.2 The upper level span gas not exceeding 5 times the concentration of the specification.

4.4.4 *Operating Procedure*

4.4.4.1 Do not change the initial flow settings for hydrogen, air and sample once established.

4.4.4.2 Introduce the zero nitrogen with known quantity of hydrocarbons and, using the 0-10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.4.4.3 Introduce the span gas standard in nitrogen and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.4.4.4 Introduce nitrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Water* — This procedure is for the determination of moisture (water) in nitrogen using a continuous flowing, cooled-surface condensation, dewpoint/ frostpoint hygrometer. (See Notes 7, 8, 9.)

4.5.1 *Detection Limit* — 0.6 ppm (vol/vol) or -79°C (-110°F).

4.5.2 *Flow Requirements*

4.5.2.1 Set sample flow rate and pressure in accordance with the instrument manufacturer's instructions.

4.5.2.2 Gas must flow past the chilled mirror where optic means are provided to detect the deposit (or frost) and to read the thermometer measuring the temperature of the mirror.

4.5.3 *Calibration Standard* — A calibration thermometer designed to indicate temperatures in the -79°C (-110°F) range required.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow of sample gas from the source using a clean stainless steel (or copper) sampling line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the dewpoint/frostpoint hygrometer for one hour to 24 hours to allow the entire system to reach equilibrium with regard to moisture content.

4.5.4.3 After equilibrium has been reached, cool down the mirror to determine the actual dewpoint/frostpoint of the sample gas. Follow the manufacturer's recommendations to create the temperatures needed.

4.5.4.4 Continue to verify the dewpoint/frostpoint for at least 30 minutes after a stable reading has been confirmed.

4.5.4.5 Correct the dewpoint reading from the measured pressure to 1 atm of pressure. The result may not exceed the specification in Section 2 of this Standard.

4.6 *Notes*

Note 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

Note 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

Note 3: Carrier gases should contain less than 0.1 ppm (mole/mole) carbon monoxide and less than 0.1 ppm (mole/mole) carbon dioxide.

Note 4: The 0-1 range can be used provided that zero and span gas standards in nitrogen with known levels of hydrocarbons between 0-1 ppm are used in the calibration of the analyzer.

Note 5: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

Note 6: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the most common hydrocarbon impurities in nitrogen can be accurately totaled and compared to methane.

Note 7: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

Note 8: The National Institute of Standards and Technology (NIST) provides calibration services for the thermometers used in dewpoint/frostpoint hygrometers.

Note 9: This method is not applicable if other constituents in the gas will condense before water vapor, e.g., carbon dioxide and/or oil contamination.

SEMI C3.48-0200
STANDARD FOR NITROGEN (N_2), BULK LIQUID, 99.9994% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on October 19, 1999. Initially available at www.semi.org December 1999; to be published February 2000. Originally published in 1993; previously published in 1996.

1 Description

1.1 Nitrogen is an odorless, tasteless, diatomic gas comprising approximately 78% of the earth's atmosphere; colorless liquid. Noncombustible; a cryogenic gas derived from liquid air by fractional distillation.

2 Specifications

QUALITY: 99.9994%

Impurities	*Maximum Acceptable Level (ppm) (See NOTE 1.)*
Carbon Dioxide (CO_2)	0.5
Carbon Monoxide (CO)	2
Hydrogen (H_2)	2
Oxygen (O_2)	0.5
Particles	(See NOTE 2.)
Total Hydrocarbons expressed as Methane (THC)	0.5
Water (H_2O) (v/v)	0.5
TOTAL SPECIFIED IMPURITIES	6

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

NOTE 2: To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	28.013	28.013
Boiling point at 1 atm	–195.8°C	–320.4°F
Density of gas at 21.1°C (70°F) and 1 atm	1.1605 kg/m^3	0.07245 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	0.967	0.967
Density of liquid at boiling point	808.8 kg/m^3	50.49 lb/ft^3

4 Analytical Procedures (See NOTES 1 and 2)

4.1 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in nitrogen using a gas chromatograph with a flame ionization detector and methanizer. (See NOTE 3.)

4.1.1 *Detection Limit* — 100 ppb (mole/mole).

4.1.2 *Instrument Parameters*

4.1.2.1 Column:

Porapak T or Q, 3 m (9.8 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID stainless steel;

or

Chromosorb 102, 2 m (6.6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID stainless steel;

or equivalent.

4.1.2.2 Carrier Flow — 30 mL/min helium

4.1.2.3 Sample Volume — 0.5 to 2.0 mL

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	60°C
Methanizer	350°C

4.1.3 *Calibration Standards* — 0.5–2.5 ppm (mole/mole) carbon monoxide, 0.5–2.5 ppm (mole/mole) carbon dioxide, balance nitrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is carbon monoxide, carbon dioxide.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat Section 4.1.4.1.

4.1.4.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The results may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration Standard} = \text{Concentration Sample}$$

4.2 *Hydrogen* — This procedure is for the determination of hydrogen in nitrogen using a gas chromatograph with a helium ionization detector.

4.2.1 *Detection Limit* — 500 ppb (mole/mole)

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 5A molecular sieve, 1.9 m (6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID stainless steel or equivalent.

4.2.2.2 Carrier Flow — 30 mL/min helium

4.2.2.3 Sample Volume — 3.0 mL

4.2.2.4 Temperatures:

Detector	125°C
Column Temperature	65°C

4.2.3 Calibration Standard — 1–5 ppm (mole/mole) hydrogen in nitrogen.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat Section 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentration of hydrogen, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration Standard} = \text{Concentration Sample}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in nitrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 100 ppb (mole/mole)

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 0.5–2.5 ppm (mole/mole) oxygen in nitrogen or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the sample flow setting once established.

4.3.4.2 Introduce nitrogen sample and record oxygen reading. The result may not exceed the specification in Section 2 of this standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in nitrogen using a continuous flow flame ionization detector equipped total hydrocarbon analyzer. (See NOTES 4, 5, and 6.)

4.4.1 *Detection Limit* — 0.1 ppm (mole/mole)

4.4.2 *Flow Requirements*

4.4.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen: 35–40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75–80 mL/min.

4.4.2.2 Dry, hydrocarbon-free (less than 0.1 ppm) air: 350–400 mL/min.

4.4.2.3 Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Nitrogen with known quantity of hydrocarbons at 0.1 ppm level.

4.4.3.2 The upper level span gas not exceeding five times the concentration of the specification.

4.4.4 *Operating Procedure*

4.4.4.1 Do not change the flow settings for hydrogen, air and sample once established.

4.4.4.2 Introduce the zero nitrogen with known quantity of hydrocarbons and using the 0–10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.4.4.3 Introduce the span gas standard in nitrogen and using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.4.4.4 Introduce nitrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in nitrogen using a continuous flowing piezoelectric hygrometer. (See NOTE 7.)

4.5.1 *Detection Limit* — 0.1 ppm (vol/vol) or –90°C (–130°F).

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the

range of interest. Verify the standards employed independently by another analytical method.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the nitrogen sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this standard.

4.6 *Notes*

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

NOTE 3: Carrier gases should contain less than 0.1 ppm (mole/mole) carbon monoxide and less than 0.1 ppm (mole/mole) carbon dioxide.

NOTE 4: The 0–1 range can be used provided that zero and span gas standards in nitrogen with known levels of hydrocarbons between 0 and 1 ppm are used in the calibration of the analyzer.

NOTE 5: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

NOTE 6: The effective response of a flame ionization detector equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the common hydrocarbon impurities in nitrogen can be accurately totaled and compared to methane.

NOTE 7: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

STANDARD FOR NITROGEN (N_2), VLSI GRADE IN CYLINDERS, 99.9996% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org January 2000, to be published February 2000. Originally published in 1985; previously in 1996.

1 Description

1.1 Nitrogen is an odorless, tasteless, diatomic gas comprising approximately 78% of the earth's atmosphere; colorless liquid; chemically unreactive. Noncombustible; an asphyxiant gas; cryogenic. Derived from liquid air by fractional distillation.

2 Specifications

QUALITY: 99.9996%

Impurities	*Maximum Acceptable Level (ppm (See NOTE 1.)*
Carbon Dioxide (CO_2)	0.5
Carbon Monoxide(CO)	0.5
Hydrogen (H_2)	1
Oxygen (O_2)	0.5
Particles	See NOTE 2.
Total Hydrocarbons expressed as Methane (THC)	0.5
Water (H_2O) (v/v)	0.5
TOTAL SPECIFIED IMPURITIES	3.5

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

NOTE 2: To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	28.013	28.013
Boiling point at 1 atm	–195.8°C	–320.4°F
Density of gas at 21.1°C (70°F) and 1 atm	1.1605 kg/m^3	0.07245 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	0.967	0.967
Density of liquid at boiling point	808.8 kg/m^3	50.49 lb/ft^3

4 Analytical Procedures (See NOTES 3 and 4)

4.1 *Carbon Monoxide and Hydrogen* — This procedure is for the determination of carbon monoxide and hydrogen in nitrogen using a gas chromatograph with a reduction gas detector.

4.1.1 *Detection Limits* — 2 ppb (mole/mole) carbon monoxide, 20 ppb (mole/mole) hydrogen

4.1.2 *Instrument Parameters* — (See NOTE 1.)

4.1.2.1 Column — Molecular Sieve 5A, 0.9 m (3 ft) by 3.2 mm ID (1/4 in) OD, stainless steel; or equivalent.

4.1.2.2 Carrier Flow — 40 mL/min air or nitrogen

4.1.2.3 Sample Volume — 2.0 mL

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	250°C

4.1.3 *Calibration Standards* — 1-5 ppm (mole/mole) carbon monoxide, 1-5 ppm (mole/mole) hydrogen, balance nitrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is hydrogen, then carbon monoxide. Run standard analysis in triplicate for stability determination relative to purging of calibration system components.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat Section 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to that of the nitrogen sample being tested. Calculate the concentrations of carbon monoxide and hydrogen, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\\text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\\text{of Sample}\end{matrix}$$

4.2 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in nitrogen using a continuous flow, non-dispersive infrared analyzer.

4.2.1 *Detection Limit* — 50 ppb (mole/mole)

4.2.2 *Flow Rate* — Set the sample flow rate and pressure in accordance with the instrument manufacturer's instructions.

4.2.3 *Calibration Standards* — Zero nitrogen with a known quantity of carbon dioxide at not more than 0.05 ppm (mole/mole). Span gas nitrogen with a known concentration of 1-10 ppm (mole/mole) carbon dioxide.

4.2.4 *Operating Procedure*

4.2.4.1 Do not change the initial sample flow setting once established.

4.2.4.2 Introduce the zero nitrogen with known quantity of carbon dioxide and set the needle (or output reading) to read the correct level using the zero adjustment knob.

4.2.4.3 Introduce the span gas standard in nitrogen and using the span adjust knob, set the needle (or output reading) to match the level of carbon dioxide in the span gas.

4.2.4.4 Repeat steps 1 and 2 (Sections 4.2.4.2 and 4.2.4.3) until reproducibility of readings is better than 1% of full scale.

4.2.4.5 Introduce nitrogen sample into the analyzer and record the concentration of carbon dioxide. The result may not exceed the specification in Section 2 of this Standard.

4.3 *Oxygen* — This procedure is for the determination of oxygen in nitrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 50 ppb (mole/mole)

4.3.2 *Flow Requirements* — Set the sample pressure and flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standards* — 1-10 ppm (mole/mole) oxygen in nitrogen or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce nitrogen containing less than 2 ppm oxygen through a deoxygenation catalyst to verify that there is no leakage of air into the system and to demonstrate that the detection limit can be achieved.

4.3.4.3 Introduce the calibration standard. Using the span adjust knob, set the needle (or output reading) to match the level of oxygen in the calibration gas.

4.3.4.4 Introduce nitrogen sample and record the oxygen reading. The result may not exceed the specification in Section 2 of this standard.

4.4 *Water* — This procedure is for the determination of trace moisture (water) in nitrogen using a continuous flowing piezoelectric hygrometer. (See NOTE 2.)

4.4.1 *Detection Limit* — 0.1 ppm (vol/vol) or –90°C (–130°F).

4.4.2 *Flow Requirements* — Set the sample pressure and flow rate set in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently by another analytical method.

4.4.4 *Operating Procedure*

4.4.4.1 Obtain a continuous flow of sample gas from the source using a clean and passivated 316 stainless steel line which has been purged dry after exposure to ambient moisture.

4.4.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric hygrometer until a stable reading is obtained. Determine the concentration of moisture by comparing the reading to the calibration curve obtained in 4.4.3. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in nitrogen using a continuous flow flame ionization detector-equipped total hydrocarbon analyzer. (See Notes 5, 6, and 7.)

4.5.1 *Detection Limit* — 0.1 ppm (mole/mole)

4.5.2 *Flow Requirements*

4.5.2.1 High purity, hydrocarbon-free (less than 1.0 ppm) hydrogen: 35–40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75–80 mL/min.

4.5.2.2 Dry, hydrocarbon-free (less than 1.0 ppm) air: 350–400 mL/min.

4.5.2.3 Set the sample flow rates in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards*

4.5.3.1 Zero nitrogen with known quantity of hydrocarbons at 0.1 ppm level.

4.5.3.2 *Span Gas* — Nitrogen with known quantity (1–10 ppm) hydrocarbons.

4.5.4 *Operating Procedure*

4.5.4.1 Do not change the initial flow settings for hydrogen, air and sample once established.

4.5.4.2 Introduce the zero nitrogen with known quantity of hydrocarbons and using the 0-10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.5.4.3 Introduce the span gas standard in nitrogen and using the span adjust knob, set the needle (or output) to match the level of hydrocarbons in the span gas.

4.5.4.4 Repeat Sections 4.5.4.2 and 4.5.4.3 until reproducibility of readings is better than 1% of full scale.

4.5.4.5 Introduce nitrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

NOTE 1: Carrier gases should contain less than 0.1 ppm (mole/mole) carbon monoxide and less than 0.1 ppm (mole/mole) hydrogen.

NOTE 2: The sampling system and hygrometer must be designed to operate under the sample pressure or the sample pressure must be reduced by a regulator with a diaphragm of stainless steel or other suitable material, to accommodate the pressure restrictions of the analytical hygrometer.

NOTE 3: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 4: All gases used in the analysis of the sample should contain not more than 10% of the sample value of the component of interest unless otherwise specified.

NOTE 5: The 0–1 ppm range can be used provided that zero and span gas standards in nitrogen with known levels of hydrocarbons between 0 and 1 ppm are used in the calibration of the analyzer.

NOTE 6: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

NOTE 7: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the most common hydrocarbon impurities in nitrogen can be accurately totaled and compared to methane.

SEMI C3.29-96 (Reapproved 0999) STANDARD FOR NITROGEN (N_2), BULK GASEOUS, 99.9995% QUALITY

This standard was technically reapproved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1986; previously published in 1996.

1 Description

1.1 Nitrogen is an odorless, tasteless, diatomic gas comprising approximately 78% of the earth's atmosphere; colorless liquid; chemically unreactive. Noncombustible; an asphyxiant gas; cryogenic. Derived from liquid air by fractional distillation.

2 Specifications

QUALITY: 99.9995% (see Note 1)

Impurities	*Maximum Acceptable Level (ppm*)*
Carbon dioxide (CO_2)	0.2
Carbon monoxide (CO)	2
Hydrogen (H_2)	2
Oxygen (O_2)	0.2
Particles	**
Total Hydrocarbons expressed as Methane (THC)	0.2
Water (H_2O) (v/v)	0.2
TOTAL IMPURITIES	4.8

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	28.013	28.013
Boiling point at 1 atm	-195.8°C	-320.4°F
Density of gas at 21.1°C (70°F) and 1 atm	1.1605 kg/m^3	0.07245 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	0.967	0.967
Density of liquid at boiling point	808.8 kg/m3	50.49 lb/ft3

4 Analytical Procedures (see Notes 2, 3)

4.1 *Carbon Monoxide and Hydrogen* — This procedure is for the determination of carbon monoxide and hydrogen in nitrogen using a gas chromatograph with a reduction gas detector (see Note 4).

4.1.1 *Detection Limits* — 2 ppb (mole/mole) carbon monoxide, 20 ppb (mole/mole) hydrogen.

4.1.2 *Instrument Parameters*

4.1.2.1 Column: 5A molecular sieve, 0.9 m (3 ft) by 3 mm (1/4 in) ss, or equivalent.

4.1.2.2 Carrier Flow: 40 mL/min air or nitrogen.

4.1.2.4 Temperatures:

Detector	280°C
Column Oven	250°C

4.1.3 *Calibration Standard* — 1-5 ppm (mole/mole) carbon monoxide, 1-5 ppm (mole/mole) hydrogen in nitrogen.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is hydrogen, then carbon monoxide. Run standard analysis in triplicate for stability determination relative to purging of calibration system components.

4.1.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Compare the average peak areas of the calibration standard to that of the nitrogen sample being tested. Calculate the concentrations of carbon monoxide and hydrogen, using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in nitrogen using a continuous flow, non-dispersive infrared analyzer.

4.2.1 *Detection Limit* — 50 ppb (mole/mole).

4.2.2 Set sample flow rate and pressure in accordance with the instrument manufacturer's instructions.

4.2.3 *Calibration Standard* — Zero nitrogen with a known quantity of carbon dioxide at not more than .05 ppm (mole/mole). Span gas nitrogen with a known concentration of 1-10 ppm (mole/mole) carbon dioxide.

4.2.4 *Operating Procedure*

4.2.4.1 Do not change the initial sample flow setting once established.

4.2.4.2 Introduce the zero nitrogen with known quantity of carbon dioxide and set the needle (or output reading) to read the correct level using the zero adjustment knob.

4.2.4.3 Introduce the span gas standard in nitrogen and using the span adjust knob, set the needle (or output reading) to match the levels of carbon dioxide in the span gas.

4.2.4.4 Repeat steps 1 and 2 until reproducibility of readings is better than 1% of full scale.

4.2.4.5 Introduce nitrogen sample into the analyzer and read the quantity of carbon dioxide on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

4.3 *Oxygen* — This procedure is for the determination of oxygen in nitrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 50 ppb (mole/mole).

4.3.2 Set sample pressure and flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standard* — 1-10 ppm (mole/mole) oxygen in nitrogen or accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the initial sample flow setting once established.

4.3.4.2 Introduce nitrogen containing less than 2 ppm oxygen through a deoxygenation catalyst to verify that there is no leakage of air into the system and to demonstrate that the detection limit can be achieved.

4.3.4.3 Introduce the calibration standard. Using the span adjust knob, set the needle (or output reading) to match the level of oxygen in the calibration gas.

4.3.4.4 Introduce nitrogen sample and record the oxygen reading. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Water* — This procedure is for the determination of trace moisture (water) in nitrogen using a continuous flowing piezoelectric hygrometer (see Note 5).

4.4.1 *Detection Limit* — 0.1 ppm (vol/vol) or -90°C (-130°F).

4.4.2 *Flow Requirements* — Set sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standard* — Construct a calibration curve which contains at least three points covering the range of interest. The standards employed will be verified independently by another analytical method.

4.4.4 *Operating Procedure*

4.4.4.1 Obtain a continuous flow of sample gas from the source using a clean and passivated 316 stainless steel line which has been purged dry after exposure to ambient moisture.

4.4.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained. The result may not exceed the specification in Section 2 of this standard.

4.5 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in nitrogen using a continuous flow flame ionization detector-equipped total hydrocarbon analyzer (see Notes 6, 7, 8).

4.5.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.5.2 Flow Requirements

4.5.2.1 High-purity, hydrocarbon-free (less than 1.0 ppm) hydrogen: 35-40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75-80 mL/min.

4.5.2.2 Dry, hydrocarbon-free (less than 1.0 ppm) air: 350-400 mL/min.

4.5.2.3 Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards*

4.5.3.1 Zero nitrogen with known quantity of hydrocarbons at 0.1 ppm level.

4.5.3.2 Span Gas: Nitrogen with known quantity (1-10 ppm) hydrocarbons.

4.5.4 *Operating Procedure*

4.5.4.1 Do not change the initial flow settings for hydrogen, air and sample once established.

4.5.4.2 Introduce the zero nitrogen with known quantity of hydrocarbons and, using the 0-10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.5.4.3 Introduce the span gas standard in nitrogen and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.5.4.4 Repeat steps 4.5.4.2 and 4.5.4.3 until reproducibility of readings is better than 1% of full scale.

4.5.4.5 Introduce nitrogen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this standard.

4.6 *Notes*

NOTE 1: A purifier is allowed to be used to meet this specification.

NOTE 2: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 3: All gases used in the analysis of the sample should contain not more than 10% of the sample value of the component of interest unless otherwise specified.

NOTE 4: Carrier gases should contain less than 0.1 ppm (mole/mole) carbon monoxide and less than 0.1 ppm (mole/mole) hydrogen.

NOTE 5: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

NOTE 6: The 0-1 range can be used provided that zero and span gas standards in nitrogen with known levels of hydrocarbons between 0-1 ppm are used in the calibration of the analyzer.

NOTE 7: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

NOTE 8: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the most common hydrocarbon impurities in nitrogen can be accurately totaled and compared to methane.

SEMI C3.49-94
STANDARD FOR BULK NITROGEN (N_2), 99.99999% QUALITY

1 Description

Nitrogen is an odorless, tasteless, diatomic gas comprising approximately 78% of the earth's atmosphere; colorless liquid. Noncombustible; a cryogenic gas derived from liquid air by fractional distillation.

2 Specifications

Quality: 99.99999%, including rare gases

Impurities	*Maximum AcceptableLevel (ppb)**
Water (H_2O)	50
Oxygen (O_2)	10
Carbon dioxide (CO_2)	10
Carbon monoxide (CO)	10
Total Hydrocarbons expressed as Methane (THC)	10
Hydrogen (H_2)	10
Particles**	max 20 per/ft^3 >0.02µm
TOTAL SPECIFIED IMPURITIES	100 ppb

*An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** May be determined after purifier/filter. Sampling point to be agreed between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	28.013	28.013
Boiling point at 1 atm	-195.8°C	-320.4°F
Density of gas at 21.1°C and 1 atm (air=1)	1.1605 kg/m^3	0.07245 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air=1)	0.0967	0.0967
Density of liquid at boiling point	808.8 kg/m^3	50.49 lb/ft^3

4 Analytical Procedures (see Notes 1 and 2)

4.1 *Carbon Monoxide and Hydrogen* — This procedure is for the determination of carbon monoxide and carbon dioxide in nitrogen using a gas chromatograph fitted with a reduction gas detector. (See Note 3.)

4.1.1 *Detection Limit* — Hydrogen 3 ppb, CO, 0.3 ppb (mole/mole).

4.1.2 *Instrument Parameters*

4.1.2.1 Column 1: 1/8" OD 77" length Unibead 1S 60-80 mesh, Column 2: 1/8" OD 30 3/4" length MS5A

4.1.2.2 Carrier Flow: 20 mL/min at 105°C nitrogen

4.1.2.3 Sample Volume: 100 µL

4.1.2.4 Temperatures:

Detector	270°C
Column Oven	105°C

4.1.2.5 Calibration Standards 0.1-0.5 ppm (mole/mole) carbon monoxide, 0.1 - 0.5 ppm (mole/mole) hydrogen, balance nitrogen.

4.1.2.6 *Calibration Standards* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

4.1.3 *Operating Procedure*

4.1.3.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is hydrogen, carbon monoxide.

4.1.3.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.1.3.3 Repeat 4.1.4.1.

4.1.3.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentrations of carbon monoxide and hydrogen using the formula below. The results may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.2 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in nitrogen using a gas chromatograph with a flame ionization detector, fitted with a methaniser.

4.2.1 *Detection Limit* — 2 ppb (mole/mole)

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 1/8" OD 77" Length Hayesep D 100-120 mesh.

4.2.2.2

Carrier Flow:	30 mL/min nitrogen
Air Flow:	250 mL/min
Hydrogen Flow:	30 mL/min

4.2.2.3 Sample Volume: 5 mL

4.2.3 *Temperatures*:

Methaniser	315°C
Column Temperature	40°C

4.2.3.1 *Calibration Standard* — 0.1 ppm (mole/mole) carbon dioxide in nitrogen.

4.2.3.2 *Calibration Standards* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat 4.2.4.1

4.2.4.4 Compare the average peak area of the calibration standard to that of the nitrogen sample being tested. Calculate the concentration of carbon dioxide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.3 *Oxygen* — This procedure is for the determination of oxygen in nitrogen using a continuous flow analyzer using an electrochemical method.

4.3.1 *Detection Limit* — 2 ppb (mole/mole).

4.3.2 *Flow Rate* — Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standards* — 50 ppb (mole/mole) oxygen in nitrogen or in accordance with the instrument manufacturer's instructions.

4.3.4 *Operating Procedure*

4.3.4.1 Introduce nitrogen sample and record oxygen reading. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in nitrogen using a gas chromatograph fitted with a flame ionization detector and a back flush valve.

4.4.1 *Detection Limit* — 2 ppb (mole/mole).

4.4.2 *Instrument Parameters*

4.4.2.1 Column: 1/8" OD 77" Length Hayesep D 100-120 mesh.

4.4.2.2

Carrier Flow:	30 mL/min nitrogen
Air Flow:	250 mL/min
Hydrogen Flow:	30 mL/min

4.4.2.3 Sample Volume: 5mL

4.4.2.4 Temperatures: Column Temperature 40°C

4.4.2.5 *Calibration Standard* — 0.1 ppm (mole/mole) methane in nitrogen.

4.4.2.6 *Calibration Standards* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in nitrogen using a continuous flowing phosphorous pentoxide hygrometer. (See Note 4.)

4.5.1 *Detection Limit* — 10 ppb (vol/vol)

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve in the range of interest. Verify the standards employed independently by established traceability to recognized national or international standards.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the

P_2O_5 moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the nitrogen sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this Standard.

4.6 *NOTES*

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

NOTE 3: Carrier gases should contain less than 0.1 ppb (mole/mole) carbon monoxide and less than 0.1 ppb (mole/mole) hydrogen.

NOTE 4: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

SEMI C3.39-0999
STANDARD FOR NITROGEN TRIFLUORIDE (NF_3)

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on October 18, 1998. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1989; previously published in 1996.

1 Description

1.1 Nitrogen trifluoride is a toxic, odorless, colorless, nonflammable gas. It is a strong oxidizer and supports combustion.

2 Specifications

2.1 QUALITY: 99.98%

Impurities	*Maximum Acceptable Level (ppm) (see NOTE 1)*
Carbon Dioxide (CO_2)	10
Carbon Monoxide (CO)	10
Carbon Tetrafluoride (CF_4)	100
Nitrogen (N_2)	10
Nitrous Oxide (N_2O)	10
Argon/Oxygen	10
Sulfur Hexafluoride (SF_6)	10
Water (H_2O) (v/v)	1
TOTAL IMPURITIES	161 (see NOTE 1)

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Chemical Specification

Hydrolyzable Fluorides as HF	1 ppm

4 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	71.00	71.00
Density of gas at 21.1°C (70°F) and 1 atm	2.94 kg/m^3	0.1838 lb./ft.^{3}

5 Analytical Procedures

5.1 *Carbon Tetrafluoride* — This procedure is for the determination of carbon tetrafluoride in nitrogen trifluoride using a gas chromatograph with a thermal conductivity detector. (See Figure 1 and Note 1.)

5.1.1 Detection Limit — 1.0 ppm.

5.1.2 *Instrument Parameters*

5.1.2.1 Column: Super Q (80/100 mesh), 4.9 m (16 ft.) by 1.75 mm (1/16 in.) ID, 3.2 mm (1/8 in.) OD ss or equivalent.

5.1.2.2 Carrier Flow: 19 mL/min helium.

5.1.2.3 Sample Volume: 0.1 mL.

5.1.2.4 Temperatures:

Detector	100°C
Oven	42°C
Gas sampling valve	42°C

5.1.2.5 Valve material: Nitronic-60 or equivalent.

5.1.3 *Calibration Standard* — 100 ppm carbon tetrafluoride, balance helium.

5.1.4 *Operating Procedure*

5.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention time and peak area.

5.1.4.2 Inject nitrogen trifluoride sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

5.1.4.3 Repeat 5.1.4.1.

5.1.4.4 Compare the average peak area of the calibration standard to that of the nitrogen trifluoride sample being tested. Calculate the concentration of carbon tetrafluoride, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.2 *Carbon Dioxide, Nitrous Oxide, and Sulfur Hexafluoride* — This procedure is for the determination of carbon dioxide, nitrous oxide, and sulfur hexafluoride in nitrogen trifluoride using a gas chromatograph with a thermal conductivity detector. (See Figure 1.)

5.2.1 *Detection Limit* — 1.0 ppm for carbon dioxide, nitrous oxide, and sulfur hexafluoride.

5.2.2 *Instrument Parameters*

5.2.2.1 Column: Super Q (80/100 mesh), 4.9 m (16 ft.) by 1.75 mm (1/16 in.) ID, 3.2 mm (1/8 in.) OD ss or equivalent.

5.2.2.2 Carrier Flow: 19 mL/min helium.

5.2.2.3 Sample Volume: 1.0 mL.

5.2.2.4 Temperatures:

Detector	100°C
Oven	42°C
Gas sampling valve	42°C

5.2.2.5 Valve Material: Nitronic-60 or equivalent.

5.2.3 *Calibration Standard* — 10 ppm carbon dioxide, 10 ppm nitrous oxide, 10 ppm sulfur hexafluoride, balance helium.

5.2.4 *Operating Procedure*

5.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is carbon dioxide, nitrous oxide, sulfur hexafluoride. (See Figure 1 for valve configuration.)

5.2.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

5.2.4.3 Repeat 5.4.2.1.

5.2.4.4 Compare the average peak area of the calibration standard to that of the nitrogen trifluoride sample being tested. Calculate the concentration of each impurity using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.3 *Carbon Monoxide* — This procedure is for the determination of carbon monoxide in nitrogen trifluoride using a gas chromatograph with a methanizer and a flame ionization detector. (See Figure 1 and Note 2.)

5.3.1 Detection Limit — 0.1 ppm.

5.3.2 Instrument Parameters

5.3.2.1 Column: Carbosphere (80/100 mesh), 0.74 m (2.4 ft) by 1.75 mm (1/16 in) ID, 3.2 mm (1/8 in) OD ss or equivalent.

5.3.2.2 Carrier Flow: 25 mL/min helium.

5.3.2.3 Sample Volume: 0.5 mL.

5.3.2.4 Fuel gases:

Hydrogen:	Zero grade or better hydrogen at a flow rate of 45 mL/min is added to the carrier gas between the column outlet and the methanizer inlet.
Air:	Zero grade or better air is used at a flow rate of 300 mL/min.

5.3.2.5 Temperatures:

Detector	150°C
Oven	42°C
Methanizer	340°C
Gas sampling valve	70°C

5.3.2.6 Valve Material: Nitronic-60 or equivalent.

5.3.3 *Calibration Standard* — 10 ppm carbon monoxide, balance helium.

5.3.4 *Operating Procedure*

5.3.4.1 Inject the the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

5.3.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention time and peak area.

5.3.4.3 Repeat 5.3.4.1.

5.3.4.4 Compare the average peak area of the calibration standard to that of the nitrogen trifluoride sample being tested. Calculate the concentration of carbon monoxide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

5.4 *Oxygen + Argon, Nitrogen* — This procedure is for the determination of oxygen + argon and nitrogen in nitrogen trifluoride using a gas chromatograph with a thermal conductivity detector. (See Figure 2 and Note 1.)

5.4.1 *Detection Limit* — 5 ppm of oxygen + argon and nitrogen.

5.4.2 *Instrument Parameters*

5.4.2.1 Column: Molecular sieve 13X (80/100 mesh), 6.1 m (20 ft) by 1.75 mm (1/16 in) ID, 3.2 mm (1/8 in) OD ss or equivalent.

5.4.2.2 Carrier Flow: 17 mL/min helium.

5.4.2.3 Sample Volume: 1.0 mL.

5.4.2.4 Temperatures:

Detector	140°C
Filament	240°C
Oven	100°C
Gas sampling valve	60°C

5.4.2.5 Valve Material: Nitronic-60 or equivalent.

5.4.3 *Calibration Standard* — 10 ppm oxygen, 10 ppm nitrogen, balance helium.

5.4.4 *Operating Procedure*

5.4.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. The order of elution is oxygen + argon (not separated) and nitrogen.

5.4.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

5.4.4.3 Repeat 5.4.4.1.

5.4.4.4 Compare the average peak area of the calibration standard to that of the nitrogen trifluoride sample being tested. Calculate the concentrations of oxygen + argon and nitrogen, using the formula below. The results may not exceed the specifications in Section 3 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

5.5 *Water* — This procedure is for the determination of trace moisture (water) in nitrogen trifluoride using a continuous flowing piezoelectric hygrometer. (See Notes 3 and 4.)

5.5.1 *Detection Limit* — 0.04 ppm (vol/vol) or -95°C (-139°F).

5.5.2 *Flow Requirements* — Set the sample pressure and flow rate set in accordance with the instrument manufacturer's instructions.

5.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed by another analytical method.

5.5.4 *Operating Procedure*

5.5.4.1 Obtain a continuous flow of sample gas from the source using a clean and passivated 316 stainless steel line which has been purged dry after exposure to ambient moisture.

5.5.4.2 After prepurging with a dry gas, allow the sample as to flow through the sampling system and the piezoelectric hygrometer until a stable reading is obtained. The result may not exceed the specification in Section 2 of this Standard.

5.6 *Hydrolyzable Fluorides as HF* — This procedure is for the determination of hydrolyzable fluorides in nitrogen trifluoride using fluoride ion selective electrode.

5.6.1 *Detection Limit* — Detection limits should be checked for any new implementation of a method. Detection limits below 0.1 ppm have been determined with this method. Detection limits can be improved by increasing the volume of gas sampled.

5.6.2 *Equipment*

5.6.2.1 mV meter (0.1 mV scale)

5.6.2.2 Reference electrode (single junction type)

5.6.2.3 Fluoride ion selective electrode

5.6.2.4 Magnetic stir bars (PTFE coated)

5.6.2.5 Magnetic stirrer

5.6.2.6 Plastic beakers (See NOTE 5.)

5.6.2.7 PTFE bubblers

5.6.2.8 1000 ml and 100 ml plastic volumetric flasks (see NOTE 5).

5.6.2.9 0.2 ml and 1 ml plastic volumetric pipettes (see NOTE 5).

5.6.2.10 Flow controller or flowmeter (0–1000 sccm NF_3)

5.6.3 *Reagents*

5.6.3.1 Distilled or deionized water

5.6.3.2 5 N sodium hydroxide

5.6.3.3 0.2 N sodium hydroxide

5.6.3.4 Glacial acetic acid

5.6.3.5 *Buffer Solution* — To 500 ml distilled or deionized water in a 1000 ml volumetric flask, add 57 ml glacial acetic acid and 58 g of sodium chloride. Adjust the pH to between 5.0–5.5 with 5 M sodium hydroxide. Cool to room temperature. Dilute to one liter with distilled or deionized water.

5.6.4 *Calibration Standard* — Sodium fluoride standard (10^{-3} M F^- in water, freshly prepared)

5.6.5 *Operating Procedure*

5.6.5.1 Prepare working standard by adding 100 ml 10^{-3} M F^- to 100 ml buffer solution.

5.6.5.2 Prepare a blank containing 50.0 ml 0.2 N NaOH and 50.0 ml buffer solution in a plastic beaker.

5.6.5.3 While stirring blank gently, record mV reading from the blank once reading is stable.

5.6.5.4 Successively add increments of working standard to the blank to generate a calibration curve. Record stable mV reading after each addition. Table 1 shows recommended increments and resultant concentrations.

Table 1 Calibration Concentrations

Added Volume of Working Standard (ml)	*Total Volume (ml)*	*Resulting F^- Concentration (M)*
0.2	100.2	1.0×10^{-6}
0.2	100.4	2.0×10^{-6}
0.4	100.8	4.0×10^{-6}
0.4	101.2	5.9×10^{-6}
0.8	102.0	9.8×10^{-6}
1.0	103.0	1.5×10^{-5}
2.0	105.0	2.4×10^{-5}

5.6.5.5 Put 50 ml 0.2 N NaOH into each of two bubblers connected in series.

5.6.5.6 Establish a flow of < 1000 sccm of NF_3 through the bubblers using a suitable flow controller or flowmeter.

5.6.5.7 Sample approximately 15 liters of NF_3. Record flowrate and time of sampling to determine total volume sampled (flowrate × time). A wet test meter can also be used to measure total volume. The amount of gas sample must be the volume at STP. If the flowmeter or wet test meter is not reference to 0º and 760 torr, use the formula below to correct sample volume.

$$\text{Liters at STP} = \text{Measured Liters} \times \frac{760\ \text{Torr}}{\text{P}} \times \frac{\text{T} + 273}{273\ \text{K}}$$

P: Pressure of sampled gas (mm Hg)

T: Temperature of sampled gas or reference temperature of the flow controller or meter in ºC.

5.6.5.8 Transfer contents of each bubbler to individual 100 ml volumetric flasks and add 50 ml Buffer solution to each. Then, if necessary, add deionized or distilled water to bring the volume up to 100 ml.

5.6.5.9 Transfer contents to a plastic beaker.

5.6.5.10 While stirring, measure and record mV readings for each sample.

5.6.5.11 Determine F^- concentration in solution using calibration curve generated in Section 5.6.5.4.

5.6.5.12 Calculate gas phase hydrolyzable fluoride concentration using the equation below. Note that the equation assumes the hydrolyzable fluoride is hydrogen fluoride.

$$\text{Gas Phase HF}\ (\text{ppm}_v) = \text{C} \times 0.11 \times \frac{22.4\ \text{l/mole}}{\text{Vs}} \times 10^6$$

C: Measured hydrolyzable fluoride concentration (M) determined in Section 5.6.5.11.

Vs: Volume of NF_3 sampled (liters at STP)

5.6.5.13 The HF concentration of the second bubbler should be insignificant compared to the first bubbler. If significant HF levels are found in the second bubbler, resample with a lower flowrate.

5.7 *Notes*

NOTE 1: Pass the carrier gas through a trap (3 m (10 ft.) by 6.4 mm (1/4 in.) OD) containing 50% by volume molecular sieve 5A and 50% by volume molecular sieve 13X submerged in liquid nitrogen.

NOTE 2: The methanizer catalyst can be destroyed by nitrogen trifluoride passing through to at high temperature. After the carbon monoxide peak is detected, the bulk nitrogen trifluoride is bypassed to vent by means of a four-port switching valve installed downstream of the separating column and before the methanizer (see Figure 1).

NOTE 3: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced, by a regulator with a diaphragm of stainless steel or other suitable material, to accommodate the pressure restrictions of the analytical hygrometer.

NOTE 4: A passivation procedure is described in the Metals Handbook, 8th ed., Vol. 2, American Society for Metals, Metals Park, OH.

NOTE 5: Polytetrafluoroethlyene, polymethylpentene and polypropylene are suitable plastic materials.

SEMI C3.13-1000

STANDARD FOR NITROUS OXIDE (N_2O) IN CYLINDERS, 99.997% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available at www.semi.org September 2000; to be published October 2000. Originally published in 1982; previously published in 1993.

1 Description

1.1 Nitrous oxide is an oxidizing, colorless, liquefied gas with a sweetish odor. It is a simple asphyxiant. Vapor pressure is about 745 psig at 70°F.

2 Specifications

QUALITY: 99.997% (See Notes 1, 2)

Impurities	*Maximum Acceptable Level (ppm)**
Ammonia (NH_3)	5
Carbon Dioxide (CO_2)	2
Carbon monoxide (CO)	1
Hydrocarbons C_1-C_5	1
Nitric Oxide (NO)	1
Nitrogen (N_2)	10
Nitrogen dioxide (NO_2)	1
Oxygen (O_2)	2
Water (H_2O) (v/v)	3
TOTAL SPECIFIED IMPURITIES	26

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	44.01	44.01
Boiling point at 1 atm	-88.5°C	-127.4°F
Density of gas at 70°F (21.1°C) and 1 atm	1.947 g/L	0.1160 lb/ft^3
Specific gravity of gas	1.53	1.53
Critical pressure	71.46 atm	1052 psia
Critical temperature	36.4 °C	97.6°F

4 Analytical Procedures (See Note 3 and Appendix 1)

4.1 *Ammonia* — This procedure is for the determination of ammonia in nitrous oxide using an apparatus employing a detector tube filled with a color-reactive chemical.

4.1.1 *Detection Limit* — 0.2 ppm (mole/mole).

4.1.2 *Apparatus*

4.1.2.1 *Pressure Regulator* — Outlet Pressure Range 0–30 psig.

4.1.2.2 *Flowmeter* — Range 0–200 mL/min.

4.1.2.3 *Detector Tube* — Range 2–30 ppm.

4.1.2.4 Stop watch.

4.1.2.5 6 mm (1/4 in) flexible tubing.

4.1.3 *Operating Procedure*

4.1.3.1 Attach a suitable regulator to the cylinder outlet.

4.1.3.2 Connect the flowmeter to the regulator using flexible tubing.

4.1.3.3 Open the cylinder valve and purge the flowmeter with nitrous oxide.

4.1.3.4 After the line is thoroughly purged, stop the flow of nitrous oxide and attach the detector tube to the outlet of the flowmeter.

4.1.3.5 Start the flow of nitrous oxide and set the flow rate to 100 mL/min. The pressure and temperature of the sample must be within the tolerances specified by the manufacturer.

4.1.3.6 Pass 100 mL of nitrous oxide through the detector tube.

4.1.3.7 Determine the concentration of ammonia according to the detector tube manufacturer's instructions. The concentration may not exceed the specification in Section 2 of this Standard.

4.2 *Carbon Monoxide and Carbon Dioxide* — This procedure is for the determination of carbon monoxide and carbon dioxide in nitrous oxide using a gas chromatograph with a flame ionization detector and methanizer with back flush. (See Note 4 and Figure A1-1.)

4.2.1 *Detection Limit* — 1 ppm (mole/mole). (50 ppb depending on conditions)

4.2.2 *Instrument Parameters*

4.2.2.1 Columns:

Column 1: Porapak QS, 4.6 m (15 ft) by 5 mm (3/16 in) or equivalent.

Column 2: Molecular sieve 5A, 1.97 m (6 ft) by 5 mm, 80/100 mesh (reference only) or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 0.5 to 2.0 mL.

4.2.2.4 Temperatures:

Detector	35°C
Column Oven	35°C
Methanizer	500°C

4.2.3 *Calibration Standard* — 1–5 ppm (mole/mole) carbon monoxide, 1–5 ppm (mole/mole) carbon dioxide, balance nitrous oxide.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak areas. Order of elution is carbon monoxide, methane, carbon dioxide, and nitrous oxide. Back flush 18 minutes.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak areas of the calibration standard to that of the nitrous oxide sample being tested. Calculate the concentrations of carbon monoxide and carbon dioxide, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Hydrocarbons* $C_1 - C_5$ — This procedure is for the determination of hydrocarbons $C_1 - C_5$ in nitrous oxide using a gas chromatograph with a flame ionization detector.

4.3.1 *Methane Determination*

4.3.1.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.3.1.2 *Instrument Parameters*

4.3.1.2.1 Column: 5A molecular sieve, 1.9 m (6 ft) by 6.4 mm (1/4 in) OD by 5.3 mm (0.210 in) ID ss or equivalent.

4.3.1.2.2 Carrier Flow: 25 mL/min helium.

4.3.1.2.3 Sample Volume: 5.0 mL.

4.3.1.2.4 Temperature:

Column Oven	30°C

4.3.2 *Ethane Determination*

4.3.2.1 *Detection Limit* — 0.3 ppm (mole/mole).

4.3.2.2 *Instrument Parameters*

4.3.2.2.1 Column: Porapak Q, 1.9 m (6 ft) by 6.4 mm (1/4 in) OD by 5.3 mm (0.210 in) ID ss or equivalent.

4.3.2.2.2 Carrier Flow: 50 mL/min helium.

4.3.2.2.3 Sample Volume: 1.0 mL.

4.3.2.2.4 Temperature:

Column Oven	60°C

4.3.3 *Ethylene, Propane, Acetylene, Propylene, n-butane, and n-pentane Determination*

4.3.3.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.3.3.2 *Instrument Parameters*

4.3.3.2.1 Column: Phenylisocyanate/Porasil C, 3 m (10 ft) by 4.8 mm (3/16 in) OD by 3.7 mm (0.147 in) ID ss or equivalent.

4.3.3.2.2 Carrier Flow: 25 mL/min helium.

4.3.3.2.3 Sample Volume: 1.0 mL.

4.3.3.2.4 Temperature:

Column Oven	30°C

4.3.4 *Calibration Standards* — 1–5 ppm (mole/mole) methane in helium, 1–5 ppm (mole/mole) ethane in helium, 1–5 ppm (mole/mole) ethylene, 1–5 ppm (mole/mole) propane, 1–5 ppm (mole/mole) acetylene, 1–5 ppm (mole/mole) propylene, 1–5 ppm (mole/mole) n-butane, and 1–5 ppm (mole/mole) n-pentane, balance in helium.

4.3.5 *Operating Procedure*

4.3.5.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.3.5.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.3.5.3 Repeat 4.3.5.1.

4.3.5.4 Compare the average peak area of the calibration standard to that of the nitrous oxide sample being tested. Calculate the concentration of hydrocarbons C_1–C_5, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.4 *Nitric Oxide* — This procedure is for the determination of nitric oxide in nitrous oxide using chemiluminescence. The detector shall have a photomultiplier tube capable of sensing the light emission of the decaying nitrous oxide. The detector shall have variable attenuation, zero and span adjustments, display, and an onboard ozone generator. (See Note 5.)

4.4.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.4.2 *Instrument Parameters*

4.4.2.1 *Flow Requirements* — Set the zero gas, span gas, and sample gas in accordance with the instrument manufacturer's instructions.

4.4.3 *Calibration Standards*

4.4.3.1 Zero argon (99.99% minimum) with less than 0.1 ppm nitric oxide.

4.4.3.2 The upper level argon span gas (99.99% minimum) not exceeding 5 times the concentration of the specification.

4.4.3.3 The oxygen supplied to the ozone generator will contain less than 0.1 ppm nitric oxide.

4.4.4 *Operating Procedure*

4.4.4.1 Introduce the zero argon and set the instrument to zero with the zero adjust knob.

4.4.4.2 Introduce the span gas in argon and, using the span adjust knob, set the output reading to match the level of nitrous oxide in the span gas.

4.4.4.3 Repeat steps 4.4.4.1 and 4.4.4.2 until reproducibility of readings is better than 1% full scale.

4.4.4.4 Introduce the nitrous oxide sample into the analyzer and read the quantity of nitric oxide. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Nitrogen and Oxygen* — This procedure is for the determination of nitrogen and oxygen in nitrous oxide using a gas chromatograph with a helium ionization detector.

4.5.1 *Detection Limit* — 0.5 ppm (mole/mole).

4.5.2 *Instrument Parameters*

4.5.2.1 Columns:

Column 1: Porapak Q, 1.9 m (6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss, or equivalent.

Column 2: Molecular sieve 5A, 2.4 m (8 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss, or equivalent.

4.5.2.2 Carrier Flow: 50 mL/min helium.

4.5.2.3 Sample Volume: 1.0 to 3.0 mL.

4.5.2.4 Temperatures:

Detector	125°C
Column Temperature	65°C

4.5.3 *Calibration Standards* — 5-20 ppm (mole/mole) nitrogen in helium and 1-5 ppm (mole/mole) oxygen in helium.

4.5.4 *Operating Procedure*

4.5.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.5.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak areas.

4.5.4.3 Repeat 4.5.4.1.

4.5.4.4 Compare the average peak area of the calibration standard to that of the nitrous oxide sample being tested. Calculate the concentrations of nitrogen and oxygen, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration} \\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration} \\ \text{of Sample}\end{matrix}$$

4.6 *Nitrogen Dioxide* — This procedure is for the determination of nitrogen dioxide in nitrous oxide using an apparatus employing a detector tube filled with a color-reactive chemical.

4.6.1 *Detection Limit* — 0.05 ppm.

4.6.2 *Apparatus*

4.6.2.1 Pressure Regulator: Outlet Pressure Range 0-30 psig.

4.6.2.2 Flowmeter: Range 0–200 mL/min.

4.6.2.3 Detector tube: Range 0.2–6 ppm.

4.6.2.4 Stop Watch.

4.6.2.5 6 mm (1/4 in) flexible tubing.

4.6.3 *Operating Procedure*

4.6.3.1 Attach a suitable regulator to the cylinder outlet.

4.6.3.2 Connect the flowmeter to the regulator using flexible tubing.

4.6.3.3 Open the cylinder valve and purge the flowmeter with nitrous oxide.

4.6.3.4 After the line is thoroughly purged, stop the flow of nitrous oxide and attach the detector tube to the outlet of the flowmeter.

4.6.3.5 Start the flow of nitrous oxide and set the flow rate to 100 mL/min. The pressure and temperature of the sample must be within the tolerance specified by the manufacturer.

4.6.3.6 Pass 800 mL of gas through the detector tube.

4.6.3.7 Determine the concentration of nitrogen dioxide according to the detector tube manufacturer's instructions. The concentration may not exceed the specification in Section 2 of this Standard.

4.7 *Water* — This procedure is for the determination of trace moisture (water) in nitrous oxide using a piezoelectronic hygrometer.

4.7.1 *Detection Limit* — 1.0 ppm (vol/vol).

4.7.2 *Flow Requirements* — Follow the flow requirements specified in the manufacturer's instrument operation manual.

4.7.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. The standards employed will be verified independently by another analytical method.

4.7.4 *Sample System and Proper Operation*

4.7.4.1 The sample system shall be as shown in Figure A1-2.

4.7.4.2 Attach sample system to nitrous oxide cylinder.

4.7.4.3 Partially open valve 2.

4.7.4.4 Open valve 1 and adjust pressure to 50 psig, ± 5 psig.

4.7.4.5 Adjust valve 2 until a flow of 500 mL/min, ± 50 mL/min is venting.

4.7.4.6 Tubing, valves and fittings are to be cleaned and passivated 316 stainless steel.

4.7.4.7 Keep tubing lengths to a minimum.

4.7.5 *Operating Procedure*

4.7.5.1 Follow the procedures outlined in the instrument manufacturer's manual.

4.7.5.2 Allow the system to run until a stable reading is obtained for ten minutes.

4.7.5.3 Read the quantity of water on the analyzer meter. The result may not exceed the specification in Section 2 of this Standard.

4.8 *Notes*

NOTE 1: This specification applies to the gas phase of the cylinder as delivered.

NOTE 2: It is recommended that the user discontinue use of the cylinder prior to complete consumption of the liquid phase. The contents of cylinders should be determined by weight, not pressure.

NOTE 3: Rapid withdrawal of gaseous nitrous oxide from a liquified source (e.g., cylinder) can result in a significant cooling effect which may condense the nitrous oxide in the sampling lines.

NOTE 4: In order to prevent nitrous oxide interference, a helium backflush to vent is needed for 3–5 times the analysis time (estimated to be 3–5 minutes). Because nitrous oxide is converted into ammonia in the methanizer, stainless steel (ss) is required; copper tubing and fittings are not used. The backflush removes the nitrous oxide from Column No. 1 preparing the column for the next sample. Careful timing is required to identify carbon monoxide and carbon dioxide distinguishing both from the time methane would appear, if present. Carbon monoxide and carbon dioxide are converted to methane in the methanizer; therefore, both will be detected by the FID detector at the specific times determined by the analytical sequence of the standard.

NOTE 5: This method does not determine nitrous oxide impurities.

APPENDIX 1
GENERAL ANALYTICAL PRACTICES

NOTE: The material in this appendix is an official part of SEMI C3.13 and was approved by full letter ballot procedures on August 28, 2000 by the North American Regional Standards Committee.

NOTE A1-1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE A1-2: All the gases used in the analysis of the sample should not contain more than 10% of the specified value at the component of interest, unless otherwise specified.

SEMI C3.50-1000
GUIDELINE FOR NITROUS OXIDE (N_2O), 99.9994% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on July 11, 2000. Initially available at www.semi.org September 2000; to be published October 2000. Originally published in 1995.

1 Description

1.1 Nitrous oxide is an oxidizing, colorless, liquefied gas with a sweetish odor. It is a simple asphyxiant. Vapor pressure is about 745 psig at 70°F.

2 Specifications

QUALITY: 99.9994% (See Notes 1, 2)

Impurities	*Maximum Acceptable Level (ppm)**
Ammonia (NH_3)	0.1
Carbon Dioxide (CO_2)	0.5
Carbon Monoxide (CO)	0.1
Methane (CH_4)	0.1
Nitric Oxide (NO)	0.1
Nitrogen (N_2)	3.0
Nitrogen Dioxide (NO_2)	0.1
Oxygen (O_2) + Argon (Ar)	0.5
Water (H_2O) (v/v)	1.0
TOTAL SPECIFIED IMPURITIES	5.5

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	44.01	44.01
Boiling point at 1 atm	-88.5°C	-127.4°F
Density of gas at 70°F (21.1°C) and 1 atm	1.947 g/L	0.1146 lb/ft^3
Specific gravity of gas	1.53	1.53
Critical pressure	71.46 atm	1052 psia
Critical temperature	36.4°C	97.6°F

Note 1: This specification applies to the gas phase of the cylinder as delivered.

Note 2: It is recommended that the user discontinue use of the cylinder prior to complete consumption of the liquid phase. The contents of cylinders should be determined by weight, not pressure.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C3.58-0600
SPECIFICATION FOR OCTAFLUOROCYLOBUTANE, C_4F_8, ELECTRONIC GRADE IN CYLINDERS

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the European Gases Committee. Current edition approved by the European Regional Standards Committee on April 4, 2000. Initially available at www.semi.org May 2000; to be published June 2000.

1 Description

1.1 Octafluorocyclobutane, also known as perfluorocyclobutane, is a gas under normal atmospheric conditions (15°C and 760 mm Hg).

1.2 The gas is a non-flammable, non-toxic, colorless and odorless gas which is stable under normal conditions.

2 Specifications

Purity: 99.99%

Impurities	*Maximum Acceptable Level*
Nitrogen/Oxygen	50 ppm
Moisture	5 ppm
Other halocarbons*	40 ppm
Acidity (as HF)	1 ppm mole

* R13, R23, R114, R113, R11, and R116

3 Referenced Standards

None.

4 Physical Constants (for information only)

Formula	C_4F_8 or $CF_2 \cdot CF_2 \cdot CF_2 \cdot CF_2$
Molecular weight	200
Melting point	-40.2°C
Boiling point	115°C
Relative density, gas	6.9 (air=1)
Relative density, liquid	1.6 (water=1)
Vapor pressure 20°C	2.7 bar
Appearance/Color	Colorless gas
Odor	none

5 Analytical Procedures

5.1 *Acidity* — This procedure is for the determination of acidity in octafluorocyclobutane using a classical chemical method of analysis, utilizing methyl red indicator.

5.1.1 *Detection Limit* — 1 ppm as HF.

5.1.2 *Apparatus*

5.1.2.1 Three 8 X one inch flat bottomed test tubes, flexible tubing, flowmeter, pressure regulator.

5.1.2.2 *Reagents* — 0.02% methyl red solution, 0.01N hydrochloric acid, freshly distilled or deionized water boiled to remove carbon dioxide.

5.1.2.2.1 0.02% methyl red: methyl red is 1-carboxybenzeneazodimethylaniline. This is the acid or alcohol soluble form which shall be used. Dissolve 20 mg of methyl red (acid form) in a mixture of 7.44 mL of 0.01M sodium hydroxide and 70 mL of alcohol and dilute to 100 mL with water. The alcohol must contain not less than 95% v/v ethanol.

5.1.2.2.2 0.01M hydrochloric acid: dilute 103.0 g of hydrochloric acid solution (SG 1.18) to 1000.0 mL with water to give 1M solution.

5.1.2.2.3 Dilute 10.0 mL of this solution to 1000.0 mL with water to give 0.01M solution.

5.1.2.2.4 Alternatively prepare by the dilution of a commercially available standard solution.

5.1.3 *Operating Procedure*

5.1.3.1 Attach a suitable regulator to the cylinder outlet.

5.1.3.2 Connect the flowmeter to the regulator using flexible tubing.

5.1.3.3 Open the cylinder valve and purge the flowmeter with octafluorocyclobutane.

5.1.3.4 Pour 50 mL of carbon dioxide free water into each of three 8 X one inch flat bottomed test tubes. Add 0.1 mL of 0.02% solution of methyl red in alcohol to each tube and label the tubes ‘a’ ‘b’ and ‘c’. Add 0.1 mL of 0.01M hydrochloric acid to tube ‘b’ and 0.2 mL of 0.01M hydrochloric acid to tube ‘c’. Pass a 23 liter gaseous sample of octafluorocyclobutane through the solution in tube ‘b’. Compare the color of tube ‘b’ after the test with the other two tubes. The intensity of the color produced in ‘b’ should be between those solutions ‘a’ and ‘c’. The formation of a pink color indicates acidity. A yellow color will be produced by alkalinity.

5.1.3.4.1 The colors of the test solutions before the test should be:

‘a’ — pale straw

‘b’ — pink

‘c’ — pink, slightly darker than ‘b’.

5.1.3.4.2 To differentiate the colors more readily after the test view the tubes by looking down through the solution rather than through the tubes. Place a sheet of white paper behind the tubes and carry out the comparisons in natural light.

6 Analytical Procedures - Instrumental Analysis

6.1 *Oxygen and Nitrogen* — This procedure is for the determination of oxygen and nitrogen in octafluorocyclobutane using a gas chromatograph with a thermal conductivity detector. Column switching is used to separate and elute the components and to backflush octafluorocyclobutane.

6.1.1 *Detection Limits* — oxygen 1 ppm (mole/mole), nitrogen 1 ppm (mole/mole).

6.1.2 *Instrument Parameters*

6.1.2.1 *Columns*: Pre-column: Molecular sieve 13X, 60/80 mesh, 2.5 m by 2.1 mm ss or equivalent. Main column: Molecular sieve 13X, 60/80 mesh, 1.5 m by 2.1 mm ss or equivalent. Ensure that all columns are conditioned before assembly.

6.1.2.2 *Gas Flows:* Helium carrier gas 25 mL/min for each column.

6.1.2.3 *Sample Volume*: 2.5 mL

6.1.2.4 *Temperatures:* Detector 100°C, Oven 90°C isothermal.

6.1.3 *Calibration Standard:* 1–50 ppm (mole/mole) oxygen and nitrogen in helium.

6.1.4 *Chromatogram* — See Figure 1.

6.2 *Halogenated Hydrocarbons* — This procedure is for the determination of halogenated hydrocarbons in octafluorocyclobutane using a gas chromatograph with a flame ionization detector.

6.2.1 *Detection Limits*

R13, R23, R114	1 ppm (mole/mole)each
R113	4 ppm (mole/mole)
R11, R116	10 ppm (mole/mole) each

6.2.2 *Instrument Parameters*

6.2.2.1 *Column* — Chromosorb 102, 80/100 mesh, 5 m by 2.1 mm ss or equivalent.

6.2.2.1.1 Ensure that the column is conditioned before assembly.

6.2.2.2 *Gas Flows* — Nitrogen carrier gas 25 mL/minute.

6.2.2.3 *Sample Volume* — 1 mL

6.2.2.4 *Temperatures* — Detector: 140°C, Oven: 80°C for 7 minutes, then increase 32°C/min up to 130°C.

6.2.3 *Calibration Standard:* 10–100 ppm (mole/mole) R11, R13, R23, R 113, R114, and R116 in nitrogen.

6.2.4 *Chromatogram* — See Figure 2.

6.3 *Water* — This procedure is for the determination of trace moisture (water) in Octafluorocyclobutane, using a continuous flowing electrolytic hygrometer.

6.3.1 *Detection Limit* — 1.0 ppm (vol/vol). This is equivalent to a frost point of -76°C (-106°F).

6.3.2 *Sample Pressure and Flow* — set in accordance with instrument manufacturer's instructions.

6.3.3 *Operation Check* — The instrument should be checked periodically for correct operation. A gas containing a known amount of moisture should be passed through the instrument. Agreement between the hygrometer and the standard should be within their relative accuracy.

6.3.4 *Operation Procedure*

6.3.4.1 Obtain a continuous flow sample of the Octafluorocyclobutane source, using a clean, electropolished or passivated (see Note 2) stainless steel line which has been purged dry after exposure to ambient moisture.

6.3.4.2 After purging with dry gas, allow the sample gas to flow through the sampling system and hygrometer until a stable reading is obtained. The reading may not exceed specification in Section 2 of this standard.

NOTE 1: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced, by a regulator with a diaphragm of stainless steel or other suitable material, to accommodate the pressure restrictions of the analytical hygrometer.

NOTE 2: A passivation procedure is described in the Metals Handbook, 8th ed., Vol. 2, American Society for Metals, Metals Park, OH.

Determination of other halogenated hydrocarbons in Octafluorocyclobutane

SEMI C3.22-1000
STANDARD FOR OXYGEN (O_2), 99.5% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on July 11, 2000. Initially available at www.semi.org August 2000; to be published October 2000. Originally published in 1983; previously published in 1993.

1 Description

1.1 Oxygen is a colorless, odorless and oxidizing gas. It supports combustion.

2 Specifications

ASSAY: 99.5%

Impurities	*Maximum Acceptable Level (ppm)**
Carbon monoxide and Carbon dioxide ($CO + CO_2$)	5
Nitrogen (N_2)	100
Nitrous oxide (N_2O)	2
Particles	**
Total Hydrocarbons expressed as Methane (THC)	25
Water (H_2O) (v/v)	1
TOTAL IMPURITIES INCLUDING RARE GASES	5,000

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	31.999	31.999
Boiling point at 1 atm	-183°C	-297.4°F
Density of gas at 25°C (77°F) and 1 atm	1.309 kg/m^3	0.082 lb/ft^3
Specific gravity of gas at 21.1°C (70°F) and 1 atm (air = 1)	1.1049	1.1049
Density of liquid at boiling point	1142 kg/m^3	71.27 lb/ft^3

4 Analytical Procedures

4.1 *Carbon Monoxide, Carbon Dioxide, and Nitrous Oxide* — This procedure is for the determination of carbon monoxide, carbon dioxide and nitrous oxide in oxygen using infrared spectrophotometry.

4.1.1 *Detection Limits* — 0.5 ppm (mole/mole) carbon monoxide, 0.1 ppm (mole/mole) carbon dioxide, and 0.2 ppm (mole/mole) nitrous oxide.

4.1.2 *Instrument Parameters*

4.1.2.1 10 meter variable path infrared gas cell.

4.1.2.2 Grating infrared spectrophotometer.

4.1.2.3 Bourdon Vacuum Gauge.

4.1.3 *Calibration Standards* — 10 ppm (mole/mole) carbon monoxide, 10 ppm (mole/mole) carbon dioxide and 10 ppm (mole/mole) nitrous oxide, balance oxygen.

4.1.4 *Operating Procedure*

4.1.4.1 Pressurize the evacuated gas cell to 50 psia with the calibration standard. Scan the following wave numbers for absorbance: carbon monoxide 2172 cm^{-1}, nitrous oxide 2235 cm^{-1}, and carbon dioxide 2360 cm^{-1}.

4.1.4.2 Evacuate the cell and pressurize to 50 psia with the oxygen sample. Scan the appropriate wave numbers as in 4.1.4.1.

4.1.4.3 Compare the absorbance of the calibration standard to that of the oxygen sample being tested. Calculate the concentrations of carbon monoxide, carbon dioxide and nitrous oxide, using the formula below. The results may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Absorbance}}{\text{Standard Absorbance}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Nitrogen* — This procedure is for the determination of nitrogen in oxygen using a gas chromatograph with a thermal conductivity detector.

4.2.1 *Detection Limit* — 10 ppm (mole/mole).

4.2.2 *Instrument Parameters*

4.2.2.1 Column: 5A molecular sieve, 4.6 m (15 ft) by 3.2 mm (1/8 in) ss or equivalent.

4.2.2.2 Carrier Flow: 30 mL/min helium.

4.2.2.3 Sample Volume: 2.0 mL.

4.2.2.4 Temperatures:

Detector	200°C
Column Oven	21°C

4.2.3 *Calibration Standard* — 100 ppm (mole/mole) nitrogen in oxygen.

4.2.4 *Operating Procedure*

4.2.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention time and peak area.

4.2.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention time and peak area.

4.2.4.3 Repeat 4.2.4.1.

4.2.4.4 Compare the average peak area of the calibration standard to that of the oxygen sample being tested. Calculate the concentration of nitrogen, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in oxygen using a continuous flow flame ionization detector equipped total hydrocarbon analyzer. (See Notes 1, 2, 3.)

4.3.1 *Detection Limit* — 0.1 ppm (mole/mole).

4.3.2 *Flow Requirements*

4.3.2.1 High purity, hydrocarbon-free (less than 1.0 ppm) hydrogen: 35–40 mL/min or 40% hydrogen in either helium or nitrogen matrix at 75–80 mL/min.

4.3.2.2 Dry, hydrocarbon-free (less than 1.0 ppm) air: 350–400 mL/min.

4.3.2.3 Set sample flow rates in accordance with the instrument manufacturer's instructions.

4.3.3 *Calibration Standards*

4.3.3.1 Zero oxygen with known quantity of hydrocarbons at 0.5 ppm level.

4.3.3.2 The upper level span gas not exceeding 4 times the concentration of the specification.

4.3.4 *Operating Procedure*

4.3.4.1 Do not change the flow settings for hydrogen, air, and sample once established.

4.3.4.2 Introduce the zero oxygen with known quantity of hydrocarbons and, using the 0–10 ppm range, set the needle (or output) to read the correct level using the zero adjust knob.

4.3.4.3 Introduce the span gas standard in oxygen and, using the span adjust knob, set the needle (or output reading) to match the level of hydrocarbons in the span gas.

4.3.4.4 Introduce oxygen sample into the analyzer and read the quantity of hydrocarbons on the analyzer meter. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Water* — This procedure is for the determination of trace moisture (water) in oxygen using a continuous flowing, cooled-surface condensation, dewpoint/frost-point hygrometer. (See Notes 4, 5, 6.)

4.4.1 *Detection Limit* — 0.6 ppm (vol/vol) at -79°C (-100°F).

4.4.2 *Flow Requirements*

4.4.2.1 Set sample flow rate and pressure in accordance with the instrument manufacturer's instructions.

4.4.2.2 Gas must flow past the chilled mirror where optic means are provided to detect the deposit (or frost) and to read the thermometer measuring the temperature of the mirror.

4.4.3 *Calibration Standard* — A calibration thermometer designed to indicate temperatures in the -79°C (-110°F) range is required.

4.4.4 *Operating Procedure*

4.4.4.1 Obtain a continuous flow of sample gas from the source using a clean stainless steel sampling line which has been purged dry after exposure to ambient moisture.

4.4.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the dewpoint/frostpoint hygrometer for one hour to 24 hours to allow the entire system to reach equilibrium with regard to moisture content.

4.4.4.3 After equilibrium has been reached, cool down the mirror to determine the actual dewpoint/frostpoint of the sample gas. Follow the manufacturer's recommendations to create the temperatures needed.

4.4.4.4 Continue to verify the dewpoint/frostpoint for at least 30 minutes after a stable reading has been confirmed.

4.4.4.5 Correct the dewpoint reading from the measured pressure to 1 atm of pressure. The result may not exceed the specification in Section 2 of this Standard.

4.5 *Assay of Oxygen* — This procedure describes the assay of oxygen using an “Orsat” device. This is a volumetric determination of nonabsorbable/reactable gas.

4.5.1 *Method Capability* — 99.9% Oxygen.

4.5.2 *Instrument Parameters* — See Diagram A.

4.5.2.1 Equipment:

1. 1-100 mL calibrated certified buret, calibrated every 0.1 mL for the top 5 mL equipped with a 3-way stopcock on the top.
2. 3-250 mL aspirator bottles.
3. 1 one-hole rubber stop.
4. 1-1/16 in OD soft copper wire made into hollow coils 3/8 in OD by 3/4 in long.
5. Sufficient 3/8 in OD tygon tubing.
6. Sufficient surgical rubber tubing.
7. 1 gallon distilled water.
8. 2 lbs technical grade ammonium chloride.
9. 1 gallon 27% ammonium hydroxide.

4.5.2.2 *Test Solution Preparation*

4.5.2.2.1 Two pounds of technical grade ammonium chloride are dissolved in one gallon of distilled water and stored in a glass jar. One-half gallon of this solution shall be combined with one-half gallon of 27% ammonium hydroxide.

4.5.3 *Equipment Assembly* — The equipment is to be assembled, as per Diagram A, in a suitable wood or metal frame so arranged that the aspirator bottle connected to the buret can be raised and lowered, as required, to transfer the gas being analyzed to and from the center aspirator bottle which is filled with copper coils. The two leveling bottles should be filled half full of testing solution and the buret and aspirator bottle, which contains the copper coils, should be completely filled.

4.5.4 *Operating Procedure*

4.5.4.1 Before analyzing the sample, perform a series of analyses using a source of oxygen of which the purity has been previously determined. This procedure is necessary to age the test solution properly and eliminate any air bubbles which may become trapped in the apparatus. Only after three consecutive analyses have been run, indicating the known purity, should you proceed with testing. (See Note 7.)

4.5.4.2 Attach rubber tubing from the regulator of the cylinder being tested to the stopcock of the buret. Rotate the stopcock so as to draw the sample into the gas measuring buret. Collect a little more than 100 mL (i.e., below the zero mark) in the buret, and then rotate the stopcock so as to shut off the oxygen flow and remove the rubber tubing attached to the intake of the buret. If the gas sample in the buret is below the zero mark raise the leveling bottle #1 so that its “water” level is even atmosphere so as to raise the “water” level in the buret to exactly zero (Diagram B, Fig. #1).

4.5.4.3 Rotate the stopcock to connect the aspirator bottle #3 containing the copper coils, and transfer the oxygen into this aspirator bottle by raising the leveling bottle #1 (Diagram B, Fig. #2). Invert bottle #3 containing the copper coils so that both the inlet stopper and the sided outlet are in a downward position and shake gently for 1 to 2 minutes. Stand test bottle #3 on its base and lower the leveling bottle so as to withdraw any residual gases into the gas measuring buret (Diagram B, Fig. #3). Transfer at least 25 to 30 mL of test solution from the left-hand leveling bottle #2 into the right-hand leveling bottle #l, through the copper coil bottle #3, and the gas buret while, at the same time, gently rocking and tapping the center bottle (Diagram B, Fig. #4). This will move any bubbles which might cling to the copper coil into the gas measuring buret.

4.5.4.4 Turn the stopcock off and raise the leveling bottle #l so that its liquid level is the same as the liquid level inside the upper portion of the gas buret. When the levels of the leveling bottle and the gas buret are the same, read the gas purity markings on the buret at the liquid level at this point.

4.5.5 *Maintenance*

4.5.5.1 Copper coils should be added to the test bottle as required to keep the bottles completely full. The gas buret should be kept clean with a strong detergent solution to eliminate drops of liquid that might hang up in the gas space and give incorrect purity readings. No readings should be taken when the space above the liquid level of the gas buret has any liquid drops hanging in it, as this will give an erroneous purity reading.

4.5.5.2 The solution must be replaced occasionally as it becomes exhausted. The necessity of replacement may be determined when the color begins to turn green, and by the increased length of shaking time required to get a minimum acceptable purity from the oxygen in a cylinder of known purity. Suspect an exhausted solution if analysis of a cylinder of known purity does not read the correct purity.

4.5.6 *Standardization*

4.5.6.1 The method of analysis stated above can be used as a primary standard, meaning cylinders analyzed by this method can be used as standards of measurement on electronic analyzers used to measure oxygen.

4.5.6.2 This method is specific to oxygen when carbon dioxide is not present in the sample gas. When carbon dioxide is one of the components of the sample gas, the carbon dioxide must first be scrubbed from the sample.

4.6 *Notes*

Note 1: The 0–1 range can be used provided that zero and span gas standards in oxygen with known levels of hydrocarbons between 0–1 ppm are used in the calibration of the analyzer.

Note 2: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

Note 3: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer to different hydrocarbons can vary and must be approximated. However, the response of the most common hydrocarbon impurities in oxygen can be accurately totaled and compared to methane.

Note 4: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

Note 5: The National Institute of Standards and Technology (NIST) provides calibration services for the thermometers used in dewpoint/frostpoint hygrometers.

Note 6: This method is not applicable if other constituents in the gas will condense before water vapor, e.g., carbon dioxide and/or oil contamination.

Note 7: This procedure will be required only immediately after changing the test solution or contaminating the apparatus with air.

Total Hydrocarbons expressed as Methane (THC)	1
Water (H_2O) (v/v)	1
TOTAL IMPURITIES	146

*An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	31.999	31.999
Boiling point at 1 atm	-183°C	-297.4°F
Density of gas at 25°C (77°F) and 1 atm	1.309 kg/m^3	0.082 lb/ft^3
Specific gravity of gas at 21.1°C (70°F) and 1 atm (air = 1)	1.1049	1.1049
Density of liquid at boiling point	1142 kg/m^3	71.27 lb/ft^3

4 Analytical Procedures (See Notes 1, 2)

4.1 *Argon* — This procedure is for the determination of argon using a gas chromatograph with a thermal conductivity detector.

4.1.1 *Detection Limit* — 25 ppm (mole/mole)

4.1.2 *Instrument Parameters*

4.1.2.1 Column: 3.6 m (12 ft) by 3.2 mm (1/8 in) stainless steel tubing packed with molecular sieve 5A, 60/80 mesh, washed to remove fines and activated at 300°C for 24 hours or equivalent.

4.1.2.2 Carrier Flow: 45 mL/min helium.

4.1.2.3 *Sample Volume:* 1–3 mL.

4.1.2.4 Temperatures:

Detector	40°C
Column	-50°C

4.1.3 *Calibration Standard* — 50–150 ppm (mole/mole) argon, balance helium.

4.1.4 *Operating Procedure*

4.1.4.1 With the valve in Position A, load the sample loop. Switch the valve to Position B to inject the sample into the column. After the argon has been detected, switch the valve back to Position A to backflush the oxygen from the column. Record the peak area and retention time.

4.1.4.2 Inject oxygen sample to be tested in the same manner as in 4.1.4.1. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Calculate the concentration of argon in the sample, using the formula below. The result may not exceed the specification Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Carbon Monoxide* — This procedure is for the determination of carbon monoxide using dual beam optical non-dispersive infrared spectrophotometry.

4.2.1 *Detection Limit* — 0.2 ppm (mole/mole)

4.2.2 *Instrument Parameters*

4.2.2.1 Detector: “Luft” type or equivalent

4.2.2.2 10" Infrared Gas Cell or gas cell with equivalent sensitivity

4.2.2.3 Sample Cell Pressure: 200 psig for full scale range 0–20 ppm carbon monoxide or appropriate pressure recommended by the cell manufacturer.

4.2.2.4 Sample Flowrate: 500 cc/minute or as specified by the instrument manufacturer.

4.2.2.5 Wavelength: 4.75 micrometers (4750 nm)

4.2.2.6 Wavenumber: 2100 cm^{-1}

4.2.3 *Calibration Standard* — 5 ppm (mole/mole) carbon monoxide, balance oxygen.

4.2.4 *Operating Procedure* (See Notes 5, 6.)

4.2.4.1 Open the zero gas (prepurified nitrogen or certified pure oxygen, independently measured to be less than 0.1 ppm CO) cylinder valve. Open valve V1, close valves V2 and V3. Flow the gas through the system and adjust the back pressure regulator to 200 psig as shown on gauge G. Adjust the flowrate on the flowmeter to 1000 cc/minute by adjusting valve V1. After a constant readout is observed, adjust the zero control knob of the analyzer to set the absorbance output to read zero.

4.2.4.2 Open the calibration gas standard cylinder valve. Close V1 and V2, and open valve V3. Flow the calibration gas through the system and adjust the back pressure regulator to 200 psig. Adjust the flowrate on the flowmeter to 1000 cc/minute. After a constant readout is observed, record the absorbance of the calibration standard, if the instrument indicates absorbance directly. If the instrument indicates concentration, adjust the span control to read the concentration of carbon monoxide in the calibration gas.

4.2.4.3 Introduce the oxygen sample into the analyzer by closing valves Vl and V3, opening valve V4 and slowly opening valve V2 until the flowrate on the flowmeter is 1000 cc/minute. Adjust the back pressure regulator to 200 psig. If the instrument indicates absorbance, read the absorbance of the sample and calculate the quantity of carbon monoxide, using the formula below. If the instrument indicates concentration, record the concentration. The results may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Measured Absorbance of Sample}}{\text{Measured Absorbance of Standard}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide using dual beam optical non-dispersive infrared spectrophotometry.

4.3.1 *Detection Limit* — 0.05 ppm (mole/mole)

4.3.2 *Instrument Parameters*

4.3.2.1 Detector: "Luft" type or equivalent

4.3.2.2 10" Infrared Gas Cell or gas cell with equivalent sensitivity

4.3.2.3 *Sample Cell Pressure* — 100 psig for full scale range 0–5 ppm carbon dioxide; 200 psig for full scale range of 0–2.5 ppm carbon dioxide or appropriate pressure as recommended by cell manufacturer.

4.3.2.4 Sample Flowrate: 500 cc/minute or as specified by the instrument manufacturer

4.3.2.5 Wavelength: 4.4 micrometers (4400 nm)

4.3.2.6 Wavenumber: 2250 cm^{-1}

4.3.3 *Calibration Standard* — 5 ppm (mole/mole) carbon dioxide, balance oxygen.

4.3.4 *Operating Procedure* — (See Notes 5 and 6)

4.3.4.1 Open the zero gas (prepurified nitrogen or pure oxygen, independently measured to be less than 0.1 ppm CO_2) cylinder valve. Open valve V1, close valves V2 and V3. Flow the gas through the system and adjust the back pressure regulator to 100 psig as shown on gauge G. Adjust the flowrate on the flowmeter to 1000 cc/minute by adjusting valve Vl. After a constant readout is observed, adjust the zero control knob of the analyzer to set the absorbance output to read zero.

4.3.4.2 Open the calibration gas standard cylinder valve. Close V1 and V2, and open valve V3. Flow the calibration gas through the system and adjust the back pressure regulator to 100 psig. Adjust the flowrate on the flowmeter to 1000 cc/minute. After a constant readout is observed, record the absorbance of the calibration standard, if the instrument indicates absorbance directly. If the instrument indicates concentration, adjust the span control to read the concentration of carbon dioxide in the calibration gas.

4.3.4.3 Introduce the oxygen sample into the analyzer by closing valves V1 and V3, opening valve V4 and slowly opening valve V2 until the flowrate on the flowmeter is 1000 cc/minute. Adjust the back pressure regulator to 100 psig. If the instrument indicates absorbance, read the absorbance of the sample and calculate the quantity of carbon dioxide, using the formula below. If the instrument indicates concentration, record the concentration. The results may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Measured Absorbance of Sample}}{\text{Measured Absorbance of Standard}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.4 *Krypton and Nitrogen* — This procedure is for the determination of krypton and nitrogen using a gas chromatograph with a thermal conductivity detector.

4.4.1 *Detection Limits* — 3 ppm (mole/mole) krypton, 3 ppm (mole/mole) nitrogen

4.4.2 *Instrument Parameter*

4.4.2.1 Column: 3.6 m (12 ft) by 3.2 mm (1/8 in) stainless steel tubing packed with molecular sieve 5A, 60/80 mesh, washed to remove fines and activated at 300°C for 24 hours or equivalent.

4.4.2.2 Carrier Flow: 45 mL/min helium.

4.4.2.3 Sample Volume: 25 mL.

4.4.2.4 Temperatures:

Detector	40°C
Column	25°C

4.4.3 *Calibration Standards* — 5–15 ppm (mole/mole) krypton, 15–5 ppm (mole/mole) nitrogen, balance helium.

4.4.4 *Operating Procedure*

4.4.4.1 With the valve in Position A, load the sample loop. Switch the valve to Position B to inject the sample into the column and allow the oxygen to pass through the column to vent. Switch valve to Position A to allow the krypton and nitrogen to be carried to the detector. Record the peak areas and retention times.

4.4.4.2 Inject the sample to be tested in the same manner as 4.4.4.1. Record the retention times and peak areas.

4.4.4.3 Repeat 4.4.4.1.

4.4.4.4 Calculate the concentrations of krypton and nitrogen using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.5 *Nitrous Oxide* — This procedure is for the determination of nitrous oxide using dual beam optical non-dispersive infrared spectrophotometry.

4.5.1 *Detection Limit* — 0.05 ppm (mole/mole)

4.5.2 *Instrument Parameters*

4.5.2.1 Detector: “Luft” type or equivalent

4.5.2.2 10" Infrared Gas Cell or gas cell with equivalent sensitivity

4.5.2.3 Sample Cell Pressure: 200 psig for full scale range 0–5 ppm nitrous oxide or appropriate pressure as recommended by the cell manufacturer.

4.5.2.4 Sample Flowrate: 500 cc/minute or as recommended by the instrument manufacturer

4.5.2.5 Wavelength: 4.5 micrometers (4500 nm)

4.5.2.6 Wavenumber: 2222 cm^{-1}

4.5.3 Calibration Standard: 5 ppm (mole/mole) nitrous oxide, balance oxygen.

4.5.4 *Operating Procedure* — (See Notes 5 and 6)

4.5.4.1 Open the zero gas (prepurified nitrogen or certified pure oxygen, independently measured to be less than 0.1 ppm N_2O) cylinder valve. Open valve V1, close valves V2 and V3. Flow the gas through the system and adjust the back pressure regulator to 200 psig as shown on gauge G. Adjust the flowrate on the flowmeter to 1000 cc/minute by adjusting valve Vl. After a constant readout is observed, adjust the zero control knob of the analyzer to set the absorbance output to read zero.

4.5.4.2 Open the calibration gas standard cylinder valve. Close Vl and V2, and open valve V3. Flow the calibration gas through the system and adjust the back pressure regulator to 200 psig. Adjust the flowrate on the flowmeter to 1000 cc/minute. After a constant readout is observed, record the absorbance of the calibration standard, if the instrument indicates absorbance directly. If the instrument indicates concentration, adjust the span control to read the concentration of nitrous oxide in the calibration gas.

4.5.4.3 Introduce the oxygen sample into the analyzer by closing valves Vl and V3, opening Valve V4 and slowly opening valve V2 until the flowrate on the flowmeter is 1000 cc/minute. Adjust the back pressure regulator to 200 psig. Read the absorbance of the sample and calculate the quantity of nitrous oxide, using the formula below. If the instrument indicates concentration, record the concentration. The result may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Measured Absorbance of Sample}}{\text{Measured Absorbance of Standard}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.6 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in oxygen using a continuous flow flame ionization detector-equipped total hydrocarbon analyzer. (See Notes 7, 8.)

4.6.1 *Detection Limit* — 0.1 ppm (mole/mole)

4.6.2 *Flow Requirements*

4.6.2.1 High purity, hydrocarbon-free (less than 0.1 ppm) hydrogen, 35–40 mL/min or 40% hydrogen in either helium or nitrogen at 75–80 mL/min.

4.6.2.2 Dry, hydrocarbon-free (less than 0.1 ppm) air, 350 mL–400 mL/min.

4.6.2.3 Set sample flow rate in accordance with the instrument manufacturer's instructions.

4.6.3 *Calibration Standards*

4.6.3.1 Zero oxygen with a known quantity of hydrocarbons of approximately 0.1 ppm.

4.6.3.2 Upper level balance oxygen span gas of not more than five times the concentration specified in Section 2 of this Standard.

4.6.4 *Operating Procedure*

4.6.4.1 Do not change initial flow settings for hydrogen, air and sample once established.

4.6.4.2 Introduce the zero oxygen with a known quantity of hydrocarbons and, using the 0–1 ppm range, set the output to read the correct level, using the zero adjust knob.

4.6.4.3 Introduce the span gas standard in oxygen and, using the span adjust knob, set the output to the level in the span gas.

4.6.4.4 Introduce the oxygen sample into the analyzer and read the quantity of hydrocarbons on the analyzer. The result may not exceed the specification in Section 2 of this standard.

4.7 *Water* — This procedure is for the determination of trace moisture (water) in oxygen using a continuous flowing, cooled-surface condensation, dewpoint/frost-point hygrometer. (See Note 9.)

4.7.1 *Detection Limit* — 0.6 ppm (vol/vol) at -79°C (-100°F)

4.7.2 *Flow Requirements*

4.7.2.1 Set sample flow rate and pressure in accordance with the instrument manufacturer's instructions.

4.7.3 *Calibration Standard* — A calibration thermometer designed to indicate temperatures in the -79°C (100°F) range is required.

4.7.4 *Operating Procedure*

4.7.4.1 An appropriately cleaned stainless steel or copper sampling line must be used. If it has been exposed to ambient moisture, it must be purged with dry gas prior to use.

4.7.4.2 Flow the sample gas through the hygrometer until the sampling system and instrument have reached equilibrium with the gas.

4.7.4.3 After equilibrium has been reached, cool the mirror of the hygrometer, as specified by its manufacturer, to determine the dewpoint/frostpoint of the sample gas.

4.7.4.4 Verify the dewpoint/frostpoint reading for at least 30 minutes after it becomes stable.

4.7.4.5 Correct the dewpoint/frostpoint reading to 1 atm pressure. Convert it to ppm (vol/vol) using an appropriate table. The result may not exceed the specification in Section 2 of this standard.

4.8 *Notes*

Note 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

Note 2: All gases used in the analysis of the sample should not contain more than 10% of the specified value of the component of interest, unless otherwise stated.

Note 3: A flow restrictor should be installed on the vent from port 8 to match the pressure drop of the detector.

Note 4: A flow controller is required on each carrier inlet.

Note 5: An example of an operating procedure is outlined below for the sample system shown in Figure 1. This procedure is appropriate only when the infrared gas cell is designed to withstand the 200 psig sample pressure.

Note 6: Operating procedures for other non-dispersive infrared analyzers vary depending on manufacturer. Refer to individual instrument vendor instructions in each case.

Note 7: As the flow rate and heat capacity of the matrix gas affect the instrument output, the zero and span gas matrices must coincide with that of the sample gas.

Note 8: The effective response of a flame ionization detector-equipped total hydrocarbon analyzer can vary among different hydrocarbons and must be approximated. However, the response of the most common hydrocarbon impurities can be accurately totaled and compared to methane.

Note 9: The sampling system and hygrometer must be designed to operate at the sample pressure, or the sample pressure must be reduced by a regulator with a diaphragm of stainless steel or other suitable material.

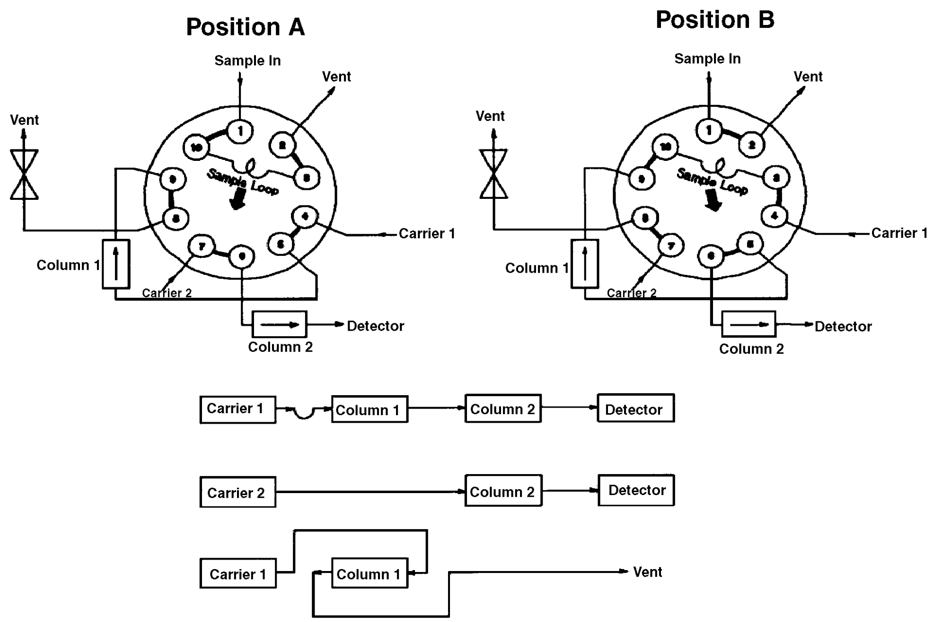

Figure 1

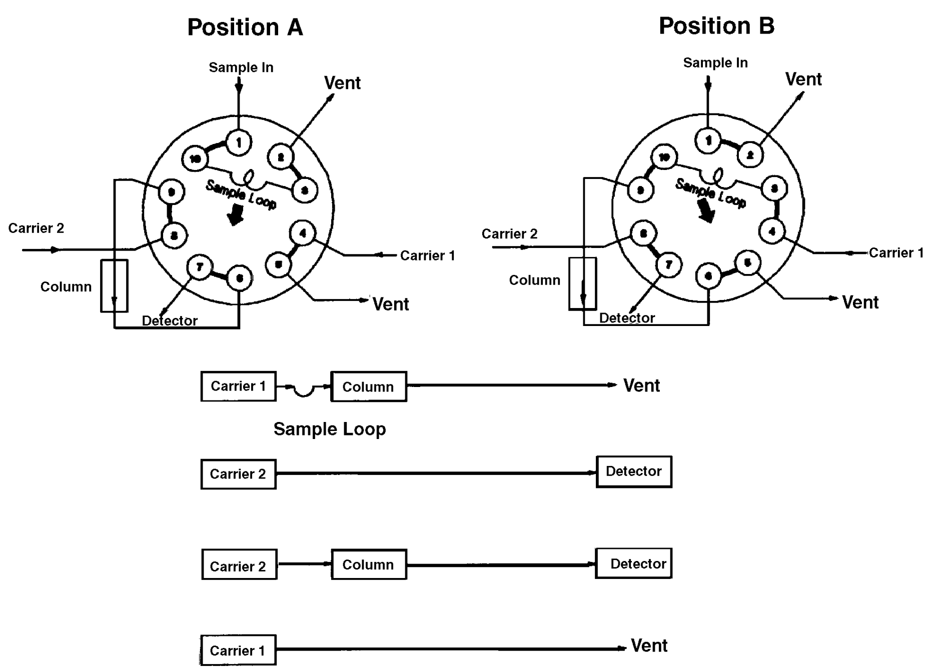

Figure 2

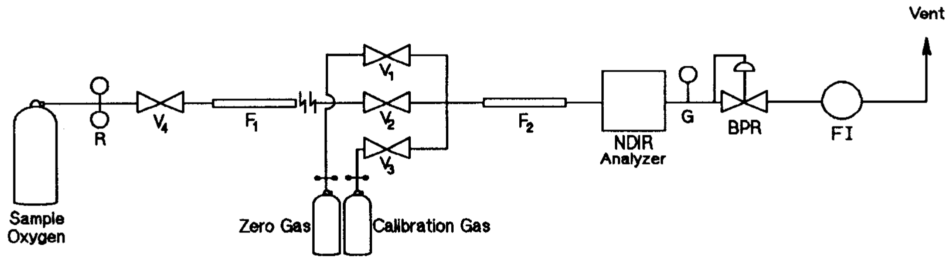

Legend:

V_4	Shut Off Valve
F_1	Particle Filter
$V_{1,2,3}$	Flow Control Valves
F_2	Fine Filter (Stainless Steel, 5 m element)
G	Sample Cell Pressure Gauge 0-500 psig
BPR	Back Pressure Regulator
FI	Flowmeter
R	Regulator

Note: All Components in contact with the sample must be contstructed of stainless steel, teflon, or glass.

SEMI C3.41-0697
STANDARD FOR OXYGEN (O_2), BULK, 99.9998% QUALITY (PROVISIONAL)

1 Description

Oxygen is a colorless, odorless, and oxidizing gas. It supports combustion.

2 Specifications

QUALITY: 99.9998% (See Note 1)

Impurities	*Maximum Acceptable Level (ppm) **
Argon (Ar)	1.0
Carbon Dioxide (CO_2)	0.1
Carbon Monoxide (CO)	0.1
Hydrogen (H_2)	0.1
Nitrogen (N_2)	0.5
Particles	**
Total Hydrocarbons (as CH_4)	0.1
Water (H_2O) (v/v)	0.1
TOTAL SPECIFIED IMPURITIES	2.0

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between user and supplier.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	31.999	31.999
Boiling point at 1 atm	-183.0°C	-297.4°F
Density of gas at 25°C (77°F) and 1 atm	1.309 kg/m^3	0.082 lb/ft^3
Specific gravity of gas	1.1049	1.1049
Density of liquid atboiling point	1142 kg/m^3	71.27 lb/ft^3

NOTE 1: A purifier is allowed to be used to meet this specification.

4 Analytical Procedures

4.1 *Argon and Nitrogen* — This procedure is for the determination of argon and nitrogen in oxygen using a gas chromatograph with a discharge ionization detector (see Figure 1).

4.1.1 *Detection Limit* — 0.1 ppm

4.1.2 Instrument Parameters

4.1.2.1 Column(s):

3 m (10 ft) by 3.2 mm (1/8") o.d. in Molecular Sieve 5A

3 m (10 ft) by 1/8 in Oxy–trap (See Figure 1)

4.1.2.2 Carrier Flow: 44 cc/min

4.1.3 Sample Volume: 0.1 mL

4.1.3.1 Temperatures:

Detector	100°C
Column	30°C
Oxytrap	150°C

4.1.4 *Calibration Standards* — 1–5 ppm nitrogen and argon in oxygen.

4.1.5 *Operating Procedures*

4.1.5.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak area. Order of elution is argon, nitrogen. If methane is present, the order is argon, nitrogen, methane.

4.1.5.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak area.

4.1.5.3 Repeat 4.1.4.1.

4.1.5.4 Compare the average peak areas of the calibration standard to that of the sample being tested. Calculate the concentrations of impurities as shown in SEMI C3. The result may not exceed the specification in Section 2 of this standard.

NOTE 2: Oxygen trap conditioned per manufacturer's recommendations using hydrogen, carbon monoxide, or blend in helium.

4.2 *Carbon Dioxide* — This procedure is for the determination of carbon dioxide in oxygen using a gas chromatograph with a flame ionization detector and a methanizer

4.2.1 *Detection Limit* — 0.02 ppm

4.2.2 *Instrument Parameters*

4.2.3 Column(s): 2.3 m (91 in) by 1/8 in HayeSep Db

4.2.3.1 Carrier Flow: 50 cc/min nitrogen

4.2.3.2 Sample Volume: 5 mL

4.2.3.3 Temperatures:

Detector	275°C
Column	50°C
Methanizer	295°C

4.2.4 *Calibration Standards* — 0.1–1 ppm carbon dioxide in oxygen.

4.2.5 *Operating Procedures*

4.2.5.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak area. Order of elution is: Oxygen + carbon monoxide, methane, carbon dioxide.

4.2.5.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak area.

4.2.5.3 Repeat 4.2.4.1

4.2.5.4 Compare the average peak areas of the calibration standard to that of the sample being tested. Calculate the concentrations of impurities as shown in SEMI C3. The result may not exceed the specification in Section 2 of this Standard.

NOTE 3: Sample and calibration sample are injected on column to vent until oxygen, carbon monoxide, and methane have eluted. Valve is returned to allow carbon dioxide to elute onto methanizer and flame ionization detector.

4.3 *Carbon Monoxide and Hydrogen* — This procedure is for the determination of carbon monoxide and hydrogen in oxygen using a gas chromatograph with a reduction gas detector.

4.3.1 *Detection Limit* — 0.002 ppm

4.3.2 *Instrument Parameters*

4.3.2.1 Column(s): 2 m (80 in) by 1/8 in Molecular Sieve 13×

4.3.2.2 Carrier Flow: 20 cc/min air

4.3.2.3 Sample Volume: 1 mL

4.3.2.4 Temperatures:

Detector	265°C
Column	105°C

4.3.3 *Calibration Standards* — 0.5 – 1 ppm hydrogen and carbon monoxide in nitrogen or oxygen.

4.3.4 *Operating Procedures*

4.3.4.1 Inject the calibration standard into the column using a gas sampling valve. Record the retention times and peak area. Order of elution is: Hydrogen, carbon monoxide.

4.3.4.2 Inject the sample to be tested in same manner as the calibration standard. Record the retention times and peak area.

4.3.4.3 Repeat 4.3.4.1

4.3.4.4 Compare the average peak areas of the calibration standard to that of the sample being tested. Calculate the concentrations of impurities as shown in SEMI C3. The result may not exceed the specification in Section 2 of this Standard.

