A recipe is considered **certified** for *agent* if the **certification-level** contained in the *agent-specific attribute* Certified is non-zero. Otherwise, the recipe is *uncertified*. A *certified* recipe is *de-certified* when the *certification-level* is set to zero.

A recipe may be *certified* and *de-certified* only by an *authorized user*. Figure 8.6 illustrates the recipe's CERTIFICATION states. For a description of the transitions, see Table 8.1 in Section 8.3.

Recipes with *variable parameters* may be *certified* for specific *values* and *restrictions* of some of these variables. If so, such values are stored in the AgentSpec_LinkParam *attribute*.

Only recipes with the Linked *attribute* set to TRUE may be *certified*.

The *certify recipe* operation is invoked with the RMNAction service.

8.2.4.3 *De-certify* — The **de-certify** operation clears the Certified attribute for a specific *agent* at the request of an *authorized user*.

A recipe may need to be *de-certified* after major maintenance has been performed and later *re-certified* only after testing its results.

8.2.5 *Recipe Protection* — The *namespace* attribute RecipeReadOnlyLevel is used as a threshold to govern the level of approval required for individual recipes to be protected. A recipe is **protected** when the value in its ApprovalLevel attribute is equal to, or greater than, RecipeReadOnlyLevel. All recipes are protected whenever the namespace's RecipeReadOnlyLevel attribute is equal to zero. Figure 8.5 illustrates the recipe's PROTECTION states. For a description of the transitions, see Table 8.1 in Section 8.3.

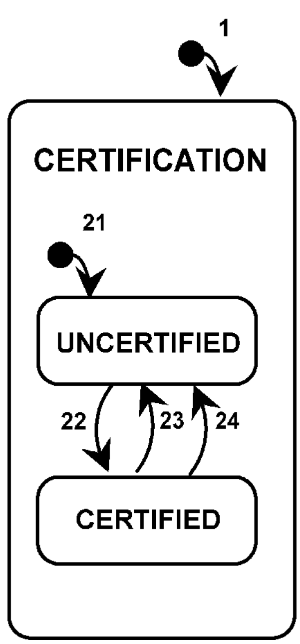

Figure 8.6
Certification State Model

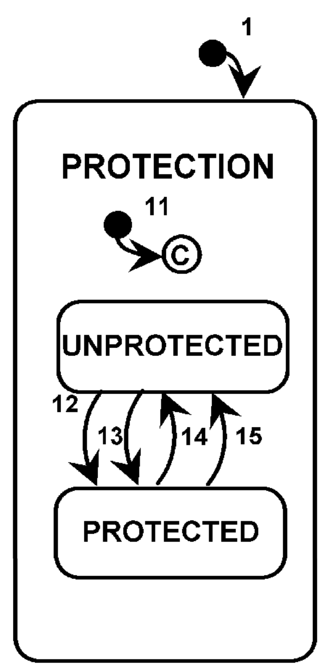

Figure 8.5
Protection State Model

If the value of RecipeReadOnlyLevel is n, then recipes with *approval levels* greater than, or equal to, n are ***read-only***. The body of a *read-only* recipe may not be changed in any way, including by over-writing or deleting. The *identifier* of a *read-only* recipe may not be renamed. A *linked* recipe that is *read-only* may not be *re-linked*.

The *recipe protect* operation sets the value of ApprovalLevel to the value in RecipeRead OnlyLevel. For *linked* recipes with *subrecipes*, the operation is denied if the resulting *approval level* for the main recipe would be higher than any *subrecipe*, as described in Section 8.2.4.

If the value in RecipeReadOnlyLevel is zero, all recipes within the *namespace* are automatically *write-protected*, regardless of the support for the ApprovalLevel *attribute*.

The *protect recipe* operation is invoked with the RMNAction service.

8.2.6 *Unprotect* — The *read-only* status of a recipe may be changed either by changing its *approval level* to a value less than the value of RecipeReadOnlyLevel or by increasing the value in RecipeReadOnlyLevel.

NOTE: If RecipeReadOnlyLevel is zero, all recipes are write-protected regardless of the value in approval-level.

A protected recipe may be changed to **unprotected** at the request of an *authorized user*. This operation *clears* the ApprovalLevel attribute.

The unprotect recipe operation is invoked with the RMNAction service.

8.2.7 *Informational Operations* — Object Services are used to request the current value of one or more recipe attributes and to set one or more values. Certain *attributes* have **restricted access** and may not be set through RMS *services*. These *attributes* are identified as "RO" (read-only) in Tables 3.1 and 3.2 in the column labeled "Access" in Section 3.4.2. When attributes identified as "RW" (read-write) are set through Object Services, the appropriate attribute *length* and *timestamp* attributes shall be updated appropriately.

In addition to Object Services, the **get descriptors** operation provides important information.

8.2.7.1 *Get Recipe Descriptors* — The **get recipe descriptor** operation returns the *descriptor* of a specified recipe: *the generic descriptor*, the *body descriptor*, and the *agent-specific descriptors* of any existing *agent-specific datasets*.

A *recipe descriptor* may be used to determine if two or more recipes are identical or which is most recent.

The *get recipe descriptors* operation is invoked with the RMNGetDescriptor service.

8.3 *Recipe State Model* — An existing recipe has different states of interest to RMS. These are shown in Figure 8.7. The Recipe Available State Model in Figure 8.7 combines the separate models for VERIFICATION, APPROVAL, PROTECTION, LINKAGE, and CERTIFICATION as AND substates of RECIPE AVAILABLE.

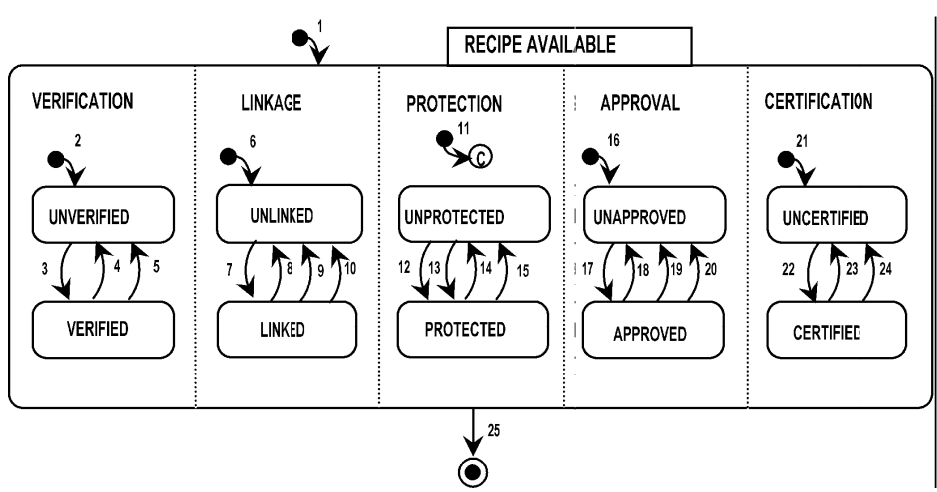

Figure 8.7
Recipe Available State Model

These states have been discussed in previous sections and are associated with one or more of the recipe's *attributes*, as follows:

VERICATION: Verified,

APPROVAL: ApprovalLevel,

PROTECTION: the interaction of ApprovalLevel and the *namespace attribute* RecipeReadOnlyLevel,

LINKAGE: Linked, and

CERTIFICATION: Certified.

The table of transitions is given in Table 8.1.

Table 8.1 Table of Transitions

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	(entry to Recipe Available)	Recipe is created.	Recipe Available.	Initialize generic attributes.	None.
2	(default entry to VERIFICATION)	Recipe is created.	UNVERIFIED	Verified reset.	Newly created recipe is unverified.
3	UNVERIFIED	Requested verification operation is successful.	VERIFIED	Set Verified to TRUE.	Verification is performed by the recipe executor.
4	VERIFIED	Requested verification operation, on previously verified recipe, fails.	UNVERIFIED	Reset Verified.	Verification is performed by the recipe executor.
5	VERIFIED	Recipe is updated.	UNVERIFIED	Reset Verified.	Updated recipe must be *re-verified*.
6	(default entry to LINKAGE)	Recipe is created.	UNLINKED	Reset Linked, LinkList, and LinkParam.	Newly created recipe is *unlinked*.
7	UNLINKED	*Authorized user* requested *link* operation is successful.	LINKED	Set Linked to TRUE. Set LinkList and LinkParam.	Single-part recipes set Linked only.
8	LINKED	Recipe is *updated*.	UNLINKED	Reset Linked, LinkList, and LinkParam.	Single-part recipes set Linked only.
9	LINKED	Recipe is *re-verified*.	UNLINKED	Reset Linked, LinkList, and LinkParam.	Single-part recipes set Linked only.
10	LINKED	*Authorized user requests the* unlink operation.	UNLINKED	Reset Linked, LinkList, and LinkParam.	Single-part recipes set Linked only.
11	(default entry to PROTECTION)	Recipe is created.	If RecipeRead-OnlyLevel is zero, new state is PROTECTED. Otherwise, it is UNPROTECTED.	None.	All recipes are *read only* when RecipeReadOnlyLevel is zero.
12	UNPROTECTED	*Authorized user* request to *protect* the recipe.	PROTECTED	Set ApprovalLevel to the value in RecipeReadOnly-Level.	Recipe is *protected* when *approval level* = RecipeReadOnlyLevel.
13	UNPROTECTED	Authorized user sets RecipeReadOnlyLevel to	PROTECTED	None.	Recipe is *protected* when *approval level* greater than

		value greater than or equal to *approval level*.			or equal to RecipeReadOnlyLevel.
14	PROTECTED	*Authorized user* sets *approval level* to a value less than RecipeReadOnlyLevel.	UNPROTECTED	None.	Recipe is *unprotected* when *approval level* less than RecipeReadOnlyLevel.
15	PROTECTED	*Authorized user* sets RecipeReadOnlyLevel to a value greater than *approval level*.	UNPROTECTED	None.	Recipe is *unprotected* when *approval level* less than RecipeReadOnlyLevel.
16	(default entry to APPROVAL)	Recipe is created.	UNAPPROVED	Reset ApprovalLevel.	Newly created recipe is *unapproved*.
17	UNAPPROVED	*Authorized user* sets non-zero *approval level*.	APPROVED	Set ApprovalLevel as specified by the user.	User assigns *approval level* to a specific value.
18	APPROVED	*Authorized user* sets *approval level* to *zero*.	UNAPPROVED	Reset ApprovalLevel.	User assigns a zero value as *approval level*.
19	APPROVED	Recipe is *linked*.	UNAPPROVED	Reset ApprovalLevel.	User is required to specifically approve a *newly linked recipe set*.
20	APPROVED	Recipe is *updated*.	UNAPPROVED	Reset ApprovalLevel.	A modified recipe is *unapproved*.
21	(default entry to CERTIFICATION)	Recipe is *created*.	UNCERTIFIED	None.	Newly created recipe has no *agent-specific attributes*.
22	UNCERTIFIED	*Authorized user* assigned non-zero *certification level*.	CERTIFIED	Create *agent-specific dataset* if necessary. Set Certified to specified value.	User assigns *certification level*.
23	CERTIFIED	*Authorized user* assigned zero *certification level*.	UNCERTIFIED	Reset Certified.	*Agent-specific dataset* not required if there are no *agent-specific attributes*.
24	CERTIFIED	*Authorized user* changes *agent-specific variable parameter restrictions*.	UNCERTIFIED	Reset Certified.	A change in restrictions affects performance of recipe.
25	CERTIFIED	*Recipe* is *unlinked*.	UNCERTIFIED	Reset Certified attribute.	Agent-specific dataset not required if there are no agent-specific attributes.
26	RECIPE AVAILABLE	Authorized user deletes unprotected recipe.	(Undefined recipe no longer exists.)	Storage occupied by recipe becomes available.	None.