4.4 *Total Hydrocarbons* — This procedure is for the determination of total hydrocarbons in oxygen with a total hydrocarbon analyzer.

4.4.1 *Detection Limit* — 0.05 ppm

4.4.2 *Instrument Parameters*

4.4.2.1 Flow Requirements:

Carrier Flow Rate: per manufacturer's recommendations

Purity: less than 0.05 ppm total hydrocarbons

Sample Flow Rate: manufacturer's recommendations

4.4.3 *Calibration Standards* — 0.1 – 1 ppm methane in oxygen.

4.4.4 *Operating Procedures*

4.4.4.1 Flow settings should not be changed once established.

4.4.4.2 Introduce the zero gas and adjust the instrument per manufacturer's recommendations to read the quantity known to be in the zero gas.

4.4.4.3 Introduce the span gas standard and adjust the instrument per manufacturer's recommendations to read the quantity known to be in the span gas. This result may not exceed specification in Section 2 of this standard.

4.5 *Water* — This procedure is for the determination of trace moisture (water) in O_2 using a continuous flowing piezoelectric hygrometer (see Note 4).

4.5.1 *Detection Limit* — 5 ppb

4.5.2 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

4.5.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently by another analytical method.

4.5.4 *Operating Procedure*

4.5.4.1 Obtain a continuous flow sample of gas from the source using a clean and passivated stainless steel line which has been purged dry after exposure to ambient moisture.

4.5.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and the piezoelectric moisture hygrometer until a stable reading is obtained.

4.5.4.3 Determine the moisture content of the oxygen sample by comparing the reading to calibration curve. The result may not exceed the specification in Section 2 of this standard.

NOTE 4: The sampling system and hygrometer must be designed to operate under the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the analytical hygrometer.

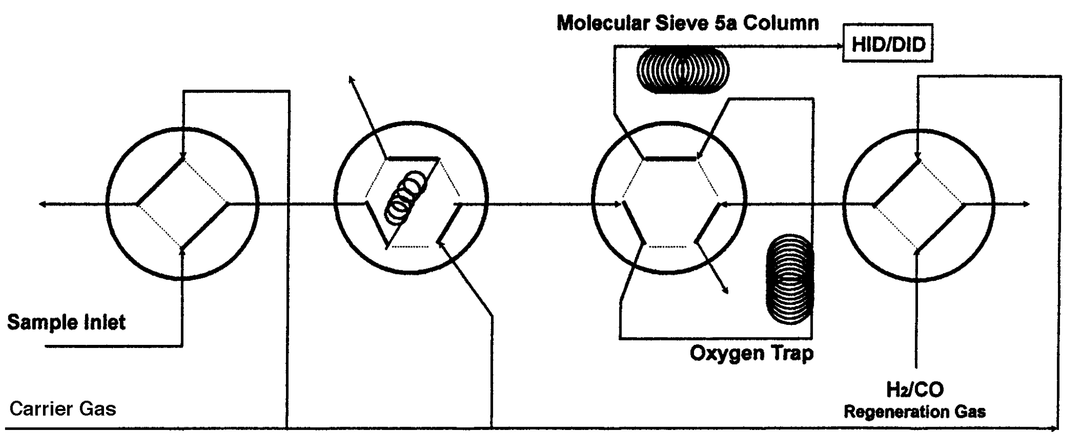

Figure 1
Analysis of Nitrogen and Argon in Oxygen Using Oxygen Trap

SEMI C3.6-0701
SPECIFICATION FOR PHOSPHINE (PH_3) IN CYLINDERS, 99.98% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001. Originally published in 1981; previously published in 1995.

1 Description

1.1 Phosphine is a highly toxic, flammable, colorless gas with an odor of decaying fish. In high concentrations, it is pyrophoric. It is shipped as a liquid in cylinders under its own vapor pressure.

2 Specifications

QUALITY: 99.98%

Impurities	*Maximum Acceptable Level (ppm)**
Arsine (AsH_3)	10
Carbon dioxide (CO_2)	10
Carbon Monoxide (CO)	1
Heavy Metals	**
Hydrogen (H_2)	100
Nitrogen (N_2)	50
Oxygen (O_2) + Argon (Ar)	5
Particles	**
Hydrocarbons expressed as Methane (C_1–C_2)	4
Water (H_2O) (v/v)	1
TOTAL LISTED IMPURITIES	181

* An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

** To be determined between supplier and user.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	33.997	33.997
Boiling point at 1 atm	-87.7°C	-125.9°F
Density of gas at 25°C (77°F) and 1 atm	1.402 kg/m^3	0.0875 lb/ft^3
Specific gravity of gas at 21.1°C (70°F) and 1 atm (air = 1)	1.146	1.146
Density of liquid at boiling point	744 kg/m^3	46.45 lb/ft^3

4 Analytical Procedures

4.1 *Carbon Monoxide, Carbon Dioxide, and Hydrocarbons (expressed as methane)* — This procedure is for the determination of carbon monoxide, carbon dioxide, and hydrocarbons in phosphine using a gas chromatograph with a methanizer and a flame ionization detector. (See Note 1 and Figure 1.)

4.1.1 *Detection Limit* — 0.1 ppm each impurity.

4.1.2 *Instrument Parameters*

4.1.2.1 *Column* — Porapak QS, 3.5 m (12 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss or equivalent.

4.1.2.2 *Carrier Flow* — 35 mL/min helium.

4.1.2.3 *Support Gases*

Hydrogen: 30 mL/min added to the carrier gas between the column outlet and the methanizer inlet.

Air: 500 mL/min.

4.1.2.4 Temperatures:

Detector	110°C
Injector	40°C
Oven	40°C
Methanizer	370–400°C

4.1.2.5 Sample Volume — 3 mL.

4.1.3 *Calibration Standards* — 1–10 ppm each: carbon monoxide, carbon dioxide, methane, ethane*, ethylene*, and acetylene*, balance helium. *These components are for reference only.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard into the column using a gas sampling valve. Record retention times and peak areas. Order of elution is carbon monoxide, methane, carbon dioxide, acetylene, ethylene.

4.1.4.2 Inject the sample to be tested in the same manner as the calibration standard. Vent the phosphine after the ethylene peak. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 *Calculation of Concentrations*

4.1.4.4.1 *Carbon Monoxide and Carbon Dioxide* — Compare the average peak areas for the calibration standard to those of the phosphine sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed the specification in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.1.4.4.2 *Total Hydrocarbons Expressed as Methane (C_1–C_2)* — Compare the peak area of methane in the calibration standard with the sum of the areas of the hydrocarbons detected in the phosphine sample. Calculate the concentration of total hydrocarbons using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sum of areas for all Hydrocarbons detected}}{\text{Standard Peak Area for Methane}} \times \text{Concentration of Methane in Standard} = \text{THC Concentration of Sample}$$

4.2 *Hydrogen, Nitrogen, and Oxygen + Argon, Arsine* — This procedure is for the determination of hydrogen, nitrogen, oxygen + argon, and arsine in phosphine using a gas chromatograph with a discharge ionization detector. (See Note 2 and Figure 2.)

4.2.1 *Detection Limits* — 100 ppb (mol/mol) hydrogen, 100 ppb (mol/mol) oxygen + argon, 500 ppb (mol/mol) nitrogen, 5 ppm (mol/mol) arsine.

4.2.2 *Instrument Parameters*

4.2.2.1 *Columns:*

Column 1:	Porapak QS, 2.5 m (8 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss or equivalent.
Column 2:	Molecular Sieve 5A, 3 m (10 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID ss or equivalent.

4.2.2.2 *Carrier Flow* — 25 mL/min helium.

4.2.2.3 *Temperatures*

Detector	10°C
Injector	30°C
Oven	40°C

4.2.2.4 *Sample Volume* — 1 mL.

4.2.3 *Calibration Standard* — 5–50 ppm (mol/mol) nitrogen, 1–10 ppm (mol/mol) oxygen, 1–10 ppm (mol/mol) argon, 10–100 ppm (mol/mol) hydrogen, 5–10 ppm (mol/mol) arsine, balance helium.

4.2.4 *Operating Procedure*

4.2.4.1 *Determination of the Switching Time* — Inject the calibration sample in 4.2.3 above and note the time when the hydrogen peak appears through detector B. Switching valve 1 at that time will give an arsine peak through detector A and hydrogen, oxygen + argon, and nitrogen peaks through detector B.

4.2.4.2 Inject the calibration standard into the column using the same gas valve. Switch at the time determined in 4.2.4.1 and record retention times and peak areas. Order of elution is hydrogen, oxygen + argon, and nitrogen on detector B. Order of elution is phosphine and arsine on detector A.

4.2.4.3 Inject the sample being tested in same manner as the calibration standard. Record the retention times and peak areas.

4.2.4.4 Repeat 4.2.4.2.

4.2.4.5 Compare the average peak areas of the calibration standard to those of the phosphine sample being tested. Calculate the concentration of each impurity, using the formula below. The results may not exceed the specifications in Section 2 of this standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \text{Concentration of Standard} = \text{Concentration of Sample}$$

4.3 *Water* — This procedure is for the determination of moisture in phosphine using continuous flow electrolysis of water in a phosphorous pentoxide (P_2O_5) cell, modified as per the manufacturer's recommendation, for use with phosphine.

4.3.1 *Detection Limit* — 0.5 ppm (vol/vol).

4.3.2 *Instrument Parameters*

4.3.2.1 *Flow Requirements* — Set the sample flow rate and pressure in accordance with manufacturer's instructions.

4.3.3 *Calibration Standards* — Construct a calibration curve which contains at least three points covering the range of interest. Verify the standards employed independently on a condensation dew point/frost point hygrometer. Standards are prepared in nitrogen.

4.3.4 *Operating Procedure*

4.3.4.1 Obtain representative sample of gas to analyze and direct to unit as with the standards.

4.3.4.2 Determine the moisture content in sample gas by comparing the indicated concentration with the calibration curve constructed in 4.3.4.1. The result may not exceed the specification in Section 2 of this standard.

4.4 *Notes*

NOTE 1: Carrier gases should contain less than 0.1 ppm (mol/mol) carbon monoxide and less than 0.1 ppm (mol/mol) carbon dioxide.

NOTE 2: Carrier gas purity of helium must be 99.9999%.

SEMI C3.54-0200
GAS PURITY GUIDELINE FOR SILANE (SiH_4)

This guideline was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org January 2000, to be published February 2000. Originally published in 1997.

1 Description

1.1 Silane is a pyrophoric, flammable colorless gas.

2 Specifications

Quality: 99.994%

Impurities	*Maximum Acceptable Level (ppm)*
Arsine (AsH_3)	1 ppb
Carbon Monoxide (CO)	0.1
Carbon Dioxide (CO_2)	0.1
Chlorosilanes (ionizable chlorides) including HC1, reported as chloride ($C1^-$)	1
Non-methane Hydrocarbons (C_2 - C_4)	0.1 total
Hydrogen (H_2)	50
Methane (CH_4)	0.1
Nitrogen (N_2)	1
Phosphine (PH_3)	0.1 ppb
Disiloxane ($H_3SiOSiH_3$)	1
Methyl Silane (SiH_3-CH_3)	1
Disilane (Si_2H_6)	1
Aluminum (Al)	0.2 ppba (See NOTE 1.)
Antimony (Sb)	0.2 ppba (See NOTE 1.)
Arsenic (As)	0.2 ppba (See NOTE 1.)
Boron (B)	0.02 ppba (See NOTE 1.)
Gallium (Ga)	0.2 ppba (See NOTE 1.)
Phosphorus (P)	0.02 ppba (See NOTE 1.)
Calcium (Ca) + Chromium (Cr) + Copper (Cu) + Iron (Fe) + Potassium (K) + Lithium (Li) + Magnesium (Mg) + Manganese (Mn) + Molybdenum (Mo) + Sodium (Na) + Nickel (Ni) + Lead (Pb) + Zinc (Zn)	1.0 ppba total (See NOTE 1.)
Water (H_20) (vol/vol)	1
Particles	(See NOTE 2.)
TOTAL SPECIFIED IMPURITIES	56.4033

NOTE 1: To be determined between supplier and user.

NOTE 2: ppba is defined to be atoms of impurity per 10^9 atoms of silicon.

3 Electrical Specification

Resistivity	greater than 10,000 ohm-cm (n-type)

4 Physical Constants

	Metric Units	*US Units*
Molecular weight	32.112	32.112
Boiling point at 1 atm.	–112°C	–169.6°F
Density of gas at 21.1°C (70°F) and 1 atm.	1.342 kg/m^3	0.0839 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm. (air = 1)	1.114	1.114
Density of liquid at boiling point.	711 kg/m^3	44.39 lb/ft^3

5 Procedures (See NOTE 1)

NOTE 1: Standardized test methods are being developed for all parameters at the purity level indicated. Until standardized test methods are published, test methodology shall be determined by user and producer.

SEMI C3.10-95 (Withdrawn 0701)
STANDARD FOR SILANE (SiH_4) (PROVISIONAL)

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Silane is a pyrophoric, flammable, colorless gas with a repulsive odor.

SEMI C3.55-0200
STANDARD FOR SILANE (SiH_4), BULK

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org January 2000; to be published February 2000.

1 Description

1.1 Silane is a pyrophoric, flammable colorless gas.

2 Specifications

QUALITY: 99.994%

Impurities	*Maximum Acceptable Level (ppm)*
Gas Phase	
Carbon Monoxide (CO)	0.1
Carbon Dioxide (CO_2)	0.1
Chlorosilanes (ionizable chlorides) including HCl, reported as chloride (Cl^-)	1
Non-methane Hydrocarbons (C_2-C_4)	0.1 total
Hydrogen (H_2)	50
Methane (CH_4)	0.1

Phosphorus (P)	0.2 ppba (See NOTE 3.)
Chromium (Cr)+ Copper (Cu)+ Iron (Fe)+ Nickel (Ni)+ Zinc (Zn)	1.0 ppba total (See NOTE 3.)

NOTE 1: To be determined between supplier and user.

NOTE 2: ppma is defined to be atoms of impurity per 10^6 atoms of silicon.

NOTE 3: ppba is defined to be atoms of impurity per 10^9 atoms of silicon.

3 Electrical Specification

Resistivity	greater than 2,000 ohm-cm (n-type)

4 Physical Constants

	Metric Units	*US Units*
Molecular weight	32.112	32.112
Boiling point at 1 atm.	-112°C	-169°F
Density of gas at 21.1°C (70°F) and 1 atm.	1.342 kg/m^3	0.0839 lb/ft^3
Specific gravity of gas at 21.1°C and 1 atm (air = 1)	1.114	1.114
Density of liquid at boiling point	711 kg/m^3	44.39 lb/ft^3

5 Analytical Procedures (see NOTE 1)

5.1 *Carbon Monoxide, Carbon Dioxide, Argon, Nitrogen and Methane* — This procedure is for the determination of of carbon monoxide, carbon dioxide, argon, nitrogen and methane in silane using a gas chromatograph with a discharge ionization detector.

5.1.1 *Detection Limit* — 30 ppb (mole/mole)

5.1.2 *Instrument Parameters*

5.1.2.1 Column:

HAYESEP D 60/80, 6.5 m (21.3 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID stainless steel; or equivalent.

5.1.2.2 *Carrier Flow* — 25 mL/min helium

5.1.2.3 *Sample Volume* — 1 mL

5.1.2.4 Temperatures:

Detector	140°C
Column Oven	40°C for 4 min., to 120°C at 10°C/min., hold 120°C for 8 min.
Injection Temperature	45°C

5.1.3 *Calibration Standards* — 1 ppm (mole/mole) for all components to be tested, balance helium.

5.1.4 *Operating Procedures*

5.1.4.1 Inject the calibration standard and sample as described in Section 6.6 of SEMI C3. The order of elution is nitrogen, argon, carbon monoxide, methane, and carbon dioxide. (See NOTE 2.)

5.1.4.2 Compare the average peak area of the calibration standard to that of the silane sample being tested. Calculate the concentrations of the analytes as described in Section 6.8 of SEMI C3. The result shall be reported in the unit of concentration needed and to the number of significant digits of the variable with the least number of significant digits. This value may not exceed that specified in Section 2.

5.2 *Total Chlorides* — This procedure is for the determination of total chlorides in silane by titration of a hydrolyzed sample of silane. (See NOTE 1.)

5.2.1 *Detection Limit* — 0.5 ppm (mole/mole)

5.2.2 *Instrument Parameters* — See Figure 1.

5.2.2.1 *Equipment*

5.2.2.1.1 Safety purge regulator with proper fittings.

5.2.2.1.2 Flow meter capable of measuring 0.25 standard liters per minute (0.5 SCF/hour) (Brooks or equivalent), calibrated for silane.

5.2.2.1.3 One cylinder of nitrogen with regulator.

5.2.2.1.4 One ice bath.

5.2.2.1.5 Three magnetic stirring bars.

5.2.2.1.6 Two 2000 mL heavy-duty sidearm flasks (Fisher Cat. No. 10-181G or equivalent).

5.2.2.1.7 One #9 one-hole rubber stopper.

5.2.2.1.8 One #9 two-hole rubber stopper.

5.2.2.1.9 Two Pyrex-brand tubes with fritted cylinders (Fisher Cat. No. 11-138B or equivalent).

5.2.2.1.10 One gas washing bottle with fritted cylinder, 125 mL cap. (Fisher Cat. No. 03-040A or equivalent).

5.2.2.1.11 One buret, 50 mL capacity with Teflon stopcock (Fisher Cat. No. 03-700-22C or equivalent).

5.2.2.1.12 One buret stand (Fisher Cat. No. 14-688 or equivalent).

5.2.2.1.13 Miscellaneous clamps, support stands, and rubber hose.

5.2.2.1.14 Two 250 mL Erlenmeyer flasks.

5.2.2.2 *Reagents*

5.2.2.2.1 Potassium hydroxide flakes, technical (Fisher Cat. No. P-246 or equivalent).

5.2.2.2.2 Mercuric nitrate crystal (Fisher Cat. No. M-168 or equivalent).

5.2.2.2.3 Sodium chloride crystal (Fisher Cat. No. S-271 or equivalent).

5.2.2.2.4 Diphenyl carbazone (Fisher Cat. No. D-86 or equivalent).

5.2.2.2.5 Bromophenol blue (Fisher Cat. No. B-392 or equivalent).

5.2.2.2.6 Nitric acid (Fisher Cat. No. AA-200 or equivalent).

5.2.2.2.7 Ethanol, denatured (Fisher Cat. No. AA-407 or equivalent).

5.2.3 *Operating Procedure*

5.2.3.1 Assemble apparatus as shown in Figure 1 and purge entire system with nitrogen for 30 minutes.

5.2.3.2 Fill each 2000 mL sidearm flask with about 1700 mL of 15% potassium hydroxide solution (15 g KOH per each 100 mL water).

5.2.3.3 Fill the gas washing bottle with about 75 mL of deionized water that has been degassed.

5.2.3.4 Pass exactly one cubic foot of silane through the system at a rate of 0.5 cubic feet per hour.

5.2.3.5 Stop silane flow and purge system for 30 minutes.

5.2.3.6 Remove gas washing bottle from system and transfer contents quantitatively and with the aid of three 25 mL deionized water washings, to a 250 mL Erlenmeyer flask.

5.2.3.7 Add a few drops of indicator solution, 5 g diphenyl carbazone plus 0.5 g bromophenol blue dissolved in 750 mL ethanol, plus 250 mL deionized water.

5.2.3.8 Add, in a drop-wise fashion, sufficient 0.2 N $HN0_3$ (13 mL concentrated. $HN0_3$, diluted to 1 L in deionized water) in order to just turn the solution to yellow from purple.

5.2.3.9 Titrate with a solution of mercuric nitrate $Hg(NO_3)_2$, (diluted to 1000 mL in deionized water; then 50 mL diluted to 500 mL in deionized water) which has been previously standardized to 5.0 mL of a sodium chloride solution (approximately 165 ng NaCl, accurately weighed, dissolved in 100 mL deionized water).

5.2.4 *Calibration*

5.2.4.1 Run titration blank consisting of 150 mL deionized water.

5.2.4.2 Calculate the concentration of chloride, using the formula below. The result may not exceed the specification in Section 2 of this standard.

$$\frac{mL_{sample} - mL_{blank}}{mL_{standard} - mL_{blank}} \times \frac{wt.\,NaCl(g)}{100.0mL} \times \frac{60.66\%Cl-}{100\%NaCl} \times$$

$$\frac{100mL}{1L} \times \frac{0.005l}{35.453g/mole} \times \frac{0.082atmL/moleK}{28.316L} \times$$

1×10^{6} ppm = ppm Cl-

5.3 *Hydrocarbons $C_2 - C_4$* — This procedure is for the determination of hydrocarbons (methane, ethane, and propane) in silane using a gas chromatograph with a flame ionization detector.

5.3.1 Detection Limit — 50 ppb (mole/mole)

5.3.2 Instrument Parameters

5.3.2.1 Columns:

Column 1:	VZ-10, 60/80, 2 m (6.6 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID stainless steel;
Column 2:	VZ-10, 60/80, 1 m (3.3 ft) by 3.2 mm (1/8 in) OD by 2.2 mm (0.085 in) ID stainless steel;

or equivalent.

5.3.2.2 Carrier Flow — 30 mL/min nitrogen

5.3.2.3 Sample Volume — 10 mL

5.3.2.4 Temperatures:

Detector	150°C
Column Oven	45°C

5.3.3 Calibration Standards — 1 ppm (mole/mole) for all components to be tested, balance helium.

5.3.4 Operating Procedures — (see SEMI C3, Section 6, Gas Chromatography for standard procedures).

5.3.4.1 Inject the calibration standard and sample as described in Section 6.6 of SEMI C3. The order of elution is methane, ethane, propane and butane (see NOTE 2).

5.3.4.2 Compare the average peak area of the methane peak in the calibration standard to that of the hydrocarbons found in the silane sample being tested. Calculate the concentrations of the analytes as described in Section 6.8 of SEMI C3 based on the methane response. The result shall be reported in the unit of concentration needed and to the number of significant digits of the variable with the least number of significant digits. This value may not exceed that specified in Section 2.

5.4 *Hydrogen* — This procedure is for the determination of hydrogen in silane using a gas chromatograph with a thermal conductivity detector.

5.4.1 *Detection Limit* — 15 ppm (mole/mole)

5.4.2 *Instrument Parameters*

5.4.2.1 Columns:

Molecular sieve 5A, 2.4 m (8 ft) by 6.4 mm (1/4 in) OD by 4.7 mm (0.185 in) ID, or equivalent.

5.4.2.2 *Carrier Flow* — 30 mL/min argon

5.4.2.3 *Sample Volume* — 1.0 mL

5.4.2.4 Temperatures:

Detector	40°C
Column Oven	40°C

5.4.3 *Calibration Standards* — 20–100 ppm (mole/mole), balance argon.

5.4.4 *Operating Procedures* — (see SEMI C3, Section 6, Gas Chromatography for standard procedures)

5.4.4.1 Inject the calibration standard and sample as described in Section 6.6 of SEMI C3. (See NOTE 2.)

5.4.4.2 Compare the average peak area of the hydrogen peak in the calibration standard to that of the hydrogen found in the silane sample being tested. Calculate the concentrations of the analytes as described in Section 6.8 of SEMI C3 based on the methane response. The result shall be reported in the unit of concentration needed and to the number of significant digits of the variable with the least number of significant digits. This value may not exceed that specified in Section 2.

5.5 *Disiloxane, Disilane and Methyl Silane* — This procedure is for the determination of disiloxane, disilane and methyl silane in silane using a gas chromatograph with flame ionization detector.

5.5.1 *Detection Limit* — 0.1 ppm (mole/mole)

5.5.2 *Instrument Parameters*

5.5.2.1 Column:

28% DC-200 on Chromosorb PAW, 45/60 mesh, 14 m (46 ft) SS, or equivalent.

5.5.2.2 Carrier Flow — 30 mL/min helium

5.5.2.3 Sample Volume — 2 mL

5.5.2.4 Temperatures — Column 60°C

5.5.2.5 *Calibration Standards* — 1–5 ppm (mole/mole)

5.5.3 *Operating Procedure* — (see SEMI C3, Section 6, Gas Chromatography for standard procedures).

5.5.3.1 Inject the calibration standard and sample as described in Section 6.6 of SEMI C3. The order of elution is silane matrix, methyl silane, siloxane (for information only) and disilane. (See NOTE 2.)

5.5.3.2 Compare the average peak area of the components being measured in the calibration standard to that of the same analytes found in the silane sample being tested. Calculate the concentrations of the analytes as described in Section 6.8 of SEMI C3. The result shall be reported in the unit of concentration needed and to the number of significant digits of the variable with the least number of significant digits. This value may not exceed that specified in Section 2.

5.6 *Water* — This procedure is for the determination of trace moisture (water) in silane using a vibrating quartz hygrometer.

5.6.1 *Detection Limit* — 0.1 ppm (vol/vol)

5.6.2 *Instrument Parameters*

5.6.2.1 *Flow Requirements* — Set the sample pressure and flow rate in accordance with the instrument manufacturer's instructions.

5.6.3 *Calibration Standards* — Check the hygrometer calibration with silane using an external permeation device. Construct a calibration curve which contains at least three points covering the range of interest. The standards employed will have been verified independently on a condensation dewpoint/frostpoint hygrometer. (See Figure 2.)

5.6.4 *Operating Procedure* — At the first start-up of the hygrometer, calibrate it with moisture standards in silane. Then check the calibration once a month and modify the hygrometer if necessary. Direct standard to unit with stainless lines which have been purged. Note that silane is spontaneously flammable. Thus the experimental set-up should be leak-free and thoroughly purged before the introduction of silane. Obtain representative sample of the gas to be analyzed and direct to the unit. Wait until the equilibrium and read the moisture content. The result may not exceed the specification.

5.6.4.1 Construct a calibration curve with previously verified standards. Direct standard to unit with stainless steel lines which have been purged.

5.6.4.2 Obtain representative sample of gas to be analyzed and direct to unit as with the standards. (See NOTE 1.)

5.6.4.3 Construct a calibration curve and determine the ppm moisture content in sample gas. The result may not exceed the specification in Section 2 of this standard.

5.7 *Elemental Analysis in Deposited Layer* — Procedures for the analysis of elemental impurities in deposited layers of polysilicon should be designated and should be referenced from a recognized industry standard (including but not limited to ISO, ASTM, etc.).

5.7.1 *Typical Detection Limits*

Compound	*Detection Limit*
Carbon (C)	0.2 ppma
Oxygen (O)	0.2 ppma
Boron (B)	0.02 ppba
Aluminum (Al)	0.02 ppba
Gallium (Ga)	0.02 ppba
Phosphorus (P)	0.02 ppba
Arsenic (As)	0.02 ppba
Antimony (Sb)	0.02 ppba
Iron (Fe)	0.3 ppba
Chromium (Cr)	0.01 ppba
Nickel (Ni)	0.2 ppba
Copper (Cu)	0.02 ppba
Zinc (Zn)	0.03 ppba

5.8 *Resistivity* — Procedures for the measurement of resistivity in deposited layers of polysilicon should be designated and should be referenced from a recognized industry standard (including but not limited to ISO, ASTM, etc.).

NOTE 1: Before performing this or any other analytical operation it is necessary to perform the following:

- Familiarize yourself with the products involved and the potential hazards by consulting the MSDS's for all hazardous substances involved and by consulting the CGA's "Handbook of Compressed Gases" for all gases involved.
- Know how to safely handle and store each hazardous gas by consulting the applicable CGA pamphlets.
- Use all necessary and applicable personal protective equipment.
- Follow all instructions relative to the safe operation of the equipment by consulting the LAC Safety Manual and applicable equipment manufacturers manual(s).

It must be noted that silane is a pyrophoric gas and all sample plumbing must be purged of air completely before introducing silane. Extra special attention must be paid to leak checking all connections and checking the vent plumbing to be certain that effluents are vented properly. If there are any questionable connections or leaks, report this to the supervisor immediately and do not proceed with the analysis.

NOTE 2: Introduce the calibration standard as many times as necessary to achieve the desired precision. Detection limit calculated on these calibrations should achieve at least that listed for this procedure.

Chloride Scrubbing Apparatus

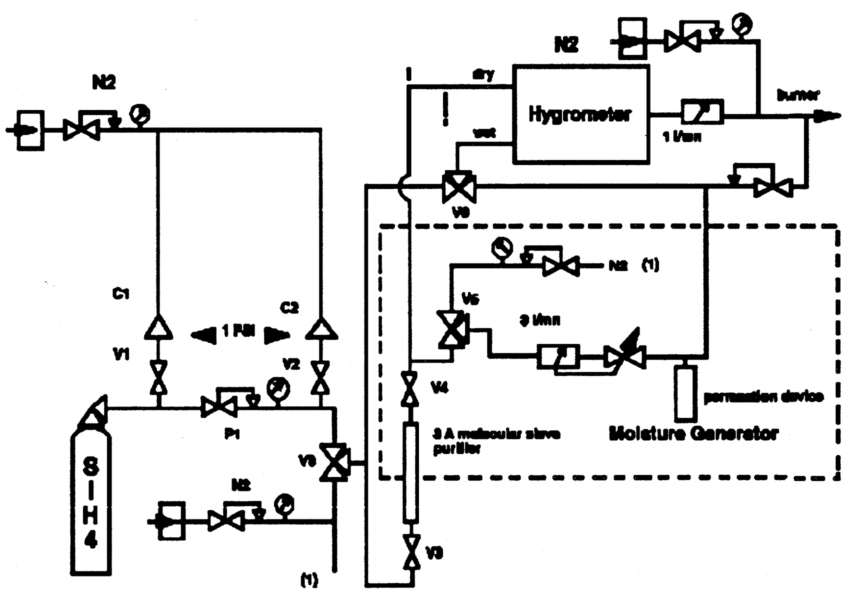

Figure 2
Moisture Analysis in Silane

SEMI C3.11-93 (Withdrawn 0701)
STANDARD FOR SILICON TETRACHLORIDE ($SiCl_4$) IN CYLINDERS (PROVISIONAL)

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Silicon tetrachloride is a corrosive, colorless liquid with a sharp pungent odor. It hydrolyzes rapidly to form hydrogen chloride.

SEMI C3.24-0301
SPECIFICATION FOR SULFUR HEXAFLUORIDE (SF_6) IN CYLINDERS, 99.97% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published in 1984; previously published in 1995.

1 Description

1.1 Sulfur hexafluoride is colorless and odorless. It is noncombustible and has a low toxicity. It is shipped as a liquefied gas under its own vapor pressure.

2 Specifications

QUALITY: 99.97%

Impurities	*Maximum Acceptable Level (ppm) (See NOTE 1.)*
Air	100
Carbon Tetrafluoride (CF_4)	100
Hydrogen Fluoride (HF)	1
Water (H_2O) (mol/mol)	8
TOTAL LISTED IMPURITIES	209

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	146.054	146.054
Boiling point at 1 atm	-63.7°C	-82.7°F
Density of gas at 20°C (68°F) and 1 atm	6.162 kg/m^3	0.385 lb/ft^3
Specific gravity of gas at 21.1°C (70°F) and 1 atm (air = 1)	5.114	5.114
Density of liquid at -50°C	1910 kg/m^3	119.2 lb/ft^3

4 Analytical Procedures (Notes 1, 2, and 3)

4.1 *Air and Carbon Tetrafluoride* — This procedure is for the determination of air and carbon tetrafluoride using a gas chromatograph with a thermal conductivity detector.

4.1.1 *Detection Limit* — 1 ppm (mol/mol)

4.1.2 *Instrument Parameters*

4.1.2.1 Column: 2.4 m (8 ft) by 6.4 mm (1/4 in) OD, 5.1 mm (0.201 in) ID stainless steel tubing packed with Porapak Q (80/100 mesh) or equivalent.

4.1.2.2 Carrier Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 1 mL.

4.1.2.4 Temperatures:

Detector	110°C
Column	70°C

4.1.3 *Calibration Standards* — 90–100 ppm (mol/mol) carbon tetrafluoride, 90–110 ppm (mol/mol) Air (O_2/N_2 blend), balance helium.

4.1.4 *Operating Procedure*

4.1.4.1 Inject the calibration standard. Analyze the standard using the conditions described above. Record the retention times and peak areas.

4.1.4.2 Inject the sample to be tested in the same manner as the calibration standard. Record the retention times and peak areas.

4.1.4.3 Repeat 4.1.4.1.

4.1.4.4 Calculate the concentrations of air and carbon tetrafluoride in the sample, using the formula below. The result may not exceed the specification in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Hydrogen Fluoride* — This procedure is for the determination of hydrogen fluoride by quantitative collection in dilute sodium carbonate ($NaHCO_3$) and subsequent analysis by ion chromatography.

4.2.1 *Detection Limit* — 0.1 ppm for the method

Equipment Required:

500 mL Greenburgh impinger

50 mL Class A pipet

Type 316 stainless steel delivery system

5' Fluorocarbon tubing, 1/4 in OD by 0.03 in wall

Reagent Grade sodium bicarbonate

Deionized water

50 mL high-density polyethylene bottles

Assorted Class A volumetric flasks

Ion chromatograph

Anion column which separates:

F^-, Cl^-, Br^-, SO_4^{-2}, PO_4^{-3}

4.2.2 *Ion Chromatograph Parameters:*

Instrument:	Dionex 2000 (or equivalent)
Integrator:	Dionex 4270 (or equivalent)
Column:	HDIC AS4A (or equivalent)
Eluent:	0.001 M Na_2CO_3 + 0.001 M $NaHCO_3$
Flow Rate:	2 mL/minute
Pressure:	960 psia
Detector Conductivity Range:	3.0 microsiemens for less than 10 ppm
Sample:	100 microliters

4.2.3 *Calibration* — Calibrate the ion chromatograph by dissolving a weighed amount of ammonium fluoride (NH_4F) in deionized water and sequentially diluting it to a fluoride concentration of 0.1 ppmw in Class A volumetric flasks and analyzing it as specified by the instrument manufacturer.

4.2.4 *Operating Procedure*

4.2.4.1 Prepare a fresh solution of 1.7 mM sodium bicarbonate in deionized water.

4.2.4.2 Pipet 200 mL of the solution into a 500 mL Greenburgh impinger.

4.2.4.3 Bubble approximately 20 L of sulfur hexafluoride (SF_6) through the solution, using the delivery system shown in Figure 1.

4.2.4.4 Analyze the solution as specified by the instrument manufacturer.

4.2.4.5 *Calculation* — Calculate the concentration of hydrogen fluoride (HF) using the following formula:

$$\text{ppmv HFg} = \frac{(F^{-}\text{ppmw}) \times Vg}{19.00 \times mg}$$

Where:

F^- ppm	=	Fluoride concentration in trapped solution.
Vg	=	Volume of collection solution (mL).
mg	=	Moles of SF_6 bubbled through the collecting solution.
19.00	=	Molecular weight of F^-.

The result may not exceed the specification in Section 2 of this Standard.

4.3 *Water* — This procedure is for the determination of trace moisture (water) in sulfur hexafluoride using a continuous flowing electrolytic hygrometer. (See Notes 4, and 5.)

4.3.1 *Detection Limit* — 1.0 ppm (vol/vol) or -76°C (-105°F).

4.3.2 *Sample Pressure and Flow* — Set in accordance with instrument manufacturer's instructions.

4.3.3 *Operation Check* — Check the instrument periodically for correct operation. A gas containing a known amount of moisture should be passed through the instrument. Agreement between the hygrometer and the standard should be within their relative accuracies.

4.3.4 *Operating Procedure*

4.3.4.1 Obtain a continuous flow sample of sulfur hexafluoride source, using a clean, electropolished or passivated stainless steel line which has been purged dry after exposure to ambient moisture. (See Note 5.)

4.3.4.2 After prepurging with a dry gas, allow the sample gas to flow through the sampling system and hygrometer until a stable reading is obtained. The reading may not exceed the specification in Section 2 of this Standard.

4.4 *Notes*

NOTE 1: Introduce the calibration standard as many times as necessary to achieve the desired precision.

NOTE 2: All gases used in the analysis of the sample should not contain more than 10% of the specified value of the component of interest, unless otherwise stated.

NOTE 3: Observe proper safety procedures for handling and disposing of sulfur hexafluoride (SF_6).

NOTE 4: The sampling system and hygrometer must be designed to operate at the sample pressure, or the sample pressure must be reduced (by a regulator with a diaphragm of stainless steel or other suitable material) to accommodate the pressure restrictions of the hygrometer.

NOTE 5: A passivation procedure is described in Metals Handbook, Eighth Edition, Volume 2, ASM International, Metals Park, Ohio.

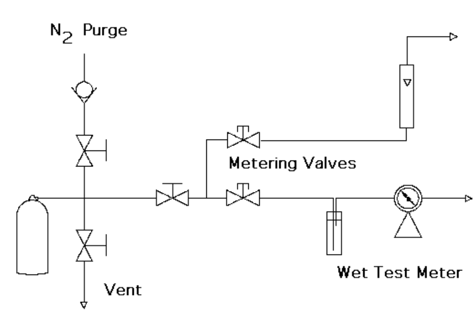

Figure 1

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials or equipment mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. SEMI C3.53-95 (Withdrawn 0701)
STANDARD FOR TRIFLUOROMETHANE (CHF_3), 99.95% QUALITY

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Description

Trifluoromethane (CHF_3) is a colorless, nonflammable, noncorrosive gas with a slight ethereal odor. It is shipped in cylinders as a liquified gas under its own vapor pressure.

SEMI C3.26-0301
SPECIFICATION FOR TUNGSTEN HEXAFLUORIDE (WF_6) IN CYLINDERS, 99.8% QUALITY

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published in 1984; previously published in 1994.

1 Description

1.1 Tungsten hexafluoride is a colorless gas or colorless liquid. It is shipped as a liquefied gas under its own vapor pressure.

2 Specifications

QUALITY: 99.8%

Impurities	*Maximum Acceptable Level (ppm) (See NOTE 1.)*
Carbon Tetrafluoride (CF_4)	10
Hydrogen Fluoride (HF)	1000
Nitrogen (N_2)	50
Oxygen (O_2) + Argon (Ar)	50
Sulfur Hexafluoride	10
Silicon Tetrafluoride	10
TOTAL LISTED IMPURITIES	1130

NOTE 1: An analysis of significant figures has not been considered. The number of significant figures will be based on analytical accuracy and the precision of the provided procedure.

3 Physical Constants (for information only)

	Metric Units	*US Units*
Molecular weight	297.85	297.85
Boiling point at 1 atm	17.1°C	62.8°F
Density of gas at 22.8°C (73°F) and 1 atm	12.9 kg/m^3	0.805 lb/ft^3
Specific gravity of gas	10.8	10.8
Density of liquid at boiling point	3440 kg/m^3	214.8 lb/ft^3

4 Analytical Procedures (See Notes 1, 2, 3, 4, 5, 6, 7)

4.1 *Nitrogen and Oxygen + Argon* — This procedure is for the determination of nitrogen and oxygen + argon in tungsten hexafluoride using a gas chromatograph with a thermal conductivity detector.

4.1.1 *Detection Limits* — 10 ppm (mol/mol) nitrogen, and 10 ppm (mol/mol) oxygen + argon.

4.1.2 *Instrument Parameters*

4.1.2.1 Columns: (See Figures 1, 2)

Column 1:	Porapak S, 80/100 mesh, 1.5 m (5 ft) by 6.4 mm (1/4 in) OD, 5.1 mm (0.2 in) ID, ss or equivalent.
Column 2:	Molecular sieve 5A, 80/100 mesh, 1.8 m (6 ft) by 4.8 mm (3/16 in) OD, 3.7 mm (0.147 in) ID, ss or equivalent.

4.1.2.2 Column Flow: 30 mL/min helium.

4.1.2.3 Sample Volume: 2 mL

4.1.2.4 Temperatures

Detector	70°C
Column	40°C

4.1.3 *Calibration Standard* — 50 ppm (mol/mol) nitrogen, 50 ppm (mol/mol) oxygen, balance helium.

4.1.4 *Operating Procedures*

4.1.4.1 Determine the times for valve switching and signal changes, and enter into the run table. An example of a run table follows.

Time	*Position*	*Function*
0 min.	1	Purge sample through loop. Backflush Porapak column. Connect MS column to the TCD.
1 min.	2	Inject sample onto Porapak column. Allow oxygen + argon and nitrogen to elute from the Porapak column to the MS column. Sequentially elute the oxygen + argon and nitrogen from the MS column to the TCD.
4 min.	1	Backflush Porapak column to vent for 8 minutes.

4.1.4.2 Set the valves in Position 1 (Figure 1).

4.1.4.3 Flow the calibration standard through the 10-port valve. Analyze standard using the conditions described above. Record retention times and peak areas.

4.1.4.4 Flow the sample to be tested through the 10-port valve for 1 minute. Analyze in the same manner as in 4.1.4.3.

4.1.4.5 The standard is again run as in 4.1.4.3.

4.1.4.6 Calculate the concentrations of nitrogen and oxygen + argon in the sample, using the formula below. The result may not exceed the specifications in Section 2 of this Standard.

$$\frac{\text{Sample Peak Area}}{\text{Standard Peak Area}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.2 *Carbon Tetrafluoride, Hydrogen Fluoride, Silicon Tetrafluoride, and Sulfur Hexafluoride* — This procedure is for the determination of these gases in tungsten hexafluoride using infrared spectrophotometry. (See Note 2.)

4.2.1 *Detection Limits* — 10 ppm (mol/mol) carbon tetrafluoride, 1000 ppm (mol/mol) hydrogen fluoride, 10 ppm (mol/mol) silicon tetrafluoride and 10 ppm (mol/mol) sulfur hexafluoride.

4.2.2 *Instrument Parameters*

4.2.2.1 Cell path length: 10 cm

4.2.2.2 Sample Cell Pressure: 1 atmosphere

4.2.2.3 Wavenumbers:

Component	*Wavenumber (cm^{-1})*
Carbon Tetraflouride (CF_4)	1283
Hydrogen Fluoride (HF)	4076
Silicon Tetrafluoride (SiF_4)	1029
Sulfur Hexafluoride (SF_6)	948

4.2.3 *Calibration Standards* — 1% (mol/mol) hydrogen fluoride in tungsten hexafluoride, 100 ppm (mol/mol) silicon tetrafluoride in nitrogen, 25 ppm (mol/mol) each carbon tetrafluoride and sulfur hexafluoride in nitrogen.

4.2.4 *Operating Procedures*

4.2.4.1 Flow each calibration gas through the system for 1 minute. Pressurize the cell to 1 atmosphere. Record the absorbance of each calibration standard at the wavenumber listed in 4.2.2.3.

4.2.4.2 Flow the sample gas through the system for 1 minute. Pressurize the cell to 1 atmosphere. Record the absorbance at each of the appropriate wavenumbers. Calculate (See Note 1) the concentration of each gas, using the formula below. The results may not exceed the specification in Section 2 of this standard.

$$\frac{\begin{matrix}\text{Measured Absorbance}\\ \text{of the Sample}\end{matrix}}{\begin{matrix}\text{Measured Absorbance}\\ \text{of the Standard}\end{matrix}} \times \begin{matrix}\text{Concentration}\\ \text{of Standard}\end{matrix} = \begin{matrix}\text{Concentration}\\ \text{of Sample}\end{matrix}$$

4.3 *Notes*

NOTE 1: Tungsten hexafluoride interferes with the direct absorbance reading for silicon tetrafluoride. The absorbance for silicon tetrafluoride is determined by compensating for the interfering absorbance from the tungsten hexafluoride. Compensation is made by subtracting the absorbance contributed to this band by tungsten hexafluoride band at 930 cm^{-1}. This absorbance is halved and subtracted from the total peak absorbance at 1040 cm^{-1}, resulting in the peak absorbance for silicon tetrafluoride.

NOTE 2: Actual detection limits will be determined by the noise level and the resolution of the spectrometer. One way is to reduce the noise level is to use a Fourier Transform Infrared Spectrometer.

NOTE 3: All gases used in the analysis of the sample should not contain more than 10% of the specified value of the component of interest, unless otherwise stated.

NOTE 4: As tungsten hexafluoride has a low vapor pressure, the cylinder should be kept at room temperature (20°C) for at least 8 hours prior to analysis.

NOTE 5: Observe proper safety procedures for handling and disposing of tungsten hexafluoride.

NOTE 6: Prior to introducing tungsten hexafluoride purge the sample lines and instrument tubing with helium to remove moisture.

NOTE 7: Upon completing the analysis, cap off the manifold and instrument lines or purge the system with helium.

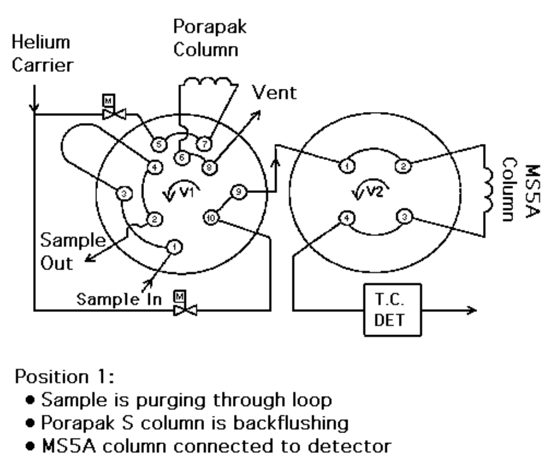

Figure 1

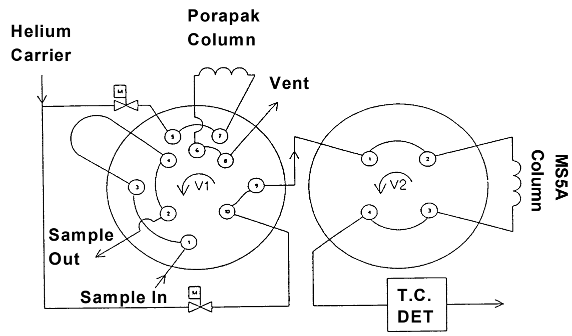

Position 2:
- **V1 is turned**
- **Sample flows through sample loop to the Porapak S column and then to MS5A column**

Figure 2

SEMI C3.52-0200
STANDARD FOR TUNGSTEN HEXAFLUORIDE, 99.996% QUALITY

This standard was technically approved by the Global Gases Committee and is the direct responsibility of the North American Gases Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org February 2000, to be published February 2000. Originally published in 1995; previously published in 1996.

1 Purpose

1.1 To define the specification and analytical methods and validate the specifications for WF_6.

2 Scope

2.1 This specification relates to a geometry of 0.5 µ or less (0.35 or 0.5 range) and describes analytical techniques using gas phase and liquid phase analysis.

3 Description

3.1 Tungsten hexafluoride is a colorless, odorless gas or a clear liquid.

4 Specifications

Quality: 99.996%

Impurities	*Maximum Acceptable Level*
Oxygen (O_2) & Argon (Ar)	1 ppm
Nitrogen (N_2)	5 ppm
Carbon Dioxide (CO_2)	1 ppm
Carbon Tetrafluoride (CF_4)	1 ppm
Hydrogen Fluoride (HF)	20 ppm
Silicon Tetrafluoride (SiF_4)	1 ppm
Sulfur Hexafluoride (SF_6)	1 ppm
Carbon Monoxide (CO)	1 ppm
TOTAL SPECIFIED IMPURITIES	31 ppm

Impurities	*Maximum Acceptable Level*
Cobalt (Co) & Manganese (Mn)	0.01 ppm w
Lead (Pb)	0.02 ppm w
Chromium (Cr), Zinc (Zn), & Uranium (U)	0.05 ppm w
Calcium (Ca) & Magnesium (Mg)	0.10 ppm w
Nickel (Ni), Copper (Cu), Sodium (Na), & Potassium (K)	0.15 ppm w
Iron (Fe)	0.02 ppm w
Thorium (Th)	0.1 ppm w
Molybdenum (Mo)	1 ppm w

5 Physical Constants

	Metric Units	*U. S. Units*
Molecular weight	297.85	297.85
Boiling point	17.1°C	62.8°F
Density of gas at 22.8°C (73°F) and 1 atm	12.9 kg/m^3	0.805 lb/ft^3
Specific gravity of gas	10.8	10.8
Density of liquid at boiling point	3440 kg/m^3	

6 Analytical Procedures (see NOTE 1)

6.1 *Carbon Tetrafluoride, Silicon Tetrafluoride, Carbon Dioxide, and Sulfur Hexafluoride* — This procedure is for the determination of carbon tetrafluoride, silicon tetrafluoride, carbon dioxide, and sulfur hexafluoride in tungsten hexafluoride using a gas chromatograph equipped with a helium ionization detector. A backflush is used in order to protect the detector from the main component.

6.1.1 *Detection Limits* — 0.3 ppm (mole/mole) carbon tetrafluoride, 1 ppm (mole/mole) silicon tetrafluoride, 0.1 ppm (mole/mole) carbon dioxide, and 0.5 ppm (mole/mole) sulfur hexafluoride.

6.1.2 *Instrument Parameters*

6.1.2.1 Columns:

Column 1:	10% Kel F Nr10 on Chromosorb T, 4.0 m (13 ft) by 3.2 mm (1/8 in) nickel or equivalent,
Column 2:	Preconditioned HAYESEP Q, 60/80 mesh, 3 m (10 ft) by 3.2 mm (1/8 in) or equivalent. The column should be treated by repeated WF_6 sample injections at 125°C.

6.1.2.2 *Carrier Flow* — 26 mL/min helium, 6.0 grade.

6.1.2.3 Temperatures:

Detector	50°C
Column Oven	50°C

6.1.2.4 *Sample Volume* — 2 mL

6.1.2.5 *Calibration Standards* — 1 and 5 ppm (mole/mole) carbon tetrafluoride, carbon dioxide, and sulfur hexafluoride in helium (see Figures 1 and 2).

10 ppm silicon tetrafluoride in helium or permeation device (see Figure 3).

6.1.3 *Operating Procedure*

6.1.3.1 Attach a suitable pressure regulator to the standard cylinders. Connect the regulator to the dedicated WF_6 handling system which is connected to the chromatographic sampling valve.

6.1.3.2 Purge the sampling lines with the standard for at least one minute.

6.1.3.3 Inject the standard into the gas chromatograph. Record the retention times and peak areas. Order of elution for the above mentioned standard is carbon tetrafluoride, silicon tetrafluoride, carbon dioxide, and sulfur hexafluoride.

6.1.3.4 Inject the WF_6 sample to be analyzed in the same manner as the calibration standard. Record the retention times and peak areas.

6.1.3.5 Compare the average peak areas of the calibration standard to that of the detected peak in tungsten hexafluoride. Calculate the concentration of each impurity using the standard and sample peak areas and the standard concentration. The results may not exceed the specifications.

6.2 *Oxygen and Argon, Nitrogen, and Carbon Monoxide* — This procedure is for the determination of oxygen and argon, nitrogen, and carbon monoxide in tungsten hexafluoride using a gas chromatograph equipped with a helium ionization detector. A backflush is used in order to protect the detector from the main component.

6.2.1 *Detection Limits*

6.2.2 *Instrument Parameters*

6.2.2.1 Columns:

Column 1:	10% Kel F Nr 10 on Chromosorb T, 4.0 m (13 ft) by 3.2 mm (1/8 in) nickel or equivalent.
Column 2:	Preconditioned HAYESEP Q, 60/80 mesh, 3 m (10 ft) by 3.2 mm (1/8 in) or equivalent. The columns should be treated by repeated WF_6 sample injections at 125°C.
Column 3:	Molecular sieve 5 A, 60/80 mesh, 2 m (6 ft) by 3.2 mm (1/8 in).

6.2.2.2 *Carrier Flow* — 26 mL/min helium, 6.0 grade.

6.2.2.3 Temperatures:

Detector	50°C
Column Oven	50°C

6.2.2.4 *Sample Volume* — 2 mL

6.2.2.5 *Calibration Standards* — 1 and 5 ppm (mole/mole) oxygen, nitrogen, and carbon monoxide in helium (see Figure 4).

6.2.3 *Operating Procedure*

6.2.3.1 Attach a suitable pressure regulator to the standard cylinder. Connect the regulator to the dedicated WF_6 handling system, which is connected to the chromatographic sampling valve.

6.2.3.2 Purge the sampling lines with the standard for at least one minute.

6.2.3.3 Inject the standard into the gas chromatograph. Switch the valves in order to operate in the same conditions as the WF_6 sample analysis. Record the retention times and peak areas. Order of elution for the above mentioned standard is oxygen and argon, nitrogen, and carbon monoxide.

6.2.3.4 Inject the WF_6 sample in the same manner as the calibration standard. Record the retention times and peak areas.

6.2.3.5 Compare the average peak areas of the calibration standard to that of the detected peak in the tungsten hexafluoride. Calculate the concentration of each impurity using the standard and sample areas and the standard concentration. The results may not exceed the specifications.

6.3 *Hydrogen Fluoride* — This procedure is for the determination of hydrogen fluoride in tungsten hexafluoride using Fourier Transform Infra Red (FTIR) analyzer.

6.3.1 *Detection Limit* — 0.5 ppm (mole/mole).

6.3.2 *Instrument Parameters*

- cell with CaF_2 windows
- HF band: 4038,8 cm^{-1}
- resolution: 2 cm^{-1}
- path length: 12 cm

6.3.3 *Calibration Standard* — Calibrate with low vapor pressure hydrogen fluoride or permeation device.

6.3.4 *Operating Procedure* — Carefully dry the cell before sampling tungsten hexafluoride. Then purge it with tungsten hexafluoride and record the concentration. When it is steady, that means the line is purged and the true hydrogen fluoride concentration is obtained.

6.4 *Elemental Impurities* — This procedure is for the determination of Ca, Co, Cr, Cu, Fe, K, Mg, Mn, Mo, Na, Ni, Pb, Th, U, and Zn in the nonvolatile residue of liquid phases tungsten hexafluoride (WF_6) and analyzed by Inductively Coupled Plasma Mass Spectrometry (ICPMS).

6.4.1 *Detection Limits (ppb wt/wt)* — Ca: 1.5; Co: 0.1; Cr: 0.8, Cu: 0.5; Fe: 1; K: 1.5; Mg: 0.1, Mn: 0.1, Mo: 0.5; Na: 0.6; Ni: 1; Pb: 0.1; Th, U: 0.01; and Zn: 0.8.

6.4.2 *Sampling Apparatus* — Figure 5 shows the sampling apparatus used for obtaining a liquid phase sample of WF_6. The sampling apparatus consists of:

- Cylinder Inverter,
- PFA Vessels,
- PFA Valves, and
- PFA Tubing.

The whole sampling system is placed inside a hood.

6.4.3 *Water* — At least 18 MΩ DI water should be used for all dilutions, blanks, and washing.

6.4.4 *Reagents* — All reagents are of the highest purity available minimizing background metal contamination. The following reagents are needed to prepare the sample and standards:

- Aqueous Ammonia,
- Aqueous HNO_3,
- Aqueous HF, and
- NIST traceable ICP standards.

6.4.5 *Sampling Liquid Tungsten Hexafluoride*

6.4.5.1 Place about 400 ml of DI water in each of the hydrolysis vessels. Obtain the weight of each of the hydrolysis vessels.

6.4.5.2 Assemble the apparatus as shown in Figure 1. Do not tighten the cylinder CGA connection. All PFA parts should be clean and dried prior to assembly.

6.4.5.3 Open valves V2, V3, V4 and V5. Set the house nitrogen pressure to approximately 15 psig. Purge the system with nitrogen for about 15 minutes. TIGHTEN THE CYLINDER CGA CONNECTION.

6.4.5.4 Close V2. The system should now be under pressure. Check for leaks and repair if necessary.

6.4.5.5 Open V1 and evacuate the system for approximately 10 minutes.

6.4.5.6 Close all valves.

6.4.5.7 Fill sample vessel by opening cylinder valve and valve V5. Fill the sample vessel approximately 2/3 full. Close cylinder valve.

6.4.5.8 Close V5. Open V2, V4, and V6. This will carry the WF_6 vapors to the hydrolysis vessel.

6.4.5.9 Purge the system with nitrogen for a few minutes after the WF_6 liquid in the sample cup has totally evaporated.

6.4.5.10 Close all valves. Remove the hydrolysis vessels and weigh the vessels.

6.4.5.11 The weight gain in the hydrolysis vessel will give the weight of the sampled WF_6. Typically the weight gain of the second and third vessels will be less than 1% of the weight gain of the first hydrolysis vessel.

6.4.5.12 Remove the sample vessel and dissolve the residue.

6.4.6 *Sample Preparation*

6.4.6.1 Add 20 ml DI water to a 100 ml volumetric flask.

6.4.6.2 Open the sample cup and add 5 ml of aqueous ammonia to the cup.

6.4.6.3 Swirl in the cup and place in a 100 ml volumetric flask.

6.4.6.4 Add 5 ml Nitric Acid to the cup.

6.4.6.5 Swirl and place in the same 100 ml volumetric flask.

6.4.6.6 Add 5 ml Hydrofluoric Acid to the cup.

6.4.6.7 Swirl and place in the same 100 ml volumetric flask as before.

6.4.6.8 Dilute the solution with DI water up to the mark of the 100 ml volumetric flask.

6.4.6.9 Analyze for metals in the sample.

6.4.7 *ICPMS Analysis Procedure*

6.4.7.1 This procedure is used to analyze for trace Na, K, Cr, Fe, Th and U using multi point calibration. Other elements can be analyzed using a single point calibration. Elements for which stable standards can not be obtained, can be analyzed using interpolation and a knowledge of the instrument response function. The ICPMS should be calibrated using matrix matched multielement standards. At least one spiked sample should be analyzed as part of the analytical procedure. The recovery of the spikes should be within ± 25%. At least three standards and a blank should be used for the calibration. Regression based approach should be used to calculate the response factors. The limit of detection (LOD) should be calculated following SEMI C10, Guide for Determination of Method Detection Limits.

6.4.7.2 The concentration of impurities in gas phase WF_6 is given by

$$\text{Conc. in } WF_6 = \frac{\text{Conc. in Solution} \times \text{Wt. of Solution}}{\text{Weight of Sampled } WF_6}$$

NOTE 1: All gases used in the analysis of the sample should contain not more than 10% of the specified value of the component of interest unless otherwise specified.

SEMI C6.3-89
PARTICLE SPECIFICATION FOR GRADE 20/0.2 HYDROGEN (H_2) DELIVERED AS PIPELINE GAS

1 Purpose

The purposes of this document are (1) to set a maximum permissible particle concentration for Grade 20/0.2 hydrogen gas and (2) to describe a reference method for its verification.

2 Scope

This document applies only to hydrogen gas delivered through pipelines; it is not applicable to cylinder gases or gases in their liquid state.

3 Selected Definitions

3.1 *Particle Size/Particle Diameter* — The optical equivalent diameter as detected by a given light scattering particle counter.

NOTE — The optical equivalent diameter varies from counter to counter and with differing particle shape and refractive index.

3.2 *Particle Concentration* — The total number of particles counted, divided by the total gas sample volume, and corrected for background count as defined in Section 3.4, rounded to the nearest integer, for particles equal to or larger than the specified size.

3.3 *Gas Sample Volume* — The volume of the sample, expressed in standard cubic feet (SCF) is the volume occupied by the gas sample at standard conditions, 20°C (68°F) and 1.00 atmosphere pressure.

3.4 *Background Count* — The total number of counts registered by a specific particle counter within the time needed to sample 1.0 SCF of gas under conditions where zero particles transverse the sensing volume, averaged over at least a sequence of twenty-four consecutive sampling periods of 1.0 SCF each or eight consecutive periods of 30 minutes each, whichever is longer. The background count is to be reported as mean number of count per SCF; the number of hours on which the average is based is also reported.

3.5 *Sampling Period* — The time needed to sample 1.0 SCF or 30 minutes, whichever is longer.

4 Apparatus

4.1 *Light Scattering Optical Particle Counter* — With a lower detection limit of 0.2 micrometers or less, based on a calibration with polystyrene latex spheres; and with a maximum background of 2 counts/SCF at 0.2 micrometers. It should be suitable for use in hydrogen service per the manufacturer's specifications or encased in an explosion-proof enclosure which satisfies Class I, Division I of the NFPA Code.

5 Test Method

NOTE — The precise details of any sampling configuration, measurement procedure, or any instrument calibration procedure and frequency must be agreed upon between user and supplier, taking into account good engineering practice.

5.1 The sampling point should be as close as practical to the downstream side of the supplier's final gas filter. Sampling lines should be as short as possible.

5.2 Suggested sampling probe configuration for turbulent main line flow:

Alternative a:	Figure 1a (preferred)
Alternative b:	Figure 1b
Alternative c:	Figure 1c
Alternative d:	Figure 1d

5.3 For configurations 1a, 1b and 1c, the flow rate in the sampling tube at pipeline pressure should be set so that the mean sampling flow velocity at the probe inlet matches as closely as possible the axial flow velocity in the pipeline. Sampling tube ID should be no less than 2 mm (0.08 in).

5.4 Determine the background count for the particle counter by using the standard method recommended by the instrument manufacturer using hydrogen gas.

6 Specification

6.1 Maximum permissible total concentration: 20 particles per SCF equal to or larger than 0.2 micrometers, after subtracting background count as defined in Section 3.4.

6.2 The specification will be considered as met, if the particle concentration does not exceed 20 particles per SCF in any five consecutive sampling periods as defined in Section 3.5.

7 Report

Report each of the five consecutive sampling periods to read as total number of particles per SCF7 of gas, equal to or larger than 0.2 micrometers optical equivalent diameter, without reference to any specific size distribution function. The background count shall be reported as defined in Section 3.4.

8 Calibration

The optical particle counter is normally calibrated using latex spheres of a known diameter suspended in a gas. Since the gas density and refractive index enter into the amount of scattering detected by the instrument, hydrogen should be used for calibration.

9 Safety

The lower explosive limit (LEL) for hydrogen in air is 4%; therefore, proper precautions should be taken to insure that the maximum possible concentration of hydrogen in air does not exceed 2%. The particle counter and any other ancillary equipment must be checked for leaks and the hydrogen exiting the equipment must be disposed of appropriately to insure that its concentration in air at any point does not exceed 2%.

SEMI C6.4-90
PARTICLE SPECIFICATION FOR GRADE 20/0.02 NITROGEN (N_2) AND ARGON (Ar) DELIVERED AS PIPELINE GAS

1 Purpose

The purposes of this document are: (1) to set a maximum permissible particle concentration for 20/0.02 grade nitrogen and argon bulk supply gases, and (2) to describe a reference method for its verification.

2 Scope

This document applies only to nitrogen gas and argon gas delivered through pipelines; it is not applicable to cylinder gases or gases in their liquid state.

3 Selected Definitions

3.1 *Variables*

V_{Mi}=	Volume of the i[th] sample interval of the pipeline gas
V_{Bi}=	Volume of the i[th] sample interval of the background
X_{Mi}=	Concentration of particles observed in the i[th] sample interval of the pipeline gas
X_{Bi}=	Concentration of particles observed in the i[th] sample interval of the background
N_M=	Number of sample intervals of the pipeline gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the pipeline gas sample
$\overline{X}_B$ =	Average observed concentration of background counts
$\overline{X}_C$ =	Calculated concentration of particles in the pipeline gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
S_C=	Standard deviation of $\overline{X}_C$

3.2 *Gas Sample Volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C° (32°F) and 1.00° atmosphere pressure. Standard Cubic Feet (SCF) is defined at 21.1°C° (70°F) and 1.00° atmosphere pressure.

3.3 *Average Observed Concentration of Counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{\sum X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{\sum X_{Bi}}{N_B}$$

3.4 *Calculated Concentration of Particles ($\overline{X}_C$)* — The concentration of particles in the pipeline gas obtained by correcting the observed concentration in the pipeline gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

3.5 *Standard Deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \left[\frac{\sum\left(X_{Mi} - \overline{X}_M\right)^2}{\left(N_M - 1\right)}\right]^{1/2} \qquad S_B = \left[\frac{\sum\left(X_{Bi} - \overline{X}_B\right)^2}{\left(N_B - 1\right)}\right]^{1/2}$$

The third is obtained from the first two, i.e.:

$$S_C = \left(S_M{}^2 + S_B{}^2\right)^{1/2}$$

Note: These expressions are derived from an assumption of a Gaussian (Normal) distribution.

4 Apparatus

4.1 *Particle Counter* — An instrument suitable for counting particles in gaseous nitrogen or argon with a minimum detection efficiency of 90 percent at 0.02 micrometers as determined by the manufacturer of the particle counter. Condensation nucleus counters (CNCs) typically satisfy this requirement.

4.2 *Pressure Reducer* — An accessory required for counters operated at atmospheric pressure, it should preferably use expansion of the gas through a critical orifice.

5 Test Method

NOTE: The details of sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice.

5.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing air, nitrogen or argon, believed to be free of particles of 0.02 micrometers or more in diameter, through the instrument and recording the total number of counts. Count a minimum of 8 sample intervals, each at least 25 standard liters (0.95 SCF) or 30 minutes, whichever is greater. A suggested assembly for performing this test, using a filter which removes particles in this size range, is shown in Figure 1. Calculate $\overline{X}_B$ as defined in Section 3. $\overline{X}_B$ must not exceed 2 particles per 25 standard liters.

5.2 The sampling point should be at outlet of system, and sampling lines should be as short as possible.

5.3 A suggested sampling probe configuration for turbulent main line flow is shown in Figure 2. The flow rate in the sampling tube at pipeline pressure should be set so that the mean sampling flow velocity at the probe inlet matches as closely as possible the axial flow velocity in the pipeline. The pitot sampling tube ID should be no less than 2 mm (0.08 inch). The orifice and sampling horn should be sized so that the mean flow velocity at the particle counter probe inlet matches the axial flow velocity in the horn as closely as possible.

5.4 Count the particles in each of at least 8 sample intervals. Each sample interval must be at least 25 standard liters or 30 minutes, whichever is greater. Record the number of counts and the sample volume for each interval. Calculate $\overline{X}_C$ and S_C, as defined in Section 3.

6 Specification

6.1 *Maximum Permissible Particle Concentration* — 20. particles per 25 standard liters as determined by the instrument specified in Section 4.

6.2 The specification will be considered met if the calculated concentration of particles plus two standard deviations does not exceed 20 particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2^* S_C \leq 20. \text{ particles/25 standard liters}$$

7 Report

The report shall contain the values of all the variables defined in Section 3.

8 Precision

This test procedure defines the requirements to satisfy the specification at the 95 percent confidence level.

PARTICLE SPECIFICATION FOR GRADE 10/0.2 NITROGEN (N_2) AND ARGON (Ar) DELIVERED AS PIPELINE GAS

1 Purpose

The purposes of this document are: (1) to set a maximum permissible particle concentration for 10/0.2 grade nitrogen and argon bulk supply gases, and (2) to describe a reference method for its verification.

2 Scope

This document applies only to nitrogen gas and argon gas delivered through pipelines; it is not applicable to cylinder gases or gases in their liquid state.

3 Selected Definitions

3.1 *Variables*

V_{Mi}=	Volume of the i[th] sample interval of the pipeline gas
V_{Bi}=	Volume of the i[th] sample interval of the background
X_{Mi}=	Concentration of particles observed in the i[th] sample interval of the pipeline gas
X_{Bi}=	Concentration of particles observed in the i[th] sample interval of the background
N_M=	Number of sample intervals of the pipeline gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the pipeline gas sample
$\overline{X}_B$ =	Average observed concentration of background counts
$\overline{X}_C$ =	Calculated concentration of particles in the pipeline gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
S_C=	Standard deviation of $\overline{X}_C$

3.2 *Particle Size/Particle Diameter* — The optical equivalent diameter as detected by a given light-scattering particle counter.

3.3 *Gas Sample Volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1.00 atmosphere pressure. Standard Cubic Feet (SCF) is defined at 21.1°C (70°F) and 1.00 atmosphere pressure.

3.4 *Average Observed Concentration of Counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{X_{Bi}}{N_B}$$

3.5 *Calculated Concentration of Particles ($\overline{X}_C$)* — The concentration of particles in the pipeline gas obtained by correcting the observed concentration in the pipeline gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

3.6 *Standard Deviation (S_M, S_B, S_C)* — a statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \left[\frac{\left(X_{Mi} - \overline{X}_M\right)^2}{\left(N_M - 1\right)} \right]^{1/2} \qquad S_B = \left[\frac{\left(X_{Bi} - \overline{X}_B\right)^2}{\left(N_B - 1\right)} \right]^{1/2}$$

The third is obtained from the first two, i.e.:

$$S_C = \left(S_M{}^2 + S_B{}^2\right)^{1/2}$$

Note: These expressions are derived from an assumption of a Gaussian (Normal) distribution.

4 Apparatus

4.1 *Particle Counter* — An instrument suitable for counting particles in gaseous nitrogen or argon with a lower detection limit of 0.2 micrometers or less, based on calibration with polystyrene latex spheres.

4.2 *Pressure Reducer* — An accessory required for counters operated at atmospheric pressure, it should preferably use expansion of the gas through a critical orifice.

5 Test Method

NOTE: The details of sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice.

5.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing air, nitrogen or argon, believed to be free of particles of 0.2 micrometers or more in diameter, through the instrument and recording the total number of counts. A suggested assemby for perfoming this test, using a filter which removes particles in this size range, is shown in Figure 1. A method recommended by the instrument manufacturer, such as internal recirculation through a filter, may be substituted for the system shown. Count a minimum of 8 sample intervals, each at least the time to sample 25 standard liters (0.95 SCF) or 30 minutes, whichever is greater. Calculate $\overline{X}_B$ as defined in Section 3. $\overline{X}_B$ must not exceed 2 particles per 25 standard liters.

5.2 The sampling point should be at outlet of system, and sampling lines should be as short as possible.

5.3 A suggested sampling probe configuration for turbulent main line flow is shown in Figure 2. The flow rate in the sampling tube at pipeline pressure should be set so that the mean sampling flow velocity at the probe inlet matches as closely as possible the axial flow velocity in the pipeline. The pitot sampling tube ID should be no less than 2 mm (0.08 inch). The orifice and sampling horn should be sized so that the mean flow velocity at the particle counter probe inlet matches the axial flow velocity in the horn as closely as possible.

5.4 Count the particles in each of at least 8 sample intervals. Each sample interval must be at least the time to sample 25 standard liters or 30 minutes, whichever is greater. Record the number of counts and the sample volume for each interval. Calculate $\overline{X}_C$ and S_C, as defined in Section 3.

6 Specification

6.1 *Maximum Permissible Particle Concentration* — 10 particles per 25 standard liters as determined by the instrument specified in Section 4.

6.2 The specification will be considered met if the calculated concentration of particles plus two standard deviations does not exceed 10 particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2^* S_C \leq 10. \text{ particles/25 standard liters}$$

7 Report

The report shall contain the values of all the variables defined in Section 3.

8 Precision

This test procedure defines the requirements to satisfy the specification at the 95 percent confidence level.

PARTICLE SPECIFICATION FOR GRADE 10/0.1 NITROGEN (N_2) AND ARGON (Ar) DELIVERED AS PIPELINE GAS

1 Purpose

The purposes of this document are: (1) to set a maximum permissible particle concentration for 10/0.1 grade nitrogen and argon bulk supply gases, and (2) to describe a reference method for its verification.

2 Scope

This document applies only to nitrogen gas and argon gas delivered through pipelines; it is not applicable to cylinder gases or gases in their liquid state.

3 Selected Definitions

3.1 *Variables*

V_{Mi}=	Volume of the i[th] sample interval of the pipeline gas
V_{Bi}=	Volume of the ith sample interval of the background
X_{Mi}=	Concentration of particles observed in the i[th] sample interval of the pipeline gas
X_{Bi}=	Concentration of particles observed in the i[th] sample interval of the background
N_M=	Number of sample intervals of the pipeline gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the pipeline gas sample
$\overline{X}_B$ =	Average observed concentration of background counts
$\overline{X}_C$ =	Calculated concentration of particles in the pipeline gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
S_C=	Standard deviation of $\overline{X}_C$

3.2 *Particle Size/Particle Diameter* — The optical equivalent diameter as detected by a given light-scattering particle counter.

3.3 *Gas Sample Volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1.00 atmosphere pressure. Standard Cubic Feet (SCF) is defined at 21.1°C (70°F) and 1.00 atmosphere pressure.

3.4 *Average Observed Concentration of Counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{X_{Bi}}{N_B}$$

3.5 *Calculated Concentration of Particles ($\overline{X}_C$)* — The concentration of particles in the pipeline gas obtained by correcting the observed concentration in the pipeline gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

3.6 *Standard Deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \left[\frac{\left(X_{Mi} - \overline{X}_M\right)^2}{\left(N_M - 1\right)}\right]^{1/2} \qquad S_B = \left[\frac{\left(X_{Bi} - \overline{X}_B\right)^2}{\left(N_B - 1\right)}\right]^{1/2}$$

The third is obtained from the first two, i.e.:

$$S_C = \left(S_M^2 + S_B^2\right)^{1/2}$$

Note: These expressions are derived from an assumption of a Gaussian (Normal) distribution.

4 Apparatus

4.1 *Particle Counter* — An instrument suitable for counting particles in gaseous nitrogen or argon with a lower detection limit of 0.1 micrometers or less, based on calibration with polystyrene latex spheres.

4.2 *Pressure Reducer* — An accessory required for counters operated at atmospheric pressure, it should preferably use expansion of the gas through a critical orifice.

5 Test Method

NOTE: The details of sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice.

5.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing air, nitrogen or argon, believed to be free of particles of 0.1 micrometers or more in diameter, through the instrument and recording the total number of counts. A suggested assembly for perfoming this test, using a filter which removes particles in this size range, is shown in Figure 1. A method recommended by the instrument manufacturer, such as internal recirculation through a filter, may be substituted for the system shown. Count a minimum of 8 sample intervals, each at least 25 standard liters (0.95 SCF) or 30 minutes, whichever is greater. Calculate $\overline{X}_B$ as defined in Section 3. $\overline{X}_B$ must not exceed 2 particles per 25 standard liters.

5.2 The sampling point should be at outlet of system, and sampling lines should be as short as possible.

5.3 A suggested sampling probe configuration for turbulent main line flow is shown in Figure 2. The flow rate in the sampling tube at pipeline pressure should be set so that the mean sampling flow velocity at the probe inlet matches as closely as possible the axial flow velocity in the pipeline. The pitot sampling tube ID should be no less than 2 mm (0.08 inch). The orifice and sampling horn should be sized so that the mean flow velocity at the particle counter probe inlet matches the axial flow velocity in the horn as closely as possible.

5.4 Count the particles in each of at least 8 sample intervals. Each sample interval must be at least 25 standard liters or 30 minutes, whichever is greater. Record the number of counts and the sample volume for each interval. Calculate $\overline{X}_C$ and S_C, as defined in Section 3.

6 Specification

6.1 *Maximum Permissible Particle Concentration* — 10 particles per 25 standard liters as determined by the instrument specified in Section 4.

6.2 The specification will be considered met if the calculated concentration of particles plus two standard deviations does not exceed 10 particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2^* S_C \leq 10. \text{ particles/25 standard liters}$$

7 Report

The report shall contain the values of all the variables defined in Section 3.

8 Precision

This test procedure defines the requirements to satisfy the specification at the 95 percent confidence level.

SEMI C6.7-93
PARTICLE SPECIFICATION FOR GRADE 10/0.2 NITROGEN IN HIGH PRESSURE GAS CYLINDERS

1 Purpose

The purposes of this document are (1) to set a maximum permissible particle concentration for 10/0.2 grade cylinder nitrogen, and (2) to describe a reference method for its verification.

2 Scope

2.1 This specification applies to nitrogen contained in high pressure gas cylinders; it is not applicable to pipeline gases.

2.2 A nitrogen cylinder consists of three components: (1) a cylinder bottle, (2) compressed nitrogen contained within, and (3) a cylinder valve. Each component can be a particle source. This specification applied to the total number of particles detected in the gas as obtained from the cylinder under a prescribed condition. No consideration is given to the origin of the particles.

2.3 It is known that pressure reduction, if not controlled, can produce a large number of artifact particles through nucleation and condensation. To avoid this complication, this specification adopts particle counters that can be operated at a pressure up to 200 bar (3000 psi), eliminating the need for pressure reduction and its associated problems.

2.4 It is known that particle content in cylinder gases varies with time because particles can be lost to cylinder walls by diffusion or sedimentation, and detached from cylinder walls by flow pulses or mechanical shocks. It is important to measure particle concentration under the worst conditions which represent typical handling of gas cylinders. This specification describes a standard shock test that fulfills the above requirements and provides a procedure to count particles immediately after the shock.

2.5 If this test method is to be used for more than one cylinder, then each cylinder must be tested. It is known that particle contamination in cylinder gases is a strong function of the handling history of the individual cylinders. Cylinders in the same batch of filling are usually returned from various customers after various periods of service. Uniform quality can not be assumed for the same batch of cylinders unless each of them has gone through a dedicated process that erases the memory of previous history prior to filling. Therefore, batch sampling at 10% or 20% cannot be accepted because of the significant differences among cylinders.

2.6 The requirement of 100% sampling restricts the total amount of gas in each cylinder that can be used for sampling purposes. This restriction, in turn, calls for certain relaxation of the statistical requirement for particle sampling at low concentration levels.

3 Definition

3.1 *Variables*

X_{Bi}=	Observed particle concentration in the i^{th} sample interval of the background
X_{Mi}=	Observed particle concentration in the i^{th} sample interval before shocks
X_{Ni}=	Observed particle concentration in the i^{th} sample after shocks
N_B=	Number of sample intervals of the background
N_M=	Number of sample intervals before shocks
N_N=	Number of sample intervals after shocks
$\overline{X}_B$ =	Averaged observed particle concentration of the background
$\overline{X}_M$ =	Averaged observed particle concentration before shocks
$\overline{X}_N$ =	Averaged observed particle concentration after shocks
X_P=	Calculated particle concentration before shocks
X_Q=	Calculated particle concentration after shocks
S_B=	Standard deviation of $\overline{X}_B$
S_M=	Standard deviation of $\overline{X}_M$
S_N=	Standard deviation of $\overline{X}_N$
SE_P=	Standard deviation of X_P
SE_Q=	Standard deviation of X_Q

3.2 *Averaged Observed Concentration (XB, XM, XN)*

$$\overline{X}_B = SUM(X_{Bi})/N_B$$

$$\overline{X}_M = SUM(X_{Mi})/N_M$$

$$\overline{X}_N = SUM(X_{Ni})/N_N$$

3.3 Calculate concentration (X_P, X_Q)

$$X_P = \overline{X}_M - \overline{X}_B$$

$$X_Q = \overline{X}_N - \overline{X}_B$$

3.4 Standard Deviation (S_B, S_M, S_N)

$S_B = [SUM(X_{Bi} - \overline{X}_B)^2/N_B - 1)]^{1/2}$

$S_M = [SUM(X_{Mi} - \overline{X}_M)2/(N_M - 1)]^{1/2}$

$S_N = [SUM(X_{Ni} - \overline{X}_N)2/(N_N - 1)]^{1/2}$

3.5 Standard Error (SE_P,SE_Q)

$SE_P = [(S_M2/N_M) + (S_B2/N_B)]^{1/2}$

$SE_Q = [(S_N2/N_N) + (S_B2/N_B)]^{1/2}$

4 Apparatus

4.1 *High-Pressure Particle Counter (HPC)* — An instrument capable of counting particles in compressed gaseous nitrogen at a pressure up to 200 bar (3000 psi), having a minimum counting efficiency of 50% at 0.2 µm and reaching 100% at 0.25 µm. This value is determined at ambient pressure by the instrument manufacturer using 0.2 µm monodisperse particles and a reference counter with a proven counting efficiency of 100% at 0.2 µm. Note that the nominal flow rate of the HPC is fixed at any pressure but the sample flow rate should be adjusted to within 5% of the manufacturer's specified flow rate, for the pressure and reported its equivalent standard flow rate at ambient pressure (1 bar).

4.2 *Impact Shock Device* — A device that can reproducibly impart an impact shock of 10^4 m/sec^2 with a 10% tolerance to a gas cylinder. A convenient set up as shown in Figure 1 can be used. A steel ball is attached to a chain with the other end fastened to the test cylinder. The ball is lifted to form a 90 degree angle with the cylinder, is released to follow a 90 degree free fall arc, and strikes the test cylinder. The desired ball mass and chain length are to be determined by monitoring the corresponding shock intensity by an accelerometer. For a typical 44 liter cylinder, a ball mass of 160 gm and a chain length of 60 cm can produce the desired impact shock.

5 Test Method

5.1 Determine the averaged background concentration ($\overline{X}_B$) by passing particle-free, compressed nitrogen through the HPC. Count a minimum of 5 sample intervals, each of at least 6 standard liters (0.2 SCF) or taken over a time period of 6 minutes, whichever is greater. A high purity gas filter can be used to remove particles greater than 0.2 µm. Calculate $\overline{X}_B$ as defined in Section 3. $\overline{X}_B$ must not exceed 1 particle per 30 second liters.

5.2 Set up the experimental apparatus as shown in Figure 2. Directly connect the test cylinder to a High-pressure Particle Counter (HPC), a pressure gauge, and a Flow Control Device (FCD). Note that NO REGULATOR is used before the HPC. The sampling line should be clean and as short as possible. The flow control device can be a metering valve and a flowmeter or a critical orifice.

5.3 Determine $\overline{X}_M$ by opening the cylinder valve and count the particles for at least 5 sample intervals, each of at least 6 standard liters (0.2 SCF) or taken over a time of 6 minutes, whichever is greater. Calculate X_P and SE_P as defined in Section 3.

5.4 Apply 4 impact shocks of approximately 10^4 m/sec^2 each, 10 sec apart, to the bare surface of the test cylinder. Each shock whould be applied at the approximate vertical midpoint of the cylinder; the four shocks should be separated from each other by approximately 90 degrees circumferentially.

5.5 Determine $\overline{X}_N$ by counting the particles after the shocks for at least 5 sample intervals, each of at least 6 standard liters (0.2 SCF) or taken over a time of 6 minutes, whichever is greater. The sampling should be completed within 2 hours after the shocks. Calculate X_Q and SE_Q as defined in Section 3.

6 Specification

6.1 *Maximum Permissible Particle Concentration* — 10 particles per 30 standard liters.

6.2 The specification will be considered met if the calculated concentration of particles plus two standard errors does not exceed 10 particles per 30 standard liters for both measurements before and after the impact shocks, i.e.:

$X_P + 2SE_P \leq 10$ particles/30 standard liters

and

$X_Q + 2SE_Q \leq 10$ particles/30 standard liters

7 Report

The report shall contain the value of the measured sample volumes, values of all the variables defined in Section 3, the mass of the steel ball, and length of the chain.

SEMI C6.2-93
PARTICLE SPECIFICATION FOR GRADE 20/0.02 OXYGEN DELIVERED AS PIPELINE GAS

1 Purpose

The purposes of this document are: (1) to set a maximum permissible particle concentration for 20/0.02 grade oxygen bulk supply gas, and (2) to describe a reference method for its verification.

2 Scope

This document applies only to oxygen gas delivered through pipelines; it is not applicable to cylinder gas or oxygen gas in its liquid state.

3 Selected Definitions

3.1 *Variables*

V_{Mi}=	Volume of the i^th sample interval of the pipeline gas
V_{Bi}=	Volume of the i^th sample interval of the background
X_{Mi}=	Concentration of particles observed in the i^th sample interval of the pipeline gas
X_{Bi}=	Concentration of particles observed in the i^th sample interval of the background
N_M=	Number of sample intervals of the pipeline gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the pipeline gas sample
$\overline{X}_B$ =	Average observed concentration of backgroundcounts
$\overline{X}_C$ =	Calculated concentration of particles in the pipeline gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
SE_C=	Standard error of $\overline{X}_C$

3.2 *Gas Sample Volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1.00 atmosphere pressure. Standard Cubic Feet (SCF) is defined at 21.1°C (70°F) and 1.00 atmosphere pressure.

3.3 *Average Observed Concentration of Counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{X_{Bi}}{N_B}$$

3.4 *Calculated Concentration of Particles ($\overline{X}_C$)* — The concentration of particles in the pipeline gas obtained by correcting the observed concentration in the pipeline gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

3.5 *Standard Deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \left| \frac{(X_{Mi} - \overline{X}_M)^2}{(N_M - 1)} \right| \qquad S_B = \left[\frac{(X_{Bi} - \overline{X}_B)^2}{(N_B - 1)} \right]$$

The third is obtained from the first two, i.e.:

$$S_C = \left(S_M^2 + S_B^2\right)^{\frac{1}{2}}$$

Note: These expressions are derived from an assumption of a Gaussian (Normal) distribution.

3.6 *Standard Deviation (S_M, S_B)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \left[\frac{(X_{Mi} - \overline{X}_M)^2}{(N_M - 1)} \right] \qquad S_B = \left[\frac{(X_{Bi} - \overline{X}_B)^2}{(N_B - 1)} \right]$$

Note: These expressions are derived from an assumption of a Gaussian (Normal) distribution.

3.7 *Standard Error (SEC)*

$$SE_C = \left[\left| \frac{S_M^2}{N_M} \right| + \left(\frac{S_B^2}{N_M} \right) \right]^{\frac{1}{2}}$$

4 Apparatus

4.1 *Particle Counter* — An instrument suitable for counting particles in gaseous oxygen with a counting efficiency of 50 percent at 0.02 micrometers as determined by the manufacturer of the particle counter.

Condensation nucleus counters (CNCs) typically satisfy this requirement.

4.2 *Pressure Reducer* — An accessory required for counters operated at atmospheric pressure, it should preferably use expansion of the gas through a critical orifice.

5 Test Method

NOTE: The details of sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice.

5.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing air or nitrogen or oxygen believed to be free of particles of 0.02 micrometers or larger in diameter, through the instrument and recording the total number of counts. Count a minimum of 8 sample intervals, each at least 25 standard liters (0.95 SCF) or 30 minutes, whichever is greater. A suggested assembly for performing this test, using a filter which removes particles in this size range, is shown in Figure 1. Calculate $\overline{X}_B$ as defined in Section 3. $\overline{X}_B$ must not exceed 2 particles per 25 standard liters.

5.2 The sampling point should be at outlet of system, and sampling lines should be as short as possible.

5.3 A suggested sampling probe configuration for turbulent main line flow is shown in Figure 2. The flow rate in the sampling tube at pipeline pressure should be set so that the mean sampling flow velocity at the probe inlet matches as closely as possible the axial flow velocity in the pipeline. The pitot sampling tube ID should be no less than 2 mm (0.08 inch). The orifice and sampling horn should be sized so that the mean flow velocity at the particle counter probe inlet matches the axial flow velocity in the horn as closely as possible.

5.4 Count the particles in each of at least 8 sample intervals. Each sample interval must be at least 25 standard liters or 30 minutes, whichever is greater. Record the number of counts and the sample volume for each interval. Calculate $\overline{X}_C$ and SE_C, as defined in Section 3.

6 Specification

6.1 *Maximum Permissible Particle Concentration* — 20. particles per 25 standard liters as determined by the instrument specified in Section 4.

6.2 The specification will be considered met if the calculated concentration of particles plus two standard errors does not exceed 20. particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2*SE_C \leq 20. \text{ Particles/25 standard liters}$$

7 Report

The report shall contain the values of all the variables defined in Section 3.

8 Precision

This test procedure defines the requirements to satisfy the specification at the 95 percent confidence level.

SEMI C9.1-93
GUIDE FOR ANALYSIS OF UNCERTAINTIES IN GRAVIMETRICALLY PREPARED GAS MIXTURES

1 Purpose

This document is intended to provide the minimum criterion for the analysis of uncertainty associated with preparation and use of gravimetric gas mixtures used for calibrating analytical instruments to determine whether various SEMI impurity specification are satisfied.

2 Scope

2.1 This guideline is intended for preparation of binary gas mixtures using individual cylinders.

2.2 It is the intent of this document to provide general guidelines for preparation of calibration gas mixtures in compliance with ISO 6142, with additional requirements to meet the needs of the semiconductor industry.

2.3 This guideline is applicable only to gaseous components which do not react between themselves or with the cylinder walls, and to condensable components which are totally vaporized under the test conditions. It is not intended for moisture calibration mixtures.

3 Reference Documents

ISO[1] 6142; Gas Analysis; Preparation of calibration gas mixtures - weighing methods.

Addendum 1 to ISO 6142 - Annex — Precautions to be taken when weighing, handling and filling cylinders.

4 Weight Traceability

The weights used to prepare the gas mixtures or certify the balance should be Class S1-tested at least annually with reference standards traceable to the National Institute of Standards and Technology or to another national standards organization.

5 Acceptable Mixture Criteria

5.1 *Cylinder* — Cylinder must comply with National or International Codes. The type of cylinder used for containment of the gas mixture may affect the stability of the mixture. Historical and experimental data should be requested from the supplier on the stability of similar mixtures. The cylinder material should be chosen based on its compatibility with the gas mixture.

5.2 *Valve* — The recommended valve should be packless type valve and the constuction materials selected according to their compatibility with the gas mixture.

5.3 *Homogenous Mixture* — The cylinder and its contents should be at room temperature prior to use. The cylinder mixture components must be mixed to insure a homogenous mixture.

5.4 *Stability* — The gas mixture will have a demonstrated stability within the acceptable relative uncertainties given in Section 6 for a period of 1 year. The minimum useful pressure should be in accordance with the suppliers recommendations.

5.5 *Balance Gas Purity* — The balance gas should be determined to contain less than 1 percent of the relative concentration for the minor component.

5.6 *Minor Component Purity* — The product used for the minor component addition should be analyzed to verify its composition.

5.7 *Analysis* — Confirmation analysis of the calibration mixture should be performed to determine if any gross weighing errors occurred.

6 Acceptable Relative Uncertainties

Using the ISO procedures the acceptable maximum relative uncertainties for the component of interest are given below.

Concentration Range	*Relative Uncertainty*
Standard Concentrations > 1000 ppm	2 percent
Standard Concentrations = < 1000 ppm > 100	2 percent
Standard Concentrations = < 100 ppm > 10	5 percent
Standard Concentrations = < 10 ppm > = 1	10 percent

7 Report

The composition of the mixture should be reported including the relative uncertainty for a given mixture.

SEMI C13-95 (Withdrawn 1101)
TEST METHOD FOR PARTICLE SHEDDING AND PENETRATION PERFORMANCE OF POINT-OF-USE GAS FILTERS

NOTE: This document was balloted and approved for withdrawal in 2001.

1 Purpose

1.1 The purpose of this document is to define a comprehensive standard test sequence to derive particle-related qualification data for point-of-use (POU) filters.

2 Scope

2.1 This test method defines an evaluation method for point-of-use filters of various media (e.g., polymeric, ceramic, and metallic) typically used for filtering inert and process gases in semiconductor applications. Point-of-use filters are designed to handle relatively low flow rates (0.5 - 100 L/min.) and moderate-to high-pressure drops (0.5-15 psig). The filter housing and filtration element are combined into one sealed and inseparable unit.

3 Limitations

3.1 These test methods do not apply to gas filter cartridges, for which separate methods (SEMI C14) have been developed.

3.2 POU filters are designed and often used to tolerate a variety of conditions (e.g., baking, high-pressure drop, transient pressure surges) without compromising the removal of particles. Therefore, a single penetration test is not sufficient. A sequence of tests, designed to measure filter responses under various conditions, is necessary for POU filter evaluation.

3.3 The order of the test sequence will affect the test results, and it is designed for fair comparisons of different aspects of filter operations. Hence, it is important to follow the prescribed test sequence.

3.4 Depending on the application, a subset of this sequence (i.e., omitting the penetration or baking tests) may be used for some filters. In this case, only those filters tested by the abridged sequence may be compared.

3.5 The penetration test as described in this method is used to give a pass or fail indication under the test conditions. A complete characterization of the filtration efficiency using monodisperse aerosols will be developed separately.

4 Summary of Method

The test sequence (shown schematically in Figure 1) consists of five steps:

1. Break-in
2. Pulse
3. Baking (optional)
4. Final Purge (optional)
5. Penetration (optional)

5 Apparatus and Facility

5.1 *Gas Source* — Clean, dry nitrogen with less than 0.5 ppm moisture and less than 0.5 ppm total hydrocarbons.

5.2 *Particle Detector* — A condensation nucleus counter (CNC) with counting efficiency of 50% at 0.01 µm, as reported by the manufacturer, is recommended to measure total particle concentration greater than 0.01 µm.

5.3 *Test Environments* — The test component should be unpacked and assembled in a Class 100 clean area to prevent ambient contamination. Refer to 5.9 for installation precautions.

5.4 *Configuration for Break-In Test* — The apparatus consists of (1) a flow control system that can accurately regulate flow at 2 flow rates, the minimum and maximum system design flow rates, (2) a 25 cm (10 in.) cartridge filter immediately upstream of the test filter to provide zero-particle gas at the maximum system flow rate, and (3) a CNC downstream of the test filter.

5.4.1 Schematic of the apparatus is shown in Figure 2. This permits an instantaneous change of flow from 10 L/min. to 100 L/min. by opening the solenoid valve.

5.5 *Configuration for Pulse Test* — The apparatus is the same as for the break-in test.

5.6 *Configuration for Baking Test* — The configuration is shown in Figure 3. It is the same as for the break-in test, except that the test filter is placed in a heating device.

5.7 *Configuration for Penetration Test* — One example of the configuration is shown in Figure 4. An air compressor may be used to compress ambient air into a tank to form a compressed aerosol with a broad and fairly stable particle-size distribution. The capacity of the air compressor should be sufficient so that the particle size distribution remains unchanged for a flow up to 100 L/min. Other sources of particles may also be used as long as the concentration remains constant for the duration of the penetration test.

5.7.1 A flowmeter is used to set the challenge aerosol flow at manufacturer-rated flow. A CNC is used to measure particle concentration with and without the test filter.

5.8 *Test Flow Rates* — Two sets of test flow rates are recommended. For the purpose of comparing various brands of POU filters, the test flow rates specified in 5.8.1 should be used. For the purpose of predicting the filter performance in a given gas distribution system, the test flow rates specified in 5.8.2 should be used.

5.8.1 For the purpose of filter comparison, the filter is tested according to the manufacturer-rated flow rate, which can be classified into three categories:

Manufacturer-Rated Flow (L/min.)	*Minimum Test Flow (L/min.)*	*Maximum Test Flow (L/min.)*
2 < rated flow ≤ 10	2 × sampling flow rate	10
10 < rated flow ≤ 50	5	50
rated flow > 50	10	100

The minimum test flow rate is used to purge the apparatus before the shedding test, and the maximum test flow rate is the actual test flow rate.

5.8.2 For the purpose of performance prediction, the maximum flow rate of a gas distribution system containing the POU filter should be used. The maximum system flow rate occurs in the transient period when the flow limiting component is opened. Valves are often the flow limiting components in a typical gas distribution system.

5.8.2.1 Knowing the system operating pressure (P) and the discharge coefficient (C_v) of the flow limiting valve, the maximum test flow rate can be calculated as follows:

$$Q = 4220.7 * P * C_v \sqrt{\left(\frac{1}{SG * T}\right)}$$

where : Q = Flow in L/min

C_v = Valve discharge coefficient

SG = Specific gravity of gas relative to air

T = Absolute temperature of flowing gas (K)

P = Absolute system operating pressure (bar)

The minimum test flow rate is 10% of the maximum test flow rate.

For a system pressure of 3 bar (44 psia) and a C_v of 0.14 for the flow limiting valve, the maximum system flow rate is approximately 100 L/min.

5.9 *Sample Installation* — Reasonable precautions should be taken when installing the test filter or spool piece to avoid particle contamination of the system from ambient. These precautions may include, but are not limited to, installation in a Class 100 laminar flow area, installation in a purged glove bag or other controlled ambient enclosure, use of a purge flow downstream of the sample point so that all parts of the system are under purge, isolation, or termination of the CNC sample flow, and isolation of the isokinetic sampler exhaust from ambient.

5.10 *Sampling System Design* — Customary practices should be employed for the design of the sampling system. Care should be taken to provide an adequate exhaust length so that back diffusion of particles does not affect the system background at 2 times the sampling flow rate. This length will depend upon the particle concentration in the ambient environment and other factors.

6 Procedure

6.1 *Static Background Test*

6.1.1 This test applies to all configurations described in this document and should be performed prior to other tests.

6.1.2 Replace the test filter with a straight piece of electropolished tubing and appropriate fittings.

6.1.3 Purge the system at 100 L/min. Measure particle concentration for a minimum of 45 sample intervals, each at least 6 standard liters (0.19 scf) or 4 minutes, whichever is greater. Continue to purge the system until 45 consecutive sample intervals without a particle being detected are recorded.