8.4 *Table of Operations* — Table 8.2 lists the *recipe management* operations in the order presented in this section. The column labelled "Rqmt" is used to indicate those operations that are required for *fundamental compliance* to RMS.

Table 8.2 Recipe Management Operations

Operation	*Description*	*Rqmt*
create recipe*	A new recipe body is entered into the namespace.	Y
update recipe*	The body of an existing recipe is replaced.	Y
verify recipe	Check the syntax or format of a recipe body for correctness.	Y
link recipe	A *main* recipe is *linked*.	Y
unlink recipe	An *unprotected linked* recipe is *unlinked*.	N
modify variable parameters	A *linked* recipe's parameter definitions are modified within an *agent-specific dataset*.	N
approve recipe	Set the recipe's *approval level* to a non-zero value.	N

protect recipe	Set the recipe's *approval level* to the value in RecipeReadOnlyLevel.	N
unprotect recipe	Set the recipe's *approval level* to zero.	N
certify recipe	A linked recipe's certification level is set to a non-zero value.	N
decertify recipe	A linked recipe's certification level is set to zero.	N
get recipe descriptor	A recipe's descriptor is requested.	Y

*This operation is also covered under Namespace Management Operations.

9 Namespace Management Operations

Namespace management operations include operations that affect the *namespace* itself in some way and those operations that provide information about the *namespace* or its *manager*, or that require knowledge about more than one recipe.

Namespace operations defined in RMS are presented in groups of similar functionality:

- *operations on the* namespace *(create, delete, and rename* namespace*),*
- *operations that provide information about the* namespace *or its recipes (get available storage, check recipe status, and get best version), and*
- *operations on recipes that affect the set of recipe identifiers within the* namespace *and/or moving a recipe as a whole (create, delete, store, retrieve, copy, and rename recipe),*
- *operations that always require interactions with a* recipe executor *(*verify*, download, and upload recipe).*

Namespace management operations may be invoked through *namespace* services defined in Section 12. In most cases, service scenarios consist of a single message request from the service user and a corresponding response from the *namespace manager*. This case is illustrated in Section 12.1.

Scenarios are shown only for operations that require additional messages. These operations are one of two types: operations that may be performed on more than one recipe (such as **delete recipe**) and operations that require interactions with a *recipe executor* to complete.

Operations such as these may require more time to complete. The initial response to the message service request only indicates the intent to perform the operation. The *namespace manager* informs the service user of the completion of each individual operation by sending the notification message RMNComplete. (See Section 12.1 for more detail.)

9.1 *Applications of Object Services* — A *manager* shall comply with SEMI E39 (Object Services Standard (OSS): Concepts, Behavior, and Services) specifications for *fundamental requirements* and with the requirements for Filters and Owner Objects.

9.1.1 *Object Specifiers* — The "owns/owned by" relationship is used by OSS to define the object specifier used for scope. Recipes within a *namespace* are *owned* by the *namespace* in which they reside. The *namespace* in turn is owned by its *manager*. The *agent* that provides the storage and services for a *centralized namespace* owns both the *manager* and the *namespace*.

An object specifier has the form of:

$$\text{“}\text{type}_1 : \text{id}_1\text{>}\ldots\text{type}_n : \text{id}_n\text{>”}$$

where "type_i" and "id_i" represent the object type and object identifier, respectively, of the ith object instance in the sequence, and where each object is owned by the preceding object in the sequence and is the owner of the succeeding object.

A **namespace specifier** is an object specifier applied to *namespaces*. A **recipe specifier** is an object specifier applied to recipes.

Object types in the object specifier may be omitted where they may be otherwise determined. For the *recipe specifier*, when omitted, they are determined by their relative positions, with the recipe identifier in the final position, preceded by a *namespace identifier*. Additional *identifiers* preceding that of the *namespace* are those of *agents*.

An example of a *namespace specifier* for a namespace "NS-MOM" owned by an *agent* "Etch01" would be "Agent:Etch01>RNS:NS-MOM>" or (where object types can be otherwise determined) "Etch01>NS-MOM". A recipe specifier for recipe "/PROCESS/ ABC;5" stored in NS-MOM would be "Agent: Etch01>RNS:NS-MOM>/PROCESS/ABC; 5>".

Where the *manager* is to be used instead of the *namespace*, the object type of the *manager* must be included.

A recipe in a *namespace* also owns its components. An *agent-specific attribute* is accessed through the recipe owner.

9.1.2 *Required Object Services* — A *manager* shall support operations for Get Attributes and Set Attributes for the *attributes* of the *namespace*, the recipes within the *namespace*, and the *manager* itself. For a *shared namespace*, access to different *agent-specific datasets* shall be supported.

When a recipe's *attributes* are changed through the Set Attributes operation, the appropriate attribute *timestamp* and *length attributes* shall be updated as well.

A *manager* shall support the Get Type and Get Attribute Name operations for the object types of *namespace*, recipe, recipe *components*, and *manager*.

9.2 *Namespace Operations* — This section describes operations that are performed on a *namespace*.

9.2.1 *Create Namespace* — The **create namespace** operation is used to define a *namespace* and assign a *name* to be used as its *identifier* ObjID. The *name* is assigned only by an *authorized* user, except that a *name* of "Default" is prohibited. Once *created*, the *namespace* shall be ready to accept recipes.

This is an optional capability that is not required if the *owner agent* that provides the *namespace* capabilities also provides an installed *default namespace* (see Section 6) that cannot be deleted. In this case, a means of recreating the *namespace* shall be provided in the event the *namespace* becomes damaged.

The *create namespace* operation is invoked with the message service RMNCreateNS.

9.2.2 *Delete Namespace* — The **delete namespace** operation is the inverse of the *create namespace* operation. A *namespace* that is not *empty* may not be *deleted*. It is recommended that the *default namespace* of a *recipe executor* should not be *deleted*. This is an optional capability required only if the *create namespace* operation is supported.

The *delete namespace* operation is invoked by the message service RMNDeleteNS.

9.2.3 *Rename Namespace* — The **rename namespace** operation allows an *authorized user* to change the *identifier* of the *namespace*. It is recommended that the *default namespace* of a *recipe executor* should not be renamed. This is an optional capability required only if the *create namespace* operation is supported.

The *rename namespace* is invoked by the message service RMNRenameNS.

9.3 *Namespace Informational Operations*

9.3.1 *Get Available Storage* — The **get available storage** operation is used to determine the size of the remaining recipe storage capacity, in bytes. The value returned shall exclude any overhead requirements for storage of one *generic* recipe. That is, it shall be assumed that sufficient storage exists for a single recipe with a combined *generic attribute length* and *body length* less than or equal to the returned value, and ignoring possible space requirements for additional *agent-specific datasets*. This is a required operation.

The *get available storage* operation is invoked by the message service RMNSpaceInquire.

9.3.2 *Check Recipe Status* — The **check recipe status** operation checks a recipe *identifier* and returns the status for existence and *read-only* (PROTECTED or UNPROTECTED state). It also returns the next available *numeric version*. This is a required operation.

This operation may be used to determine if a given recipe *identifier* will be accepted prior to sending it to the *namespace* and to obtain an available version if the original *identifier* is used for a *read-only* recipe.

The *check recipe status* operation is invoked by the message service RMNRecStatInquire.

9.3.3 *Get Best Version* — The **get best version** operation checks for the best *default version* of a recipe with a specified *class* and *name* and for an optional specific *member agent*. If a *member agent* is specified, then in addition to the rules for selection of a default version defined in Section 3.2.3.4.1, the *version* with the highest *certification level* for that *agent* is selected. This is a required operation.

The *get best version* operation is invoked by the message service RMNVersionInquire.

9.4 *Namespace Recipe Operations* — This section describes the recipe operations that affect the set of recipe *identifiers* within the *namespace* and/or involve moving an entire recipe.

9.4.1 *Create Recipe* — A recipe is created through the **create recipe** operation when a *namespace* is sent a recipe with an *identifier*, *body*, *body descriptor*, and the *attributes* BodyFormat and EditedBy only. This operation sets the attributes AttrLength and AttrChgTime and *clears* the remaining *generic attributes*.

This capability allows a recipe body that has been created off-line to be stored in a *namespace*. It is required of any *namespace* intended for use other than as a *default namespace* for hardware-specific recipes only[10].

The *create recipe* operation is invoked by the message service RMNCreate.

9.4.2 *Delete Recipe* — The **delete recipe** operation has the effect of deleting a recipe from the *namespace*. Complete physical erasure of the recipe is not required, but the recipe is no longer considered to be stored in the *namespace*, is no longer accessible, and the storage space that it used is freed.

A *read-only* recipe may not be *deleted*.

The *delete recipe* operation is invoked by the message service RMNAction. More than one recipe may be specified by the service user. Figure 9.1 illustrates the flow of messages in this case. The *namespace manager* responds to the initial request with an intent to comply before performing any deletions. As each deletion is completed, the *manager* notifies the service user of the results using RMNComplete.

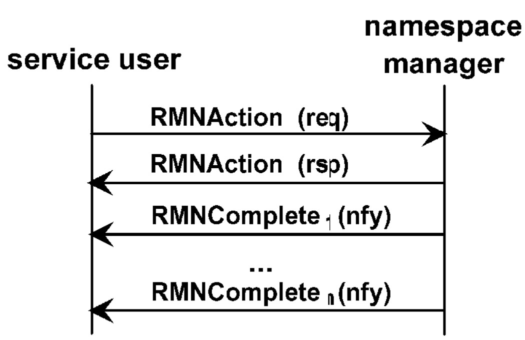

Figure 9.1

Delete Recipe Scenario

9.4.3 *Store Recipe* — The **store recipe** operation is used to store a complete recipe, including its *body, generic attributes*, and one or *more agent-specific datasets*, in a *namespace*. Note: methods of storing recipes are not specified by RMS.

Storage shall be denied if the specified recipe *identifier* is already used by an existing *read-only* recipe or if there is insufficient storage available for the recipe. Otherwise, the recipe shall be accepted into the *namespace*.

The *store recipe* operation is invoked by the message service RMNStore.

9.4.4 *Retrieve Recipe* — The **retrieve recipe** request specifies the *identifier* of a recipe. If the recipe exists within the *namespace*, the *namespace manager* returns the requested recipe. Otherwise, it shall deny the request. This is a required operation.

It is also possible to *retrieve* a recipe's *generic attributes* set to a *non-default value* and/or one or more of its *agent-specific datasets* without *retrieving* its *body*.

The retrieve recipe operation is invoked by the message service RMNRetrieve.

9.4.5 *Copy Recipe* — The copy recipe operation causes a new copy of a recipe, with a different *identifier* from the original recipe, to be created within the *namespace*. If the *identifier* for the new *copy* is already in use by a pre-existing *read-only* recipe, the namespace shall deny the request.

The *copy recipe* operation is invoked by the message service RMNCopy.

9.4.6 *Rename Recipe* — The rename recipe operation causes a recipe to be assigned a new *identifier* within the *namespace*. If the new *identifier* is already in use by a pre-existing *read-only* recipe, the namespace shall deny the request. In this case, it may suggest a new *version* according to the rules in Section 3.2.3.3.