6.2 *Dynamic Background Test*

6.2.1 This test applies to the apparatus for pulse test as shown in Figure 2.

6.2.2 Replace the test filter with a straight piece of electropolished tubing and appropriate fittings.

6.2.3 Purge at a flow rate of Q = 10 L/min. until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.2.4 Set the CNC sample interval time to 180 seconds. Synchronize the start of this test with the start of a CNC sample interval.

6.2.5 Purge at a flow rate of 10 L/min. for 190 seconds.

6.2.6 Instantaneously switch to a flow rate of 100 L/min. by turning ON the solenoid valve and purge for 160 seconds.

6.2.7 Turn OFF the solenoid valve and purge at a flow rate of 10 L/min. for 200 seconds.

6.2.8 Repeat 6.2.6 and 6.2.7 until no particles are detected from 20 consecutive flow pulses.

6.3 *Break-in Test*

6.3.1 The apparatus is shown in Figure 2. Purge at a flow rate of Q = 100 L/min. with a straight piece of electropolished tubing and appropriate fittings in place of the test component until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.3.2 Decrease the flow rate to the minimum test flow rate specified in 5.8. Replace the electropolished tubing with the test component and purge until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.3.3 Increase the flow rate to the maximum flow rate specified in 5.8 and record hourly particle concentration averages.

6.3.4 Stop the test when the first set of three consecutive hourly sampling intervals shows no particles being detected or when a maximum duration of 8 hours is reached.

6.4 *Pulse Test*

6.4.1 The apparatus is shown in Figure 2. Purge at the maximum test flow rate until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.4.2 Set the CNC sample interval time to 180 seconds. Synchronize the start of this test with the start of a CNC sample interval.

6.4.3 Purge at the minimum test flow rate for 190 seconds.

6.4.4 Instantaneously switch to the maximum test flow rate by turning ON the solenoid valve and purge for 160 seconds.

6.4.5 Turn OFF the solenoid valve and purge at the minimum test flow rate for 200 seconds.

6.4.6 Repeat 6.4.4 and 6.4.5 (160 secs. ON and 200 secs. OFF) for a series of 10 flow pulses.

6.5 *Baking Test*

6.5.1 The apparatus is shown in Figure 3. A straight piece of electropolished tubing and appropriate fittings are in place of the test component.

6.5.2 Set the flow at the minimum test flow rate. Bake the electropolished tubing at the same temperature as the filter manufacturer-specified maximum temperature. Monitor the concentration until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.5.3 Replace the electropolished tubing with the test component and bake the filter at the manufacturer specified maximum temperature for 20 minutes. Monitor the concentration.

6.5.4 Allow the filter to cool for 20 minutes. Monitor the concentration.

6.5.5 Repeat 6.5.3 and 6.5.4 for a series of 3 baking cycles.

6.6 *Final Purge Test*

6.6.1 Perform a final purge at the maximum test flow rate and record hourly particle concentration averages.

6.6.2 The test is stopped when the first set of 3 consecutive hourly sampling intervals without a particle being detected are recorded or when a maximum duration of 8 hours is reached.

6.7 *Penetration Test*

6.7.1 The apparatus is shown in Figure 4. The input particle concentration is measured by CNC-B, while the output particle concentration is measured by CNC-A. Set flowmeter-B at the minimum test flow rate and flowmeter-A at the manufacturer-rated flow rate.

6.7.2 Measure the input and output particle concentration simultaneously for a minimum of 5 sample intervals, each at least 6 standard liters (0.19 scf) or 4 minutes, whichever is greater.

6.7.3 Calculate the averaged ratio of output to input particle concentration.

7 Reporting of Test Results

7.1 Raw data should be reported for each test in the format of a table, including the number of sample intervals, the sampling volume of each interval, the sampling time of each interval, and the total number of particles registered in each interval. In addition, the relevant parameters for each test described in 7.2 - 7.8 should be identitified.

7.2 *Static Background Test* — Identify the period of time required to obtain 3 consecutive hourly sampling intervals without a particle being detected.

7.3 *Dynamic Background Test* — Identify the period of time required to obtain 20 consecutive flow pulses without a particle being detected.

7.4 *Break-in Test* — Identify the period of time required to obtain 3 consecutive hourly sampling intervals without a particle being detected at the maximum test flow rate and the total number of particles recorded during this period.

7.5 *Pulse Test* — Identify number of pulses during which particles were detected and the total number of particle counts.

7.6 *Baking Test* — Identify the total number of particles measured during the 3 cycles.

7.7 *Final Purge Test* — Identify the total number of particles counted and the time to reach the background level established in the break-in test.

7.8 *Penetration Test* — Identify the input concentration, which is approximately 3500 particles/sec. (10^8 particles/scf), the output concentration, and the ratio of output to input concentration.

SEMI C14-95
TEST METHOD FOR PARTICLE SHEDDING PERFORMANCE OF 25 cm GAS FILTER CARTRIDGES

1 Purpose

1.1 The purpose of this document is to define a comprehensive standard test sequence to derive particle-related qualification data for 25 cm (10 inch) filter cartridges.

2 Scope

2.1 This test method defines a particle shedding evaluation method for 25 cm filter cartridges of various media (e.g., PTFE, PVDF, polycarbonate, nylon, and polysulfone) commonly used individually or in assemblies to remove particles from gas lines. The filter cartridges are separable from the housings which can be cleaned and tested independently.

3 Limitations

3.1 These test methods do not apply to point-of-use (POU) filters, for which separate methods (SEMI C13) have been developed.

3.2 Cartridge filter performance cannot be characterized by a single data point, as conditions of use (e.g., pressure drop, transient pressure surges) determine the importance of a particular measurement. A sequence of tests, designed to measure filter responses under various conditions, is necessary when evaluating cartridge filters.

3.3 The order of the test sequence will affect the test results, and it is designed for fair comparisons of different aspects of filter operations. Hence, it is important to follow the prescribed test sequence.

4 Summary of Method

4.1 The test sequence (shown schematically in Figure 1) consists of three steps:

1. Break-in
2. Pulse
3. Final Purge

5 Apparatus and Facility

5.1 *Gas Source* — Clean, dry nitrogen or dry air with less than 0.5 ppm moisture and less than 0.5 ppm total hydrocarbons.

5.2 *Particle Detectors* — A condensation nucleus counter (CNC) with a counting efficiency of 50%, as reported by the manufacturer, at 0.01 µm is recommended to measure total particle concentration greater than 0.01 µm.

5.3 *Test Environments* — A clean room environment is not required during testing; however, the test component should be unpacked and assembled in a Class 100 clean area to prevent ambient contamination.

5.4 *Configuration for Break-in Test* — The schematic of the test setup apparatus is shown in Figure 2. All components used in the test apparatus, including the flowmeter, valves, tubing, and filter housing, are 2.5 cm (1 inch) components or have 2.5 cm (1 inch) inlet and outlet connections. The apparatus consists of (1) a differential pressure sensor that can accurately measure Δp in the range 0.01 bar (0.15 psid) to 0.2 bar (3.0 psid) between the upstream and downstream pressure of the test component, (2) a flow control system that permits instantaneous change of flow corresponding to a Δp of 0.01 bar to 0.2 bar across the filter, and (3) a CNC downstream of the test filter.

5.5 *Configuration for Pulse Test* — The schematic of the test setup is the same as the break-in test.

5.6 *Sample Installation* — Reasonable precautions should be taken when installing the test filter or spool piece to avoid particle contamination of the system from ambient air. These precautions may include, but are not limited to, installation in a Class 100 laminar flow area, installation in a purged glove bag or other controlled ambient enclosure, use of a purge flow downstream of the sample point so that all parts of the system are under purge, isolation, or termination of the CNC sample flow, and isolation of the isokinetic sampler exhaust from ambient.

5.7 *Sampling System Design* — Customary practices should be employed for the design of the sampling system. Care should be taken to provide an adequate exhaust length so that back diffusion of particles does not affect the system background at 2 times the sampling flow rate. This length will depend upon the particle concentration in the ambient environment and other factors.

6 Procedure

6.1 *Static Background Test*

6.1.1 This test applies to all apparatus described in this document and should be performed prior to other tests.

6.1.2 Remove the filter cartridge from the filter housing and replace the test filter in Figure 2 with the empty housing.

6.1.3 Purge the system at 100 m^3/hr (3530 standard cubic feet per hour (scfh)). Measure particle concentration for a minimum of 45 sample intervals, each at least 6 standard liters (0.19 scf) or 4 minutes, whichever is greater. Continue to purge the system until 45 consecutive sample intervals without a particle being detected are recorded.

6.2 *Dynamic Background Test*

6.2.1 This test applies to the apparatus for pulse test as shown in Figure 2 with the test filter replaced by an empty filter housing.

6.2.2 Purge at a flow rate of 5 m^3/hr (177 scfh) until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.2.3 Set the CNC sample interval time to 180 seconds. Synchronize the start of this test with the start of a CNC sample interval.

6.2.4 Purge at a flow rate of 5 m^3/hr (177 scfh) for 190 seconds.

6.2.5 Instantaneously switch to a flow rate of 100 m^3/hr (3530 scfh) by turning ON the solenoid valve and purge for 160 seconds.

6.2.6 Turn OFF the solenoid valve and purge at a flow rate of 5 m^3/hr (177 scfh) for 200 seconds.

6.2.7 Repeat 6.2.5 and 6.2.6 until 20 consecutive pulses without a particle being detected are recorded.

6.3 *Break-in Test*

6.3.1 The test setup apparatus is shown in Figure 2. Purge at a relatively low flow rate corresponding to a Δp of 0.01 bar (0.15 psid) across the filter until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.3.2 Increase the purge flow rate so that the corresponding Δp is at least 0.1 bar and the flow rate is at least 45 m^3/hr (1590 scfh).

6.3.3 Record hourly particle concentration averages.

6.3.4 Stop the test when no particles are detected in 3 consecutive hourly sampling intervals.

6.4 *Pulse Test*

6.4.1 The apparatus is shown in Figure 2. Purge at a relatively low flow rate corresponding to a Δp of 0.01 bar across the filter until 5 consecutive 60-second sample intervals without a particle being detected are recorded.

6.4.2 Set the CNC sample interval to 180 seconds. Synchronize the start of this test with the start of a CNC sample interval.

6.4.3 Purge at a low flow rate corresponding to a Δp of 0.01 bar across the filer for 190 seconds.

6.4.4 Instantaneously switch to a higher flow rate corresponding to a Δp of 0.1 bar (0.15 psid) across the filter by turning ON the solenoid valve and purge for 160 seconds.

6.4.5 Turn OFF the solenoid valve and purge at a low flow rate (Δp=0.01 bar) of 200 seconds.

6.4.6 Repeat 6.4.4 and 6.4.5 (160 secs ON and 200 secs OFF) for a series of 10 flow pulses.

6.5 *Final Purge Test*

6.5.1 Purge the filter at a Δp of 0.2 bar (3 psid) or a flow rate of 90 m^3/hr (3180 scfh), whichever is greater, for 3 hours. Record the particle concentration.

6.5.2 Decrease the flow so that Δp = 0.1 bar (0.15 psid) or the flow rate is 45m^3/hr (1590 scfh), whichever is greater, and purge for 1 hour. Record the particle concentration.

7 Reporting of Test Results

7.1 Raw data should be reported for each test in the format of a table including the number of sample intervals, the sampling volume of each interval, the sampling time of each interval, and the total number of particles registered in each interval. In addition, the relevant parameters for each test described in Sections 7.2 - 7.6 should be identified.

7.2 *Static Background Test* — Identify the period of time required to obtain 3 consecutive hourly sampling intervals without a particle being detected.

7.3 *Dynamic Background Test* — Identify period of time required to obtain 20 consecutive flow pulses without a particle being detected.

7.4 *Break-in Test* — Identify the period of time required to obtain 3 consecutive one hour sampling intervals without detection of particles and the total number of particles recorded during this period.

7.5 *Pulse Test* — Identify the number of pulses during which particles were detected and the total number of particle counts.

7.6 *Final Purge Test* — Identify the average particle concentration at each pressure.

SEMI C15-95

TEST METHOD FOR ppm AND ppb HUMIDITY STANDARDS

1 Purpose

1.1 This test will determine whether or not the quantity of moisture delivered by a gaseous moisture standard is in agreement with that predicted for the standard on the basis of physical principles. It is expected that this method will be used to validate moisture standards before they are first placed in use, when deviation from expected performance is likely or suspected, and at other times as seems necessary.

1.2 The test method assumes the existence of a reliable moisture analyzer. Although extensive precautions are described to ensure the validity of the analyzer, it is always possible that the test could yield a faulty result through some unforeseen defect in the analytical equipment.

1.3 Given that moisture generation is subject to many pitfalls, it will be required that the predicted moisture concentration delivered by the standard and the measurement of that level by the analyzer be independent, and that they agree. The level of agreement can vary depending on the degree of precision claimed for the moisture standard, but in any case the measured and predicted results should be within 10% over the entire range of the moisture standard. If not, then the validation should be repeated after verifying the physical measurement upon which the prediction is based and any other parameters deemed suspect.

2 Scope

2.1 This method is intended to be applicable to any type of gaseous standard delivering a quantity of moisture in the ppm range or lower, provided the delivered moisture concentration is predictable on the basis of fundamental principles of physics. Thus, any standards which rely solely on characterization by analysis are specifically excluded.

2.2 As part of this test, a procedure is described for qualifying certain moisture analyzers considered suitable for use in qualifying moisture standards. Moisture analyzers intended for other applications may need to satisfy different criteria.

2.3 As the most accurate and reliable moisture analyzers currently available operate primarily in the ppm range, this test focuses on validation of moisture standards in this range. The need for ppb moisture standards is addressed by specifying procedures for reducing the output of ppm moisture standards to the ppb range.

3 Limitations

3.1 If no higher level of accuracy is specified by the user, then a moisture standard shown to be valid by this method will generate moisture levels which deviate from the expected values by no more than 20%. The method leaves open to the user the option of using sound statistical methods to specify that a given moisture standard will generate levels showing a closer agreement with expected values.

3.2 Validation based on this test method is good for a limited time. The acceptable interval between validations depends on the nature of the standard and is not addressed by this method. Thus any citation of validation results should be accompanied by the date(s) on which validation was performed.

4 Referenced Documents

This method is based upon principles outlined in F. Mermoud, M.D. Brandt, and J.J.F. McAndrew, “Low Level Moisture Generation,” Analytical Chemistry, 63 (2): 198-202 (1991).

5 Device under Test (Test Specimen)

5.1 *Definition of a Moisture Standard* — A moisture “standard” is defined to be any device capable of delivering a flow of humidified gas at controlled pressure, with no input being provided by the user except nitrogen of UHP grade (moisture < 1 ppm) or air of equivalent purity. Any device, such as a permeation tube, which can provide a predictable amount of moisture but does not include a means to deliver gas to and from it, will not be considered a moisture standard by itself. A device which requires gas of higher purity than UHP grade will include a purifier capable of purifying UHP nitrogen to this level.

5.2 *Examples of Moisture Standards* — Some examples of moisture standards and the principles upon which they are based are as follows:

— Permeation and effusion tube standards. These must include purification means and some means of regulating the outlet pressure. The moisture delivery rate can be calculated based on the weight loss of the tube.

— Cylinder standards. The “standard” will include a regulator specified for use with the cylinder. The moisture concentration delivered can be calculated based on that added to the cylinder in preparation. A minimum use pressure must be specified.

— Methods based on saturation of gas with water vapor at a fixed temperature and pressure. The moisture concentration in the gas may then be calculated from a knowledge of the saturation vapor pressure of water over a plane of the pure phase of ice at the saturation temperature and of the interaction virial coefficients of the gas-vapor mixture. The two-pressure and two-temperature methods are refinements of this approach requiring additional chambers whose temperature and pressure must be known.

5.3 *Dilution of Standards* — For all moisture generation methods, lower concentrations can be generated by dynamic dilution (i.e., by combining a known flow of the standard gas with a known flow of dilution gas). A diluted standard is acceptable provided:

— The standard is validated at high concentration (with the lowest concentration validated being no more than 10,000 times the use concentration),

— The dilution gas has a moisture level below the stated precision of the analysis (to be verified using the same flow path as during the subsequent analysis, and at the lowest flow rate to be used),

— The absolute accuracies of the dilution system components are verified by comparison with a reliable flow standard,

— The linearity of the dilution system can be demonstrated over the entire range of operation.

The last criterion is particularly important whenever some portion of the combined flow is discarded, as mixing problems can easily arise at large dilution factors.

6 Procedure

Validation will be performed using a hygrometer whose output can be directly related to the moisture concentration on the basis of physical laws or using an analyzer which has recently been calibrated by comparison with such an analyzer.

6.1 *Hygrometer Qualification*

6.1.1 *Primary Hygrometers* — Hygrometers can be certified by the National Institute for Standards and Technology (NIST) in the U.S., and similar certification is available in other countries, although the lowest concentration at which certification is available will vary. Repeated certification at yearly or longer intervals can be used to establish reliability. A hygrometer which has been certified by a national standards laboratory to 1 ppm (or lower) moisture in air or nitrogen, and for which reliability has been established over a period greater than or equal to that which has elasped since certification occurred, is acceptable for validation of a moisture standard and will be referred to as a “primary” hygrometer.

Because hygrometers which are suitable for use as primary hygrometers may be less convenient or less readily available than other hygrometers, the use of other hygrometers for validation is also acceptable, provided adequate precautions are taken to ensure that they are operating correctly. These precautions (to be described below) require using a moisture source to compare a secondary hygrometer with the primary hygrometer. The moisture source need not have been validated in this case.

6.1.2 *Validation of Secondary Hygrometers* — Secondary hygrometers may be validated by comparing their output with a primary hygrometer when connected in parallel to the same moisture source. The degree of agreement required can vary depending upon the precision to be claimed, but in any case the difference in reading between the two hygrometers should be no more than 10% at any point. Comparison should be made at four moisture concentrations or at two per decade of proposed operation, whichever is less. Half of the comparisons should be made while increasing concentration and half while decreasing, including at least one comparison at the highest point of the concentration range. The first and last comparisons should be at the lowest point of the concentration range. For example, in order to validate a hygrometer for operation between 1 and 100 ppm, it would be acceptable to generate moisture levels at 1, 30, 100, 50, 1 ppm (in that order) and compare the primary with the secondary hygrometer. Comparison of the measured level between the two 1 ppm tests provides a ready indication of hysteresis in the system. If the secondary hygrometer requires calibration using its own standard, calibration should be effected before validation. However, it is acceptable to adjust the calibration in order to improve agreement with the primary hygrometer.

6.1.3 *Frequency of Hygrometer Validation* — The frequency of validation required for a secondary hygrometer will vary dependent upon the performance established for hygrometers of the same general type. If three successive monthly validations show continuing agreement (within 10%) with the primary hygrometer without calibration adjustment, the validation interval may be extended to three months. Similar extensions of validation interval to six months and one year may be made if no drift is apparent and no calibration adjustments are necessary to bring the secondary within 10% of the primary at all points.

6.2 *Validation Procedure for Moisture Standards*

6.2.1 *Validation Within the Range of an Available Primary Hygrometer* — If a primary hygrometer is available, and its detection limit is no higher than the lowest concentration at which it is desired to use the moisture standard, this is the simplest case. Use the standard to generate four concentration levels or two per decade (whichever is less) in which the standard will be used, half of the concentrations generated while increasing concentration, half while decreasing, including at least one comparison at the highest point of the concentration range. The first and last comparisons should be at the lowest point of the concentration range. If the generated levels, calculated according to the basic properties of the generator (e.g., weight loss of a permeation tube) agree with the measured levels to within 10%, the standard may be considered validated with an accuracy of 10%. Higher validation accuracy requires better agreement. It has been assumed that the precision of the primary hygrometer, as determined by a national standards laboratory, is much better than 10% and may be neglected for validation at the 10% level. Validation at higher accuracy requires explicit consideration of the certification precision.

If a standard only generates one level, connect it to the hygrometer and allow to come to equilibrium. Assuming the equilibrium level agrees with the calculated level of the generator, disconnect the hygrometer and bring it to equilibrium with either dry nitrogen or ambient air. Then reconnect the moisture standard and reestablish equilibrium between the standard and the hygrometer. Disconnect again and repeat a third time. If the three measurements agree within 10% among themselves and with the generated level, the standard is validated.

It is implicit in the above that the background moisture level of the system be less than 50 ppb so that it can be neglected for all measurements above 1 ppm with an error no larger than 5%. We can usually neglect background moisture in validating moisture standards in this concentration range.

6.2.2 *Validation Using Secondary Hygrometers* — If no primary hygrometer is available, then validation can be performed using a secondary hygrometer. If the lowest concentration to be generated using the standard is no higher than the detection limit of the primary hygrometer used for validation of the secondary hygrometer, then the procedure is as above, except that the secondary must first have been validated over the entire concentration range which the standard will be used to generate. (A secondary hygrometer and a moisture standard can be validated simultaneously if the primary and secondary hygrometers are connected in parallel to the moisture standard.)

When assessing the accuracy of validation using a secondary hygrometer, it is necessary to take into account the precision of the comparison of the primary hygrometer with the secondary hygrometer as well as the precision of the comparison of the generator with the secondary hygrometer.

7 Practice for Generating ppb Moisture Standards

The detection limit of the primary hygrometer will generally be on the order of 1 ppm, whereas it will frequently be necessary to use the moisture standard at concentrations below this level, by a factor of as much as 10,000. Therefore, valid methods for reducing concentration are necessary.

7.1 *Dilution of Validated Moisture Standards* — If a moisture standard validated in accordance with 6.2.0 or 6.2.1 is diluted with a zero gas stream satisfying the criteria of 5.3, then the resultant diluted standard may be considered valid and may be used for calibration of analyzers, such as APIMS.

7.2 *Consideration of Background Moisture* — In any ppb or lower moisture measurement, it is necessary to consider the background moisture level due to outgassing in the sampling system and residual moisture in the generator + analyzer. Often the background will be sufficiently large that it must be taken into account explicitly. The background moisture level is the moisture concentration measured in the absence of a moisture source (i.e., when the driest carrier gas available is fed to the analyzer using the same flow rate and flow path as is used for the sample gas during analysis).

It should be noted that the importance of the background level increases for measurements at low concentrations, and that the background level is sensitive to the materials of construction, to the design of the moisture generator, and to its operating temperature.

If the background moisture concentration is B (ppb), the concentration delivered by the moisture standard is C (ppb) and the dilution factor x is given by

$$x = \frac{\text{flow of moisture standard}}{\text{total flow}} \qquad (1)$$

then c, the delivered moisture concentration is given (in ppb) by

$$c = (1 - x)B + xC \qquad (2)$$

The accuracy of calibration will reflect the combined accuracy of the standard and the dilution system, together with the accuracy of the background determination; all must be taken into account in any statement of analytical uncertainty.

7.3 *Changing the Range of Performance of a Moisture Standard* — If a moisture standard is based on some device which is believed to deliver moisture at a constant rate, such as a permeation or effusion tube, the concentration range delivered by the moisture standard may be changed by delivering a substantially different flow of carrier gas. This usually requires changing a mass flow controller or other flow control device inside the standard for a flow controller of a different range. This may be done provided the new flow controller's performance is verified by comparison with a reliable flow standard.

The definition of dilution factor is revised to

$$x = \frac{\text{flow generated by original flow controller}}{\text{flow generated by new flow controller}} \qquad (3)$$

The background, B, is determined by removing the permeation or effusion tube from the system and capping off its point of connection, or by preventing the source from delivering moisture by some other means. The same equation for c applies as does the statement regarding analytical uncertainty.

7.4 *Validation at Intermediate Concentrations* — It may be desirable to validate a moisture standard at a concentration below the detection limit of the primary hygrometer, if that standard is to be used for very low-level generation. For example, if a standard based on a permeation device is intended to generate levels between 0.5 and 5 ppb at flows of 1 to 10 slm, it could be validated in the 0.5 to 5 ppm range using a frost-point hygrometer by replacing the flow controller with one operating between 1 and 10 sccm[1] . However, such a flow controller may not be readily available and is difficult to calibrate in any case. Instead, it is preferable to use a flow controller operating between 50 and 500 sccm to generate concentrations between 0.1 and 1.0 ppm together with a secondary hygrometer having a detection limit no higher than 50 ppb. This procedure is acceptable, provided that

— the secondary hygrometer has been validated with a primary hygrometer at least at one point in the range to be used for validation of the moisture standard,

— the moisture concentrations generated by the standard and that observed by the secondary hygrometer agree throughout the range of validation of the standard.

This approach could lead to errors if the hygrometer and the standard each exhibited a deviation from predicted performance, but these deviations would have to be the same and cancel, which is extremely unlikely.

In the case of operation in this mode, it will be necessary to know the background level of the system and use this as an input to the calculation of generated moisture levels. To continue the example of a permeation based system, if the permeation rate determined by weight loss is P (ng/min), the flow rate of carrier gas is F (sccm), K is a factor to convert ng/min to sccm moisture, and B is the experimentally determined background, then the generated moisture level, c_{gen}, is calculated according to

$$c_{gen} = \frac{KP}{F} + B \qquad (4)$$

For other moisture generation systems, it is similarly possible to calculate the generated moisture level while taking into account the background level of the system. This assumes that the background moisture concentration is constant, which is only approximately true. Thus, in applying this approach, in addition to the sources of error mentioned above, the estimate of analytical uncertainty must also include the variation in background moisture.

8 Validation Precision and Accuracy

This procedure does not explicitly consider the estimation of the accuracy of a moisture standard in detail, because such a calculation can be made by applying procedures described elsewhere. The accuracy required in validation will vary with the proposed application of the moisture standard and may be left to the discretion of the user of the procedure. It is recommended that a propagation of errors calculation be carried out to estimate the accuracy of the validation. If no such calculation is made, and the minimum criteria of the procedure are followed, it is estimated that a validated moisture generator may output moisture levels which differ from the true values by up to 20%.

1 It is assumed that, although flow controllers are calibrated using a standard, no unusual measures are used to enable the full accuracy of calibration to be achieved over the entire range of the flow controller. In practice this means that a flow controller has a usable dynamic range of 10-100% of its flow rating.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C52-0301
SPECIFICATION FOR THE SHELF LIFE OF A SPECIALTY GAS

This specification was technically approved by the Global Gases Committee and is the direct responsibility of the European Gases Committee. Current edition approved by the European Regional Standards Committee on December 20, 2000. Initially available at www.semi.org January 2001; to be published March 2001.

1 Purpose

1.1 The purpose of this document is to define terminology and to recommend minimum periods for the shelf lives of specialty gases. It is meant to provide consistency in terminology among gas suppliers and to provide a general guideline for users of these gases.

2 Scope

2.1 This document applies to the shelf life of properly packaged, filled and analyzed specialty gases as stored or supplied by a specialty gas manufacturer or supplier. In this document, shelf life is viewed from a quality point of view. The document does not address safety aspects associated with the prolonged storage of gases.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

None.

4 Terminology

4.1 *container* — a lecture bottle, cylinder, cylinder pack, drum or any other vessel which is used to supply a specialty gas.

4.2 *residual level* — The amount of product, as a fraction of the fill weight or fill pressure, which should be left in a container in order to minimize the impact on manufacturing processes of the higher level of impurities in the last gas fraction from a container.

4.3 *shelf life* — the period of time for which the specification of a gas is guaranteed by the supplier, starting from the time of analysis. It defines the period for which the supplier guarantees the actual level of impurities, as analyzed, to remain at or below the specification limit for a particular gas grade.

5 Requirements

5.1 *Factors Affecting the Shelf Life of a Specialty Gas* — Shelf life is a function of the following factors:

a. Thermal stability of the gas

b. Quality of the container and valve

- material selection
- leak tightness

c. Time-dependent reactions between

- gas and impurities
- gas and packaging materials

d. Filling and analytical operations

e. Transport and storage conditions

f. Amount of product in the container

5.1.1 The integrity of the valve is a key factor determining the shelf life of a gas, in particular for low vapor pressure gases. Time dependent reactions can be significantly reduced by purification of the gas to a level where impurities no longer have a significant effect over time, and by selection of proper packaging materials. Chemical and physical treatment of the internal container surface and/or passivation of this surface before filling also reduces the effect of time-dependent reactions. For material and gas compatibility information, please refer to the individual SEMI gas standards.

5.2 *Classification of Specialty Gases on the Basis of Shelf Life* — While there are a large number of specialty gases used in semiconductor manufacturing, for the purpose of defining shelf lives, they can be divided into four groups. It should be noted that for example chemically reactive gases are sometimes classified as non-reactive in the table below as the classification is done from a shelf-life point of view only.

5.2.1 *Non-reactive* — Under normal storage conditions, these gases do not react with ambient air, the packaging materials or the impurities commonly found in the specialty gas.

5.2.2 *Reactive* — These gases react either with ambient air or standard packaging materials.

5.2.3 *Corrosive* — These gases react with packaging materials usually in the presence of traces of moisture.

5.2.4 *Unstable* — These gases are thermally unstable and spontaneously decompose over time.

Table 1 Classification of Specialty Gases on the Basis of Shelf Life

Non-reactive	*Reactive*	*Corrosive*	*Unstable*
Air	AsH_3	BCl_3	B_2H_6
Ar	CO	BF_3	NO
CFH_3	D_2	$^{11}BF_3$	
CF_2H_2	GeH_4	ClF_3	
CF_3H	H_2	Cl_2	
CF_4	NF_3	F_2	
CH_4	PH_3	GeF_4	
CO_2	SeH_2	HBr	
C_2F_6	SiH_4	HCl	
C_3F_8	Si_2H_6	HF	
C_4F_8		NH_3	
C_5F_8		PF_5	
He		$SiCl_2H_2$	
Kr		$SiCl_3H$	
Ne		$SiCl_4$	
N_2		SiF_4	
N_2O		WF_6	
O_2			
SF_6			
Xe			

5.3 *Guaranteed Shelf Life Period* — The following guaranteed shelf life periods are recommended as a minimum.

Table 2 Guaranteed Shelf Life Period

Non-reactive	*Reactive*	*Corrosive*	*Unstable*
36 months	24 months	18 months	6 months

5.3.1 When proper packaging materials are chosen and the container is properly prepared (and passivated), impurity levels should in theory remain constant over time for an electronics grade specialty gas with the exception of the thermally unstable gases. For this reason, no maximum shelf life periods are recommended as these will depend on the level of analytical data collected by the manufacturer or supplier.

5.4 *Mixtures* — The shelf life of a mixture is recommended to be equal to the shelf life of the component in the mixture with the lowest shelf life. For example, the minimum shelf life of a reactive gas in a non-reactive gas matrix would be 24 months. The shelf life of a mixture should apply both to the impurity specifications and to the assay of the mixture.

5.4.1 Special attention should be paid to the preparation of the package for mixtures containing less than 1,000 ppm of a component. At such levels, adsorption effects may reduce the shelf life and minimization of the package internal surface roughness and/or passivation of the surface may be required.

5.5 *Residual Level* — The impact of the depletion of a container on impurity levels is still a matter of debate among gas suppliers. In general, the impurity levels of the first gas fraction from a container will differ from the last gas fraction. In particular moisture levels tend to rise at lower gas pressures as a result of the relative increase in importance of the internal container wall and its adsorbed moisture. In addition, in liquefied gases the co-existence of both a gas phase and a liquid phase can have a measurable effect on the distribution of impurities over the gas fractions. It is argued that at the point of liquid-dry some impurities, which prefer solution in the liquid phase over the gas phase, may see a dramatic rise. It is therefore recommended to always leave an amount of product in the container and to avoid a situation of "liquid dry" (i.e., when all of the liquid phase of a liquefied gas has been used).

SEMI INTERNATIONAL STANDARDS

MATERIALS

Semiconductor Equipment and Materials International

SEMI M1-0302
SPECIFICATIONS FOR POLISHED MONOCRYSTALLINE SILICON WAFERS

These specifications were technically approved by the Global Silicon Wafer Committee and are the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1978; previously published July 2001.

1 Purpose

1.1 These specifications cover requirements for monocrystalline high-purity silicon wafers used in semiconductor device manufacturing. Dimensional and crystallographic orientation characteristics and limits on surface defects are the only standardized properties set forth below.

1.2 A complete purchase specification requires that additional physical properties be specified along with test methods suitable for determining their magnitude. SEMI M18 provides a comprehensive listing of such properties and associated test methods and may be used for this purpose (see also Section 4).

1.3 These specifications apply specifically to silicon wafers with one chem-mechanically polished surface. Wafers polished on both sides, or unpolished, or with epitaxial deposits are not covered. Values given for thickness, TTV, bow, and warp apply only to wafers without back surface films or extrinsic gettering treatments. However, purchasers of such wafers may find these specifications to be a useful guide in defining their requirements.

1.4 For referee purposes, U.S. customary units shall be used for wafers of 2 and 3-inch nominal diameters, and SI (system international, commonly called metric) units for 80 mm and larger diameter wafers.

1.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory practices prior to use.

SEMI T1 — Specification for Back Surface Bar Code Marking of Silicon Wafers

SEMI T2 — Specification for Marking of Wafers with a Two-Dimensional Matrix Code Symbol

NOTE 1: A revision to SEMI T2 to extend it to include rectangular code symbols is currently being balloted in a companion document.

2.2 *ASTM Standards*[1]

E 122 — Practice for Choice of Sample Size to Estimate Average Quality of a Lot or Process

F 21 — Test Method for Hydrophobic Surface Films by the Atomizer Test

F 22 — Test Method for Hydrophobic Surface Films by the Water-Break Test

F 26 — Test Methods for Determining the Orientation of a Semiconductive Single Crystal

F 28 — Method for Measuring the Minority-Carrier Lifetime in Bulk Germanium and Silicon

F 42 — Test Methods for Conductivity Type of Extrinsic Semiconducting Materials

F 43 — Test Methods for Resistivity of Semiconductor Materials

F 47 — Test Method for Crystallographic Perfection of Silicon by Preferential Etch Techniques

F 76 — Test Methods for Measuring Hall Mobility and Hall Coefficient in Extrinsic Semiconductor Single Crystals

F 81 — Method for Measuring Radial Resistivity Variation on Silicon Slices

F 84 — Method for Measuring Resistivity of Silicon Slices with a Collinear Four-Probe Array

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

F 154 — Practices and Nomenclature for Identification of Structures and Contaminants Seen on Specular Silicon Surfaces

F 391 — Test Method for Minority Carrier Diffusion Length in Silicon by Measurement of Steady-State Surface Photovoltage

F 398 — Test Method for Majority Carrier Concentration in Semiconductors by Measurement of Wave Number or Wavelength of the Plasma Resonance Minimum

F 416 — Test Method for Detection of Oxidation Induced Defects in Polished Silicon Wafers

F 419 — Test Method for Net Carrier Density in Silicon Epitaxial Layers by Voltage-Capacitance of Gated and Ungated Diodes

F 523 — Practice for Unaided Visual Inspection of Polished Silicon Slices

F 533 — Test Method for Thickness and Thickness Variation of Silicon Slices

F 534 — Test Method for Bow of Silicon Slices

F 613 — Test Method for Measuring Diameter of Silicon Slices and Wafers

F 657 — Test Method for Measuring Warp and Total Thickness Variation on Silicon Slices and Wafers by a Noncontact Scanning Method

F 671 — Test Method for Measuring Flat Length on Slices of Electronic Materials

F 673 — Test Method for Measuring Resistivity of Semiconductor Slices or Sheet Resistance of Semiconductor Films with a Noncontact Eddy-Current Gage

F 847 — Test Methods for Crystallographic Orientation of Flats on Single Crystal Silicon Slices and Wafers by X-Ray Techniques

F 928 — Test Methods for Edge Contour of Silicon Wafers

F 951 — Test Method for Radial Interstitial Oxygen Variation

F 1188 — Test Method for Interstitial Atomic Oxygen Content of Silicon by Infrared Absorption

F 1241 — Terminology of Silicon Technology

F 1366 — Test Method for Measuring Oxygen Concentration in Heavily Doped Silicon Substrates by Secondary Ion Mass Spectroscopy

F 1388 — Test Method for Generation Lifetime and Generation Velocity of Silicon Material by Capacitance-Time Measurements of MOS (Metal-Oxide-Silicon) Capacitors

F 1390 — Test Method for Measuring Warp on Silicon Wafers by Automated Noncontact Scanning

F 1391 — Test Method for Substitutional Atomic Carbon Content of Silicon by Infrared Absorption

F 1451 — Test Method for Measuring Sori on Silicon Wafers by Automated Noncontact Scanning

F 1526 — Standard Test Method for Measuring Surface Metal Contamination on Silicon Wafers by Total Reflection X-Ray Fluorescence Spectroscopy

F 1528 — Standard Test Method for Measuring Boron Contamination in Heavily Doped N-Type Silicon Substrates by Secondary Ion Mass Spectrometry

F 1530 — Test Method for Measuring Flatness, Thickness, and Thickness Variation on Silicon Wafers by Automated Noncontact Scanning

F 1535 — Test Method for Carrier Recombination Lifetime is Silicon Wafers by Noncontact Measurement of Photoconductivity Decay by Microwave Reflectance

F 1617 — Standard Test Method for Measuring Surface Sodium, Aluminum, and Potassium on Silicon and Epi Substrates by Secondary Ion Mass Spectrometry

F 1619 — Standard Test Method for Measurement of Interstitial Oxygen Content of Silicon Wafers by Infrared Absorption Spectroscopy with P-Polarized Radiation Incident at the Brewster Angle

2.3 *DIN Standards*[2]

50430 — Messung des spezifischen elektrischen Widerstandes von stabformigen Einkristallen aus Silicium oder Germanium mit dem Zwei-Sonden-Gleichstrom-Verfahren (Measurement of the Electrical Resistivity of Silicon or Germanium Single Crystals in Bars by Means of the Two Point-Probe Direct Current Method)

50431 — Messung des spezifischen elektrischen Widerstandes von Einkristallen aus Silicium oder Germanium mit dem Vier-Sonden Gleichstrom-Verfahren bei linearer Anordnung der Sonden (Measurement of the Electrical Resistivity of Silicon or Germanium Single Crystals by Means of the Four-Point-Probe Direct Current Method with Collinear Four Probe Array)

50432 — Bestimmung des Leitungstyps von Silicium oder Germanium mittels Richttest oder Thermosonde (Determination of the Conductivity Type of Silicon or

2 DIN Standards, Deutsches Institut fur Normung e.v., available from Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-1000 Berlin 30, Germany

Germanium by Means of Rectification Test or Hot-Probe)

50433/1 — Bestimmung der Orientierung von Einkristallen mit einem Roentgengoniometer (Determination of the Orientation of Single Crystals by Means of X-Ray Diffraction)

50433/2 — Bestimmung der Orientierung von Einkristallen nach der Lichtfiguren-methode (Determination of the Orientation of Single Crystals by Means of Optical Reflection Figure)

50433/3 — Bestimmung der Orientierung von Einkristallen mittels Laue-Ruckstrahl-verfahren (Determination of the Orientation of Single Crystals by Means of Laue Back Scattering)

50434 — Nachweis von Kristalldefekten in Silizium-Einkristallen mittels Atztechnik an {111}- und {100}-Flachen (Detection of Crystal Defects in Silicon Monocrystals by Etching on {111} and {100} Surfaces)

50435 — Bestimmung der radialen Variation des spezifischen elektrischen Widerstandes an Silicium oder Germanium-Scheibenmitdem Vier-Sonden-Gleichstromverfahren (Determination of the Radial Resistivity Variation of Silicon or Germanium Slices by Means of a Four-Point-DC-Probe)

50438/1 — Bestimmung des Verunreinigungs-gehaltes in Silicium mittels Infrarot Absorption; Sauerstoff (Determination of Impurity Content in Silicon by Infrared Absorption; Oxygen)

50438/2 — Bestimmung des Verunreinigungs-gehaltes in Silicium mittels Infrarot Absorption; Kohlenstoff (Determination of Impurity Content in Silicon by Infrared Absorption; Carbon)

50440/1 — Messung der Rekombinations-Tragerlebensdauer in Silicium-Einkristallen nach der Photoleitfahigkeitsverfahren; Messung an quaderformigen Proben (Measurement of Recombination Carrier Lifetime in Silicon Single Crystals by Means of Photoconductive Decay Method; Measurement on Bar-Shaped Test Samples)

50441/1 — Messung der geometrischen Dimensionen von Halbleiterscheiben; Messung der Dicke (Measurement of the Geometric Dimensions of Semiconductor Slices; Measurement of Thickness)

50441/2 — Messung der geometrischen Dimensionen von Helblaiterscheiben; Prufung der Kantenverrundung (Measurement of the Geometric Dimensions of Semiconductor Slices; Testing of Edge Rounding)

50441/4 — Messung der geometrischen Dimensionen von Halbleiterscheiben: Scheibendurchmesser und Flattiefe (Measurement of the Geometrical Dimensions of Semiconductor Slices: Diameter and Flat Depth of Slices)

2.4 *JIS Standards*[3]

H 0609 — Test Methods of Crystalline Defects in Silicon by Preferential Etch Techniques

H 0611 — Methods of Measurement of Thickness Taper and Bow for Silicon Wafers

2.5 *Other Standards*

ANSI/ASME B46.1 — Surface Texture (Surface Roughness, Waviness, and Lay)[4]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes[5]

ISO 4287/1 — Surface Roughness – Terminology – Part 1: Surface and its Parameters[6]

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3 Terminology

3.1 Many terms relating to silicon technology are defined in ASTM Terminology F 1241.

3.2 Definitions for many of the polished wafer defect terms in Table 1 are given in ASTM Practices F 154 and F 523 and in ASTM Test Method F 416.

3.3 Other terms are defined as follows:

3.3.1 *acceptor* — an impurity in a semiconductor which accepts electrons excited from the valence band, leading to hole conduction.

3.3.2 *anisotropic, in semiconductor technology* — exhibiting different physical properties in differing crystallographic directions.

3.3.3 *anisotropic etch* — a selective etch which exhibits an accelerated etch rate along specific crystallographic directions.

3 Japanese Standards Association, 1-24, Akasaka 4 Chome, Minato-ku, Tokyo 107, Japan

4 This standard is currently being revised by a committee of The American Society of Mechanical Engineers, United Engineering Center, 345 E. 47th St., New York, NY 10017. In this draft revision, terminology is collected in a document designated B46.1.1; this document should be referred to in connection with additional terms related to surface roughness. Note that the nomenclature and symbols in ASME B46.1.1 may differ from those employed herein. Also note that ASME B46.1.1 is still under development, and the terms and definitions therein may change prior to approval by ASME and ANSI.

5 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

6 ISO Central Secretariat, C.P. 56, CH-1211 Geneve 20 Switzerland; available in the U.S. from American National Standards Institute, 11 West 42nd Street, 13th Floor, New York, NY 10036

3.3.3.1 Discussion: Anisotropic etches are used to determine crystal orientation, to fabricate micromechanical structures, and to facilitate dielectric component isolation.

3.3.4 *azimuth, in ellipsometry* — the angle between the major axis of the ellipse and the plane of incidence.

3.3.5 *backside* — not preferred, use *back surface* as defined in ASTM Terminology F 1241.

3.3.6 *bipolar* — semiconductor device fabrication technology which produces transistors that use both holes and electrons as charge carriers.

3.3.7 *carrier, in semiconductor materials* — an entity capable of carrying electric charge through a solid, for example, valence holes and conduction electrons in semiconductors; charge carrier.

3.3.8 *chem-mechanical polish, in semiconductor technology* — a process for the removal of surface material from the wafer which uses chemical and mechanical actions to achieve a mirror-like surface for subsequent processing.

3.3.9 *chuck mark* — any physical mark on either surface of a wafer caused by a robotic end effector, chuck, or wand.

3.3.10 *cleavage plane* — a crystallographically preferred fracture plane.

3.3.11 *conductivity (electrical)* — a measure of the ease with which charge carriers flow in a material; the reciprocal of resistivity.

3.3.11.1 Discussion: In a semiconductor, the conductivity is proportional to the product of free carrier density, electron electrical, and carrier mobility. Most variant of all crystal properties, conductivity can range over 13 orders of magnitude. Conductivity can be locally modified by temperature, carrier injection, irradiation, or magnetic field. Symbol is σ and units are $(\Omega\bullet cm)^{-1}$.

3.3.12 *conductivity type, of a semiconductor crystal or wafer* — a property that identifies the majority charge carrier in the semiconductor; see also *n-type*, *p-type*.

3.3.13 *contaminant, particulate* — see *light point defect*.

3.3.14 *contamination, area* — matter, unintentionally added to the surface of a wafer, of extent greater than a single localized light scatterer.

3.3.14.1 Discussion: Area contamination may be foreign matter on the wafer surface resulting from chuck marks, finger or glove prints, stains, wax or solvent residues, etc.

3.3.15 *contamination, particulate* — a particle or particles on the surface of a wafer.

3.3.16 *crystal defect* — departure from the ideal arrangement of atoms in a crystal.

3.3.17 *crystal indices* — see *Miller indices*.

3.3.18 *crystallographic notation* — a symbolism based on Miller indices used to label planes and directions in a crystal as follows:

plane	(111)
family of planes	{111}
direction	[111]
family of directions	<111>

3.3.19 *depletion layer* — a region in which the mobile carrier charge density is not sufficient to neutralize the net fixed charge density of donors and acceptors; barrier layer; blocking layer; space-charge layer.

3.3.20 *dimple* — a shallow depression with gently sloping sides that exhibits a concave, spheroidal shape and is visible to the unaided eye under proper lighting conditions.

3.3.21 *donor* — an impurity or imperfection in a semiconductor which donates electrons to the conduction band, leading to electron conduction.

3.3.22 *dopant* — a chemical element, usually from the third or fifth columns of the periodic table, incorporated in trace amounts in a semiconductor crystal to establish its conductivity type and resistivity.

3.3.23 *doping* — addition of specific impurities to a semiconductor to control the electrical resistivity.

3.3.24 *edge exclusion area* – the area between the FQA and the actual periphery of the wafer. The area varies with the actual dimensions of the wafer.

3.3.25 *edge exclusion, nominal* (EE) – the distance from the FQA boundary to periphery of a wafer of nominal dimensions.

3.3.26 *edge profile* — on edge contoured wafers (whose edges have been shaped chemically or mechanically), a description of the contour of the boundary of the wafer that joins the front and back surfaces.

3.3.27 *etch* — a solution, a mixture of solutions, or a mixture of gases that attacks the surfaces of a film or substrate, removing material either selectively or nonselectively; see also *anisotropic etch*, *preferential etch*.

3.3.28 *fixed quality area (FQA)* — the central area of a wafer surface, defined by a nominal edge exclusion, *EE*, over which the specified values of a parameter apply.

3.3.28.1 Discussion: The boundary of the FQA is at all points the distance *EE* away from the periphery of a wafer of nominal dimensions. (See Figure 1.) The size of the FQA is independent of wafer diameter and flat length tolerances. For the purposes of defining the FQA, the periphery of a wafer of nominal dimensions at locations with notch fiducials is assumed to follow the circumference of a circle with diameter equal to the nominal wafer diameter. It may be necessary to specify exclusion areas where the values of a specified parameter do not apply for regions like: the notch, laser marks, or where handling/gripping devices contact the wafer.

3.3.29 *flat, on a semiconductor wafer* — a portion of the periphery of a circular wafer that has been removed to a chord; see also *primary orientation flat*, *secondary flat*.

3.3.30 *flat diameter* — the linear dimension across the surface of a semiconductor wafer from the center of the flat through the wafer center to the circumference of the wafer on the opposite edge along the diameter perpendicular to the flat. (See Figure 3.)

3.3.30.1 Discussion: The flat diameter may be associated with the primary orientation flat, with a secondary flat, if present, or with any other flat, if present. In such cases, the term may be modified as primary orientation flat diameter, *secondary flat diameter*, etc. In the case of opposing primary orientation and secondary flats, as occurs on [100] *n*-type wafers 125 mm and smaller in diameter, the concept of flat diameter does not apply because the diameter perpendicular to the flats does not intersect the wafer circumference.

3.3.31 *flatness* — for wafer surfaces, the deviation of the front surface, expressed in TIR or maximum FPD relative to a specified reference plane when the back surface of the wafer is ideally flat, as when pulled down by a vacuum onto an ideally clean flat chuck.

3.3.31.1 Discussion: The flatness of a wafer may be described as either:

1. The global flatness, or
2. The maximum value of site flatness as measured on all sites, or
3. The percentage of sites which have a site flatness equal to or less than a specified value.

3.3.32 *focal plane* — the plane perpendicular to the optical axis of an imaging system which contains the focal point of the imaging system.

3.3.32.1 Discussion: The reference plane used by an imaging system is coincident with or parallel with the focal plane. Full field imaging systems employ coincident global focal and reference planes. Partial field imaging systems employ either coincident site focal and reference planes or displaced site focal and global reference planes. If the reference plane is not coincident with the focal plane, it is displaced from the focal plane so that the point on the front surface at a site center lies in the focal plane.

3.3.33 *focal plane deviation (FPD)* — the distance parallel to the optical axis from a point on the wafer surface to the focal plane.

3.3.34 *four-point probe* — an electrical probe arrangement for determining the resistivity of a material in which separate pairs of contacts are used (1) for passing current through the specimen and (2) measuring the potential drop caused by the current.

3.3.35 *front side* — not preferred; use *front surface* as defined in ASTM Terminology F 1241.

3.3.36 *global flatness* — the TIR or the maximum FPD relative to a specified reference plane within the FQA.

3.3.37 *goniometer* — an instrument to measure angles.

3.3.37.1 Discussion: Goniometers are frequently used with x-ray diffraction equipment to measure crystal axis angles or for optical angle measurement.

3.3.38 *gradient, resistivity* — not preferred; see *resistivity variation*.

3.3.39 *groove, in a semiconductor wafer* — a shallow scratch with rounded edges that is usually the remnant of a scratch not completely removed by polishing.

3.3.40 *haze* — non-localized light-scattering resulting from surface topography (microroughness) or from dense concentrations of surface or near-surface imperfections; see also *laser light-scattering event*.

3.3.40.1 Discussion: Haze due to the existence of a collection of imperfections is a mass effect; individual imperfections of the type which result in haze cannot be readily distinguished by the eye or other optical detection system without magnification. In a particle counter, haze results in a background signal; this signal and laser light-scattering events together comprise the signal due to light-scattering from a wafer surface.

3.3.41 *hole* — a mobile vacancy in the electronic valence structure of a semiconductor which acts like a positive electron charge with positive mass; the majority carrier in *p*-type material.

3.3.42 *ingot, in silicon technology* — a cylinder or rectangular solid of polycrystalline or single crystal silicon, generally of slightly irregular dimensions.

3.3.42.1 Discussion: Silicon wafers are usually sliced from cylindrical single-crystal ingots that have been ground to a uniform diameter prior to slicing.

3.3.43 *laser light-scattering event* — a signal pulse that exceeds a preset threshold, generated by the interaction of a laser beam with a discrete scatterer at a wafer surface as sensed by a detector; see also *haze*.

3.3.43.1 Discussion: The amplitude of the signal, as measured by any combination of incidence orientation and collection orientation, does not convey topographic information (i.e., pit or particle). It does not allow the observer to deduce the size or origin of the scatterer without other detailed knowledge, such as its index of refraction and shape. In a particle counter, the background signal due to haze and laser light-scattering events together comprise the signal due to light-scattering from a wafer surface.

3.3.44 *lay* — the predominant direction of the surface texture.

3.3.44.1 Discussion: Although the texture of polished silicon wafers is generally isotropic, some epitaxial wafers exhibit a pattern of steps and ledges when examined by atomic force microscopy at near atomic resolution. Contoured wafer edges may also exhibit lay even after polishing.

3.3.45 *light point defect (LPD)* — not preferred, see *localized light-scatterer (LLS).*

3.3.45.1 Discussion: To some, the term light point defect implies a defective part; hence, a search was undertaken for a more neutral term. Several were tried, and finally, despite some objection to the difficulty of saying the code, the term localized light scatterer was approved as a replacement. This term is general in nature and can refer to features detected both visual inspection and by automated inspection using a scanning laser system.

3.3.46 *localized light-scatterer (LLS)* — an isolated feature, such as a particle or a pit, on or in a wafer surface, resulting in increased light-scattering intensity relative to that of the surrounding wafer surface; sometimes called light point defect.

3.3.46.1 Discussion: Localized light scatterers of sufficient size appear as points of light under high intensity optical illumination; these points of light can be observed visually, but the observation is a qualitative one. Localized light scatterers are observed by automated inspection techniques as laser-light scattering events. Automated inspection techniques are quantitative in the sense that scatterers with different scattering intensities can be segregated. However, the amplitude of the scattered light intensity (laser light-scattering event), as measured by any combination of incident beam direction and collection optics, does not by itself convey topographical information; particles and pits cannot be distinguished solely on the basis of amplitude data. Also, the observer cannot deduce the size or shape of the LLS from the signal amplitude alone. The presence of LLS's does not necessarily decrease the utility of the wafer.

3.3.47 *lot* — for the purposes of this document, (a) all of the wafers of nominally identical size and characteristics contained in a single shipment, or (b) subdivisions of large shipments consisting of wafers as above which have been identified by the supplier as constituting a lot.

3.3.48 *majority carrier* — type of charge carrier constituting more than one half the total charge-carrier concentration (e.g., holes in *p*-type material).

3.3.49 *maximum FPD* — the largest of the absolute values of the focal plane deviations.

3.3.50 *microroughness* — surface roughness components with spacing between irregularities (spatial wavelength) less than about 100 µm.

3.3.51 *Miller indices, of a crystallographic plane* — the smallest integers proportional to the reciprocals of the intercepts of the plane on the three crystal axes of unit length.

3.3.52 *minority carrier* — type of charge carrier constituting less than one half the total charge-carrier concentration (e.g., electrons in *p*-type material).

3.3.53 *notch, on a semiconductor wafer* — an intentionally fabricated indent of specified shape and dimensions oriented such that the diameter passing through the center of the notch is parallel with a specified low index crystal direction.

3.3.54 *orthogonal misorientation* — in wafers cut intentionally "off orientation," the angle between the projection of the vector normal to the wafer surface onto a {111} plane and the projection on that plane of the nearest <100> direction. (See Figure 2.)

3.3.55 *particle* — a small, discrete piece of foreign material or silicon not connected crystallographically to the wafer.

3.3.55.1 Discussion: Particles may be pieces of solid material or condensate from liquids or gases. Particles are observed by automated inspection as laser light-scattering events, but they may also be observed visually under high intensity illumination as points of light or studied by other methods, including scanning electron microscopy. Particles on wafer surfaces can usually be removed by non-etching cleaning.

3.3.56 *point defect* — a localized crystal defect such as a lattice vacancy, interstitial atom, or substitutional impurity. Contrast with *light point defect*.

3.3.57 *preferential etch* — a selective etch that etches regions of different crystal strain or conductivity at different rates, used to delineate crystal defects or regions of differing conductivity on wafer surfaces.

3.3.58 *primary orientation flat* — the flat of longest length on the wafer, oriented such that the chord is parallel with a specified low index crystal plane; *major flat*.

3.3.59 *profilometer* — an instrument for measuring the topographical profile of a surface.

3.3.60 *rms microroughness* (R_q) — the root mean square of the surface profile height deviations Z(x) from the mean line taken within the evaluation Length L.

3.3.60.1 Discussion: *rms microroughness,* R_q is one of several statistical metrics which can be used to describe a surface profile; definitions for other metrics and for such concepts as mean line, evaluation length, and power spectral density function, may be found in ANSI/ASME B46.1 and ISO 4287/1.

3.3.60.2 The function R_q is related to a one-dimensional measurement of the surface profile as follows:

$$R_q = \left[\frac{1}{L} \int_0^L Z(x)^2 dx \right]^{1/2}$$

3.3.60.3 The digital approximation of R_q for a profile consisting of N equally spaced points is:

$$R_q = \left[\frac{1}{N} \sum_{i=1}^{N} Z_i^2 \right]^{1/2}$$

3.3.60.4 Experimentally, the profile is always limited by the spatial bandwidth of the measurement. For a profile of length L, consisting of N equally spaced points, the lower spatial frequency limit f_1 can never be less than $1/L$ and the upper spatial frequency limit f_2 can never be greater than the Nyquist limit, $N/2L$. In practical cases, $f_1 \approx 2/L$; the achievable value of f_2 depends on instrumental parameters.

3.3.60.5 R_q can also be estimated by integrating the one-dimensional power spectral density (PSD) function, *PSD(f)*, over the spatial frequency range between two spatial frequencies, f_1 and f_2, which lie within the bandwidth of the measurement:

$$R_q = \left[\int_{f_1}^{f_2} PSD(f) \mathrm{d}f \right]^{1/2}$$

3.3.60.6 In all cases, R_q must be reported together with the lower and upper limits, f_1 and f_2, respectively, of the spatial frequency bandwidth over which it has been determined. Alternatively, the spatial bandwidth may be expressed in terms of the upper and lower spatial wavelengths, λ2 (=1/f_2) and λ1 (=1/f_1), respectively.

3.3.61 *rms area microroughness,* (R_{qA}) — the root mean square of the topographic deviations of a surface Z(x,y) from the mean surface taken within the evaluation area A_e (=L_xL_y).

3.3.61.1 Discussion: The rms area microroughness is one of several statistical metrics which can be used to describe surface topography; definitions for other metrics and for such concepts as mean surface and evaluation area may be found in ANSI/ASME B46.1 and ISO 4287/1.

3.3.61.2 The function R_{qA} is related to a two-dimensional measurement of the surface profile as follows:

$$R_{qA} = \left[\frac{1}{A_e} \int_0^{L_x} \int_0^{L_y} Z(x,y)^2 \ \mathrm{d}x\mathrm{d}y \right]^{1/2}$$

3.3.61.3 The digital approximation of R_{qA} for a surface profile consisting of N by M data points equally spaced along the x and y directions, respectively, is:

$$R_{qA} = \left[\frac{1}{NM} \sum_{i=l}^{M} \sum_{j=l}^{N} Z_{ij}^2 \right]^{1/2}$$

3.3.61.4 Experimentally, the profile is always limited by the spatial bandwidth of the measurement. In the x direction, the profile length is Lx divided into N equally spaced points; the lower spatial frequency limit for fx can never be less than $1/L_x$ and the upper spatial frequency limit can never be greater than the Nyquist limit, $N/2L_x$. Similarly, in the y direction, the profile length is L_y divided into M equally spaced points; the lower frequency limit for f_y can never be less than $1/L_y$ and the upper spatial frequency limit can never be greater than the Nyquist limit, $M/2L_y$. Practical limits to the spatial bandwidth are governed by considerations similar to those for the one-dimensional case (see Discussion under *rms microroughness*).

3.3.61.5 R_{qA} can also be estimated by integrating the two-dimensional power spectral density (PSD) function, $PSD(f_x, f_y)$, over the spatial frequency range between spatial frequencies which lie within the bandwidth of the measurement:

$$R_{qA} = \left[\int_{f_{x1}}^{f_{x2}} \int_{f_{y1}}^{f_{y2}} PSD_A(f_x, f_y)\, df_x df_y \right]^{1/2}$$

3.3.61.6 If the surface is assumed to be isotropic and the instrument response function is neglected, the rms microroughness over the spatial frequency range between f_1 and f_2 can also be obtained by integrating the isotropic PSD function:

$$R_{qA} = \left[\int_{f_1}^{f_2} PSD_{iso}(f)\, df \right]^{1/2}$$

where $PSD_{iso}(f) = \int_0^{2\pi} PSD_A(f_x, f_y) f\, d\beta = 2\pi f\, PSD_A(f_x, f_y)$ and $f = (f_x^2 + f_y^2)^{1/2}$.

3.3.62 *radial gradient* — not preferred; see *resistivity variation*.

3.3.63 *reference plane* — a plane defined by one of the following:

1. Three points at specified locations on the front surface of the wafer, or
2. The least squares fit to the front surface of the wafer using all points within the FQA, or
3. The least squares fit to the front surface of the wafer using all points within a site, or
4. An ideal back surface (equivalent to the ideally flat chuck surface that contacts the wafer).

3.3.63.1 Discussion: The specified reference plane should be chosen with due regard for the capabilities of the imaging system. Front surface or back surface reference planes should be selected depending on the wafer mounting system. If the wafer cannot be gimbaled in the imaging system, a back surface reference plane should be specified.

3.3.64 *resistivity, (electrical)* — the measure of difficulty with which charged carriers flow through a material; the reciprocal of *conductivity*.

3.3.64.1 Discussion: the resistivity of a semiconductor or other material is the ratio of the potential gradient (electric field) parallel with the current to the current density. Symbol is σ and units are $(\Omega \bullet cm)^{-1}$.

3.3.65 *roughness* — the more narrowly spaced components of surface texture.

3.3.65.1 Discussion: These components are considered within defined limits of spatial wavelength (or frequency).

3.3.66 *scan direction* — the direction of successive subsites in a scanner site flatness calculation.

3.3.66.1 Discussion: The scanner site flatness value obtained for a site may depend on scan direction.

3.3.67 *scanner site flatness* — the maximum subsite TIR or the maximum subsite FPD, of a site. The subsite TIR is the TIR of the portion of the subsite that falls within the FQA and within the site; the subsite FPD is the maximum FPD of the portion of the subsite that falls within the FQA and within the site. The reference plane is calculated using all points within the subsite that fall within the FQA.

3.3.67.1 Discussion: Precise scanner site flatness measurement requires measurement points located closely enough to reveal the surface topography in detail. It is recommended that the scanner site flatness be measured using a data point array with adjacent points separated by 1 mm or less.

3.3.68 *secondary flat* — a flat of length shorter than the primary orientation flat, whose position with respect to the primary orientation flat identifies the type and orientation of the wafer.

3.3.69 *shape* — for wafer surfaces, the deviation of a specified wafer surface relative to a specified reference plane when the wafer is in an unclamped condition, expressed as the range or total indicator reading (TIR) or as the maximum reference plane deviation (maximum RPD) within the specified fixed quality area.

3.3.69.1 Discussion: This definition is analogous to the definition of flatness, which applies to the front surface geometry when the wafer is in the clamped condition.

3.3.70 *site* — a rectangular area, on the front surface of the wafer, whose sides are parallel and perpendicular to the primary orientation flat or to the notch bisector, and whose center falls within the FQA.

3.3.71 *site array* — a set of contiguous sites.

3.3.72 *site flatness* — the TIR or the maximum FPD of the portion of a site which falls within the FQA.

3.3.72.1 Discussion: Precise site flatness measurement requires measurement points located closely enough to reveal the surface topology in detail. It is recommended that site flatness be measured using a data point array with adjacent points separated by 2 mm or less. It is also recommended that the data set used to calculate site flatness have data at each site corner and along each site boundary. This makes the effective site measurement area equal to the site size.

3.3.73 *smudge* — dense local area of contamination usually caused by handling or fingerprints.

3.3.74 *sori* — the difference between the maximum positive and maximum negative deviations of the front surface of a wafer that is not chucked from a reference plane that is a least-squares fit to the front surface.

3.3.75 *subsite, of a site* — a rectangular area, Lss × Wss, on the front surface of a wafer, associated with a particular site. The center of the subsite must be within the site. Some part of the subsite must be within or on the FQA boundary. A subsite corresponds to the instantaneous area exposed by a scanning stepper (see Figures 8 and 9).

3.3.76 *surface texture* — the topographic deviations of a real surface from a reference surface.

3.3.76.1 Discussion: Surface texture includes roughness, waviness, and lay.

3.3.77 *total indicator reading (TIR)* — the smallest perpendicular distance between two planes, both parallel with the reference plane, which encloses all points on the front surface of a wafer within the FQA, the site, or the subsite, depending on which is specified.

3.3.78 *waves* — uneven contours in the surface of a wafer visible to the unaided eye under large-area diffuse illumination.

3.3.79 *waviness* — the more widely spaced component of surface texture.

3.3.79.1 Discussion: Waviness may be caused by such factors as machine or work piece deflections, vibration, and chatter. Roughness may be considered as superimposed on a wavy surface.

4 Wafer Ordering Information

4.1 Purchase orders for silicon wafers furnished to this specification shall include the following items:

4.1.1 Nominal diameter (see applicable polished silicon wafer standard).

4.1.2 Crystal growth method (see NOTE 4).

4.1.3 Surface orientation (see applicable polished silicon wafer standard).

4.1.4 Conductivity type (see applicable polished silicon wafer standard) and dopant (see NOTE 4).

4.1.5 Resistivity or resistivity range.

4.1.6 Lot acceptance procedures (see Section 8).

4.1.7 Certification (if required) (see Section 11).

4.1.8 Packing and marking (see Section 12).

4.1.9 Selection of test method to be used in evaluating those items for which alternate tests exist (see Section 9).

4.2 *Optional Criteria* — The following items may be specified optionally in addition to those listed above.

4.2.1 Doping method and thermal treatment (see NOTE 4).

4.2.2 Radial resistivity variation.

4.2.3 Crystal perfection.

4.2.4 Impurities other than common intentionally added dopant elements, such as interstitial atomic oxygen and substitutional carbon or in heavily doped n-type silicon, boron contamination.

4.2.5 Surface metal contaminants.

4.2.6 *Flatness* — The following conditions must be specified in connection with flatness measurement:

A. Type of Measurement
   1. Global flatness
   2. Maximum site flatness
   3. Percentage of sites within specification

B. Parameter: TIR or maximum FPD

C. Nominal Edge Exclusion: X

D. For site flatness (where specified):
   1. Site dimensions: x_{site} and y_{site} are relative to the SEMI M20 wafer coordinate system. The first site dimension listed in a site flatness specification shall be the x_{site} and the second dimension shall be the y_{site}.

2. Array offsets: x_{array} and y_{array} relative to FQA center and to the SEMI M20 wafer coordinate system.

NOTE 3: The array offsets are composed of the distance x_{array} and the distance y_{array} between the center of the wafer and the corner of the site that is nearest the wafer center.

E. Reference Plane:

1. Three point (also, specify point locations)
2. Least squares fit to the front surface within the FQA
3. Least squares fit to the front surface within a site
4. Ideal back surface

F. Focal Plane:

1. Global
2. Site

4.2.7 Edge contour

4.2.8 Hall or conductivity mobility (see NOTE 5).

4.2.9 Diffusion length (see NOTE 5).

4.2.10 Minority carrier lifetime (see NOTE 5).

NOTE 4: The dopant, crystal growth method (for example, Czochralski or floating zone), and doping method (for example, ion implantation or neutron transmutation) with subsequent heat treatment are difficult to ascertain in the finished wafers. Verification test procedures or certification of these characteristics (see Section 11) shall be agreed upon between the user and supplier.

NOTE 5: Items 4.2.7, 4.2.8, and 4.2.9 are less commonly specified than the others, but are included for completeness as parameters for which methods of evaluation have been developed.

5 Dimensions and Permissible Variations

5.1 The material shall conform to the dimensions and dimensional tolerances as specified in the polished silicon wafer standard applicable to the specified nominal diameter.

NOTE 6: Wafers of the same nominal diameter may typically have different dimensional configurations in different regions of the world. Many of these configurations are represented in this specification. In selecting the appropriate polished wafer standard, consideration should be given to compatibility with processes and equipment generally available in the region of use.

5.1.1 Sori is an attribute that may be specified between the user and supplier in lieu of bow or warp or both.

5.1.2 If bow is specified, a sign may be included in the specification to denote convex (positive) or concave (negative) curvature of the median surface of the wafer with the front surface up. If no sign is included in the specification, bow may vary between -a and +a, where “a” is the specified maximum magnitude of bow.

5.2 If edge-contoured wafers are specified on the purchase order, the profile shall conform to the following requirements at all points on the wafer periphery (except interior portions of notches, if present).

5.2.1 When the wafer is aligned with the SEMI Wafer Edge Profile Template (see Figure 4) so that the x-axis of the template is coincident with the wafer surface and the y-axis of the template is tangent with the outermost radial portion of the contour, the wafer edge profile must be contained within the clear region of the template. (See Figure 5 for examples of acceptable and unacceptable contours.)

5.2.2 No sharp points or protrusions are permitted anywhere on the wafer edge contour.

5.2.3 Cosmetic attributes of the edge contour are not covered by this specification. They shall be agreed upon between user and supplier.

5.3 Fiducial indications shall conform to the requirements of the appropriate polished silicon wafer standard.

5.3.1 Where secondary flats are specified, they shall be located as shown in Figure 6.

5.3.2 Where notches are specified, they shall conform to the dimensions in Figure 7.

5.4 Where alphanumeric marking is specified, the code character properties and code field location shall conform to SEMI M13 or to SEMI M12. Where back surface bar code marking is specified, the code symbol and its location shall conform to SEMI T1. Where two-dimensional matrix code marking is specified, the code symbol and its location shall conform to SEMI T2.

6 Materials and Manufacture

6.1 The material shall consist of wafers from ingots grown by the process specified in the purchase order or contract.

7 Physical Requirements

7.1 The material shall conform to the crystallographic orientation details as specified in the appropriate polished silicon wafer standard.

7.1.1 For ion implant applications, the following tolerance issues should be considered:

7.1.1.1 For general use where channeling is to be avoided, the current wafer orientation specification of ± 1.0° deviation from the [100] axis (perpendicular to the

(100) plane of the wafer) is adequate. This specification is suitable for minimum channeling applications, provided that the appropriate ion implant equipment angle settings are employed.

7.1.1.2 Uniform, maximum channeling along the [100] axis perpendicular to the (100) wafer surface is strongly dependent on strict adherence to a 0° tilt angle. To achieve maximum channeling, crystallography requires the orientation to be within ± 0.1° of a <100> direction. Also, the user must remove all overlying oxide, nitride, poly, etc., layers from the wafer prior to a channeling implant. The user must maintain very rigid control of the ion implant equipment angle setting in order to achieve maximum channeling across the wafer.

7.1.1.3 The tolerance of ± 0.1° is derived from experimental ion implant profile data and ion implant modeling activity for implants into (100) silicon wafers. The ranges for which data was obtained are:

Species	*Energy Range (keV)*
B	15–80
BF_2	15–65
As	15–180

7.2 The material shall conform to the details specified in the purchase order or contract, as follows:

7.2.1 Conductivity type and dopant (see NOTE 4),

7.2.2 Resistivity,

7.2.3 Doping methods and thermal treatment (see NOTE 4),

7.2.4 Radial resistivity variation,

7.2.5 Crystal perfection,

7.2.6 Amounts of impurities other than common dopants,

7.2.7 Hall or conductivity mobility,

7.2.8 Diffusion length, and

7.2.9 Minority-carrier lifetime.

7.3 The material shall conform to the limits on visually observable surface defects specified in Table 1. If surface metal contamination levels are specified on the purchase order, the maximum area densities shall be designated in units of atoms/cm^2 for specific individual elements (see Related Information 1).

8 Sampling

8.1 Unless otherwise specified, ASTM Practice E 122 shall be used to define the sampling plan. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) or lot tolerance percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL or LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

9 Test Methods

NOTE 7: Silicon wafers are extremely fragile. While the mechanical dimensions of a wafer can be measured by use of tools such as micrometer calipers and other conventional techniques, the wafer may be damaged physically in ways that are not immediately evident. Special care must, therefore, be used in the selection and execution of measurement methods.

9.1 *Diameter* — Determine in accordance with ASTM Test Method F 613 or DIN 50441/4.

9.2 *Thickness, Center Point* — Determine in accordance with ASTM Test Method F 533, ASTM Test Method F 1530, or DIN 50441/1.

9.3 *Flat Length* — Determine in accordance with ASTM Test Method F 671.

9.3.1 If flat diameter is specified instead of flat length, determine in accordance with Paragraph 6.2.1 of DIN 50441/4 or by a dial gauge method as agreed upon between the user and supplier.

9.4 *Bow and Warp* — Determine bow in accordance with ASTM Test Method F 534 and warp in accordance with ASTM Test Method F 1390 or Test Method F 657.

NOTE 8: ASTM has standardized two methods for measuring warp. ASTM Test Method F 1390 is an automated, noncontact method which provides for correction of the wafer deflection due to gravitational effects. The scan pattern covers the entire fixed quality area. ASTM Test Method F 657 is a manual, noncontact method which has a continuous, prescribed scan pattern which covers only a portion of the wafer surface. There is no provision for correction of the wafer deflection due to gravitational effects. As noted in Appendix 2, different reference planes are used for the two methods. Because Test Method F 657 employs a back surface reference plane, the measured warp may include contributions from thickness variation of the wafer. Test Method F 1390 employs a median surface reference plane and is not susceptible to interferences from thickness variations. In general, Test Method F 1390 is preferred, especially for wafers 150 mm in diameter and larger.

9.4.1 *Sori* — If sori is specified in lieu of bow or warp or both, determine in accordance with Test Method F 1451.

9.5 *Total Thickness Variation* — Determine in accordance with ASTM Test Method F 533, ASTM

Test Method F 657, ASTM Test Method F 1530, DIN 50441/1, or JIS H 0611.

NOTE 9: ASTM Test Method F 533, DIN 50441/1 and JIS H 0611 are all 5 point methods, while Test Method F 657 involves a continuous scan pattern over a portion of the wafer surface and Test Method F 1530 involves an automated continuous scan pattern over the entire wafer surface. JIS H 0611 differs from ASTM Test Method F 533 and DIN 50441/1, in that the measurements in JIS H 0611 are taken at the center and at 5 mm from the edge on diameters parallel and perpendicular to the primary orientation flat or notch bisector, while the measurements in ASTM Test Method F 533 and DIN 50441/1 are taken at the center and at the same radial distance ($R_{nominal}$ -6 mm) on diameters 30 degrees and 120 degrees counterclockwise from the bisector to the primary orientation flat or notch (with the wafer facing front surface up).

9.6 *Flat Orientation* — Determine in accordance with ASTM Test Method F 847.

9.7 *Surface Orientation* — Determine in accordance with ASTM Test Method F 26 or DIN 50433.

9.8 *Orthogonal Misorientation* — Determine by a method agreed upon between the user and supplier.

9.9 *Surface Defects and Contamination*

9.9.1 *Visually Observable Surface Defects* — Determine in accordance with ASTM Practice F 523. The following conditions shall be used:

a. Background light intensity: 8 ± 2 fc (86 ± 22 lux),

b. Angle (alpha): 45° ± 10°, and

c. Angle (beta): 90° ± 10°.

See Section 10 for surface defect minimal conditions or dimensions and Table 1 for allowable limits. In the event the wafers fail to meet these criteria, they may be conditioned according to a procedure as agreed upon between user and supplier and retested.

9.9.2 *Surface Metal Contamination* — Determine by a method or methods agreed upon between the supplier and the purchaser.

NOTE 10: ASTM Methods F 1526 and F1617 can be used to measure surface contamination levels of selected metals (see Related Information 1). ASTM Practices F 154 are useful guides for defining a variety of surface features found on silicon surfaces and for establishing commonly understood terms for describing them. It also gives detailed procedures for illumination and microscopical examination of surfaces. The presence of contaminating materials on silicon surfaces can be determined by ASTM Methods F 21 or F 22, as appropriate.

9.10 *Conductivity Type* — Determine in accordance with ASTM Test Method F 42 or DIN 50432.

9.11 *Resistivity* — Determine by methods agreed upon between the user and supplier.

NOTE 11: Resistivity of wafers is most appropriately determined for referee purposes by ASTM Method F 84 or DIN 50431. Under some circumstances these tests may be considered destructive, and an alternative means may be required. One nondestructive test is ASTM Test Method F 673, having a range from 0.0001 to 100 ohm cm. Another nondestructive test is ASTM Test Method F 398. This method is limited to carrier concentrations in the ranges from 1.5×10^{18} to 1.5×10^{21} cm^{-3} for *n*-type silicon and from 3×10^{18} to 5×10^{20} cm^{-3} for *p*-type, and has only moderate inter-laboratory precision. Other available methods include ASTM Test Method F 43 or DIN 50430 (referee methods requiring a bar-shaped sample) and ASTM Test Method F 419 (which is destructive, and of limited range).

9.12 *Radial Resistivity Variation* — Determine in accordance with ASTM Method F 81 or DIN 50435.

9.13 *Crystal Perfection* — Determine in accordance with ASTM Test Method F 47, DIN 50434, or JIS H 0609 (to determine grain boundaries, twinning, slip, dislocations, and lineage) and ASTM Test Method F 416 (to determine oxidation-induced defects).

9.14 *Other Impurities* — Determine by methods agreed upon between the user and supplier.

NOTE 12: ASTM Test Methods F 1188 and F 1619 and DIN 50438/1 are specific tests for oxygen in silicon, and ASTM Test Method F 1391 and DIN 50438/2 are specific tests for carbon in silicon; the test specimen cannot be heavily doped, and special thick test specimens may be necessary. ASTM Test Method F 1366 is a specific test for oxygen in heavily doped silicon. Radial variation of oxygen in silicon may be determined in accordance with ASTM Test Method F 951. Boron contamination in heavily doped *n*-type silicon can be determined in accordance with ASTM Test Method F 1528.

9.15 *Flatness* — Determine in accordance with ASTM Test Method F 1530 or by another method as agreed upon between the supplier and the purchaser.

9.15.1 For scanning site flatness, orient the wafer so the effective Scan Direction is along the wafer's Y-axis. For scanning site flatness, subsite width, Wss, shall be 8 mm.

9.16 *Edge Contour* — Determine in accordance with ASTM Test Methods F 928 or DIN 50441/2.

9.17 *Mobility* — If Hall mobility is specified, determine in accordance with ASTM Test Methods F 76; if conductivity mobility is specified, determine by a method agreed upon between the user and supplier.

9.18 *Diffusion Length* — Determine in accordance with ASTM Test Method F 391.

9.19 *Minority Carrier Lifetime* — Determine in accordance with ASTM Method F 28, ASTM Test Method F 1535, or DIN 50440/1.

NOTE 13: These test methods determine minority carrier lifetime only when the measurement is made in low injection conditions. ASTM Test Method F 28 and DIN 50440/1 both require the use of special test specimens; ASTM Test Method F 1535 is applicable to measurements on wafers but special surface passivation procedures may be required to obtain meaningful results. Minority carrier lifetime may also be inferred from measurements made in accordance with ASTM Test Method F 1388. This method yields generation lifetime if the measurements are made at or near room temperature and recombination lifetime if they are made at slightly elevated temperature (50 to 75°C). The test specimens required for Test Method F 1388 can be made by procedures which are compatible with typical wafer processing.

10 Standard Defect Limits

10.1 Minimal conditions or dimensions for surface defects are stated below. These limits shall be used for determining wafer acceptability; anomalies smaller than these limits shall not be considered defects.

10.1.1 *area contamination* — Any foreign matter on the surface in localized areas which is revealed under the inspection lighting conditions as discolored, mottled, or cloudy appearance resulting from smudges, stains, water spots, etc.

10.1.2 *crack* — Any anomaly conforming to the definition and greater than 0.010 inch (0.25 mm) in total length.

10.1.3 *crater* — Any individually distinguishable surface anomaly conforming to the definition and visible when viewed under diffused illumination.

10.1.4 *crow's foot* — Any anomaly conforming to the definition and greater than 0.010 inch (0.25 mm) in total length.

10.1.5 *dimple* — Any smooth surface depression greater than 3 mm in diameter.

10.1.6 *edge chip and indent* — Any edge anomaly including saw exit marks conforming to the definition and greater than 0.010 inch (0.25 mm) in radial depth and peripheral length.

10.1.7 *groove* — Any anomaly conforming to the definition and greater than 0.0005 inch (0.13 mm) wide or 0.030 inch (0.76 mm) in length.

10.1.8 *haze* — Haze is indicated when the image of a narrow beam tungsten lamp filament is detectable on the polished wafer surface. (Under some conditions, contamination may appear as haze.)

10.1.9 *mound* — Any anomaly conforming to the definition and greater than 0.010 inch (0.25 mm) in maximum dimension.

10.1.10 *orange peel* — Any visually detectable roughened surface conforming to the definition and observable under diffused illumination.

10.1.11 *particulate contamination* — Distinct particles resting on the surface which are revealed under collimated light as bright points.

10.1.12 *pit* — Any individually distinguishable nonremovable surface anomaly conforming to the definition and visible when viewed under intense illumination.

10.1.13 *scratch* — Any anomaly conforming to the definition and having a length-to-width ratio greater than 5:1.

10.1.14 *striation* — Any feature conforming to the definition and detectable under diffused lighting conditions.

11 Certification

11.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

11.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 9. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

12 Packing and Marking

12.1 Special packing requirements shall be subject to agreement between the user and supplier. Otherwise, all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination and in accordance with the best industry practices to provide ample protection against damage during shipment.

12.2 The wafers supplied under these specifications shall be identified by appropriately labeling the outside of each box or other container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include as a minimum the nominal diameter, conductivity type, dopant, orientation, resistivity range, and lot number. The lot number, either (1) assigned by the original manufacturer of the wafers, or (2) assigned subsequent to wafer manufacture but providing reference to the original lot number, shall provide easy access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the manufacturer's facility for at least one month after that particular lot has been accepted by the user.

Table 1 Polished Wafer Defect Limits

Item	*Characteristics*	*Maximum Defect Limit*	*AQL (See NOTE 5.)*	*Illumination Conditions (See NOTE 7.)*	*NOTES*

19	ALL LISTED CHARACTERISTICS (Items 1 through 18)		Total 2.5%		

NOTE 1: The outer 0.062 inch (1.57 mm) annulus is excluded from these criteria.

NOTE 2: Accept/reject criterion shall be agreed upon between user and supplier for wafers which are not mechanically edge-rounded.

NOTE 3: Striations may be visible on low resistivity wafers (less than 0.020 ½ ¥ cm).

NOTE 4: The cumulative AQL for both front surface and back surface of wafer is 1.0%.

NOTE 5: Single, Normal, Level II Sampling Plan as defined in ANSI/ASQC Z1.4.

NOTE 6: Accept/reject criterion shall be agreed upon between user and supplier for non-lapped wafers.

NOTE 7: See ASTM Practice F 523 for definition of Illumination Conditions.

Point	*x*		*y*	
	in.	*µm*	*in.*	*µm*
A	0.0047	120	0.00	0
B	0.0200	508	0.00	0
C	0.0040	100	1/4 Nominal Wafer Thickness (See NOTE 2.)	
D	0.00	0	0.0020	50

NOTE 1: For referee purposes, U.S. Customary units are to be used for 2 and 3 in. diameter wafers. SI units are to be used for all other diameters.

NOTE 2: See the appropriate polished silicon wafer standard for numerical values.

NOTE 3: Only one-half of the template is shown; the wafer surface is aligned with the *x*-axis, and the outermost radial portion of the edge contour is aligned with the *y*-axis. The template in Figure 4 is not intended for use in measuring wafer thickness.

NOTE 4: Constant radius profile with blended, tangential front and back surface intercepts is preferred for ease of manufacture and reduced particle and chip generation.

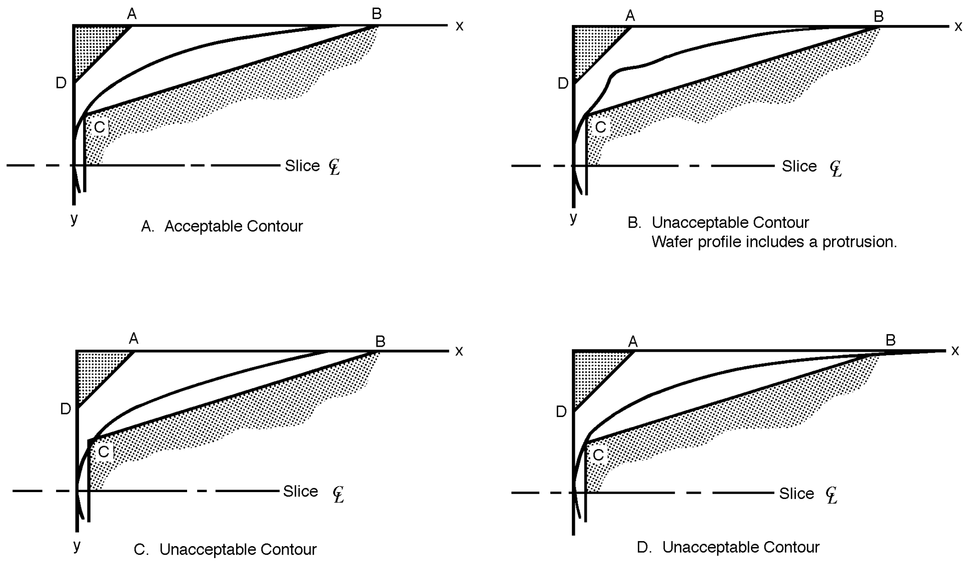

Figure 5
Examples of Acceptable and Unacceptable Wafer Edge Profiles

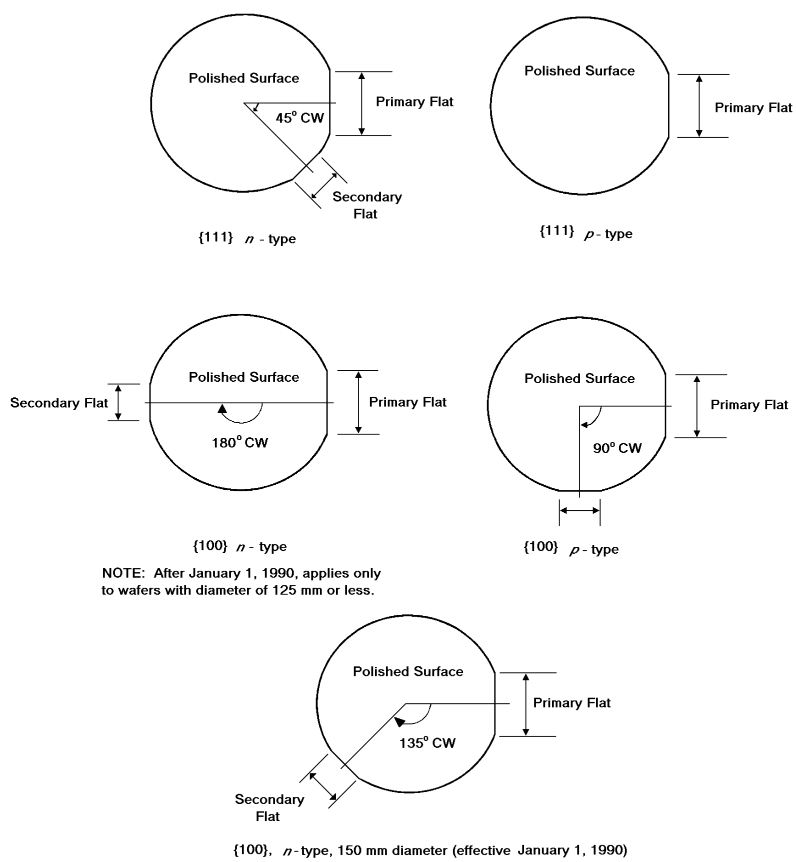

Figure 6
Secondary Flat Location

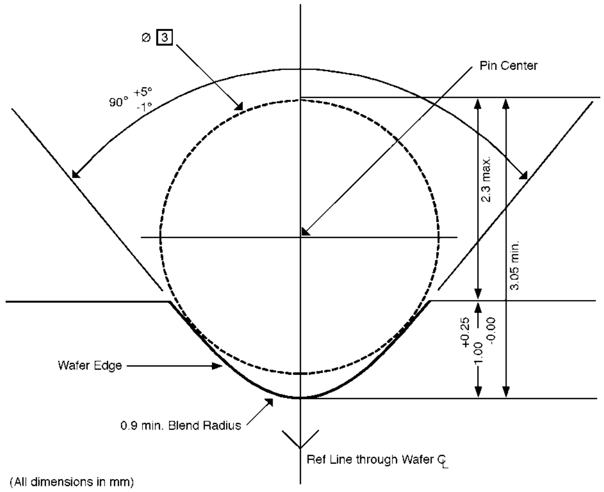

Figure 7
Notch Dimensions

12.3 For referee purposes, metric (SI) units apply. To ensure that the product shipped is within specification, any conversion to U.S. Customary Equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down, and the rightmost digit of the maximum values should be rounded up to avoid rejection of the material that is within the specification when measured by the referee system of units.

NOTE 14: The significance of the rightmost digit may vary depending on the quantity being measured and on the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

NOTE 15: The pin shown in the outline on this figure is used to align the notched wafer in a fixture during use. The pin is also used to reference the notched wafer during testing for notch dimensions and dimensional tolerances. The notch dimensions shown in the figure assume a 3 mm diameter for this alignment pin.

APPENDIX 1
FLATNESS DECISION TREE

NOTE: The material in this appendix is an official part of M1 and was approved by full letter ballot procedures on October 21, 1999 by the North American Regional Standards Committee.

A1-1 Scope

A1-1.1 The increasing complexity of integrated circuits and the reduction in design rule dimensions place new demands on the characterization of wafer surface geometry. Various high resolution optical lithographic systems have very limited depth of field and use a variety of methods to hold the wafer, to establish the focal plane, and to position the wafer relative to the focal plane during exposure. These varying focusing and location methods differ enough to make a single, simple flatness criterion (such as global TIR) ineffective in predicting successful or unsuccessful lithography in all cases.

A1-1.2 To clarify the requirements for wafer flatness characterization for the various classes of lithographic equipment, the decision tree depicted in Figure A1-1 has been developed. This tree gives an orderly procedure for selecting the various parameters outlined in Section 4.2.5.

A1-1.3 In this tree, it is assumed that the focal point is the site center for all parameters, except for SFQD, SFQR, SFSD, and SFSR, where the focal plane is identical to the reference plane. Most flatness characterization systems employ this convention. However, a number of photolithographic aligners use slightly different conventions for determining the focal plane. Currently, the difference between the centerpoint and other focusing conventions has not been quantified, but it is presumed to be insignificant for material characterization purposes.

A1-2 Use of the Flatness Decision Tree

A1-2.1 In the decision tree, there are decision blocks, shown as diamonds, whose use requires some knowledge of the lithographic tool to be used. The rectangular blocks require information to be furnished; this information is dependent on the device layout and the manufacturing procedures to be employed (such as dedicated or mixed aligner use).

A1-2.2 Step 1. Select the Fixed Quality Area (FQA): Decide on and specify the nominal edge exclusion, X, which defines the FQA. (See Figure 1.)

A1-2.3 Step 2. Choose the Measurement Method: Choose global flatness (G) if the lithographic tool uses a single, global exposure of the wafer, or choose site flatness (S) if the lithographic tool steps across the wafer, exposing only a portion of the wafer at a time.

A1-2.3.1 If global flatness is chosen, proceed to Step 3. If site flatness is chosen, it is also necessary to specify site size (related to exposure area dimensions) and site array (including (a) number of sites, (b) location of sites relative to the center of the FQA and to each other, as in an offset or bricklaying pattern, and (c) whether or not partial sites are to be excluded).

A1-2.4 Step 3. Choose the Reference Surface: Choose front surface (F) or back surface (B), depending on whether the lithographic tool is referenced to the front or back surface.

A1-2.5 Step 4. Choose the Reference Plane and Area:

A1-2.5.1 For global flatness measurements, a global reference plane is appropriate. If the lithographic tool is referenced to the back surface, an ideal plane (I) defined by the chuck which holds the wafer is appropriate. If the lithographic tool is referenced to the front surface, either a 3-point plane (3) defined by three points equally spaced about the edge of the front surface of the wafer or a plane defined by the least squares fit to the front surface (L) may be appropriate. The 3-point plane is appropriate if the lithographic tool holds the wafer in this fashion and does not allow interactive gimbaling of the wafer, while the least squares plane is appropriate if the lithographic tool allows interactive gimbaling of the wafer.

A1-2.5.2 For site flatness measurements, any of the above three planes [(1), (3), or (L)] may be suitable or, if the wafer is regimballed once at each site, a site least squares reference plane (Q) may be appropriate or, if the wafer is regimballed more than once at each site, a subsite least squares reference plane (S) may be appropriate.

A1-2.6 Step 5. Choose the Measurement Parameter: Choose either TIR, also known as range (R), or FPD, also known as deviation (D). In the case of site measurements, it is possible to specify the maximum value of (R) or (D) or the percentage of the sites (or FQA) which have an (R) or (D) less than some specified value.

A1-2.7 The codes in parentheses in Steps 2 through 5 may be used to form a code which uniquely defines the measurement technique as follows:

Position 1: Measurement Method (G) or (S), Position 2: Reference Surface (F) or (B),

Position 3: Reference Plane and Area (1), (3), (L), (Q), or (S), and

Position 4: Measurement Parameter (R) or (D).

A1-2.7.1 Stating this code, the numerical values for the FQA parameters (and, if required, information on site size and array), and the numerical limit for the measurement parameter provides enough information to describe the measurement and provide numerical limits.

A1-3 Future Developments

A1-3.1 As noted above, there may be specific systems which are not exactly described by one of the branch ends on this decision tree. This tree is an approximation of the more complete one which would describe all existing and possible lithographic technologies.

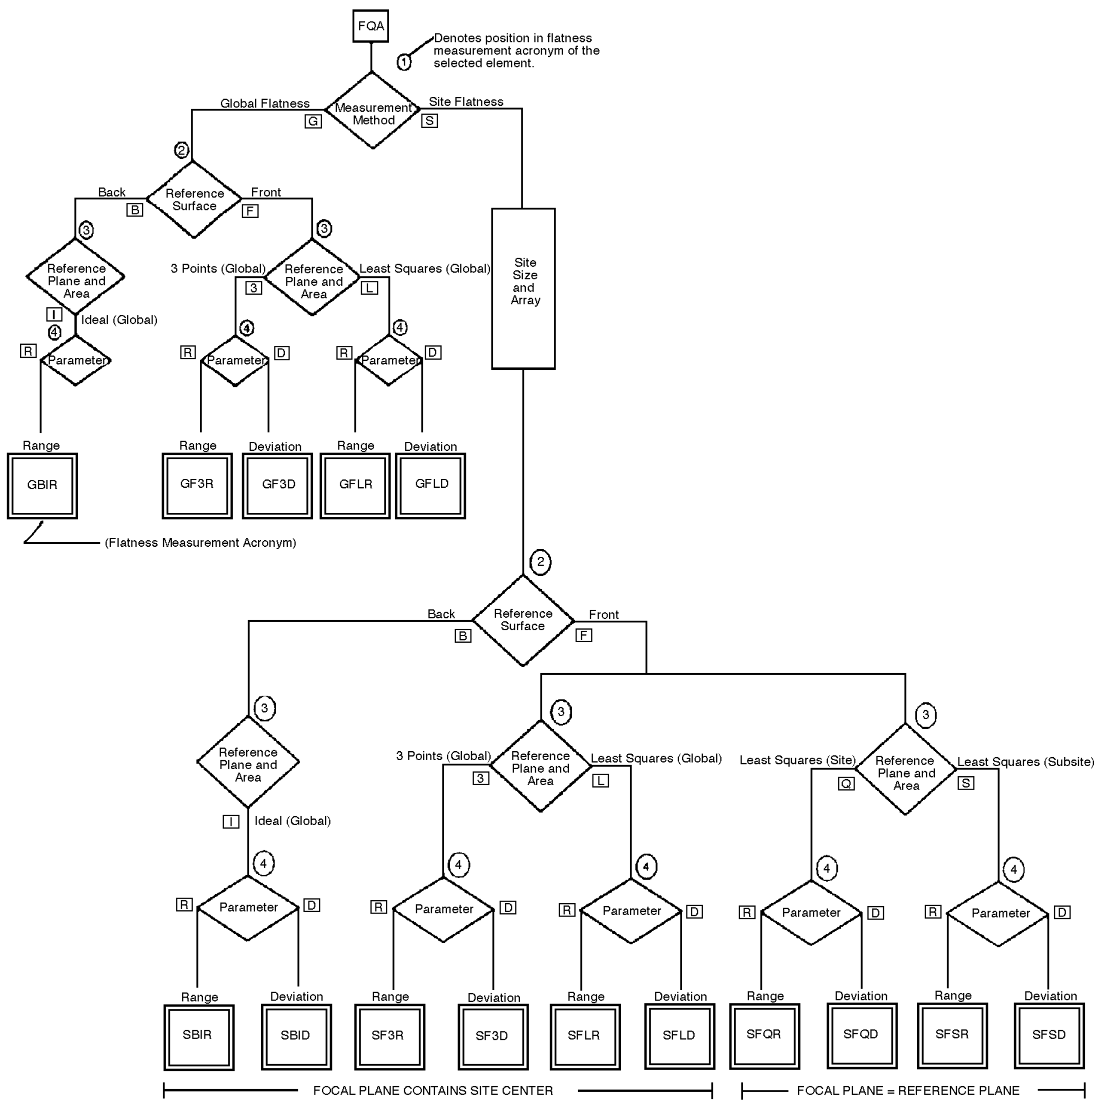

Figure A1-1
Flatness Decision Tree

APPENDIX 2
SHAPE DECISION TREE

NOTE: The material in this appendix is an official part of M1 and was approved by full letter ballot procedures on October 21, 1999 by the North American Regional Standards Committee.