The *rename recipe* operation is invoked by the message service RMNRename.

9.4.7 *Verify Recipe* — A *manager* is not required to understand the syntax or semantics of the recipe language of a *source* recipe or to understand the internal format of an *object form* recipe. To *verify* a recipe, the *manager* may require the services of a *recipe executor*, described in Section 6. In this case, the *manager* shall request *verification* from the *recipe executor* of one of the *agents* listed in its Members attribute and shall return the resulting status and error information to the initial requestor. (See Section 11 for more detail.) This is a required operation.

10 In the case of the default namespace dedicated to hardware-specific recipes, the recipes may always be created initially by the recipe executor and uploaded to namespace.

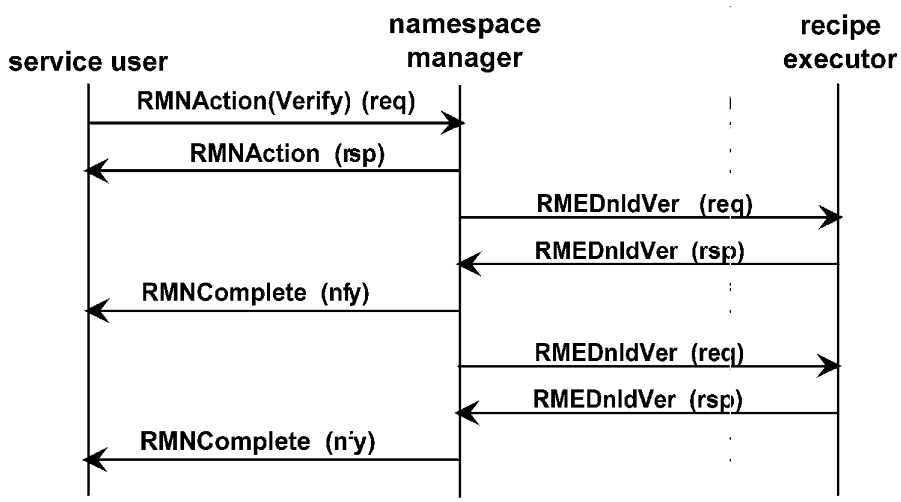

Figure 9.2
Verify Scenario

The *verify recipe* operation is invoked by the message service RMNAction. Figure 9.2 shows a typical sequence of the message flow when the *verify* operation is requested for multiple recipes. The *namespace manager* responds to the service request RMNAction (Verify) with an intent to perform the requested operations. Each recipe specified in the request is downloaded to a *recipe executor* of an *agent* listed in the *namespace* attribute Members. (Note: where the *namespace manager* and *recipe executor* are provided by the same *agent*, formal RMS services are not required for communications between the two.) In this example, the *recipe executor* responds to the *namespace manager* with an intent to comply, *verifies* the recipe, and returns the information required for the completion of the *verify* operation as described in Section 8.2.3.1. The *namespace manager*, in turn, returns the final status of the operation for that recipe in the notification message RMNComplete.

The *recipe executor* provides two operations for performing verifications, "download and verify" and "verify". The former operation does not typically *re-verify* already *verified* recipes. See Sections 11.2.1 and 11.2.2 for detail.

The *verify recipe* operation is invoked by the message service RMNAction.

9.4.8 *Download Recipe* — The **download recipe** operation causes the *namespace manager* to download a recipe to the *recipe executor* of a specified *agent* (see Section 11.2.1). This operation differs from the verify operation, which results in a download to an unspecified recipe executor if the *namespace manager* is not able to perform the verification without help.

The *namespace manager* is responsible for converting the form of a *managed recipe* to that of an *execution recipe* for downloading. This is accomplished through the following steps:

1. If the recipe is not *verified*, then no conversion is performed. The attributes ExecAttrLength and ExecAttrChgTime are set and maintained only by the *recipe executor*. These attributes are not sent with the downloaded recipe.

2. The *generic* attributes ExtRef and Parameters of the *verified* recipe are not sent with the downloaded recipe.

3. If an *agent-specific dataset* exists that corresponds to the destination *recipe executor*, and if the *agent-specific* attributes AgentSpec Comments and Certified are non-empty, they are included in the attributes of the downloaded recipe.

4. The *execution recipe* attribute ExecLinkParam combines the contents of the *generic* attribute LinkParam and the *agent-specific* attribute AgentSpec LinkParam. If an *agent-specific dataset* exists that corresponds to the destination *recipe executor*, and if there are *variable parameter initial values* and *restrictions* in the *agent-specific* attribute AgentSpec LinkParam, then they replace their corresponding elements in the *generic attribute* LinkParam, and the results are placed in the ExecLinkParam attribute of the downloaded recipe.

The *download recipe* operation is invoked by the message service RMNAction.

9.4.9 *Upload Recipe* — The **upload recipe** operation causes the *manager* to upload a recipe from the *recipe executor* of a specified *agent* (see Section 11.2.3). This operation is the equivalent of a *namespace-initiated recipe create* (if the specified recipe *identifier* does not already exist in the *namespace*) or a recipe update.

The *upload* operation allows recipes that have been *created* or modified by the *recipe executor* to be placed under management in a *namespace*. Such recipes are always *unlinked*.

In addition, it is possible to upload previously downloaded recipes. However, due to the differences in the attributes, certain intermediate information available in a *managed recipe*, such as ExtRef and Parameters, must be re-created for the uploaded recipe by requesting the *recipe executor* to *verify* the recipe and send the results.

In the case of the *derived object form* recipe, where the original source recipe identified in the SrcRcpID attribute (common to both recipe types) exists within the *namespace*, most of the attributes of the *derived object form* recipe are identified to those of the original. The exceptions are the attributes AttrLength, AttrChgTime, BodyLength, BodyFormat, and EditTime, which are all set by the *recipe executor* at the time the *derived object form* recipe is derived.

The *namespace manager* is responsible for converting the uploaded *execution recipe* to a *managed recipe* for storage in the *namespace*. This is accomplished through the following steps:

1. If the recipe is not *verified*, then no conversion is performed. The attributes ExecAttrLength and *ExecAttrChgTime*, if uploaded, are discarded.

2. The *generic* attributes ExtRef and Parameters of the *verified* recipe are not sent with the uploaded recipe. They must be obtained separately through the *verify*.

3. If an *agent-specific dataset* exists that corresponds to the destination *recipe executor*, then if the *execution recipe* attributes AgentSpec Comments and Certified are non-empty, they are placed in the corresponding attributes of an *agent-specific dataset* for that *recipe executor*. If necessary, an *agent-specific dataset* is created.

4. Any *variable parameter initial values* and *restrictions* in the *execution recipe* attribute AgentSpec-LinkParam replace their corresponding elements in the corresponding *agent-specific attribute* (if the *dataset* for that *agent* exists) in the uploaded recipe. If it can be determined that the contents of AgentSpec LinkParam are not different from those of the *generic* attribute LinkParam (as in the case of a *derived object form* recipe), then AgentSpec LinkParam should be discarded. If necessary, an *agent-specific dataset* is created for the appropriate *agent*.

The *upload recipe* operation is invoked by the message service RMNAction.

9.5 *Synchronization* — In addition to the explicit operations that are invoked through specific message services, the *recipe namespace manager* may provide the optional capability of **sychronization** of the *managed recipes* with *execution recipes* stored by the *recipe executors* of its *member agents*. This section describes the *synchronization* capability.

The ExecChgCtrl attribute of a recipe is used to specify types of permitted changes in *execution recipes*. The *recipe executor* is permitted to change the recipe body or to save the last settings used for *variable parameters* in the ExecLinkParam attribute of the *execution recipe* only when expressly granted permission in ExecChgCtrl.

ExecChgCtrl may also require the *recipe executor* to send a **change notification** message to the recipe's **originating namespace**. The **originating namespace** is either the *namespace* from which the recipe was *downloaded* or to which a new recipe will be *uploaded*. *Change notification* applies to both the explicitly permitted changes (modification and saving the *last value*) and to a *derived object form recipe* built from a *source form recipe*. *Change notification* informs the *namespace* that a change of interest to the *namespace* has occurred.

Namespaces with *synchronization* capability provide two additional attributes, SynchOn and SynchFail. The first allows the user to disable *synchronization* or to select the types of synchronization desired, and the second records *execution recipe specifiers* of recipes for which *synchronization failed*.

Synchronization for a new or changed recipe, or a new recipe *form*, consists of *uploading* the *execution recipe* for which a *change notification* has been received and, when necessary to protect a *read-only* recipe, assigning it a new *version number* and requesting the *recipe executor* to rename the corresponding *execution recipe*. Note that the *recipe executor* is required to deny attempts to rename a currently *selected execution recipe*.

The *recipe executor* saves the *last value* of a *variable parameter* in the *execution recipe* attribute Exec-LinkParam. **Synchronization** for a new *last value* consists of getting the value of this attribute from the *recipe executor* and updating the AgentSpec LinkParam attribute of the *agent-specific dataset* for the *recipe executor's agent*. Note that attributes of a recipe may change without affecting the *version number*.

Synchronization may fail either through failure to properly *upload* an *execution recipe*, through failure to properly retrieve the value of the *execution recipe's* ExecLinkParam attribute, or through failure to successfully rename the recipe stored by the *recipe executor*. The attribute SynchFail contains a list of *recipe specifiers* of the *execution recipes* for which *synchronization* was attempted but failed to be successfully completed. A *recipe specifier* shall be deleted from SynchFail if a later attempt at the failed operation for that recipe is successful. The *authorized user* may also remove one or all *recipe specifiers* from this attribute.

The attribute SynchOn is set by the user to indicate the types of changes for which *synchronization* shall be performed. SynchOn may be set to specify *synchronization* for changes to the body, changes to the *last value*, creation of a new recipe, building a new *derived object form* recipe from a *source form*, or any combination of these settings. A value of zero disables *synchronization*.

SynchOn is an unsigned integer. Possible values are either 0 (disabled) or any combination (sum) of one or more of the following decimal values:

0 = synchronization disabled

1 = changes in body

2 = new *execution recipes*

8 = changes in the *last value* of one or more *variable parameters* (i.e., to the ExecParam attribute of the *execution recipe*)

16 = new *derived object form execution recipes*

NOTE: Where possible, the values of SynchOn and ExecChgCtrl address the same change issues. For this reason, a value of 4 is not used, and a new value of 16 is added.

9.6 *Table of Operations* — Table 9.1 lists all the operations defined for *namespace management*.

The column labeled "Rqmt" is used to indicate those operations that are required for *fundamental compliance* to RMS as a *recipe namespace resource*.

Table 9.1 Namespace Operations

Operation	*Description*	*Rqmt*
create namespace	A new *namespace* is created and assigned an identifier.	N
delete namespace	A *namespace* is deleted.	N
rename namespace	The *namespace identifier* is re-assigned.	N
get available storage	Determine the amount of recipe storage available.	Y
check recipe status	Determine the existence and *read-only* status of a recipe, and obtain the next numeric *version*.	Y
get best version	Determine the default version for a given recipe class and *name* and for an optional *agent*.	Y
create recipe	A new recipe body is entered into the namespace.	Y
delete recipe	A recipe's identifier is removed from the *namespace.*	Y
store recipe	A recipe is stored in a namespace.	Y
retrieve recipe	A recipe is sent from the namespace.	Y
copy recipe	A new recipe is originated as a copy of an existing recipe.	N
rename recipe	A recipe is assigned a new identifier.	N
verify recipe	Check the syntax or format of a recipe body for correctness.	Y
download recipe	A recipe is downloaded to a specified agent's *recipe executor.*	Y
upload recipe	A recipe is created or updated by uploading a recipe *body* from a specified agent's *recipe executor*.	N

9.7 *Namespace Events* — A user of recipe namespace services is potentially interested in any change that occurs to or within a namespace that was not initiated by the user itself. Two such events are defined: Recipe Namespace Change and Recipe Change. A Recipe Namespace Change event occurs when a namespace is created, deleted, or renamed, or when a recipe is created, deleted, copied, or renamed. A Recipe Change event occurs whenever the body or any of the attributes, including *agent-specific attributes*, of an existing recipe is changed.