A2-1 Scope

A2-1.1 In modern wafer fabrication processes, wafer surface geometry in the unclamped state can be a sensitive indicator of process effects. Larger wafer diameters and increasing complexity of processes and circuits have increased the need for accurate, standardized measurement of unclamped wafer geometry. The quantities that have historically been used, Bow and Back Surface Referenced Warp, may be inadequate to describe and quantify the geometries of interest in advanced processes. Additional surface geometry quantities, such as Sori and Median Surface Referenced Warp, have been introduced into standards.

A2-1.2 In addition, there is considerable confusion as to the precise meaning of these quantities, even though they are defined in the applicable ASTM test methods.

A2-1.3 The Shape Decision Tree was developed to provide an orderly method of identifying each of the variables involved in the quantities used to quantify unclamped wafer surface geometry. As such, the tree provides a concise and precise description of each shape quantity. A branch of the tree consists of a selection of one of the choices for each variable. The variables and the choices for each are listed in Table A2-1.

A2-1.4 Four branches of the tree, representing quantities for which standard measurement methods have been developed by ASTM, are depicted in Figure A2-1. There are many other branches of the tree, not all of which may represent practical combinations of variables.

A2-2 Use of the Shape Decision Tree

A2-2.1 Step 1. Select the value of the Nominal Edge Exclusion to define the Fixed Quality Area.

NOTE A2-1: This value must be provided whenever a shape quantity is specified.

A2-2.2 Step 2. Select the measurement method: global (over the entire fixed quality area) or local (over a site).

NOTE A2-2: At present, all shape quantities in common use are global measurements. The significance and use of local shape quantities have yet to be defined.

A2-2.3 Step 3. Select the reference surface: front, median, or back, to be used to establish the reference plane.

A2-2.4 Step 4. Select the type of reference plane: least-squares or 3-point.

NOTE A2-3: A measurement made with a least-squares reference plane is less affected by small changes in wafer position within the measurement apparatus than is a measurement made with a 3-point reference plane.

A2-2.5 Step 5. Determine whether the effects of gravitational sag on the wafer are accounted for (yes) or not (no).

NOTE A2-4: Gravitational effects may be accounted for by inverting the wafer during the measurement, by placing the wafer in a vertical or nearly vertical position during the measurement, or mathematically.

A2-2.6 Step 6. Select the measurement surface: front, median, or back, for which the deviations are to be measured.

A2-2.7 Step 7. Select the measurement pattern: full scan (a regular array of measurement points over the entire measurement area), partial scan (a specified pattern of measurement points covering only a portion of the measurement area), or centerpoint (measurement at the center of the wafer only).

A2-2.8 Step 8. Select the parameter to be determined: range (TIR) or maximum RPD.

A2-2.9 Step 9. Compare the branch thus obtained with the branches in Figure A2-1. If the branch obtained matches one of the branches illustrated in Figure A2-1, the resulting quantity is given by the code shown in the box at the bottom of the branch. The ASTM test method used for its measurement is also shown in the box. If the branch obtained does not match any of the branches illustrated in Figure A2-1, the quantity obtained has not been given a standardized term, nor has a standard test method been adopted for its measurement.

A2-2.9.1 These codes, which uniquely describe the various branches, are formed from the codes in Table A2-1. Stating this code together with the numerical value for the FQA exclusion distance provides enough information to describe the shape parameter and to establish numerical limits for it.

A2-2.9.2 Table A2-2 summarizes the shape parameters for which ASTM has developed test methods. This table lists the code, the term in common use for the parameter, the ASTM test method, and the expanded form of the code.

A2-2.9.3 If the branch obtained does not match any of the branches illustrated in Figure A2-1, the quantity obtained has not been formally defined nor has a standard test method been adopted for its measurement.

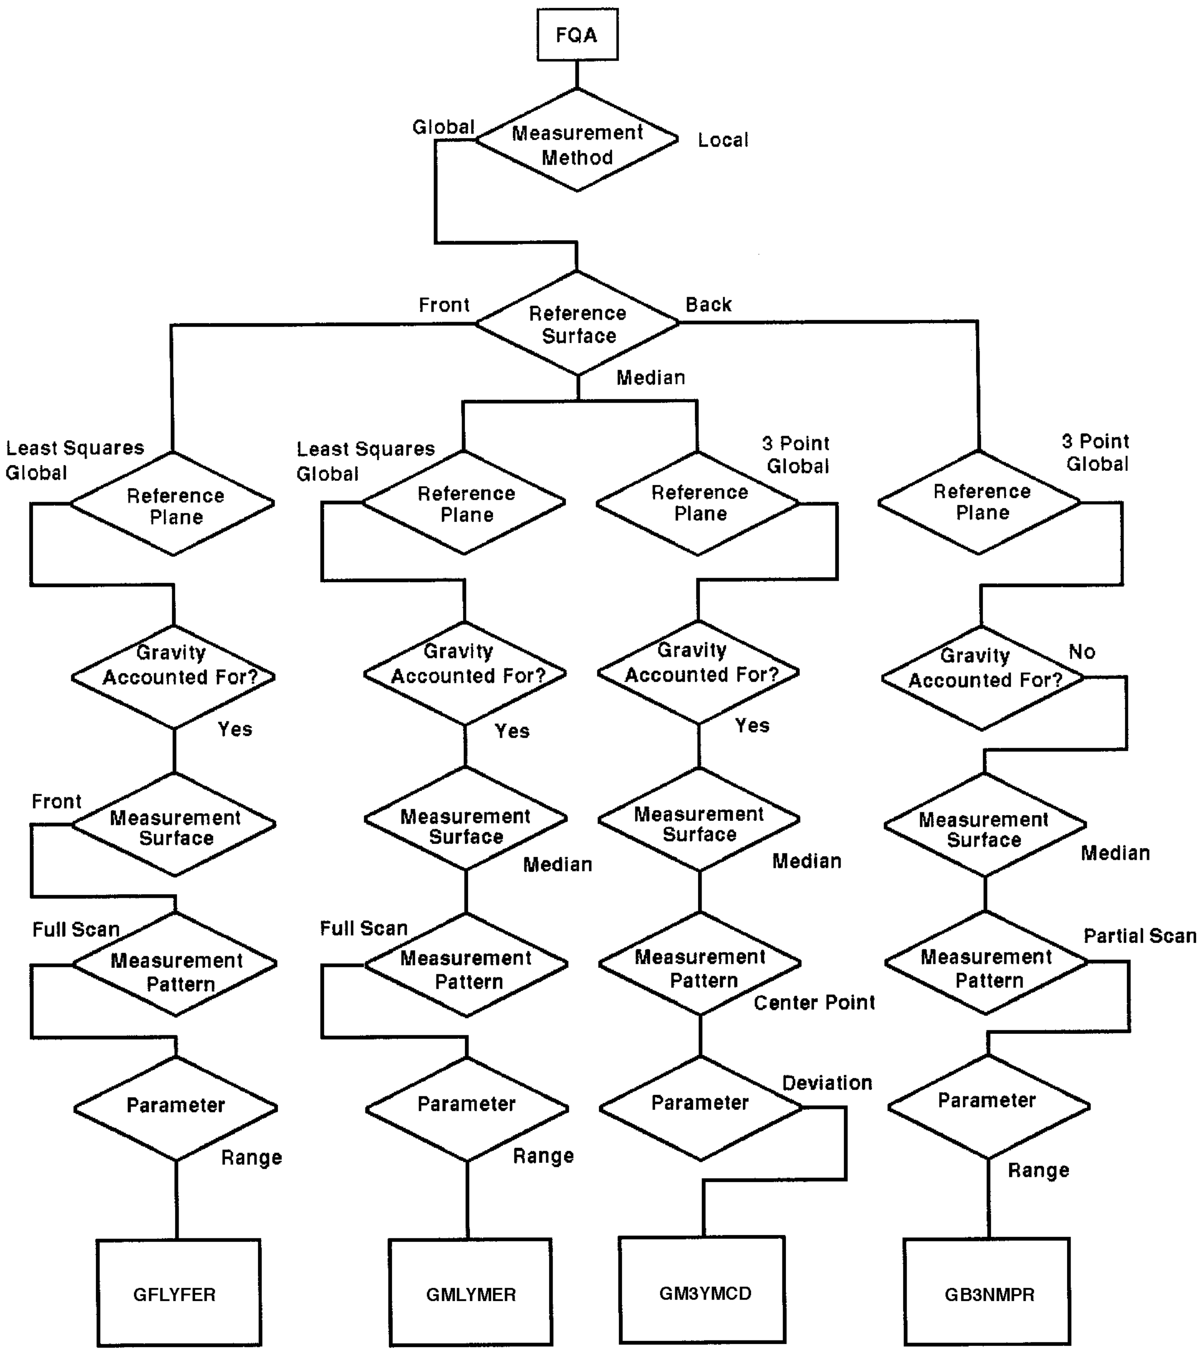

Figure A2-1
Four Branches of the Shape Decision Tree

Table A2-1 Variables in Shape Quantities

Variable	*Options*	*Code*
Measurement Method	Global	G
	Local (Site)	S
Reference Surface	Front	F
	Median	M
	Back	B
Reference Plane	Least-Square	L
	3-Point	3
Corrected for Gravitational Sag	Yes	Y
	No	N
Measurement Surface	Front	F
	Median	M
	Back	B
Measurement Pattern	Full Scan (Entire)	E
	Partial Scan	P
	Centerpoint	C
Parameter	Range (TIR)	R
	Maximum RPD	D

Table A2-2 Shape Code Summary

Code	*Term*	*ASTM Test Method*	*Expanded Form of Code*
GFLYFER	sori	F 1451	Global, Front-surface Least-squares reference plane, Yes (corrected for gravitational sag), Front-surface measurement, Entire surface scanned, Range
GMLYMER	warp	F 1390	Global, Median-surface Least-squares reference plane, Yes (corrected for gravitational sag), Median-surface measurement, Entire surface scanned, Range
GM3YMCD	bow	F 534	Global, Median-surface 3-point plane, Yes (corrected for gravitational sag), Median-surface measurement at Center point, Deviation
GB3NMPR	warp	F 657	Global, Back-surface 3-point reference plane, No (not corrected for gravitational sag), Median-surface measurement, Partial surface scanned, Range

RELATED INFORMATION 1
SURFACE METAL CONTAMINATION

NOTE: This related information is not an official part of SEMI M1 and is not intended to modify or supercede the official standard. Publication was authorized by full letter ballot procedure. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Scope

R1-1.1 Maximum allowable surface metal contamination levels generally depend upon the IC device density and upon the IC process design. In general, as the device density increases, the allowable surface metal contamination levels become lower.

R1-1.2 This related information is intended to provide guidance regarding allowable surface concentrations of metal contaminants which have been reported to be deleterious to circuit and device performance.

R1-2 Suggested Allowable Surface Metal Contamination Levels for 1 µm Geometries

R1-2.1 Table R1-1 lists suggested surface metal limits for circuits and devices with a minimum linewidth in the range of 0.8 µm to 1.2 µm for two alkali metals (Na, K), a light metal (Al), and five heavy metals (Cr, Fe, Ni, Cu, Zn).

R1-3 Test Methods

R1-3.1 Some commonly used test methods for each surface metal contaminant are also listed in Table R1-1. TXRF measurements should be made in accordance with ASTM Test Method F 1526 and SIMS measurements should be made in accordance with ASTM Test Method F 1617. Measurements involving vapor phase decomposition (VPD) have not yet been standardized. The following sections list some issues concerning application of the VPD methods.

R1-3.2 VPD is chemical preconcentration of the surface metals using vapor phase HF to decompose the surface native oxide and a water (or acid-spiked water) droplet to scan across the wafer dissolving the surface metals. The recovery rate of this preconcentration method is dependent upon the chemistry of the surface metals and upon the chemistry used for the preconcentration. An alternative preconcentration method to VPD is to scan an acid droplet across the wafer surface.

R1-3.3 VPD/AAS (vapor phase decomposition followed by graphite furnace atomic absorption spectroscopy) is a single element technique which is widely used in Japan: it is element-specific and very sensitive. VPD/ICP-MS (vapor phase decomposition followed by inductively coupled plasma mass spectrometry) is a rapid multi-element technique which is a more recent development: it is also very sensitive, but its reproducibility is dependent upon the injection process into the ICP-MS. VPD/TXRF (vapor phase decomposition followed by total reflection x-ray fluorescence) is a more recently developed multi-element technique. It is also very sensitive, but its reproducibility is dependent on the residue-drying process.

Table R1-1 Suggested Polished Wafer Surface Metal Contamination Limits Appropriate to Circuits and Devices with a Minimum Linewidth in the Range 0.8 µm to 1.2 µm

Element	*Contaminant Level*	*Test Method*
Na	10^{11} atoms/cm^2	SIMS, VPD/(AAS or ICP-MS)
Al	10^{11} atoms/cm^2	SIMS, VPD/(AAS or ICP-MS)
K	10^{11} atoms/cm^2	SIMS, VPD/(AAS, ICP-MS, or TXRF)
Cr	10^{11} atoms/cm^2	TXRF, VPD/(AAS, ICP-MS or TXRF)
Fe	10^{11} atoms/cm^2	TXRF, VPD/(AAS, ICP-MS or TXRF)
Ni	10^{11} atoms/cm^2	TXRF, VPD/(AAS, ICP-MS or TXRF)
Cu	10^{11} atoms/cm^2	TXRF, VPD/(AAS, ICP-MS or TXRF)
Zn	10^{12} atoms/cm^2	TXRF, VPD/(AAS, ICP-MS or TXRF)

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M1.1-89 (Reapproved 0299)
STANDARD FOR 2 inch POLISHED MONOCRYSTALLINE SILICON WAFERS

This standard was technically reapproved by the Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on October 18, 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1980; previous published revision in 1989.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	2.000	± 0.015	in.
	50.80	± 0.38	mm
THICKNESS, CENTER POINT	0.0110	± 0.0010	in.
	279	± 25	µm
PRIMARY FLAT LENGTH	0.625	± 0.065	in.
	15.88	± 1.65	mm
SECONDARY FLAT LENGTH	0.315	± 0.065	in.
	8.00	± 1.65	mm
BOW, MAX	0.0015		in.
	38		µm
TOTAL THICKNESS VARIATION, MAX	0.0005		in.
	12		µm
EDGE PROFILE COORDINATE: C_y	0.0037		in.
(see Figure 4)	93		µm

[A] For referee purposes, the U.S. Customary units apply. Conversion to metric (SI) equivalents was done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the metric equivalents are used for incoming inspection measurements, the rightmost digit of the minimum values should be reduced by 1 and the rightmost digit of the maximum values should be increased by 1 to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{ 110} ± 1°
SECONDARY FLAT LOCATION (see Figure 6)	
{ 111}*p*-type	No secondary flat
{ 100}*p*-type	(90° ± 5°) clockwise from primary flat
{ 111}*n*-type	(45° ± 5°) clockwise from primary flat
{ 100}*n*-type	(180° ± 5°) from primary flat
SURFACE ORIENTATION[B]	
On-orientation for { 111} and { 100} wafers:	± 1°
Off-orientation { 111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent { 110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE — This standard was originated in the United States. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M1.2-89 (Reapproved 0299)
STANDARD FOR 3 inch POLISHED MONOCRYSTALLINE SILICON WAFERS

This standard was technically reapproved by the Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on October 18, 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1978; previous published revision in 1989.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	3.000	± 0.025	in.
	76.20	± 0.63	mm
THICKNESS, CENTER POINT	0.0150	± 0.0010	in.
	381	± 25	µm
PRIMARY FLAT LENGTH	0.875	± 0.125	in.
	22.22	± 3.17	mm
SECONDARY FLAT LENGTH	0.440	± 0.060	in.
	11.18	± 1.52	mm

SEMI M1.5-89 (Reapproved 0699)
STANDARD FOR 100 mm POLISHED MONOCRYSTALLINE SILICON WAFERS (525 μm THICKNESS)

This standard was technically re-approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org February 1999; to be published June 1999. Originally published 1978; previously published 1989.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	100.00	± 0.50	mm
THICKNESS, CENTER POINT	525	± 20	μm
PRIMARY FLAT LENGTH	32.5	± 2.5	mm
SECONDARY FLAT LENGTH	18.0	± 2.0	mm
BOW, MAX	40		μm
WARP, MAX	40		μm
TOTAL THICKNESS VARIATION, MAX	10		μm
EDGE PROFILE COORDINATE: C_y (see Figure 4)	175		μm

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down and maximum values rounded up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{110} ± 1°
SECONDARY FLAT LOCATION (see Figure 6)	
{111} *p*-type	No secondary flat
{100} *p*-type	(90° ± 5°) clockwise from primary flat
{111} *n*-type	(45° ± 5°) clockwise from primary flat
{100} *n*-type	(180° ± 5°) from primary flat
SURFACE ORIENTATION[B]	
On-orientation for {111} and {100} wafers:	± 1°
Off-orientation {111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent {110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE — This standard was originated in the United States. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. SEMI M1.6-89 (Reapproved 0699)
STANDARD FOR 100 mm POLISHED MONOCRYSTALLINE SILICON WAFERS (625 μm THICKNESS)

This standard was technically re-approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org February 1999; to be published June 1999. Originally published 1978; previously published 1989.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	100.00	± 0.50	mm
THICKNESS, CENTER POINT	625	± 20	μm
PRIMARY FLAT LENGTH	32.5	± 2.5	mm
SECONDARY FLAT LENGTH	18.0	± 2.0	mm
BOW, MAX	40		μm
WARP, MAX	40		μm
TOTAL THICKNESS VARIATION, MAX	10		μm
EDGE PROFILE COORDINATE: C_y (see Figure 4)	208		μm

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down and maximum values rounded up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{ 110} ± 1°
SECONDARY FLAT LOCATION (see Figure 6)	
{ 111}*p*-type	No secondary flat
{ 100}*p*-type	(90° ± 5°) clockwise from primary flat
{ 111}*n*-type	(45° ± 5°) clockwise from primary flat
{ 100}*n*-type	(180° ± 5°) from primary flat
SURFACE ORIENTATION[B]	
On-orientation for { 111} and { 100} wafers:	± 1°
Off-orientation { 111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent { 110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE — This standard was originated in the United States. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M1.7-89 (Reapproved 0699)
STANDARD FOR 125 mm POLISHED MONOCRYSTALLINE SILICON WAFERS

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org February 1999; to be published June 1999. Originally published 1978; previously published 1989.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	125.00	± 0.50	mm
THICKNESS, CENTER POINT	625	± 20	μm
PRIMARY FLAT LENGTH	42.5	± 2.5	mm
SECONDARY FLAT LENGTH	27.5	± 2.5	mm
BOW, MAX	40		μm
WARP, MAX	40		μm
TOTAL THICKNESS VARIATION, MAX	10		μm
EDGE PROFILE COORDINATE: C_y (see Figure 4)	208		μm

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down and maximum values rounded up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{ 110} ± 1°
SECONDARY FLAT LOCATION (see Figure 6)	
{ 111}*p*-type	No secondary flat
{ 100}*p*-type	(90° ± 5°) clockwise from primary flat
{ 111}*n*-type	(45° ± 5°) clockwise from primary flat
{ 100}*n*-type	(180° ± 5°) from primary flat
SURFACE ORIENTATION[B]	
On-orientation for { 111} and { 100} wafers:	± 1°
Off-orientation { 111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent { 110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE — This standard was originated in the United States. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

SEMI M1.8-0699
STANDARD FOR 150 mm POLISHED MONOCRYSTALLINE SILICON WAFERS

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on March 4, 1999. Initially available at www.semi.org March 1999; to be published June 1999. Originally published 1979; previously published February 1998.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1 Dimension and Tolerance Requirements

Property		*Dimension*		*Tolerance*	*Units*[A]
DIAMETER		150.00		± 0.20	mm
THICKNESS, CENTER POINT		675		± 20	μm
PRIMARY FLAT LENGTH		57.5		± 2.5	mm
SECONDARY FLAT LENGTH		37.5		± 2.5	mm
BOW, MAX		60			μm
WARP, MAX		60			μm
TOTAL THICKNESS VARIATION, MAX		10			μm
EDGE PROFILE	Table	2 (T/3)	3 (T/4)[B]		
COORDINATE: (see Figure 4)	C_y	225	169		μm
	C_x	50	100		μm
EDGE PROFILE SURFACE FINISH		Not Specified[C]			

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded-up and the maximum values are rounded-down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded-down and maximum values rounded-up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION: The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

[B] Use of edge gripping or CMP (chemical-mechanical planarization) processing may necessitate edge profile restrictions, resulting in a generally blunter profile as required by the template in Figure 4 and Table 3 of SEMI M1.

[C] Surface finish shall be agreed upon between the supplier and purchaser. If polished, this term is meant to imply a surface condition and not a particular processing technique. If desired, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or wavelength) range. Because a standardized test method has not yet been developed for this metric, both values and test procedures, including sampling plan and detrending procedures, shall be agreed upon between supplier and purchaser.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{110} ± 1°
SECONDARY FLAT LOCATION (see Figure 6)	
{111}*p*-type	No secondary flat
{100}*p*-type	(90° ± 5°) clockwise from primary flat
{111}*n*-type	(45° ± 5°) clockwise from primary flat
{100}*n*-type	(135° ± 5°) clockwise from primary flat
SURFACE ORIENTATION[B]	
On-orientation for {111} and {100} wafers:	± 1°
Off-orientation {111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent {110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE: This standard was originated in the United States. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

NOTICE: – These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M1.9-0699
STANDARD FOR 200 mm POLISHED MONOCRYSTALLINE SILICON WAFERS (NOTCHED)

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on March 4, 1999. Initially available at www.semi.org March 1999; to be published June 1999. Originally published 1984; previously published February 1998.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1 Dimension and Tolerance Requirements

Property		*Dimension*		*Tolerance*	*Units*[A]
DIAMETER		200.00		± 0.20	mm
THICKNESS, CENTER POINT		725		± 20	µm
NOTCH (see Figure 7)					
Depth		1.00		+ 0.25, - 0.00	mm
Angle		90		+ 5, -1	Degrees
BOW, MAX		65			µm
WARP, MAX		75			µm
TOTAL THICKNESS VARIATION, MAX		10			µm
EDGE PROFILE	Table	2 (T/3)	3 (T/4)[B]		
COORDINATE: (see Figure 4)	C_y	242	181		µm
	C_x	50	100		µm
EDGE PROFILE SURFACE FINISH		Not Specified[C]			

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded-up and the maximum values are rounded-down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded-down and maximum values rounded-up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION: The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

[B] Use of edge gripping or CMP (chemical-mechanical planarization) processing may necessitate edge profile restrictions, resulting in a generally blunter profile as required by the template in Figure 4 and Table 3 of SEMI M1.

[C] Surface finish shall be agreed upon between the supplier and purchaser. If polished, this term is meant to imply a surface condition and not a particular processing technique. If desired, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or wavelength) range. Because a standardized test method has not yet been developed for this metric, both values and test procedures, including sampling plan and detrending procedures, shall be agreed upon between supplier and purchaser.

Table 2 Orientation Requirements

Property	*Requirement*
ORIENTATION OF NOTCH AXIS[A]	<110> ± 1°
SECONDARY FIDUCIAL LOCATION	No secondary fiducial
SURFACE ORIENTATION[B]	
On-orientation for { 111} and { 100} wafers:	± 1°
Off-orientation { 111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane perpendicular to notch axis	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent <110> planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE: This standard was originated in the United States. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

NOTICE: – These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M1.10-0699
STANDARD FOR 200 mm POLISHED MONOCRYSTALLINE SILICON WAFERS (FLATTED)

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on March 4, 1999. Initially available at www.semi.org March 1999; to be published June 1999. Originally published 1989; previously published 1992.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1 Dimension and Tolerance Requirements

Property		*Dimension*		*Tolerance*	*Units*[A]
DIAMETER		200.00		± 0.20	mm
THICKNESS, CENTER POINT		725			µm
PRIMARY (ORIENTATION)FLAT DIAMETER		195.50		± .20	mm
BOW, MAX		65			µm
WARP, MAX		75			µm
TOTAL THICKNESS VARIATION, MAX		10			µm
EDGE PROFILE	Table	2 (T/3)	3 (T/4)[B]		
COORDINATE: (see Figure 4)	Cy	242	181		µm
	C_x	50	100		µm
EDGE PROFILE SURFACE FINISH		Not Specified[C]			

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded-up and the maximum values are rounded-down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded-down and maximum values rounded-up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION: The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

[B] Use of edge gripping or CMP (chemical-mechanical planarization) processing may necessitate edge profile restrictions, resulting in a generally blunter profile as required by the template in Figure 4 and Table 3 of SEMI M1.

[C] Surface finish shall be agreed upon between the supplier and purchaser. If polished, this term is meant to imply a surface condition and not a particular processing technique. If desired, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or wavelength) range. Because a standardized test method has not yet been developed for this metric, both values and test procedures, including sampling plan and detrending procedures, shall be agreed upon between supplier and purchaser.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{110} ± 1°
SECONDARY FLAT LOCATION[B]	No secondary flat
SURFACE ORIENTATION	
On-orientation for {111} and {100} wafers:	± 1°
Off-orientation {111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent {110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE - This standard was originated in Japan. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

NOTICE: – These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. SEMI M1.11-90 (Reapproved 0299)
STANDARD FOR 100 mm POLISHED MONOCRYSTALLINE SILICON WAFERS WITHOUT SECONDARY FLAT (525 µm THICKNESS)

This standard was technically reapproved by the Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on October 18, 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1990.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	100.00	± 0.20	mm
THICKNESS, CENTER POINT	525	± 15	µm
PRIMARY FLAT LENGTH	32.5	± 2.5	mm
BOW, MAX	40		µm
WARP, MAX	40		µm
TOTAL THICKNESS VARIATION, MAX	10		µm
EDGE PROFILE COORDINATE: C_y (see Figure 4)	175		µm

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down and maximum values rounded up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{ 110} ± 1°
SECONDARY FLAT LOCATION	No secondary flat
SURFACE ORIENTATION[B]	
On-orientation for { 111} and { 100} wafers:	± 1°
Off-orientation { 111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent { 110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE — This standard was originated in Japan. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

SEMI M1.12-90 (Reapproved 0299)
STANDARD FOR 125 mm POLISHED MONOCRYSTALLINE SILICON WAFERS WITHOUT SECONDARY FLAT

This standard was technically reapproved by the Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on October 18, 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1990.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1. Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
DIAMETER	125.00	± 0.20	mm
THICKNESS, CENTER POINT	625	± 15	µm
PRIMARY FLAT LENGTH	42.5	± 2.5	mm
BOW, MAX	40		µm
WARP, MAX	40		µm
TOTAL THICKNESS VARIATION, MAX	10		µm
EDGE PROFILE COORDINATE: C_y (see Figure 4)	208		µm

[A] For referee purposes, metric (SI) units apply. To ensure that the product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down and maximum values rounded up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{ 110} ± 1°
SECONDARY FLAT LOCATION	No secondary flat
SURFACE ORIENTATION[B]	
On-orientation for { 111} and { 100} wafers:	± 1°
Off-orientation { 111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent { 110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE — This standard was originated in Japan. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

SEMI M1.13-0699
STANDARD FOR 150 mm POLISHED MONOCRYSTALLINE SILICON WAFERS WITHOUT SECONDARY FLAT (625 µm THICKNESS)

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on March 4, 1999. Initially available at www.semi.org March 1999; to be published June 1999. Originally published 1990.

The complete specification for this product includes all general requirements of SEMI M1.

Table 1 Dimension and Tolerance Requirements

Property		*Dimension*		*Tolerance*	*Units*[A]
DIAMETER		150.00		± 0.20	mm
THICKNESS, CENTER POINT		625		± 15	µm
PRIMARY FLAT LENGTH		47.5		± 2.5	mm
BOW, MAX		60			µm
WARP, MAX		60			µm
TOTAL THICKNESS VARIATION, MAX		10			µm
EDGE PROFILE	Table	2 (T/3)	3 (T/4)[B]		
COORDINATE: (see Figure 4)	C_y	208	156		µm
	C_x	50	100		µm
EDGE PROFILE SURFACE FINISH		Not Specified[C]			

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded-up and the maximum values are rounded-down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded-down and maximum values rounded-up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION: The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

[B] Use of edge gripping or CMP (chemical-mechanical planarization) processing may necessitate edge profile restrictions, resulting in a generally blunter profile as required by the template in Figure 4 and Table 3 of SEMI M1.

[C] Surface finish shall be agreed upon between the supplier and purchaser. If polished, this term is meant to imply a surface condition and not a particular processing technique. If desired, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or wavelength) range. Because a standardized test method has not yet been developed for this metric, both values and test procedures, including sampling plan and detrending procedures, shall be agreed upon between supplier and purchaser.

Table 2. Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION[A]	{110} ± 1°
SECONDARY FLAT LOCATION	No secondary flat
SURFACE ORIENTATION[B]	
On-orientation for {111} and {100} wafers:	± 1°
Off-orientation {111} wafers: Tilt angle of normal to wafer surface toward nearest <110> direction in a plane parallel to primary flat	2.5° ± 0.5°, or 4.0° ± 0.5°
ORTHOGONAL MISORIENTATION[C] (see Figure 2)	± 5° max

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent {110} planes are $(01\bar{1})$, (011), $(0\bar{1}1)$, and $(0\bar{1}\bar{1})$.

[B] Note that if the off-orientation angle is determined with the seed end up, the polished surface of the finished wafer must be the surface toward the seed end, and vice versa. Polishing of the incorrect wafer surface results in an incorrect wafer tilt which can cause unwanted pattern shifts and distortions during subsequent epitaxial growth.

[C] The contribution of 5° of orthogonal misorientation to the total off-orientation angle will be less than 0.5°.

NOTE - This standard was originated in Japan. Care should be taken applying this configuration to specific applications (see Note 15 in SEMI M1).

SEMI M1.14-96
GUIDELINE FOR 350 and 400 mm POLISHED MONOCRYSTALLINE SILICON WAFERS

The complete specification for this product includes all general requirements of SEMI M1.

Although 300 mm has been chosen as the next wafer diameter larger than 200 mm and separate 300 mm wafer specifications are being developed[1] , it may be appropriate to continue advanced research activities on larger wafers. This guideline is intended to provide guidance regarding the selection of dimensional and related characteristics of such wafers for the development of materials, equipment, and processes.

Table 1 Dimension and Tolerance Requirements

Property	*Target*	*Target*	*Tolerance*	*Units*[A]
DIAMETER	350.00	400.00	± 0.25	mm
THICKNESS, CENTER POINT	800	825	± 25	µm
NOTCH FIDUCIAL[B] (see Figure 7)				
Depth	1.00	1.00	+ 0.25, − 0.00	mm
Angle	90	90	+ 5, − 1	degrees
WARP, MAX	100	100		µm
NINE-POINT THICKNESSVARIATION, MAX	25	25		µm
BACK SURFACE FINISH[C]	BRIGHT ETCHED/POLISHED			
EDGE PROFILE COORDINATE: C_y (see Figure 4)	267	275		µm
EDGE PROFILE SURFACE FINISH[D]	POLISHED			
NOMINAL WAFER MASS[E]	179	242		g
	6.3	8.5		oz.

[A] For referee purposes, SI units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the specified range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded down, and maximum values rounded up, to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

[B] An alternative technique for crystal alignment to replace the notch could be an inscribed fiducial by laser marking.

[C] This term is not meant to imply any particular processing method for achieving the desired back surface finish, but rather to indicate a surface finish that is smoother than the usual finish achieved with caustic etching but not as smooth as the mirror polish typically obtained on front surfaces of wafers. Because the most appropriate magnitude of the back surface roughness is not yet established, wafer manufacturers are encouraged to report typical values of gloss or rms microroughness of the back surface finish of the wafers supplied, together with the method by which these values were determined, and, if rms microroughness is reported, the range of spatial frequencies (or spatial wavelengths) over which it was determined. Measurement procedures used to obtain this data are at the option of the wafer manufacturer. If necessary for a particular application, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or spatial wavelength) range. Because a standardized test method has not yet been developed for this measure, both values and test procedures shall be agreed upon between user and supplier.

[D] This term is meant to imply a surface condition and not a particular processing technique. If necessary for a particular application, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or spatial wavelength) range. Because a standardized test method has not yet been developed for this

[1] A specification for developmental 300 mm wafers has been approved as SEMI M28.

measure, values and test procedures, including sampling plan and detrending procedures, shall be agreed upon between user and supplier.

E Note for material handling/processing: These wafers are heavy. The mass of a single wafer of nominal dimensions, taking the density of silicon as 2.33 g/cm3, is given in the table for information only.

Table 2 Orientation Requirements

Property	*Requirement*
ORIENTATION OF NOTCH AXIS[A]	<110> ± 1¡
SECONDARY FLAT LOCATION	No secondary flat
SURFACE ORIENTATION	{ 110} ± 1¡

A For (100) wafers, the allowable equivalent <110> directions are [011], [011], [011], and [011].

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M1.15-0302
STANDARD FOR 300 mm POLISHED MONOCRYSTALLINE SILICON WAFERS (NOTCHED)

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the European Regional Standards Committee on October 14,2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1997; previously published November 2001.

1 Referenced Standards

1.1 *SEMI Standard*

SEMI M12 — Specification for Alphanumeric Marking of the Front Surface of Silicon Wafers

SEMI T7 — Specification for Back Surface Marking of Double-Side Polished Wafers with a Two-Dimensional Matrix Code Symbol

1.2 *ASTM Standards*[1]

D 523 — Test Method for Specular Gloss

F 1530 — Test Method for Measuring Flatness, Thickness, and Thickness Variation on Silicon Wafers by Automated Noncontact Scanning

1.3 *JIS Standard*[2]

Z 8741 — Method of Measurement for Specular Glossiness

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

2 Requirements

2.1 The complete specification for this product includes all general requirements of SEMI M1 except for the following:

2.1.1 The exclusion of wafers polished on both sides in Section 1.3 of SEMI M1 is deleted.

2.1.2 Particulate contamination (localized light scatterer) requirements listed in Table 1 of SEMI M1 (Polished Wafer Defect Limits) do not apply to these wafers. Specification criteria and test methods for automated surface inspection of large wafers are under development.

2.1.3 Wafers shall be marked with a two-dimensional matrix code symbol on the back surface outside the fixed quality area as soon after slicing as practical in the manner specified in SEMI T7 in order to provide both identification of these wafers and traceability of each wafer back to the ingot from which it was cut. The back surface is identified as the wafer surface with the two-dimensional matrix code symbol.

2.1.4 Optionally, the user may specify that no mark be placed on the wafer.

NOTE 2: It is expected that the option of “no mark” will eventually become obsolete after or if experience with the SEMI T7 mark demonstrates success.

2.1.5 Optionally, the user may specify an additional back-surface mark (Note 3) that contains alphanumeric characters with

2.1.5.1 The same message characters as the SEMI T7 mark and appropriate checksum characters as defined by SEMI M12, and

2.1.5.2 Character string as specified in SEMI M12,

2.1.5.3 Single density dot matrix, 5 dots horizontal and 9 dots vertical, shall be used,

2.1.5.4 Dot diameter shall be the same as that used for the two-dimensional matrix code symbol (see Section 2.1.3).

2.1.5.5 Adjacent dots shall not touch.

2.1.5.6 Character dimensions shall be as defined in SEMI M12, Table 1 (nominal spacing = 1.42 mm, nominal width = 0.812 mm, nominal height = 1.624 mm).

2.1.5.7 Mark location (center of bottommost dot rows) relative to the reference point of the SEMI T7 mark shall be 1.40 ± 0.05 mm toward the wafer center, as shown in Figure 1,

2.1.5.8 Mark field height, as defined by the distance between the centers of the topmost and bottommost dot rows of the A/N characters, shall be 1.62 ± 0.03 mm (Note 4),

2.1.5.9 Mark field length , as defined by the distance between the centers of the leftmost and rightmost dot columns of the A/N characters, shall be 16.43 ± 0.07 mm (Note 4).

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 Both Japanese editions and English translation available from Japan Standards Association, 1-24, Akasaka 4-chome, Minato-ku, Tokyo 107, Japan

2.1.5.10 The mark-field shall be centered on the radius that passes through the reference point of the SEMI T7 mark as shown in Figure 1.

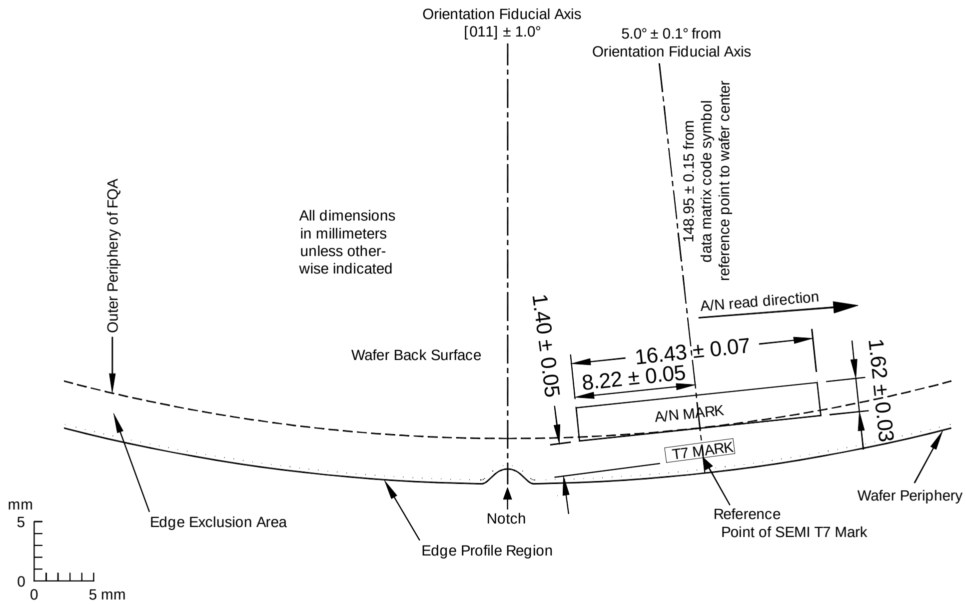
2.1.5.11 Character baseline shall be toward wafer OD and parallel with the row of the SEMI T7 mark that contains that mark's reference point.

NOTE 3: It is expected that this optional alphanumeric mark will not be used after users have developed successful experience with SEMI T7 mark usage.

NOTE 4: The overall length tolerance of the A/N mark is more stringent than that in SEMI M12. Also the height tolerance of the overall mark imposes tighter skew and offset tolerances than required in SEMI M12.

2.2 Dimension and tolerance requirements are given in Table 1.

2.3 Orientation requirements are given in Table 2.



NOTE: A/N mark field dimensions are defined by the centers of the topmost and bottommost dot rows and the center of the leftmost and rightmost dot columns of the A/N characters. The field dimensions are more tightly controlled than those of a field constructed using SEMI M12. This results from the availability of laser marking capabilities not available when SEMI M12 was developed. In addition, the tolerance on the field dimensions is not cumulative.

Figure 1
Optional A/N Code Field Location on Back Surface of Notched 300 mm Diameter Wafer

Table 1 Dimension and Tolerance Requirements

Property		*Dimension*	*Tolerance*	*Units*[A]
DIAMETER		300.00	± 0.20	mm
THICKNESS, CENTER POINT		775	± 20	µ m
NOTCH (see Figure 7)				
Depth		1.00	+ 0.25, -0.00	mm
Angle		90	+ 5, -1	degrees
WARP, MAX[B]		100		µ m
TOTAL THICKNESS VARIATION (GBIR), MAX[C]		10		µ m
BACK SURFACE GLOSS[D]		³ 0.80		
EDGE PROFILE SURFACE FINISH[E] POLISHED				
EDGE PROFILE COORDINATE:	Table 3 (T/4)[F]			
(see Figure 4)	C_y	194		µ m
	C_x	100		µ m

[A] For referee purposes, metric (SI) units apply. To ensure that product shipped is within specification, any conversion to U.S. Customary equivalents should be done following the maximum-minimum convention in which the minimum values are rounded-up and the maximum values are rounded-down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection, minimum values should be rounded-down and maximum values rounded-up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION: The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.
[B] Warp is corrected for gravitational effects. However, warp is not an adequate wafer shape specification for all applications.
[C] Full wafer scan as described in ASTM Test Method F 1530. However, a nine-point test pattern can be specified until full scan thickness measurement equipment is available.
[D] Gloss as measured in accordance with ASTM D 523 or JIS Z 8741 with visible illumination at a 60° angle of incidence referenced to a mirror polished silicon wafer front surface. This metric may not describe the back surface finish adequately to establish detectability of small localized light scatterers (LLSs). If it is necessary to detect LLSs smaller than 0.25 µm LSE, another quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or wavelength) range. Because a standardized test method has not yet been developed for this metric, both values and test procedures shall be agreed upon between supplier and purchaser.
[E] This term is meant to imply a surface condition and not a particular processing technique. If desired, a quantitative measure of surface finish may optionally be indicated by specifying the rms microroughness over a specified spatial frequency (or wavelength) range. Because a standardized test method has not yet been developed for this metric, both values and test procedures, including sampling plan and detrending procedures, shall be agreed upon between supplier and purchaser.
[F] Use of edge gripping or CMP (chem-mechanical planarization) processing may necessitate further edge profile restrictions, resulting in a generally blunter profile as required by the template in Figure 4 and Table 3 of SEMI M1.

Table 2 Orientation Requirements

Property	*Requirement*	
ORIENTATION OF NOTCH AXIS[A]	<110>	± 1°
SECONDARY FLAT LOCATION	No secondary flat	
SURFACE ORIENTATION	{100}	± 1°

[A] For (111) wafers, the $(1\bar{1}0)$, $(01\bar{1})$, and $(\bar{1}01)$ planes are equivalent, allowable planes. For (100) wafers, the allowable equivalent <110> planes are [011], $[01\bar{1}]$, $[0\bar{1}\bar{1}]$, and $[0\bar{1}1]$.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. RVSI Acuity CiMatrix has filed a statement with SEMI asserting that the patented or copyrighted item can be used by the public for the purpose of implementing this standard without specific license and without payment of royalty or other charge. Attention is also drawn to the possibility that some elements of this standard may be subject to patented technology or copyrighted items other than those identified above. Semiconductor Equipment and Materials International (SEMI) shall not be held responsible for identifying any or all such patented technology or copyrighted items. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights and the risk of infringement of such rights are entirely their own responsibility.

SEMI

SEMI M2-0997
SPECIFICATION FOR SILICON EPITAXIAL WAFERS FOR DISCRETE DEVICE APPLICATIONS

1 Purpose

1.1 This specification defines silicon epitaxial wafer requirements for discrete semiconductor device manufacture. It is restricted to wafers with device feature sizes in excess of 1 µm or wafers with epi layers thicker than 25 µm.

2 Scope

2.1 By defining inspection procedures and acceptance criteria, suppliers and consumers may uniformly define product characteristics and quality requirements.

2.2 The characteristics specified relate to the substrate (as specified in SEMl M1) and to the epitaxial layer, including handling and packaging. The primary standardized properties set forth in this specification relate to physical, electrical, and surface defect parameters.

2.3 A complete purchase specification requires that additional physical properties be specified along with suitable test methods for their measurement. SEMI M18 may be used for this purpose.

3 Limitations

3.1 This specification is specifically directed to silicon homoepitaxial deposits thicker than 25 µm on homogeneous silicon substrates or similar epitaxial wafers that are to be used to make discrete devices.

NOTE 1: Specifications for epitaxial wafers with greater uniformity and more stringent surface defect criteria are given in SEMI M11.

4 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

F 1393 — Test Method for Determining Net Carrier Density in Silicon Wafers by Miller Feedback Profiler Measurements with a Mercury Probe

4.3 *Other Standards*[2]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

5 Terminology

Many terms relating to silicon technology are defined in ASTM Terminology F 1241.

Definitions for the epitaxial wafer defects covered in Table 1 are given in ASTM Test Methods F 47, F 522, and F 815, and in ASTM Practices F 154.

Other terms are defined as follows:

5.1 *autodoping, of an epitaxial layer* — Incorporation of dopant originating from the substrate into the epitaxial layer. Also called *self-doping*.

NOTE 2: Sources of autodoping can be the back and front surfaces and edges of the substrate, other substrates in the reactor, the susceptor, or other parts of the deposition assembly.

5.2 *chemical vapor deposition, in semiconductor technology* — A process in which a controlled chemical reaction produces a thin surface film.

NOTE 3: Epitaxial growth is an example of a special case of chemical vapor deposition (CVD).

5.3 *edge crown* — The difference between the surface elevation 1/8 inch (3.2 mm) from the edge of the wafer and the elevation at the wafer edge.

5.4 *effective layer thickness, of an epitaxial layer* — The depth from the front surface in which the net carrier density is within the specified limits.

5.5 *epi profile slope, of an epitaxial layer* — The difference between the net carrier density at 0.75 of the layer thickness and the net carrier density at 0.25 of the layer thickness divided by one-half the layer thickness:

$$\text{epi profile slope} = \frac{N_{0.75t} - N_{0.25t}}{0.5t}$$

where :

N = net carrier density, cm^{-3}, and

t = layer thickness, μm.

5.6 *epitaxial layer* — A layer of single crystal semiconductor material grown on a host substrate which determines its orientation.

5.7 *epitaxy* — The growth of a single crystal layer on a substrate of the same material, homoepitaxy; or on a substrate of different material with a compatible crystal structure, heteroepitaxy.

5.8 *flat zone, of an epitaxial layer* — The depth from the front surface to the point where the net carrier density is 20% greater than or less than the average net carrier density (see Section 9.3.2) of the region between 0.25 and 0.75 of the layer thickness.

5.9 *thickness, of an epitaxial layer* — The distance from the surface of the wafer to the layer-substrate interface.

5.10 *transition width, of an epitaxial layer deposited on a more heavily doped substrate of the same conductivity type* — The difference between the layer thickness as determined by infrared reflectance (see Section 9.3.1) and the flat zone based on the same thickness measurement.

6 Ordering Information

6.1 Purchase orders for the epitaxial layer on substrates furnished to this specification shall include the following items:

6.1.1 Substrate characteristics,

6.1.2 Silicon source (if required) (see Note 4),

6.1.3 Conductivity type and doping source (see Note 4),

6.1.4 Etch removal (if required),

6.1.5 Center point thickness and thickness tolerances,

6.1.6 Radial thickness variation range,

6.1.7 Centerpoint net carrier density and net carrier density tolerances (see Note 5),

6.1.8 Radial net carrier density variation range,

6.1.9 Epitaxial wafer defect limits,

6.1.10 Methods of test and measurements (see Section 6),

6.1.11 Lot acceptance procedures (see Section 9),

[2] *American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202*

6.1.12 Certification (if required) (see Section 10),

6.1.13 Packing and marking (see Section 11).

NOTE 4: The dopant, doping method, and growth method are difficult to ascertain in the finished wafers. Verification test procedures or certification of these characteristics shall be agreed upon between the supplier and the purchaser (see Section 10).

NOTE 5: Care should be taken in converting between carrier density and resistivity using ASTM Practice F 723. Multiple conversions may introduce differences in values. For example, converting from carrier density (C_i) to resistivity and back to carrier density (C_f), may result in C_i not equaling C_f.

7 Requirements

7.1 The substrate shall conform to SEMI M1 and to the appropriate polished silicon wafer standard.

7.2 Epitaxial wafer defects shall not exceed the limits as given in Table 1.

NOTE 6: When an unetched wafer is observed for slip, it is impossible to differentiate between slip and linear misfit lines.

7.3 *Layer Thickness Variation* — Unless otherwise specified, the radial thickness variation shall be determined from values measured at the center and R/2 locations, on diameters both parallel and perpendicular to the primary flat, and shall be ≤ 6% defined as follows:

$$\text{Variation (\%)} = \frac{\left|\frac{R}{2} - C\right|_{max}}{C} \times 100$$

where R/2 denotes one of the values measured at R/2 and C denotes the value at the center.

7.4 *Net Carrier Density Variation*— The radial net carrier density variation shall be determined from values measured at the center and R/2 locations, on diameters both parallel and perpendicular to the primary flat, and shall be ≤ 10% for net carrier density ≥ 1×10^{15} cm^{-3} and≤ 15% for net carrier density < 1×10^{15} cm^{-3} defined as follows:

$$\text{Variation (\%)} = \frac{\left(\frac{R}{2} - C\right|_{max}}{C} \times 100$$

where R/2 denotes one of the values measured at R/2 and C denotes the value at the center.

8 Sampling

8.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot according to ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) in accordance with ANSI/ASQC Z1.4. Inspection levels shall be agreed upon between supplier and purchaser.

8.2 Unless otherwise specified, the following AQL's shall be assigned:

8.2.1 Epitaxial layer thickness, 6.5%,

8.2.2 Epitaxial layer net carrier density, 6.5%,

8.2.3 Epitaxial wafer defects, cumulative, 4.0%.

9 Test Methods

9.1 Measurements shall be carried out in conformance with the specified ASTM methods. Where no methods are specified or where choices are given, the supplier and purchaser shall agree in advance on the means for making the measurement.

9.2 *Substrate* — Determine in accordance with methods defined in SEMI M1.

9.3 Epitaxial Layer

9.3.1 *Thickness* — Determine in accordance with ASTM Test Methods F 95 or F 110.

NOTE 7: There is a possibility that various types of infrared reflectance instrumentation may result in different values of epitaxial layer thickness. Therefore, the instrumentation used shall be agreed upon between supplier and purchaser.

9.3.2 *Net Carrier Density* — Determine by method(s) agreed upon between supplier and purchaser.

NOTE 8: ASTM Test Method F 419 is a standardized differential-capacitance method for net carrier density, but it requires fabrication of a p-n junction. ASTM Test Methods F 1392 and F 1393 are methods for measuring net carrier density using a mercury probe contact. If resistivity is measured, as by ASTM Test Methods F 374 or F 525, conversion to dopant density shall be made using ASTM Practice F 723. Net carrier density of very heavily doped layers (or substrates) may be found using ASTM Test Method F 398. Net carrier density profiles may be determined directly in accordance with ASTM Test Method F 419, F 1392, or F 1393 or indirectly in accordance with ASTM Test Method F 672, with conversion from resistivity to net carrier density in accordance with ASTM Practice F 723. If the method used for determining the net carrier density profile is not the same as that used to determine the centerpoint net carrier density, correlation between the two methods used shall be established.

9.3.3 *Epitaxial Wafer Defects* — Determine in accordance with the methods given in Table 1.

9.3.3.1 Surface inspection shall be performed before any other testing. Wafers may be cleaned prior to inspection to minimize difficulty in the visual inspection of defects other than foreign matter.

9.3.3.2 Inspection for slip shall be done using grid elements constructed in accordance with SEMI M17. An element is defective if it contains one or more slip lines. The total number of defective elements shall be less than or equal to *n*, where *n* is listed in Table 1.

9.4 If substrates of different type and net carrier density than the product substrates are to be used for deposition control, their type, net carrier density, and quantity per run or lot shall be agreed upon between supplier and purchaser.

10 Certification

10.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

10.2 The user and supplier may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 9; however, if the user performs the test and the material fails to meet the requirement, the material may be subject to rejection.

11 Packing and Package Labeling

11.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise, all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide protection against damage during shipment.

11.2 The wafers supplied under these specifications shall be identified by appropriately labeling the outside of each box or container, and each subdivision thereof, in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include supplier's name and reference number, purchaser's p.o. number, quantity, dopant, orientation, conductivity type of substrates and epitaxial layers, carrier density, and thickness of the epitaxial layer. The reference number assigned by the supplier shall provide ready access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the manufacturer's facility for at least one year after the particular lot has been shipped.

Table 1 Discrete Epitaxial Wafer Defect Limits

Item	*Characteristics*	*Maximum Limit*				*Test Method*	*Notes*
1	Stacking Faults	15 per cm^2				Nomarski Interference Contrast Microscopy ASTM F 522	1
2	Slip	*n* = 36 grid elements				SEMI M17, F 523, or F 80	1, 2, 3
3	Haze	NONE				F 523 Section 12.2	1, 4, 5

6	Edge Crown	Projection above wafer surface not to exceed 1/3 of epi layer thickness				To be defined	2, 8
7	Foreign Matter	NONE				F 523 Section 12.3	1, 4
8	Back Surface Contamination	NONE				F 523 Section 12.4	1, 4
Front Surface Characteristics Dependent on Layer Thickness		Epitaxial Layer Thickness					
		< 25 µm	25–50 µm	50–100 µm	> 100 µm		
9	Large Point Defects (Density per m^2)	700	900	1200	1500	F 523 or ≥ 20 µm LSE, based on calibration of surface scanning inspection systems with polystyrene latex spheres, 90% capture rate	1, 2, 5, 9
10	Total Localized Light Scatterers (Density per m^2)	2000	2400	2700	3000	F 523 or ≥ 0.5 µm LSE, based on calibration of surface scanning inspection systems with polystyrene latex spheres, 90% capture rate	1, 2, 5, 9

Notes:

1. Defect limits shall apply to quality area, which is defined as the entire wafer surface except a defined outer annulus: 2 inch and 3 inch = 2 mm; 100 mm and 125 mm = 3 mm; 150 mm and 200 mm = 4 mm and any are included in a window where there is a laser indentification mark.

2. Test method(s) to be agreed upon between supplier and purchaser.

3. For observation of gross slip, examine the epi layer under illumination conditions specified in Section 12.2 of ASTM Practice F 523. For more demanding applications, it may be desirable to etch the surface in accordance with ASTM Method F 80 prior to the visual inspection.

4. Any adherent contaminants, such as stains, glovemarks, dirt, smudges, and solvent residues. This characteristic does not include point defects. Any nonadherent contaminant or particulate matter easily removed by industry accepted cleaning techniques shall not constitute foreign matter or haze.

5. In today's technology, it may be possible to do this inspection using automated laser scanning systems; however, a standard test procedure has yet to be developed. Application of automated inspection must be agreed upon between supplier and user.

6. The cumulative AQL for both front surface and back surface of wafer is 2.5%.

7. The cumulative AQL for both front surface and back surface of wafer is 1.0%. Maximum radial penetration, 1.0 mm; maximum single chip peripheral length, 6.3 mm; maximum cumulative peripheral length, 6.3 mm.

8. Edge crowning may be reduced by pre-epitaxy edge rounding, or removed by post-epitaxy edge rounding.

9. See Table 2 in SEMI M25.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M3-1296
SPECIFICATIONS FOR POLISHED MONOCRYSTALLINE SAPPHIRE SUBSTRATES

1 Preface

1.1 These specifications cover requirements for four sizes of monocrystalline high-purity polished sapphire substrates used for silicon growth and subsequent semiconductor device manufacture. Dimensional and crystallographic orientation characteristics are the only standardized properties set forth below. A purchase specification may require that additional physical properties and allowable levels of bulk and surface defects be defined. These properties are listed, together with test methods suitable for determining their magnitude.

1.2 These specifications are directed specifically to sapphire substrates with one polished surface. Substrates polished on both sides, or unpolished, or with epitaxial deposits, are not covered; however, purchasers of such substrates may find this specification to be a useful guide in defining their requirements.

1.3 For referee purposes, U.S. customary units shall be used for substrates of 2.0 and 3.0 in. nominal diameters, and SI (System International, commonly called metric) units for 100 mm and larger diameter substrates.

2 Applicable Documents

2.1 *ASTM Standards*[1]

E 122 — Practice for Choice of Sample Size to Estimate the Average Quality of a Lot or Process

F 21 — Test Method for Hydrophobic Surface Films by the Atomizer Test

F 22 — Test Method for Hydrophobic Surface Films by the Water-Break Test

F 24 — Method for Measuring and Counting Particulate Contamination on Surfaces

F 26 — Test Methods for Determining the Orientation of a Semiconductive Single Crystal

F 154 — Practices and Nomenclature for Identification of Structures and Contaminants Seen on Specular Silicon Surfaces

F 523 — Practice for Unaided Visual Inspection of Polished Silicon Slices

F 533 — Test Method for Thickness and Thickness Variation of Silicon Slices

F 534 — Test Method for Bow of Silicon Slices

2.2 *Other Standard*[2]

ANSI/ASQC Z1.4-1993 — Sampling Procedures and Tables for Inspection by Attributes

3 Selected Definitions

3.1 *Lot* — For the purposes of this document, (a) all of the substrates of nominally identical size and characteristics contained in a single shipment, or (b) subdivisions of large shipments consisting of substrates as (a) above which have been identified by the supplier as constituting a lot.

3.2 *Sapphire* — Single crystal Al_2O_3 having a definite orientation that allows epitaxial deposition.

3.3 *Substrate* — The polished sapphire slice upon which the epitaxial layer of silicon is grown.

4 Ordering Information

4.1 Purchase orders for sapphire substrates furnished to these specifications shall include the following items:

4.1.1 Nominal diameter (see applicable SEMI Standard for Sapphire Substrates),

4.1.2 Crystal growth method (see Note 1),

4.1.3 Surface orientation (see Figures 1 and 2),

4.1.4 Lot acceptance procedures (see Section 8),

4.1.5 Certification (if required) (see Section 14),

4.1.6 Packing and marking (see Section 15).

4.2 The following items may be specified optionally in addition to those listed in Paragraph 4.1:

4.2.1 Crystal perfection,

4.2.2 Surface defect and contaminant levels,

4.2.3 Impurities other than common doping elements,

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959 (All cited standards except for E 122 may be found in Volume 10.05 of the Annual Book of ASTM Standards; E 122 may be found in Volume 14.02.)

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

4.2.4 Surface finish quality level (see Figures 5 through 8),

4.2.5 Back surface finish,

4.2.6 Secondary flat (see Figure 3, Section 10),

4.2.7 Flatness (see Table 1, Section 11).

NOTE 1 The crystal growth method (for example, Czochralski or EFG ribbon) is difficult to ascertain in the finished substrates. Verification test procedures or certification of these characteristics (see Section 14) shall be agreed upon between the supplier and the purchaser.

NOTE 2 Items in Paragraph 4.2 are less commonly specified than the others but are included for completeness as parameters for which methods of evaluation have been developed.

5 Dimensions and Permissible Variations

5.1 The material shall conform to the dimensions and dimensional tolerances as specified in the appropriate sapphire substrate standard.

6 Materials and Manufacture

6.1 The material shall consist of slices from sapphire grown by the process specified in the purchase order or contract.

7 Physical Requirements

7.1 The material shall conform to the crystallographic orientation details of the appropriate sapphire substrate standard (see Figure 1).

7.2 The following items, if included, shall conform to the requirements specified in the purchase order or contract:

7.2.1 Crystal perfection,

7.2.2 Surface defect and contaminant levels,

7.2.3 Amount of impurities other than common dopants,

7.2.4 Surface finish quality level,

7.2.5 Back surface finish.

8 Sampling

8.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4-1993. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4-1993 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

9 Test Methods

9.1 *Dimensions* — Measure as follows:

9.1.1 *Diameter* — Determine in accordance with ASTM Test Method F 613.

NOTE 3 Sapphire substrates are susceptible to surface damage. While the mechanical dimensions of a slice can be measured by use of tools such as micrometer calipers and other conventional techniques, the substrate may be damaged physically in ways that are not immediately evident. Special care must therefore be used in the selection and execution of measurement methods. Figure 2 of Section 12 illustrates the standard measurement location convention.

9.1.2 *Thickness, Center Point* — Determine in accordance with ASTM Test Method F 533.

9.1.3 *Flat Length* — Determine in accordance with ASTM Test Method F 671.

9.1.4 *Bow* — Determine in accordance with ASTM Test Method F 534.

9.1.5 *Total Thickness Variation* — Determine in accordance with ASTM Test Method F 533.

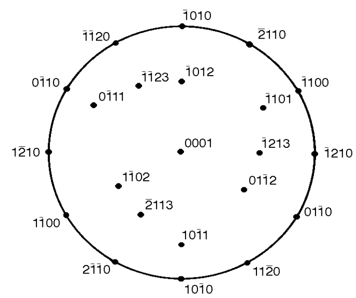
9.2 *Flat Orientation* — Determine by a method agreed upon between the supplier and the purchaser.

9.3 *Surface Orientation* — Determine in accordance with ASTM Test Methods F 26.

9.4 *Crystal Perfection* — Determine by a method agreed upon between the supplier and the purchaser.

9.5 *Surface Defects and Contamination* — Determine defects in accordance with ASTM Practice F 523. See Section 13 for surface defect definitions and Table 3 for allowable levels of defects. In the event the substrates fail to meet these criteria, they shall be conditioned according to ASTM Practice F 612 and retested.

Structural Indices	Mineralogical Symbols
$1\bar{1}02$	r
$01\bar{1}2$	r
$\bar{1}012$	r
0001	c
1010	m
$11\bar{2}0$	a
$10\bar{1}1$	s
$2\bar{1}\bar{1}3$	n



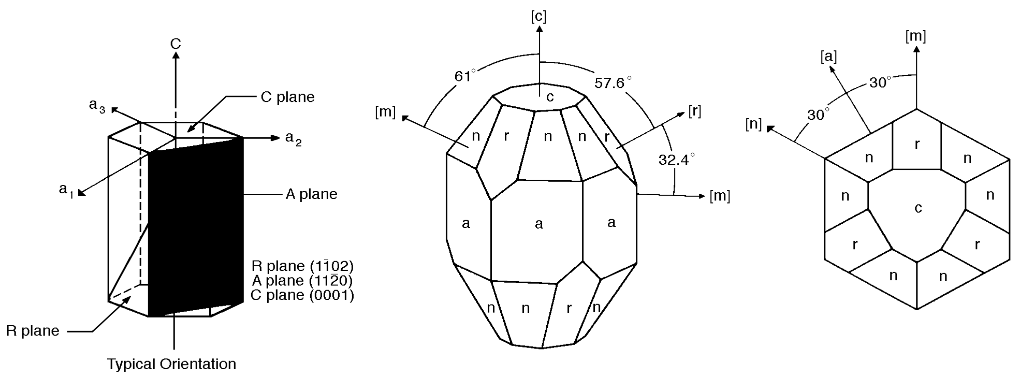


Figure 1
Sapphire Crystallographic Diagrams

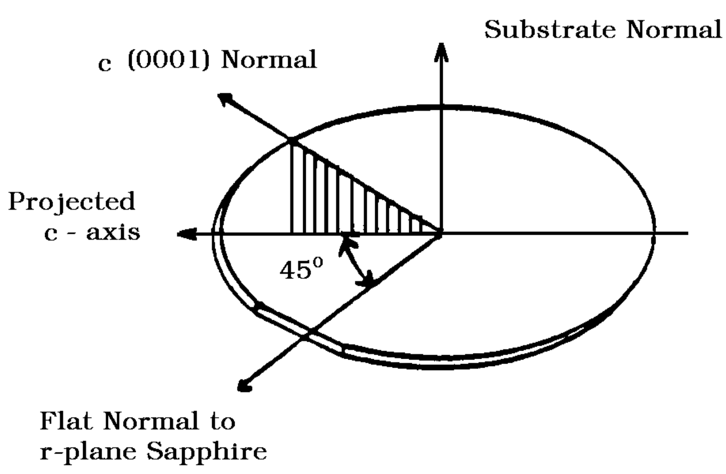

Figure 2
Sapphire Surface Orientation

NOTE 4 — ASTM Practices F 154 is a useful guide for defining a variety of surface features found on silicon slice surfaces and for establishing commonly understood terms for describing them. It also gives detailed procedures for illumination and microscopical examination of surfaces. The presence of contaminating materials on silicon surfaces can be determined by ASTM Test Methods F 21, F 22, or F24, as appropriate.

9.6 *Other Impurities* — Determine by methods agreed upon between the supplier and the purchaser.

9.7 *Surface Finish* — Determine by methods agreed upon between the supplier and the purchaser. Limits are given in the individual specifications.

9.8 *Backside Finish* — Determine by methods agreed upon between the supplier and the purchaser.

9.9 *Secondary Flat* — Standard location is determined as described in Section 10. Flat length is determined as described in Paragraph 9.1.3.

9.10 *Flatness* — Determine by a method agreed upon between the user and supplier.

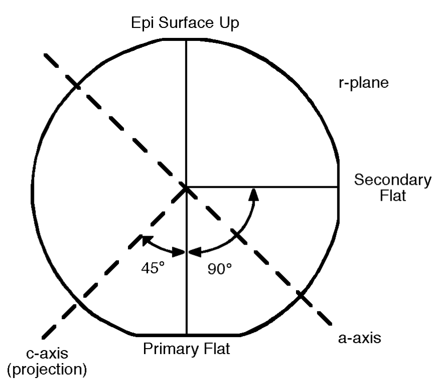

Figure 3

10 Flat System

10.1 Figures 2 and 3 describe the primary and secondary flat system.

Primary Flat: 45° ± 2° in the counter-clockwise direction from the projection of the c-axis along an r-plane.

Secondary Flat (Optional): 90° ± 2° in the counter-clockwise direction from the primary flat, along an r-plane.

The a-axis lies between the two flats bisecting the 90° angle. Projection of the c-axis lies 45° in the clockwise direction from the primary flat and 90° in the clockwise direction from the a-axis.

11 Flatness

Specifications for flatness of polished monocrystalline sapphire substrates shall be as given in Table 1.

Table 1

Class	*Sapphire Substrate ((TIR), μm)*
I	25 max
II	14 max
III	10 max
IV	8 max
V	6 max

12 Measurement Location Convention

12.1 Figure 4 illustrates the standard measurement location convention.

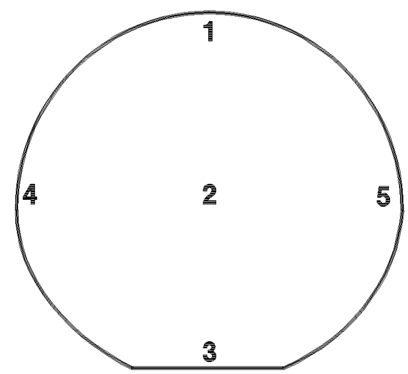

Figure 4

13 Standard Defect Limits

Definitions for surface defects are found in ASTM Practice F 523, where defects commonly found on silicon slices are defined. Some of these terms do not apply to sapphire substrates, but are present in Table 2 for a convenient reference point to the silicon slice standards.

Minimal Conditions and/or Dimensions — Minimal conditions or dimensions for defects are stated below and shall be used for determining substrate acceptability unless other minimal limiters are agreed upon by the interested parties. Anomalies less than these limits shall not be considered defects.

Area Contamination — Foreign matter on the surface in localized areas which is revealed as discolored, mottled, or cloudy appearance resulting from smudges, stains, water spots, etc.

Contamination — Any foreign matter detectable under the inspection lighting conditions.

Edge Chips and Indents — Any edge or surface anomaly conforming to the accepted definition greater than .010 inch in radial depth and peripheral length.

Cracks — Any anomaly conforming to the accepted definition greater than 0.010 inch (0.25 mm) in total length.

Craters — Any individually distinguishable surface anomaly conforming to the accepted definition visible when viewed under diffuse illumination.

Crow's Feet — N.A.

Grooves — N.A.

Haze — Haze is indicated when the image of a narrow beam tungsten lamp filament is detectable on the epi silicon surface. (Under some conditions, contamination may appear as haze.)

Mounds — N.A.

Orange Peel — Any visually detectable roughened surface conforming to the accepted definition observable under diffuse illumination.

Pits — Any individually distinguishable nonremovable surface anomaly conforming to the accepted definition visible when viewed under intense illumination.

Saw Exit Mark — N.A.

Scratch — Any anomaly conforming to the definition with a length-to-width ratio greater than 5:1.

Striation — Any feature conforming to the accepted definition detectable under background lighting conditions.

14 Certification

Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 9. However, if the purchaser performs the test and the material fails to meet the requirements, the material may be subject to rejection.

15 Packing and Marking

Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise all slices shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide ample protection against damage during shipment.

The substrates supplied under these specifications shall be identified by appropriately labeling the outside of each box or other container, and each subdivision thereof, in which it may reasonably be expected that the substrates will be stored prior to further processing. Identification shall include, as a minimum, the nominal diameter, orientation, and lot number. The lot number, either (1) assigned by the original manufacturer of the substrates, or (2) assigned subsequent to substrate's manufacture, but providing reference to the original lot number, shall provide ready access to information concerning the fabrication history of the particular substrates in that lot. Such information shall be retained on file at the manufacturer's facility for at least one month after that particular lot has been accepted by the purchaser.

Table 2 Sapphire Substrate Defect Limits

ITEM	*CHARACTERISTICS*	*MAX DEFECT LIMIT*	*AQL (see NOTE 6)*	*ILLUMINATION*	*NOTES*
1	SCRATCHES Maximum Number Maximum Length	3 R/2		High Intensity	1
2	PITS Maximum Number 2" Diameter Substrate 3" Diameter Substrate 100 mm Diameter Substrate	4 9 15	4% Cum.		1, 2
3	HAZE	None — see Note 4	4% Cum.		4
4	CONTAMINATION/PARTICULATE Maximum Number 2" Diameter Substrate 3" Diameter Substrate 100 mm Diameter Substrate	4 9 15	4% Cum.	Diffuse	1, 2
5	CONTAMINATION/AREA	None			
6	EDGE CHIPS Maximum Number Maximum Radial Penetration Maximum Single Chip Peripheral Length Maximum Cumulative Peripheral Length	see Note 3 2 0.12" (3 mm) 0.250" (6.35 mm) 0.250" (6.35 mm)	4% Cum.	Diffuse	3
7	CRACKS,CROW'S FEET		see Note 6		6
8	CRATERS	None			1, 5
9	DIMPLES	None			1
10	GROOVES	None	4% Cum.		1, 5
11	MOUNDS	None			1, 5
12	ORANGE PEEL	None		Diffuse	1
13	SAW MARKS	None			1, 5
14	STRIATIONS				
SLICE BACK SURFACE					
15	CHIPS	see Note 3	see Note 3	Diffuse	3
16	CRACKS, CROW'S FEET	None	see Note 6		6
17	CONTAMINATION/AREA	None			
18	SAW MARKS Incidence Maximum Depth	N.A.	see Note 5		5

Notes:

1. The outer 4 mm annulus is excluded from these criteria.
2. Ninety percent of substrate shall be free of contaminants after pre-inspection treatment. Balance of substrate may have light-reflecting particles up to the limit established for Item 2 — Pits.
3. All chips shall be beveled. Chips less than 0.4 mm should not be counted.
4. Haze refers to epitaxial silicon appearance only, not to condition of polished sapphire substrate.
5. These defects are not observed in SOS wafers. Terms remain for convenient reference to silicon specification.
6. Cracks are observed in sapphire substrates as fractures or as surface separations along cleavage planes. The cumulative AQL for both front surface and back surface of substrate is 4% for both. Crow's feet.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M3.2-91
STANDARD FOR 2 inch SAPPHIRE SUBSTRATES

The complete specification for this product includes all general requirements of SEMI M3.

Property	*Min*	*Max*	*Units*[D]
DIAMETER	50.55	51.05	mm
	1.990	2.010	in.
THICKNESS, CENTER POINT	280	380	µm
	0.011	0.015	in.
PRIMARY FLAT LENGTH	14.23	17.52	mm
	0.56	0.69	in.
SECONDARY FLAT LENGTH	6.35	9.65	mm
	0.25	0.38	in.
BOW		38	µm
		0.0015	in.
TOTAL THICKNESS VARIATION		51	µm
		0.002	in.

SURFACE ORIENTATION[A]	(1102) ± 2.0°
FLAT LOCATION[B]	See Section 10 of SEMI M3.
BACK SURFACE FINISH	Approximately 32 µin
FRONT SURFACE FINISH[C]	The substrate shall be polished on one side suitable for the epitaxial growth of silicon. The quality of this surface may be determined by optical examination at 70× using Nomarski interference contrast microscopy after etching the substrate in potassium hydroxide at 310°C for one to three minutes. Using the photographs as a guide, Figure 5 shall be considered acceptable, while Figure 8 is unacceptable. Figure 6 and Figure 7 are questionable surfaces and subject to individual evaluation.

[A] See Figure 1 for orientation diagrams.

[B] See Figure 3 for flat diagram.

[C] See Figures 5 through 8 for surface finish quality levels.

[D] For referee purposes, the U.S. Customary units apply. Conversion to metric (SI) equivalents was done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the metric (SI) equivalents are used for incoming inspection measurements, the rightmost digit of the minimum values should be reduced by 1 and the rightmost digit of the maximum values should be increased by 1 to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M3.4-91
STANDARD FOR 3 inch SAPPHIRE SUBSTRATES

The complete specification for this product includes all general requirements of SEMI M3.

Property	*Min*	*Max*	*Units*[D]

SEMI M3.6-88
STANDARD FOR 3 inch RECLAIMED SAPPHIRE SUBSTRATES

The complete specification for this product includes all general requirements of SEMI M3.

Property	*Min*	*Max*	*Units*[B]
DIAMETER	As received for reclamation.		
THICKNESS, CENTER POINT[A]	0.014	0.019	in.
FLAT LENGTH	As received for reclamation		
BOW		0.002	in.
FLATNESS[A]		25	µm
		14	µm
		10	µm
		8	µm
		6	µm

SURFACE ORIENTATION	As received for reclamation
FLAT LOCATION	As received for reclamation
BACK SURFACE FINISH	As received for reclamation
FRONT SURFACE FINISH	To SEMI M3

A: Amount of surface damage and flatness of as-received substrate determines final flatness and substrate thickness.

B: For referee purposes, the U.S. Customary units apply. To ensure that product shipped is within specification, any conversion to metric (SI) equivalents should be done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the metric (SI) equivalents are used for incoming inspection measurements, minimum values should be rounded down and maximum values rounded up to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M3.7-91
STANDARD FOR 125 mm SAPPHIRE SUBSTRATES

The complete specification for this product includes all general requirements of SEMI M3.

Property	*Min*	*Max*	*Units*[D]
DIAMETER	124.0	126.0	mm
THICKNESS, CENTER POINT	600	650	µm
PRIMARY FLAT LENGTH	40.0	45.0	mm
SECONDARY FLAT LENGTH	18.0	22.0	mm
BOW		60	µm
WARP		60	µm
TOTAL THICKNESS VARIATION		50	µm

SURFACE ORIENTATION[A]	(1102) ± 2.0°
FLAT LOCATION[B]	See Section 10 of SEMI M3.
BACK SURFACE FINISH	Approximately 32µin.
FRONT SURFACE FINISH[C]	The substrate shall be polished on one side suitable for the epitaxial growth of silicon. The quality of this surface may be determined by optical examination at 70× using Nomarski interference contrast microscopy after etching the substrate in potassium hydroxide at 310°C for one to three minutes. Using the photographs as a guide, Figure 5 shall be considered acceptable, while Figure 8 is unacceptable. Figure 6 and Figure 7 are questionable surfaces and subhect to individual evaluation.

[A] See Figure 1 for orientation diagrams.

[B] See Figure 3 for flat location diagram.

[C] See Figures 5 through 8 for surface finish quality levels.

[D] For referee purposes, the metric (SI) units apply. Conversion to U.S. Customary equivalents was done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection measurements, the rightmost digit of the minimum values should be reduced by 1 and the rightmost digit of the maximum values should be increased by 1 to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

semi™

SEMI M3.8-91
STANDARD FOR 150 mm SAPPHIRE SUBSTRATES

The complete specification for this product includes all general requirements of SEMI M3.

Property	*Min*	*Max*	*Units*[D]
DIAMETER	149.0	151.0	mm
THICKNESS, CENTER POINT	650	700	µm
PRIMARY FLAT LENGTH	55.0	60.0	mm
SECONDARY FLAT LENGTH	35.0	40.0	mm
BOW		60	µm
WARP		60	µm
TOTAL THICKNESS VARIATION		60	µm

SURFACE ORIENTATION[A]	(1102) ± 2.0°
FLAT LOCATION[B]	See Section 10 of SEMI M3.
BACK SURFACE FINISH	Approximately 32 µin.
FRONT SURFACE FINISH[C]	The substrate shall be polished on one side suitable for the epitaxial growth of silicon. The quality of this surface may be determined by optical examination at 70× using Nomarski interference contrast microscopy after etching the substrate in potassium hydroxide at 310°C for one to three minutes. Using the photographs as a guide, Figure 5 shall be considered acceptable, while Figure 8 is unacceptable. Figure 6 and Figure 7 are questionable surfaces and subhect to individual evaluation.

[A] See Figure 1 for orientation diagrams.

[B] See Figure 3 for flat location diagram.

[C] See Figures 5 through 8 for surface finish quality levels.

[D] For referee purposes, the metric (SI) units apply. Conversion to U.S. Customary equivalents was done following the maximum-minimum convention in which the minimum values are rounded up and the maximum values are rounded down to ensure that the equivalent range is always inside the referee range. If the U.S. Customary equivalents are used for incoming inspection measurements, the rightmost digit of the minimum values should be reduced by 1 and the rightmost digit of the maximum values should be increased by 1 to avoid rejection of material that is within the specification when measured by the referee system of units. CAUTION — The significance of the rightmost digit may vary, depending on the quantity being measured and the precision of the test procedure. Refer to the relevant test method for precision data which can be used to construct appropriate guard bands.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M4-1296
SPECIFICATIONS FOR SOS EPITAXIAL WAFERS

1 Preface

1.1 These specifications cover requirements for monocrystalline silicon epitaxial layers on sapphire substrates, used for semiconductor device manufacture. By outlining an inspection process and defining various reject criteria, both users and suppliers can uniformly define epitaxial layer quality.

1.2 The defects discussed originate from two sources: those which are caused by imperfection in the sapphire substrate and those related to the epitaxial layer, including handling and packaging.

2 Applicable Documents

2.1 *SEMI Standard*

SEMI M3 — Specifications for Polished Monocrystalline Sapphire Substrates

2.2 *ASTM Standards*[1]

E 122 — Practice for Choice of Sample Size to Estimate the Average Quality of a Lot or Process

F 95 — Test Method for Thickness of Epitaxial Layers of Silicon on Substrates of the Same Type by Infrared Reflectance (Modifications to this procedure are required for use on SOS wafers.)

F 110 — Test Method for Thickness of Epitaxial or Diffused Layers in Silicon by the Angle Lapping and Staining Technique

F 154 — Practices and Nomenclature for Identification of Structures and Contaminants Seen on Specular Silicon Surfaces

F 374 — Test Method for Sheet Resistance of Silicon Epitaxial Layers Using a Colinear Four-Probe Array

F 523 — Practice for Unaided Visual Inspection of Polished Silicon Slices

2.3 *Other Standard*[2]

ANSI/ASQC Z1.4-1993 — Sampling Procedures and Tables for Inspection by Attributes

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959 (All cited standards except for E 122 may be found in Volume 10.05 of the Annual Book of ASTM Standards; E 122 may be found in Volume 14.02.)

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

3 Terminology

3.1 *Deposition* — The technique involved in the vapor deposition of single-crystal silicon on oriented sapphire substrates.

3.2 *Dopant* — A chemical element, usually from the third or fifth columns of the periodic table (typically phosphorous, arsenic, or boron), incorporated in trace amounts in the epitaxial layer to establish its conductivity type and resistivity.

3.3 *Doping* — The process of incorporation of a dopant into the epitaxial layer while the film is growing.

3.4 *Epitaxial Layer* — The layer of semiconductor material that is grown on the substrate.

3.5 *Lot* — For the purpose of this document, (a) all of the wafers of nominally identical specification and characteristics contained in a single shipment, or (b) subdivisions of large shipments consisting of epitaxial wafers as above which have been identified by the supplier as constituting a lot.

3.6 *Pre-Epitaxial Treatment* — The process of etching an amount of material from the sapphire substrate in situ prior to deposition. H_2 is commonly used for this purpose.

3.7 *Resistivity (ohm-cm)* — For the purpose of this method, the volume resistivity which is defined as the ratio of the potential gradient parallel to the current in the material to the current density.

3.8 *Silicon Source* — Volatile or gaseous silicon compounds; silane (SiH_4) is commonly used for this purpose.

3.9 *Substrate* — The polished sapphire slice upon which the epitaxial layer is deposited.

3.10 *Surface Defects* — Refers to mechanical imperfections, SiO_2 residual dust, and other imperfections visible on the wafer surface. Some examples of surface defects are: dimples, pits, particulates, spots, scratches, smears, hillocks, and polycrystalline regions. Definitions given in ASTM Practices F 154 shall be used.

3.11 *Wafer, SOS Epitaxial Wafer* — The combined sapphire substrate with the deposited epitaxial layer.

4 Ordering Information

4.1 Purchase orders for sapphire substrates furnished to this specification shall refer to SEMI M3, Specifications for Polished Monocrystalline Sapphire Substrates.

4.2 Purchase orders for the epitaxial layer on sapphire substrates furnished to this specification shall include the following additional items:

4.2.1 Silicon source (if required),

4.2.2 Conductivity type and doping source,

4.2.3 Pre-epitaxial treatment (if required),

4.2.4 Thickness,

4.2.5 Resistivity,

4.2.6 Surface defects,

4.2.7 Methods of test and measurements (see Section 6),

4.2.8 Lot acceptance procedures (see Section 7),

4.2.9 Certification (if required) (see Section 8),

4.2.10 Packing and marking (see Section 9).

NOTE 1 Correlation of these characteristics (see Section 4) and verification test procedures or certification of these characteristics (see Section 8) shall be agreed upon between the user and supplier.

5 Requirements

5.1 The substrate material shall conform to the requirements of SEMI M3.

5.2 The epitaxial layer shall meet the requirements specified in the purchase order or contract.

5.3 *Layer Thickness Variation* — Unless otherwise specified, the radial thickness variation shall be determined from values measured at the center and edge locations, as shown in Figure 1. Point 2, at wafer center, is the nominal film thickness for the wafer. Points 1, 3, 4, and 5 are located 6 mm in from the wafer periphery and define the edge measurements. All thickness values must be within the specified range. For example, for a film specified at 0.50 10% µm, all readings at points 1–5 must range from 0.45 to 0.55 µm.

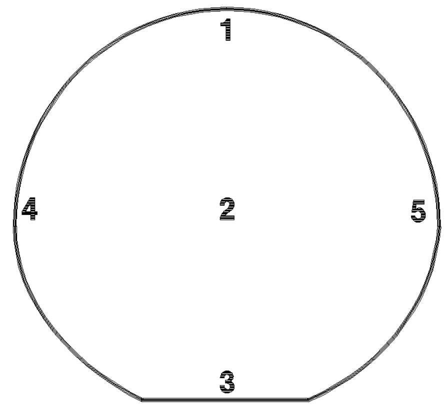

Figure 1

5.4 *Film Crystallinity* — SOS films can display varying degrees of haze due to polycrystalline silicon deposits in the film. These polycrystalline deposits can result from improper deposition temperatures, substrate surface contaminants, or contaminants in the reactor or reactor gases. Haze can be seen visually and can be quantitatively measured by ultraviolet light reflectance spectroscopy or by x-ray diffraction (pole figure) measurements. The ultraviolet light reflectance (UVR) value is commonly measured to determine the film crystalline quality. In this technique, the reflectance at two wavelengths, 280 and 440 nm, is measured using a clean, polished (100) silicon substrate as a reference. The difference between the two reflectance values, R_{280}–R_{440}, is recorded as the UVR value. For films in the thickness range 0.5 to 0.8 mm, the R_{280}–R_{440} value shall be less than 15 units. This value is an average of 5 points measured in the wafer as shown in Figure 1. The edge measurements are located at 12.5 mm in from the wafer periphery. For thinner films at 0.2 to 0.6 µm, the reflectance value at the single wavelength of 280 nm can be used. X-ray pole figure analysis measures the volume concentration of microtwins, as % (111), in the silicon film. The ultraviolet reflectance values and pole figure values are dependent on film thickness, so specified limits are listed for each film thickness in Table 1.

Table 1 Ultraviolet Reflection and X-Ray Pole Figure Values

Film Thickness	*Average Value, (MAX)*		*1 Peripheral Value, (MAX)*	
μm	ΔR_{280}	*%(111)*	ΔR_{280}	*%(111)*
0.20	15	7.0	23	11.5
0.30	17	5.5	28	9.5
0.40	21	5.0	33	8.0
0.50	27	4.5	42	7.0
0.60	32	4.0	51	6.5

$$\Delta R_{280} = \frac{|R_{ref} - R_{SOS}|}{R_{ref}}$$

NOTE 2 Currently, there is no ASTM method for this procedure. The procedure is described in the following references: M.T. Duffy, et al, National Institute of Standards and Technology Report No. NBS SP400-62, Semiconductor Measurement Technology, Contract NBS 5-35915 August 1980. M.T. Duffy, et al, J. Crystal Growth 58 (1982) 10.

5.5 *Microparticulate Density* — SOS films can display varying degrees of surface cleanliness as viewed with a microscope. Small particles trapped in the film can cause yield losses in some devices. The density of small particles can be determined by counting the particles observed during an X-Y scan across the wafers using Normarski Interference contrast at 100×. For particles greater than 2 mm in diameter, the particle density shall be less than 2 defects per square centimeter, excluding the outer 6 mm of the wafer periphery.

6 Methods of Test and Measurement

6.1 *Substrates* — Determined by methods agreed upon between the user and supplier. For measurement methods, see SEMI M3.

6.2 *Epitaxial Layer*

6.2.1 *Thickness* — Determine by method agreed upon between user and supplier. Recommended: ASTM Test Method F 95.

6.2.2 *Resistivity* — Determine by method(s) agreed upon between user and supplier. Recommended: ASTM Test Method F 374.

6.2.3 *Surface Defects and Contamination* — Determine by methods agreed upon between user and supplier. ASTM Practices F 154 is a useful guide for defining a variety of surface features and establishing commonly understood terms for describing surface defects and contamination. ASTM Practice F 523 is also recommended.

NOTE 3 SOS wafers are susceptible to surface damage. The thin film on the hard sapphire substrate may be damaged physically in ways that are not immediately evident. Special care must therefore be used in the selection and execution of measurement procedures.

NOTE 4 In this practice, defects commonly found in silicon slices are defined. Some of these terms do not apply to SOS wafers, but are present in Table 2 to provide a convenient reference point to the silicon wafer and epitaxial wafer standards.

7 Sampling

7.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot according to ANSI/ASQC Z1.4-1993. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4-1993 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between user and supplier.

8 Certification

8.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

8.2 In the interest of controlling inspection costs, the supplier and purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 6; however, if the purchaser performs the test and the material fails to meet the requirements, the material may be subject to rejection.

9 Packing and Marking

9.1 Special packing requirements shall be subject to agreement between the user and supplier. Otherwise all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide protection against damage during shipment.

9.2 The wafers supplied under these specifications shall be identified by appropriately labeling the outside of each box or container, and each subdivision thereof, in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include supplier's name and reference number, purchaser's part number, purchaser order number, quantity, dopant, conductivity type of epitaxial layers, resistivity and thickness of the epitaxial layer; the reference number assigned by the supplier shall provide ready access to information concerning the fabrication history of the particular substrates in that lot. Such information shall be retained on file at the manufacturer's facility for at least one month after that particular lot has been accepted by the purchaser.

10 Specification Limits

10.1 *Sampling Methods*

Epi layer thickness — As specified

Epi layer resistivity — As specified

General surface — As specified

10.2 *Surface Conditions*

10.2.1 Surface inspection shall be done before any other testing is to be done. Wafers may be cleaned prior to inspection to minimize difficulty in the visual inspection of defects other than foreign matter. Requirements shall apply to the entire surface, excepting the region 4 mm from the periphery.

10.2.2 Most of the following surface defects are defined in ASTM Practices F 154. Limits are defined in Table 2.

10.2.2.1 *Appearance* — Film shall be specular in appearance.

10.3 *Thickness*

10.3.1 Epitaxial layer thickness shall be as specified when determined by the method agreed upon between user and supplier. Standard test methods, correction factors, and correlation of these characteristics shall be agreed upon between user and supplier.

10.3.2 Layer thickness variation shall be specified as described in Section 5.3.

10.4 *Resistivity*

10.4.1 Resistivity range of the epitaxial layer shall be as specified, determined by the method agreed upon between user and supplier. Standard test methods, correction factors, and correlation of these characteristics shall be agreed upon and verified between user and supplier.

10.4.2 The radial resistivity gradient shall be measured at the center and R/2, and shall be as specified.

10.5 *Film Crystallinity*

10.5.1 Film crystallinity shall be as specified when determined by the method agreed upon between user and supplier. Common practice is described in Section 5.4.

10.6 *Microparticulate Density*

10.6.1 Microparticulate density shall be as specified when determined by the method agreed upon between user and supplier. Common practice is described in Section 5.5.

Table 2 Surface Defects by Non-Destructive Means

ITEM	*CHARACTERISTICS*	*MAX ACCEPTABLE LIMIT*	*TEST METHOD*	*DEFECT DEFINITION PER*	*NOTES*
1	STACKING FAULTS	N.A.			2
2	SLIP	N.A.			2
3	PROTRUDING DEFECTS (Including spikes, hillocks, pyramids, and inclusions)	N.A.			2
4	PITS	Diameter No. 2" 4 3" 9 100 mm 15	F 523	F 154	1, 3
5	SCRATCHES	Cumulative L 1/2 wafer radius	F 523	F 154	1, 3
6	CRACKS, FRACTURES	None	F 523	F 154	5
7	ORANGE PEEL	N.A.			2
8	EDGE CHIPS	Max No. 2	F 523	F 154	2
9	EDGE CROWN	N.A.			2
10	HAZE	None	F 523	F 154	1, 6
11	FOREIGN MATTER FINGER PRINTS	None	F 523	F 154	1, 7

Notes:

1. The outer 4 mm annulus is excluded from these criteria.
2. These defects are not observed in SOS wafers. Terms remain for convenient reference to epitaxial silicon wafer specification.
3. Ninety percent of the wafers shall be free of these defects. Balance of wafer may have defects at these limits.
4. All chips shall be beveled. Maximum penetration 3 mm. Pointed apex chips none. Chips less than 0.4 mm (0.015 in.) shall not be counted. See SEMI M3, Table 3.
5. Cracks are observed in sapphire as fractures or as surface separations along cleavage planes.
6. Haze refers to the presence of polycrystalline silicon deposits in the film, as described in Section 5.4. Haze shall not be visible under lighting conditions of ASTM F 154.
7. Particulate matter easily removed by industry-accepted cleaning techniques shall not constitute foreign matter.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M6-1000
SPECIFICATION FOR SILICON WAFERS FOR USE AS PHOTOVOLTAIC SOLAR CELLS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the European Materials Committee. Current edition approved by the European Regional Standards Committee on July 28, 2000. Initially available at www.semi.org September 2000; to be published October 2000. Originally published in 1981; previously published in 1985.

NOTE: This document replaces the previous version of SEMI M6 and M6.1, M6.2, M6.3, M6.4, and M6.5 in their entirety.

1 Purpose

1.1 This specification covers the requirements for silicon wafers for use in photovoltaic (PV) solar cell manufacture.

2 Scope

2.1 The dimensional characteristics, crystalline defects and commonly used wafer electronic properties are described. Two classes of crystalline silicon materials are recognized: monocrystalline and multicrystalline.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2.3 SI (System International) units are used throughout.

3 Referenced Standards

NOTE 1: The specification recognizes only two discrete material forms monocrystalline and multicrystalline. In the monocrystalline form one crystallographic orientation describes the whole wafer and in the multicrystalline case there is more than one crystallographic orientation present.

3.1 *SEMI Standard*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

3.2 *ASTM Standards*[1]

E 122 — Standard Practice for Choice of Sample Size to Estimate the Average for a Characteristic of a Lot or Process

F 26 — Standard Test Methods for Determining the Orientation of a Semiconductive Single Crystal

F 28 — Standard Test Methods for Minority-Carrier Lifetime in Bulk Germanium and Silicon by Measurement of Photoconductivity Decay

3.4 *ASQC standard*[3]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

3.5 *JEIDA standard*[4]

JEIDA-53 — Test Method for Carrier Recombination Lifetime in Silicon Wafers by Measurement of Photoconductivity Decay by Microwave Reflectance

NOTE 2: As listed or revised, all documents shall be the latest publications of adopted standards.

4 Terminology

4.1 *dopant* — A chemical element, usually from the third or fifth columns of the periodic table, incorporated in trace amounts in a semiconductor crystal to establish its conductivity type and resistivity. Common doping elements are boron and phosphorous.

4.2 *lot* — For the purposes of this document, (a) all of the wafers of nominally identical size and characteristics contained in a single shipment, or (b) subdivisions of large shipments consisting of wafers as listed above which have been identified by the supplier as constituting a lot.

4.3 *monocrystalline* — (synonym: single crystal) A body of crystalline material that contains no large-angle boundaries or twin boundaries.

4.4 *multicrystalline* — A body of crystalline material that contains large-angle boundaries or twin boundaries. Most crystals of this body have dimensions in the millimeter up to centimeter range.

5 Ordering Information

5.1 Purchase orders for silicon wafers furnished to this specification shall include the following items:

5.1.1 Nominal dimensions,

5.1.2 Either monocrystalline or multicrystalline,

5.1.3 Crystal growth method,

5.1.4 Surface orientation, crystal planes for monocrystalline wafers

5.1.5 Conductivity type and dopant,

NOTE 3: The dopant is difficult to ascertain in the finished wafers. Verification test procedures or certification (see Section 9) shall be agreed upon between the supplier and the purchaser.

5.1.6 Resistivity or resistivity range,

3 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

4 Japan Electronic Industry Development Association, 3-5-8 Shibakoen, Minato-ku, Tokyo 105, Japan

5.1.7 Lot acceptance procedures (see Section 6.4),

5.1.8 Certification (if required) (see Section 8),

5.1.9 Packing and marking (see Section 9),

5.1.10 Selection of test method to be used in evaluating those items for which alternate tests exist (see Section 7), and

5.1.11 Carbon and oxygen content.

5.2 Optional criteria. The following items may be specified optionally in addition to those listed above:

NOTE 4: Items in Paragraph 5.2 are less commonly specified than the others, but are included for completeness as parameters for which methods of evaluation have been developed.

5.2.1 Impurities other than common doping elements,

5.2.2 Diffusion length, and

5.2.3 Minority carrier lifetime.

NOTE 5: Up to now diffusion length and minority carrier lifetime cannot be measured with sufficient inter-laboratory accuracy. Subsequent recommendations, following lifetime round robin experiments, will be available in the future and will be presented in an addendum to this standard.

Even in the case of comparable and reproducible lifetime and diffusion length measurements, the measured characteristics must be regarded as an indication for solar cell efficiency. There is no general relation between initial minority carrier lifetime and solar cell efficiency as other parameters such as carbon or oxygen content will also influence the wafer in the solar cell process. However, in practical cases a dependence between minority carrier lifetime and solar cell efficiency can be found for a fixed solar cell process and a certain silicon wafer material. If one of them is changed the relation between them is suspect to change too.

6 Requirements

6.1 *Dimensions and Permissible Variations*

6.1.1 *Wafer Thickness and Variation*

6.1.1.1 Wafer thickness is typically 330 micrometer in 1999. In the future wafers should be specified in 50 micrometer intervals in the range between 150 and 400 micrometers.

6.1.1.2 The variation of wafer thickness in a lot as measured according to 7.2 at the center point of each wafer will be less than 15% of the specified wafer thickness.

6.1.2 *Rectangular Mainly Square Wafer Dimensions* — Depending upon the wafer type, one of the sections 6.1.2.1, 6.1.2.2 or 6.1.2.3 applies.

6.1.2.1 *Square Crystalline Silicon Wafer Dimensions*

6.1.2.1.1 *Physical dimensions* — See Figure 1, Table 2

Rectangular cells are permitted as long as the measures of A and B are according to the nominal size measures in Table 2.

Example: A = 100 mm, B = 150 mm.

Dimension D (identical for all sizes) min = 0.5 mm, max = 2.0 mm. By bilateral agreement, one corner can be of different angle and size to indicate the orientation of the wafer.

Squareness: The wafer will fit inside a square of the maximum dimension A and contain a square of the minimum dimension A.

6.1.2.1.2 TTV: 50 micrometer.

6.1.2.2 *Circular Monocrystalline Photovoltaic Solar Cell Silicon Wafers*

6.1.2.2.1 Diameters (mm): 100, 125, 150, 175, 200: Variation in diameter: ± 1 mm all sizes

6.1.2.2.2 TTV: 30 micrometer.

6.1.2.2.3 Warp: 75 micrometer.

6.1.2.3 *Pseudo-Square Monocrystalline Photovoltaic Solar Cell Silicon Wafers*

6.1.2.3.1 Physical dimensions: See Figure 2, Table 3

6.1.2.3.2 TTV: 30 micrometer.

6.1.2.3.3 Warp: 75 micrometer.

6.2 *Materials and Manufacture*

6.2.1 The material shall consist of wafers conforming to the structural class specified in the purchase order or contract.