The selection of events to be reported, and the mechanisms for reporting these events, are defined in SEMI E53 (Event Reporting).

10 Distributed Recipe Namespace Management Operations

This section defines the operations required for the *distributed recipe namespace* capability. Operations are defined for the *DRNS segment*, the *DRNS recorder*, and the *DRNS manager*, in that order. Support for the *distributed recipe namespace capability* is not required for RMS compliance.

10.1 *Distributed Recipe Namespace Segment Operations* — This section defines the operations that shall be supported by the *distributed recipe namespace segment*.

10.1.1 *Object Services* — The *DRNS segment* is considered to own the recipes that it stores.

The **segment specifier** is the object specifier for a *DRNS segment* and has the form "type1:id1>...>type2:id2". An attached *DRNS segment* is owned by the *agent* providing the *DRNS segment* capabilities, by the *distributed recipe namespace* of which it is a component, and by the *DRNS manager* to which it is attached, and shall be accessible by any of these three paths. An unattached *DRNS segment* is owned by the providing *agent*.

An example of a *segment specifier* for a *DRNS segment* named ABC_Etch_Seg, a component of a *namespace* named WetEtchA provided by an *agent* named WetEtch003, is

"Agent:WetEtch003>RNSD:WetEtchA>RNSDSegment:ABC_Etch_Seg".

For a *master segment* Alpha provided by *agent* RecipeServer, this becomes

"Agent:RecipeServer>RNSD:WetEtchA>RNSDMaster:Alpha."

NOTE: The form of the specifier used for *DRNS segments* and *DRNS recorders* will vary. For example, to specify a *segment* to be attached to a *DRNS manager*, the specifier must include the object type and identifier for the *agent* providing the *segment* capability. Once the *segment* is attached, it may be specified through the *namespace* hierarchy, as in the example above.

10.1.1.1 *Attribute Read/Write* — The *DRNS segment* shall support the get attributes operation for itself and all recipes that it has stored.

It shall support the set attributes operation for its recipes only according to the restrictions against change defined in Section 5.4.2 and within Section 10.1.

If requested to change *read/write* attributes, it shall request and receive permission to change attributes prior to making such change.

A request to change either several *generic* attributes at the same time, or several *agent-specific* attributes for a specific *agent-specific dataset* at the same time, is considered for approval purposes as one change. However, changes to both *generic* and *agent-specific* attributes shall not be included in one change request or change.

10.1.1.2 *Create and Delete Operations* — The *segment* may support both the create object and delete objects pair of operations. The *authorized user* who invokes the create object operation shall assign a name to be used as its *name* ObjID. The *name* "Default" is prohibited. Once *created*, the *segment* shall be attached to a specific *manager* before it is permitted to accept recipes.

The create and delete operations are optional if the *owner agent* that provides the *distributed recipe namespace segment* capabilities provides an installed *distributed recipe namespace segment* that cannot be deleted. In this case, a means of recreating the *segment* shall be provided in the event the *segment* becomes damaged. If one of these two operations is supported, both are required.

The attributes Namespace, NamespaceManager, and RecipeReadOnlyLevel shall be set to null values at the time the *segment* is *created*.

A *segment* that is attached or that contains recipes (is not **empty**) shall not be *deleted*.

10.1.1.3 *Object Attachment Operations* — The *segment* shall support the operations to attach and reattach to a *DRNS manager*, and also the operations invoked by its *manager* to detach itself from a *DRNS namespace manager*. It shall also support the attach set attributes operation. Certain RMS operations shall be accepted only when received from its *manager*, as indicated below.

All requests for changes to recipes within the *segment* shall be sent to the *DRNS manager* to which it is attached.

The *manager* shall set the *segment* attributes Namespace, NamespaceManager, and RecipeRead-OnlyLevel when attaching or reattaching a *segment*. It may change these attributes for an attached *segment* at any time.

The detach operation breaks the logical connection between the *segment* and its *manager*. The *segment* becomes unattached, and the values of Namespace, NamespaceManager, and RecipeReadOnlyLevel are set to a null value. All recipes and recipe attributes are considered as *read-only* during the time the *segment* is unattached.

The reattach object operation is used in rebuilding a *distributed recipe namespace*. This operation sets the value of the attribute NamespaceManager to the name of the new *manager*. The *segment* returns a new token value to the *manager*.

The request to reattach itself serves to inform the *segment* that any of its *pending change requests* not previously approved have now been forgotten. The *segment* should either discard the request or resubmit it to its new *manager*.

10.1.2 *Segment Recipe Management Operations* — Within a *distributed recipe namespace* environment, all recipe management operations (Section 8) and namespace recipe operations (Section 9.4) are performed by the *DRNS segment*. The *DRNS segment* shall support all operations defined in these sections.

Operations defined in Section 9.4 that involve a *recipe executor*, such as *download* and *upload*, shall be performed only with a *recipe executor* that is either owned by the *agent* providing the *DRNS segment* capability or is owned by a component within the internal hierarchy of that *agent*. For example, a *DRNS segment* provided by a cluster tool may *download* to a *recipe executor* owned by a cluster module but not to equipment external to the cluster.