6.3 *Physical Parameters*

6.3.1 The material shall conform to the crystallographic orientation details as specified in the purchase order or contract.

6.3.2 The material shall conform to the details specified in the purchase order or contract, as follows:

6.3.2.1 Conductivity type and dopant (see Note 3),

6.3.2.2 Resistivity,

6.3.2.3 Amounts of impurities other than common dopants (such as phosphorous, boron), especially oxygen and carbon content (optional),

6.3.2.4 Diffusion length (optional), and

6.3.2.5 Minority-carrier lifetime (optional).

6.4 *Wafer defect limits* — See Table 1.

Table 1 Wafer Defect Limits

Item	*Characteristics**	*Max Defect Limits*	*Notes*
1	Saw Marks	20 µm TIR	1
2	Area Contamination	To be determined	
3	Edge Chips/Indents	2 per wafer max up to l mm wide and l mm deep	2
4	Cracks/crow's feet	None	

* Characteristics are defined in SEMI M1, Section 10.

NOTE 1: The outer l mm (0.040") is excluded from these criteria.

NOTE 2: Excluding conchoidal chips.

6.5 *Sampling*

6.5.1 Unless otherwise specified, Practice E 122 shall be used.

6.5.1.1 When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot tolerance percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

7 Test Methods

NOTE 6: Silicon wafers are extremely fragile. While the mechanical dimensions of a wafer can be measured by use of tools such as micrometer calipers and other conventional techniques, the wafer may be damaged physically in ways that are not immediately evident. Special care must therefore be used in the selection and execution of measurement methods.

7.1 *Length, Width, or Diameter* — Determine the diameter of circular wafers in accordance with ASTM Test Method F 613. Determine the side length of square wafers by a method agreed upon between the supplier and the purchaser.

7.2 *Thickness, Center Point* — Determine in accordance with ASTM Test Methods F 533 or DIN 50441-1.

7.3 *Thickness Variation* — Determine in accordance with ASTM Test Methods F 533 or F 657.

7.4 *Structural Class* — Determine the structural class by a method agreed upon between the supplier and the purchaser.

7.5 *Surface Orientation* — Determine in accordance with ASTM Test Methods F 26 or DIN 50433-1, DIN 50433-2 and DIN 50433-3.

7.6 *Conductivity Type* — Determine in accordance with ASTM Test Methods F 42 or DIN 50432.

7.7 *Resistivity* — Determine by methods agreed upon between the supplier and the purchaser.

NOTE 7: Resistivity of wafers is most appropriately determined for referee purposes by ASTM Method F 84 or DIN 50431. Reliable measurements with these methods can only be made in regions of a wafer which contain no grain boundaries; these methods are therefore not appropriate for multicrystalline material. Under some circumstances these tests may be considered destructive, and an alternative means may be required. One non-destructive test is ASTM Test method F 673, having a range from 0.001 to 100 Ω-cm. This method is relatively insensitive to the presence of grain boundaries and is recommended for all material types. Another nondestructive test is ASTM Test Method F 398. This method is limited to carrier concentrations in the ranges from 1.5×10^{18} cm^{-3} to 1.5×10^{21} cm^{-3} for n-type silicon and from 3×10^{18} cm^{-3} to 5×10^{20} cm^{-3} for p-type, and has only moderate inter-laboratory precision. Other available methods include ASTM Test methods F 43 or DIN 50430 (referee methods requiring a bar-shaped sample).

7.8 *Other Impurities* — Determine by methods agreed upon between the supplier and the purchaser.

NOTE 8: ASTM Test Methods F 1188, F 1619 and DIN 50438-1 are specific tests for oxygen. ASTM F 1391 and DIN 50438-2 are specific tests for carbon; special thick test specimens are necessary.

7.9 *Minority Carrier Diffusion Length* — Determine by methods agreed upon between the supplier and the purchaser.

NOTE 9: Methods for minority carrier diffusion length are listed in ASTM F 391.

7.10 *Minority Carrier Lifetime* — Determine by methods agreed upon between the supplier and the purchaser.

NOTE 10: Methods for minority carrier lifetime measurements are given in ASTM F 28 (bulk material), ASTM F 1535 (wafers) and JEIDA-53 (wafers). As the wafer methods measure an effective lifetime, the sample preparation (surface passivation) and measurement conditions will influence the results and must be considered.

8 Certification

8.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

8.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as ‘capable of meeting’ certain requirements. In this context, ‘capable of meeting’ shall signify that the supplier is not required to perform the appropriate tests in Section 7. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

9 Packing and Package Labeling

9.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide ample protection against damage during shipment.

9.2 The wafers supplied under these specifications shall be identified by appropriately labeling the outside of each box or other container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include as a minimum the nominal diameter, conductivity type, dopant, orientation, resistivity range, and lot number. The lot number, either (1) assigned by the original manufacturer of the wafers, or (2) assigned subsequent to wafer manufacture but providing reference to the original lot number, shall provide easy access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the manufacturer’s facility for at least one year after that particular lot has been accepted by the purchaser.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI M6 and was approved by full letter ballot procedures on July 28, 2000 by the European Regional Standards Committee.

A1-1 *Crystal Orientation of Monocrystalline silicon wafers*

A1-1.1 A typical crystal orientation for monocrystalline silicon wafers is <100>.in the plane of the wafer.

A1-2 *Wafer resistivity*

A1-2.1 Typical wafer resistivity is between 0.5 Ω-cm and 2 Ω-cm.

A1-3 *Oxygen and Carbon Contents*

A1-3.1 Typical values.

A-1.3.1.1 Interstitial oxygen < 1×10^{18} at/cm^3 for CZ material and less than 8×10^{17} at/cm^3 for multicrystalline wafers.

A-1.3.1.2 Substitutional carbon < 5×10^{17} at/cm^3 for CZ and 1×10^{18} at/cm^3 for multicrystalline material.

A1-4 *Lifetime and Minority Carrier Diffusion Length*

A1-4.1 Typical minority carrier lifetime values for wafers used in the solar cell manufacturing process lie in a range between 1 µs and 20 µs.

NOTICE: SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of these guidelines is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M8-0301
SPECIFICATION FOR POLISHED MONOCRYSTALLINE SILICON TEST WAFERS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published in 1984; previously published September 1999.

1 Purpose

1.1 This specification covers requirements for virgin silicon test wafers to be used for testing and process monitoring in semiconductor manufacturing.

2 Scope

2.1 Dimensional and crystallographic orientation characteristics and limits on surface defects are the only standardized properties included in this specification.

2.2 A complete purchase specification requires that additional physical properties be defined. These properties are listed, together with test methods suitable for determining their magnitude.

2.3 This specification is directed specifically to silicon wafers with one polished surface. Wafers polished on both sides, or unpolished, or with epitaxial deposits are not covered; however, purchasers of such wafers may find this specification to be a useful guide in defining their requirements.

2.4 This specification classifies test wafers according to surface condition defect levels and dimensional tolerances. Test wafer classifications are summarized in Tables 1 and 2.

2.5 For applications placing higher demands on silicon wafers such as particle counting, measuring particle resolution in a photolithography process, or surface ion contamination monitoring, the user may reference the SEMI M1 or M24 standards.

2.6 For referee purposes, U.S. customary units shall be used for wafers of 2- and 3-inch nominal diameter and SI (System International), commonly called metric units, for 100 mm and larger diameter wafers.

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 Definitions of terms related to silicon wafer technology are given in ASTM Terminology F 1241.

4.2 Definitions for some additional terms are given in SEMI M1.

4.3 The following definitions apply in the context of this specification:

mechanical test wafer — silicon wafer suitable for testing equipment with emphasis on dimensional and structural characteristics only.

process test wafer — silicon wafer suitable for processes as well as area and process cleanliness (higher grade than mechanical test).

test wafer — silicon wafer suitable for process monitoring in semiconductor manufacturing. Also called *monitor wafer*.

virgin test wafer — test wafer that has not been used previously in semiconductor manufacturing.

5 Ordering Information

5.1 Purchase orders for 2", 3", 100 mm and 125 mm silicon test wafers furnished to this specification shall include the items from the appropriate specification groups listed in Table 1.

Table 1 Wafer Classifications

Classification	*Applicable Specification Groups*
A	1, 2, 3
B	1, 2
C	1

5.2 Items which may be specified when ordering silicon wafers are listed in SEMI M18. Not all of these items are required for ordering test wafers. The following items are included in the three specification groups; numbers in square brackets following the item are the item numbers in SEMI M18:

5.2.1 *Group 1*, *General and Geometrical* — Growth method [1.1], diameter [6.1], surface orientation [6.9], thickness [6.7], orientation fiducials (flats and notches) [6.2–6.5], and edge profile [6.6].

5.2.2 *Group 2, Surface Characteristics* — Surface defects as listed in Tables 3 and 4 [7.1–7.2, 8.1–8.16].

5.2.3 *Group 3, Basic Intrinsic Properties* — Conductivity type [1.3], dopant [1.4], and resistivity [2.1].

5.3 Not all of the above items must be specified explicitly; the specifications for many of the items are determined by the combination of wafer classification and nominal diameter. In all cases, the following must be specified on the purchase order for all classes of 2", 3" 100 mm and 125 mm test wafers.

5.3.1 Wafer Classification (A, B or C)

5.3.2 Nominal diameter and surface orientation

5.3.3 Growth method (see Section 7)

5.3.4 Lot acceptance procedures (see Section 9)

5.3.5 Certification (if required) (see Section 12)

5.3.6 Packing and Marking (see Section 13)

5.4 For Class A and B test wafers, that require controlled surface characteristics (see Section 11), in addition to the items listed in Section 5.3, see Table 4, Sections 8.1–8.16.

5.5 For Class A wafers, the following must be specified in addition to the items listed in Sections 5.3 and 5.4 (see Section 8):

5.5.1 Conductivity type

5.5.2 Resistivity

5.6 Purchase Orders for 150 mm, 200 mm, and 300 mm silicon test wafers shall include the items from the appropriate specification groups listed in Table 2.

Table 2 Wafer Classifications

Classifications	*Applicable Specification Groups*
Mechanical	1
Process	1, 2

5.6.1 *Group 1, General and Geometrical* — Growth method [1.1], diameter [6.1], surface orientation [6.9], thickness [6.7], orientation fiducials (flats and notches) [6.2–6.5], and edge profile [6.6].

5.6.2 *Group 2, Surface and Intrinsic Properties* — Surface defects as listed in Table 3 [7.1–7.2, 8.1–8.16], conductivity type [1.3], dopant [1.4], and resistivity [2.1].

5.7 Not all the specifications must be specified explicitly; the specifications for many of the items are determined by wafer classification and nominal diameter. In all cases the following must be specified on the purchase order for all classes of 150 mm, 200 mm, and 300 mm test wafers:

5.7.1 Wafer Classification (*Mechanical* or *Process)*

5.7.2 Nominal diameter and surface orientation

5.7.3 Growth method (see Section 7)

5.7.4 Lot acceptance procedures (see Section 9)

5.7.5 Certification (if required) (see Section 12)

5.7.6 Packing and Marking (see Section 13)

6 Dimensions and Permissible Variations

6.1 The material shall conform to the parameters as specified in Tables 3 or 4.

6.2 If test wafers are specified to be edge contoured, the profile shall conform to the requirements in Section 5.2 of SEMI M1 and to the dimension C_y in the associated polished silicon wafer standard applicable to the same nominal diameter and thickness. If edge profiling is not specified explicitly, there is no specification for the geometrical dimensions of any profiles which may exist on the wafers.

6.3 The material shall conform to the crystallographic orientation details as listed in the tables.

7 Materials and Manufacture

7.1 The material shall consist of wafers from crystals grown by the process specified in the purchase order or contract.

8 Electrical Requirements

8.1 The material shall conform to the details specified in the purchase order or contract, as follows:

8.1.1 Conductivity type

8.1.2 Resistivity

9 Sampling

9.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

10 Test Methods

NOTE 2: Silicon wafers are extremely fragile. While the mechanical dimensions of a wafer can be measured by use of tools such as micrometer calipers and other conventional techniques, the wafer may be damaged physically in ways that are not immediately evident. Special care must therefore be used in the selection and execution of measurement methods.

NOTE 3: The crystal growth method (for example, Czochralski or Float Zone) and dopant (for example, boron, phosphorous or antimony) used are difficult to ascertain in finished wafers. Verification test procedures for certification of these characteristics shall be agreed upon between the supplier and the purchaser.

10.1 *Diameter* — Determine in accordance with ASTM Test Method F 613.

10.2 *Thickness, Center Point* — Determine in accordance with ASTM Test Method F 533 or DIN 50441/1, or JIS H 0611.

10.3 *Flat Length* — Determine in accordance with ASTM Test Method F 671.

10.4 *Flat Orientation* — Determine in accordance with ASTM Test Methods F 847.

10.5 *Surface Orientation* — Determine in accordance with ASTM Test Methods F 26 or DIN 50433.

10.6 *Surface Defects and Contamination* — Determine in accordance with ASTM Practice F 523. The following conditions shall be used (unless otherwise specified in the purchase or contract):

a. Background light intensity: 8 ± 2 fc (86 ± 22 lux)

b. Angle α (alpha): 45° ± 10°

c. Angle β (beta): 90° ± 10°

See Section 11 for surface defect criteria and Table 2 for allowable levels of defects. In the event the wafers fail to meet these criteria, they shall be conditioned according to ASTM Practice F 612 or other cleaning procedure as agreed upon between supplier and user and retested.

NOTE 4: ASTM Practices F 154 is a useful guide for defining a variety of surface features found on silicon surfaces and for establishing commonly understood terms for describing them. It also gives detailed procedures for illumination and microscopical examination of surfaces.

10.7 *Conductivity Type* — Determine in accordance with ASTM Test Methods F 42 or DIN 50432.

10.8 *Resistivity* — Determine by methods agreed upon between the supplier and the purchaser.

NOTE 5: Resistivity of wafers is most appropriately determined for referee purposes by ASTM Method F 84 or DIN 50431. Under some circumstances these tests may be considered destructive, and an alternative means may be required. A widely used nondestructive test is ASTM Test Methods F 673, having a range from 0.0001 to 200 Ω • cm.

10.9 *Radial Resistivity Variation* — Determine in accordance with ASTM Test Methods F 81 or DIN 50435.

10.10 *Crystal Perfection* — Determine in accordance with ASTM Test Method F 47 or DIN 50434 (to determine grain boundaries, twinning, slip, dislocations, and lineage).

10.11 *Edge Profile* — Determine in accordance with ASTM Test Methods F 928 or DIN 50441/2.

11 Surface Defect Criteria

11.1 *Minimal Conditions or Dimensions* — The minimal conditions or dimensions for defects stated below shall be used for determining wafer acceptability. Anomalies smaller than these limits shall not be considered defects.

11.2 *area contamination* — any foreign matter on the surface in localized areas which is revealed under the inspection lighting conditions as discolored, mottled, or cloudy appearance resulting from smudges, stains, water spots, etc.

11.3 *crack* — any anomaly conforming to the definition and greater than 0.25 mm (0.010 inch) in total length.

11.4 *crow's foot* — any anomaly conforming to the definition and greater than 0.25 mm (0.010 inch) in total length.

11.5 *dimple* — any smooth surface depression greater than 3 mm in diameter.

11.6 *edge chip and indent* — any edge anomaly including saw exit marks conforming to the definition and greater than 0.25 mm (0.010 inch) in radial depth and peripheral length.

11.7 *hand scribe mark* — any mark such as that caused by a diamond scribe that is visible under diffuse illumination.

11.8 *haze* — haze is indicated when the image of a narrow beam tungsten lamp filament is detectable on the polished wafer surface. (Under some conditions contamination may appear as haze.)

11.9 *orange peel* — any roughened surface conforming to the definition that is observable under diffuse illumination.

11.10 *particulate contamination* — distinct particles resting on the surface which are revealed under collimated light as bright points.

11.11 *pit* — any individually distinguishable non-removable surface anomaly conforming to the definition and visible when viewed under high intensity illumination.

11.12 *saw marks* — any surface irregularities conforming to the definition that is observable under diffuse illumination.

11.13 *scratch* — any anomaly conforming to the definition and having a length-to-width ratio greater than 5:1.

11.14 *slip* — any pattern of short ridges aligned along <110> directions and visible under diffuse illumination.

11.15 *striations* — any helical features conforming to the definition and visible under diffuse illumination.

12 Certification

12.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

12.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 10. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

13 Packing and Marking

13.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise, all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices, to provide ample protection against damage during shipment.

13.2 The wafers supplied under this specification shall be identified by appropriately labeling the outside of each box or other container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing.

	TBD	Edge Condition	Polished

NOTE 1: Dislocation etch pit density is not specified. Wafers are permitted to be vacancy-rich or self-interstitial rich, and "ring" structures are allowable (V-I boundary within the FQA).

NOTE 2: Backside T7 per SEMI M1.15; backside M12 OCR mark per SEMI M1.15 may be optionally added but is expected to be used only on a temporary basis and to become obsolete after experience with the T7 mark demonstrates success.

NOTE 3: Site flatness specified as SFQR, 25 mm × 25 mm site size, x-offset=y-offset=ø, 112 sites. 100% inspection for site flatness is not recommended — process capability of 100% usable area @ ≤ 0.4 µm or 99% usable area @ ≤ 0.18 µm should be demonstrated.

NOTE 4: The number of Localized Light Scatterers (LLS) per wafer is to be determined by user/supplier agreement; the LLS size in PSL equivalents is specified as ≥ 0.16 µm with a goal of decreasing to 0.12 µm.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copy-righted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M9-0999
SPECIFICATIONS FOR POLISHED MONOCRYSTALLINE GALLIUM ARSENIDE SLICES

NOTE: This specification was modified in September 1999 to correct an editorial error present in Figure 4A. A Publication Improvement Proposal (PIP) form was submitted in August 1999.

1 Preface

1.1 These specifications cover two groups of substrate requirements for monocrystalline high-purity gallium arsenide wafers used in semiconductor and electronic device manufacture. Dimensional and crystallographic orientation characteristics and limits on surface defects are the only standardized properties set forth below.

1.2 A complete purchase specification may require that additional physical, electrical, and bulk properties be defined. These properties are listed, together with test methods suitable for determining their magnitude where such procedures are documented.

1.3 These specifications are directed specifically to gallium arsenide wafers with one or both sides polished. Unpolished wafers or wafers with epitaxial films are not covered; however, purchasers of such wafers may find these specifications helpful in defining their requirements.

1.4 The material is Single Crystal Gallium Arsenide (GaAs) having a cubic zinc blende structure and having the following properties. The following properties are for use as guidelines:

Density	5.316 gm/cm^3
Melting Point	1238°C
Dielectric Constant	13.1
Lattice Parameter	5.654 Å
Energy Gap	1.42 eV

1.5 For reference purposes, SI (System International, commonly called metric) units shall be used.

2 Applicable Documents

2.1 *ASTM Standards*[1]

E 122 — Practice for Choice of Sample Size to Estimate Average Quality of a Lot or Process

F 26 — Test Methods for Determining the Orientation of a Semiconductive Single Crystal

F 76 — Test Methods for Measuring Hall Mobility and Hall Coefficient in Extrinsic Semiconductor Single Crystals

F 154 — Practices and Nomenclature for Identification of Structures and Contaminants Seen on Specular Silicon Surfaces

F 523 — Practice for Unaided Visual Inspection of Polished Silicon Slices

F 533 — Test Method for Thickness and Thickness Variation of Silicon Slices

F 534 — Test Method for Bow of Silicon Slices

F 613 — Test Method for Measuring Diameter of Silicon Slices and Wafers

F 657 — Test Method for Measuring Warp and Total Thickness Variation on Silicon Slices and Wafers by a Non-Contact Scanning Method

F 671 — Test Method for Measuring Fiducial Flat Length and Deviation

F 928 — Test Method for Edge Contour of Silicon Wafers

2.2 *Other Standard*[2]

ANSI/ASQC Z1.4-1993 — Sampling Procedures and Tables for Inspection by Attributes

3 Definitions

3.1 *Bow* — of a semiconductor slice or wafer, a measure of concave or convex deformation of the median surface of a slice or wafer, independent of any thickness variation which may be present. Bow is a bulk property of the test specimen, not a property of an exposed surface. Generally, bow is determined with a test specimen in a free, unclamped condition. Units of bow are generally micrometers or inches.

3.2 *Dopant* — a chemical element, usually from the second, fourth, or sixth columns of the periodic table for the case of III-V compounds, incorporated in trace amounts in a semiconductor crystal to establish its conductivity type and resistivity.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959 (All cited standards except for E 122 may be found in Volume 10.05 of the Annual Book of ASTM Standards; E 122 may be found in Volume 14.02.)

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

3.3 *Lot* — for the purpose of this document, (a) all of the wafers of nominally identical size and characteristics contained in a single shipment, or (b) subdivisions of large shipments consisting of wafers as above which have been identified by the supplier as constituting a lot.

3.4 *Flat Diameter* — the linear dimension across the surface of a semiconductor wafer from the center of the flat through the wafer center to the circumference of the wafer on the opposite edge along the diameter perpendicular to the flat. (See Figure 6.)

NOTE 4 — The flat diameter may be associated with the primary orientation flat, with a secondary flat, if present, or with any other flat, if present. In such cases, the terms may be modified as primary orientation flat diameter, secondary flat diameter, etc.

3.5 *Orthogonal Misorientation* — in { 100} wafers cut intentionally "off-orientation," the angle between the projection of the vector normal to the slice surface onto the { 100} plane and the projection on that plane of the nearest direction. (See Figure 5.)

3.6 *Total Thickness Variation* — (TTV) the difference between the maximum and minimum thickness values of a slice or wafer encountered during a scan pattern or a series of point requirements. TTV is generally expressed in micrometers or mils (thousandths of an inch).

3.7 *Warp* — of a semiconductor slice or wafer, the difference between the maximum and minimum distances of the median surface of the slice or wafer from a reference plane, encountered during a scan pattern. Warp is a bulk property of the test specimen, not a property of an exposed surface. Warp is generally expressed in micrometers or mils (thousandths of an inch).

3.8 *Edge Contouring* — on slices whose edges have been shaped by mechanical and/or chemical means, a description of the profile of the boundary of the slice joining the front and back sides.

4 Ordering Information

4.1 Purchase orders for gallium arsenide wafers furnished to this specification shall include the following items:

4.1.1 Nominal diameter (see applicable SEMI Standard for polished GaAs wafers),

4.1.2 Thickness (see applicable SEMl Standard for polished GaAs wafers),

4.1.3 Total Thickness Variation (see applicable SEMI Standard for polished GaAs wafers),

4.1.4 Surface orientation (see applicable SEMI Standard for polished GaAs wafers). There are two options of flat location for 2" and 3" diameter polished mono-crystalline GaAs wafers for integrated circuit and optoelectronic applications. They are V-Groove (as illustrated in Figures 1 and 3) and Dove-Tail (as illustrated in Figures 2 and 4). These designations describe the shape of groove that can be etched perpendicular to the primary flat.

The following are the options of wafer surface orientation:

A. (100) ± 0.5° as shown in Figures 1 and 2

B. For V-Groove option:

(100) off 2° toward the (110) plane which is located between the primary and secondary flats as shown in Figure 3. Figure 5 illustrates orthogonal misorientation.

For Dove-Tail option:

(100) off 2° toward any of the nearest (110) planes as shown in Figure 4. Figure 5 illustrates orthogonal misorientation.

4.1.5 Lot Acceptance Procedures (see Section 8),

4.1.6 Certification (see Section 11),

4.1.7 Packing and Marking (see Section 12).

4.2 *Optional Criteria* — The following items may be specified optionally in addition to those listed above:

4.2.1 Crystal Growth Method,

4.2.2 Etch Pit Density (EPD) of Crystal,

4.2.3 Crystal Growth Perfection,

4.2.4 Impurity Type,

4.2.5 Surface Condition of Wafer,

4.2.6 Edge Contour,

4.2.7 Mobility,

4.2.8 Resistivity,

4.2.9 Carrier Concentration,

4.2.10 Thermal Conversion Characteristics.

5 Dimensions and Permissible Variations

5.1 The material shall conform to the dimensions and dimensional tolerances as specified in the applicable polished gallium arsenide slice standard.

5.2 If edge contoured wafers are specified on the purchase order, the profile shall conform to the following requirements at all points on the wafer periphery.

5.2.1 When the wafer is aligned with the SEMI Wafer Edge Profile Template (see Figure 6) so that the x-axis of the template is coincident with the wafer surface and the y-axis of the template is tangent with the outermost radial portion of the contour, the wafer edge profile must be contained within the clear region of the template. (See Figure 7 for example of acceptable and unacceptable contours.)

5.2.2 No sharp points or protrusions are permitted anywhere on the wafer edge contour.

5.2.3 Cosmetic attributes of the edge contour are not covered by this specification. They shall be agreed upon between supplier and purchaser.

6 Materials and Manufacture

6.1 The material shall consist of wafers from ingots grown to the material definition specified in the purchase order or contract.

7 Physical Requirements

7.1 The material shall conform to the crystallographic orientation details as specified in the applicable polished gallium arsenide slice standard.

7.2 The material shall conform to the details specified in the purchase order or contract as follows:

7.2.1 Conduction Type,

7.2.2 Dopant,

7.2.3 Carrier Concentration,

7.2.4 Resistivity,

7.2.5 Thermal Conversion Characteristics,

7.2.6 Etch Pit Density,

7.2.7 Mobility,

7.2.8 Surface Characteristics,

7.2.9 Growth Methods.

8 Sampling

8.1 Unless otherwise specified, Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) or lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL or LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

9 Test Methods

9.1 *Diameter* — Determine by ASTM Test Method F 613.

9.2 *Thickness, Center Point* — Determine by ASTM Test Method F 533.

NOTE 2 — GaAs wafers are extremely fragile. While the mechanical dimensions of a slice can be measured by use of tools such as a micrometer calipers and other conventional techniques, the slice may be damaged physically in ways that are not immediately evident. Special care must therefore be used in the selection and execution of measurement methods.

9.3 *Flat Length* — Determine by ASTM Test Method F 671.

9.4 *Flat Orientation* — Determine by etching method identified in the appropriate polished GaAs wafer standard.

9.5 *Bow and Warp* — Determine bow in accordance with ASTM Test Method F 534 and warp in accordance with ASTM Test Method F 657.

9.6 *Total Thickness Variation* — Determine by ASTM Test Method F 533 or F 657.

9.7 *Surface Orientation* — Determined by ASTM Test Methods F 26.

9.8 *Orthogonal Misorientation* — Determined by a method agreed upon between the supplier and purchaser.

9.9 *Surface Defects and Contamination* — Determined by a method agreed upon between the supplier and purchaser.

9.10 *Mobility* — Determined by ASTM Test Methods F 76.

9.11 *Crystal Perfection* — Determined by a method agreed upon between the supplier and purchaser.

10 Standard Defect Limits

10.1 Determined by agreement between supplier and purchaser as to limits.

11 Certification

11.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification together, with a report of the test results, shall be furnished at the time of shipment.

11.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as “capable of meeting” certain requirements. In this context, “capable of meeting” shall signify that the supplier is not required to perform the appropriate tests in Section 9. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

12 Packing and Marking

12.1 Special packing and marking requirements shall be subject to agreement between the supplier and the purchaser. Otherwise, all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination in accordance with the best industry practices to provide ample protection against damage during shipment.

12.2 The wafers supplied under these specifications shall be identified by appropriately labeling the outside of each box or other container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include as a minimum the nominal diameter, conductive dopant, orientation, resistivity range, and lot number.

12.3 The lot number, either (1) assigned by the original manufacturer of the wafers, or (2) assigned subsequent to slice manufacture but providing reference to the original lot number, shall provide easy access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the manufacturer’s facility for at least one month or as negotiated between vendor and user after that particular lot has been accepted by the purchaser.

Table 1. Equivalent Orientations — V-Groove Option

Surface orientation:	(100)	(100)	$(\bar{1}00)$	$(\bar{1}00)$
Primary flat location:	$(01\bar{1})$	$(0\bar{1}1)$	$(0\bar{1}\bar{1})$	(011)
Secondary flat location:	(011)	$(0\bar{1}\bar{1})$	$(0\bar{1}1)$	$(01\bar{1})$
For Surface orientation B, the off-orientation tilt direction is toward:	(110)	$(1\bar{1}0)$	$(\bar{1}\bar{1}0)$	$(\bar{1}10)$

Table 2. Equivalent Orientations — Dove-Tail Option

Surface orientation:	(100)	(100)	$(\bar{1}00)$	$(\bar{1}00)$
Primary flat location:	$(0\bar{1}\bar{1})$	(011)	$(01\bar{1})$	$(0\bar{1}1)$
Secondary flat location:	$(0\bar{1}1)$	$(01\bar{1})$	(011)	$(0\bar{1}\bar{1})$
For Surface orientation B, the off-orientation tilt direction is toward:	$(1\bar{1}0)$	(110)	$(\bar{1}10)$	$(\bar{1}\bar{1}0)$

The symmetry of GaAs crystal structure allows other Miller indices to be used for identifying surface and flat orientations. This table lists various possibilities which meet the requirements for the above two options.

NOTE: For V-Groove Option, the relative directions in a single column must be maintained. For Dove-Tail Option, any of the 110 tilt directions are considered equivalent.

SEMI M9.1-96
STANDARD FOR ROUND 50.8 mm POLISHED MONOCRYSTALLINE GALLIUM ARSENIDE WAFERS FOR ELECTRONIC DEVICE APPLICATIONS

NOTE: This entire document was rewritten in 1995.

The complete specification for this product includes all general requirements of SEMI M9.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*
DIAMETER[A]	50.8	± 0.5	mm
THICKNESS, CENTER POINT	450	± 25	µm
PRIMARY FLAT LENGTH	16	± 2	mm
SECONDARY FLAT LENGTH	8	± 2	mm

[A] The diameter standard means that the dimension is centered to this value.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION	$(01\bar{1})$ ± 0.5° [A], under an Arsenic facet. The primary flat shall be perpendicular to the "V" etch figure.[B]
SECONDARY FLAT ORIENTATION	90° ± 5° counterclockwise from the primary flat.
SURFACE ORIENTATION[C]	(100) ± 0.5°
A.	(See Figure 1 in SEMI M9.)
B.	(100) off 2° ± 0.5° toward the (110) plane which is between the primary and secondary flats (see Figure 3 in SEMI M9.)
ORTHOGONAL MISORIENTATION	± 5° (See Figure 5 in SEMI M9.)

[A] See Table 1 in SEMI M9.

[B] Using A-B, bromine-methanol, ammonium hydroxide: hydrogen peroxide etch. See Figures 1 and 3 in SEMI M9. Figure 1 also shows the orientation of the V-groove figures relative to KOH etch pits.

[C] The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted toward the (110) plane of the crystal.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M9.2-96
STANDARD FOR ROUND 76.2 mm POLISHED MONOCRYSTALLINE GALLIUM ARSENIDE WAFERS FOR ELECTRONIC DEVICE APPLICATIONS

NOTE: This entire document was revised in 1995.

The complete specification for this product includes all general requirements of SEMI M9.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*
DIAMETER[A]	76.2	± 0.5	mm
THICKNESS, CENTER POINT	625	± 25	µm
PRIMARY FLAT LENGTH	22	± 2	mm
SECONDARY FLAT LENGTH	11	± 2	mm

[A] The diameter standard means that the dimension is centered to this value.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION	($(01\bar{1})$) ± 0.5° [A], under an Arsenic facet. The primary flat shall be perpendicular to the "V" etch figure.[B]
SECONDARY FLAT ORIENTATION	90° ± 5° counterclockwise from the primary flat.
SURFACE ORIENTATION[C]	(100) ± 0.5°
A.	(See Figure 1 in SEMI M9.)
B.	(100) off 2° ± 0.5° toward the (110) plane which is between the primary and secondary flats (see Figure 3 in SEMI M9.)
ORTHOGONAL MISORIENTATION	± 5° (See Figure 5 in SEMI M9.)

[A] See Table 1 in SEMI M9.

[B] Using A-B, bromine-methanol, ammonium hydroxide: hydrogen peroxide etch. See Figures 1 and 3 in SEMI M9. Figure 1 also shows the orientation of the V-groove figures relative to KOH etch pits.

[C] The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted toward the (110) plane of the crystal.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. SEMI M9.5-96
STANDARD FOR ROUND 100 mm POLISHED MONOCRYSTALLINE GALLIUM ARSENIDE WAFERS FOR ELECTRONIC DEVICE APPLICATIONS

NOTE: This entire document was revised in 1995.

The complete specification for this product includes all general requirements of SEMI M9.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*
DIAMETER[A]	100.0	± 0.5	mm
THICKNESS, CENTER POINT	625	± 25	µm
PRIMARY FLAT LENGTH	32.5	± 2	mm
SECONDARY FLAT LENGTH	18	± 2	mm

[A] The diameter standard means that the dimension is centered to this value.

Table 2 Orientation and Flat- Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION	$(01\bar{1})$ ± 0.5° [A], under an Arsenic facet. The primary flat shall be perpendicular to the "V" etch figure.[B]
SECONDARY FLAT ORIENTATION	90° ± 5° counterclockwise from the primary flat.
SURFACE ORIENTATION[C]	(100) ± 0.5°
A.	(See Figure 1 in SEMI M9.)
B.	(100) off 2° ± 0.5° toward the (110) plane which is between the primary and secondary flats (See Figure 3 in SEMI M9.)
ORTHOGONAL MISORIENTATION	± 5° (See Figure 5 in SEMI M9).

[A] See Table 1 in SEMI M9.

[B] Using A-B, bromine-methanol, ammonium hydroxide: hydrogen peroxide etch. See Figures 1 and 3 in SEMI M9. Figure 1 also shows the orientation of the V-groove figures relative to KOH etch pits.

[C] The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted toward the (110) plane of the crystal.

SEMI M9.6-95
STANDARD FOR ROUND 125 mm DIAMETER POLISHED MONOCRYSTALLINE GALLIUM ARSENIDE WAFERS

The complete specification for this product includes all general requirements of SEMI M9.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*
DIAMETER	125.0	± 0.3	mm
THICKNESS, CENTER POINT	625	± 25	µm
PRIMARY ORIENTATION FLAT DIAMETER[A]	121.0	± 0.3	mm
SECONDARY FLAT DIAMETER[B]	123.5	± 0.3	mm

[A] Actual Primary Orientation Flat Length depends on allowed variation in the wafer diameter and the orientation flat diameter. Variation in Primary Orientation Flat Length is calculated assuming that the end points of Primary Orientation Flat will have curvature of a circle of radius R = 0 or R = 3 mm; this circle will be tangent to the orientation flat and also tangent to the wafer circumference. Calculated nominal linear length of Primary Orientation Flat (the straight part of the flat) are 44.00 mm in a case of R = 0 mm and 42.90 respectively on a case of R = 3 mm.

[B] Actual Secondary Flat Length also depends on allowed variation in the wafer diameter and the Secondary Flat Diameter. Variation in Secondary Flat Length is calculated. Calculated nominal linear lengths of the Secondary Flat (the straight part of the flat) are 27.22 mm in the case of R = 0 mm, and 26.25 mm, respectively, in the case of R = 3 mm.

Table 2 Orientation and Flat-Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION	(011) ± 1.0°, under an Arsenic facet. The primary flat shall be perpendicular to the "V" etch figure.[C]
SECONDARY FLAT ORIENTATION	90° ± 5° counterclockwise from the primary flat.
SURFACE ORIENTATION	
A.	(100) ± 0.5° (see Figure 1 in M9.)
B.	(100) off 2° ± 0.5° towards the (110) plane which is between the primary and secondary flats (see Figure 3 in M9.)
ORTHOGONAL MISORIENTATION	± 5° (see Figure 5 in M9.)

[A] The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted towards the (110) plane of the crystal.

[B] See Table 1.

[C] Using A-B, bromine-methanol, ammonium hydroxide: hydrogen peroxide etch. See Figures 1 through 4. Figure 1 also shows the orientation of the V-groove figure relative to the KOH etch pits.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M9.7-0200
SPECIFICATION FOR ROUND 150 mm POLISHED MONOCRYSTALLINE GALLIUM ARSENIDE WAFERS (NOTCHED)

This specification was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the North American Compound Semiconductor Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org January 2000; to be published February 2000. Originally published in 1995; previously published in 1996.

NOTE: This document was rewritten in its entirety in February 2000.

1 Purpose

1.1 This specification defines properties of 150 mm monocrystalline GaAs substrates, in agreement with presently established industry practice. It uniquely defines those mechanical parameters that do not need, for technical reasons, a choice of different values.

2 Scope

2.1 The parameters defined include the values and tolerances of wafer diameter, thickness and surface orientation. The position and depth of the notch and laser marking are also specified.

2.2 The complete specification of this product includes the requirements of SEMI M9, excluding those that are not relevant to this specification (e.g., flat positions).

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

STANDARD NOMENCLATURE FOR IDENTIFICATION OF STRUCTURES AND FEATURES SEEN ON GALLIUM ARSENIDE WAFERS

1 Scope

1.1 The purpose of this document is to list, illustrate, and define various characters, features, and contaminants that are seen on highly polished GaAs wafers and present recommended practices for observation of these defects. These occurrences are frequently referred to as surface defects. The defects and common synonyms are arranged alphabetically in Section 4, and each structure is referred to by its most common name and, in some cases, probably origins.

1.2 Two cases of surface preparations are considered in this document: (1) surfaces after chemical polishing, and (2) mechanically and chemically polished surfaces.

1.3 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2 Applicable Documents

2.1 *SEMI Standard*

SEMI M9 — Specifications for Round Polished Monocrystalline Gallium Arsenide Slices

2.2 *ASTM Standard*[1]

F 47 — Crystallographic Perfection of Silicon by Preferential Etch Techniques

2.3 *Other Standard*[2]

ANSI/ASQC Z1.4-1993 — Sampling Procedures and Tables for Inspection by Attributes

3 Significance and Use

3.1 This document contains a compilation of the most commonly observed singularly discernable structures on polished GaAs surfaces. Ambiguities and uncertainties regarding surface defects may be resolved by reference to this document.

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

4 Definitions and Descriptions of Terms

cell structure — (block structure): Malformations attributable to crystal inhomogeneities and that have their origins in the crystal growth process.

chips — (edge chips, peripheral chips, peripheral indents, surface chips): Areas of material mechanically removed from the surface or edge of a wafer.

> Chips indicate crystallographic damage in the adjacent material. The origins of some chips are in the handling of wafers arising from the physical transfer or placement of the specimen for process, measurement, or inspection purposes. The size of a chip is defined by its maximum radial depth and peripheral chord length as measurable on an orthographic shadow projection of the specimen outline.

apex chip —Any material missing from the edge of a wafer having at least 2 distinct interior boundaries which form one or more distinct intersections.

chuck marks — Any physical mark on either surface of a wafer caused by a chuck or wand.

contaminant — (solvent residue, wax residue, film, mottled surface, smudge): Surface feature that cannot be removed by the pre-inspection (non-etching) cleaning.

NOTE Contaminant may be foreign matter on the surface such as localized areas which are smudged, stained, discolored, mottled, etc., or larger areas exhibiting a hazy or cloudy appearance resulting from a film of foreign material.

> Solvent residue: type of film found on wafer surfaces after solvent evaporation from the surface. Note: The residue comes from either the solvent itself or material that the solvent has removed from the surface and redeposited. Wax residue: film of wax that migrated onto the wafer surface from several possible sources.

NOTE The wax originally may have been used to hold the crystal in place during slicing or polishing. Excessive heat used in mounting or demounting, during lapping or polishing processes, may cause the wax to polymerize.

crack — Cleavage or fracture that extends to the surface of a slice. It may or may not pass through the entire thickness of the slice. Often cracks are caused by the improper handling of wafers.

NOTE Some crack-defect structures can be traced to process related events.

cavity — (void) A vacancy or hole in the wafer.

NOTE Usually left by dissolved precipitates and Ga inclusions, As disassociation or created by excess vapor pressure.

Dimple — Deformation appearing in mechanically polished GaAs wafers.

NOTE This surface texture can be induced by floating the wafers during the initial stages of polishing.

Dislocation — See *slip, lineage, pit*.

edge chip — See *chip*.

Embedded — abrasive grains Abrasive particles mechanically forced into the surface of the wafer.

etch pi t — See *pit*.

film — See *contaminant*.

flake — Material missing from one, but not the other, side of a wafer, whose sole interior boundary is one distinct line or arc not exceeding 2 mm in length, nor projecting into the wafer beyond the specified edge exclusion.

gallium inclusion — A segregated Ga-rich droplet incorporated into the surface structure.

NOTE Normally caused by insufficient As vapor pressure at the termination of the crystal growth process or by Ga complexing with some dopants near saturation.

grain boundary — See *lineage*.

haze — (cloud, nebula): Attributable to light scattering by concentrations of microscopic surface irregularities such as pits, oxides, small ridges or scratches, particles, etc. The light reflection from an individual irregularity probably could not be readily detected by the unaided eye, so haze is a mass effect. It is seen as a high density of tiny reflections.

NOTE This type of contamination may occur during slicing, lapping, or polishing.

lamella — A special case of the twin. A multiple twin, extremely thin and relatively long, which may intersect more than one plane.

lineage — (dislocation pits, grain boundary): Low-angle grain boundary resulting from an array of dislocations. This angle may vary from a fraction of a second to a minute of arc difference in orientation from one part of the crystal to another. The array of dislocations will appear as rows of pits on a preferentially etched surface.

NOTE Lineage can be induced into the material in crystal growth or in subsequent thermal or epitaxial processes. Lineage will be visible to the unaided eye only after preferential etching.

macroscratch —See *scratch*.

microscratch — See *scratch*.

microtwin — See *twin*.

orange peel — (roughness, texture): Large featured roughened type of surface visible to the unaided eye, occasionally seen on all types of polished wafers.

NOTE Orange peel is usually symptomatic of a process control problem. In the case of chemical polishing for instance, an excessively fast polishing rate, or nonuniform flow of oxidizer during polishing, can result in orange peel. Conversely, it can also be caused by insufficient stock removal.

particulate — (dust): Discrete particle of material which can usually be removed by (non-etching) cleaning.

pit — (dislocation, etch pit): Depression in the wafer surface which has a definite and distinguishable shape, that is, a place where the sloped sides of the pit meet the wafer surface.

NOTE Pits can be caused by the various growths or polishing processes.

Preferential etch pits result where dislocations intersect the wafer surface after treatment with a preferential etch. These pits so formed usually have a characteristic shape related to the surface and bulk crystallographic orientation.

polycrystalline — (poly): Body of semiconductor materials that contain large-angle grain boundaries, twin boundaries, or both.

precipitates — A localized concentration of dopant at its solubility limit formed during crystal growth.

probe damage — Any damage to the wafer surface caused by mechanical probing or measurement.

roughness — see *orange peel*.

saw blade defects —A depression in the wafer surface made by the blade, which may not be visible before polishing.

saw exit chip —A particular kind of edge chip, found at the point where the saw blade completed its cut of the wafer. It is typically flat or arc shaped instead of irregular in shape, and can sometimes be confused with the orientation flats.

scratch — (macroscratch, microscratch): Long, narrow, shallow groove or cut below the established plane of the surface, seen either before or after etching. The ratio of the length of the figure to the width of the figure must be greater than 5:1 in order to be defined as a scratch.

Macroscratches are visible to the unaided eye under high intensity illumination.

Microscratches are not visible to the unaided eye under high intensity illumination.

slip — (dislocation pit, preferential etch pits, stress effect) (see also *pit*): Process of plastic deformation in which one part of a crystal undergoes a shear displacement relative to another in a fashion which preserves the crystallinity of the material. Slip is evidenced by a pattern of one or more straight lines of 10 or more dislocation etch pits per millimeter which do not necessarily touch each other.

striations — Striations appear in Czochralski grown crystals regardless of their resistivity.

tweezer mark — Any mark on the wafer caused by handling with tweezers.

twin — A body of crystal within the wafer in which the lattice is of two parts, related to each other in orientation as mirror images, across a coherent planar interface known as the twinning plane or twin boundary.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M11-0702
SPECIFICATIONS FOR SILICON EPITAXIAL WAFERS FOR INTEGRATED CIRCUIT (IC) APPLICATIONS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published in 1988; previously published March 2001.

1 Purpose

1.1 This specification defines and provides examples of silicon epitaxial wafer requirements for integrated circuit device manufacture. It is restricted to wafers of diameters 100 mm or greater with epitaxial layer thicknesses less than or equal to 25 µm. By defining inspection procedures and acceptance criteria, both suppliers and consumers may uniformly define product characteristics and quality requirements.

1.2 The characteristics specified relate to the substrate (as specified in SEMI M1) and to the epitaxial layer, including handling and packaging. The primary standardized properties set forth in this specification relate to physical, electrical, and surface defect parameters.

1.3 A complete purchase specification requires that additional physical properties be specified along with suitable test methods for their measurements. SEMI M18 may be used for this purpose.

1.4 These specifications are specifically directed to silicon homoepitaxial deposits on homogeneous silicon substrates only, for which more stringent uniformity and surface defect criteria are required than specified in SEMI M2.

1.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2.3 *Other Standard*[2]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3 Terminology

3.1 Many terms relating to silicon technology are defined in ASTM Terminology F 1241.

3.2 Definitions for the epitaxial wafer defects covered in Table 1 are given in ASTM Test Methods F 47, F 522, and F 815, and in ASTM Practices F 154.

3.3 Definitions of selected epi wafer defects, extended to consider automatic surface inspection are given below.

3.3.1 *mound (epi)* — a rounded protrusion on a semiconductor wafer surface, which may have one or more partially developed facets (see Figure 1).

NOTE 2: Scattering event size reported by SSIS will differ from the physical size of the object. The figure captions in the examples highlight this fact. No useful method exists at the present time to quantify this relationship (see Section 6.3.3.3)

3.3.1.1 *Discussion* — Related characteristics include the following:

- *Device characteristics that may be affected* — critical feature dimensions, lithographic equipment focus, gate oxide integrity.
- *Detection characteristics used for characterization* — mound height, diameter at 50% height.
- *Discrimination characteristics used for characterization* — positive height: 10–100 nm, or approximately 20% of the epi layer thickness; diameter: 0.1–6 µm; circular symmetry.
- *Specification characteristics used for wafer qualification* — number per wafer, mound height, height to diameter.

3.3.2 *epi stacking fault* — a two dimensional effect that results from a deviation from the normal stacking sequence of atoms in a crystal. [ASTM F 154, F 522, F1727]

NOTE 3: Discrimination and specification characteristics are given in this section to facilitate equipment development (see Section 6.3.3.3) and are not intended for use in commercial wafer specifications.

3.3.2.1 *Discussion* — Epi stacking faults are typically linked together into squares in the case of {100} oriented wafers, and triangles in the case of {111} oriented wafers. Most stacking faults are nucleated at the epi layer substrate boundary, though some have been observed being nucleated further into the epi growth process. Faults are aligned along specific crystallographic directions. For {100} wafer the sides of the faults are aligned along <110> directions. The length of a side is typically proportional to the epi layer thickness and related to the crystallographic orientation. In order to minimize the strain around a stacking fault contaminants may diffuse to these defects. Some stacking faults may have an effect on the local growth rate giving the stacking fault a three dimension aspect. This three dimensional aspect changes their light scattering cross section when observed by an SSIS (see Figures 3 through 7). Still more complicated are overlapping stacking faults which scatter even more than a single stacking fault of the same size (see figure 4). Other types of defects may be composites of stacking faults and polysilicon growth which can also appear larger than a single stacking fault of the same lateral dimensions (see Figures 5 and 6). Related characteristics include the following:

- *Device characteristics that may be affected* — leakage and gate oxide integrity, from crystallographic changes.
- *Detection characteristics used for characterization* — side length and depth, orientation parallel to a <110> direction.
- *Discrimination characteristics used for characterization* — shape, length ~ epi layer thickness: 1–10 µm. Stacking faults may cluster (see Figure 7) and scatter more than a single stacking fault.

[2] American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

- *Specification characteristics used for wafer qualification* — Number per wafer. Since certain types of epi stacking faults have no observed impact on device performance while others are killer defects no number can be assigned without a clear identification of the type of epi stacking fault that is involved.

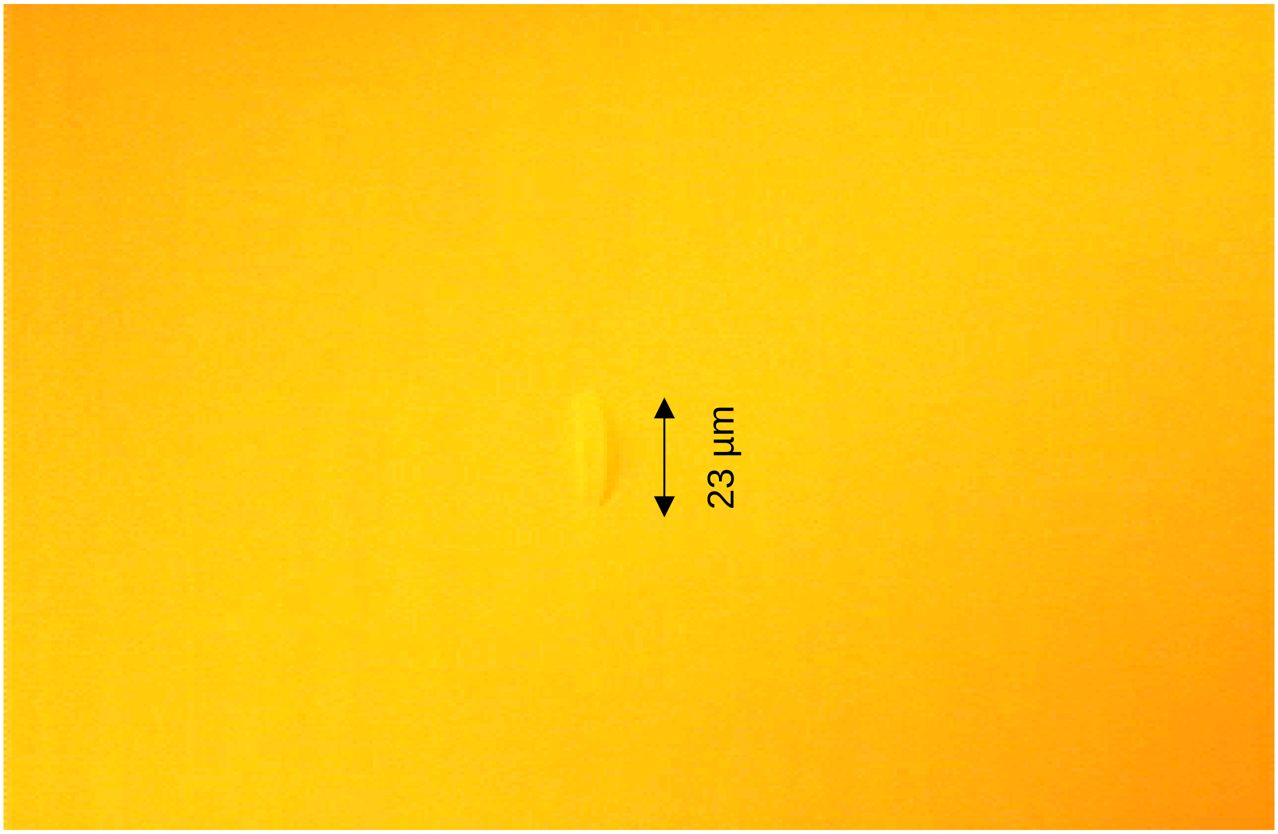

Figure 1
A Mound. Magnification 1000 times using Nomarksi Interference Microscopy. Approximate SSIS scattering event size 0.22 µm.

Figure 2
This is a mound that does not have the sharp edges of an Epitaxial Stacking Fault, but is not as high as a Bump. They are typically sized much smaller in a SSIS than their actual size, but some have facets that scatter enough light to be more easily detected. Some people refer to this feature as a hillock which is a type of mound. The shape can be either circular or square. Magnification 500 times using Nomarski Interference Microscopy. Approximate SSIS event size: 0.15 µm

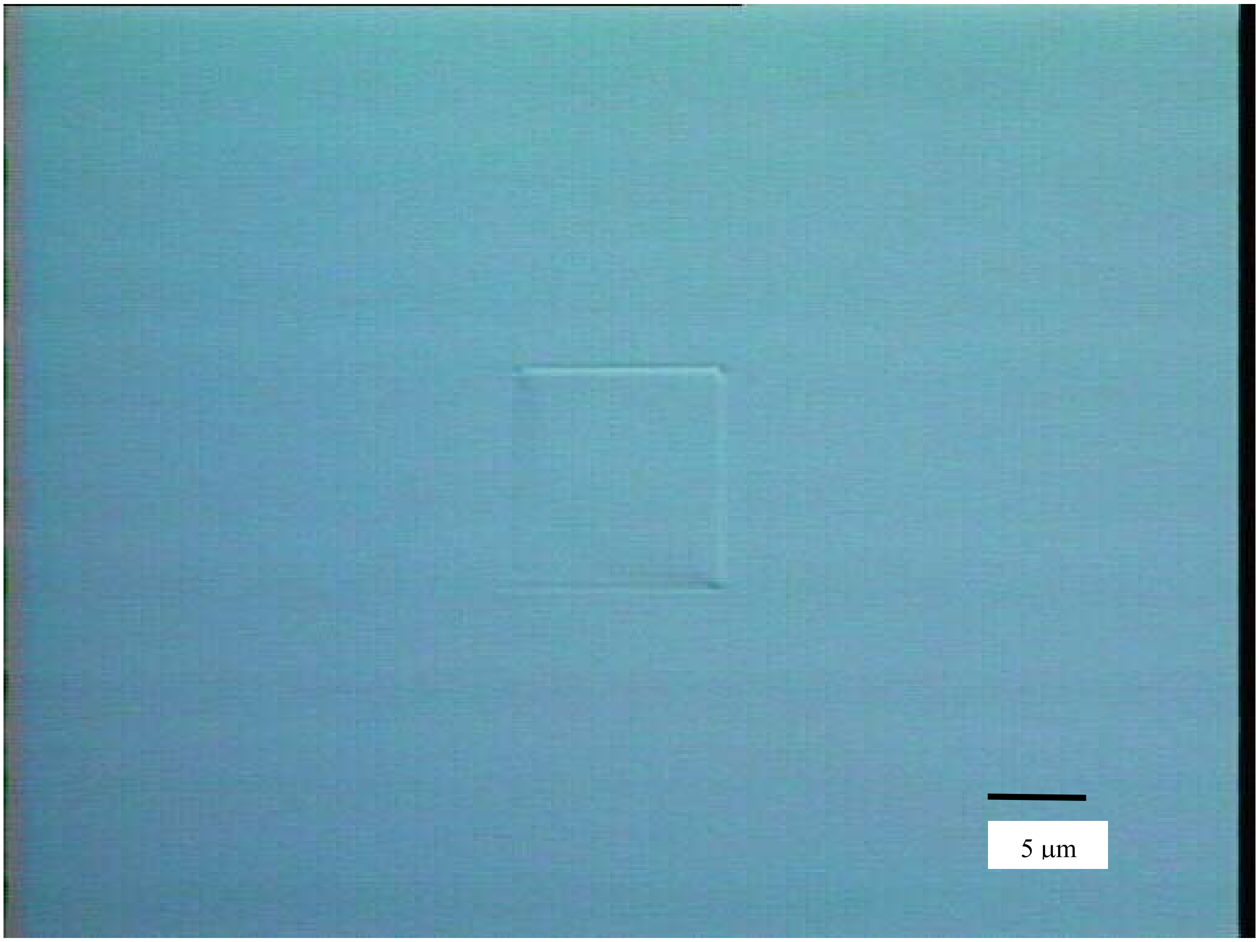

Figure 3
The Epi Stacking Fault (ESF) defect is a grown-in defect with 1 to 4 sides of a square visible. Magnification 1500 times using Nomarski Interference Microscopy. Approximate SSIS event size: 0.165 µm

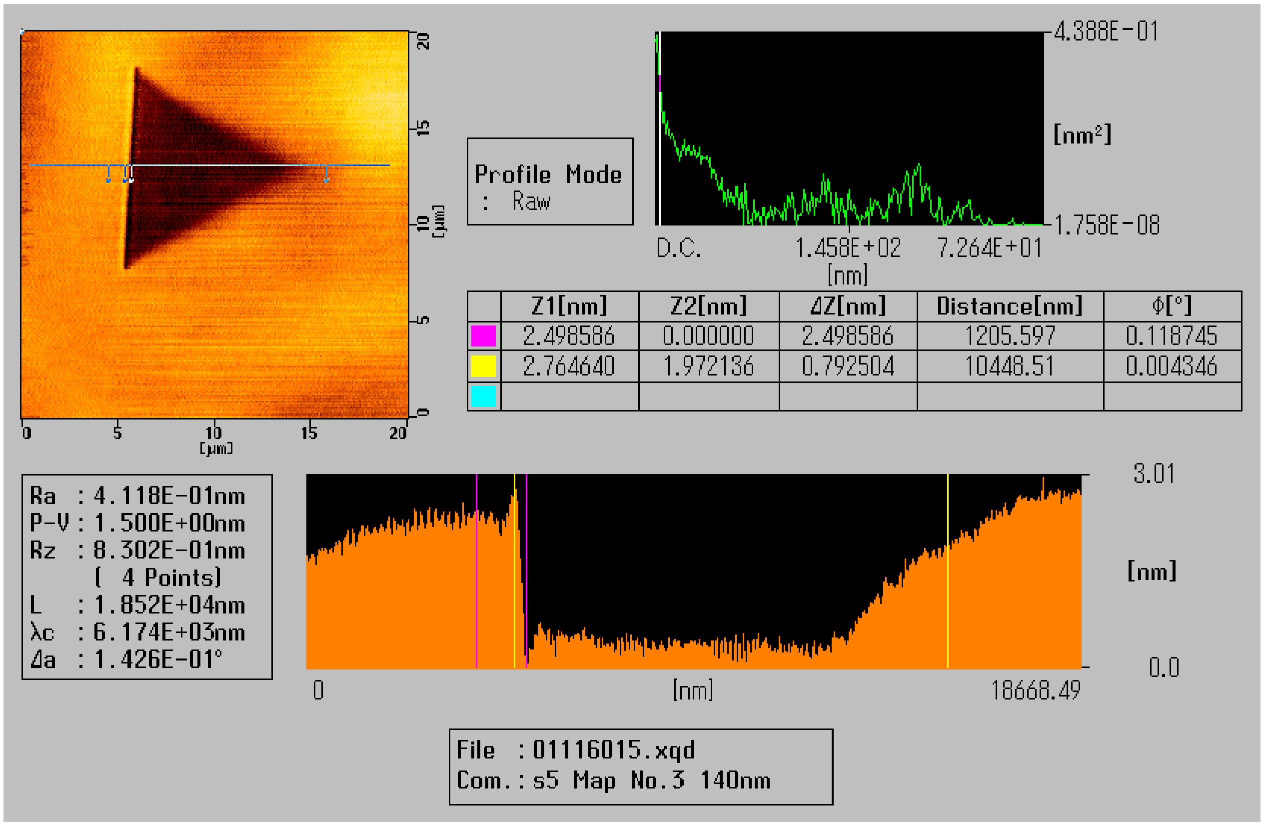

Figure 4
Epitaxial Stacking Fault. Atomic Force Microscope (AFM) Image. Approximate SSIS scattering event size 0.12 µm.

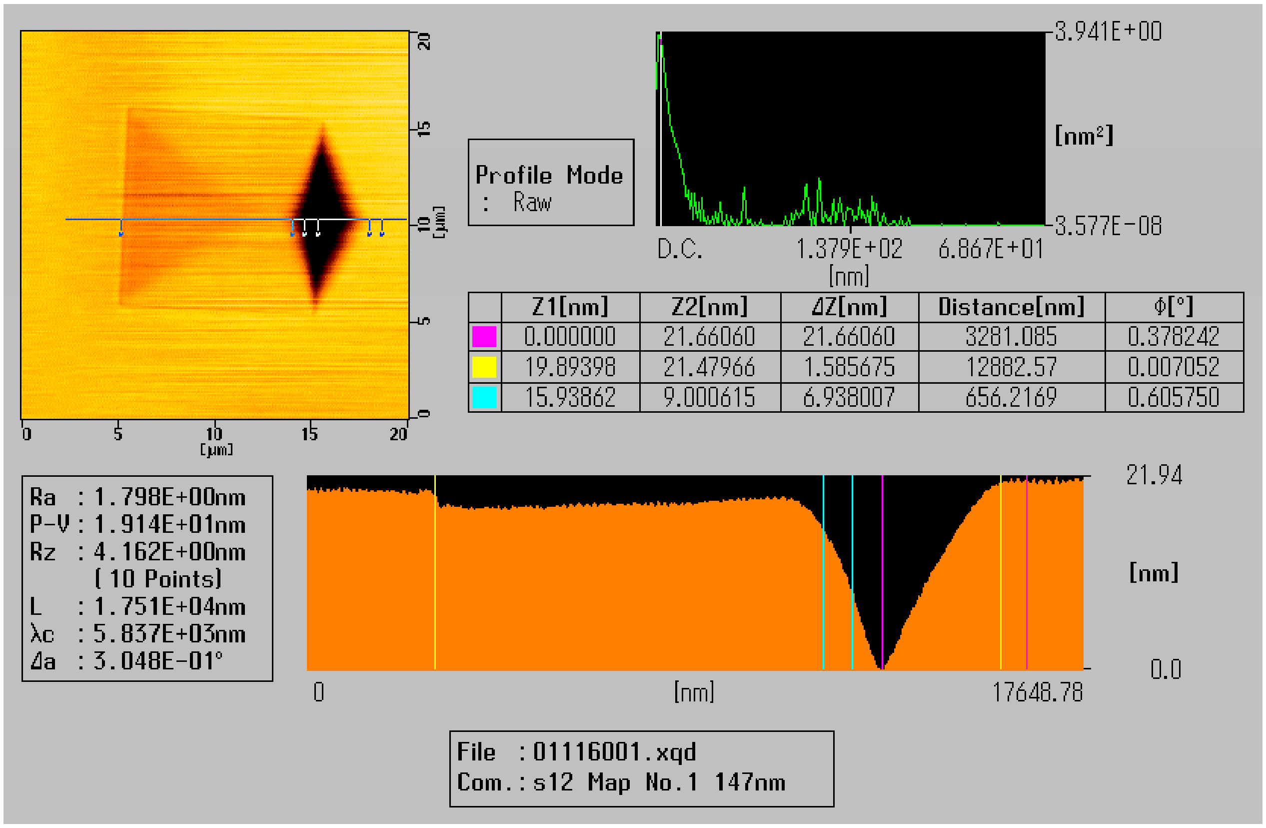

Figure 5
Epitaxial Stacking Fault showing four sides and a deep depression on on side of about 20 nm. Atomic Force Microscope Image. Approximate SSIS scattering event size, 0.30 µm.

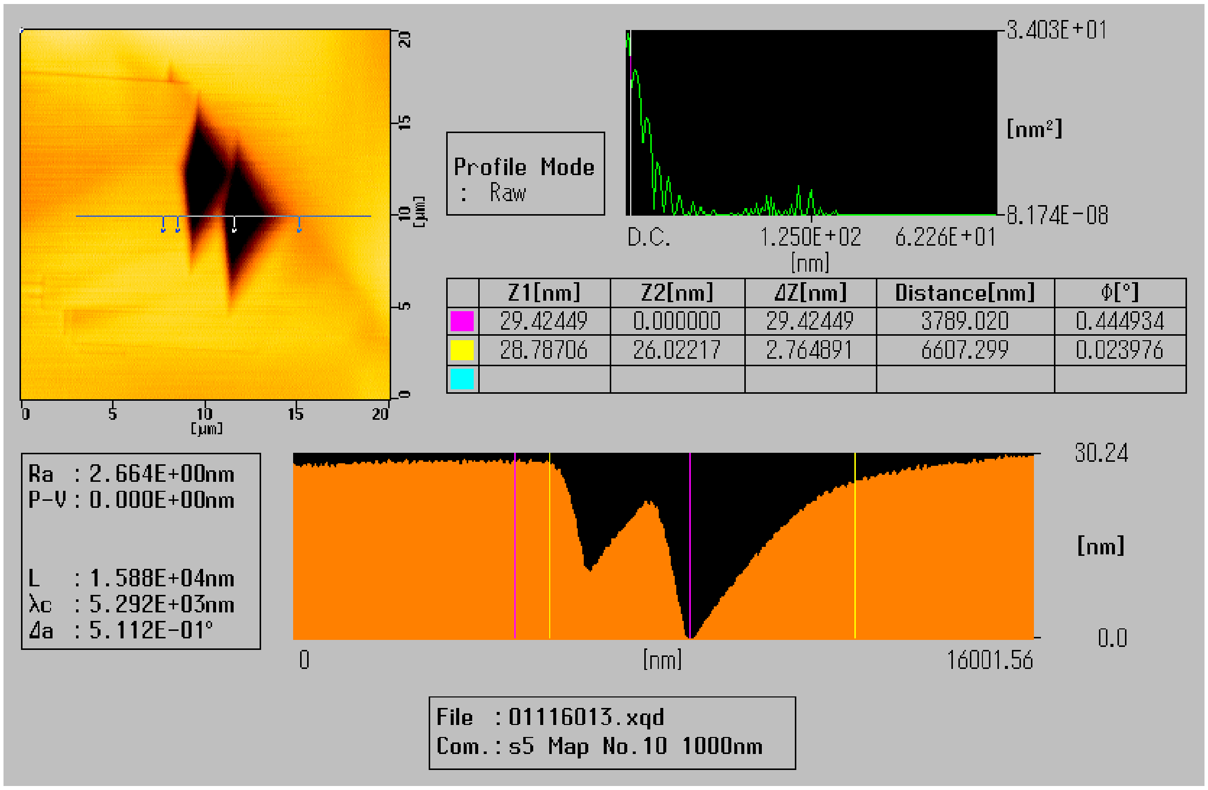

Figure 6
Double Epi taxial Stacking Fault. Atomic Force Microscope image. Approximate SSIS event scattering size 1.05 µm

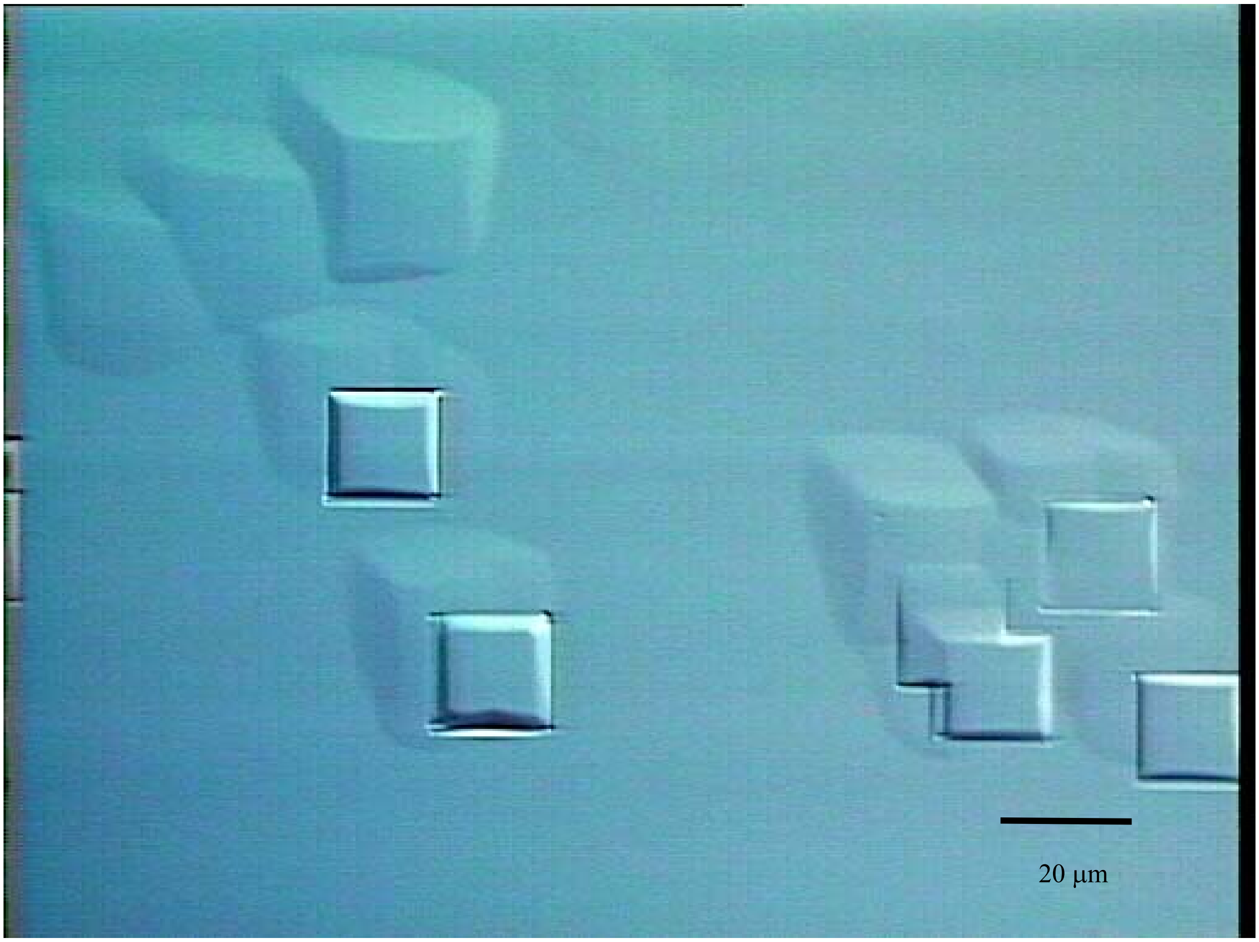

Figure 7
The Epitaxial Stacking Fault Cluster classification is used to define a group of ESFs in close proximity on the wafer surface. The group can either be overlapping or in a line (except when the line appears to be part of a Pre-Epi Scratch). Magnification 500 times using Nomarski Interference Microscopy. Approximate SSIS event size, 0.20 µm

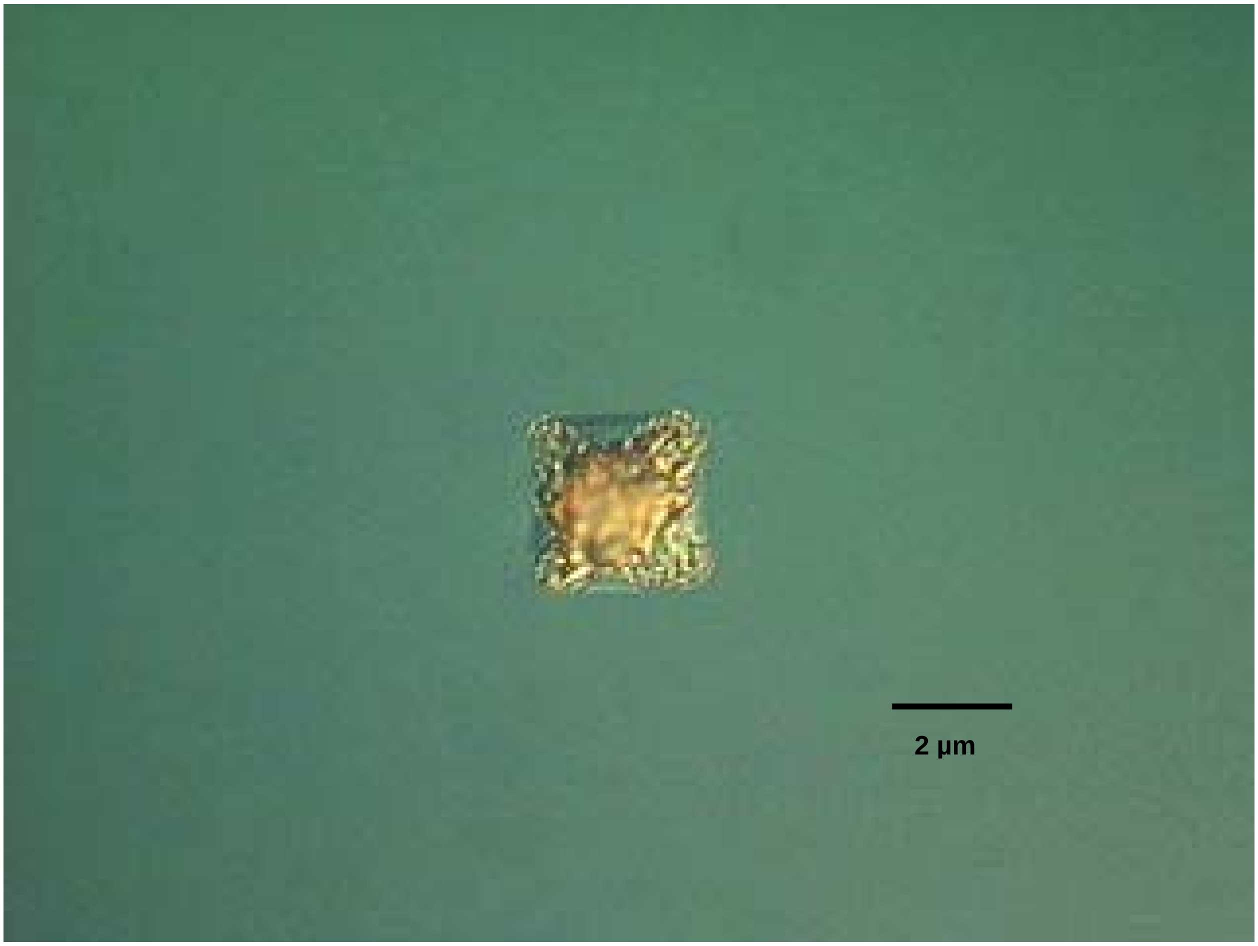

Figure 8
Composite Defect of polysilicon growth and stacking faults. Magnification 1000 times by Nomarksi Interference Microscopy. Approximate SSIS image event size >>1.0 µm

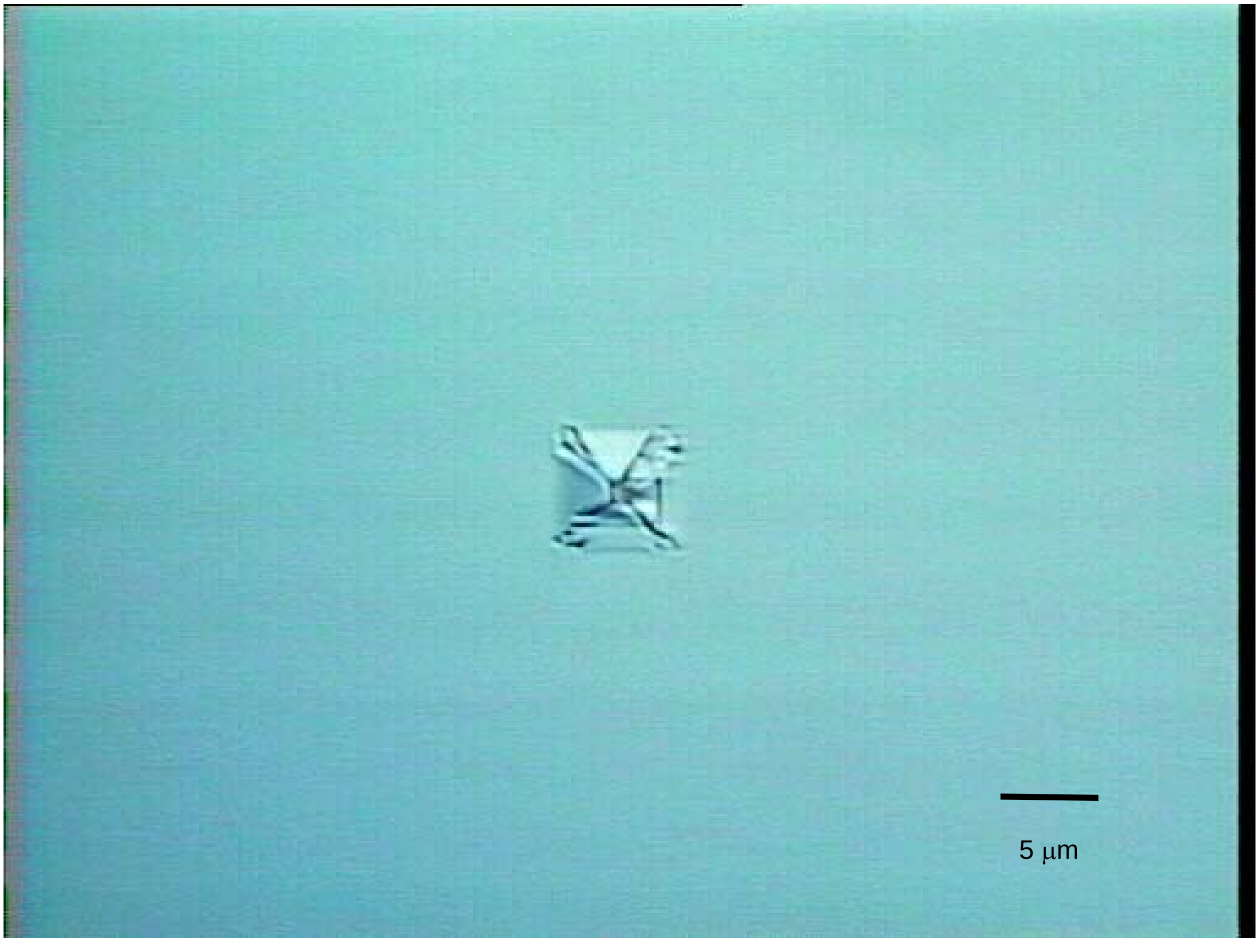

Figure 9
The Compound ESF defect is an epi stacking fault that has a broken surface, but maintains the square shape of an ESF. It typically scatters more light than a normal ESF because of the extra facets, so it is sized larger in a SSIS. Magnification 500 times using Nomarski Interference Microscopy. Approximate SSIS event size: 280 µm

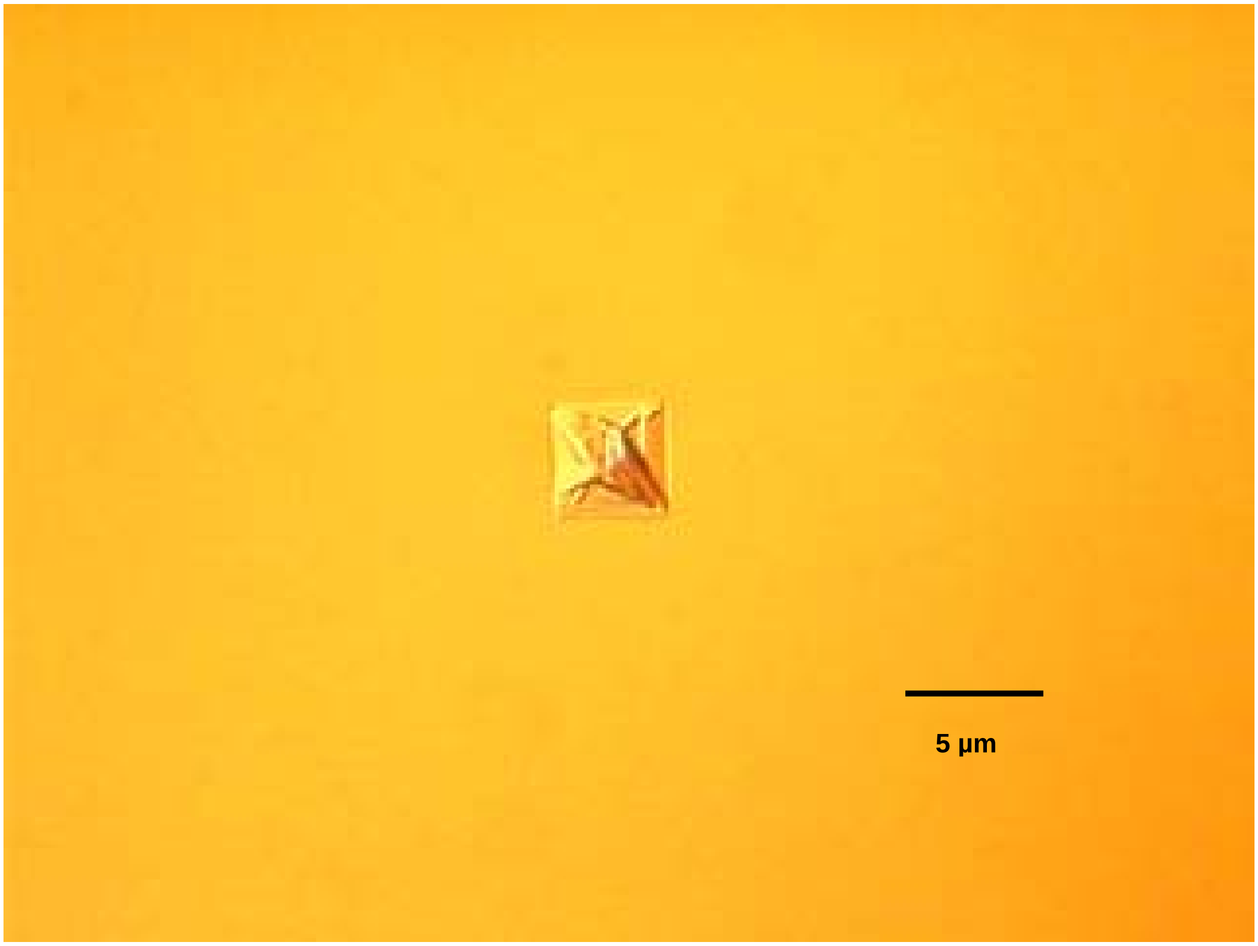

Figure 10
Composite Defect of polysilicon growth and stacking faults. Magnification 500 times by Nomarksi Interference Microscopy. Approximate SSIS image event size >>1.0 µm

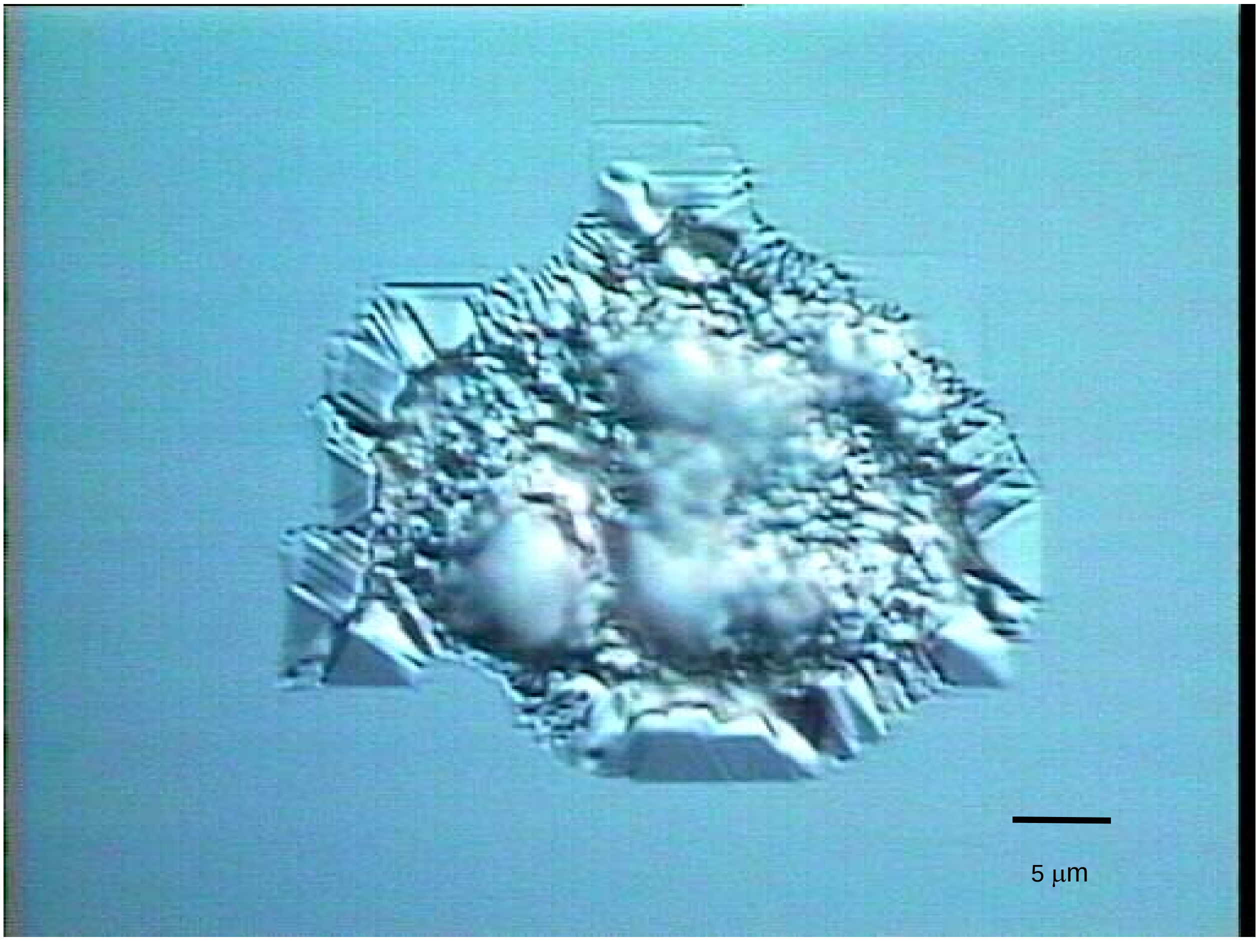

Figure 11
A Polysilicon Epitaxial Stacking Fault is a defect that covers a large area and is covered or surrounded by ESFs. This classification is used when the surface appears to be poly-crystalline rather than single crystal. It is almost always a Large Area Defect and is caused by a large particle that may still be visible (see Buried Particle). Magnification 1500 times using Nomarski Interference Microscopy. Approximate SSIS event size, 440 µm

3.4 Other terms are defined as follows:

3.4.1 *autodoping, of an epitaxial layer* — incorporation of dopant originating from the substrate into the epitaxial layer. Also called *self-doping*.

NOTE 4: Sources of autodoping can be the back and front surfaces and edges of the substrate, other substrates in the reactor, the susceptor, or other parts of the deposition assembly.

3.4.2 *chemical vapor deposition, in semiconductor technology* — a process in which a controlled chemical reaction produces a thin surface film.

NOTE 5: Epitaxial growth is an example of a special case of chemical vapor deposition (CVD).

3.4.3 *edge crown* — the difference between the surface elevation 1/8 inch (3.2 mm) from the edge of the wafer and the elevation at the wafer edge.

3.4.4 *effective layer thickness, of an epitaxial layer* — the depth from the front surface in which the net carrier density is within the specified limits.

3.4.5 *epi profile slope, of an epitaxial layer* — the difference between the net carrier density at 0.75 of the layer thickness and the net carrier density at 0.25 of the layer thickness divided by one-half the layer thickness:

$$\text{epi profile slope} = \frac{N_{0.75t} - N_{0.25t}}{0.5t}$$

where :

N = net carrier density, cm^{-3}, and

t = layer thickness, μm.

3.4.6 *epitaxial layer* — a layer of single crystal semiconductor material grown on a host substrate which determines its orientation.

3.4.7 *epitaxy* — the growth of a single crystal layer on a substrate of the same material, homoepitaxy; or on a substrate of different material with a compatible crystal structure, heteroepitaxy.

3.4.8 *flat zone, of an epitaxial layer* — the depth from the front surface to the point where the net carrier density is 20% greater than or less than the average net carrier density (see Section 6.3.2) of the region between 0.25 and 0.75 of the layer thickness.

3.4.9 *laser light scattering event* — a signal pulse that exceeds a preset threshold, generated by the interaction of a laser beam with a discrete scatterer at a wafer surface as sensed by a detector.

3.4.10 *thickness, of an epitaxial layer* — the distance from the surface of the wafer to the layer-substrate interface.

3.4.11 *transition width, of an epitaxial layer deposited on a more heavily doped substrate of the same conductivity type* — the difference between the layer thickness as determined by infrared reflectance (see Section 6.3.1) and the flat zone based on the same thickness measurement.

4 Ordering Information

4.1 Purchase orders for the epitaxial layer on substrates furnished to this specification shall include the following items:

4.1.1 *Substrate Characteristics*

4.1.2 *Epitaxial Layer Characteristics*

4.1.2.1 Silicon Source for Epitaxial Growth (if required) (see Note 4)

4.1.2.2 Epitaxial Layer Conductivity Type and Doping Source (see Note 4)

4.1.2.3 Etch Removal (if required)

4.1.2.4 Epitaxial Layer Center Point Thickness and Thickness Tolerances

4.1.2.5 Epitaxial Layer Thickness Variation Range

4.1.2.6 Epitaxial Layer Centerpoint Net Carrier Density and Net Carrier Density Tolerances (see Note 5)

4.1.2.7 Epitaxial Layer Net Carrier Density Variation Range

4.1.2.8 Epitaxial Layer Defect Limits

4.1.3 Methods of Test and Measurements (see Section 6)

4.1.4 Lot Acceptance Procedures (see Section 7)

4.1.5 Certification (if required) (see Section 8)

4.1.6 Packing and Marking (see Section 9)

NOTE 6: The dopant, doping method, and growth method are difficult to ascertain in the finished wafers. Verification test procedures or certification of these characteristics shall be agreed upon between the supplier and the purchaser. (See Section 8.)

NOTE 7: Care should be taken in converting between carrier density and resistivity using ASTM Practice F 723. Multiple conversions may introduce differences in values. For example, converting from carrier density (C_i) to resistivity and back to carrier density (C_f), may result in C_i not equaling C_f.

5 Requirements

5.1 As a minimum, the substrate shall conform to SEMI M1 and the appropriate individual polished monocrystalline silicon wafer standard.

5.2 Epitaxial wafer defects shall not exceed the limit as given in Table 1.

5.2.1 Limits for slip, which may require destructive testing, shall be specified in a purchase order together with an appropriate test method. In the absence of another specification, the wafer will contain no slip lines within the quality area. (See Table 1, Note 1.)

NOTE 8: When an unetched wafer is observed for slip it is impossible to differentiate between slip and linear misfit lines.

5.3 *Layer Thickness Variation* — Unless otherwise specified, the thickness variation shall be determined from value measured at the center and locations centered 12 mm ± 1 mm from the periphery, on diameters both parallel and perpendicular to the primary flat,

$$\text{Variation}(\%) = \frac{t_{max} - t_{min}}{t_{max} + t_{min}} \times 100$$

where t_{max} and t_{min} denote the maximum and minimum thickness values measured. The 12 mm locations have been defined based on instrument processing and fixturing considerations.

5.4 *Layer Net Carrier Density Variation* — The net carrier density variation shall be determined from values measured at the center and locations with center of the probe at 12 mm ± 1 mm from the periphery, on diameters both parallel and perpendicular to the primary flat,

$$\text{Variation}(\%) = \frac{N_{max} - N_{min}}{N_{max} + N_{min}} \times 100$$

where N_{max} and N_{min} denote the maximum and minimum values measured. The 12 mm locations have been defined based on instrument processing and fixturing considerations.

6 Test Methods and Measurements

6.1 Measurements shall be carried out in conformance with the specified ASTM Test Methods. Where no methods are specified or where choices are given, the supplier and purchaser shall agree in advance on the means for making the measurement.

6.2 *Substrates* — Determine in accordance with methods specified in SEMI M1.

6.3 *Epitaxial Layer*

6.3.1 *Thickness* — Determine in accordance with ASTM Test Method F 95 or F 110.

NOTE 9: In the case of thin layers and graded doping transitions, ASTM Test Methods F 95 and F 110 may not be suitable. See the scopes of these test methods to determine their limitations. In all cases, there is a possibility that various types of infrared reflectance instrumentation may result in different values of epitaxial layer thickness. Therefore, the instrumentation used shall be agreed upon between supplier and purchaser.

6.3.2 *Net Carrier Density* — Determine by method(s) agreed upon between supplier and purchaser.

NOTE 10: ASTM Test Method F 419 is a standardized differential-capacitance method for net carrier density, but it requires fabrication of a *p-n* junction. ASTM Test Methods F 1392 and F 1393 are methods for measuring net carrier density using a mercury probe contact. If resistivity is measured, as by ASTM Test Method F 374 or F 525, conversion to dopant density shall be made using ASTM Practice F 723. Net carrier density of very heavily doped layers (or substrates) may be found using ASTM Test Method F 398. Net carrier density profiles may be determined directly in accordance with ASTM Test Method F 419, F 1392, or F 1393 or indirectly in accordance with ASTM Test Method F 672, with conversion from resistivity to net carrier density in accordance with ASTM Practice F 723. If the method used for determining the net carrier density profile is not the same as that used to determine the centerpoint net carrier density, correlation between the two methods used shall be established.

6.3.3 *Epitaxial Wafer Defects* — Determine in accordance with the methods given in Table 1.

6.3.3.1 Surface inspection shall be performed before any other testing. Wafers may be cleaned prior to inspection to minimize difficulty in the visual inspection of defects other than foreign matter.

6.3.3.2 *Slip* — Determine by methods agreed upon between supplier and purchaser.

6.3.3.3 Automatic surface inspection technology is being developed to detect and discriminate surface defects. The extended definitions in Section 3.3 are intended to facilitate this development.

NOTE 11: For observation of gross slip, examination of the epitaxial layer under the illumination conditions specified in Section 12.2 of ASTM Practice F 523 may suffice. For more demanding applications, it may be desirable to etch the surface in accordance with ASTM Test Method F 80 prior to the visual inspection.

6.4 If substrates of different type and net carrier density than the product substrates are to be used for deposition control, their type, resistivity, and quantity per run or lot shall be agreed upon between supplier and purchaser.

Table 1 IC Epitaxial Wafers - Basic Surface Criteria

Item	*Characteristics*	*Maximum Acceptability Limits*	*Test Method*	*Notes and Reference Documents*
1	Stacking Faults	1 per cm^2	ASTM F 522	1
2	Slip	None	ASTM F 523 or F80	1, 5, 6
3	Dislocations	None	ASTM F 80	1
4	Total Localized Light Scatterers	2000 per m^2	≥ 0.5 µm LSE, based on calibration of surface scanning inspection systems with latex spheres, 90% capture rate	1, 7, SEMI M25 Table 2
5	Haze	None	ASTM F 523 Section 12.2	4, 7
6	Scratches	None	ASTM F 523 Section 12.2	2, 7
7	Edge Chips	None	ASTM F 523 Section 12.2	
8	Foreign Matter	None	ASTM F 523 Section 12.3	4
9	Back Surface Contamination	None	ASTM F 523 Section 12.4	4

NOTE 1: Defect limits shall apply to quality area, which is defined as the entire wafer surface except a defined outer annulus of 4 mm and any area included in a window where there is a laser identification mark.
NOTE 2: The cumulative AQL for both front surface and back surface of wafer is 2.5.
NOTE 3: The cumulative AQL for both front surface and back surface of wafer is 1.0.
NOTE 4: Any adherent contaminants, such as stains, glovemarks, dirt, smudges, warps, and solvent residues. This characteristic does not include point defects. Any nonadherent contamination or particulate matter easily removed by industry-accepted cleaning techniques shall not constitute foreign matter or haze.
NOTE 5: Test method(s) to be agreed upon between supplier and purchaser.
NOTE 6: For observation of gross slip, examine the epitaxial layer under illumination conditions specified in Section 12.2 of ASTM Practice F 523. For more demanding applications, it may be desirable to etch the surface in accordance with ASTM Test Method F 80.
NOTE 7: In today's technology, it may be possible to do this inspection using automated laser scanning systems; however, a standard test procedure has yet to be developed. Application of automated inspection must be agreed upon between supplier and user.

7 Sampling

7.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot according to ANSI/ASQC Z1.4-1993. Quality characteristics shall be assigned an acceptable quality level (AQL) in accordance with ANSI/ASQC Z1.4-1993. Inspection levels shall be agreed upon between supplier and purchaser. Accept and reject criteria are to be based on defective wafers, not on defective characteristics.

7.2 Unless otherwise specified, the following AQL's shall be assigned:

7.2.1 Epitaxial Layer Center Thickness and Variation, 1%;

7.2.2 Epitaxial Layer Center Net Carrier Density and Variation, 1%;

7.2.3 Epitaxial Wafer Defects, Cumulative, 2.5%.

8 Certification

8.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

8.2 The supplier and purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 6; however, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

9 Packing and Marking

9.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide protection against damage during shipment.

9.2 The wafers supplied under this specification shall be identified by appropriately labeling the outside of each box or container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include supplier's name and reference number, purchaser's p.o. number, quantity, dopant, orientation, conductivity type of substrates and epitaxial layers, carrier density, and thickness of the epitaxial layer. The reference number assigned by the supplier shall provide ready access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the manufacturer's facility for at least one year after that particular lot has been shipped.

10 Guides

10.1 The specifications in the epitaxial guides are examples which were formed by a consensus of viewpoints. They may or may not be used as a foundation to specify an epitaxial wafer for use in device manufacture. Their usefulness can be increased by considering the guides prior to developing a device design or process. The required specification is deter-mined by the device and the process design, the guides are suggestions from which a specification can evolve.

10.2 An epitaxial guide can be viewed as a generic epitaxial wafer specification or as an example of a specification. These tables provide common epitaxial wafer characteristics which describe starting wafers useful for the manufacture of some twin tub CMOS devices.

10.3 The guides in Tables 3, 4, 5, 6, 7, 8 and 9 provide a series of options intended to increase the awareness of epitaxial specifications and to provide information from which a specification can be formulated.

10.4 SEMI M18 was used as a template for formulating these tables. When suitable to the application, the guides can be used intact, reducing the proliferation of specifications and formats.

10.4.1 Table 3 is representative of 1.0 µm design rule epitaxial wafer criteria.

10.4.2 Table 4 is typical of an epitaxial wafer criteria for custom twin tub CMOS, 0.35 µm design rule devices, such as, but not limited to ASIC's, FPGA's, linears, DSP's, and microprocessors.

10.4.3 Table 5 is typical of an epitaxial wafer criteria for 0.35 µm design rule devices such as 64 megabit DRAM's.

10.4.4 Table 6 is typical of epitaxial wafer criteria for twin tub CMOS, 0.25 µm design rule devices, such as, but not limited to ASIC's, FPGA's, linears, DSP's, and microprocessors.

10.4.5 Table 7 is typical of epitaxial wafer criteria for twin tub CMOS, 0.18 µm design rule devices.

10.4.6 Table 8 is typical of epitaxial wafer substrate criteria for a wafer pre-epitaxial that will be used in twin tub CMOS, 0.25 µm design rule devices.

10.4.7 Table 9 is typical of epi wafer criteria for twin tub CMOS, 0.13 µm design rule devices.

Table 2 Equivalent Units for Localized Light Scatterers

	Diameter[1]					
Density per m^2	*100*	*125*	*150*	*200*	*300*	*Density per cm*^{2}
	Localized Light Scatterers per Wafer					
100	1	1	2	3	7	0.01
200	1	2	3	6	13	0.02
300	2	3	5	9	20	0.03

NOTE 1: * indicates substrate specification.
NOTE 2: NS is the abbreviation for Not Specified.
NOTE 3: Non-destructive metrology did not exist at the time this document was approved.
NOTE 4: The site size is 25 mm × 32 mm. Partial sites are included. The metrology was being developed at the time this document was being balloted.
NOTE 5: These values are mathematically consistent. The 0.09 µm count limit was transformed using draft international standard: ISO/DIS 14644-1 which follows the equation: 112 counts per wafer = 200 counts per wafer $/(0.12\mu m/0.09\mu m)^2$.
NOTE 6: The process control capability is expected to be: ≤ 500 @ ≥ 0.25 µm.
NOTE 7: Large Area Defects (LAD's) are surface imperfections or particles that have geometry with at least one side or diameter that is a minimum of 1 micron in length .
NOTE 8: Tested per ASTM F80; a depth < 100nm is acceptable.
NOTE 9: Only process control data is required. Data not required on Certificate of Compliance.
NOTE 10: The first column under item references SEMI M18. M18 was in the process of substantial revision at the time this documented was balloted. Many M18 line references remain to be determined. TBD is the abbreviation for "to be determined".
NOTE 11: The intent in specifying carrier density using a range, rather than the center nominal with tolerance accompanied by a wafer variation limit, is to minimize the importance of edge variations and to emphasize meeting the range of carrier density as it is allowed by the process and the designers.

SEMI M12-0998[E]
SPECIFICATION FOR SERIAL ALPHANUMERIC MARKING OF THE FRONT SURFACE OF WAFERS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Silicon Wafer Committee on July 12, 1998. Initially available at www.semi.org May 1999; to be published June 1999. Originally published in 1988.

[E] This document was modified by the Global Traceability Committee in April 1999 to reflect the creation of SEMI AUX1 as the source for vendor identification codes. Changes were made to numerous sections.

1 Scope

1.1 This specification defines the geometric and spatial limits of the alphanumeric code, specifically for serial identification of flatted and notched silicon wafers. It also defines the basic code used to characterize the individual wafer, using database systems. This specification will ensure the consistency of all wafer marking performed by wafer manufacturers. This will allow simplification of the performance requirements of Automatic Optical Character Reading (OCR) equipment, provide unassisted and immediate human readability without wafer handling, and facilitate resolution of wafer level process variations. This document does NOT address the marking techniques that may be employed when complying with this standard. The marking code is intended to be valid for a broad range of wafer products (i.e., epi, SOI, processed polished wafers).

2 Referenced Documents

2.1 *SEMI Standards*

SEMI AUX1 — List of Vendor Identification Codes

2.2 *ANSI Standard*[1]

ANSI X 3.17 — Character Set and Print Quality for Optical Character Recognition (OCR-A).

3 Selected Definitions

3.1 *adjacent character misalignment* — the vertical distance, R, between the character baselines of two adjacent characters on the same line (see Figure 6a).

3.2 *character separation* — the horizontal distance between the adjacent boundaries of any characters (see Figure 1).

3.3 *character spacing* — the horizontal distance between the character centerlines of the adjacent characters (see Figure 1).

3.4 *character window* — the rectangular window within which all characters must be contained as shown on Figures 3 and 4 with dimensions of 18.5 mm long and 2.8 mm high as located on these figures.

3.5 *front surface of the wafer* — the exposed surface upon which active semiconductor devices have been or will be fabricated.

3.6 *line character misalignment* — the vertical distance, R, between the character baselines of two characters on the same line (see Figure 6b).

4 Shape and Size of Marking

4.1 Solid line or dot matrix method may be used to write characters. The minimum matrix shall be 5 dots horizontal and 9 dots vertical. More dots may be used, up to and including a solid line. Higher density is recommended to achieve improved read reliability (see Related Information 1).

4.2 *Character Dimensions and Spacing* — (see Table 1 and Figure 1)

Table 1 Character Dimensions

Character	*mm*
Height	1.624 ± 0.025
Width	0.812 ± 0.025
Thickness (See NOTE 1)	0.200 + 0.050/-0.150
Spacing	1.420 ± 0.025

NOTE 1: The thickness of the diagonal in the letter "N" is 0.138 ± 0.05 mm for single density dot matrix.

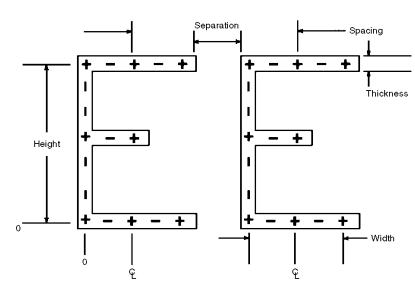

Figure 1

Table 2 Code

Character Location	*CharacterStyle*	*Parameter*	*Code*	*Definition*
1	Alpha/Numeric	IDENTIFICATION NUMBER	A through Z and 0 through 9	Vendor-Assigned (see NOTE 1)
2	Alpha/Numeric	IDENTIFICATION NUMBER		Vendor-Assigned (see NOTE 1)
3	Alpha/Numeric	IDENTIFICATION NUMBER		Vendor-Assigned (see NOTE 1)
4	Alpha/Numeric	IDENTIFICATION NUMBER		Vendor-Assigned (see NOTE 1)
5	Alpha/Numeric	IDENTIFICATION NUMBER		Vendor-Assigned (see NOTE 1)
6	Alpha/Numeric	IDENTIFICATION NUMBER		Vendor-Assigned (see NOTE 1)
7	Alpha/Numeric	IDENTIFICATION NUMBER		Vendor-Assigned (see NOTE 1)
8	Numeric Only	IDENTIFICATION NUMBER	0 through 9	Vendor-Assigned (see NOTE 1)
9	Alpha Only	VENDOR IDENTIFICATON CODE	A through Z	(see SEMI AUX1 and NOTE 1)
10	Alpha Only	VENDOR IDENTIFICATION CODE		(see SEMI AUX1 and NOTE 1)
11	Alpha Only	CHECK CHARACTERS	A through H	Error-Detecting Method (see Section 13)
12	Numeric Only	CHECK CHARACTERS	0 through 7	Error-Detecting Method (see Section 13)

NOTE 1: In the absence of information at any assigned location, a dash (-) must be used.

5 Alphanumeric Code

5.1 The code consists of one line of 12 characters. The first eight characters are an identification number which is unique to the wafer for a given vendor. These characters may be alphanumeric except character 8 which must be numeric (see Table 2). Characters 9 and 10 are the vendor identification codes (see SEMI AUX1). Characters 11 and 12 are check characters (see Sections 8 through 13). These check characters are machine generated for code acceptance.

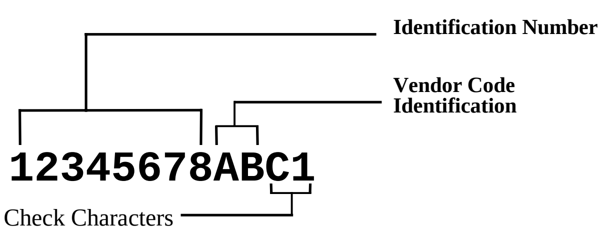

Figure 2

Example of Code

5.2 In the absence of a character at any assigned location, a dash (-) must be used.

5.3 An example of the code is given in Figure 2.

5.4 *SEMI-OCR Standard Character Set* — See Table 3 and Appendix 1.

Table 3 Standard Character Set

ABCDEFGHIJKLMNO
PQRSTUVWXYZ-
0123456789.

6 Character Window

6.1 Character window must be located on the front surface of the wafers.

6.2 All characters must be contained within the character window dimensions specified in Figures 3 and 4 (dashed lines).

6.3 The top of the characters is toward the side of the character window nearest to the flat or notch.

	100 mm Diameter Wafer	125 mm Diameter Wafer	150 mm Diameter Wafer
L min	30.0 mm	40.0 mm	55.0 mm

Figure 3

Character Window Location for Flatted Wafers

NOTE: The vertical center line referenced in Figure 3 is the bisector of the primary fiducial (flat).

	150 mm Diameter Wafer	200 mm Diameter Wafer
R_1	71.2 mm	96.5 mm

Figure 4

Character Window Location for Notched Wafers

NOTE: The vertical center line referenced in Figure 4 is the bisector of the primary fiducial (notch).

7 Character Alignment

7.1 *Character Skew* — the maximum angle between the character baseline and a line parallel with the bottom of the character window is 3 (see Figure 5).

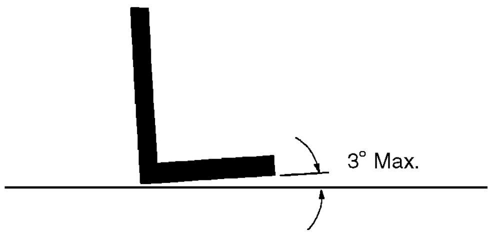

Figure 5

Character Skew

NOTE: This line is parallel to the bottom of the character window.

7.2 *Maximum Character Misalignment* — the maximum misalignment between adjacent characters is 0.23 mm (see Figure 6a), and the maximum line character misalignment is 0.46 mm (see Figure 6b).

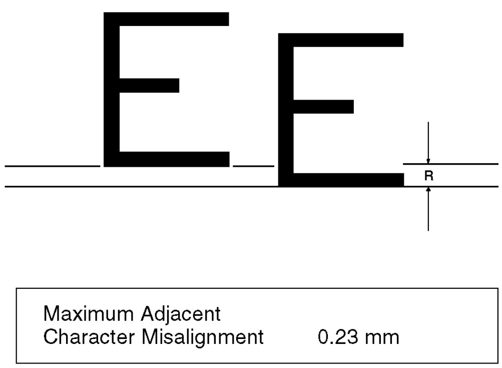

Figure 6A

Character Misalignment

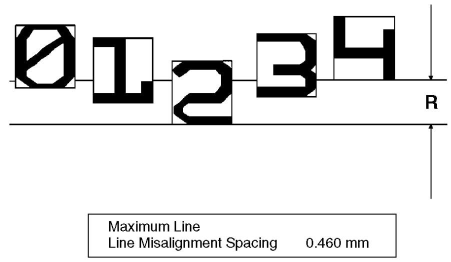

Figure 6B

Line Spacing Misalignment

8 Alphanumeric Error-Detecting Method

8.1 The alphanumeric check characters in character locations 11 and 12 are a required part of the Vendor Code.

8.2 All single-character substitution errors are detected.

8.3 All two-character transposition errors are detected for any message up to 58 characters in length.

8.4 The character set may be expanded to include the first 59 characters of the ASCII 64-character set.

8.5 There exist simple recursive algorithms for error detection and check character generation that do not require the use of multiplication or division.

9 Definition of the Error-Detecting Method

9.1 For the purpose of describing the error-detecting method, we define the following symbols:

A_i represents the ith ASCII character.

a_i represents the numerical value assigned to A_i.

9.2 The characters are numbered from left to right, so that the message is given by

$$A_1A_2A_3\ldots A_{12}$$

9.3 A complete description of the error-detecting method is given by the following seven rules:

9.3.1 The numerical value a_i is found by subtracting 32 from the ASCII decimal representation of A_i (refer to Table 4 — Character Values).

9.3.2 An ASCII character A_i is allowed only if its numerical value a_i is one of

$$0,1,2,\ldots 58.$$

9.3.3 The check character A_{11} must be one of the ASCII characters A,B,C,D,E,F,G,H.

9.3.4 The check character A_{12} must be one of the ASCII characters 1,2,3,4,5,6,7.

9.3.5 The check character pair $A_{11}A_{12}$ may not be one of the combinations H3, H4, H5, H6, H7.

9.3.6 When the message is written, the check characters A_{11} and A_{12} are chosen such that 59 divides the expression

$$8^{11}a_1 + 8^{10}a_2 \ldots + 8^2 a_{10} + 8a_{11} + a_{12}$$

without a remainder.

9.3.7 If, on reading the message, 59 does not evenly divide the expression given above, an error has occurred.

10 Suggestions for Implementation

10.1 The error-detecting method can be implemented directly by calculating the expression given above, and the check characters can be found by exhaustive search. However, this approach is unnecessarily complex; a decrease in complexity can be made by taking advantage of three simple observations.

10.2 First, since we are interested only in the remainder of the final expression after dividing it by 59, we can avoid working with large numbers by subtracting 59 repeatedly after each operation until the result is less than 59.

10.3 Second, we can rearrange the error-detecting expression, using Horner's Rule, to form

$$a_{12} + 8\left(a_{11} + \ldots 8\left(a_3 + 8\left(a_2 + 8a_1\right)\right)\ldots\right)$$

which can be calculated recursively from the inside out by successive multiplication and addition.

10.4 Third, multiplication by eight can be accomplished by adding a quantity to itself three times in succession.

11 An Algorithm for Error Detection [2]

11.1 When implementing error detection, it is convenient to imagine a checksum for each individual character position. This partial checksum forms a check on all preceding characters, as well as the present character. Then using Horner's Rule, one can calculate a running checksum (that is, calculate each partial checksum in order). This leads to the following algorithm.

11.2 Add the checksum (or the previous character position to itself. (For the first character position, the

[2] *Formal proofs of the properties of the error detecting method (as well as descriptive notes and other reference materials) are on file at SEMI, and are available upon request.*

value of the previous checksum is zero.) If the result is 59 or greater, subtract 59. This leaves a value in the range 0-58.

11.3 Add the result of step 1 to itself. If the result is 59 or greater, subtract 59.

11.4 Add the result of step 2 to itself. If the result is 59 or greater, subtract 59. The result of this step is eight times the previous position checksum, modulo 59.

11.5 Add the result of step 3 to the numerical value of the character in the present position. If the result is 59 or greater, subtract 59. The result of this step is the checksum for the present character position.

11.6 Repeat steps 1 through 4 for each character position. If the checksum for the final character position is nonzero, an error has occurred.

12 An Algorithm for Generating the Check Characters

12.1 The check characters can be generated as follows:

12.2 Initially, assume that the check characters are A0 (the first check character is the letter A, the second is the digit 0).

12.3 Calculate the final checksum in the manner described above for error detection. If the result is zero, the check characters are correct, and the algorithm terminates.

12.4 If the result of step 2 is nonzero, subtract it from 59, yielding a number in the range 1-58.

12.5 Convert the result of step 3 to binary.

12.6 Add the least significant three bits of the binary number to the numerical value of the second assumed check character 0 (zero). This will yield a value that corresponds to an ASCII character in the range 0-7.

12.7 Add the next higher three bits of the binary number to the numerical value of the first assumed check character A. This will yield a numerical value that corresponds to an ASCII character in the range A-H.

13 An Illustrative Example

13.1 For the purpose of illustrating the check character generating algorithm, assume that the message consists of only two characters, the digits 2 and 3. Initially, assume that the check characters are A and 0 (zero) yielding the composite message 23A0.

13.2 Using the algorithm described above, the final checksum is found to be 33. Since this is nonzero, it is subtracted from 59, yielding 26 in decimal, or 011010 in binary.

13.3 The least significant three bits 010 (decimal value 2) added to the numerical value of the ASCII character 0 (zero), which is 16, yields 18 (the numerical value of the ASCII character 2).

13.4 The next higher three bits 011 (decimal value 3) added to the numerical value of the ASCII character A, which is 33, yields 36 (the numerical value of the ASCII character D). The final composite message is 23D2.

APPENDIX 1
SEMI OCR CHARACTER OUTLINES

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI M12 but was approved for publication on July 12, 1998.

R1-1 Considerations for Reliable Automatic Reading of the Marking

R1-1.1 The following suggestions are offered to assist in assuring the most reliable automatic reading of the alphanumeric marking.

R1-1.2 *Character Stroke Thickness* — If a 5 × 9 dot matrix is chosen for marking, it is recommended that the minimum dot size be 0.100 mm. Double or higher density dot matrix is recommended — when used, smaller dot diameters may be employed. Stroke thickness should be constant within 20% over the entire character set so that the reader settings may be optimized for the specific wafer run.

R1-1.3 *Contrast* — The character should have sufficient contrast to be legible. Contrast may be affected by depth and other conditions.

R1-1.4 *Clear Zone* — It is recommended that the area immediately beneath and a minimum of 0.500 mm around the marking characters be of uniform reflectivity and free of any lithography and process overlay edges.

R1-2 Considerations for the Use of Front Surface Markings

R1-2.1 Marks can impinge upon areas where devices may be printed. Since mask geometries are varied, considerations of the mark area should be made in mask design and also when applying the mark specifications to existing mask designs.

R1-2.2 When the mark is applied prior to epitaxial deposition, a crown or epi may grow along the mark edge. The height of this crown will depend upon the epi thickness and the deposition process.

SEMI M13-0998[E]
SPECIFICATION FOR ALPHANUMERIC MARKING OF SILICON WAFERS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Silicon Wafer Committee on July 12, 1998. Initially available at www.semi.org May 1999; to be published June 1999. Originally published in 1988; previously published in September 1998.

[E] This document was modified by the Global Traceability Committee in April 1999 to reflect the creation of SEMI AUX1 as the source for vendor identification codes. Changes were made to numerous sections.

1 Scope

1.1 This specification defines the geometric and spatial limits of the alphanumeric code, specifically for flatted and notched silicon wafers. It also defines the basic code used to characterize the individual wafer, thereby providing practical operator interpretation. This specification will ensure the consistency of all wafer marking performed by silicon manufacturers. This will allow simplification of the performance requirements of Automatic Optical Character Reading (OCR) equipment. This document does NOT address the marking techniques that may be employed when complying with this standard.

2 Applicable Documents

2.1 *SEMI Standards*

SEMI AUX1 — List of Vendor Identification Codes

2.2 *ANSI Standard*[1]

ANSI X 3.17 — Character Set and Print Quality for Optical Character Recognition (OCR-A).

3 Selected Definitions

3.1 *character misalignment* — the vertical distance, R, between the character baselines of two adjacent characters on the same line (see Figure 6a.).

3.2 *character separation* — the horizontal distance between the adjacent boundaries of any characters (see Figure 1).

3.3 *character spacing* — the horizontal distance between the character spacing reference lines of the adjacent characters (see Figure 1).

3.4 *line spacing misalignment* — the vertical distance, R, between the character baselines of two characters on the same line (see Figure 6b).

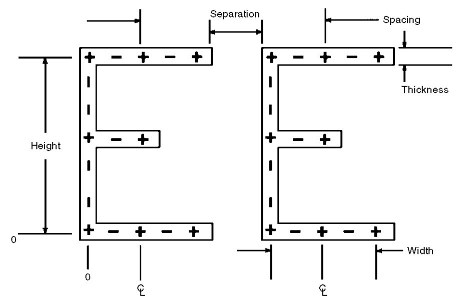

Figure 1

Character Outline

4 Method of Marking

4.1 Solid line or dot matrix method may be used to write characters. The minimum matrix shall be 5 dots horizontal and 9 dots vertical as shown in Figure 1.

NOTE 1: The 5 × 9 dot matrix shown in Figure 1 is the minimum number of dots allowed. More dots may be used, up to and including a solid line.

NOTE 2: The diagonal thickness of the letter "N" is 0.138 + 0.05 mm.

4.2 *Character Dimensions and Spacing* — See Table 1 and Figure 1.

4.3 *SEMI OCR Standard Character Set* — See Table 2 and Appendix 1.

5 Alphanumeric Code

5.1 *Vendor Code* — Limited to one line of 18 characters (See Figure 2 and Table 3.)

NOTE 3: In the absence of a character at any assigned location, a dash (-) must be used.

8 Alphanumeric Error-Detecting Method[2]

8.1 The alphanumeric check characters in character locations 17 and 18 are a required part of the Vendor Code.

8.2 All single-character substitution errors are detected.

8.3 All two-character transposition errors are detected for any message up to 58 characters in length.

8.4 The character set may be expanded into the first 59 characters of the ASCII 64-character set.

8.5 There exist simple recursive algorithms for error detection and check character generation that do not require the use of multiplication or division.

9 Definition of the Error-Detecting Method

9.1 For the purpose of describing the error-detecting method, we define the following symbols:

A_i represents the i^{th} ASCII character.
a_i represents the numerical value assigned to A_i.

9.2 The characters are numbered from left to right, so that the message is given by

$$A_1A_2A_3...A_{18}.$$

9.3 A complete description of the error-detecting method is given by the following seven rules:

9.3.1 The numerical value a_i is found by subtracting 32 from the ASCII decimal representation of A_i (refer to Table 4 — Character Values).

9.3.2 An ASCII character A_i is allowed only if its numerical value a_i is one of

$$0, 1, 2, ..., 58.$$

9.3.3 The check character A_{17} must be one of the ASCII characters A,B,C,D,E,F,G,H.

9.3.4 The check character A_{18} must be one of the ASCII characters 0,1,2,3,4,5,6,7.

9.3.5 The check character pair A_{17} A_{18} may not be one of the combinations H3, H4, H5, H6, H7.

9.3.6 When the message is written, the check characters A_{17} and A_{18} are chosen such that 59 divides the expression

$$8^{17}a_1 + 8^{16}a_2 ... + 8^2a_{16} + 8a_{17} + a_{18}$$

without a remainder.

[2] *Formal proofs of the properties of the error-detecting method (as well as descriptive notes and other reference materials) are on file at SEMI, and are available upon request.*

9.3.7 If, on reading the message, 59 does not evenly divide the expression given above, an error has occurred.

10 Suggestions for Implementation

10.1 The error-detecting method can be implemented directly by calculating the expression given above, and the check characters can be found by exhaustive search. However, this approach is unnecessarily complex; a decrease in complexity can be made by taking advantage of three simple observations.

10.2 First, since we are interested only in the remainder of the final expression after dividing it by 59, we can avoid working with large numbers by subtracting 59 repeatedly after each operation until the result is less than 59.

10.3 Second, we can rearrange the error-detecting expression, using Horner's Rule, to form

$$a_{18} + 8(a_{16} + ...8(a_3 + 8(a_2 + 8a_1))...)$$

which can be calculated recursively from the inside out by successive multiplication and addition.

10.4 Third, multiplication by eight can be accomplished by adding a quantity to itself three times in succession.

11 An Algorithm for Error Detection

11.1 When implementing error detection, it is convenient to imaging a checksum for each individual character position. This partial checksum forms a check on all preceding characters, as well as the present character. Then, using Horner's Rule, one can calculate a "running" checksum (that is, calculate each partial checksum in order). This leads to the following algorithm.

11.2 Add the checksum for the previous character position to itself. (For the first character position, the value of the previous checksum is zero.) If the result is 59 or greater, subtract 59. This leaves a value in the range 0-58.

11.3 Add the result of Step 1 to itself. If the result is 59 or greater, subtract 59.

11.4 Add the result of Step 2 to itself. If the result is 59 or greater, subtract 59. The result of this step is eight times the previous position checksum, modulo 59.

11.5 Add the result of Step 3 to the numerical value of the character in the present position. If the result is 59 or greater, subtract 59. The result of this step is the checksum for the present character position.

11.6 Repeat Steps 1 through 4 for each character position. If the checksum for the final character position is nonzero, an error has occurred.

12 An Algorithm for Generating the Check Characters

12.1 Initially, assume that the check characters are A0 (the first check character is the letter A, the second is the digit 0).

12.2 Calculate the final checksum in the manner described above for error detection. If the result is zero, the check characters are correct, and the algorithm terminates.

12.3 If the result of Step 2 is nonzero, subtract it from 59, yielding a number in the range 1-58.

12.4 Convert the result of Step 3 to binary.

12.5 Add the least significant three bits of the binary number to the numerical value of the second assumed check character 0 (zero). This will yield a value that corresponds to an ASCII character in the range 0-7.

12.6 Add the next higher three bits of the binary number to the numerical value of the first assumed check character A. This will yield a numerical value that corresponds to an ASCII character in the range A-H.

13 An Illustrative Example

13.1 For the purpose of illustrating the check character generating algorithm, assume that the message consists of only two characters, the digits 2 and 3. Initially, assume that the check characters are A and 0 (zero) yielding the composite message 23A0.

13.2 Using the algorithm described above, the final checksum is found to be 33. Since this is nonzero, it is subtracted from 59, yielding 26 in decimal, or 011010 in binary.

13.3 The least significant three bits 010 (decimal value 2) added to the numerical value of the ASCII character 0 (zero), which is 16, yields 18 (the numerical value of the ASCII character 2).

13.4 The final composite message is 23D2. The next higher three bits (011) (decimal value 3) added to the numerical value of the ASCII character A, which is 33, yields 36 (the numerical value of the ASCII character D).

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI M13 and is not intended to modify or supercede the official standard. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

R1-1 Consideration for Reliable Automatic Reading of the Marking

R1-1.1 The following suggestions are offered to assist in assuring the most reliable automatic reading of the alphanumeric marking.

R1-1.2 *Character Stroke Thickness* — If a 5 × 9 dot matrix is chosen for marking, it is recommended that the minimum dot size be 0.100 mm. With a higher density dot matrix format, smaller dot diameters may be employed. Stroke thickness should be constant within 20% over the entire character set so that the reader settings may be optimized from the specific wafer run.

R1-1.3 *Contrast* — The character should have sufficient contrast to be legible. Contrast may be affected by depth and other conditions.

R1-1.4 *Clear Zone* — It is recommended that the area immediately beneath, and a minimum of 0.500 mm around, the marking characters be of uniform reflectivity and free of any lithography and process overlay edges.

SEMI M14-89
SPECIFICATION FOR ION IMPLANTATION AND ACTIVATION PROCESS FOR SEMI-INSULATING GALLIUM ARSENIDE SINGLE CRYSTALS

1 Scope

The purpose of this document is to present a process for ion implantation, activation, and measurement of the resulting layers so that meaningful comparisons can be made between various lots of semi-insulating GaAs. This test will be performed by the supplier so that product may be represented in a standard way.

NOTE: This is intended to be an interim procedure for use until a standard test method is developed by ASTM.

2 Process

2.1 Candidate lots must pass SEMI GaAs specifications for resistivity, mobility, and thermal stability using standard ASTM referee techniques.

2.2 *Implantation Process*

2.2.1 *Surface Preparation* — The surface treatment shall be designed to remove residual oxide.

2.2.2 *Implant Angle Energy Species and Dose* — An energy of 150 keV using Si_{29} to a dose of $2 \times 10^{12}/cm^2$ and a tilt of 11° to 13° from the (100) toward the (110).

2.3 *Activation Process*

2.3.1 *Surface Preparation* — No chemical treatment should be performed prior to activation.

2.3.2 *Activation* — The samples shall be subjected to a temperature of 850°C for 10 minutes with a second proximity wafer directly in contact with the implanted surface. The proximity wafer shall be identical to the subject wafer except not subjected to ion implantation. The ambient of the furnace shall be a gas such as nitrogen or argon.

2.4 *Layer Evaluation*

2.4.1 Evaluation of the activated samples shall be based upon CV profiling, mobility, and resistivity as specified according to standard ASTM techniques.

SEMI M15-0298
POLISHED WAFER DEFECT LIMITS TABLE FOR SEMI-INSULATING GALLIUM ARSENIDE WAFERS

NOTE: This entire document was revised in 1998.

1 Purpose

1.1 This document defines the maximum number of defects, by type, that an acceptable polished Semi-Insulating Gallium Arsenide (GaAs) wafer may exhibit.

2 Scope

2.1 This document, established separately from SEMI M15, in accordance with the latest requirements for the material in advanced applications, covers polished semi-insulating GaAs wafers. The defect limits table can also be applied to conducting GaAs wafers, except for the specification of Light Point Defects (LPD) mentioned hereinafter. “Polished” shall refer to those wafers which have a specular chemical or chemical/mechanical finish applied to one side of the wafer, with the backside being as cut and etched, lapped and etched, ground and etched, or polished. The definition of defects is covered in ASTM Practices F 523 and F 154.

NOTES:

1. These defect limits are meant to apply only to those characteristics which can be seen with the unaided eye under high-intensity illumination according to ASTM Practice F 523. Limits for other defects listed and defined in this section which require the aid of a microscope, preferential etching, or other apparatus must be agreed upon between supplier and user.

2. Peripheral Edge Allowance — The outer edge exclusion for observation shall be determined from the following tabe:

Diameter	*Outer Edge Exclusion for Observation*
2 inch	2 mm
3 inch	3 mm
4 inch	3 mm

3. LPD shall be counted by measuring equipment designed for detecting laser light scatter. Selection of the measuring equipment and the requirement for the precision are to be agreed upon between supplier and user.

4. Back Surface Stain — An area of undercutting, texturing, or oxidation, common in waxless polished wafers.

5. The depth of allowed saw marks is to be no greater than 5 µm. The measuring method is to be agreed upon between supplier and user.

6. Item #20 — To be agreed upon between supplier and user.

SEMI M16-1296
SPECIFICATION FOR POLYCRYSTALLINE SILICON

1 Preface

1.1 This specification covers requirements for polycrystalline silicon (poly) used to produce single crystal silicon by the Czochralski (Cz) crystal growth technique for applications in the semiconductor device industry. Form and dimensional characteristics are the only standardized properties set forth below.

1.2 A purchase specification may require that additional physical properties be defined. These properties are listed, together with test methods suitable for determining their magnitude.

2 Applicable Documents

2.1 *ASTM Standards*[1]

E 122 — Practice for Choice of Sample Size to Estimate Average Quality of a Lot or Process

F 574 — Test Method for Evaluation of Polysilicon (In Revision)

P 213 — Proposed Test Method for Photoluminescence Analysis of Single Crystal Silicon for III-V Impurities

2.2 *Other Standards*

ANSI/ASQC Z1.4-1993 — Sampling Procedures and Tables for Inspection by Attributes[2]

AQAP-4 — NATO Inspection System Requirements for Industry

3 Terminology

etched polysilicon — polysilicon that has been etched with acid to remove surface contamination.

lot — all of the material of nominally identical purity and characteristics contained in a single shipment, manufactured with similar processing conditions, and traceable to the manufacturing conditions. A lot may be further defined as the polysilicon produced from one reactor run.

polycrystalline silicon — (Poly, polysilicon) silicon, formed by chemical vapor deposition from a silicon source gas, having a structure which contains large angle grain boundaries, twin boundaries, or both.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959 (All cited standards except for E 122 may be found in Volume 10.05 of the Annual Book of ASTM Standards; E 122 may be found in Volume 14.02.)

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

4 Ordering Information

4.1 Purchase orders for polysilicon furnished to this specification shall include the following items:

4.1.1 Form

4.1.2 Size

4.1.3 Purity

4.1.4 Surface Texture

4.1.5 Surface Condition

4.1.6 Appearance

4.1.7 Lot Acceptance Procedures

4.1.8 Certification (if required)

4.1.9 Packing and Marking

5 Dimensions and Permissible Variations

5.1 The material shall conform to the dimensions and dimensional tolerances as specified in the appropriate polysilicon standard.

6 Materials and Manufacture

6.1 The material shall consist of polysilicon with the form specified in the purchase order or contract.

7 Physical Requirements

7.1 The material shall conform to the properties specified in the purchase order or contract, as follows:

7.1.1 Purity

7.1.2 Size

7.1.3 Surface Texture

7.1.4 Surface Condition

7.1.5 Appearance

8 Sampling

8.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4-1993. Inspection levels shall be agreed upon between the supplier and the purchaser. Alternately AQAP-4 may be used to determine sampling plan.

9 Test Methods

9.1 *Size* — Determine by a method agreed upon by the purchaser and the supplier.

9.2 *Purity* — Determine in accordance with ASTM Test Method F 574.

NOTE 1: Newer test methods are being developed, including photoluminescence (ASTM Proposed Test Methods P 213) and low temperature FTIR.

9.3 *Surface Texture* — Determine by a method agreed upon by the purchaser and the supplier. Visual limit standards shall be used to describe acceptable limits.

10 Certification

10.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with the specification shall be furnished at the time of shipment (Certificate of Compliance). Upon request, a report of the test results may also be required (Certificate of Analysis).

10.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate test in Section 9. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

11 Packing and Marking

11.1 Special packing requirements shall be subject to agreement between the supplier and purchaser. Otherwise all poly shall be handled, inspected, and packed in bags and boxes in such a manner as to minimize abrasion, chipping, and contamination, and in accordance with the best industry practices to provide ample protection against damage during shipment.

11.2 The poly supplied under the specification shall be identified by appropriately labeling the outside of each box and each bag therein. Identification shall include, as a minimum, the weight and lot number of the polysilicon. The lot number shall provide traceability to information concerning the manufacturing history of the particular poly in that lot. Such information shall be kept on file at the manufacturer's facility for at least three years after that particular lot has been accepted by the purchaser.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M16.1-89
STANDARD FOR NUGGET-FORM POLYCRYSTALLINE SILICON

The complete specification for this product includes all general requirements of SEMI M16.

1 Purity

1.1 Values to be determined by the purchase order are listed as follows:

Acceptor, max = Maximum allowable content of acceptor impurities to be specified as parts per billion, atomic (ppba).

Donor, max = Maximum allowable content of donor impurities to be specified as parts per billion, atomic (ppba).

Carbon, max = Maximum allowable content of carbon impurity to be specified as parts per million, atomic (ppma).

2 Size Distribution

2.1 Nuggets shall have irregular shape and a random size distribution resulting from the breaking of rod-form poly. The minimum linear dimension of a nugget shall be 6 mm, the maximum linear dimension 100 mm.

2.2 Size distribution shall be:

< 6 mm size	1% by weight, maximum
< 12 mm size	2% by weight, maximum
12 –25 mm size	10% by weight, maximum
25–50 mm size	15–35% by weight
50–100 mm size	65% by weight, minimum

3 Surface Texture

3.1 Visual limit standards shall be agreed upon between the purchaser and the supplier.

4 Surface Condition

4.1 All polysilicon shall be identified as to its surface condition, whether or not it has been etched.

5 Appearance

5.1 Surface of nuggets shall be clean, with no stains, discolorations, or visible contaminants.

SEMI M17-0998
SPECIFICATION FOR A UNIVERSAL WAFER GRID

1 Scope

1.1 This document defines a grid pattern which is useful for quantifying surface defects on a nominally circular semiconductor wafer. The grid is defined such that it contains 1000 elements of approximately equal area. Each grid element thus contains 0.1 percent of the total quality area of the surface being inspected. Defects which are non-uniformly distributed (for example, slip) can be quantified in terms of the percent defective (or percent useful) area on the wafer surface.

1.2 The quantification of defective area is done by overlaying a transparency of the grid onto a map of wafer defects or by mapping observed defects onto the grid. The number of grid elements which contain defects is counted. The element count divided by 10 corresponds to the percent of defective area. This grid could also be superimposed onto a CRT display, photograph, or computer generated map, where applicable. In use, grid pattern diameters must be scaled to the size of the map or image of the wafer to be overlaid.

1.3 The grid described is referenced to the center of the wafer. A concept of a "Fixed Quality Area" is used, based on nominal wafer diameter, such as is specified in SEMI M1.

1.4 Maximum allowable slip and other non-uniformly distributed defects on epitaxial layers are specified in SEMI M2 and SEMI M11, and are observed in accordance with ASTM Test Methods F 80 or F 523.

2 Applicable Documents

2.1 *SEMI Standards*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

SEMI M2 — Specifications for Silicon Epitaxial Wafers

SEMI M11 — Specifications for Silicon Epitaxial Wafers for Advanced Applications

2.2 *ASTM Standards*[1]

F 47 — Test Method for Crystallographic Perfection of Silicon by Preferential Etch Techniques

F 80 — Test Method for Crystallographic Perfection of Epitaxial Deposits of Silicon by Etching Techniques

F 154 — Standard Practice and Nomenclature for Identification of Structures and Contaminants Seen on Specular Silicon Surfaces

F 523 — Practice for Unaided Visual Inspection of Polished Silicon Slices

F 1241 — Terminology for Silicon Technology

3 Terminology

3.1 Selected definitions (for information only) are listed in the glossary, Definitions for Semiconductor Materials, at the end of this volume.

3.2 Definitions for many surface defects are given in ASTM Terminology F 1241. Additional information is provided in ASTM Test Method F 47 and ASTM Practices F 154.

4 Grid Element Layout

4.1 *Grid Element Scheme*

4.1.1 Two types of grids are defined: one for wafers without a primary flat (for example, wafers where the primary fiducial is a notch), and one for wafers with a primary flat. The grid is divided by 18 concentric circles containing radial divisions which are assigned according to the diameter of each circle (see Table 1). The relative diameters of the concentric circles are established by the areas of each annulus. To find the actual diameter of any circle, multiply the relative diameter by the outer diameter of the grid.

4.1.2 The outer diameter of the grid is chosen to be the size appropriate for a particular application. This diameter would normally be chosen to be the nominal diameter of the fixed quality area to allow for such things as an edge exclusion, tolerance variations in the wafer diameter, and edge rounding. Table 2 shows (as an example) the circle diameters for a series of grids which have a fixed quality area radius 3 mm smaller than the nominal radius of selected wafers specified in SEMI M1.

4.1.3 Identification of each grid element is done by referring to a circle number and a division number on that circle. Circles are numbered from the center out, with the center circle being number 01 and the outermost circle being number 18. The divisions are numbered starting with the first division counterclockwise from the horizontal line which starts

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959 (All cited standards except for E 122 may be found in Volume 10.05 of the Annual Book of ASTM Standards; E 122 may be found in Volume 14.02.)

at the center of the grid and extends to the right, when the primary fiducial (flat or notch) is placed at the bottom of the grid. Divisions are progressively numbered counterclockwise from 01 to n, where n equals the total number of divisions on the circle. An element's address is given by two sets of numbers separated by a comma: circle (0 –18), division (01–n). Elements 18, 01 and 18, 100 are identified in Figure 1.

4.2 *Wafers without a Primary Flat*

4.2.1 The grid elements for wafers without a primary flat are illustrated in Figure 1. This pattern is generated by making concentric circles with relative diameters and radial divisions as specified in Table 1. In this table the circle number is given in the leftmost column. The number of divisions and the included angle of each division in the circle are given in the second and third columns. The total number of divisions (from the center outward) is given in the fourth column. The included area ratio, given in the fifth column, is the total number of divisions included within a circle divided by 1000, the total number of divisions in the grid. The relative diameter, given in the rightmost column, is the square root of the included area ratio.

4.3 *Wafers with a Primary Flat*

4.3.1 For wafers with a primary flat, a standard included angle of 43.2° is used for all wafer sizes. This angle was chosen because it lies between the maximum and minimum included angles of the primary flats specified in SEMI M1 for 100 mm, 125 mm, 150 mm, and 200 mm diameter wafers. In addition, if a fixed quality area of radius 3 mm less than the nominal wafer radius is used, the grid will not in any case extend beyond the edge of the wafer in the region of the primary flat.

4.3.2 This flat is propagated into the wafer as illustrated in Figure 2. The diameter of each circle is the same as for wafers without a primary flat. The flat is propagated vertically downward (starting with circle number 3) by the intersection of the circle with a horizontal chord which subtends 43.2°.

4.3.3 The areas of the grid elements within the propagated flat region are slightly smaller than the areas of the regular grid elements. This difference is ignored when counting grid elements for wafers with a primary flat. All grid elements are assumed to be 0.001 of the total fixed quality area.

4.4 *Secondary Flats*

4.4.1 The grid ignores secondary flats. These are shallow enough that the outer circle does not extend beyond the wafer edge if a fixed quality area of radius 3 mm less than the nominal wafer radius is used.

NOTE In this sense, the fixed quality area used by the Universal Wafer Grid deviates somewhat from the formal definition in SEMI M1 which embodies an edge exclusion of constant width around the entire periphery of the wafer including the region of the secondary flat.

Table 1 Grid Element Scheme

SEMI M18-0702
FORMAT FOR SILICON WAFER SPECIFICATION FORM FOR ORDER ENTRY

This format was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published in 1990; previously published March 2002.

1 Purpose

1.1 This format provides a standard form for specifying several classifications of silicon wafers, as follows:

1.1.1 Polished Silicon Wafers.

1.1.2 Epitaxial Silicon Wafers.

1.1.3 Epitaxial Silicon Wafers with Buried Layer.

1.1.4 Annealed Silicon Wafer.

1.2 This format also lists the Electronic Data Interchange (EDI) codes used in SEMI T6 to identify the type of data being reported in the EDI message.

2 Scope

2.1 The form is designed to be used in conjunction with other SEMI specifications where details of the dimensional, physical, electrical, and chemical properties are defined or specified. However, the form includes many items that are not currently included in the SEMI specifications. Also, many items are not now commonly specified, but may find increased importance in the future. The intention is to provide for flexibility and expansion of the technology.

2.2 This format provides for specifying and ordering silicon wafers with varying levels of complexity. The minimum level of completeness is shown in each case, with additional options included to allow for customization of the wafer to the specific processing requirements of the user. If a particular item is not of interest, no entry is required. The only required entries are those marked as such for the purpose of minimal specification (diameter, orientation, dopant, resistivity, etc.).

2.3 Values for many items are listed either in the polished silicon wafer standards in SEMI M1 or in the defect limits tables in SEMI M1, SEMI M2, or SEMI M11. If these standard specifications are sufficient for defining the wafers, only a single entry is required in each section of the form.

2.4 This format also lists the codes required by SEMI T6 to identify the parameter being reported in the EDI message. Where necessary, secondary characteristics or identifier codes are listed within a generalized characteristic.

2.5 For referee purposes, U.S. Customary units shall be used for wafers of 2- and 3-inch diameters, and SI (System International, commonly called metric) units for 100 mm and larger diameter wafers.

2.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

F 1152 — Standard Test Method for Dimensions of Notches on Silicon Wafers

F 1188 — Standard Test Method for Interstitial Atomic Oxygen Content of Silicon by Infrared Absorption

F 1239 — Standard Test Methods for Oxygen Precipitation Characterization of Silicon Wafers by Measurement of Interstitial Oxygen Reduction

F 1241 — Standard Terminology of Silicon Technology

F 1366 — Test Method for Measuring Oxygen Concentration in Heavily Doped Silicon Substrates by Secondary Ion Mass Spectroscopy

F 1388 — Test Method for Generation Lifetime and Generation Velocity of Silicon Material by Capacitance-Time Measurements of Metal-Oxide-Silicon (MOS) Capacitors

F 1390 — Standard Test Method for Measuring Warp on Silicon Wafers by Automated Noncontact Scanning

F 1391 — Standard Test Method for Substitutional Atomic Carbon Content of Silicon by Infrared Absorption

F 1392 — Test Method for Determining Net Carrier Density Profiles in Silicon Wafers by Capacitance-Voltage Measurements with a Mercury Probe

F 1393 — Test Metod for Determining Net Carrier Density Profile in Silicon Wafers by Capacitance-Voltage Measurements with a Mercury Probe

F 1451 — Standard Test Method for Measuring Sori on Silicon Wafers by Automated Noncontact Scanning

F 1526 — Standard Test Method for Measuring Surface Metal Contamination on Silicon Wafers by Total Reflection X-ray Fluorescence Spectroscopy

F 1530 — Standard Test Method for Measuring Flatness, Thickness, and Thickness Variation on Silicon Wafers by Automated Noncontact Scanning

F 1528 — Test Method for Measuring Boron Contamination in Heavily Doped N-Type Silicon Substrates by Secondary Ion Mass Spectrometry

F 1535 — Standard Test Method for Carrier Recombination Lifetime in Silicon Wafers by Noncontact Measurement of Photoconductivity Decay by Microwave Reflectance

F 1617 — Standard Test Method for Measuring Surface Sodium, Aluminum, and Potassium on Silicon and EPI Substrates by Secondary Ion Mass Spectroscopy

F 1619 — Standard Test Method for Measurement of Interstitial Oxygen Content of Silicon Wafers by Infrared Absorption Spectroscopy with p-Polarized Radiation Incident at the Brewster Angle

F 1620 — Standard Practice for Calibrating a Scanning Surface Inspection System Using Monodisperse Polystyrene Latex Spheres Deposited on Polished or Epitaxial Surfaces

F 1621 — Standard Practice for Determining Positional Accuracy Capabilities of a Scanning Surface Inspection System

F 1725 — Standard Guide for Analysis of Crystallographic Perfection of Silicon Ingots

F 1726 — Standard Guide for Analysis of Crystallographic Perfection of Silicon Wafers

F 1727 — Practice for Detection of Oxidation Induced Defects in Polished Silicon Wafers

F 1809 — Guide for Selection and Use for Etching Solutions to Delineate Structural Defects in Silicon

F 1810 — Test Method for Counting Preferentailly Etched or Decorated Structural Defects on Silicon Wafers

F 1982 — Test Method for Analyzing Organic Contamination on Silicon Wafers Surfaces by Thermal Desporption Gas Chromatography

3.4 *DIN Standards*[3]

NOTE 1: DIN Standards are available in both German and English editions. ASTM equivalents are given in square brackets following the title.

50431 — Measurement of the Electrical Resistivity of Silicon or Germanium Single Crystals by Means of the Four-Point-Probe Direct Current Method with Colinear Four-Probe Array

50432 — Determination of the Conductivity Type of Silicon or Germanium by Means of Rectification Test or Hot-Probe

50433/1 — Determination of the Orientation of Single Crystals by Means of X-Ray Diffraction

50433/2 — Determination of the Orientation of Single Crystals by Means of Optical Reflection Figure

3 Available from Deutches Institut für Normung e.V., Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-10787 Berlin, Germany, website: www.din.de

50433/3 — Determination of the Orientation of Single Crystals by Means of Laue Back Scattering

50434 — Determination of Crystal Defects in Monocrystalline Silicon Using Etching Techniques on {111} and {100} Surfaces

50435 — Determination of the Radial Resistivity Variation of Silicon or Germanium Slices by Means of a Four-Point-DC-Probe

50436 — Measurement of Metallurgical Thicknes of Epitaxial Layers of Silicon by the Stacking Fault Method

50437 — Measuring the Thickness of Silicon Epitaxial Layers of Silicon by Infrared Intereference Method [F95]

50438/1 — Determination of Impurity Content in Silicon by Infrared Absorption: Oxygen

50438/2 — Determination of Impurity Content in Silicon by Infrared Absorption: Carbon

50439 — Determination of the Dopant Concentration Profile of Single Crystalline Semiconductor Material by Means of the Capacitance-Voltage Method and Mercury Contact [F 1392, F 1393]

50438/3 — Determination of Impurity Content in Silicon by Infrared Absorption: Boron and Phosphorus

50440/1 — Measurement of Recombination Carrier Lifetime in Silicon Single Crystals by Means of Photoconductive Decay Method; Measurement on Bar-Shaped Test Samples [F28]

50441/1 — Determination of the Geometric Dimensions of Semiconductor Slices: Measurement of Thickness

50441/2 — Determination of the Geometric Dimensions of Semiconductor Slices: Testing of Edge Rounding

50441/3 — Measurement of the Geometric Dimensions of Semiconductor Slices; Determination of Flatness Deviation of Polished Slices by Means of Multiple Beam Interference

50441/4 — Determination of the Geometrical Dimensions of Semiconductor Slices: Diameter and Flat Depth of Slices

50443/1 — Recognition of Defects and Inhomogenities in Semiconductor Single Crystals by X-Ray Topography: Silicon

50444 — Conversion Between Resistivity and Dopant Density; Silicon [F723 (phosphorous and boron only)]

50445 — Contactless Determination of the Electrical Resistivity of Semiconductor Wafers with the Eddy Current Method

50446 — Determination of Defect Types and Defect Densities of Silicon Epitaxial Wafers [no direct ASTM equivalent, compare F 1726 and associated standards]

3.5 *ISO Standards*[4]

ISO 4287/1 — Surface Roughness – Terminology – Part 1: Surface and its Parameters

ISO 14644/1-7 — Clean Room and Associated Controlled Environments

3.6 *JEITA (formerly JEIDA) Standards*[5]

18 — Determining the Orientation of a Semiconductor Silicon Single Crystal

27 — Standard Specification for Dimensional Properties of Silicon Wafers with Specular Surface

43 — Terminology of Silicon Wafer Flatness

53 — Test Method for Recombination Lifetime in Silicon Wafers by Measurement of Photoconductivity Decay by Microwave Reflectance

56 — Standard Test Method for Substitutional Atomic Carbon Content of Silicon by Infrared Absorption

61— Standard Test Method for Interstitial Atomic Oxygen Content of Silicon by Infrared Absorption

3.7 *JIS Standards*[6]

NOTE 2: ASTM equivalents are given in square brackets following the title.

H 0602 — Testing Method of Resistivity for Silicon Crystals and Silicon Wafers with Four-Point Probe

H 0604 — Measurement of Minority Carrier Life Time in Silicon by Photoconductive Decay Method [F 28]

H 0607 — Testing Methods for Conductivity Type of Semiconductor Materials

H 0609 — Test Methods of Crystalline Defects in Silicon by Preferential Etch Techniques

H 0611 — Methods of Measurement of Thickness, Taper, and Bow of Silicon Wafers

H 0612 — Testing Method of Resistivity for Single Crystal Silicon Wafers (with Four Point Probe) [F 84]

H 0614 — Visual Inspection for Silicon Wafers with Specular Surfaces

Z 8741 — Method of Measurement for Specular Glossiness

3.8 *Other Standard*[7]

ANSI/ASME B46.1 — Surface Texture (Surface Roughness, Waviness, and Lay)

NOTE 3: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 The items listed in the form are referenced and defined in various documents. A reference for most items in Parts 2 and 3 of the form is listed in Table 1. The entries in the table are keyed to the form by item number. Because terms related to epitaxial wafers with buried layer are defined in this standard and because no standardized test methods for the buried layer parameters exist, Table 1 does not include line items from Part 4 of the form.

4.2 General term used in this standard:

4.2.1 *required (req. or req'd)* — when applied to a parameter listed in the order form, a user-supplied value is necessary to minimally define the material for manufacture.

4.3 Terms related to epitaxial wafers with buried layers:

4.3.1 *buried layer* — a diffused region in a substrate that is, or is intended to be, covered with an epitaxial layer.

4.3.2 *alignment precision* — pattern displacement in first mask photolithography process.

NOTE 4: Alignment precision is specified by maximum values of X and Y, the displacement of the center of the pattern from a reference position defined in the wafer specification in terms of the wafer coordinate system defined in SEMI M20, and the maximum value of θ, the angle between the x-axis of the pattern and the primary orientation flat (see Figure 1).

4.3.3 *pattern distortion ratio* — absolute magnitude of the quotient of the (1) difference between the width of the pattern on the substrate and the width of the pattern on the top surface of the epitaxial layer and (2) the thickness of the epitaxial layer.

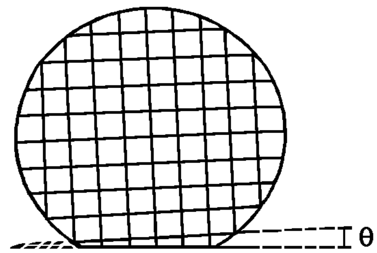

Figure 1
First Mask Showing Angular Displacement *θ*

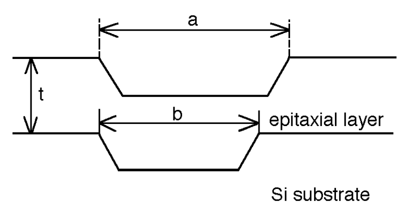

Figure 2
Cross-Section View of Epitaxial Layer Showing the Pattern Widths, *a*, at the Epi Surface, and *b*, at the Layer-Substrate Interface

4.3.4 *pattern shift ratio* — lateral distance between the center point of the pattern on the surface of the substrate and the center point of the pattern on the surface of the epitaxial layer divided by the epitaxial layer thickness.

NOTE 5: Pattern shift ratio, *d/t* (see Figure 4), is specified in terms of a nominal value, *X*, and a tolerance, ± *Y*, both of which are dimensionless because both *d* and *t* are in µm.

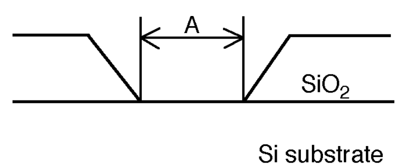

Figure 3
Schematic Diagram Showing Line Width, *A*, of Pattern on Substrate Wafer

7 The Amercan Society of Mechanical Engineers, United Engineering Center, 345 E. 47th St., New York, NY 10017.

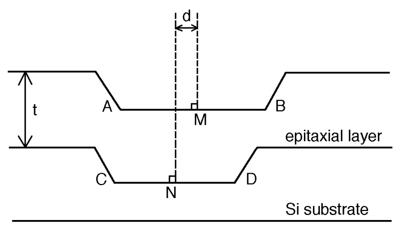

Figure 4
Cross-Section View of Epitaxial Wafer Showing the Pattern Shift, *d*. Not to scale: AM = MB and CN = ND

4.3.5 *pattern step height* — difference in vertical position of the diffused (buried layer) surface and the original substrate surface, after removal of oxide.

NOTE 6: Pattern step height, *A*, is specified as a nominal value, *X*, and a tolerance ± *Y*, both in nm. See Figure 5.

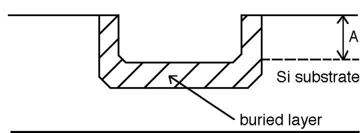

Figure 5
Cross-Sectional View of Epitaxial Substrate After Oxide Removal but Before Deposition of the Epitaxial Layer Showing the Pattern Step Height, *A*

4.4 *Terms Related to Annealed Wafers*

4.4.1 *Annealed wafer* — Wafer that has defects (COP) free zone near the surface produces by high temperature annealing.

4.4.1.1 *Hydrogen annealed wafer* — Annealed wafer produced under hydrogen atmosphere.

4.4.1.2 *Argon annealed wafer* — Annealed wafer produced under argon atmosphere.

5 Use of the Form

5.1 For annealed wafer, parts 1, 2 and 5 shall be completed.

5.2 If this form is used in conjunction with purchase orders for silicon wafers, Parts 1 and 2 shall be completed. For epitaxial wafers, Parts 1, 2, and 3 shall be completed. For epitaxial wafers with buried layer, Parts 1, 2, 3, and 4 shall be completed.

5.3 In all cases, items listed as required must have a value or choice indicated to minimally specify the material.

5.4 Certain required dimensional items may be specified as a group according to the standard values presented in the applicable SEMI specification, or they may be specified individually.

5.5 Visual inspection criteria may be specified as a group according to the standard values listed in the applicable SEMI specification, or they may be specified individually.

5.6 For either dimensional values or visual inspection criteria, the appropriate SEMI specification may be marked and an optional line item (or items) marked as well. In this case, the value marked on each individual line item takes precedence over the standard value.

5.7 If the suggested form included in this format is not reproduced and used as a fill-out form, the items and responses must be adequately identified so that the information and requirements are clear to all parties.

6 Test Methods

6.1 Measurements shall be made or certifiable to the ASTM, JEIDA, JIS, or DIN standard test method as cited in Table 1.

6.2 When standard test methods from different geographic regions are available, the default method shall be the method in common usage for the region of the purchaser of the wafer.

6.3 If several different standard test methods for an item are commonly used within a region, a specific entry must be made to identify which method of test is applicable.

6.4 If no standard test method for an item is available, the test procedure must be specified.

7 Testing Level and Certification

7.1 Material ordered using this format shall be tested and/or certified to the limits set forth in the individual criteria.

7.2 The actual testing level, whether the test is performed on all wafers, a sample of the wafers, special test pieces representing all portions of the material, or a sample of the test pieces, may be specified using this format.

7.3 In some cases, the material may be certified as “capable of meeting” certain requirements. In this context, the supplier is not required to perform the tests outlined in this format. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

8 EDI Codes and Sub-Parameter Codes

8.1 The EDI Codes for each parameter are listed in the following Table. Where necessary for clarity, additional sub-parameters are listed. These sub-parameter identify a specific measurement technique or method to be used.

8.2 If additional codes are required in the future, they will be added to the table, beginning with the next available EDI code identifier. This will allow the table to be rearranged for clarity while maintaining unique and consistent EDI codes for existing parameters. Table 2 provides a numerically sorted list of the EDI Codes.

[A] Item is defined or described and/or a test procedure applicable to the item is included in the cited reference.
[B] Value is/is not required to minimally specify a wafer.
[C] Individual value is not required if wafer is specified according to SEMI M1.
[D] In today's technology, it may be possible to inspect for some of these items using automated laser scanning systems; however, a standard test procedure has yet to be developed. Application of automated inspection must be agreed upon between supplier and user.

SEMI M19-91
SPECIFICATION FOR ELECTRICAL PROPERTIES OF BULK GALLIUM ARSENIDE SINGLE CRYSTAL SUBSTRATES

1 Introduction

For the specification, three principal types of material were identified: semi-insulating, n-type, and p-type. This encompasses the full range of conductivity characteristics for Gallium Arsenide (GaAs). Section 3 considers subclasses of these characteristics defining the species which may be used for producing the conductivity type. For semi-insulating material, special cases have been isolated.

Undoped, Grade A1 represents those materials which are of high resistivity and stable following growth, without necessitating any additional annealing or processing. The Grade A2 material, "high purity", requires additional thermal processing following growth to bring the resistivity to a level > 10^7 Ω-cm. At this time, most producers have indicated that the majority of the Grade A2 ingots have resistivity characteristics which rise into the acceptable range after an appropriate thermal cycle. However, this phenomenon is sensitive to the details of the time-temperature cycle, and thus, such an increase cannot be guaranteed in every application. Thus, the label "Grade A2" is used to denote this material.

Chromium doping produces a high resistivity material. However, due to the rapid diffusion of Cr during processing and the propensity for surface accumulation, it is not as well suited to processing as grades 3.A.1 and 3.A.2, thus we assign this material "grade A".

Iso-electric dopant additions do not appear to affect the resistivity significantly, but rather, permit the reduction of dislocation generation in the final product. Thus, this material is classified Grade A. While In is the most effective hardening agent, Al, P, and Sb are also viable species. They are included for completeness and to reduce the likelihood of document revision at a later date. The Grade B specification encompasses those materials where the impurity and point defect densities are not quite in the proper balance, but the resistivity is suitable for less-stringent applications.

For conducting material, the best characterized, non-transition metal species have been included as n-type dopants; for p-type, a broader range of species has been included, as transition metals are useful acceptor impurities.

Section 4 defines the resistivity and stability of semi-insulating material as specified in Section 3. A stringent limit was placed on the Grade A2 material to minimize the likelihood that this material converts to low resistivity upon annealing. The issue of surface conversion in Cr-doped material was dealt with by eliminating a requirement for n-type characteristics following annealing.

The resistivity ranges for n-type conducting material were determined from the carrier concentration table (Section 5) and mobility values, using the analysis of Walukiewicz et al, J. Appl. Phys. 50 (1979) 899. This places a constraint on the permissible compensation ratio, selected to be in the range of approximately 0.0 to 0.7. The specification was designed then to exclude abnormally poor crystals. As limited data and demand exist for p-type material, there are no ranges specified at this writing. Should a significant body of data evolve, this specification may be designed and balloted as appropriate.

Section 5 deals with impurity concentrations, net electron yields and implicitly, with point defect concentrations. For semi-insulating material of high quality, the impurities are, at the present time, not reliably measurable (carbon is the notable exception). Thus the "unspecified" nomenclature. For types A-3 and A-4, the determination of the amount of the relevant impurity species is given to the appropriate party, the user, and producer, respectively.

For n-type materials, the ranges were selected to define a high purity regime ($n \leq 4 \times 10^{16}$ cm^{-3}), an intermediate regime where donor density is not more than ~10 times the typical deep level density; the transition region wherein deep levels are suppressed (range B-3); a highly doped range (> 10 ppm net electron concentration yield); and "saturation" doping range where the crystal growth process and thermodynamics determine the limits of impurity incorporation and electron yield.

In Section 6, the electron mobility values and ranges are stated. For semi-insulating materials, the values that have been determined by consensus are 5000 cm^2/V-s for Grade A1 and 6000 cm^2/V-s. In the interest of harmony, and to prevent further debilitating discussions, the authors and participants at the SEMI meetings, and responses from producers have been used to set this value at 5000 cm^2/V-s. The producers indicated that the Grade A2 material nearly always exceeds 6000 cm^2/V-s, and thus this value was adopted. For chromium doped materials, the mobility is less predictable and, therefore, is negotiated between the user and producer. In-doped materials have consistently lower mobilities, resulting from strain-effects, scattering, and other related phenomena. Thus, based on producer experience, the minimum value was set at 3500 cm^2/V-s.

For n-type materials, the mobility ranges were selected to represent compensation ratios in the range of approximately 0.0 to 0.7 for a given net electron concentration. P-type material is not yet characterized sufficiently to warrant a specification.

2 Scope

This document specifies the characteristics and ranges of electrical properties for bulk GaAs crystals and substrate wafers. For high resistivity and n-type conducting materials, the permissible growth conditions or impurity species are stated; the electrical properties corresponding to the appropriate range(s) are noted. Due to the limited understanding, experience and demand for p-type materials only guidelines are provided in this specification at the present writing.

3 Conductivity Type

A. Semi-insulating, n-type

B. Conducting, n-type

C. Conducting, p-type

4 Dopant Species

A. 1. Undoped; Grade A1

2. Undoped; Grade A2

3. Chromium; Grade A

4. Isoelectronic impurity; Grade A Dopant specified by producer: In, Al, P, Sb

5. Undoped; Grade B

B. Dopant specified by user: Si, S, Se, Te, Sn

C. Dopant specified by user: Zn, Cd, Be, Mn, Fe, Co, Mg

NOTE See Sections 4 and 5 below for grade definition.

5 Resistivity at 300K

A. Semi-insulating, n-type*

B. 1. $\geq 1 \times 10^7$ Ω-cm, n-type before and after anneal

2. $\geq 5 \times 10^6$ Ω-cm becoming $\geq 1 \times 10^7$ Ω-cm after anneal n-type before and after anneal

3. $\geq 1 \times 10^7$ Ω-cm, n-type before anneal

4. $\geq 1 \times 10^7$ Ω-cm, n-type before and after anneal

5. $\geq 5 \times 10^6$ Ω-cm, n-type before and after anneal

1×10^7 Ω-cm = 1.6×10^8 Ω/❐; 5×10^6 Ω-cm = 8×10^7 Ω/❐;

* 1×10^6 Ω-cm = 1.6×10^7 Ω/❐ based on 625 µm wafer thickness

C. Conducting, n-type

D. 1. ≥ 0.0026 Ω-cm (at $n - 4 \times 10^{16}$ cm^{-3}; $\mu = 6000$ cm^2/V-s

2. ≤ 0.06 Ω-cm

3. ≤ 0.042 Ω-cm

4. ≤ 0.012 Ω-cm

5. $< 5.2\ 10^{-3}$ Ω-cm

6. to be determined between user and producer

NOTE Ranges overlap due to the interrelationship of ρ, n, and µ.

E. Ranges to be determined between the user and producer.

6 Free Carrier or Impurity Concentration

A. 1. Unspecified impurity concentration

2. Unspecified impurity concentration

3. Cr concentration range in atomic ppm specified by user

4. Isoelectronic impurity concentration range in atomic ppm specified by producer

5. Unspecified impurity concentration

6. To be determined between user and producer

B. 1. $\leq 4 \times 10^{16}$ cm^{-3}

2. $> 4 \times 10^{16} - 1 \times 10^{17}$ cm^{-3}

3. $> 1 \times 10^7 - 5 \times 10^{17}$ cm^{-3}

4. $> 5 \times 10^7 - 3 \times 10^{18}$ cm^{-3}

5. $> 3 \times 10^{18}$ cm^{-3}

C. Carrier concentration agreed upon between user and producer

7 Electron Mobility, 300K (determined by Hall Effect)

A. 1 ≥ 5000 cm^2/V-s

2. ≥ 6000 cm^2/V-s

3. Concentration dependent: to be agreed upon between user and producer
4. $\geq$ 3500 cm^2/V-s
5. Unspecified

B. 1. $\geq$ 4000 cm^2/V-s
2. $\geq$ 2500 cm^2/V-s
3. $\geq$1500 cm^2/V-s
4. $\geq$ 1000 cm^2/V-s
5. $\geq$ 400 cm^2/V-s
6. to be determined between user and producer

C. To be agreed upon between user and producer

SEMI M20-0998
SPECIFICATION FOR ESTABLISHING A WAFER COORDINATE SYSTEM

1 Scope

1.1 This specification defines a wafer coordinate system which can be used to locate uniquely any point on a wafer using the wafer center as the origin and either polar (r-θ-z) or Cartesian (x-y-z) coordinates.

1.2 For unpatterned wafers, this wafer coordinate system can be used directly or in conjunction with a rectangular or polar overlay array.

1.3 This wafer coordinate system can also be used to locate the origins or other reference points of other coordinate systems used to define or report position data of site, die, or map arrays on a patterned or unpatterned wafer. In this way, the array coordinate system may be referenced to the physical geometry of the wafer.

2 Referenced Documents

2.1 *SEMI Standards*

SEMI E5 — Equipment Communications Standard 2, Message Content (SECS II)

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

SEMI M12 — Specifications for Serial Alphanumeric Marking of the Front Surface of Wafers

SEMI M17 — Specification for a Universal Wafer Grid

3 Interferences

3.1 Mask alignment conventions are not necessarily consistent with the wafer coordinate system.

3.2 In SEMI M1, the position of the secondary flat on silicon wafers is defined by the clockwise rotation from the primary flat. This is opposite to the convention used for the polar angle in the wafer coordinate system.

3.3 In SEMI E5, the "normal" position of the wafer is defined similarly to that in the wafer coordinate system; that is, the primary fiducial is downward and its bisector is the negative y-axis. However, the rotational position of the wafer is defined by its clockwise rotation from the "normal" position, again opposite to the convention used for the polar angle in the wafer coordinate system. Further, in SEMI E5, the coordinate system axes do not rotate; the wafer rotates with respect to these axes. In the wafer coordinate system, the coordinate axes are referenced to the wafer itself, independent of the physical position of the wafer in space.

3.4 SEMI M12 and SEMI M13 specify the mark field location for 100 mm, 125 mm, or 150 mm diameter flatted wafers relative to the flat rather than the wafer center. Thus, the mark field location may vary with respect to the wafer center and the coordinates of the corners of the mark field location (in the wafer coordinate system) may vary from wafer to wafer. However, the mark field location for notched wafers 150 and 200 mm in diameter is referenced to the wafer center.

3.5 There are some circumstances in which the front surface of an unpatterned wafer is not readily distinguished from the back surface.

4 Procedure for Establishing the Wafer Coordinate System

4.1 Position the wafer front surface up.

4.2 Find the center of the wafer. For purposes of this document, the periphery of a wafer is assumed to be the smallest circle enclosing the wafer, disregarding fiducials and all other edge anomalies. The center of this circle is to be used as the center of the wafer.

4.3 Erect a right-handed Cartesian coordinate system with:

4.3.1 its origin at the geometric center of the wafer,

4.3.2 the y-axis on the diameter in the plane of the front surface which bisects the primary fiducial (flat or notch), and

4.3.3 the x-axis on the diameter in the plane of the front surface which is perpendicular to the bisector of the primary fiducial.

4.4 Orient the wafer so the primary fiducial is in the negative y-direction (see Figure 1).

NOTE 1 The usual convention is that the negative y-direction is pointing downward (on a page) or toward the operator (on a table or chuck).

4.5 Reference the polar coordinates, r and θ to the positive x-axis.

4.6 Choose Cartesian or polar coordinates according to the application.

5 Applications of the Wafer Coordinate System

5.1 Many, though not all, processing systems now employed in advanced device manufacturing use aligning mechanisms to position the wafer rotationally and in *x-y* prior to processing. Many of these scan the wafer periphery and determine the geometric center of the wafer. This is most often seen on stepping aligners, to minimize the effects of wafer-to-wafer diameter variation in mixed aligner type fabs. Similar center-referencing subsystems are found on many characterization systems. The wafer coordinate system provides a method for referencing any other coordinate system, such as a site, pattern, or mapping array, to the physical geometry of the wafer. If the points of the array lie on the front surface of the wafer, only the *x* and *y* (or *r* and θ) coordinates are relevant. If the point or points lie above or below the front surface, the *z* coordinate must also be used.

5.2 It has become increasingly important in semiconductor material and device manufacturing to describe, in unambiguous terms, the position of a point on a wafer that automatic processing, test, or characterization equipment can recognize and locate. For example, characterization equipment needs to report the precise locations of defects and anomalies discovered in wafers before or after processing in order to relate the presence or absence of such defects and anomalies to device yield variations. The wafer coordinate system can be used to establish the coordinates of each point of interest, and, through transformation to the yield analysis coordinate system, relate them to the die yield map.

5.3 SEMI E5, in Stream 12 - Wafer Mapping, delineates how a coordinate system for reporting position data may be communicated. The origin of this coordinate system, which is specified by the equipment when generating the wafer map, may be the site at any of the four corners of the array or at the array center. In addition, the stream provides for transmission of an arbitrary number of reference points to relate the map coordinate system to the physical wafer. The wafer coordinate system may be used to establish the locations of these reference points and of the origin of the map coordinate system.

5.4 SEMI M17 defines a polar array of 1000 elements which can be used to identify the locations on a wafer of extended defects such as slip. This array is consistent with the wafer coordinate system.

SEMI M21-0998
SPECIFICATION FOR ASSIGNING ADDRESSES TO RECTANGULAR ELEMENTS IN A CARTESIAN ARRAY

NOTE: This specification reflects input from equipment producers and users; from SEMI Standards groups in the U.S. and Japan with interest in silicon wafers (including epi), equipment automation, and micropatterning metrology; and from individuals in the U.S., Japan, and Europe.

1 Scope

1.1 This specification defines an element addressing convention which can be used to locate and identify rectangular elements in a Cartesian array. The array may be regular or tiled in one direction. Such arrays are useful in locating sites for site flatness characterization, defect mapping, determination of parametric distributions, etc. on unpatterned semiconductor wafers. The position of the array on the wafer may be established through use of the wafer coordinate system defined in SEMI M20. For complex patterns, more than one array on a wafer may be defined and related to the same coordinate axes.

1.2 This specification provides a unique identification (address) for each element in the array.

1.3 The element addressing convention in this specification is consistent with that of the polar array specified in SEMI M17. In addition, element addresses can be readily transformed to addresses in other types of addressing conventions for cartesian arrays.

1.4 The element addressing convention in this specification provides an orderly progression along perpendicular directions with addresses of adjacent elements in any direction differing by 1. Consequently, distances may be calculated in a unified way.

2.2 *ASTM Standard*[1]

F 1241 — Terminology of Silicon Technology

3 Terminology

3.1 Many terms used in silicon wafer technology are defined in ASTM Terminology F 1241.

3.2 Definitions of additional terms may be found in SEMI M1, SEMI M2, or SEMI M11.

3.3 Selected definitions are also listed (for information only) in the glossary, Definitions for Semiconductor Materials, at the end of this volume.

4 Array Element Layout

4.1 The array is constructed from m vertical columns and n horizontal rows of identical elements of dimension a horizontally and b vertically. The number of elements in different rows and columns may vary to suit the application.

4.2 The address of an element is given by two numbers separated by a comma: (i,j). The first number, i, indicates the column and the second, j, the row.

4.3 The longest row and the longest column are used in identifying the Starting Element, which is assigned the address (0,0).

4.4 The array may have a tiled appearance, either with one or more rows offset relative to the row containing the Starting Element (row tiling) or with one or more columns offset relative to the column containing the Starting Element (column tiling).

4.4.1 For row tiling, the offset, t_r, is a fraction (p_r/q_r) of the horizontal element dimension, a, where p_r and q_r are small whole numbers.

4.4.2 For column tiling, the offset, t_c, is a fraction (p_c/q_c) of the vertical element dimension, b, where p_c and q_c are small whole numbers.

4.4.3 In either case, the offset may be constant or it may vary from row to row or column to column. When the offset is constant, the array pattern is repeated every q_r rows or q_c columns.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

5 Element Addresses

5.1 Define the array center as the intersection of the vertical and horizontal array centerlines, found as follows:

5.1.1 If the array is regular (not tiled):

5.1.1.1 Count the number of elements, *m*, in the longest row.

5.1.1.2 If *m* is even, start at the leftmost element, count *m*/2 elements to the right, and construct a line along the right vertical boundary of this element. This line is the vertical array centerline (see Figure 1a).

5.1.1.3 If *m* is odd, start at the leftmost element, count the integer of *m*/2 elements to the right, continue to the next element to the right, and construct a line through the center of this element. This line is the vertical array centerline (see Figure 1b).

5.1.1.4 Count the number of elements, *n*, in the longest column.

5.1.1.5 If *n* is even, start at the topmost element, count down *n*/2 elements, and construct a line along the bottom horizontal boundary of this element. This line is the horizontal array centerline (see Figure 1c).

5.1.1.6 If *n* is odd, start at the topmost element, count down the integer of *n*/2 elements, continue down to the next element, and construct a line through the center of this element. This line is the horizontal array centerline (see Figure 1d).

5.1.2 If the columns of the array are tiled (see Figure 2a):

5.1.2.1 Count the number of columns, *m*, in the widest part of the array from left to right.

5.1.2.2 If *m* is even, start at the leftmost column, count *m*/2 columns to the right, and construct a line along the right vertical boundary of this column. This line is the vertical array centerline.

5.1.2.3 If *m* is odd, start at the leftmost column, count the integer of *m*/2 columns to the right, continue to the next column to the right, and construct a line through the center of this column. This line is the vertical array centerline.

5.1.2.4 Count the number of elements, *n'*, in the column which contains or is immediately to the right of the vertical array centerline, depending on whether *m* is odd or even, respectively.

NOTE 1 The number, *n'*, is usually equal to but may be less than *n*.

5.1.2.5 If *n'* is even, start at the topmost element, count down *n'*/2 elements, and construct a line along the bottom horizontal boundary of this element. This line is the horizontal array centerline.

5.1.2.6 If *n'* is odd, start at the topmost element, count down the integer of *n'*/2 elements, continue down to the next element, and construct a line through the center of this element. This line is the horizontal array centerline.

5.1.3 If the rows of the array are tiled (see Figure 2b):

5.1.3.1 Count the number of rows, *n*, in the widest part of the array from top to bottom.

5.1.3.2 If *n* is even, start at the topmost row, count down *n*/2 rows, and construct a line along the bottom horizontal boundary of this row. This line is the horizontal array centerline (see Figure 1c).

5.1.3.3 If *n* is odd, start at the topmost row, count down the integer of *n*/2 rows, continue down to the next row, and construct a line through the center of this row. This line is the horizontal array centerline (see Figure 1d).

5.1.3.4 Count the number of elements, *m'*, in the row which contains or is immediately above the vertical array centerline, depending on whether *n* is odd or even, respectively.

NOTE 2 The number, *m'*, is usually equal to but may be less than *m*.

5.1.3.5 If *m'* is even, start at the leftmost element, count *m'*/2 elements to the right, and construct a line along the right vertical boundary of this element. This line is the vertical array centerline.

5.1.3.6 If *m'* is odd, start at the leftmost element, count the integer of *m'*/2 elements to the right, continue to the next element to the right, and construct a line through the center of this element. This line is the vertical array centerline.

5.2 Locate the Starting Element (0,0) as follows:

5.2.1 If the array center falls within an element, designate that element as the Starting Element (see Figure 3a).

5.2.2 If the array is regular and the array center lies at an element corner, designate the element to the right and immediately above the array center as the Starting Element (see Figure 3b).

5.2.3 If the array is regular and the array center lies on a vertical element boundary, designate as the Starting Element that element which contains the horizontal array centerline and is immediately to the right of the vertical array centerline (see Figure 3c).

5.2.4 If the array is regular and the array center lies on a horizontal element boundary, designate as the Starting

Element that element which contains the vertical array centerline and is immediately above the horizontal array centerline (see Figure 3d).

5.2.5 If columns of the array are tiled and the array center lies on a vertical boundary between columns, designate that element immediately to the right of the vertical centerline and containing the horizontal array centerline as the Starting Element. If the horizontal array centerline also falls on an element boundary in the column immediately to the right of the vertical array centerline, designate the element in this column and immediately above the horizontal array centerline as the Starting Element (see Figure 4a).

5.2.6 If rows of the array are tiled and the array center lies on a horizontal boundary between rows, designate that element immediately above the horizontal array centerline and containing the vertical array centerline as the Starting Element. If the vertical array centerline also falls on an element boundary in the row immediately above the horizontal array centerline, designate the element in this row and immediately to the right of the vertical array centerline as the Starting Element (see Figure 4b).

5.3 Assign addresses to the array elements as follows:

5.3.1 Elements along the horizontal array centerline:

5.3.1.1 If the horizontal array centerline passes through an element, assign that element the address (*i*,0), where *i* is the column number. The first column to the right of the vertical array centerline is numbered 1, the next column to the right is numbered 2, the next column to the right is numbered 3, etc. Similarly, the first column to the left of the vertical array centerline is numbered -1, the next column to the left is numbered -2, the next column to the left is numbered -3, etc. (see Figure 3a).

5.3.1.2 If the horizontal array centerline falls along an element boundary in any column, *i*, assign the address (*i*,0) to the element in that column which lies immediately above the horizontal array centerline (see Figure 3b).

5.3.2 Elements along the vertical array centerline:

5.3.2.1 If the vertical array centerline passes through an element, assign that element the address (0,*j*), where *j* is the row number. The first row above the horizontal array centerline is numbered 1, the next row up is numbered 2, the next row up is numbered 3, etc. Similarly the first row below the horizontal array centerline is numbered -1, the next row down is numbered -2, the next row down is numbered -3, etc. (see Figure 3a).

5.3.2.2 If the vertical array centerline falls along an element boundary in any row, *j*, assign the address (0,*j*) to the element in that row which lies immediately to the right of the vertical array centerline (see Figure 3b).

5.3.3 Remaining elements:

5.3.3.1 Assign addresses (*i*,*j*) to the remaining elements based on their position relative to the elements along the horizontal and vertical array centerlines. For example the address of the element immediately above (1,0) is (1,1) and the element immediately below (1,0) is (1,-1) (see Figure 5).

6 An Example

6.1 An example of a regular 29-column by 9-row array, truncated for application to a wafer, is shown in Figure 6. The Starting Element includes the array center because there are odd numbers of both columns and rows. In addition, Figure 6 shows the element addresses for elements along the right half of the horizontal array centerline, for elements along column 1, and for selected other elements in the array. Also shown are the left hand corner elements (which lie outside the truncated array).

6.2 Figure 7 shows the same truncated array fitted onto a wafer. Because the truncation is not symmetrical around the vertical array centerline, the array center is located to the left of the wafer center.

7 Extensions to Other Element Addressing Conventions

7.1 Element addressing conventions other than that covered by this specification are also widely used in engineering. Two of these are illustrated in Figure 8 with the use of the same truncated array discussed in the previous section.

7.2 *First-Quadrant Convention*

7.2.1 Addresses in this convention start at the lower left corner of the array and increase to the right and upward in the same way as in the convention covered by this specification. The lower left corner of the array is defined by the intersection of the bottom boundary of the lowest row and the left boundary of the leftmost column. In the case of tiling, the boundaries are those of the lowest elements and the leftmost elements in the array. The lower left corner may fall outside the useful portion of the array. The lower left element of the array is the element immediately to the right and above the lower left corner of the array.

7.2.2 The First-Quadrant Convention uses a column, row address but does not have a zero row or a zero column.

7.2.3 The addresses of the corners of an array with *m* columns and *n* rows in the First-Quadrant Convention are as follows:

lower left (Starting Element)	(1,1)
lower right	(*m*,1)
upper left	(1,*n*)
upper right	(*m*,*n*)

7.2.4 The general formulas for obtaining the addresses of any element (i_f,j_f) in the First-Quadrant Convention from the addresses (i,j) in the convention covered by this specification are as follows:

$$i_{\mathrm{f}} = i + \mathrm{integer}(m/2) + 1$$
$$j_{\mathrm{f}} = j + \mathrm{integer}(n/2) + 1$$

7.2.5 These equations also apply to arrays with column or row tiling if $n' = n$ or $m' = m$, respectively. If this condition is not met, the displacement of the row or column which defines the array centerline with respect to the boundary of the array must be known to transform the addresses.

7.3 *Row, Column (Matrix) Convention*

7.3.1 Addresses in this convention start at the upper left corner of the array and increase to the right and downward. The upper left corner of the array is defined by the intersection of the top boundary of the highest row and the left boundary of the leftmost column. In the case of tiling, the boundaries are those of the highest elements and the leftmost elements in the array. The upper left corner may fall outside the useful portion of the array. The upper left element of the array is the element immediately to the right and below the upper left corner of the array.

7.3.2 The Row, Column (Matrix) Convention uses a row, column address and, like the First-Quadrant Convention, does not have a zero row or a zero column.

7.3.3 The addresses of the corners of an array with *m* columns and *n* rows in the Row, Column (Matrix) Convention are as follows:

upper left (Starting Element)	(1,1)
upper right	(1,*m*)
lower left	(*n*,1)
lower right	(*n*,*m*)

7.3.4 The general formulas for obtaining the addresses of any element (i_m,j_m) in the Row, Column (Matrix) Convention from the addresses (i,j) in the convention covered by this specification are as follows:

$$i_{\mathrm{m}} = \mathrm{integer}(n/2) + 1 + j$$
$$j_{\mathrm{m}} = \mathrm{integer}(m/2) + 1 + i$$

7.3.5 These equations also apply to arrays with column or row tiling if $n' = n$ or $m' = m$, respectively. If this condition is not met, the displacement of the row or column which defines the array centerline with respect to the boundary of the array must be known to transform the addresses.

Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M22-1296
SPECIFICATION FOR DIELECTRICALLY ISOLATED (DI) WAFERS

1 Scope

1.1 These specifications define requirements for dielectrically isolated (DI) wafers used for semiconductor device manufacture. By defining inspection procedures and acceptance criteria, both suppliers and consumers may uniformly define product characteristics and quality requirements.

NOTE This document currently applies to 100 mm nominal diameter DI wafers.

1.2 The primary standardized properties set forth in this specification relate to physical, electrical, and surface defect parameters of DI wafers.

1.3 A complete purchase specification requires that additional physical properties be specified along with suitable test methods for their measurements.

2 Applicable Documents

2.1 *SEMI Standard*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

2.2 *ASTM Standard*[1]

F 523 — Practice for Unaided Visual Inspection of Polished Silicon Slices

2.3 *Other Standard*[2]

ANSI/ASQC Z1.4-1993 — Sampling Procedures and Tables for Inspection by Attributes

3 Terminology

connected tubs — Adjacent tubs which are not completely surrounded by an oxide but are connected by silicon (see Figure 1).

concentricity — The distance between the centerpoint of the DI wafer and the centerpoint of the photolithographic pattern.

DI wafer — A wafer consisting of polysilicon, oxide, and single crystal silicon regions. A typical cross-section is shown in Figure 2.

edge indent — An edge defect on a DI wafer that extends from the front surface to the back surface.

pattern deformation — A microscopic defect associated with missing or indented tub features of 4 microns or more (see Figure 3).

layer of polycrystalline silicon — The thick matrix material of a DI wafer in which the silicon tubs reside.

void in the polycrystalline silicon — A microscopic depression on the surface of polysilicon areas in DI wafers (see Figure 4).

rotation — The angle of deviation between the primary flat of the DI wafer and the x-axis of the photolithography pattern.

tub — A single crystal silicon region in a DI wafer which is surrounded by an oxide layer on the sides and bottom.

tub depth — The thickness of the tub as measured from the wafer surface to the buried oxide layer parallel to the wafer surface (see Figure 2).

electrical die — An identifiable repetitive monolithic combination of tubs and polysilicon areas in a DI wafer surrounded by a grid border which as packaged becomes a component.

4 Ordering Information

4.1 Purchase orders for dielectrically isolated wafers shall include the following items:

4.1.1 Tub Characteristics

A. Resistivity

B. Conductivity and Dopant Type

C. Crystal Growth Method (Czochralski or Float Zone)

4.1.2 Tub Diffused Layers (if required)

A. Sheet Resistance

B. Junction Depth

C. Dopant Type

4.1.3 Polysilicon Resistivity

4.1.4 Nominal Tub Depth

4.1.5 Method of Pattern Transfer from User to Supplier

The pattern transfer of electrical die information may be accomplished through a physical exchange of photomasks or through a data exchange. Issues such as corner compensations, design rules, and alignment

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

features shall be agreed upon between the supplier and purchaser.

4.1.6 Oxide Thickness of Isolation Layer

4.1.7 Methods of Test and Measurements (see Section 6)

4.1.8 Lot Acceptance Procedures (see Section 7)

4.1.9 Certification (if required) (see Section 8)

4.1.10 Packing and Marking (see Section 9)

5 Requirements

5.1 The complete specification for the starting substrates to produce DI wafers includes all general requirements of SEMI M1.

5.2 The Dimension and Tolerance Requirements for 100 mm DI wafers are listed in Table 1.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
Diameter	100	± 0.50	mm
Thickness, Center Point	508	± 25	mm
Surface Orientation, referenced to tub crystal axes	{ 100}	± 1	deg
Primary Flat Orientation, referenced to tub crystal axes	{ 110}	± 1	deg
Primary Flat Length	32.5	± 2.5	mm
Secondary Flat Location, optional			
Secondary Flat Length	18.0	± 2.0	mm
Bow, Max.	+380		µm
Total Thickness Variation, Max.	25		µm
Concentricity, Max.	3		mm
Rotation, Max.	2		deg
Edge Profile Coordinate, Cy[B]	170		µm

[A] For referee purposes the metric (SI) units apply.

[B] See Figure SEMI M1, Figure 3.

5.3 Visual defects on a wafer shall not exceed the limits is established in Table 2, Part A.

Table 2 DI Wafer Defect Limits
A. Visual

Item	*Characteristics*	*Defect Limit*	*Illumination See Note #3*	*Notes*
1	Edge Chips Maximum Number Maximum Size	3 6.35 mm^2	Diffused	
2	Contamination, Area Minimum % of clean surface area	95%	High Intensity	1, 2
3	Cracks	None	Diffused	
4	Fractures	None	Diffused	
5	Holes	None	High Intensity	
6	Scratches Total Cumulative Length Not to Exceed	1/2 Diameter	High Intensity	1, 2
7	Pits Maximum Number Maximum Size	5 0.1 mm^2	High Intensity	1, 2

Table 2 DI Wafer Defect Limits
B. Microscopic

Item	*Characteristics*	*Defect Limit (per die)*	*Defect Limit (per wafer)*	*Notes*
8	Connected Tubs	None	"	
9	Pattern Deformation	None	"	
10	Polysilicon Voids	None	"	
11	Tub Depth (> +5% or < -5% from nominal value)	None	"	
12	Defective Die		25%	4

Notes:

1. The outer 5 mm annulus is excluded from these criteria.
2. These criteria are concerned only with polished front surfaces of DI wafers.
3. See ASTM F 523 for definition of Illumination Conditions.
4. The number of defects per die is not cumulative; an electrical die with one or more defects is counted as a single defective die.

5.4 Microscopic defects on a die and defective die on a wafer shall not exceed the limits as established in Table 2, Part B. To meet these specifications, at least 75% of the die on a wafer must be defect free.

6 Test Methods and Measurements

6.1 The supplier and purchaser shall agree in advance on the means for making all measurements (see Section 8).

6.2 *DI Wafer Characteristics*

6.2.1 *Tub Characteristics* — The resistivity, conductivity, dopant type, and crystal growth method are difficult to ascertain in the finished DI wafers. Verification test procedures or certification of these characteristics shall be agreed upon between the supplier and the purchaser (see Section 8).

6.2.2 *Tub Diffused Layers* — The test procedures to measure the sheet resistance, junction depth, and dopant type shall be agreed upon between supplier and purchaser (see Section 8).

6.2.3 *Visual Surface Defects and Contamination* — Determine in accordance with ASTM Practice F 523.

6.2.4 *Microscopically Observed Die Defects* — Examine a representative sampling of die (see 7.2) with an optical microscope with magnification such that one complete electrical die fills the field of view. If necessary for verification of defects, move to higher magnifications as required. Due to the extensive microscopic inspections required, verification test procedures or certification of these characteristics shall be agreed upon between the supplier and the purchaser (see Section 8).

7 Sampling

7.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot according to ANSI/ASQC Z1.4-1993. Each quality characteristic shall be an assigned an acceptable quality level (AQL) in accordance with ANSI/ASQC Z1.4-1993. Inspection levels shall be agreed upon between supplier and purchaser.

7.2 The sampling plan for microscopic inspection of die on the wafer, including number and location of inspected die, shall be agreed upon between supplier and purchaser.

8 Certification

8.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of test results, shall be furnished at the time of shipment.

8.2 The supplier and purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 6; however, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

9 Packing and Marking

9.1 Special packing requirements shall be subject to agreement between the supplier and purchaser. Otherwise all wafers shall be handled, inspected, and packed in such a manner to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide protection against damage during shipment.

9.2 The wafers supplied under this specification shall be identified by appropriately labeling the outside of each box or container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include supplier's name and reference no., date, quantity, DI wafer diameter, DI wafer thickness, and customer code no. The reference number assigned by the supplier shall provide ready access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the manufacturer's facility for at least one year after the particular lot has been shipped.

SEMI M23-0302
SPECIFICATION FOR POLISHED MONOCRYSTALLINE INDIUM PHOSPHIDE WAFERS

This specification was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the North American Compound Semiconductor Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1993; previously published October 2000.

1 Purpose

1.1 These specifications cover the substrate requirements for monocrystalline high-purity indium phosphide wafers used in semiconductor and electronic device manufacturing. Dimensional and crystallographic orientation characteristics are the only standardized properties set forth below.

1.2 A complete purchase specification may require that additional physical, electrical, and bulk properties be defined. These properties are listed together with test methods suitable for determining their magnitude where such procedures are documented.

2 Scope

2.1 These specifications are directed specifically to indium phosphide wafers with one or both sides polished. Unpolished wafers or wafers with epitaxial films are not covered; however, purchasers of such wafers may find these specifications helpful in defining their requirements.

2.2 The material is Single Crystal Indium Phosphide (InP) having a cubic zinc blende structure and the following properties:

Density	4.787 g/cm^3
Melting Point	1062°C
Dielectric Constant	12.4
Lattice Parameter	5.869 A at 27°C
Energy Gap	1.351 eV at 27°C

2.3 For reference purposes SI (System International, commonly called metric) units shall be used.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 *Definitions*

NOTE 1: The selected terminology defined here has been adopted from ASTM Standard F 1241. Updates to this section are dependent on information exchange between ASTM and SEMI. Definitions are included for the benefit of the user, however, for a complete list, please refer to ASTM Standard F 1241.

4.1.1 *bow (of a semiconductor wafer)* — the deviation of the center point of the median surface of a free, unclamped wafer from a median-surface reference plane established by three points equally spaced on a circle with diameter a specified amount less than the nominal diameter of the wafer. Contrast flatness. Also see warp.

4.1.2 *dopant* — a chemical element, usually from the second, fourth, or sixth column of the periodic table for the case of III-V compounds, incorporated in trace amounts in a semiconductor crystal to establish its conductivity type and resistivity.

4.1.3 *edge profile* — on wafers whose edges have been rounded by mechanical and/or chemical means, a description of the contour of the boundary of the wafer that joins the front and back surfaces.

4.1.4 *lot* — for the purpose of this document, (a) all of the wafers of nominally identical size and characteristics contained in a single shipment, or (b) subdivisions of large shipments consisting of wafers as above which have been identified by the supplier as constituting a lot.

4.1.5 *orthogonal misorientation* — in { 100} wafers cut intentionally "off-orientation," the angle between the projection of the vector normal to the wafer surface onto the { 100} plane and the projection on that plane of the nearest direction (see Figure 5).

4.1.6 *TIR* — on a wafer surface, the smallest perpendicular distance between two planes, both parallel with the reference plane, which enclose all points on the front surface of a wafer within the flatness quality area or the site, depending on which is specified.

4.1.7 *TTV, total thickness variation* — of a semiconductor wafer, the difference between the maximum and minimum values of the thickness of the wafer.

4.1.8 *warp* — of a semiconductor wafer, the difference between the maximum and minimum distances of the median surface of a free, unclamped wafer from a reference plane, encountered during a scan pattern.

5 Ordering Information

5.1 Purchase orders for indium phosphide wafers furnished to this specification shall include the following items:

5.1.1 Nominal diameter (see applicable SEMI Standard for Polished InP wafers),

5.1.2 Thickness (see applicable SEMI Standard for polished InP Wafers),

5.1.3 Total Thickness Variation, TIR, warp and bow (determined by agreement between supplier and purchaser as to limits),

5.1.4 Surface orientation (see applicable SEMI Standard for polished InP wafers). There is only one option of flat location for 2" diameter polished monocrystalline InP wafers. The Dove-Tail option as

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

3 Deutsches Institut fur Normung e.v., available from Beuth Verlag, Burggrafenstrasse 6, D-10787 Berlin, Germany

illustrated in Figures 1 and 3 is used for 2" diameter InP. There is a choice of dovetail or V-Groove options for 3" and 100mm diameter wafers. These designations describe the shape of groove that can be etched perpendicular to the primary flat. The following are the options of wafer surface orientation:

A. (100) ± 0.5° as shown in Figures 1 and 2

B. (100) off 2° toward any of the nearest (110) planes. Examples shown in Figures 3 and 4.

Direction of off-orientation can be designated by α angle. (See Figure 5)

Figure 5 illustrates orthogonal misorientation.

5.1.5 Lot acceptance procedures (see Section 8),

5.1.6 Certification (see Section 11),

5.1.7 Packing and Marking (see Section 12).

5.2 *Optional Criteria* — The following items may be specified optionally in addition to those listed above:

5.2.1 Crystal growth method,

5.2.2 Etch Pit Density (EPD) of Crystal,

5.2.3 Crystal Growth Perfection,

5.2.4 Impurity Type,

5.2.5 Surface Condition of Wafer,

5.2.6 Edge Profile (see Figures 6 and 7),

5.2.7 Mobility,

5.2.8 Resistivity, and

5.2.9 Carrier Concentration.

6 Materials and Manufacture

6.1 The material shall consist of wafers from ingots grown to the material defined in the purchase order or contract.

7 Physical and Electrical Requirements

7.1 The material shall conform to the crystallographic orientation details as specified in the applicable polished indium phosphide wafer standard.

7.2 The material shall conform to the details specified in the purchase order or contract as follows:

7.2.1 Conduction Type,

7.2.2 Dopant,

7.2.3 Carrier Concentration,

7.2.4 Resistivity,

7.2.5 Etch Pit Density,

7.2.6 Mobility,

7.2.7 Surface Characteristics, and

7.2.8 Growth Methods.

8 Sampling

8.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4-1993. Each quality characteristic shall be assigned an acceptable quality level (AQL) or lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4-1993 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL or LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

9 Test Methods[4]

9.1 *Diameter* — Determined by ASTM Test Method F 613.

9.2 *Thickness, Center Point* — Determined by ASTM Test Method F 533.

9.3 *Flat Length* — Determined by ASTM Test Method F 671.

9.4 *Flat Orientation*[5] — Determined by etching method identified in the appropriate InP wafer standard.

9.5 *Total Thickness Variation* — Determined by ASTM Test Method F 533 or F 657.

9.6 *Surface Orientation* — Determined by ASTM Test Method F 26.

9.7 *Orthogonal Misorientation* — Determined by a method agreed upon between the supplier and purchaser.

9.8 *Surface Defects and Contamination* — Determined by ASTM Test Methods F154, F523 or a method agreed upon between the supplier and purchaser.

9.9 *Mobility* — Determined by ASTM Test Methods F 76 or SEMI M39.

---

4 InP wafers are extremely fragile. While the mechanical dimensions of a wafer can be measured by use of tools such as a micrometer calipers and other conventional techniques, the wafer may be damaged physically in ways that are not immediately evident. Special care must, therefore, be used in the selection and execution of measurement methods.

5 Relating to the etchant used for identifying V-groove and/or dovetail direction, see reference: “HBr-K2 Cr2O7 – H2O etching system for indium phosphide” J.L. Weyher, et al. Materials Science and Engineering B28 (1994) 488-492.

9.10 *Resistivity of Semi-insulating Wafers* — Determined by ASTM Test Method F76 or SEMI M39 or DIN 50448.

9.11 *Conductivity or Resistivity of Doped Wafers* — Determined by ASTM Test Method F76 or F84 or F673.

9.12 *Carrier concentration* — Determined by ASTM Test Method F76 or F1392 or F1393 or Electrochemical CV[6].

9.13 *Conductivity Type* — Determined by ASTM Test Method F42 or F76.

9.14 *Crystal Perfection* — Determined by a method agreed upon between the supplier and purchaser.

9.15 *Edge Contouring* — Determined by ASTM Test Method F 928.

9.16 *Bow* — Determined by ASTM Test Method F534 or a method agreed upon between the supplier and purchaser.

9.17 *Etch Pit Density* (*EPD*) — Determined by DIN Standard Test Method 50454-2

10 Standard Defect Limits

10.1 Limits are determined by an agreement between supplier and purchaser.

11 Certification

11.1 A manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results. A certification shall be furnished at the time of shipment, upon the request of the purchaser in the contract or order.

12 Packing and Marking

12.1 Special packing and marking requirements shall be subject to agreement between the supplier and the purchaser. Otherwise, all wafers shall be handled, inspected, and packed with the best industry practices to provide ample protection against damage during shipment.

12.2 The wafers supplied under these specifications shall be identified by appropriately labeling the outside of each box or other container and each subdivision that the wafers will be stored prior to further processing. Identification shall include lot number and wafer number. Per the agreement between the supplier and purchaser, the following must be accessible from the lot and wafer numbers: nominal diameter, conductive dopant, orientation, resistivity, and EPD. Such information shall be retained on file at the manufacturer's facility for at least one month or as negotiated between vendor and user after that particular lot has been accepted by the purchaser.

Property	*Requirement*
OPTION	Dove-Tail
PRIMARY FLAT ORIENTATION	$(0\bar{1}1)$ ± 0.5°, under an indium facet. The primary flat shall be perpendicular to the “Dove-tail” etch figure.
SECONDARY FLAT ORIENTATION	90 ± 5° clockwise from the primary flat.
SURFACE ORIENTATION	
A	{ 100} ± 0.5°
B	{ 100} off 2° ± 0.5° toward any { 110} plane
ORTHOGONAL MISORIENTATION	± 5°

SEMI M23.2-1000
STANDARD FOR ROUND 3 inch (76.2 mm) DIAMETER POLISHED MONOCRYSTALLINE INDIUM PHOSPHIDE WAFERS

This specification was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the North American Compound Semiconductor Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available on SEMI OnLine September 2000; to be published October 2000.

NOTE: The complete specification for this product includes all requirements of SEMI M23.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units (See NOTE 1.)*
DIAMETER	76.2	± 0.5	mm
THICKNESS, CENTER POINT	600	± 25	µm
PRIMARY FLAT LENGTH	22	± 2	mm
SECONDARY FLAT LENGTH	11	± 2	mm
BOW	to be specified		
TOTAL THICKNESS VARIATION	to be specified		

NOTE 1: For reference purposes, the metric (SI) units apply.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*	
Option	*Dove-Tail*	*V-Groove*
PRIMARY FLAT ORIENTATION	$(0\overline{11})$ ± 0.5°, (see NOTE 1) under an indium facet. The primary flat shall be perpendicular to the “Dove-tail” etch figure. (See NOTE 2.)	$(01\bar{1})$ ± 0.5°, (see NOTE 1) under a phosphorus facet. The primary flat shall be perpendicular to the “V-Groove” etch figure. (See NOTE 2.)
SECONDARY FLAT ORIENTATION	90 ± 5° clockwise from the primary flat.	90 ± 5° counterclockwise from the primary flat.
SURFACE ORIENTATION (See NOTE 3.)		
A	{ 100} ± 0.5° (see Figure 1, SEMI M23)	{ 100} ± 0.5° (see Figure 2, SEMI M23)
B	{ 100} off 2° ± 0.5° toward any { 110} plane (see Figure 3)	{ 100} off 2° ± 0.5° toward the { 110} plane which is between the primary and secondary flats (see Figure 4)
ORTHOGONAL MISORIENTATION	± 5° (see Figure 5)	± 5° (see Figure 5)

NOTE 1: See Table 1 in SEMI M23.

NOTE 2: See Figures 1 and 2 in SEMI M23, which show the orientation of the Dovetail and V-groove figures relative to crystallographically anisotropic pits (see NOTE 4).

NOTE 3: The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted towards the (110) plane of the crystal.

NOTE 4: Relating to the etchant used for identifying V-groove and/or dovetail direction, see reference: “HBr-$K_2Cr_2O_7$ - H_2O etching system for indium phosphide” J.L.Weyher, et al. Materials Science and Engineering B28 (1994) 488-492.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M23.3-0600
STANDARD FOR RECTANGULAR POLISHED MONOCRYSTALLINE INDIUM PHOSPHIDE WAFERS

This standard was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the Japanese Compound Semiconductor Committee. Current edition approved by the Japanese Regional Standards Committee on April 28, 2000. Initially available at www.semi.org May 2000; to be published June 2000. Originally published in 1994; previously published in 1996.

The complete specification for this product includes all general requirements of SEMI M23.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*[A]
IA-1			
LONGITUDINAL SIDE LENGTH	32.6	± 0.3	mm
LATERAL SIDE LENGTH	23.1	± 0.3	mm
THICKNESS, CENTER POINT	350	± 25	µm
IA-2			
LONGITUDINAL SIDE LENGTH	23.1	± 0.3	mm
LATERAL SIDE LENGTH	16.3	± 0.3	mm
THICKNESS, CENTER POINT	350	± 25	µm
IB-1			
LONGITUDINAL SIDE LENGTH	53.0	± 0.3	mm
LATERAL SIDE LENGTH	37.5	± 0.3	mm
THICKNESS, CENTER POINT	600	± 25	µm
IB-2			
LONGITUDINAL SIDE LENGTH	37.5	± 0.3	mm
LATERAL SIDE LENGTH	26.5	± 0.3	mm
THICKNESS, CENTER POINT	600	± 25	µm

[A] For reference purposes, the metric (SI) units apply.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
LONGITUDINAL SIDE ORIENTATION	$(01\bar{1})$ ± 0.5°, under a phosphorus facet.
LATERAL SIDE ORIENTATION	$(0\overline{11})$ ± 0.5°, under an indium facet.
SURFACE ORIENTATION	{ 100} ± 0.5°
FRONT SURFACE FINISH	Polished
BACK SURFACE FINISH	Lapped and etched
WAFER EDGE PROFILE	Cleaved face

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI M23.3 and was approved by full letter ballot procedures on April 21, 2000 by the Japanese Regional Standards Committee.

A1-1 InP is a promising material for photonic devices such as LDs, LEDs, and photodetectors for fiber communications. The consumption of InP wafers is increasing year by year due to the fiber communication systems such as LAN, ISDN, and others.

A1-2 In order to fabricate these devices, many rectangular wafers with more than 30 different sizes are industrially used but most of the sizes are not reasonably determined. From the viewpoint of material yield as explained below, the standardization of rectangular InP wafers is useful not only for InP wafer manufacturers, but also for device manufacturers.

A1-3 Figure A1-1 shows the effective area (A) as a function of ratio of longitudinal length (a) and of lateral length (b). It is a fact that the largest area can be obtained when the shape is square. However, it is difficult to distinguish V-Groove and Dove-Tail Groove orientations when the shape is square. It is, therefore, necessary to make the shape rectangular in a way that one can distinguish the orientations. It is however, noted that if the length ratio becomes too large, the effective area is dramatically decreased as seen in Figure A1-1. For instance, rectangular wafers at the point P have very little area, and most of wafer is cut off in vain. It is, therefore, very reasonable to select the length ratio at which the effective area is not largely decreased. When the length ratio (a/b ratio) is √2, the area decrease is only 5.7% as seen in Table A1-1 and Figure A1-1. It is also interesting to note that if the length ratio is determined as √2, each half of the rectangular wafer again gives a similar shape with the same ratio. In fact, this length ratio is used for paper standardization as A3/A4 or B3/B4. Rectangular wafers are therefore determined SEMI M23.3.

A1-4 Since there are already standardized 50 mm and 75 mm round wafers, the standardization is made in a way that large rectangular wafers can be obtained from these standardized wafers by removing 5 mm from the periphery as seen in Figure A1-2. Removing of 5 mm is due to EPD measurement specifications in which 5 mm periphery is excluded from the measurement.

A1-5 As explained above, it is highly recommended to use the standardized rectangular wafers because this standardization is very important in preventing proliferation of various sizes of rectangular wafers in the future.

Table A1-1

a/b Ratio	*A (mm^2)*	*A/square*
1.000	800.0	100%
1.414	754.2	94.3%
2.000	640.0	80.0%

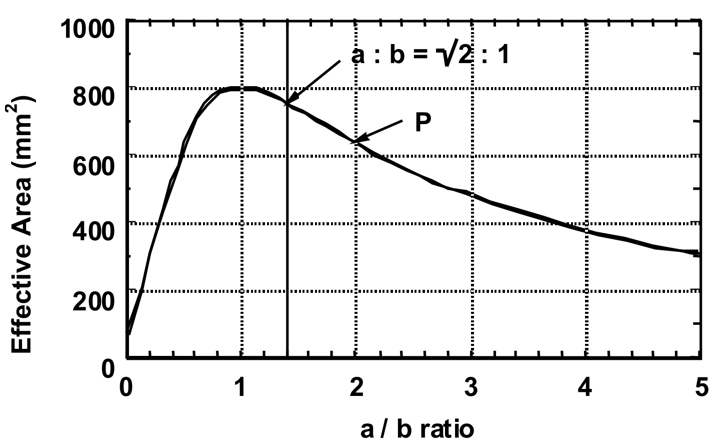

Figure A1-1
Effective Area as a Function of a/b Ratio

SEMI M23.4-0999
SPECIFICATION FOR ROUND 100 mm POLISHED MONOCRYSTALLINE INDIUM PHOSPHIDE WAFERS FOR ELECTRONIC AND OPTOELECTRONIC DEVICE APPLICATIONS (DOVE-TAIL TYPE)

This specification was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the Japanese Compound Semiconductor Committee. Current edition approved by the Japanese Regional Standards Committee on June 1, 1999. Initially available at www.semi.org August 1999; to be published September 1999.

NOTE: The complete specification for this product includes all general requirements of SEMI M23.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*
DIAMETER (See NOTE 1.)	100.0	± 0.5	mm
THICKNESS, CENTER POINT	625.0	± 25	µm
PRIMARY FLAT LENGTH	32.5	± 2	mm
SECONDARY FLAT LENGTH	18.0	± 2	mm

NOTE 1: The diameter standard means that the dimension is centered to this value.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
OPTION	Dove-Tail
PRIMARY FLAT ORIENTATION	$(0\bar{1}\bar{1})$ ± 0.5 (see Figure 1 in SEMI M23) under an indium facet. The primary flat shall be perpendicular to the "Dove-Tail" etch figure (see NOTE 1).
SECONDARY FLAT ORIENTATION	$(0\bar{1}1)$ 90° ± 5° clockwise from the primary flat.
SURFACE ORIENTATION	
A.	(100) ± 0.5° (See Figure 1 in SEMI M23.)
B.	(100) off 2° ± 0.5° toward the $(1\bar{1}0)$ plane (see NOTE 2). (See Figure 2 in SEMI M23.)
ORTHOGONAL MISORIENTATION	± 5° (See Figure 3 in SEMI M23.)

NOTE 1: Since there are various etchants, the appropriate etching method for revealing etch pits can be determined by each manufacturer. For example, see reference "HBr-$K_2Cr_2O_7$-H_2O etching system for indium phosphide" J.L. Weyher *et al.*, *Materials Science and Engineering*, B28 (1994) 488-492.

NOTE 2: The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted toward the $(1\bar{1}0)$ plane of the crystal.

SEMI M23.5-1000
SPECIFICATION FOR ROUND 100 mm POLISHED MONOCRYSTALLINE INDIUM PHOSPHIDE WAFERS FOR ELECTRONIC AND OPTOELECTRONIC DEVICE APPLICATIONS (V-GROOVE OPTION)

This specification was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the North American Compound Semiconductor Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available at www.semi.org September 2000; to be published October 2000.

NOTE: The complete specification for this product includes all requirements of SEMI M23.

Table 1 Dimension and Tolerance Requirements

Property	*Dimension*	*Tolerance*	*Units*
DIAMETER (See NOTE 1.)	100.0	± 0.5	mm
THICKNESS, CENTER POINT	625	± 25	µm
PRIMARY FLAT LENGTH	32.5	± 2	mm
SECONDARY FLAT LENGTH	18	± 2	mm

NOTE 1: The diameter standard means that the dimension is centered to this value.

Table 2 Orientation and Flat Location Requirements

Property	*Requirement*
PRIMARY FLAT ORIENTATION	$(01\bar{1})$ ± 0.5° (see NOTE 1) under a Phosphorus facet. The primary flat shall be perpendicular to the "V" etch figure. (See NOTE 2.)
SECONDARY FLAT ORIENTATION	(011), 90°± 5° counterclockwise from the primary flat.
SURFACE ORIENTATION (See NOTE 3.)	
A.	{ 100} (see NOTE 1) ± 0.5° (See Figure 2 in SEMI M23.)
B.	{ 100} (see NOTE 1) off 2° ± 0.5° toward the (110) plane which is between the primary and secondary flats (See Figure 4 in SEMI M23.)
ORTHOGONAL MISORIENTATION	± 5° (See Figure 5 in SEMI M23.)

NOTE 1: See Table 1 in SEMI M23.

NOTE 2: See Figure 2 in SEMI M23, which shows the orientation of the V-groove figure relative to crystallographically anisotropic pits (see NOTE 4).

NOTE 3: The frame of reference is the (100) plane of the crystal. It is the wafer normal that is tilted toward the (110) plane of the crystal.

NOTE 4: Relating to the etchant used for identifying V-groove and/or dovetail direction, see reference: "HBr-$K_2Cr_2O_7$ - H_2O etching system for indium phosphide" J.L.Weyher, et al. Materials Science and Engineering B28 (1994) 488–492.

SEMI M24-1101
SPECIFICATION FOR POLISHED MONOCRYSTALLINE SILICON PREMIUM WAFERS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the Japanese Silicon Wafer Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; published November 2001. Originally published in 1994; previously published March 2001.

1 Purpose

1.1 This document specifies requirements for virgin silicon premium wafers with nominal diameter from 150 mm to 300 mm used for particle counting, metal contamination monitoring, and measuring pattern resolution in the photolithography process in semiconductor manufacturing. The premium wafer has tighter specification values in some specific items for the specific usage, and looser or equal specification values in other items than a prime wafer has.

2 Scope

2.1 This specification classifies premium wafers according to surface condition and dimensional tolerances. Premium wafer classifications are summarized in Table 1.

2.2 Specification values are determined by the use for which the wafers are intended.

2.3 This specification provides premium wafers that can be used to test and evaluate leading edge device process.

2.4 For referee purposes, SI (System International) units shall be used.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 Definitions of terms related to silicon wafer technology are given in ASTM Terminology F 1241.

4.2 Definitions for some additional terms are given in SEMI M1.

4.3 The following definitions apply in the context of this specification:

4.3.1 *furnace and thermal processes* — wafers intended for use in evaluating metal contamination in thermal process.

4.3.2 *hand scribe mark* — any marking, usually on the back surface of a wafer, scratched manually into the silicon surface, as with a diamond-tipped scribe, for purposes of wafer identification.

4.3.3 *lithography and patterning* — wafers intended for use in evaluating pattern resolution.

4.3.4 *particle counting* — wafers intended for use in evaluating the particulate contamination added by a process tool. LLSs (Localized Light Scatterers) include particles and COP (Crystal Originated Pits).

4.3.5 *premium wafer* — a silicon wafer suitable for particle counting, metal contamination monitoring, and measuring pattern resolution in the photolithography process. The premium wafer has tighter specification values in some specific items for the specific usage, and looser or equal specification values for other items than a prime wafer has.

5 Ordering Information

5.1 Purchase orders for silicon premium wafers furnished to this specification shall include the items from the appropriate specification groups listed in Table 1.

Table 1 Wafer Classifications

Classification	*Application*
Particle Counting	Particle counting
Furnace and Thermal Process	Metal contamination monitoring
Lithography and Patterning	Measurement of pattern resolution in photolithography

5.2 Items which may be specified when ordering silicon wafers are listed in attached specification tables. Not all of these items are required for ordering premium wafers.

6 Dimensions and Permissible Variations

6.1 The material shall conform to the dimensions and dimensional tolerances in attached specification tables.

7 Materials and Manufacture

7.1 The material shall consist of wafers from crystals grown by the process specified in the purchase order or contract.

8 Physical Requirements

8.1 The material shall conform to the details specified in the purchase order.

9 Sampling

9.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

10 Test Methods

10.1 Table 1 of SEMI M18 contains a complete listing of ASTM, DIN, and JEIDA/JIS test methods that may apply to the testing of specified premium silicon wafers. These attributes are listed in the order they are found in the specification (which corresponds to the order in SEMI M18).

10.2 *Conductivity Type* — Use any of the methods in ASTM Test Methods F 42, JIS H 0607, or DIN 50432 for confirming the conductivity type of silicon wafers covered by this specification.

10.3 *Dopant* — Confirm the dopant of high resistivity silicon by the photoluminescence method of ASTM Test Method F 1389 or by the low-temperature infrared method of ASTM Test Method F 1630 or DIN 50438/3.

10.4 *Resistivity* — Determine the electrical resistivity of the wafer in accordance with ASTM Test Method F 673 or DIN 50445 (eddy current), or ASTM Test Method F 84, JIS H 0602, or DIN 50431 (four point probe) using a suitable fixture to hold the wafer.

10.5 *Carrier Recombination Lifetime* — Determine in accordance with F 1535 or JEIDA 53.

10.6 *Oxygen Content* — Determine the interstitial oxygen content of wafers with resistivity greater than a few ohm-cm by infrared absorption. ASTM Test Method F 1188 is the method that was used in analyzing the results of the international round robin experiment that established the IOC-88 conversion coefficient. DIN 50438/1 provides improved procedures of correcting for back surface roughness and multiple internal reflections. ASTM Test Method F 1619, based on work carried out in JEIDA (JEIDA 61) and SEMI Japan, is an alternative procedure for significantly reducing errors associated with these two phenomena.

10.7 *Carbon Content* — For all but very heavily doped epitaxial substrates, establish the carbon content in accordance with ASTM Test Method F 1391, JEIDA 56, or DIN 50438/2.

10.8 *Total Bulk Iron* — No standardized test method exists for direct determination of total bulk iron content in silicon. ASTM Test Method F 978 can be used for direct determination of the electrically active iron. Extensions of the surface photovoltage method (ASTM Test Method F 391) and of the microwave lifetime method (ASTM Test Method F 1535) have been reported in the literature to provide information on total bulk iron content of boron-doped silicon; both these extensions are based on the iron-boron pairing process.

10.9 *Structural Characteristics* — When feasible observe crystal defects such as dislocation etch pits, slip, lineage, twins, etc., in accordance with ASTM Test Method F 47, JIS H 0609, or DIN 50434. These methods are destructive, and with the exception of JIS H 0609 are based on chromium-containing etchants. Some structural defects, especially slip, can be determined nondestructively by means of X-ray topographic analysis in accordance with DIN 50443/1. Swirl and oxidation induced stacking faults (OSFs) are best observed after heat treatment such as those specified in ASTM Practice F 416. However, the heat cycles in this practice were developed for 100 mm wafers and are not suitable for 300 mm wafers. Accordingly, thermal cycles used shall be agreed upon between supplier and purchaser. For observation of OSFs, a 2-hour heat treatment at 1100°C in steam is recommended. Observe shallow pits in accordance with ASTM Practice F 1049.

10.10 *Diameter* — Diameter may be determined in accordance with ASTM Test Method F 613 or DIN 50441/4. Because notched wafers do not have flats, it is not necessary to make the measurements along the particular diameters identified in ASTM Test Method F 613; rather it is suggested that measurements be made along the diameter perpendicular to the <100> orientation fiducial axis (0° in the coordinate system specified in SEMI M20), the diameter 120° counter-clockwise, and the diameter 240° counterclockwise. However, a more precise method of determining the diameter is to find the circle that best fits the circumference of the wafer by a least squares method; the diameter of the wafer is twice the radius of this circle.

10.11 *Flat Orientation* — Determine in accordance with ASTM Test Method F 847.

10.12 *Flat Length* — Determine in accordance with ASTM Test Method F 671.

10.12.1 If flat diameter is specified instead of flat length, determine in accordance with Section 5.2.1 of DIN 50441/4 or by a dial gauge method (see NOTE 8) as agreed upon between supplier and purchaser.

10.13 *Notch Dimension* — Determine the depth and angle of the fiducial notch in accordance with ASTM Test Method F 1152 with the use of a wafer holding fixture appropriate for silicon wafers.

10.14 *Notch Orientation* — No test method for verifying the crystal axis of the orientation fiducial axis of notched wafers has yet been standardized. Accordingly, test procedures for making this determination shall be agreed upon between supplier and purchaser. A starting point may be an extension of ASTM Test Method F 847 with fixturing appropriate to notched wafers.

10.15 *Edge Profile Shape* — Determine the suitability of the edge profile in accordance with ASTM Test Method F 928 or DIN 50441/2.

10.16 *Edge Surface Finish* — Establish the surface finish of the edge region of the wafer by a method agreed upon between supplier and purchaser.

10.17 *Thickness, Center Point* — Determine thickness, center point may in accordance with ASTM Test Method F 533, JIS H 0611, or DIN 50441/1; special jigs or fixtures may be needed to allow the probe to reach the center point of the wafer.

10.18 *Total Thickness Variation* — Determine in accordance with ASTM Test Method F 533, ASTM Test Method F 657, DIN 50441/1, and JIS H 0611.

NOTE 2: ASTM Test Method F 533, DIN 50441/1, and JIS H 0611 are all 5-point methods, while Test Method F 657 involves a continuous scan pattern. JIS H 0611 differs from ASTM Test Method F 533 and DIN 50441/1 in that the measurements in JIS H 0611 are taken at the center and at 5 mm from the edge on diameters parallel and perpendicular to the major flat, while the measurements in the latter two test methods are taken at the center and at the same radial distance (R nominal - 6 mm) on diameters 30 degrees and 120 degrees counterclockwise from the bisector to the primary flat or notch (with the wafer facing front surface up).

10.19 *Surface Orientation* — Determine the crystallographic orientation of the wafer surface in accordance with ASTM test methods F 26, JEIDA Method 18, or DIN 50433 using a suitable fixture to hold wafer.

10.20 *Bow and Warp* — Determine bow in accordance with ASTM Test Method F 534 and warp in accordance with ASTM Test Method F 1390 or Test Method F 657.

NOTE 3: ASTM has standardized two methods for measuring warp. ASTM Test Method F 1390 is an automated, non-contact method which provides for correction of the wafer deflection due to gravitational effects. The scan pattern covers the entire fixed quality area. ASTM Test Method F 657 is a manual, non-contact method which has a continuous, prescribed scan pattern which covers only a portion of the wafer surface. There is no provision for correction of the wafer deflection due to gravitational effects. As noted in Appendix 2, different reference planes are used for the two methods. Because Test Method F 657 employs a back surface reference plane, the measured warp may include contributions from thickness variation of the wafer. Test Method F 1390 employs a median surface reference plane and is not susceptible to interferences from thickness variations. In general, Test Method F 1390 is preferred, especially for wafers 150 mm in diameter and larger, although ASTM Test Method F 1530 may also be used for this determination.

10.21 *Sori* — If sori is specified in lieu of bow or warp or both, determine by a method agreed upon between the supplier and the purchaser.

NOTE 4: Because sori is a property of the top surface of an unclamped wafer, it may be measured on many types of flatness measuring instruments. ASTM Test Method F 1451 may, in principle, be used for determination of sori.

10.22 *Flatness* — Determine by a method agreed upon between the supplier and the purchaser. It is recommended that site flatness is determined in accordance with ASTM Test Method F 1530 using a site-by-site front surface reference (indicated by the acronym SFQR in the Flatness Decision tree (see SEMI M1, Figure A1-1)). The percent usable area (PUA) shall be calculated as the percentage of the total number of full sites within the FQA that meet the specification.

10.23 *Surface Metal Contamination* — Determine surface metal contamination by a method agreed upon between supplier and purchaser; ASTM Test Method F 1617 is suitable for sodium and aluminum, and ASTM Test Method F 1526 is suitable for chromium, iron, nickel, copper, and zinc at the specified levels. Other, more sensitive methods may also be utilized by agreement between supplier and purchaser.

10.24 *Back Surface Gloss* — Determine test method in accordance with ASTM D523 or JIS Z8741 using a 60 degree of incidence and referencing the zero to a mirror polished wafer front surface instead of reference gloss surface as described in these feat method.

11 Surface Defect Criteria

11.1 Front surface defect criteria are shown in Item 8 in attached specification tables.

11.2 *Minimal Conditions or Dimensions* — The minimal conditions or dimenions for defects stated below shall be used for determining wafer acceptability. Anomalies smaller than these limits shall not be considered defects.

11.2.1 *area contamination* — Any foreign matter on the surface in localized areas which is revealed under the inspection lighting conditions as discolored, mottled, or cloudy appearance resulting from smudges, stains, water spots, etc.

11.2.2 *crack* — Any anomaly conforming to the definition and greater than 0.25 mm (0.010 inch) in total length.

11.2.3 *crow's foot* — Any anomaly conforming to the definition and greater than 0.25 mm (0.010 inch) in total length.

11.2.4 *dimple* — Any smooth surface depression greater than 3 mm in diameter.

11.2.5 *edge chip and indent* — Any edge anomaly, including saw exit marks, conforming to the definition and greater than 0.25 mm (0.010 inch) in radial depth and peripheral length.

11.2.6 *hand scribe mark* — Any mark such as that caused by a diamond scribe that is visible under diffuse illumination.

11.2.7 *haze* — Haze is indicated when the image of a narrow beam tungsten lamp filament is detectable on the polished wafer surface. (Under some conditions, contamination may appear as haze.)

11.2.8 *orange peel* — Any roughened surface conforming to the definition that is observable under diffuse illumination.

11.2.9 *particulate contamination* — Distinct particles, resting on the surface, which are revealed under collineated light as bright points.

11.2.10 *pit* — Any individually distinguishable non-removable surface anomaly conforming to the definition and visible when viewed under high intensity illumination.

11.2.11 *saw marks* — Any surface irregularities conforming to the definition that are observable under diffuse illumination.

11.2.12 *scratch* — Any anomaly conforming to the definition and having a length-to-width ratio greater than 5:1.

11.2.13 *slip* — Any pattern of short ridges aligned along <111> directions and visible under diffuse illumination.

11.2.14 *striations* — Any helical features conforming to the definition and visible under diffuse illumination.

11.3 Back surface defect criteria are specified in attached specification tables.

12 Certification

12.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

12.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 10. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

13 Packing and Marking

13.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise, all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices, to provide ample protection against damage during shipment.

13.2 The wafers supplied under this specification shall be identified by appropriately labeling the outside of each box or other container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification shall include, as a minimum, wafer classification, nominal diameter, surface orientation, growth method, lot number, and origin. In addition, identification of premium wafers shall include conductivity type and resistivity range of the lot. The lot number, either (1) assigned by the original manufacturer of the wafer, or (2) assigned subsequent to wafer manufacture but providing reference to the original lot number, shall provide easy access to information concerning the fabrication history of the particular wafers in that lot. Such information shall be retained on file at the vendor's facility for at least one month after that particular lot has been accepted by the purchaser.

Table 2 Specification for Polished Monocrystaline Silicon Premium Wafers for 250 nm Design Rule Usage

	CLASSIFICATION ITEMS (SEMI M18)	*Particle Counting*	*Furnace & Thermal Process*	*Lithography & Patterning*	*Test Method*
1.	GENERAL CHARACTERISTICS				
1.1	Growth Method	CZ or MCz	CZ or MCz	Cz or MCz	
1.2	Crystal Orientation	(100) ± 1°	(100) ± 1°	(100) ± 1°	ASTM F 26, DIN 50433
1.3	Conductivity Type	*n* or *p*	*n* or *p*	*n* or *p*	ASTM F 42, JIS H 607, DIN 50432
1.4	Dopant	P or B	P or B	P or B	ASTM F 1389, F 1630, DIN 50438/3
1.5	Nominal Edge Exclusion (Distance for Fixed Quality Area)	3 mm	3 mm	3 mm	
2.	ELECTRICAL CHARACTERISTICS				
2.1	Resistivity, Center Point	NS	≥ 1 Ω-cm	NS	ASTM F 84, F 673, JIS H 602, DIN 50431, 50445
2.2	Radial Resistivity Variation	NS	NS		ASTM F 81, DIN 50435
2.4	Carrier Recombination Lifetime (see NOTE 1)	NS	≥ 200 µs		JEIDA 53, F 1535
3.	CHEMICAL CHARACTERISTICS				
3.1	Oxygen Concentration: Spec. Range of Center Point: Target	NS	$\leq 1.2 \times 10^{18}/cm^3$	NS	ASTM F 1188, F 1619, DIN 50438/1, JEIDA 61
3.1.1	Oxygen Concentration: Tolerance Around Center Point: Target		≤ 10%		
3.2	Radial Oxygen Variation		NS		
3.3	Carbon Concentration		≤ 0.2 ppma		ASTM F 1391, DIN 50438/2, JEIDA 56
3.-	Total Bulk Iron Concentration (see NOTE 2)		$\leq 5 \times 10^{10}/cm^3$		ASTM F 987
4.	STRUCTURAL CHARACTERISTICS				
4.1	Dislocation Etch Pit Density	NS	$\leq 500/cm^2$	NS	ASTM F 47, JIS H 609, DIN 50434, 50443/1
4.2	Slip		None		ASTM F 47, JIS H 609, DIN 50434, 50443/1
4.3	Lineage		None		ASTM F 47, JIS H 609, DIN 50434, 50443/1
4.4	Twin		None		ASTM F 47, JIS H 609, DIN 50434, 50443/1
4.5	Swirl	NS	None	NS	ASTM F 416, JIS H 614, DIN 50443/1
4.6	S-pits		None		ASTM F 416, F 1049
4.7	Oxidation-Induced Stacking Faults (OSF) (see NOTE 3)		User/Vendor		ASTM F 416 User/Vendor mutual agreement
4.8	Oxide Precipitates (BMD) Interstitial Oxygen Reduction (Δ O_i) (see NOTE 4)		User/Vendor		ASTM F 1239 User/Vendor mutual agreement

8.-	Microroughness	NS	NS	NS	
9.	BACK SURFACE VISUAL INSPECTION CHARACTERISTICS				
9.1	Edge Chips	None	None	None	ASTM F 154, F 523, JIS H 614
9.6	Roughness, rms	NS	NS	NS	
9.7	Brightness (Gloss) (see NOTE 6)	300 mm ≥ 80% 150, 200 mm NS	300 mm ≥ 80% 150, 200 mm NS	≥ 80% 150, 200 mm NS	ASTM D 523, JIS Z 8741
9.8	Localized Light Scatters (LLSs)	NS	NS	NS	ASTM F 523, F 1620, F 1621, JIS H 614
9.9	Scratches, Macro	≤ 0.25 × D mm	≤ 0.25 × D mm	≤ 0.25 × D mm	ASTM F 154, F 523, JIS H 614
9.10	Scratches, Micro	NS	NS	NS	ASTM F 154, JIS H 614

NOTE 1: Carrier recombination lifetime is well known to be dependent on dopant concentration. If there exist any difficulties to realize resistivity of 1 ohm-cm and recombination lifetime of 200 ms simultaneously, it is advised that specification of those two items be determined based upon user-supplier mutual agreement.

NOTE 2: Specification of bulk iron requires mutual agreement between supplier and purchaser as to both the specification limit and test procedure.

NOTE 3: Specification of OSFs requires mutual agreement between supplier and purchaser.

NOTE 4: Specification of BMDs requires mutual agreement between supplier and purchaser.

NOTE 5: Surface metal contamination should be determined by a method agreed upon between supplier and purchaser; ASTM Test Method F 1617 is suitable for sodium and aluminum, and ASTM Test Method F 1526 is suitable for chromium, iron, nickel, copper, and zinc at the specified levels. More sensitive methods may also be utilized with agreement between supplier and purchaser. Surface Metal Contamination specifications for "Furnace & Thermal Process" wafer are based on NTRS 1997.

NOTE 6: Gloss: As measured with visible light at an incident angle of 60°, referenced to a mirror polished silicon wafer front surface.

Table 3 Specification for Polished Monocrystalline Silicon Premium Wafers for 180 nm Design Rule Usage

CLASSIFICATION ITEMS (SEMI M18)	*Particle Counting*	*Furnace & Thermal Process*	*Lithography & Patterning*	*Test Method*
1. GENERAL CHARACTERISTICS				
1.1 Growth Method	Cz or MCz	Cz or MCz	Cz or MCz	
1.2. Crystal Orientation	(100) ± 1°	(100) ± 1°	(100) ± 1°	ASTM F 26, DIN 50433
1.3 Conductivity Type	n or p	n or p	n or p	ASTM F 42, JIS H607 DIN 50432
1.4 Dopant	P or B	P or B	P or B	ASTM F 1389, F 1630, DIN 50438/3
1.5 Nominal Edge Exclusion (Fixed Quality Area) (See NOTE 1)	300 mm: 2 mm 200 mm: 3 mm	300 mm: 2 mm 200 mm: 3 mm	300 mm: 2 mm 200 mm: 3 mm	
2. ELECTRICAL CHARACTERISTICS				
2.1 Resistivity, Center Point	NS	≥ 1 Ω-cm (See NOTE 4)	NS	ASTM F 84, F 673, JIS H 602, DIN 50431, 50445

9.7 Brightness (Gloss)	300 mm $\geq$ 80% 200 mm NS	300 mm $\geq$ 80% 200 mm NS	300 mm $\geq$ 80% 200 mm NS	ASTM D 523, JIS Z8741

CLASSIFICATION ITEMS (SEMI M18)	*Particle Counting*	*Furnace & Thermal Process*	*Lithography & Patterning*	*Test Method*
9.8 Localized Light Scatterers (LLSs)	NS	NS	NS	ASTM F 523, F 1620, F 1621, JIS H 614
9.9 Scratches, Macro	≤ 0.25 × D mm	≤ 0.25 × D mm	≤ 0.25 × D mm	ASTM F 154, F 523, JIS H 614
9.10 Scratches, Micro	NS	NS	NS	ASTM F 154

NOTE 1: Nominal Edge Exclusion: 2 mm can be achievable in new 300 mm equipment; however, it will be difficult in conventional 200 mm equipment. Edge Exclusion Task Force is now making activities for developing a guide containing definition of edge exclusion when a measurement is made over a finite sampling area.

NOTE 2: Wafer ID Marking: SEMI M1 specification shall be applied, if ID mark is applied.

NOTE 3: LLSs: LLSs for particle counting wafer is specified only by the half size of design rule. These specification values shall be reviewed when the evaluation techniques for distinguishing particle and COP are established. The nominal particle size can be transferred to another particle size using coefficient value and the latter can be applicable for the usage.

NOTE 4: Carrier Recombination Lifetime: Carrier recombination lifetime is affected by carrier concentration (resistivity) and metallic impurities. Specified resistivity and bulk iron concentration are only necessary conditions for obtaining the specified carrier recombination lifetime.

NOTE 5: Surface Metal Contamination for Furnace and Thermal Process: The proposed specification values are recommended ones considering NTRS 1997 and current measuring technology and accuracy.

NOTE 6: Surface Metal Contamination for Particle Counting and Lithography & Patterning: The values are proposed considering current process capabilities and the necessary level for their usage.

NOTE 7: LLSs for Furnace & Thermal Process and Lithography & Patterning: The values are proposed considering current process capabilities and the necessary level for their usage.

NOTE 8: The nominal particle size can be transferred to another particle size using coefficient value and the latter can be applicable for the usage.

8.12 Orange Peel	None	None	None	ASTM F 154, F 523, JIS H 614
8.14 Saw Marks	None	None	None	ASTM F 154, F 523, JIS H 614
8.15 Dopant Striation Ring	None	None	None	ASTM F 154, F 523, JIS H 614
8.- Microroughness	NS	NS	NS	
9. BACK SURFACE VISUAL INSPECTION CHARACTERISTICS				
9.1 Edge Chips	None	None	None	ASTM F 154, F 523, JIS H 614
9.6 Roughness, rms	NS	NS	NS	
9.7 Brightness (Gloss) 300 mm 200 mm	≥ 80% User/Vendor	≥ 80% User/Vendor	≥ 80% User/Vendor	ASTM D 523, JIS Z8741
9.8 Localized Light Scatterers (LLSs)	NS	NS	NS	ASTM F 523, F 1620, F 1621, JIS H 614
9.9 Scratches, Macro	≤ 0.25 × D mm	≤ 0.25 × D mm	≤ 0.25 × D mm	ASTM F 154, F 523, JIS H 614
9.10 Scratches, Micro	NS	NS	NS	ASTM F 154

NOTE 1: Nominal Edge Exclusion is proposed as the same as in Table2 and as in Table3, however, more discussion will be necessary. Edge Exclusion Task Force is now making activities for developing a guide containing definition of edge exclusion when a measurement is made over a finite sampling area.
NOTE 2: Wafer ID Marking: SEMI M1 specification shall be applied, if ID mark is applied.
NOTE 3: Surface Metal Contamination for Furnace and Thermal Process: The specification values are based on ITRS '99 Roadmap.
NOTE 4: Surface Metal Contamination for Particle Counting and Lithography & Patterning: The specified values are based on 180 nm process requirement in ITRS 1999.
NOTE 5: Visual techniques are neither sufficient nor appropriate for 0.13 µm design rules. Automatic surface inspection tools can be used for reporting values such as scratches and haze. Test method and standardization for automatic surface inspection tools is under development, visual inspection is now used as a supplemental method.

NOTE 6: LLSs (Localized Light Scatterers: 90 nm): These specification values shall be reviewed when the evaluation techniques for distinguishing particle and COP are established. Critical surface LLS size should be the half of CD, however, tools are not well established. 65 nm count limit was transferred to 90 nm count limit using draft international standard: ISO/DIS 14644-1 which follows the equation: 90 nm LLS counts per wafer = 65 nm LLS counts per wafer /$(90 \text{ nm} /65 \text{ nm})^2$.

NOTE 7: LLSs for Furnace & Thermal Process and Lithography & Patterning: New concept is proposed for LLSs for Furnace and Thermal Process. The critical surface LLS size for prime wafer is proposed as a half size of CD in IRTS Roadmap. The half of CD is not necessarily requested for monitor test wafers. In actual business, an additional specification of LLS, the size of which is around CD is used, however, the size is not standardized. TF proposes the additional LLS size as the same size as CD. This size is used for specifying LLS for Furnace & Thermal Process.

SEMI M25-95
SPECIFICATION FOR SILICON WAFERS FOR CALIBRATION OF LIGHT POINT DEFECT WAFER INSPECTION SYSTEMS WITH RESPECT TO THE DIAMETER OF POLYSTYRENE LATEX SPHERES

1 Purpose

1.1 This document describes the specifications to be met by bare silicon wafers used for calibrating surface inspection systems with respect to the diameter of polystyrene latex spheres. This document does not intend to establish manufacturing procedures for calibration wafers.

Note 1: This specification might be used as the basis for making calibration substrates with other materials and/or surfaces.

2 Scope

2.1 Bare silicon wafers on which latex-spheres of a known diameter are deposited are used as standards for the calibration of bare wafer inspection systems. The response curve of the systems is generated for the calibration of the systems with respect to the sizing of polystyrene latex (PSL) spheres, not for counting them.

3 Referenced Documents

3.1 *SEMI Standard*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

4 Terminology

4.1 *Light-Point Defect (LPD)* — An isolated, localized effect on the wafer surface or in the substrate wafers resulting in increased light scattering intensity above a threshold (unit LSE).

Note 2: LPD is a general term and it includes for example latex spheres and other localized surface irregularities.

4.2 *Latex-Sphere Equivalent (LSE)* — The size unit of an LPD expressed as the diameter of a latex-sphere which scatters the same amount of light as the LPD. This is indicated by adding “LSE” to the length unit used, e.g., 0.2 µm LSE.

Note 3: Sizing may be different for other materials and shapes than PSL spheres because of the different optical designs of inspection systems.

4.3 *Response Curve (RC)* — The relation between measured scattered light intensity and latex-sphere diameters for a calibration surface inspection system. The RC depends on the light source used and may contain non-monotonic regions.

4.4 *LPD histogram* — The distribution of the counts of LPD’s per unit length over their size as expressed in LSE.

5 Requirements

5.1 *Substrates* — The wafers used as substrates for the deposition of latex-spheres must be bare silicon with a native oxide surface and they have to meet the requirements of SEMI M1. In addition to the M1 specification, the surface conditions (for example, roughness) must be in compliance with Section 5.5.2.

Note 4: The substrate wafer must be measured before latex sphere deposition with the same type of instrument to ensure that the conditions of 5.5.2 are fulfilled.

5.2 *Latex-Spheres* — The latex-spheres used must be certified with respect to their diameter and they must be traceable to the Standard Reference Materials (SRM) of the National Institute of Standards and Technology (NIST), former National Bureau of Standards (NBS). The certification methodology must be in accordance with the technologies used by NIST.

Note 5 : If the PSL are not traceable to NIST, the certification method should be fully documented.

5.3 *Range of Latex-Sphere Diameters* — The diameters of the latex-spheres used for calibration must be selected so that the measurement range for the intended application is covered. Sufficient latex-sphere diameters must be used to achieve the required accuracy of the RC.

Note 6: For surface inspection systems using laser light source(s), it is recommended to avoid latex-sphere diameters corresponding approximately to the wavelength of the laser used and its multiples of the laser used.

5.4 *Density of Latex-Spheres Deposited* — The density of the deposited latex-spheres, full or partial wafer coverage, must be selected in such a way that the peak of the histogram of the latex-sphere diameters is at least 100% above the background counts. It has to be verified that the indicated (relevant) peak in the histogram is generated by single, isolated latex-spheres of the specified diameter. A density of 5–15 latex-spheres per square centimeter is recommended.

5.5 *Background Contamination*

5.5.1 Calibration wafers must be handled and stored with great care to avoid contamination and damage.

5.5.2 The bell-shaped peak in the LPD histogram of a calibration wafer which is generated by the latex-spheres must be well-defined and must be well above the background level. The bell-shaped curve has to go down to less than 50% of its peak value on both sides of the maximum within a diameter range of ± 15% as referred to the nominal latex-sphere diameter.

5.6 *Multiple Deposition of Latex-Spheres* — Deposition of latex-spheres with different, well-defined diameters on a calibration wafer is allowed if all the conditions of this specification are met for each kind of deposited latex-sphere size.

6 Packaging

6.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices to provide ample protection against damage during shipment.

7 Data to Accompany Calibration Wafers

7.1 Certificate for average and standard deviation of the diameter of the latex spheres used, including the production lot number of latex-spheres used.

7.2 Date of production and certification of calibration wafer.

7.3 Histogram, as defined above.

7.4 Approximate number of deposited latex-spheres in a specified area.

7.5 Wafer identification.

7.6 Name and address of the originator of the calibration wafers.

7.7 LPD's wafer map.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M26-96
GUIDE FOR THE RE-USE OF WAFER BOXES AND CASSETTES USED TO TRANSPORT WAFERS

1 Purpose

This document is a guide for box cleaning services, wafer suppliers, and wafer users for the re-use of boxes and cassettes. Its purpose is to encourage the re-use of wafer boxes and cassettes, thereby reducing waste.

2 Scope

None.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI E1 — Specification for 3", 100 mm, 125 mm, and 150 mm Plastic and Metal Wafer Carriers

SEMI T3 — Specification for Semiconductor Wafer Box Labels

3.2 *ANSI Document*[1]

ANSI/EIA - 556-A — Outer Shipping Container Bar Code Label Standard

4 Terminology

4.1 *box wrap* — The wrapping or bagging applied over the wafer box to comprise the product package.

4.2 *cassette* — A device to hold wafers during transport or processing. Also called *wafer carrier*.

Note: In this guide, the emphasis is on the cassette for holding wafers in transport, not in processing. Cassettes for re-use inside the wafer boxes should not be exposed to processing chemicals nor metal contaminants. (Compare SEMI E1 in which the emphasis is on cassettes to hold wafers during processing.)

4.3 *recycle* — To pass through a cycle or process for the purpose of recovering any useful substances from waste material. Compare with *re-use*.

4.4 *re-use* — To re-employ an article in its original form for a purpose which is the same or similar to its initial purpose.

4.5 *seam tape* — Adhesive-coated tape employed to seal the seam between the cover and the base of a box.

4.6 *secondary packaging* — Packaging materials, molded or unmolded, inside the shipping container, which serve to protect the wafer package from damage during transportation.

4.7 *shipping container* — A carton used to transport wafer boxes; it is typically constructed of corrugated cardboard.

4.8 *wafer box* — A sealable container, consisting of a base and a cover, used for storing or transporting wafers. Compare with transport package in ANSI/EIA 556-A.

4.9 *wafer box label* — The label on the box identifying the product and its manufacturer (see SEMI T3).

5 Suitability for Re-Use

5.1 The ability to re-use wafer boxes and cassettes is adversely affected by certain characteristics. Some of these characteristics also impact on the ability to recycle.

5.1.1 The following characteristics are recommended:

5.1.1.1 generic embossed markings (e.g., model name, model number, manufacturer's information, such as name and location),

5.1.1.2 embossed recycle symbol, trademark symbol, mold markings,

5.1.1.3 embossed instructions,

5.1.1.4 removable labels with low residue, low tack adhesives,

5.1.1.5 removable seam tape with low residue, low tack adhesives,

5.1.1.6 removable methods of identification,

5.1.1.7 stackable wafer box bases and covers,

5.1.2 The following characteristics are not recommended:

5.1.2.1 “custom” embossed markings,

5.1.2.2 end-user specific logos, symbols, and markings,

5.1.2.3 high residue tape and labels,

5.1.2.4 labels which are difficult to remove or are non-removable,

5.1.2.5 non-removable marks such as inks and other coloring.

1 American National Standards Institute, 1430 Broadway, New York, NY 10018

6 Procedural Guidelines

6.1 *Collection Method at the Wafer User Facility*

6.1.1 Unpack shipping containers and save for re-use or recycle.

6.1.2 Remove box wrap and seam tape from boxes under a clean air module or in a cleanroom. Exercise care when removing the box wrap; avoid scuffing or cutting the box surface. If recyclable, collect box wrap material and seam tape in designated containers.

6.1.3 Remove wafers from box in cleanroom area. Remove all labels from the box.

6.1.4 Place boxes and cassettes for re-use in a designated collection container or collection area.

6.1.5 Maintain the cassettes and boxes for re-use in an environment free from contact with metal contaminants and process chemicals.

6.1.6 Periodically return boxes and cassettes for reclean to the reclean service location or the wafer supplier.

6.1.7 Whenever possible, cycle cassettes and boxes between the same wafer user and wafer supplier.

6.2 *Box and Cassette Cleaning at the Reclean Service Location*

6.2.1 The supplier of the reclean service must engineer the reclean process.

6.2.2 At the service supplier's option, visually inspect the boxes and cassettes prior to cleaning. The wafer supplier and wafer user should agree to acceptable and unacceptable levels of defects, recognizing that there will be some normal wear. These levels should be provided to the service supplier. Inspect for the following defects:

6.2.2.1 deformation or warp,

6.2.2.2 razor cuts, scuffs, breaks, cracks, voids, and fractures,

6.2.2.3 contamination and imbedded silicon,

6.2.2.4 damage to tension springs or other wafer retention mechanisms,

6.2.2.5 markings and labels.

6.2.3 Collect defective parts for recycle, and clean acceptable parts as follows:

6.2.3.1 Clean using an aqueous-based or non-aqueous-based chemistry,

6.2.3.2 Chlorofluorocarbon chemistries are not permitted.

6.2.3.3 Confirm the compatibility of the box and cassette materials with the cleaning method and drying conditions.

6.2.4 Visually inspect the boxes and cassettes after cleaning using a high intensity or an ultraviolet light. The wafer user and the wafer supplier should agree to acceptable and unacceptable levels of defects, recognizing that there will be some normal wear. Inspect for all the defects noted in 5.2.2.2 and, in addition, for:

6.2.4.1 residues from labels, markings, or tape,

6.2.4.2 failure of the box halves to seat and seal together.

6.2.5 Collect defective parts for recycle.

6.2.6 Return acceptable boxes and cassettes to the wafer supplier using box wrap, nesting material, and shipping containers as required to maintain cleanliness and mechanical integrity.

6.3 *Maximum Number of Re-Use Cycles*

6.3.1 Base the total number of re-use cycles on the ability to maintain both mechanical integrity and cleanliness.

Note: By following this guide, some users have found that boxes and cassettes processed through more than four re-use cycles were still satisfactory.

SEMI M27-96
PRACTICE FOR DETERMINING THE PRECISION OVER TOLERANCE (P/T) RATIO OF TEST EQUIPMENT

1 Purpose

1.1 This practice covers a procedure for estimating the capability of a test instrument with respect to the tolerance (specification) of a parameter.

NOTE 1: If the variability associated with the measurement of the parameter by this instrument is very small compared with the width of the specification range, the chances of obtaining a test result outside the specification limits when the parameter actually lies within the specification limits (or conversely) is quite small. On the other hand, if this variability is too large, the probability of obtaining a false test result is much greater.

2 Scope

2.1 This practice provides a standardized method for determining the relationship between the measurement precision of a single instrument and the specification range.

2.2 The ratio of precision to tolerance *(P/T)* can be used as a measure of the suitability of a measurement process to evaluate a specific parameter against a given specification. Calculation of the *P/T* ratio requires knowledge both of the precision of the measurement process and of the specification range or tolerance of interest.

NOTE 2: If the tolerance has been arbitrarily defined without regard to process variability or other considerations, the *P/T* ratio might be meaningless.

NOTE 3: Another metric for the suitability of test equipment is the signal to noise *(S/N)* ratio, which relates the process variability to the measurement variability; consideration of this metric is beyond the scope of this practice.

NOTE 4: The *P/T* ratio does not provide any information about the bias of the test instrument being evaluated; hence, it is not a suitable metric for test instrument accuracy.

2.2.1 A procedure is given for estimating the overall measurement precision of the measurement process as carried out by an automated (self-calibrating) or non-automated (non-self calibrating) test instrument under the conditions normally encountered in applying the instrument. No information is developed concerning the components of the precision; consequently, this practice cannot be used to determine the origins of measurement variability. Such information can be developed through the use of a full measurement capability analysis such as a properly designed gauge repeatability and reproducibility study.[1]

2.2.2 Both double-sided and single-sided specifications are covered by this practice.

NOTE 5: It is not meaningful to compare *P/T* ratios between single-sided and double-sided specifications of the same parameter.

3 Referenced Documents

3.1 *SEMI Standard*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

4 Terminology

4.1 *accuracy* — The closeness of agreement between a test result or the mean of a group of test results and the true value (accepted reference value).

DISCUSSION — Accuracy depends on both precision and bias of the measurement process. Since in routine use, random components of error (resulting in imprecision) and systematic components of error (resulting in bias) cannot be completely separated, the reported accuracy must be interpreted as a combination of these two elements. In part, because of the inability to separate the random and systematic components of error, the ISO Guide to the Expression of Uncertainty in Measurement[2] separates uncertainty components of a measurement result into two categories (Type A and Type B) based on their method of evaluation. Type A uncertainties are those that are evaluated by the statistical analysis of a series of observations. Type B uncertainties are those that are evaluated by other (non-statistical) means.

4.2 *bias* — The systematic difference between the population mean of the test results from a measurement process and the accepted reference value of the property being measured.

1 Steven A. Eastman, "Evaluating Automated Wafer Measurement Instruments," in Semiconductor Characterization: Present Status and Future Needs, W.M. Bullis, D.G. Seiler, and A. C. Diebold, eds. (AIP Press, Woodbury, NY, 1995) pp. 248 - 251.

2 ISO/TAG 4/WG 3 Guide to the Expression of Uncertainty in Measurement (October 1993), available from ISO Central Secretariat, C. P. 56, CH-1211 Genève 20, Switzerland, or (in the U.S.) from American National Standards Institute, 11 West 42nd Street, 13th floor, New York, NY 10036. Also see: Barry Taylor and Chris Kuyatt, Guidelines for Evaluating and Expressing the Uncertainty of NIST Measurement Results, 1994 Edition, NIST Technical Note 1297 (September 1994).

DISCUSSION — One or more systematic error components may contribute to the bias. Because the population mean involves the totality of all possible test results, it cannot be determined directly. The sample mean, x is an unbiased estimator of the population mean.

4.3 *precision* — A measure of the variability of a measurement process about the mean value of the test results obtained.

DISCUSSION — For purposes of this practice, the precision of the test instrument is quantified as 6 times the sample standard deviation of a set of individual test results made under conditions typical of those encountered in the normal use of the measurement equipment being evaluated. Among other factors, drift between instrument calibrations and known and unknown variabilities caused by ambient conditions must be considered. If the data set consists only of a small number of samples, the estimate of precision may be in error.

4.4 *tolerance* — The absolute magnitude of the range of the product specification.

DISCUSSION — Tolerance and specification are sometimes used interchangeably. Certain industries prefer one term to the other. In some cases, in particular in SEMI M1, the tolerance is given in terms of the deviation from the mean. For the purpose of this practice, the tolerance is always the full range of the specification.

5 Procedure

5.1 *Determine the Tolerance (T)*

5.1.1 For a double-sided specification, calculate T from:

$$T = USL - LSL$$

where USL is the upper specification limit and LSL is the lower specification limit ($USL > LSL$). If the specification is given as "DIMENSION," $T = 2a$.

5.1.2 For a single-sided specification with only an LSL or USL, take T as the magnitude of the LSL or USL.

5.2 *Determine the Precision (P)*

5.2.1 Ensure that the test instrument being evaluated is under acceptable statistical control by the methods customarily employed to evaluate the state of control of test instrumentation in the laboratory carrying out the evaluation.

5.2.2 Make a series of measurements of the desired parameter on a test specimen with the test instrument being evaluated under conditions and for a period of time typical of those encountered in use of the test instrument. Record each individual test result as x_i, where i ranges from 1 to n, the total number of test results in the set. Note and record the range of operating conditions (operator, temperature, humidity, automatic recalibration, loading and unloading of the test specimen, repositioning, illumination, etc., as appropriate) encountered while the set of test results is being collected.

NOTE 6: The test specimen should have characteristics including uniformity that are typical of test specimens to be measured in practice. If evaluation of the test instrument is desired over a range of parameter values (levels), the procedure may be carried out at each level of interest.

NOTE 7: Specification of sampling plans is beyond the scope of this practice. Related Information 1 gives examples of what constitutes a test result for several different types of automated measurement instrumentation.

5.2.3 Estimate the overall standard deviation, $\hat{\sigma}$, of the test results as follows:

$$\hat{\sigma} \approx s = \left| \sum_{i=1}^{n} \frac{(x_i - \bar{x})^2}{n - 1} \right|^{1/2}$$

where:

s = the sample standard deviation of the set of n test results, and

$\bar{x}$ = the sample mean $\left(\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \right)$.

5.2.4 Take as the precision, P, the quantity

$$P = 6\hat{\sigma}$$

5.2.5 Calculate the P/T ratio, in percent, as follows:

$$P/T(\%) = \frac{P}{T} \times 100$$

and round to the nearest percent.

6 Interpretation

6.1 The value against which the P/T ratio is judged depends upon the application. In general, one prefers that the value of the measurement precision, P, be much smaller than the specification range, T. A test instrument is usually deemed to be suitable for the purpose if P/T lies below 10%. If P/T is greater than 30%, the test instrument is not likely to be suitable for the purpose. Cases for which P/T lies between 10% and 30% must be judged on an individual basis, depending on the requirements being placed on the measurement system.

6.2 Evaluation of the risk of erroneously obtaining a measurement result outside the specification range is dependent upon the instrument response function and the shape of the process distribution, neither of which is determined by the procedures of the practice.

NOTE 8: This practice cannot determine the suitability of the measurement instrument for evaluating the process variation (see NOTE 3).

7 Report

7.1 Report the following information:

7.1.1 Description of the test instrument being evaluated,

7.1.2 Parameter being measured,

7.1.3 Level or levels of the parameter being measured,

7.1.4 A description of the range of measurement conditions used in the evaluation experiments,

7.1.5 Specification range of interest (or the *LSL* and *USL*), and

7.1.6 The *P/T* ratio, in percent.

RELATED INFORMATION 1
EXAMPLES OF TEST RESULTS

NOTE: This related information is not an official part of SEMI M27 and is not intended to modify or supercede the official standard. The standard should be referred to in all cases; this information is provided to illustrate the types of test results anticipated to be used with this standard. This related information accompanied the standard through the consensus balloting process. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

R1-1 Scope

R1-1.1 This related information illustrates the concept of a test result for several types of automated measurements commonly encountered in evaluating silicon materials in the semiconductor industry.

R1-2 Referenced Documents

R1-2.1 *ASTM Standards*[3]

F 673 — Test Methods for Measuring Resistivity of Semiconductor Slices or Sheet Resistance of Semiconductor Films with a Noncontact Eddy-Current Gage

F 1392 — Test Method for Determining Net [sic] Carrier Density Profiles in Silicon Wafers by Capacitance-Voltage Measurements with a Mercury Probe

F 1530 — Test Method for Measuring Flatness, Thickness, and Thickness Variation on Silicon Wafers by Automated Noncontact Scanning

F 1618 — Practice for the Determination of Uniformity of Thin Films on Silicon Wafers

F 1619 — Test Method for Measurement of Interstitial Oxygen Content of Silicon Wafers by Infrared Absorption Spectroscopy with P-Polarized Radiation Incident at the Brewster Angle

R1-2.2 *DIN Standard*[4]

50438, Part 1 — Testing Materials for Semiconductor Technology: Determination of Impurity Content in Semiconductors by Infrared Absorption — Oxygen in Silicon

R1-3 Illustrative Examples

R1-3.1 *Single Reading per Test Result: Flatness, Thickness, or Thickness Variation by Noncontact Scanning* — Consider each reported determination of the desired parameter in accordance with ASTM Test Method F 1530 to be an individual test result; this is the simplest situation likely to be encountered in practice. Note, however, that substantial internal computation may be required to generate the reported determination and that the gauge may or may not be recalibrated or restandardized between individual determinations. Figure R1-1 illustrates an example of flatness (GFLR or TIR) data taken over a period of 261 days. Note that the reported values are discrete, limited by the resolution of the test instrument. The inset shows a histogram of the data, together with a fitted normal distribution with the same mean (0.9693 µm) and standard deviation (0.02657 µm). Note that if a smaller data set had been used, the fit of the normal curve to the actual data would be expected to be much worse than in this example.

3 Annual Book of ASTM Standards, Volume 10.05, published annually by the American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

4 DIN Standards, Deutsches Institut fur Normung e.v., available from Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-1000 Berlin 30, Germany. An English translation is available in Reference 3.

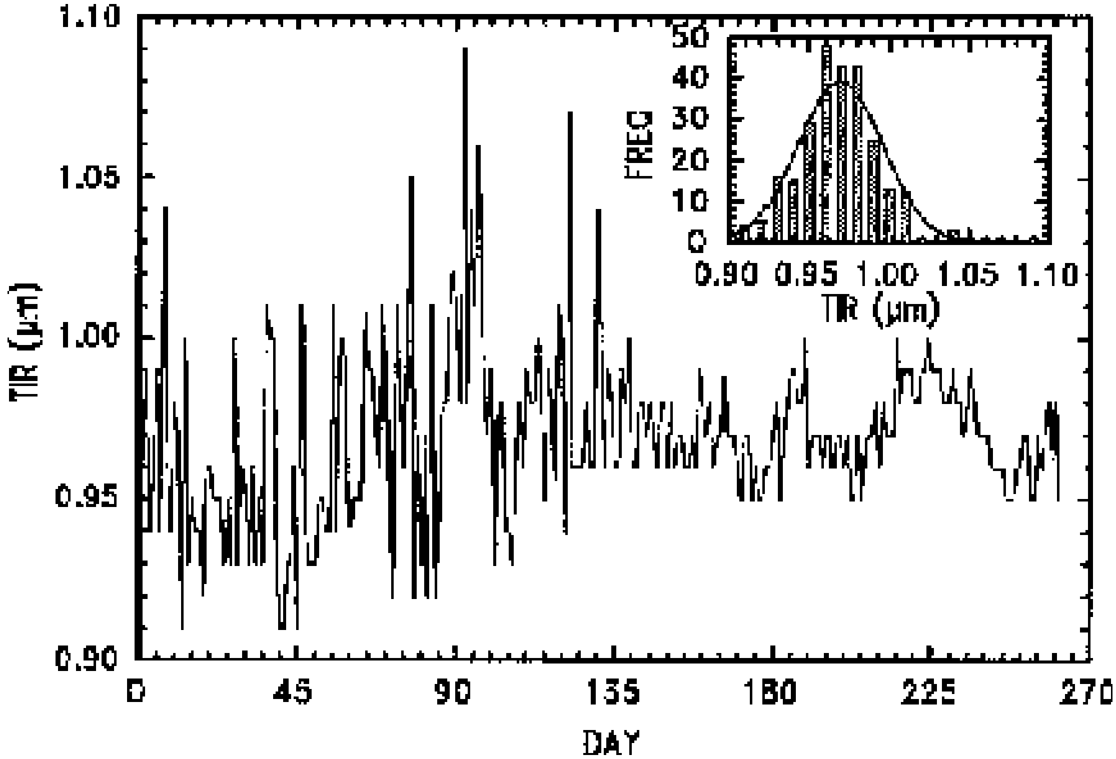

Figure R1-1
Flatness (GFLR) Data Taken on a Wafer Once per Day for a Period of 261 Days

NOTE 9: The resolution of the measurement system is 0.01 µm, so the data have discrete values on the scale shown. The inset shows a histogram of the measured data, together with a normal distribution, having the same mean (0.9693 µm) and standard deviation (0.02657 µm) as the measured data distribution.

R1-3.2 *Single Reading (of an attribute explicitly dependent on the value of another attribute) per Test Result: Resistivity by Eddy Current Gauge* — Consider each determination of the resistivity in accordance with ASTM Test Method F 673 at a given location on the test specimen to be an independent test result; note, however, that although a thickness value is required for each test result, the thickness may or may not be determined for each determination of the resistivity. The choice should be made based on the practice usually used when making measurements with the test instrument being evaluated.

R1-3.3 *Average Reading (of repetitive measurements) per Test Result: Interstitial Oxygen Content by Fourier Transform Infrared Spectroscopy* — In the case of measurements of interstitial oxygen content with FTIR spectrometers in accordance with ASTM Test Method F 1619 or DIN Method 50438/1, each determination reported by the instrument is found by averaging n scans; consider each reported average determination as a test result, and also report the number of scans used in evaluating the test instrument. Note that this number of scans should remain constant throughout the evaluation.

R1-3.4 *Average Reading (of a linear spatial distribution) per Test Result: Average Carrier Density by Mercury Probe C-V* — In the case of measurements of average carrier density in accordance with ASTM Test Method F 1392, a series of measurements of carrier density as a function of depth into the semiconductor is averaged to obtain the average carrier density in the test specimen; consider the average value as a test result. Note that the same depth range should be used throughout the evaluation.

R1-3.5 *Mean Value and Sample Standard Deviation (of an area spatial distribution) per Test Result: Wafer Mapping* — Frequently film thickness, sheet resistance, or other data obtained from wafer maps in accordance with Practice F 1618 is reported as a mean and sample standard deviation in order to facilitate comparisons of one wafer with another. In the context of this practice, the mean and standard deviation each may be treated as a test result. Alternatively, data from each measurement location (or a subset of the measurement locations) may be treated individually.

SEMI M28-0997 (Withdrawn 1000)
SPECIFICATION FOR DEVELOPMENTAL 300 mm DIAMETER POLISHED SINGLE CRYSTAL SILICON WAFERS

This document was balloted and approved for withdrawal in 2000.

1 Purpose

1.1 The developmental wafers covered by this specification are intended for use in research on and development of process and metrology equipment and fabrication processes required to manufacture high-density integrated circuits on 300 mm diameter single crystal silicon wafers. They can also be used to establish the techniques and metrology necessary to support a dimensional specification for 300 mm diameter circuit-quality (prime) wafers.

SEMI M29-1296
SPECIFICATION FOR 300 mm SHIPPING BOX

1 Purpose

This specification defines a container for safe transportation of 300 mm wafers from a wafer maker to a receiving dock of an IC maker site.

2 Scope

2.1 This specification additionally defines the parts necessary for a shipping box among cassettes specified in SEMI E57 and SEMI E1.9, within the range of the specifications in SEMI E57 and SEMI E1.9.

2.2 This specification also defines the size of a box containing a shipping cassette containing 300 mm wafers.

2.3 Although, as for material, use of plastic is a premise, actual material names are not defined for free selection based on progress of maker's technologies.

2.4 Although this specification directs a high-performance shipping box, this does not concretely define the performance on particle generation and sealing capability.

2.5 As for the count of contained wafers, this defines two sorts, that is, 13 and 25 wafers.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI E57 — Provisional Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI E1.9 — Provisional Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

4 Terminology

4.1 *box bottom* — A lower half of an outer box.

4.2 *box top* — An upper half of an outer box.

4.3 *cassette* — A cassette defined in SEMI E57 and SEMI E1.9.

4.4 *clamp* — A part to fix a box top and a box bottom mutually.

4.5 *clamping indent* — A groove formed with a box top and a box bottom. The groove which a clamp hooks for setting.

4.6 *front retainer* — A retainer which is attached in a front side of a cassette, the front side which is defined in SEMI E1.9.

4.7 *gasket area* — An area where gaskets are attached so as to reduce air flow in a shipping box which is generated by the difference between internal pressure and external pressure.

4.8 *orientation mark* — A mark expressed on a part for confirmation of cassette direction.

4.9 *outer box* — A container part of a shipping box, surrounding the whole objects so as to protect a shipping cassette, except gasket and clamps.

4.10 *poka-yoke* — A device applied to a rib so as not to be set in an incorrect direction in order to avoid an orientation failure when the part is set.

4.11 *rear retainer* — A retainer which is attached in a rear side of a cassette, the rear side which is defined in SEMI E1.9.

4.12 *retainer* — A part to be attached to a shipping cassette for retaining wafers in transportation so that the wafers do not move. There are two types, that is, a front retainer and a rear retainer.

4.13 *retainer hook* — A projection formed on a shipping cassette for attaching a retainer.

4.14 *setting hole* — A hole formed in a retainer for attaching the retainer. This makes a pair with a retainer hook.

4.15 *shipping box* — A whole container containing a shipping cassette. This is composed of a shipping cassette, an outer box, retainers, gasket, and clamps.

4.16 *shipping cassette* — A cassette additionally defined herein for shipping among cassettes.

4.17 *stacking rib* — A rib formed on a top surface of a box top and on a bottom surface of a box bottom so as not to collapse when shipping boxes are stacked. A rib positioned on the top is called a top rib, and a rib on the bottom a bottom rib.

4.18 *supporting rib* — A rib inside an outer box for supporting a cassette.

5 Requirements

5.1 *Part Construction* — A shipping box defined herein is composed of the parts shown in Figure 1.

The appearance of this part is one of embodiments of this definition.

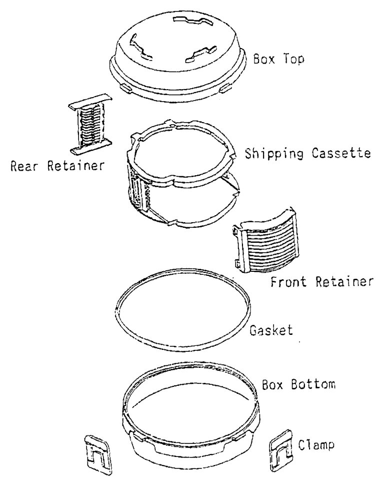

Figure 1
Components

5.2 *Shipping Cassette*

5.2.1 *Additional Dimensions* — Dimensions of a shipping cassette should conform to SEMI E57 and SEMI E1.9. However, in the above documents, there are many Max. or Min. notations, and hence, they are not sufficient to design a shipping box. Therefore, in Figure 2 and Table 1, necessary dimensions are added within the ranges defined in the above documents.

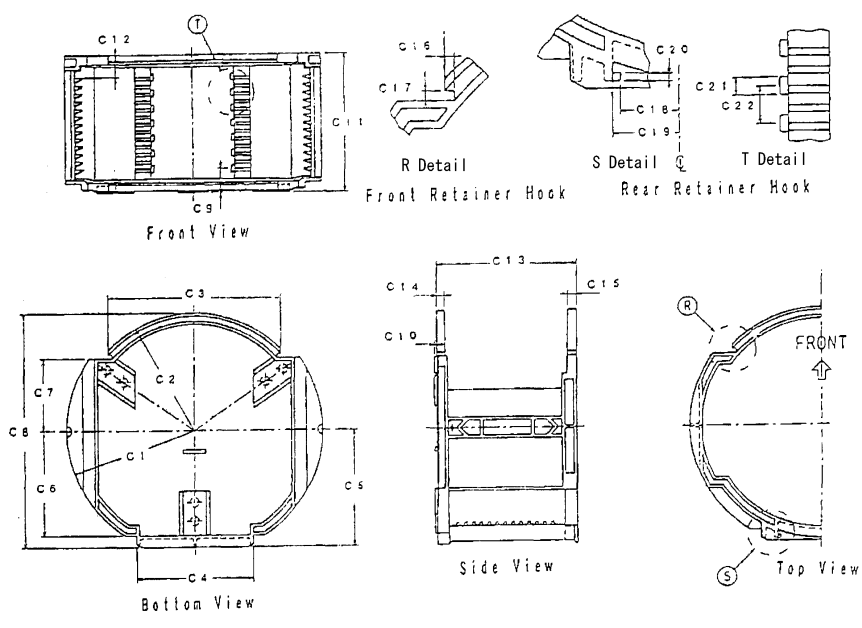

Figure 2
Additional Definition of Shipping Cassette

5.2.2 *Orientation Mark* — The orientation mark indicating the front side of a cassette is shown in Figure 3 and Table 1. This supports a user to manually set a cassette on a box bottom or a platform of equipment.

5.3 *Box Top*

5.3.1 *Outer Dimensions* — Outer dimensions of a box top are shown in Figure 4 and Table 2.

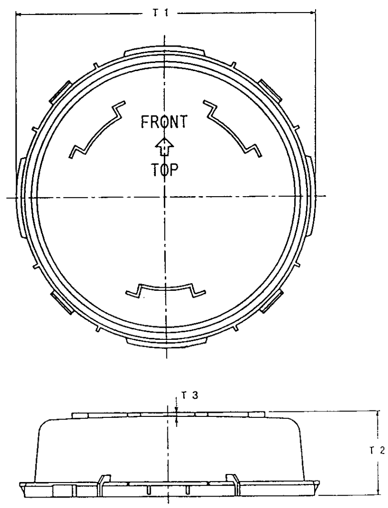

Figure 4
Outer Dimensions of Box Top

5.3.2 *Supporting Rib and Poka-yoke Rib* — Positions of a supporting rib for supporting a shipping cassette inside a box top and a poka-yoke (fool-proof) rib for avoiding setting the box top in a wrong orientation are shown in Figure 5 and Table 2.

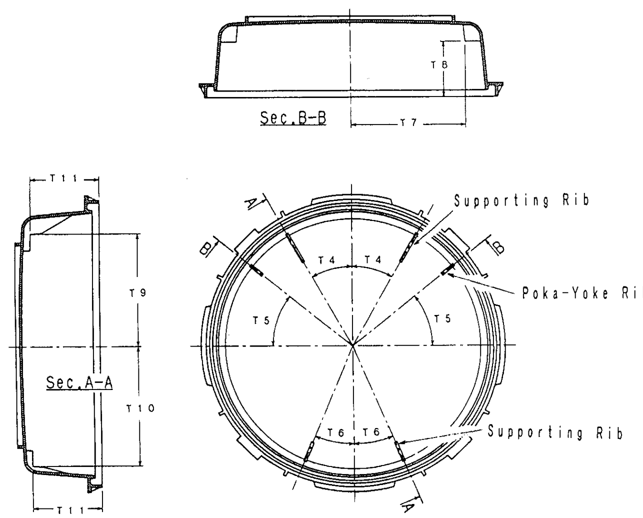

Figure 5
Supporting Rib and Poka-yoke Rib of Box Top

5.3.3 *Gasket Area* — It is required to provide a gasket in an area shown in Figure 6 and Table 2 if the gasket is provided.

5.3.4 *Clamping Indent* — Figure 7 and Table 2 show dimensions of a concave part for receiving a clamp. Refer to Figure 8 and Table 2 for horizontal positions.

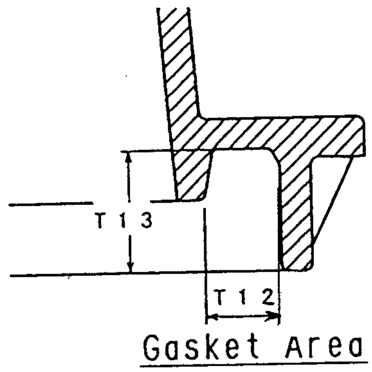

Figure 6
Gasket Area

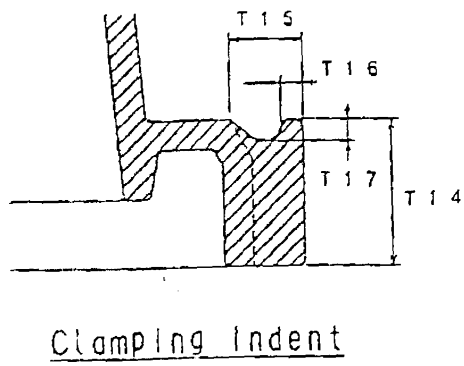

Figure 7
Clamping Indent

5.3.5 *Top Rib and Orientation Mark* — Dimensions of a top rib to avoid collapsing when shipping boxes stacked, and the position of an orientation mark are shown in Figure 8 and Table 2. In addition, since this rib makes a pair with a bottom rib, and is a poka-yoke rib, the shipping boxes can be stacked in a correct direction.

5.7 *Gasket* — A gasket is a part to be mainly designed with maker's know-how regarding its material and form. In addition, this is frequently revised for increase of quality.

Since there is no practical problem so long as its position is decided, the gasket is not defined. However, it should be provided in the area defined in Sections 5.3.3 and 5.4.3.

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was approved as a part of SEMI M29 by full letter ballot procedure.

A1-1 Heat-Resistant Temperature

Parts defined herein are not considered to be used under high temperature because it is assumed to be used under the usual conditions. As for operating temperature of each part, information from its maker should be confirmed.

A1-2 Orientation of Wafers in Transportation

It is necessary to vertically keep wafers in transportation. Therefore, it is necessary to clarify vertical holding indicated on buffering material and carton boxes.

A1-3 Using Procedure

The procedure for using a shipping box defined in this document is shown in Figure 17.

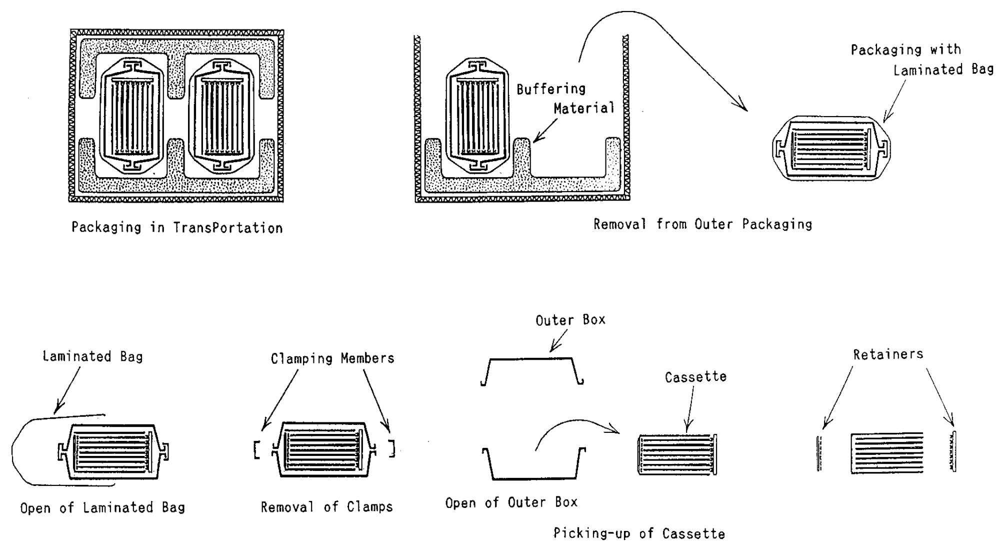

Figure 17
Example of Procedure for Using a Shipping Box

A1-4 Maximum Dimensions and Attached Location of Label

In case it is necessary to attach a label on a shipping box, the label should be attached in the area shown in Figure 18 and Table 7, and hence, a designer of a shipping box should not provide a projection in this area.

SEMI M30-0997
STANDARD TEST METHOD FOR SUBSTITUTIONAL ATOMIC CARBON CONCENTRATION IN GaAs BY FOURIER TRANSFORM INFRARED ABSORPTION SPECTROSCOPY

1 Purpose

The purpose of this document is to test substitutional atomic carbon concentration in GaAs by Fourier Transform Infrared Absorption Spectroscopy (FT-IR).

2 Scope

2.1 This referee test method covers the determination of substitutional carbon concentration in single crystal GaAs.

2.2 The useful range of carbon concentration measurable at room temperature by this test method is from the maximum amount of substitutional carbon soluble in GaAs to 1×10^{15} cm^{-3}. The detection limit depends on the equipment and measurement conditions. It is expected that many users of this test method can reduce the detection limit to 10^{14} cm^{-3} level. 77K measurement is effective to reduce the detection limit. In the case of 77K measurement, the upper limit is 1.3×10^{16} cm^{-3}, as described in the following article:

T.Arai et al : J. Electronic Industry, Vol. 30, 9 (1988) 38

2.3 The test method utilizes the relationship between carbon concentration and absorption coefficient at 580 cm^{-1} for room temperature measurement (around 582 cm^{-1} for 77K measurement), the infrared absorption band is associated with substitutional carbon in GaAs. These specific absorption bands in GaAs have been associated with the local vibration mode of C_{as}.

2.4 The method is applicable to Semi-Insulating (SI) GaAs. Slices can be any crystallographic orientation and should be polished or lapped and etched on both surfaces.

2.5 This test method is intended to be used with FT-IR spectrometers that are equipped to operate in the region including the wave number range from 700 to 500 cm^{-1}.

2.6 This standard may involve hazardous materials, operation, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 *Acronyms*

4.1.1 *CPAA* — Charged particle activation analysis

4.1.2 *FWHM* — Full width at half maximum, the width of the absorption band at half its magnitude as measured from the baseline.

4.1.3 *MCT* — Mercury cadmium telluride

4.1.4 *TGS* — Triglycine sulfate

4.2 Many of the terms associated with this test method can be found in ASTM Definitions E 131.

4.2.1 *baseline* — A linearly interpolated pattern over a limited spectral region of the ratio recording used to derive an absorption coefficient (see Figure 1 and refer to ASTM Practice E 168).

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

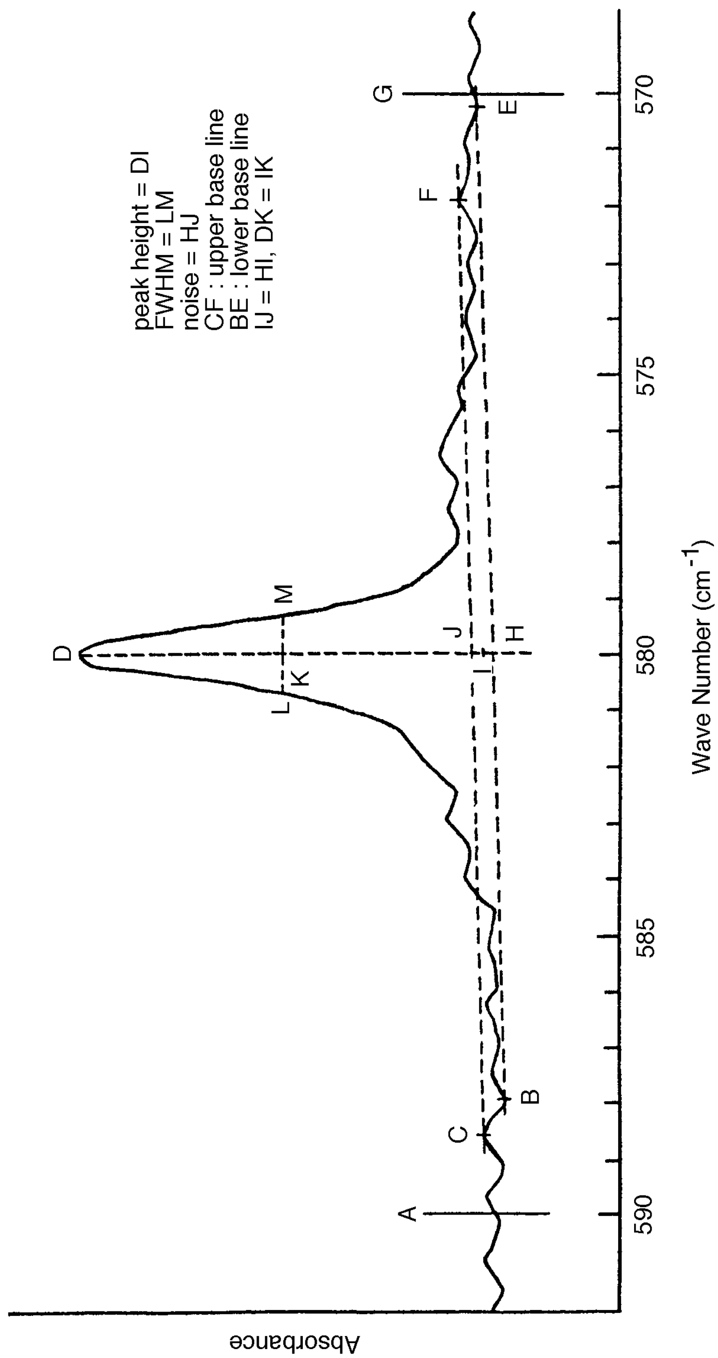

Figure 1
FT-IR Spectrum of C_{as} Local Mode Absorption in GaAs

4.2.2 *calibration coefficient* — Conversion factor to carbon concentration from absorbance or absorption coefficient of each FT-IR instrument.

4.2.3 *carbon concentration* — For purposes of this test method, the volume density of atomic carbon incorporated in the crystal lattice at substitutional positions. It is proportional to the absorption coefficient following Beer's law. Units are atoms per cubic centimeter.

4.2.4 *primary standard samples* — Samples where the carbon concentration is already known, as measured by the CPAA method (see Section 4.1.1). A set of primary standard samples is composed of 4 specimens with each carbon concentration as follows:

No.	*Thickness (mm)*	*Carbon Concentration* (cm^{-3})
#3	5.103	1.4×10^{15}
#5	5.013	12.0×10^{15}
#7	5.015	2.4×10^{15}
#15	4.994	3.2×10^{15}

These samples are preserved at SEMI Japan. Details (actual measured values and measurement errors, etc.) for these samples are described in the following article:

T.Arai et al : J. Electronic Industry, Vol. 30, 9 (1988) 38

4.2.5 *reference sample* — The nearly carbon-free GaAs sample used for calculating the subtracted spectrum which are used for determination of carbon concentration. The reference sample is used for room temperature measurement. It is recommended that the carbon concentration of the reference sample is $< 3 \times 10^{14}$ cm^{-3}.

4.2.6 *secondary standard samples* — The samples of which the carbon concentration was determined in a round-robin test by the FT-IR method using the primary standard samples. More than 3 samples covering the carbon concentration range from 1.5×10^{15} to 10.0×10^{15} cm^{-3} must be used. These samples are preserved as SEMI Japan, and will be lent out for determination of the calibration coefficient for specific FT-IR spectrometers.

5 Summary of Test Method

5.1 Test slices are prepared that are polished or lapped and etched on both sides to a thickness from 3 to 6 mm.

5.2 Apparatus should be calibrated by using the primary standard samples or secondary standard samples. This calibration coefficient is used to calculate the carbon concentration of specimens.

5.3 For room temperature measurement, a baseline is drawn in the differential spectrum (after subtraction of the reference sample spectrum) from which an absorption coefficient is derived. The range of baseline should be wider than ± 10 cm^{-1}. The baseline has to be determined in an interval of the spectra which is neither influenced by main peak at 580 cm^{-1} nor the side peak at 576 cm^{-1}. For 77K measurement, the range of baseline should be wider than ± 1.5 cm^{-1}.

6 Significance and Use

6.1 Carbon plays an important role in the determination of the compensation mechanism which determines the semi-insulating behavior of GaAs. As such the concentration is critical in determining the substrate resistivity.

6.2 As a dominant acceptor in SI-GaAs substrates, carbon could, potentially impact ion implantation activation.

7 Interferences

7.1 Stray light that reaches the detector will tend to reduce the calculated absorption coefficient value and thereby reduce the reported carbon concentration.

7.2 FT-IR instrument instruction manuals should be consulted if problems with the technique are suspected.

7.3 The carbon absorption band half width at room temperature must be less than 2 cm^{-1} for acceptable measurement results. Excessive width can be due to improper thickness matching or stress.

7.4 Specimens that do not exceed the instrument beam size will cause error. Use of apertures, or preferably beam condensers, can correct this problem.

7.5 The minimum detection level of this method is limited by the signal-to-noise ratio of the recording.

8 Apparatus

8.1 FT-IR with an operating range that includes the region of 700 to 500 cm^{-1}. Instrument resolution or spectral resolution at the carbon absorption band of 580 cm^{-1} for room temperature measurement and around 582 cm^{-1} for 77K measurement must not exceed 0.5 cm^{-1}, which means the effective resolution after apodization must not exceed 1.0 cm^{-1}.

8.1.1 Beam sizes and sample holder active areas for both the specimen and the reference must be within 10% of each other.

8.2 Instrument suitable for thickness measurement to an accuracy of 0.0025 mm.

8.3 Holders for these test and reference specimens that prevent any source of infrared radiation from bypassing the specimen.

8.4 For use at 77K, low-temperature cryostat capable of maintaining the specimen and reference at 77K temperature with suitable window materials (refer to ASTM Practice F 120).

8.5 Equipment and materials for slicing and polishing GaAs to a final thickness tolerance of 0.005 mm or less, and a total thickness variation of 0.01 mm or less.

9 Sampling

Unless otherwise specified, a GaAs slice used for the carbon test is to be measured at the nominal slice center. And if a slice is to be reduced in area prior to test, it is shaped such that the original slice center area is that which is tested.

10 Test Specimens

10.1 A single crystal slice of GaAs with a thickness from 3 to 6 mm must be used for carbon determination.

10.2 The test specimen must be carefully shaped to the following criteria:

10.2.1 Thickness variation over the measurement area of 0.005 mm or less.

10.2.2 Same surface preparation on both front and back surfaces. For room temperature measurement, surface preparation of specimen should be same with reference sample. For 77K measurement, mirror polishing on both surface or same surface preparation with standard sample is recommended.

10.2.3 Final thickness agreement between specimen and reference samples of 0.1 mm.

10.2.4 Surface area large enough such that with respect to the holders no incident radiation can bypass either specimen or reference.

11 Procedure

11.1 Prepare FT-IR in accordance with the manufacture's instructions.

11.2 Determine the differential transmission spectrum from 700 to 500 cm^{-1} in accordance with of ASTM Practice F 120.

11.2.1 The FWHM must not exceed 2 cm^{-1} to achieve reliable results. If this is not met, recheck test and reference specimen mechanical properties, use slower scan speed, or longer measuring time, and reverify FT-IR operating conditions.

11.2.2 Reference to Figure 1 and Recommended ASTM Practice E 168, Section 7, for assistance in establishing a baseline on the finished spectrogram. Baseline determination is very important to this method, and becomes more critical as the measured carbon level decreases (refer to ASTM Practice E 168).

11.2.3 For room temperature meansurement, the following conditions are recommended:

- Detector : Broadband MCT (or TGS) (see Sections 4.1.3 and 4.1.4)
- Resolution : 0.5 cm^{-1}
- S/N ratio : > 3
- Range of wave number : including 700 – 500 cm^{-1}
- Aperture : Optimum for each FT-IR
- Apodization function : Triangle
- Smoothing : Not applicable
- Reference : Air, reference sample
- Temperature : 290 ~ 300K

11.2.4 Make the determination at low temperature (77K) if increased sensitivity is required. Follow the same test conditions as described in Sections 11.1 and 11.2 except reference and temperature.

11.3 Determination of the calibration coefficient should be done once or more times per year. Four or more secondary standard samples should be used for this calibration. The user of this method can have and use the internal standard samples to check the spectrometer frequently.

12 Calculations

12.1 Calculate the absorption coefficient, α, using the expression:

$$\alpha = 1X \cdot 1n\,(I_0/I) = 1/X \cdot 2.303 \cdot (\text{peak height of absorption})$$

where :

α = absorption coefficient

X = specimen thickness, cm,

I = transmitted intensity at peak absorption (580 cm^{-1} for room temperature, 582 cm^{-1} for 77K, and

I_0 = baseline intensity at peak absorption, I.

12.2 Determine the calibration coefficient of each FT-IR using the least square method in the following equations:

$$[C_0] = \beta \cdot \alpha_0 \cdot \Delta_0 \text{ or } [C_0] = \beta \cdot \alpha_0$$

where :

$[C_0]$ = already known carbon concentration in standard samples

α_0 = absorption coefficient of standard samples

Δ_0 = FWHM of standard samples

β = calibration coefficient of each FT - IR

12.3 Calculate the concentration of substitutional carbon in atoms/cm^3 with the use of the following equations:

$$[C] = \beta \cdot \alpha \cdot \Delta \text{ or } [C] = \beta \cdot \alpha$$

where :

[C] = carbon concentration in test specimen

α = absorption coefficient of test specimen

Δ = FWHM of test specimen

β = calibration coefficient of each FT - IR, determined in 12.2

13 Report

13.1 The following information shall be included in the report for referee and research measurements:

13.1.1 Instruments used, detector, resolution, measurement time, range of wave number, aperture, apodization function, smoothing, specimen measurement temperature (room temperature or 77K).

13.1.2 Specimen thickness, and identification.

13.1.3 Calibration coefficient of FT-IR used, width of base line.

13.1.4 FWHM in cm^{-1}, calculated absorption coefficient or absorption, and carbon concentration.

13.1.5 Date of measurement, organization performing test, and location.

13.1.6 Use of any special techniques, such as beam condenser, scale expansion, scan suppression, etc.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M31-0999
PROVISIONAL MECHANICAL SPECIFICATION FOR FRONT-OPENING SHIPPING BOX USED TO TRANSPORT AND SHIP 300 mm WAFERS

This provisional specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the North American Physical Interfaces & Carriers Committee. Current edition approved by the North American Regional Standards Committee on July 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999. Originally published in 1998; previously published June 1999.

1 Purpose

1.1 This standard partially specifies the front-opening shipping box (FOSB) used to ship 300 mm wafers from wafer suppliers to their customers (typically IC manufacturers).

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces. Only the physical interfaces for FOSB are specified; no materials requirements or micro-contamination limits are given. However, this standard has been written so that both metal and injection-molded plastic FOSBs can be manufactured in conformance with it.

2.2 This standard assumes that the FOSB is used in the last process in wafer manufacturing, in acceptance and inspection, and in transferring the wafers from the FOSB to a FOUP or open cassette inside an IC manufacturing facility. The FOSB is not intended to be used in IC manufacturing processes. It is recommended that wafers be transferred from the FOSB to a FOUP or open cassette using automated methods. As described in Section 5.3, the purchaser needs to specify which type of shipper door is required:

1) Manual door as described in Section 5.3.1; or

2) Automated door as described in Section 5.3.2.

2.3 This standard (as well as other 300 mm standards) is provisional. Once FOSB testing and initial volume production is done (or any change related to the FOSB is made to a document listed in Section 3 below), this standard should be modified and upgraded from provisional status. Where possible, the specified design features are in accord with like features in SEMI E1.9 and SEMI E47.1.

2.4 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

bilateral datum plane — a vertical plane that bisects the wafers and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

box — a protective portable container for a carrier and/or substrate(s) (as defined in SEMI E44).

carrier — an open structure that holds one or more substrates.

carrier bottom domain — volume (below *z*6 above the horizontal datum plane) that contains the bottom of the carrier (as defined in SEMI E1.9).

carrier capacity — the number of substrates that a carrier holds (as defined in SEMI E1.9).

carrier sensing pads — surfaces on the bottom of the carrier for triggering optical or mechanical sensors (as defined in SEMI E1.9).

carrier side domains — volumes (from *z*6 above the horizontal datum plane to *z*15 above the top nominal wafer seating plane) that contain the mizo teeth or slots that support the wafer and the supporting columns on the sides and rear of the carrier (as defined in SEMI E1.9).

carrier top domain — volume (higher than *z*15 above the top wafer) that contains the top of the carrier (as defined in SEMI E1.9).

facial datum plane — a vertical plane that bisects the wafers and that is parallel to the front side of the carrier (where wafers are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the carrier is loaded and unloaded (as defined in SEMI E57).

front-opening shipping box (FOSB) — a shipping box with a front-opening interface.

front-opening unified pod (FOUP) — a box (that complies with SEMI E47.1) with a non-removable cassette (so that its interior complies with SEMI E1.9) and with a front-opening interface (that mates with a FIMS port that complies with SEMI E62) (as defined in SEMI E47.1).

horizontal datum plane — a horizontal plane from which projects the kinematic-coupling pins on which the carrier sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

minienvironment **—** a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

nominal wafer centerline — the line that is defined by the intersection of the two vertical datum planes (facial and bilateral) and that passes through the nominal centers of the seated wafers (which must be horizontal when the carrier is placed on the coupling) (as defined in SEMI E57).

optical wafer sensing paths — lines of sight for optically sensing the positions of the wafers. Several horizontal optical wafer sensing paths are present in between the carrier side domains. In addition, two vertical optical wafer sensing paths are created by rectangular exclusion zones in the front of the carrier top and bottom (as defined in SEMI E1.9).

shipping box — a protective portable container for a carrier and/or wafer(s) that is used to ship wafers from the wafer suppliers to their customers.

shipping-box front-opening mechanical interface (SFMI) — optional automated door style for a shipping box that is compatible with SEMI E62, with exceptions as noted in Section 5.3.2.

virtual tracking unit — an entity (which could be a number of substrates or an individual die or mask group) that the factory floor control system treats as a single unit for tracking purposes (as defined in SEMI E1.9).

wafer carrier — any cassette, box, pod, or boat that contains wafers (as defined in SEMI E15).

wafer extraction volume — the open space for extracting a wafer from the carrier (as defined in SEMI E1.9).

wafer pick-up volume — the space that contains entire bottom of a wafer if the wafer has been pushed to the rear of the carrier (as defined in SEMI E1.9).

wafer set-down volume — the open space for inserting and setting down a wafer in the carrier (as defined in SEMI E1.9).

5 Requirements

The shipping box has the following components and sub-components:

Key:

- Required feature

◊ Optional feature

- Door on front
  - ◊ Manual door (optional)
  - ◊ Automated door (optional)
  - Holes for latch keys that lock the door to the SFMI interface when the door is unlatched from the box
  - Holes for registration pins
  - Door presence sensing areas
- Top
  - ◊ Top robotic handling flange (optional)
- Interior
  - Non-removable cassette with supports for 13 or 25 wafers
  - Wafer capture mechanism
  - 2 end effector exclusion zones

- Sides
  - ◊ Ergonomic manual handles (optional)
- Bottom
  - 5 carrier sensing pads
  - 4 Info pads
  - 3 features that mate with kinematic coupling pins and provide a 10 mm lead-in
  - ◊ 3 features that mate with kinematic coupling pins and provide a 15 mm lead-in (optional)

5.1 *Kinematic Couplings* — The physical alignment mechanism from the FOSB to the tool load-port (or a nest on a vehicle or in a stocker) consists of features (not specified in this standard) on the top entity that mate with three or six pins underneath as defined in SEMI E57. The three features that mate with the kinematic coupling pins must provide a lead-in capability that corrects a FOSB misalignment of up to *r*69 in any horizontal direction.

5.2 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*65 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*66 to prevent small contact patches with large stresses that might cause wear and particles. Note that these limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the FOSB supplier. Note also that this radius applies to every required feature unless another radius is called out specifically. Here a required feature is an area on the surface of the FOSB supplier. Note also that this radius applies to every required feature unless another radius is called out specifically. Here a required feature is an area on the surface of the FOSB specified by a dimension (or intersections of dimensions) that has a tolerance and not just a maximum or minimum (such as the edges of the robotic handling flange).

5.3 *Door* — It is recommended that the FOSB not be vertical when it is opened or closed. When the FOSB is in a vertical orientation with the door removed, the wafers must be restrained from touching each other by appropriate wafer support design or other retaining techniques.

5.3.1 *Manual Door* — If chosen, the manual door option requires no automation to open the door. An exclusion zone surrounding the manual door area is specified in the standard. There are several possible techniques for sealing and clamping the manual door that meet user requirements. Therefore, only an exclusion zone surrounding the manual door area is specified in this standard. All features of the door and door retaining mechanism must lie within the exclusion zone illustrated in Figure 1 and must not interfere with other specified features (including the kinematic couplings). Figure 1 and dimensions *x*81, *y*81, *y*82, *z*82, and *z*83 define the manual door area and therefore apply only to the manual door option as described in this section.

5.3.2 *Automated Door* — If chosen, the SFMI automated door must be designed to mate with a port that conforms to SEMI E62. Note the following exceptions: the maximum required latch torque is 4.4 N-m instead of 1.7 N-m. It is recommended then that the automated door opener provide at least 4.5 N-m to open or close the automated door in conjunction with the increased torque. If the increased torque does not allow for the FOSB to be clamped solely using the front clamping feature, the FOSB might need to be supported with additional devices attached to the equipment load port.

5.3.2.1 Since the FOSB has a $y51 \geq 50$ mm, instead of 140 mm as in SEMI E47.1, a longer stroke is required to remove the door. Note that there must be a provision for opening the automated door without a loadport.

5.4 *Seal Zones for Door* — On the exterior side of the port (at a distance *y*33 from FOSB facial datum plane) are areas for sealing to the FOSB. It is recommended that FOSBs be designed with surfaces opposite these seal zones that are at a distance of *y*33 from the facial datum plane (where *r*38 and *y*33 are specified in SEMI E62) and that have a flatness of *y*42. The frame seal zone is on the frame of the port door in the area between *x*34 and *x*35 from the facial datum plane and between *z*34 and *z*35 from the vertical centerline of the port (see Figure 2). Table 2 defines the dimensions.

5.5 *Wafer Capture and Centering* — When the FOSB is closed, the wafers must be captured in the FOSB to prevent movement during subsequent handling, including shipping. It should be noted that wafers are typically shipped in a vertical orientation and generally require support from a secondary package. It is recommended that this secondary package be designed to allow for easy removal of the FOSB from the secondary package.

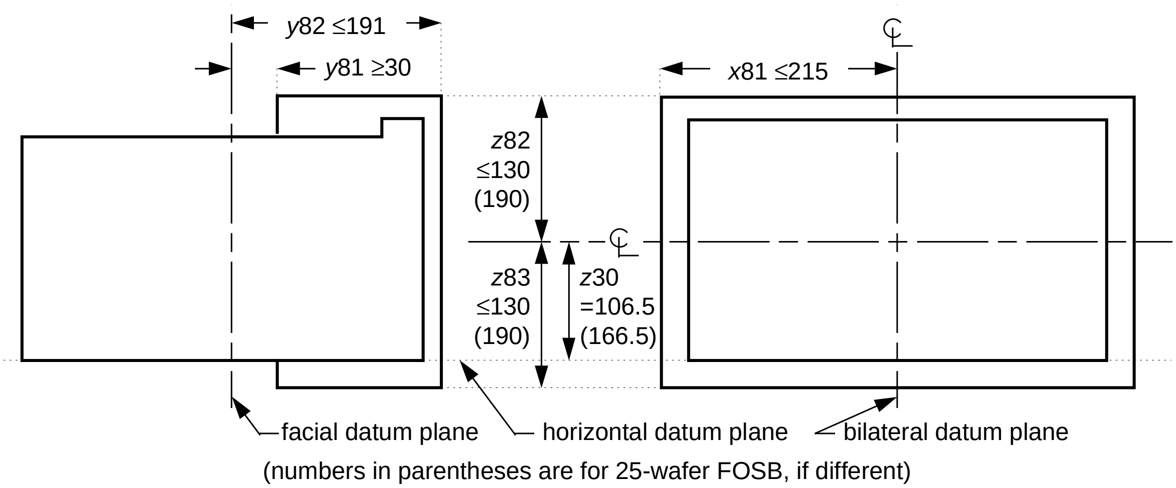

Figure 1
Manual Door Area

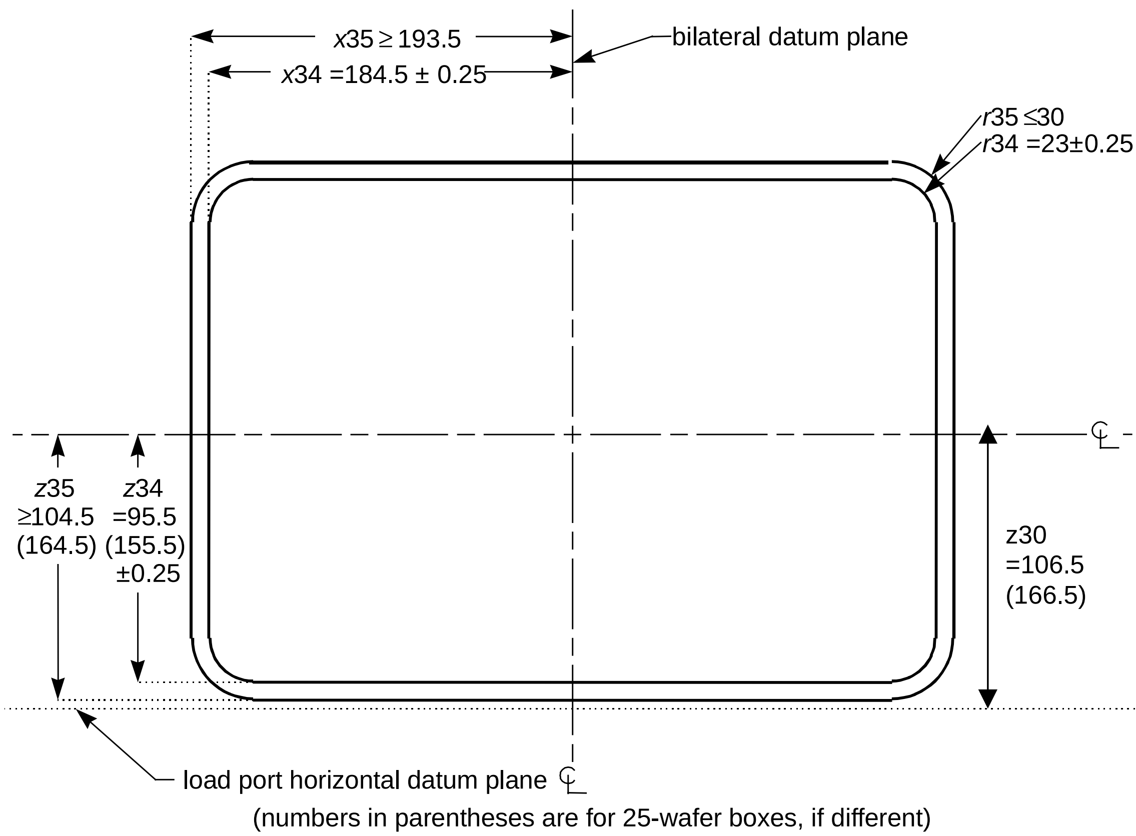

Figure 2
Dimensions for Front-Opening Interface

5.6 *Wafer Orientation and Numbering* — The wafers must be horizontal when the FOSB is placed on the coupling, and the wafers slots are numbered in increasing order from bottom to top (so the bottom wafer is wafer number 1, the next wafer up is wafer number 2, etc.).

5.7 *Internal Horizontal Dimensions* — Figure 3 shows a cross-section of the horizontal boundaries of the FOSB side domains (which contain the parts of the FOSB higher than *z*6 above the horizontal datum plane and lower than *z*15 above the top wafer). In this and following figures, the most heavy lines are used for surfaces that have tolerances (not surfaces that have only maximum or minimum dimensions). Table 2 defines the dimensions shown in this and following figures.

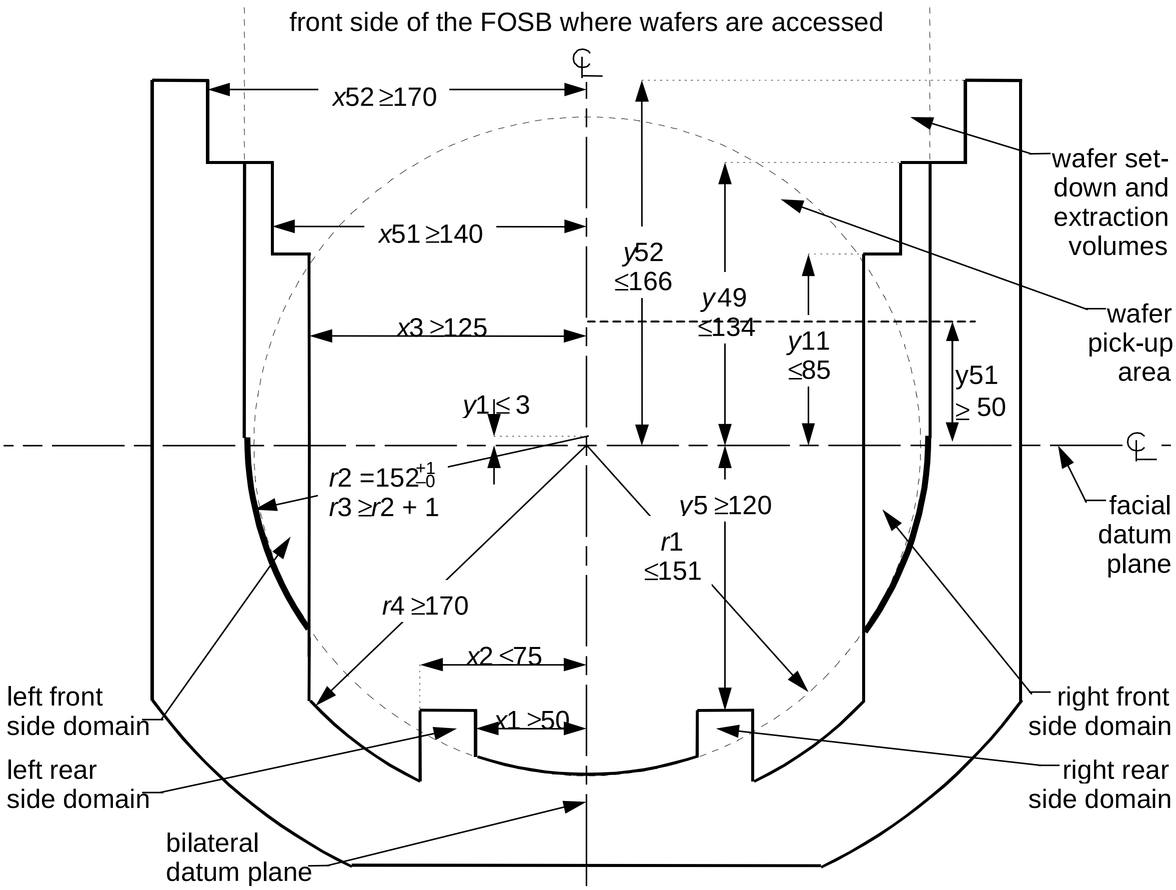

Figure 3
Top View of FOSB Internal Dimensions

5.8 *Internal Vertical Dimensions* — Figures 4 through 8 show the vertical dimensions of the internal FOSB. Note that *z*8 (the height of the bottom nominal wafer seating plane above the horizontal datum plane) and *z*12 (the distance between adjacent nominal wafer seating planes) are given as absolute distances with no tolerance. This means that the sum of actual height variations in the FOSB from the kinematic coupling to the supporting features holding each wafer must be contained within the tolerance of *z*10 with no further stack-up at each higher wafer. The method for meeting this requirement is left up to the FOSB supplier. Table 2 defines all dimensions for Figures 4 through 8.

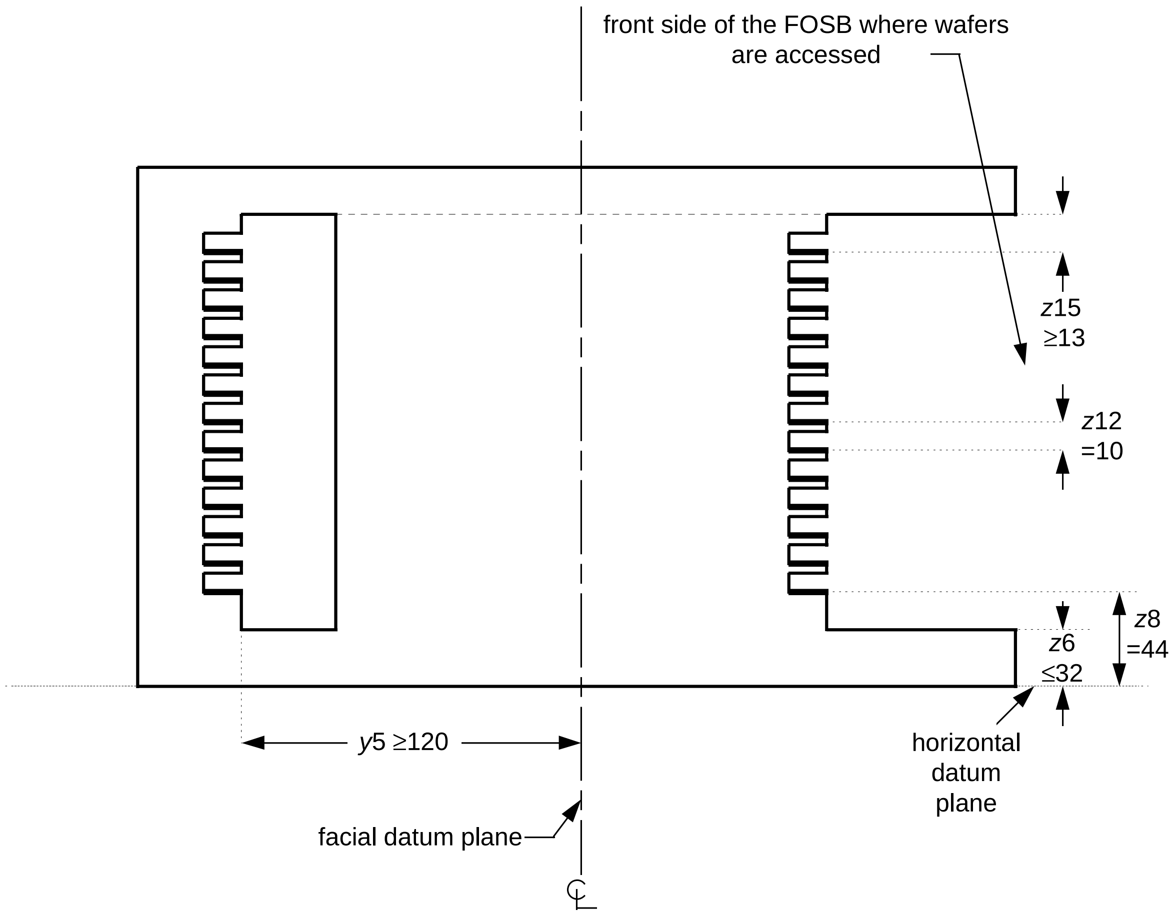

Figure 4
Side View of FOSB Internal Dimensions

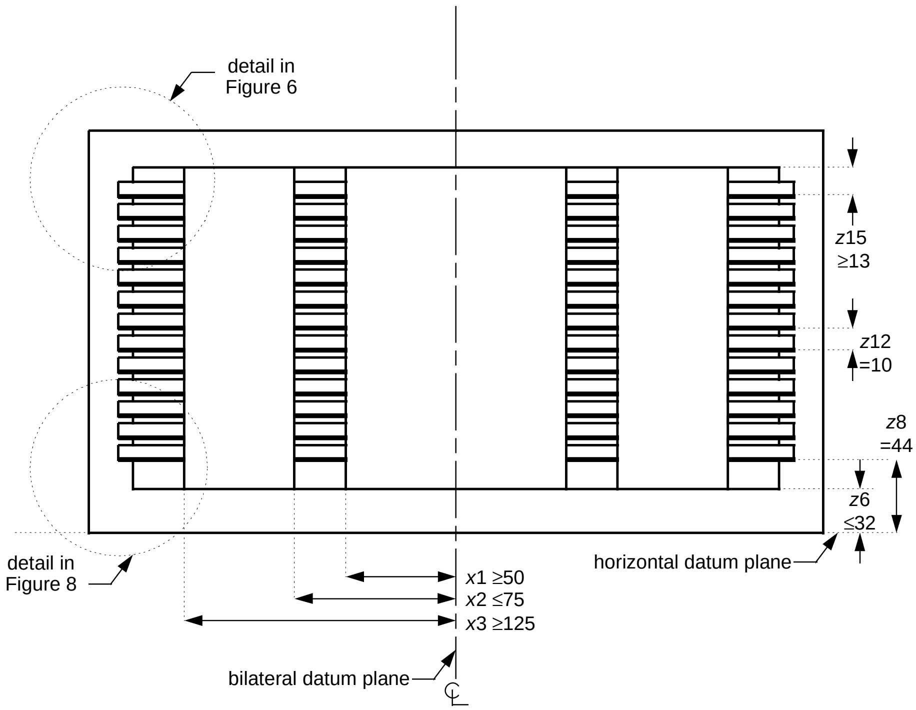

Figure 5
Front View of FOSB Internal Dimensions

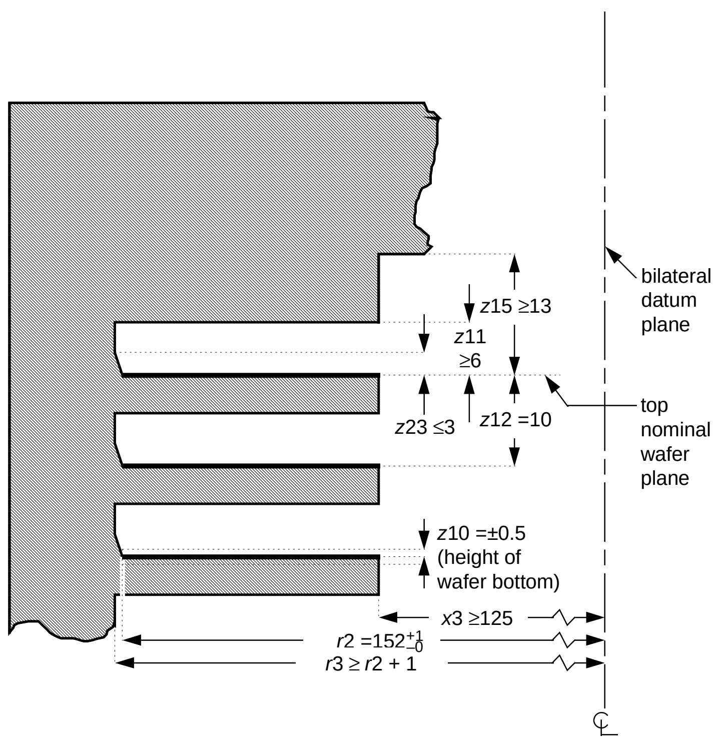

Figure 6
Upper Cross-Section at Facial Datum Plane

5.8.1 *Wafer Set-Down Volume* — The open space for the wafer set-down volume consists of a cylindrical section with radius *r*2 and a main axis parallel to and *y*1 in front of the nominal wafer centerline. The top of this cylindrical section is *z*11 above the nominal wafer seating plane and its bottom is *z*10 above the nominal wafer seating plane. The implications for wafer positioning of the tolerance on *r*2 are as follows. The wafers should be placed in the FOSB within a circle of radius corresponding to the smaller bound on *r*2 to avoid touching the edge of the wafer to the side of the FOSB. Once the wafer has been placed, the FOSB must not allow a wafer to move outside of a circle of radius corresponding to the larger bound on *r*2. There are two exceptions to this limit on wafer movement. When the wafer is pushed toward the rear of the FOSB, the location of the wafer is defined by the wafer pick-up volume (see Section 5.8.3). When the FOSB is gently tilted forward up to 45°, the wafers may slide forward, but it is recommended that they not extend further than *y*20 from the facial datum plane. This may be accomplished by designing the teeth supporting the wafers to include a "wafer stopper" at the front that is outside of *r*2 and under *z*29 as illustrated in Figure 7.

5.8.2 *Wafer Extraction Volume* — The open space for the wafer extraction volume includes a cylindrical section with radius *r*3 and a main axis parallel to and *y*1 in front of the nominal wafer center line. The top of this cylindrical section is *z*11 above the nominal wafer seating plane and its bottom is *z*23 above the nominal wafer seating plane. The wafer extraction volume also includes the extrusion out the front of the FOSB of this cylindrical section and the portion of the wafer set-down volume above *z*29. The implications for wafer extraction of the definition of dimension *r*3 ($r3 \geq r2 + 1$) are as follows. The FOSB must give an extra 1 mm (0.04 in.) of horizontal clearance once the wafer is picked up from wherever it ends up (within the bounds of *r*2) after transport in the FOSB.

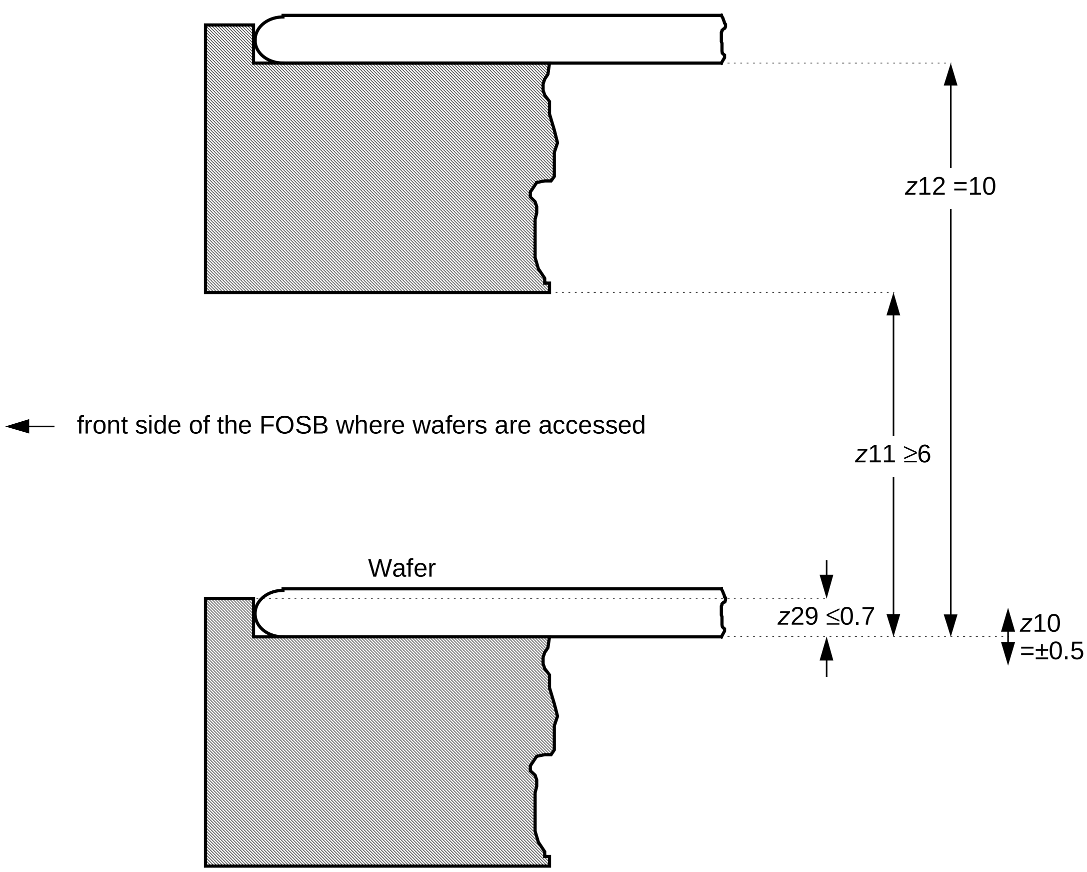

Figure 7
Features That Prevent Wafer Creep-Out

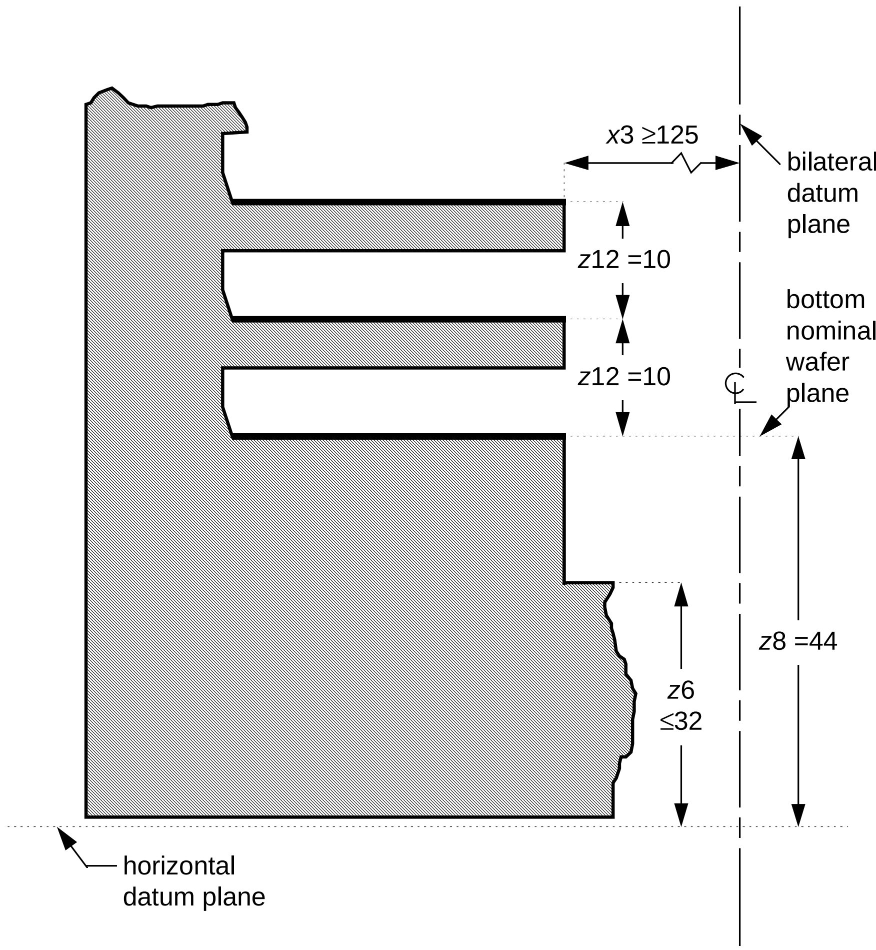

Figure 8
Lower Cross-Section at Facial Datum Plane

5.8.3 *Wafer Pick-Up Volume* — If a wafer is placed in the wafer set-down volume and is then pushed toward the rear of the FOSB, then the entire bottom of the wafer must be contained in the wafer pick-up volume. However, if the wafer is not pushed toward the rear of the FOSB, then the wafer may only be somewhere within the wafer extraction volume. The wafer pick-up volume is defined by a cylindrical section with radius *r*1 and a main axis at the nominal wafer centerline. Its top and bottom are the upper and lower tolerance of *z*10 around the nominal wafer seating plane.

5.9 *Pitch and Capacity* — Table 1 shows the different options with regard to the wafer pitch (spacing) and the FOSB capacity. Again, no tolerance is given on the wafer pitch (*z*12), for reasons given in Section 5.8.

Table 1 Pitch and Capacity Options

Option Number	*FOSB Capacity (c)*	*Wafer Pitch (z12)*	*Wafer Clearance (z11)*
1	13 wafers	10 mm (0.39 in.)	6 mm (0.24 in.) minimum
2	25 wafers	10 mm (0.39 in.)	6 mm (0.24 in.) minimum

Table 2 Internal FOSB Dimensions (Figures 2–8)

Symbol Used	*Figure Number*	*Value Specified*	*Datum Measured from*	*Boundary or Feature Measured to*
*r*1	3	151 mm (5.94 in.) maximum	nominal wafer centerline	outer edge of wafer pick-up volume
*r*2	3, 6	152 = 1 – 0 mm (5.99 + 0.03 – 0 in.)	*y*1 in front of nominal wafer centerline	encroachment of FOSB side domains on wafer set-down volume
*r*3	3, 6	*r*2 + 1 mm (0.04 in.) minimum	*y*1 in front of nominal wafer centerline	encroachment of FOSB side domains on wafer extraction volume
*r*4	3	170 mm (6.69 in.) minimum	nominal wafer centerline	encroachment of FOSB on end effector exclusion zone between front and rear FOSB side domains
*x*1	3, 5	50 mm (1.97 in.) minimum	bilateral datum plane	inside of rear FOSB side domains
*x*2	3, 5	75 mm (2.95 in.) maximum	bilateral datum plane	outside of rear FOSB side domains
*x*3	3, 5, 6, 8	125 mm (4.92 in.) minimum	bilateral datum plane	inside of front FOSB side domains
*x*51	3	140 mm (5.51 in.) minimum	bilateral datum plane	interior of FOSB sides between *y*11 and *y*49
*x*52	3	170 mm (6.69 in.) minimum	bilateral datum plane	interior of FOSB sides between *y*49 and *y*52
*y*1	3	3 mm (0.12 in.) maximum	facial datum plane	origin of *r*2 and *r*3 on bilateral datum plane
*y*5	3, 4	120 mm (4.72 in.) minimum	facial datum plane	front of rear FOSB side domains
*y*11	3	85 mm (3.35 in.) maximum	facial datum plane	interior of FOSB sides between *x*3 and *x*51
*y*20‡	None	158 mm (6.22 in.)	facial datum plane	maximum protrusion of wafers toward the front of the FOSB
*y*49	3	134 mm (5.28 in.) maximum	facial datum plane	interior of FOSB sides between *x*51 and *x*52
*y*51	3	50 mm (1.97 in.) minimum	facial datum plane	rear of door
*z*6	4, 5, 8	32 mm (1.26 in.) maximum	horizontal datum plane	top of FOSB bottom domain
*z*8	4, 5, 8	44 mm (1.73 in)	horizontal datum plane	bottom nominal wafer seating plane
*z*10	6, 7	0 ± 0.5 mm (0.00 ± 0.02 in.)	each nominal wafer seating plane	entire bottom of the wafer
*z*11	6, 7	See Table 1.	each nominal wafer seating plane	encroachment of FOSB side domains on clearance above the wafer
*z*12	4, 5, 6, 7, 8	See Table 1.	each nominal wafer seating plane	adjacent nominal wafer seating planes
*z*15	4, 5, 6	13 mm (0.51 in.) minimum	top nominal wafer seating plane	bottom of FOSB top domain
*z*23	6	3 mm (0.12 in.) maximum	each nominal wafer seating plane	bottom of wafer extraction volume
*z*29	7	0.7 mm (0.028 in.) maximum	each nominal wafer seating plane	encroachment of FOSB side domains under wafer extraction volume

‡ These dimensions are for optional features.

5.10 *External Dimensions* — Figures 9 through 13 respectively show the side view, rear view, top view, robotic flange, and bottom view for the front-opening FOSB. Table 3 defines all of the dimensions. If an identification tag is used, it must be located at the bottom rear centered on the bilateral datum plane and must be contained within the maximum outer dimensions of the FOSB.

5.11 *Human Handles* — All handles for use by humans must either be contained within the maximum outer dimensions of the FOSB, be detached when not in use, or be retractable into the maximum outer dimensions when not in use. Although such handles may extend past *x*53, they must still be contained within *x*50, *y*40, and *r*67. Handles for use by humans (if present) must follow SEMI S8, and they must require the use of both hands (each using a full wrap-around grip, given the minimum clearance requirement in SEMI E15.1). Automation handling features shall not be considered dual purpose unless they are designed to meet SEMI S8 guidelines.

5.12 *Automation Handling* — On the top of the FOSB, there is an optional robotic handling flange for manipulating the FOSB as illustrated in Figure 12. On the bottom of the FOSB, there are optional rails for use with roller conveyors or forklifts. Although they are only required to extend *y*58 to the left and right, it is recommended that they be as long as possible. Beyond *y*58, only the lower bound on *z*43 apply. These optional conveyor rails (defined by *x*56, *x*57, and *z*43) are located on the left and right bottom edges of the front-opening shipping box. The conveyor rails also have vertical cylindrical pin holes for fork lift centering (defined by *d*65).

(numbers in parentheses are for 25-wafer FOSB, if different)

Top Robotic Handling Flange

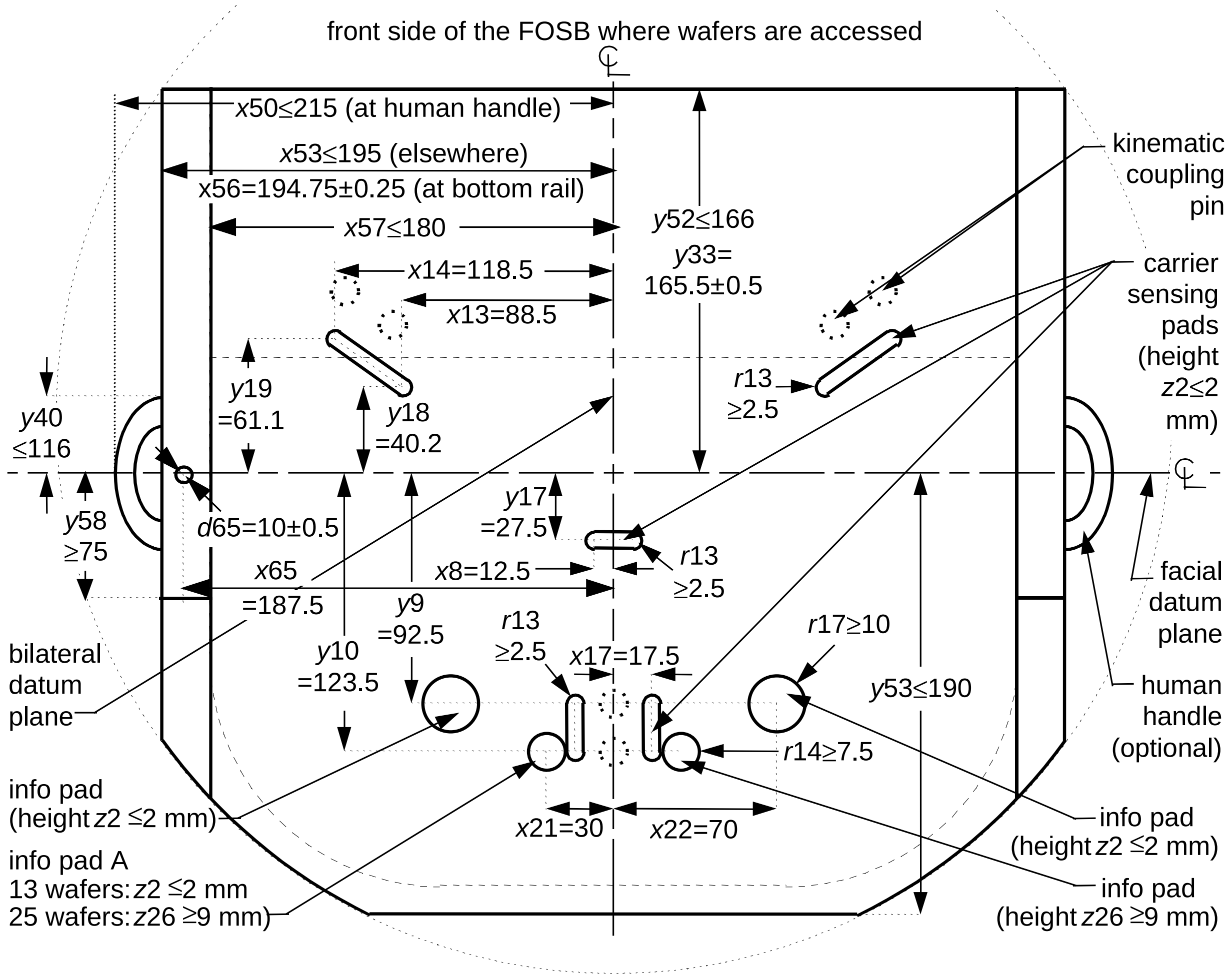

Figure 13
Bottom View of FOSB

5.13 Sensing Pads — As shown in Figure 13, when the FOSB is fully down on the kinematic coupling, the carrier sensing pads must be z2 above horizontal datum plane. It is recommended that the areas surrounding all of the carrier sensing pads be designed in conjunction with the features that mate with kinematic coupling pins so that a mechanical sensor pin cannot interfere with the lead-in function of the kinematic couplings. Other sensing pads (called info pads and given letter names) communicate information about the carrier. Note that since this is a bottom view, the positions of sensors on a load port will be switched, with the sensor for info pad A on the right and the sensor for info pad B on the left as one faces the tool from the front. Info pad A (on the lower left in Figure 13) indicates the FOSB capacity (the number of wafers). Info pad A must be in the down position (at z2 above horizontal datum plane) if the FOSB holds 13 wafers and must be in the up position (at z26 above horizontal datum plane) if the FOSB holds 25 wafers. Info pad B is allowed to be at either height (up or down) as specified by the purchaser. If such information is not required by the purchaser, info pad B must be up. Info pads C and D (slightly forward and to the outside of info pads A and B) are allowed to be at either height (up or down) as specified by the purchaser. If such information is not required by the purchaser, info pads C and D must both be up. Table 3 defines all dimensions.

Table 3 External FOSB Dimensions (Figures 9–13)

Symbol Used	*Figure Number*	*Value Specified*	*Datum Measured from*	*Feature Measured to*
α‡	12	60°	bilateral datum plane	centerline of the right and left kinematic grooves in the top robotic handling flange
β‡	12	45 ± 1°	nominal wafer centerline	surface of the center hole in the top robotic handling flange
γ‡	12	52 ± 1°	bilateral datum plane or vertical plane rotated α away from it about nominal wafer centerline	angled surface of the kinematic grooves in the top robotic handling flange
θ‡	12	45 ± 0.5°	either vertical datum plane	sides of position and orientation notches
*d*63‡	12	35 ± 0.1 mm (1.378 ± 0.004 in.)	diameter centered on the nominal wafer centerline	sides the center hole in the top robotic handling flange at height *z*47
*d*65	9, 10, 13	10 ± 0.5 mm (0.39 ± 0.02 in.)	diameter centered on the intersection of *x*65 and the facial datum plane	surface of cylindrical fork-lift pin holes in left and right bottom conveyor rails
*r*13	13	2.5 mm (0.10 in.) minimum	line segment along center of carrier sensing pad	edge of carrier sensing pad
*r*14	13	7.5 mm (0.30 in.) minimum	intersection of *x*21 and *y*10	edge of info pads A and B
*r*17	13	10 mm (0.39 in.) minimum	intersection of *x*22 and *y*9	edge of info pads C and D
*r*34	2	23 ± 0.25 mm (0.906 ± 0.010 in.)	not applicable	inside corner of frame seal zone
*r*35	2	30 mm (1.18 in.) maximum	not applicable	outside corner of frame seal zone
*r*59‡	12	6 mm (0.24 in.) maximum	not applicable	radius on peak of kinematic grooves in the top robotic handling flange

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix is an official part of SEMI M31 and was approved by full letter ballot procedures on July 15, 1999.

A1-1 Although FOSB parameters supporting effective reuse and cleaning (washing/drying) are not defined in this document, it is essential that these capabilities be considered for a successful overall shipping box design.

A1-2 It is important to note that shipping boxes containing wafers are typically bagged for shipment to the IC manufacturer. It is therefore important to design the outer surfaces of the shipping box to be compatible with this common practice.

SEMI M32-0998
GUIDE TO STATISTICAL SPECIFICATIONS

1 Purpose

1.1 Specifications are based on requirements negotiated between trading partners. This document describes an explicit specification form that defines the risk level as a part of parametric specifications. This approach uses process capability information to focus quality improvement efforts, reduce sampling, and maintain low risks. It is based on the fundamental belief that specifications should facilitate the movement toward processed-in quality instead of inspected-in quality.

1.2 It is important for users and suppliers to acknowledge and mutually agree on quality levels so the methods employed will satisfy their expectations. Statistical specifications provide a convenient way to do this.

1.3 Statistical specifications are designed to facilitate the movement toward processed-in quality. They are most appropriate for processes that have been statistically characterized. This means the shape of the statistical distribution that created the product is known, or can be approximated to the satisfaction of the user and the supplier. It also implies that the statistical control of the process and the measurement systems are defined to the level that is necessary to meet the current needs.

2 Scope

2.1 This guide may be used when changing or adding specifications to SEMI M18.

2.2 Statistical specifications apply to all processes that have been statistically characterized. Solutions are given for two product distribution shapes (normal & lognormal), and the advantages of these solutions are explained. Appendix 3 shows the statistically characterized shape for many common silicon wafer processes.

2.3 This guide applies to processes related to the production and use of silicon wafers. It may also be applied to the production and use of other materials.

2.4 This approach implies that the quality level shipped is the same as the quality level produced.

2.5 This methodology can be an effective tool for driving quality improvement.

2.6 This procedure can be coupled with other techniques for centering the mean and reducing the variation within the process distribution as deemed necessary by the user and supplier.

2.7 Appendix 4 further explains the rationale for this approach.

3 Limitations

3.1 Outlier effects are beyond the scope of this document.

5 Terminology

5.1 *Acronyms*

5.1.1 *Cpk* — Process capability index

5.1.2 *ppm* — Parts per million

5.2 *Definitions*

5.2.1 *capability based sampling* — Any method that uses the process capability as a factor in determining the required sampling.

5.2.2 *ECPK* — Process capability index on a non-normal process which is corrected for non-normality.

5.2.3 *error* — The difference between the quality level committed to a user and the level that could be received.

5.2.4 *process capability index (Cpk)* — The smaller of (upper spec limit - mean) ÷ 3 sigma, or (mean - lower spec limit) ÷ 3 sigma.

5.2.5 *quality level* — The maximum defect level agreed upon by the user and the supplier.

5.2.6 *supplier risk* — The risk of rejecting material that is within the user specifications.

5.2.7 *user risk* — The risk of accepting material that is outside the user specifications.

6 Solutions

6.1 The following are examples of statistical specifications for normal and lognormal distributions.

6.1.1 *Normal* — The normal distribution describes processes that target a specific value and have symmetric random variation about that value. The first portion of the normal statistical specification is the familiar tolerance. It uses an upper specification limit (USL) and a lower specification limit (LSL), or the target plus and/or minus a value. The second portion, after the @ sign below, is a measure of the quality level, in ppm.

LSL to USL @ yy ppm, or

Target ± xx @ yy ppm

6.1.2 *Lognormal* — The lognormal function describes many of the one-sided distributions that are encountered in the silicon industry. It applies to those parameters such as flatness and warp that are bounded by zero. For lognormal processes, the value of a parameter could be specified as:

≤ xx @ yy ppm

6.2 More details, and examples of use, are shown in Appendix 1 for normal applications and Appendix 2 for lognormal applications.

6.3 For process distributions not following normal or lognormal forms, Pearson or other distributions may be used.

APPENDIX 1
USING STATISTICAL SPECIFICATIONS FOR NORMAL PROCESSES

NOTE: This appendix was approved as an official part of SEMI M32 by full letter ballot procedure.

A1-1 Statistical Specification Format for Normal Distributions

A1-1.1 The normal distribution is quite well-known. It describes processes that target a specific value and have symmetric random variation about that value. Below are examples of statistical specifications for normal processes. The first portion is the familiar tolerance, and the second portion is a measure of the quality level.

LSL to USL @ yy ppm, or

Target ± xx @ yy ppm

Other standard tolerance definitions could be substituted, or other definitions of the quality level such as Cpk, Z-value, or percent could be used.

A1-1.2 Adding the quality level removes the potential for misunderstanding and makes the specification more meaningful.

A1-2 Example of Use

A1-2.1 Functionally, statistical specifications are similar to conventional tolerances, except that the quality level is stated rather than just implied. They can be directly substituted for tolerances or other forms of specifications. Statistical specifications are especially useful for focusing quality improvement efforts, achieving ship-to-stock relationships, promoting processed in quality, and reducing after the fact inspection. In this environment they could be used as follows:

A1-2.1.1 Through audits and capability reporting a particular parameter is targeted for improvement or chosen as a ship-to-stock candidate.

A1-2.1.2 The control methods, distribution shape, and statistical specification are agreed upon. The tolerance and quality level defined in the statistical specification completely define the needed process capability.

A1-2.1.3 Once it is shown that the required capability is consistently exceeded then reduced inspection sampling can be implemented without increasing the risk to the customer or supplier. In this way the process controls can gradually become the guarantee for quality, and after the fact inspection can be gradually reduced to the level that is needed for outgoing quality reporting.

A1-3 Discussion

A1-3.1 Statistical specifications remove ambiguity, allow small risks, and promote the movement toward better process controls and less after the fact inspection. The quality level (i.e., the yy portion) is often misunderstood. Some people say they want ppm level quality but introduce methods that allow 50,000 to 200,000 ppm in error. This causes confusion.

A1-3.2 Many people have the misconception that tolerances are goal posts that require 100% of the material to fall inside. Processes are usually described by statistical distributions, so specifications have little meaning if a quality level is not defined. For many years, 99.73% (i.e., ± 3 sigma) was considered to be satisfactory. "Within tolerance" was understood to mean within tolerance with a 99.73% confidence, or a 0.27% quality level. Later the 99.73% process was defined as "cruel". 0.27% was no longer an acceptable quality level, and process drift was understood to cause even higher reject rates. This led to the demand for better process capabilities (i.e., higher Cpk's), which demanded corresponding improvements in process characterization and control methodologies. At the same time other users tightened their tolerances to the point that led to over-control. Either extreme can cause a mismatch between expectations and capabilities if the risks are not carefully evaluated.

A1-3.3 Capability-based sampling is perhaps the only way to rigorously transfer from inspection-based quality to process control-based quality, without incurring high risks. Statistical specifications create the environment for this to work. Once the specification is clearly defined, it can be clearly achieved. The details of capability based sampling are beyond the scope of this document, but the basic concept is easy to understand. If a process is very capable and controlled, then the system can be relied upon to create the necessary quality level with less after the fact inspection. This is good for both sides. Users get more reliable quality, and suppliers get the information needed to focus quality improvement efforts and direct resources at the most critical processes.

A1-3.4 Once a process has been statistically characterized, everything becomes much easier. Calculations can be done in milliseconds instead of minutes. This includes spec acceptance, comparisons, and many forms of analysis. Multiple levels like % < A, % < B, and % < C are also clearly unnecessary if the distribution shape is known. This prevents a large amount of duplicate work.

APPENDIX 2
USING STATISTICAL SPECIFICATIONS FOR LOGNORMAL PROCESSES

NOTE: This appendix was approved as an official part of SEMI M32 by full letter ballot procedure.

A2-1 Statistical Specification Format for Lognormal Distributions

A2-1.1 The lognormal probability distribution function describes many of the one-sided distributions encountered in the silicon industry. It applies to those one-sided parameters like flatness and warp that are bounded by zero. Below is an example of a statistical specification for a lognormal process.

$$\leq \text{ xx @ yy ppm}$$

A2-1.2 Other standard tolerance definitions could be substituted, or other quality level definitions such as ECPK, Z-value, or percent could be used. Again, ECPK is the Equivalent normal Cpk that corrects for non-normality. More information on the Equivalent Cpk is shown at the end of this appendix.

A2-1.3 As with the normal distribution, adding the quality level removes the potential for misunderstanding and makes the specification more meaningful.

A2-2 Example of Use

A2-2.1 Again, the major objectives are to focus quality improvement efforts, achieve ship-to-stock relationships, promote processed in quality, and reduce after the fact inspection. The steps are the same as shown in Paragraph A1-2 for the normal distribution. The major difference is that only the upper tail needs to be considered. However, since the lognormal tail goes so much farther out, it might be necessary to accept a less critical quality level.

A2-3 Discussion

A2-3.1 Statistical specifications work very well for processes with lognormal distributions. They have all the benefits described for normal distributions, and in some respects, they are even easier. Since lognormal processes only have one tail, checking each tail to decide which is the most critical is not necessary. Also, it has been empirically observed that lognormal processes are not as prone to mean drifting, so they tend to be more stable. The main hurdle is realizing how much error is introduced if the distribution shape is assumed to be normal when it is not.

A2-3.1.1 Figure A2-1 illustrates the difference between a lognormal and a normal process. The curve which has a solid line (and is clearly not symmetrical) is the lognormal distribution. The curve with the dashed line is the normal distribution. The error when mistakenly using a normal distribution to characterize a lognormal process is shown in Table A2-1. For values that increment by 1 sigma from the mean, the ppm greater than that value is given for each curve, and the difference (or error) is calculated. To make it easier to visualize, increments of the simple normal mean and sigma (1.8263 and 0.7568 respectively) are used in the "value" column. For calculating the lognormal statistics the correct lognormal geometric mean of 1.8258 and the lognormal geometric sigma of 0.7550 are used. The error between the curves increases as the point of interest moves toward the center of the distribution, but the most important issue is the length of the tail. The right tail of the lognormal distribution extends along with the histogram, but the normal distribution is much shorter. Visually, the significance might be overlooked in Figure A2-1, but when the tail probabilities are shown in ppm (Table A2-1) the difference is very apparent.

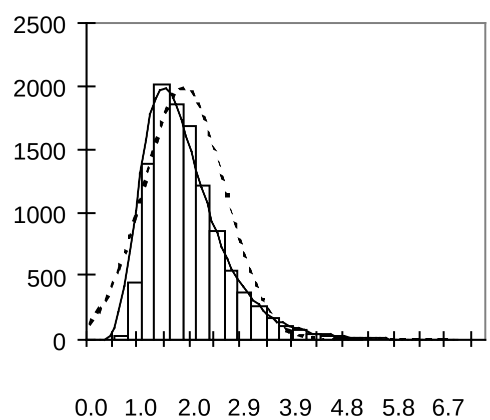

Figure A2-1
Lognormal vs. Normal Curves

Table A2-1 Lognormal vs. Normal Data

Value	*Value Description*	*Normal ppm >*	*Lognormal ppm >*	*Error*
1.8263	mean	500000	420997	79003
2.5831	+ 1 s	158655	141869	16786
3.3399	+ 2 s	22750	42836	20086
4.0967	+ 3 s	1350	12783	11433
4.8535	+ 4 s	32	3914	3882
5.6103	+ 5 s	0.3	1247	1247
6.3671	+ 6 s		415	415
7.1239	+ 7 s		144	144
7.8807	+ 8 s		52	52
8.6375	+ 9 s		20	20
9.3943	+ 10 s		8	8
10.1511	+ 11 s		3	3
10.9079	+ 12 s		1	1

A2-3.2 Lognormal distributions can be handled mathematically as easily as normal distributions, if the formulas are known. The difficulty in the past was that many of the calculations developed for the normal distribution were not available for lognormal. The equivalent normal Cpk (ECPK) was developed to address this issue. For the lognormal distribution, ECPK is calculated as shown below. It is an exact mathematical derivation with no estimations or assumptions. It was designed to allow people to see real data and keep all transformations and conversions inside the computer where they are totally invisible. Two cases are presented. Section A2-3.3 describes the case where a statistical software is available, and Section A2-3.4 describes a shortcut that may be used when the computation is derived from scratch. In both cases, it is important to remember that only the computer will see these formulas.

A2-3.3 Statistical software packages will usually output the geometric mean and geometric sigma. If μ is the lognormal geometric mean, σ is the lognormal geometric sigma, and 1n is the natural log function, then ECPK is calculated as:

$$\mathrm{ECPK} = \frac{1\mathrm{n}\,[\mathrm{USL}] - 1\mathrm{n}\left|\dfrac{\mu^2}{\sqrt{\mu^2+\sigma^2}}\right|}{3\left(\sqrt{1\mathrm{n}\left(\dfrac{\mu^2+\sigma^2}{\mu^2}\right)}\right)}$$

For the example in Figure A2-1 the lognormal geometric mean is 1.826 and the lognormal geometric sigma is 0.755. If an upper spec limit (USL) of 6 is applied, then the ECPK is 1.06. This will usually be done in a computer. A programming version of this formula is written as:

$$\mathrm{ECPK} = ((\log\,(\mathrm{USL})) - \log\,(\mathrm{Gmean}**2 \,/\, (\mathrm{sqrt}\,(\mathrm{Gmean}**2 + \mathrm{Gsigma}**2)))) \,/\, (3 * \mathrm{sqrt}\,(\log\,((\mathrm{Gmean}**2 + \mathrm{Gsigma}**2) \,/\, \mathrm{Gmean}**2)))$$

A2-3.4 If the computation is programmed from scratch for raw data, it may be convenient to take the natural log of each data point (i.e., do a log transformation) then compute the mean of the transformed data (Tmean) and sigma of the transformed data (Tsigma). Again, ln is the natural log function. In this case, the ECPK formula can be written as:

$$\mathrm{ECPK} = (1\mathrm{n}(\mathrm{USL}) - \mathrm{Tmean})/(3 * \mathrm{Tsigma})$$

The geometric mean and geometric sigma could then be calculated as follows:

$$\mathrm{Gmean} = \exp(\mathrm{Tmean} + (\mathrm{Tsigma}**2)/2)$$

$$\mathrm{Gsigma} = \mathrm{sqrt}((\exp((2*\mathrm{Tmean}) + (\mathrm{Tsigma}**2)))*(\exp((\mathrm{Tsigma}**2)) - 1))$$

A2-4 Conclusion

Lognormal calculations can be as easy as normal calculations. Again, the formulas reside only in the computer where they are never seen by the user. They allow the user to view the actual measures and the actual distributions.

APPENDIX 3
CURRENT STATISTICAL CHARACTERIZATION OF SILICON PROCESS PARAMETERS

NOTE: This appendix was approved as an official part of SEMI M32 by full letter ballot procedure.

A3-1 Statistical Characterization of Silicon Process Parameters

A3-1.1 The following table describes the statistical characterization on a number of silicon wafer processes. The comments column indicates the level of characterization that has been achieved. “Characterized” means that the process should, under usual conditions, display the distribution shape shown. “Conditional” means that there are conditions that might need to be considered before deciding if the shape shown is satisfactory. The chi-square goodness of fit test was used to characterize the distribution shapes. Actual chi-square goodness of fit values will typically be proprietary information that is shared only between a given supplier and user.

Table A3-1 Characterization of Silicon Processes

Process or Parameter Description	*Distribution Shape*	*Comments*
Diameter	Normal	Characterized
Flatness/Global (GBIR, GF3R, GF3D, GFLR, or GFLD)	Lognormal	Characterized
Flatness/Site (SF3R, SF3D, SFLR, SFLD, SFQR, SFQD, SBIR, or SBID)	Lognormal	Characterized
Oxygen Concentration	Normal	*Conditional* — Non-normalities are mostly attributed to measurement error, so the normal distribution is usually satisfactory.
Shape, Bow (Reference SEMI M1, Figure A2-1.)	Normal	Characterized
Shape, Warp, or Sori (Reference SEMI M1, Figure A2-1.)	Lognormal	Characterized
Thickness (Polished or EPI)	Normal	Characterized

APPENDIX 4
RATIONALE FOR STATISTICAL SPECIFICATIONS

NOTE: This appendix was approved as an official part of SEMI M32 by full letter ballot procedure.

A4-1 Introduction

A4-1.1 The purpose of a specification is either to define acceptance criteria or to assist in quality improvement planning. The basic intent is to quantify user need so suppliers can accommodate that need. Developing a clear link between user needs and the control methods used on the production floor is one of the most critical steps for creating a Total Quality Management (TQM) environment. Following are some key background concepts that allow the reader to understand the conclusions drawn in this document.

A4-1.2 For most manufacturing processes there is no such thing as “zero defects”. Processes are described by statistical probability distributions, and the tails of these functions can go all the way to infinity. For many years, 99.73% (i.e., ± 3 sigma) was used as the basis for tolerances. “Within tolerance” was understood to mean within tolerance with a 99.73% confidence, or a 0.27% quality level. When users requested better levels, then new standards such as 33 ppm or 3.4 ppm were made. In any case, this quality level needs to be agreed upon for a specification method to have meaning. It can be measured in terms of ppm, Z, Cpk (which is equal to Z divided by 3), or percent. Z tables or Cpk tables can be obtained which provide this information.

A4-1.3 Errors in the 10% or higher range can be generated if a percentile specification is based on the central portion of the distribution. An example of such a specification is “50% ≤ 1.2 microns”. These errors are not obvious and require careful statistical analysis based upon real process variation. Multiple percentile specifications are also difficult to apply. Paragraph A4-3 provides more details on these issues.

A4-1.4 Conversely, if specifications get too far out on the tail, they tend to become abstract and are not used as the primary factor driving quality improvements. This is especially true for non-normal processes where the tail of the distribution goes out much farther than expected from a normal distribution. Figure A4-1 shows where a 3.4 ppm specification would be on a lognormal process. Users usually will not allow that much tolerance. However, if the specification is tightened while the process capability remains the same, then the consequence is a degradation in the quality level.

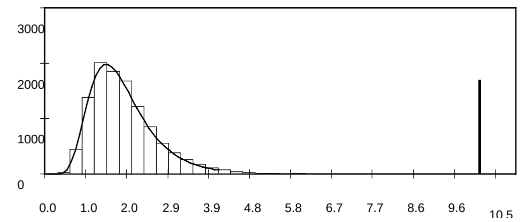

Figure A4-1
Lognormal Tolerance for 3.4 ppm Quality Level

A4-1.5 The mean and sigma specification is another proposed approach. Intuitively, this seems promising, but it has many of the same problems as multiple percentile specifications. More details are given in Paragraph A4-4.

A4-1.6 Errors in the 5% to 10% range can also be generated if process distributions are assumed to be normal when they are not. Knowing the actual distribution shape is a key factor that opens up a tremendous amount of knowledge. Figure A4-2 shows an example of real data that illustrates a lognormal process. In the past, this was considered to be difficult because non-normal distributions were only supported by high-level statistical software. Now even spreadsheets have them. It should also be noted that once the process characterization has been done, the shape of the distribution typically does not change, so this knowledge can be shared throughout the industry. Regularly monitoring the process by overlaying the distribution on the process histogram or cumulative frequency plot is extremely valuable to confirm that the process is not taking on unnatural bimodal or outlier effects. One-sided distributions such as flatness and warp are so well-characterized by the lognormal distribution that “goodness-of-fit” results are very close to 100%. Again, the error gets larger as the point-of interest moves toward the “center” of the distribution, but the major concern is the length of the tail. The lognormal distribution in Figure A4-2 (the curve with a solid line which is clearly not symmetrical) has a tail that extends much farther to the right than the normal distribution which is shown with a dashed line. This effect, and the impact, is shown in more detail in Appendix 2.

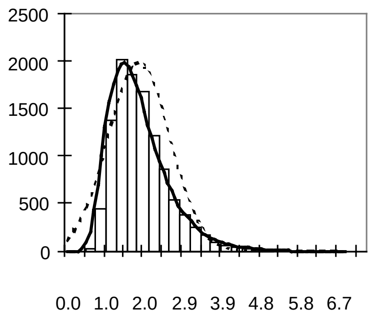

Figure A4-2
Normal vs. Lognormal Shape

A4-1.7 Statistical specifications quantify the quality level so it is not an abstract assumption left to conjecture. This allows both the user and supplier to optimize their control systems to that level. Capability based sampling is one example. Simply put, this means to use process capability information to help define the sampling plan for a process. A detailed discussion of this subject is beyond the scope of this document, but the basic concept is easy to understand. If a process is very capable and controlled it does not need as much sampling as one that is not. Implementing this strategy is a big step ahead of standard sampling theory. It might be the only way to rigorously transfer from inspection based quality to process control based quality, without incurring high risks. Statistical specifications create the environment which facilitates this improved strategy. Hopefully, the quality levels would be defined in ppm, but any level agreed upon by both the user and the supplier would work.

A4-2 Tolerance Specifications

LSL to USL, or Target ± xx

A4-2.1 The main problem with a conventional tolerance is that many people perceive it as a goal post that requires 100% of the material to fall inside. This document has shown in detail that this is simply a wrong perception. Stating the quality level in the specification, instead of just implying it, corrects this problem.

A4-2.2 Another common misconception is that tolerances and tail probabilities divert attention away from centering the process. Of course, centering is important. Considering the impact of poor quality on all customers, it is clear that a well centered process is far more efficient than one that is not. It is also generally true that the suitability of the product is not significantly different immediately on one side of a tolerance line compared to the other. However, there are a number of issues that warrant discussion.

A4-2.2.1 First, centering is usually not difficult, so it usually does not need a major emphasis. Those who are experienced in quality improvement techniques would certainly not forget to center the process. Simply monitoring the mean trend gives an excellent measure of centering, and it keeps the focus on the process rather than the specification. Industry carries a long history where specifications prevented the attainment of good process control. Many of the issues have been explained earlier in this document. To summarize, process controls are the only way to truly maintain a centered process, and these controls can only work if there is enough tolerance in the specification to accommodate the sensitivity limitations of the control methods.

A4-2.2.2 The second issue is that it might not be possible to center. This is clearly the case in one-sided processes that are bounded by zero. Optimizing multiple parameters might also dictate that some parameters get worse.

A4-2.2.3 The final, and most important, issue is the challenge of teaching statistical methods to the factory population. It is very easy to teach averages and centering since they tend to be well understood already. It is not as easy to teach sigma and the fact that sigma trends must be thoroughly understood before much of anything can be said about averages. Confirming that the R or S chart is controlled before studying the Xbar chart and doing an F-test before doing a t-test are just two examples. These are very important concepts that must be fully understood in order to apply statistical methods. Over-stressing centering de-emphasizes sigma and creates an environment where it is not appreciated. Thinking in terms of sigma is the most important concept that most people will learn about process control methods. It deserves a major emphasis.

A4-2.2.4 Of course, centering would be a concern if mixing and matching of lots is the control method, but this can be easily spotted in the statistical characterization process. The fact that some of the alternatives to tolerances are much more likely to cause this practice will be further explained in Paragraphs A4-3 and A4-4.

A4-3 Multiple Distributional Percentile Specifications

$\% \leq A$, $\% \leq B$, and $\% \leq C$

A4-3.1 Errors in the 10% or higher range can be generated if a specification in the central portion of the distribution is used. An example of such a specification is “50% ≤ 1.2 microns”.

A4-3.2 No control method can hold a process perfectly still. Even the best real-time control methods can allow a process to drift as much as ± 1.5 sigma. For this reason, a 6-sigma design was defined as 4.5 sigma to the nearest tolerance.

A4-3.3 Sampling issues are a major concern. Many kinds of variation can be quantified by rigorously studying the appropriate samplings (within batch samples for batch-to-batch variation, monthly samples for month-to-month variation, etc.). However, there are practical limits on how many kinds of variation can be continuously monitored. There is a large amount of work involved, and there are hundreds of potential sources of variation. Resource restrictions regularly force suppliers to concentrate on the known key variables and leave the rest as error in the system (at least for now). As sample periods get longer, there is more statistical sensitivity, but also more probability that the drift will be confounded with user-driven process improvements. For example, month-to-month random drift is hard to quantify because production processes are often improved before many months of data can be observed. Measurement error is another main contributor which further complicates the other sensitivity issues. These factors all combine to allow a certain amount of undetectable process drift. This process drift needs to be considered when defining the specification approach.

A4-3.4 These variations cannot be detected because of statistical sensitivity limitations. Table A4-1 shows the sample sizes needed to detect different levels of process shift. Delta will be defined as the number of sigma of undetectable mean drift. For simplicity, a one-way shift is shown, but in most practical cases, the shift could go plus or minus. Using the old standard of 5% supplier risk and 10% user risk, 72 samples are needed to detect a delta of 0.25 sigma. This example (0.25 sigma of mean drift) has been used throughout this document. Since most of the discussion will relate to process drift, the terms “drift” and “shift” will be used interchangeably. Clearly, 72 is too large a sampling for most real-time control systems, but it is still an understatement of the problem. Most users currently expect their risk to be much smaller than 10%. The last row shows that the sample size would need to be 311 to reach 0.1% user and supplier risks. It is generally agreed that 0.1% (i.e., 1000 ppm) is the lowest level that is feasible using standard probability theory. For lower levels, it is necessary to move farther out on the distribution tails where it is necessary to rely on more than just stndard sampling probabilities.

Table A4-1 Sampling Requirements

(a = supplier risk, b = user risk)

Detectable Mean Shift (in Sigma)	*0.125*	*0.25*	*0.50*	*0.75*	*1.0*
Min N a = 20% b = 20%	92	24	7	4	4
Min N a = 5% b = 10%	280	72	20	10	7
Min N a = 1% b = 1%	696	177	47	23	15
Min N a = 0.1% b = 0.1%	1228	311	82	40	25

A4-3.5 Figures A4-3a, A4-3b, and A4-3c show the error generated by 0.25 sigma of undetectable mean drift. Again, the number of sigma of undetectable mean drift will be defined as delta. Notice how the error grows as the point of interest moves toward the center of the distribution. At the four sigma point (out on the tail) there is very little error, so suppliers can be generous with internal buffer specifications to protect the user. This is not as feasible in the center of the distribution because there is so much material at stake. A percentile specification in the center of the process shown would have about 1000 times more undetected, out-of-spec product than a specification at the 4 sigma point. Since the shift could go either way, this could also be 1000 times more material that was rejected and should not have been.

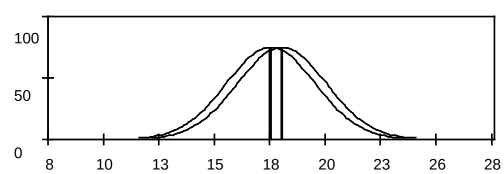

Figure A4-3a
Error at 0 Sigma

A4-3.6 The left curve in Figure A4-3a shows a distribution with an expected mean of 18. The right curve shows the same distribution with an undetectable drift of 0.25 sigma. If a specification limit is placed at 18, then 50% of the material is below the specification for the nominal distribution. However, only 40.13% is below the specification for the distribution that has drifted. The error, shown by the area between the vertical lines and below the right curve, is 9.87% or 98,700 ppm.

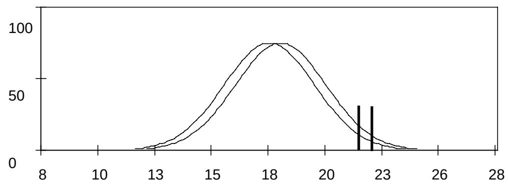

Figure A4-3b
Error at 2 Sigma

A4-3.7 The error when the specification is 2 sigma from the mean, shown in Figure A4-3b as the area between the vertical lines and below the right curve, is 1.73% or 17,300 ppm.

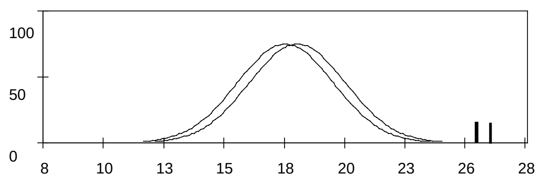

Figure A4-3c
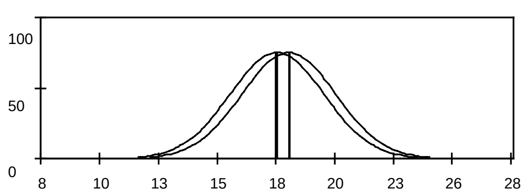
Error at 4 Sigma

A4-3.8 The error when the specification is 4 sigma from the mean, shown in Figure A4-3c as the area between the vertical lines and below the right curve (but indistinguishable), is 0.01% or 100 ppm.

A4-3.9 Figure A4-4 further quantifies this error. Percent-less-than calculations are shown for each curve at increments of 1 sigma from the mean. The starting mean is 18, and the sigma is 2.



Value	*Value Description*	*Left Curve %*	*Right Curve %*	*Error %*
10	- 4 s	0.01	0.00	0.01
12	- 3 s	0.13	0.06	0.07
14	- 2 s	2.28	1.22	1.06
16	- 1 s	15.87	10.56	5.31
18	mean	50.00	40.13	9.87
20	+ 1 s	84.13	77.34	6.79
22	+ 2 s	97.72	95.99	1.73
24	+ 3 s	99.87	99.70	0.17
26	+ 4 s	100.00	99.99	0.01

Figure A4-4
Percentage Error

A4-3.10 Please note that this is a very conservative example. The delta and the resulting error can get much larger.

A4-3.11 A major concern is what to do when the specification is not met. Users would certainly not want suppliers to reject material in the center of the distribution. Alternatives are to (1) reject the whole shipment, (2) reject nearby lots, (3) mix and match lots, or (4) translate the percentage hypothetically lost in the center back out to the tail in order to reject the worst material. The first two alternatives are really more like penalties and would lead to unnecessary loss of good material. The third is the worst form of inspecting in quality. It is generally agreed that this is the main thing to avoid. Translating the error back to the tail is possible but not necessarily a good approach. This would involve translating a reject percentage with a large potential error back out to a region that would have had a very small error. A multiple percentile specification can also be quite difficult in a production environment. Each of the percentile criteria must be evaluated to determine which one requires the highest reject rate. That reject rate must then be translated back to the tail, and 100% sample data must be used to determine which actual pieces to reject. If the statistical distribution is defined, one specification would give the same amount of information with much less work. If only one criterion is used, and it is well out on the tail (hopefully in the ppm range) then this method is very similar to a statistical specification.

A4-3.12 A commonly stated goal of multiple percentile specifications is to focus on centering rather than distribution tails. All of the discussion in Section A4-2.2 concerning centering is equally applicable here. Multiple percentile specifications are more likely to cause inspected-in quality which detracts from process control based centering.

A4-3.13 Ease of use is another stated goal, but for all of the reasons stated above, this method is one of the most difficult to use. Statistical calculations can be done in milliseconds while the potential of large samplings, raw data manipulation, and duplicate effort associated with multiple distributional percentile specifications create much more work. Characterizing with percentiles is an alternative for processes that have not yet been statistically characterized, but once that hurdle is crossed, everything gets many times easier.

A4-4 Mean and Sigma Specifications

Mean ≤ Value, Sigma ≤ Value, or

Low to High Mean, Sigma ≤ Value

A4-4.1 First, please note that the term "sigma" is intentionally used, rather than "standard deviation". This does not in any way imply 100% sampling. Instead, the implication is that the process would need to be monitored long enough to understand the "process sigma" (i.e., the state at which the process can be controlled).

A4-4.2 Mean and sigma specifications intuitively seem very promising, but they have many of the same problems as multiple distributional percentile specifications. Here, the issue of statistical sensitivity is particularly important. Table A4-1, and the discussion in Section A4-3.4 concerning sampling requirements, explain the central issue. The sample sizes required to detect smaller mean shifts are very large, so they usually are not feasible at the process control point. As a result, mean and sigma specifications could lead to much more sampling in an inspection area or in the warehouse, where larger quantities are available. To keep the sample sizes small, it is necessary to allow a specified amount of process drift. Therefore, some form of tolerance is necessary.

A4-4.3 Another factor that needs careful consideration is the movement toward controlling surrogate variables instead of outgoing parameters. Many types of variation can be controlled by carefully applying the appropriate samplings (within batch samples for batch-to-batch variation, within lot samples for lot-to-lot variation, etc.). However, there are practical limitations on how many types of variation can be continuously monitored. There is a large amount of work involved, and there are hundreds of potential sources of variation. Resource restrictions regularly force suppliers to concentrate on the known key variables and leave the rest as error in the system (at least for now). This practice, called homogeneous sampling, is designed to continuously home in on the variables that have the greatest impact on the distribution. Strictly speaking, for characterizing process capability, a random and over-time sampling which covers all sources of variation should be used. In practice, this is difficult to do, so engineering judgment is needed to select the most appropriate homogeneous sampling. This is yet another issue that could generate significant errors if it is not fully understood.

A4-4.4 From an ease-of-use standpoint, mean and sigma specifications have many of the same issues as multiple distributional percentile specifications. Mixing and matching of lots would be especially tempting with this approach because it might be the only practical alternative.

SEMI M33-0998
TEST METHOD FOR THE DETERMINATION OF RESIDUAL SURFACE CONTAMINATION ON SILICON WAFERS BY MEANS OF TOTAL REFLECTION X-RAY FLUORESCENCE SPECTROSCOPY (TXRF)

1 Purpose

1.1 The test provides the analytical procedure to determine the trace level of contaminating elements of an atomic number higher than 15 on polished or epitaxial silicon wafer surfaces in native or thermally grown or tetraethylorthosilicate (TEOS) oxide or in residues of microdroplets of process chemicals or media as analyzed with TXRF on silicon wafer surfaces as described in Sections 15.1 and 15.2.

2 Scope

2.1 This document specifies a VPD-TXRF (Vapor Phase Decomposition Total Reflection X-Ray Fluorescence Spectroscopy) method to analyze the elemental composition and areal density of impurities, that include cations and anions with atomic numbers between 16 (S) and 92 (U) independent of their chemical state, with the exception of the X-ray source material, on polished or epitaxial silicon wafer surfaces in native or thermally grown oxide or in residues of microdroplets of process chemicals or media as analyzed with TXRF on silicon wafer surfaces.

2.2 This test is especially useful for analyzing metallic elements such as K, Ca, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, (Mo), Pd, Ag, Sn, Sb, Ta, (W), Pt, (Au), Hg, and Pb and non-metallic elements such as S, Cl, As, Br, and I through their characteristic K and L lines. (Elements in brackets are usual X-ray sources.) For limitations in the nature of analytes refer to the note in Section 14.7.

2.3 This test method can be used to analyze areal surface contamination that can be collected in a microdroplet during the specified VPD preparation and the collection of the digested surface contamination in the range of 5×10^8 through 5×10^{12} atoms/cm^2.

2.4 Theoretically, the detection limit (LOD) of each analyte depends upon its atomic number. As defined by DIN 32645 "Limit of detection, determination and quantification" the LOD of TXRF is also depending upon many parameters, such as:

- excitation energy,
- intensity of incident X-ray,
- instrumental background,
- crystallographic interferences, such as Bragg diffraction conditions,
- impurities in the beam path,
- contamination of the blank scanning solution (see Section 4.5),
- contamination level in the analytical ambient,
- surface microroughness of wafer at the microdroplet (see Section 6.7), and
- integration time.

2.5 Concerning the surface conditions to be analyzed, the VPD-TXRF method is invasive. Nevertheless, the TXRF analysis of the microdroplet residue can be repeated many times provided that the prepared specimen is stored in a clean environment. The substrate and/or surrogate wafers can be recycled for monitoring purposes.

2.6 The user of this test method must assure that the metrology equipment is under control by the procedures commonly utilized in the performing laboratory. In the absence of established control procedures the use of 4.11.2 EN-ISO 9001 is recommended.

NOTICE SAFETY PRECAUTIONS — This standard does not purport to address the safety concerns, associated with its use. It is the responsibility of the user of this standard to establish and maintain appropriate safety and health practices and comply with the local regulatory ordinance. X-ray irradiation and handling of HNO_3, HF and H_2O_2 are dangerous. Operators must comply with X-ray safety regulations and be trained to wear protective garments and glasses when handling HNO_3, HF and H_2O_2. These chemicals should be handled in a ventilated area (under exhaust.)

4 Terminology

4.1 *anglescan* — A measurement of the emitted fluorescene signal as a function of the glancing angle of incident X-ray beam.

4.2 *areal density* — Amount of impurities in a unit area of native or thermally grown silicon oxide as converted from the detected amount of analytes into the whole analyzed (i.e., scanned surface area).

4.3 *as-polished wafer* — Mirror-finished wafer planarized by chemi-mechanical polishing.

4.4 *azimuthal position* — Orientation around the z-crystal/ingot axis as specified in SEMI M20.

4.5 *contamination collection* — Microanalytical method to collect the VPD decomposition products from the silicon surface by rolling a scanning microdroplet on the hydrophobic silicon wafer surface after VPD preparation as originally described in Sections 15.2, 15.4, and 15.5 (also see Section 8.3 of this document).

4.6 *critical angle* — The incident X-ray glancing angle below which total reflection of the incident X-ray occurs. At the critical angle the X-ray reflection equals 0.5.

4.7 *detection spot area* — The surface area where above the fluorescence counts are integrated.

4.8 *epitaxial wafer* — As-polished wafer covered with a layer of monocrystalline silicon deposited from a heterogeneous phase.

4.9 *glancing angle* — Incidence angle of X-ray excitation.

4.10 *hydrophobic surface* — Contact angle of wafer > 60° (e.g., virgin epitaxial or HF- or HMDS (hexamethyldisilazane) -treated surface as described in Section 15.3).

4.11 *impurities* — Elements in/on the specimen other than silicon or elements in ultra pure process media as listed in Section 2.2.

4.12 *native oxide* — Compound of silicon, oxygen, and water on as-polished or epitaxial wafer, grown in air or in cleaning solutions.

4.13 *recovery rate* — The ratio of analytes found after the first VPD and contamination collection procedure to the sum of the analytes found after two or more repeated scanning with unused scanning droplet of unchanged chemical composition.

NOTE: Recent efforts of the Statistical Task Force of the SEMI Chemicals and Gases Committee may result in a new definition (see Section 14.2 of this document).

4.14 *spurious peaks* — Peaks that are detected but not originated from impurities of the silicon wafer (c.f., 6.1).

4.15 *thermally grown oxide* — SiO_2 up to 1000 nm thickness deposited or grown in thermal processing in oxygen containing atmosphere.

4.16 *vapor phase decomposition (VPD)* — Vapor phase decomposition of silicon oxides using HF vapor at room temperature as a surface preparation method for

microanalysis, as originally described in Sections 15.2, 15.4, or 15.5 (also see Sections 5.1 and 11 of this document).

5 Summary of Method

5.1 The native or thermally grown oxide layer of the silicon surface is converted with HF vapor into fluid droplets that contain the impurities of the oxide layer. With a scanning droplet the fluid reaction products are collected in one microdroplet. That microdroplet is dried on the wafer under controlled conditions and analyzed with TXRF.

5.2 Similarly, a microdroplet of process chemicals or media can be dried on hydrophobic polished or epitaxial silicon wafer under controlled conditions and analyzed with TXRF.

5.3 Preferably, monochromatic and collimated X-rays irradiate a planarized and chemi-mechanically polished, monocrystalline silicon wafer surface. The X-rays impinge the surface at a glancing angle that is below the angle for total reflection of the X-rays, preferably, at an incident angle 70% of the angle of total reflection [1.3 mrad (or 0.07 degrees) for Mo target and 2.0 mrad (or 0.11 degrees) for W target].

5.4 The evanescent waves excite the fluorescence energy levels of the surface atoms, which then emit fluorescence X-rays characteristic of their atomic number. The emitted X-rays are detected by a solid state detector that is an energy dispersive spectrometer. In the range of specified areal density (compare with Section 2.3 of this document) the integrated count rate (cps) is linearly proportional to the elemental areal density.

5.5 For quantification, the linear regression must be established (c.f., Section 15.6) or a linear proportionality is anticipated between the cps data that are measured above the certified reference microdroplet(s) and the cps data that are measured above the microdroplet of the unknown analytes without changing the anglescan conditions, according to Sections 9.1, 13.6, and 15.7.

6 Interferences

6.1 The known interferences in X-ray fluorescence spectroscopy also affect TXRF. Thus, overlapping fluorescence lines, escape peak, energy gain drift, X-ray source stability, beam path background contamination must be evaluated according to Section 15.7 of this document.

6.2 Baseline corrections due to varying background contamination must be controlled by the rules of statistical analysis (e.g., as described in Section 15.8 of this document).

6.3 Under the specified conditions, no corrections are required for secondary fluorescence or for oscillations or for matrix absorption as described in Sections 15.9–15.11 of this document.

6.4 Accuracy of the standard reference specimen and positioning accuracy and precision of the detector define the bias in the assigned areal density.

6.5 Mechanical vibration may degrade the detector resolution and it can also decrease the selectivity.

6.6 Multielement contamination degrades the LOD compared with monoelement contamination.

6.7 Increased surface microroughness and/or high-total signal count rates result in high deadtime and can lead to non-linearity of detected fluorescence signal versus areal density (i.e., to degradation of LOD).

6.8 Under optical conditions satisfying the Bragg reflections the background noise depends upon the azimuthal orientation of the sample. Before quantification, a determination of the azimuthal angular range, that shows minimum Bragg reflection background, is recommended. Otherwise the LOD may degrade due to high background and spurious peaks.

6.9 During handling and measurement particles or volatile contamination (e.g., NH_3) from the analytical environment must be controlled and avoided.

6.10 During measurement Ar must be excluded from the analytical ambient (e.g., by evacuating the chamber or flushing it with He).

6.11 Curve smoothing and evaluation algorithms with controlled Fourier parameters or Digital Filtering are preferred to direct count rate evaluation because these algorithms provide a higher level of statistical confidence than a software that directly quantifies cps as described in Section 15.12 of this document.

6.12 Recovery rates as defined in Section 4.13 of this document depend upon the distribution of the analytes between the scanning solution (solubility) and silicon surface (adsorption and plating). Therefore, recovery rates depend on the:

- applied scanning solution (Sections 4.5, 8.3),
- chemical nature of the different analytes/elements, and
- physical and physicochemical state of the silicon surface.

6.13 Automated contamination collection procedure (scanning) increases the wafer-to-wafer reproducibility of the described method as reported in Section 15.13 of this document.

7 Apparatus

7.1 The VPD treatment and contamination collection particularly, but also the handling and measurement of the specimen wafer is to be carried out in a specified and controlled ambient (e.g., Cl. 10 (U.S. Federal Standard 209)).

7.2 TXRF system equipped with:

— an X-ray source,

— a monochromator (preferable),

— a sample stage capable of manipulating in the x-, y-, and z-direction,

— automated test specimen handling,

— an energy-dispersive spectrometer X-ray detector,

— software sub-routine for glancing angle calibration,

— software for baseline setting and for peak-fitting and/or range-of-interest (ROI) peak finding identification and evaluation, and

— analysis ambient without Ar background (see Sections 6.10 and 7.1 of ASTM F 1526). The system is preferably equipped with a flat/notch-finder and quick-search option. For details, see Section 6.10 of this document and Section 7.1 of ASTM F 1526.

7.3 The VPD and the advisable drying chamber(s) will have opening(s) made of polyvinylidenfluoride (PVDF), polyfluoroalkoxyethylene (PFA), polyfluoro-ethylene (PTFE) or similar resistant and pure polymer materials that will not be attacked by HF. The chamber(s) may contain one or more wafers on stacks. The use of a drying chamber is advisable for the preparation of the calibration reference microdroplet (c.f., Section 10.1), but optional for the analysis procedure. When a drying chamber is used, it must be evacuable to below 1 kPa. After evacuation the chamber is to be flushed with filtered N_2 until the complete drying of the microdroplet residue is achieved (see Section 9.1 of this document).

7.4 For the aliquots of standard stock and scanning solutions validated micropipettes must be used. Validation procedure can follow the requirements of DIN 12650 Part 6.

8 Reagents and Materials

SAFETY PRECAUTIONS — Handling HNO_3, HF and H_2O_2 is dangerous. Operators must comply with X-ray safety regulations and be trained to wear protective garments and glasses when handling HNO_3, HF and H_2O_2 under efficient exhaust.

8.1 *Ultra Pure Water, HNO_3, HF, H_2O* — As specified in ASTM D 5127, SEMI C7.3, C7.5, and C7.6, respectively.

8.2 *Standard Stock Solution* — Certified and traceable standard reference “stock” solution with known amount(s) of nitrate salt of the metals and sodium salt of the non-metallic elements to be analyzed. Dilutions have to be acidified with HNO_3 at pH ≤ 2. Note that the shelf life of diluted solutions in the ppb-range of µg/L or ng/L is less than 2 days.

8.3 *Tested Scanning Droplet (Sections 4.5 and 6.12)* — 50 to 100 µL of ultra pure water or other scanning solutions (e.g., aqueous HF (1 volume %) and H_2O_2 (30 volume %)). The composition of the scanning droplet must provide a controlled recovery rate above 90% for each analyte, including Cu.

8.4 *Blank Scanning Solution* — The composition and the amount of a scanning droplet without surface impurities.

8.5 *Microdroplet Residue* — Microdroplet calibration standard reference solution and/or scanning or microdroplet of a liquid process medium dried at room temperature under controlled conditions according to Section 7.3. Above the microdroplet residue the fluorescence count rate remains independent of azimuthal position and of varying incident angle for angles below 80% of the critical angle as described in Section 15.6 of this document.

8.6 *Surrogate Wafers* — Polished or epitaxial wafers used as carrier plates for scanning droplets collected from other specimen wafers.

9 Preparation of Certified Reference Microdroplet for Calibration Standard

9.1 *Tested Preparation Conditions* — Deposit microdroplets containing 0.01 ng, 0.1 ng and 1 ng Ni in Ni $(NO_3)_2$ in 100 µL of a diluted standard stock solution onto (a) hydrophobic (see Section 4.12 of this document) polished or epitaxial wafer(s). Dry it (them) under controlled conditions (e.g., in a drying chamber at room temperature). When a drying chamber is used, flush the chamber with a slow flow of N_2 for 20 minutes, then evacuate it (see Section 7.3 of this document). The droplets must not explode or extend during drying. They should not exceed an areal dimension of 1 mm in any direction. Elements forming volatile compounds must not be applied (see the note in Section 14.7).

10 Calibration Procedure

SAFETY PRECAUTIONS — X-ray irradiation is dangerous. It is the responsibility of the user of this standard to establish and maintain appropriate safety and health practices and comply with the local regulatory ordinance. The X-ray source must be inactivated when beam path is unshielded. Operators must be trained to avoid exposure to X-ray irradiation.

10.1 The calibration standard is a microdroplet of 100 µL of a diluted certified standard reference "stock" solution. Note that the shelf life of diluted solutions in the sub-ppb-range of µg/L or ng/mL is less than 2 days.

10.2 Locate the calibration standard microdroplet residue and place it under the detector. Adjust the glancing angle into the range where the fluorescence count rate is independent of varying incidence angle (see Section 8.5 of this document).

10.3 Position the detector window as follows. Set mapping or quick search parameters for covering the residue(s) with 3 × 3 detection spots (see Figure 1), which are placed around the residue(s) as described in Section 15.6 of this document. The mapped surface must cover at least 95% of the square around the residue(s) that is lying about in the center of the detection spot. The analyzed part of microdroplet residue under the detection spot must be higher than 95%.

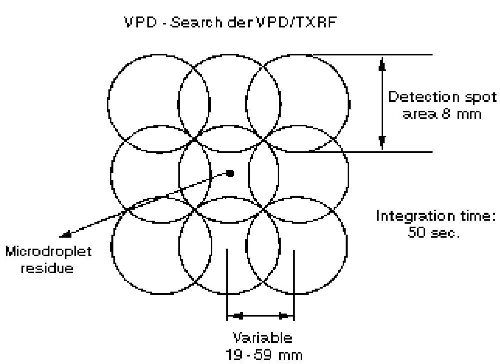

Figure 1
VPD-Search VPD/TXRF

10.4 Set for mapping around the microdroplet residue with a 50-sec integration time program at each detection spot. Integrate at the maximum position(s) for at least 1000 sec. These data provide the final result of calibration due to the algorithm given in Section 13.6 of this document.

10.5 Repeat calibration cycle (load-analyze-unload) at least 3-times.

10.6 In order to distinguish relevant results from particle contamination from the environment and from inefficient contamination collection, repeat measurement on blank surface adjacent to the microdroplet solution. The data are to be considered as background data in the quantification algorithm (see Section 15.12 of this document). For valid calibration, background fluorescence counts must remain less than 20% of the fluorescence counts of microdroplet residues, particularly, at lower areal densities ($< 1 \times 10^9$ atoms/cm^2).

10.7 The integrated fluorescence counts measured with the specified Ni calibration standard can be converted by known sensitivity factors into other elements of interest as described in the References section (see Sections 15.14 and 15.15 of this document).

10.8 Keep the calibration standards in closed, identifiable wafer holders in a clean room at room temperature under conditions that will not change the fluorescence reproducibility.

10.9 Optional linearity tests should deploy the methods described in References section (see Section 15.16 of this document). Similar statistical linearity tests can also be applied.

10.10 Upon the users request, the absolute instrumental calibration factor can be obtained. Due to the Fresnel theory of X-ray absorption and enhancement on pure metal (Ni) surfaces, the absolute calibration can be carried out under specific optical conditions. (See Referenced Documents section and specifically Section 15.17.). Then, that absolute calibration can be correlated to the external microdroplet calibration.

11 Preparation Procedure

11.1 VPD treatment of the wafer surface (Section 4.16) and the collection of contamination collection with a scanning microdroplet (Section 4.5).

SAFETY PRECAUTIONS — Handling HF is dangerous. It is the responsibility of the user of this standard to establish and maintain appropriate safety and health practices and comply with the local regulatory ordinance. Operators must be trained to wear protective garments and glasses when handling HF under efficient exhaust.

11.2 In the VPD chamber wafers are treated with HF vapor (e.g., isothermally distilled at room temperature from an aqueous solution (20–50 volume %) within the VPD chamber). The analytical specimen, the calibration droplet and the scanning droplet must be handled, prepared and dried under specified and controlled conditions. Drying means the evaporation of the solvents on the wafer surface in a clean and controlled environment without loosing analytes from the microdroplet residue.

11.3 The wafers are exposed to the HF vapor in the VPD chamber at room temperature. The exposure time depends on the concentration of the HF used and on the preceeding wafer treatment. The time has to be long enough to ensure that the wafer surface will become hydrophobic. After the HF treatment the solubilized reaction products are collected by scanning a microdroplet over the whole surface. Automatic scanning is preferable (see Section 6.13 of this document). The composition of the scanning solution is optional but its volume and drying conditions should be the same as under the preparation of calibration standards (see Sections 8 and 15.18 of this document).

11.4 An example for tested preparation conditions according to Section 15.18 of this document. A PTFE or PFA petri dish of a diameter > 25 cm is filled with 20 volume % HF by mixing DI ultra pure water and 40 volume % HF of ULSI grade in a clean room ambient of Cl 10 by U.S. Federal Standard 209. The petri dish is positioned in the bottom of the VPD chamber, loaded with specimen wafers. The wafers are exposed to the HF wafer at room temperature. Exposure time is between 30 minutes and 6 hours. Longer exposure times can lead to deliberate etching. After the HF treatment the solubilized, reaction products are collected by rolling a scanning microdroplet over the whole surface. Automatic scanning is preferable. Please refer also to Section 4.5 and Section 8.3 of SEMI E45.

11.5 Rinse the validated micropipette at least 5 times with ultra pure water or with the selected scanning solution. Then fill the micropipette with the required amount of ultra pure water or with the scanning solution. For scanning surfaces with thicker silicon oxide (> 300 nm) only about 50 µL of scanning solution is sufficient. The microdroplet to be dried for analysis should not extensively (+10%) exceed 100 µL together with the VPD reaction products.

11.6 Put the scanning microdroplet on the wafer surface and roll the scanning microdroplet around the wafer edge 2 times and then over the whole surface in a zigzag pattern. Automatic equipment can scan in a spiral pattern with overlapping paths (see Section 6.13). An edge exclusion of less than 1 mm is attainable for manual or automatic scanning. Edge exclusion is well below 1 mm at automatic scanning.

11.7 Position the scanning microdroplet in the center of the wafer.

11.8 For monitoring the cleanliness of the VPD preparation and contamination collection and that of the analytical ambient, put the same volume of the blank scanning solution, as applied to the preparation of the calibration standard (100 µL under tested preparation conditions), with the validated micropipette onto the scanned specimen surface at least 3 cm off the position of the scanning solution. For valid results fluorescence counts above the blank must remain less than 20% of the fluorescence counts above the droplet residues. Use ultra pure water (100 µL) for blanks of process chemical and media samples. If the scanning solution consists only of ultra pure water of controlled quality, no blanks are required.

NOTE: In the absence of oxidation agent(s), Cu recovery rates can be reduced (see Section 15.18).

11.9 Dry the wafers as specified in Sections 7.3, 9.1, and 11.2 of this document.

12 Analysis Procedure

12.1 Localize the microdroplet residues of the collected scanning solution or the microdroplet residues of the liquid process medium and the microdroplet residue of the blank scanning solution. Detect fluorescence counting rates above these microdroplet residues and above the scanned blank surface under the instrumental parameter adjusted for calibration. The quantification algorithm is given in Section 13.6. Integrated counts above both the blanks and the VPD prepared surface must not exceed 20% of the integrated counts above the microdroplet residue of the collected scanning solution (see Section 9.6 of this document).

13 Quantification Procedure

13.1 The instrument must run under established statistical process control (e.g., as described in Section 15.19 of this document).

13.2 Before releasing results, quote instrumental parameters such as:

- rotating or sealed anode,
- voltage and current applied to the X-ray source,
- characteristic excitation line(s) of the incident X-ray,
- glancing angle(s),
- type of monochromator,
- amount [ng] or [number of atoms] of e.g., Ni in the calibration standard reference microdroplet,
- location of the microdroplet(s) analyzed,
- peak evaluation technique (ROI or peak-fitting),

- measurement time,
- analysis results on the blank microdroplet,
- compositions and amount of the scanning droplet,
- running time since last calibration or frequency of SPC measurement,
- lab environment classification by U.S. Federal Standard 209,
- edge exclusion, if any (c.f., Sections 4.2 and 11.6).

13.3 Quantification of areal density is in units of 10^{10} atoms/cm^2.

13.4 Detection spot area is the surface area where above the fluorescence counts are integrated.

13.5 Scanned surface area is the surface area where the impurities are collected from, according to Section 9.1.

13.6 Calculate the areal density of impurity i according to the following algorithm:

$$c_{i,VPD} = \frac{c_i}{\frac{A_w}{A_m} \cdot R_i} \text{ (atoms/cm}^2\text{)}$$

$$= \frac{n_i}{A_w \cdot R_i} \text{ (atoms/cm}^2\text{)}$$

where;

$c_{i,VPD}$ = density of impurity (i) at scanned area of wafer surface in [atoms/cm ^{2}]

c_i = measured concentration of impurity i at measured spot [atoms/cm ^{2}]

A_w = VPD - scanned wafer area in [cm ^{2}]

A_m = measuring spot area in [cm ^{2}]

R_i = recovery rate of the collected impurity ($0 < R_i < 1$) c.f., Section 4.13

n_i = measured number of atoms of analyte i

The measured concentration c_i of impurity (i) can be related to the reference standard by means of the following expression.

NOTE: The reference standard element is assumed to be Ni in this section.

$$ci = RSF_i \cdot c_{\text{Ni}} / I_{\text{Ni}} \cdot I_i \text{ [atoms/cm}^2\text{]}$$

where;

$c_{\text{Ni}} = n_{\text{Ni}} / A_m$

n_{Ni} = number of impurity atoms (Ni) in the standard reference specimen

I_i = measured fluorescence intensity of impurity (i) in counts per second [cps]