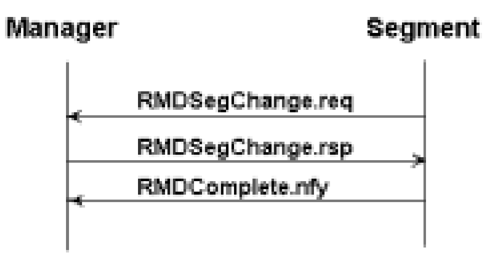

Figure 10.1

Segment-Initiated Change Request Message Flow

10.1.2.1 *Requirements for Approval* — Operations that change a recipe in any way shall be denied unless the *DRNS segment* is attached to a *DRNS manager*. All changes to logical recipes within a *DRNS segment* shall be approved by the *DRNS manager* before the changes are made to the recipe stored within the *DRNS segment*.

Changes to *agent-specific datasets* stored by attached *dedicated segments* are pre-approved. This is possible since, at most, one *dedicated segment* has an *agent-specific dataset* for a specific *agent* for any given recipe. However, the *segment* shall notify its *manager* immediately after any such change by sending the RMDNotify notification, which shall include the attribute AgentSpec_Agent, to identify the *agent-specific dataset*, as well as all *agent-specific* attributes that changed, regardless of whether they have been reset to their default value or set to a non-default value. (Otherwise, the entire *agent-specific dataset* would be required.)

A *master segment*, however, is prohibited from changing an *agent-specific dataset* without explicit permission from the *manager*.

Requests for changes that are made with RMS services defined in Section 12 may be sent from any service user, including the *DRNS manager*. The *DRNS segment* may reject requests for invalid changes, such as a request to modify a *read-only* recipe. Otherwise, the *DRNS segment* shall request approval from its *DRNS manager* for each change (Section 10.3.5). The *manager* responds by either approving, denying, or putting the request on hold.

NOTE: Service requests sent directly to a *DRNS segment* may not, in some circumstances, be fulfilled.

If the *change request* is denied, then the change is prohibited immediately. If it is put on hold, the *segment* shall retain the information necessary to effect the desired change at a later time.

If the *change request* is approved, the *DRNS segment* shall proceed with the change and shall notify its *DRNS manager* when the change is completed, either normally or abnormally, through sending the notification RMDComplete with the results, as illustrated in Figure 10.1.

The *DRNS manager* will put a *change request* on hold when another *change request* exists for the same recipe and the recipe is *locked*. In this case, the *DRNS manager* responds to the *segment's change request* with an *operation identifier* that the *manager* uses later when sending a **segment change approval** request.

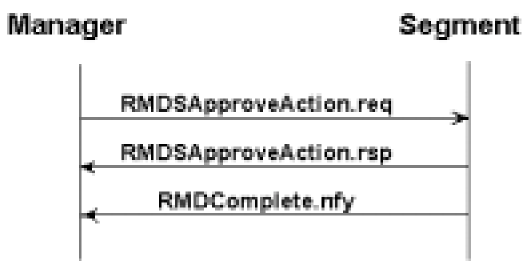

Figure 10.2

Message Flow for Manager Approval of Change Request

10.1.2.2 *Segment Change Approval* — The *DRNS segment* may receive a **segment change approval** request for an action that the *DRNS segment* had earlier requested. This informs the *DRNS segment* that an earlier *change request* made by the *DRNS segment* has now been approved for immediate action or has been completely denied.

The *segment* shall respond in one of three ways:

— It may reject the approval due to changes in circumstances since the original request was made (Figure 10.2(a).

— It may first fulfill the change request and then respond that the change request has now been completed, either successfully or unsuccessfully (Figure 10.2(a).

— It may first respond that it accepts the change request and then attempt to complete the change. When change request has been completed, normally or abnormally, the *segment* shall notify the *manager* of the results with the RMDComplete notification service (Figure 10.2(b).

Rejection of *segment change approval* shall be used when the change is no longer desired. For example, a *DRNS segment* "S" may request to *link* a *write-protected* recipe, and the *manager* responds that the request is on hold. Before the *segment* receives approval for that change, the same *logical recipe* is *linked* by a different attached *DRNS segment*, and the results are updated to each *DRNS segment* having a copy of the *logical recipe*, including *segment* "S". In this case, the recipe may not be relinked.[11]

The *segment change approval* operation is invoked by the message service RMDSApproveAction by the *segment's DRNS manager* and is otherwise invalid.

10.1.2.3 *Scenario of a Segment Change Request* — A typical scenario is illustrated in Table 10.3.

In this scenario, a local operator wants to change the generic attribute EditedBy. The *segment* requests approval for a generic attributes change. However, an *active change request* exists for this recipe.

11 Both the DRNS manager and the DRNS segment are responsible for compliance to RMS namespace requirements

Table 10.3 Typical Change Request Scenario

Manager	*Segment*
	Receives request for attribute change from local operator. Requests change from manager.
	<- RMDChangeRequest.req
Manager already has an active change request to link that recipe and answers that the request is on hold:	
RMDChangeRequest.rsp ->	
The active change request completes. The manager updates the change to the segment:	
RMNStore.req ->	
	The segment responds that it will make the change and notify the requestor when done.
	<- RMNStore.rsp
	The segment requests approval to make the second change:
	<- RMDChangeRequest.req
The manager approves the second request immediately:	
RMDChangeRequest.rsp ->	
	The segment stores the generic attributes sent by its manager.
	<- RMDComplete.nfy
	The segment notifies the requestor of the second change (in this case, its manager) that the change is complete.
	<- RMNComplete.nfy
When all other segments are similarly updated, the manager now approves the segment's earlier request to change generic attributes:	
RMDSApproveAction.req ->	
	The segment makes the approved change to <u>EditedBy</u> and then responds:
	<- RMDSApproveAction.rsp
	The segment sends notification to the operator making request for first change.
	change:
	<- RMNComplete.nfy
The manager requests the new set of generic attributes:	
RMNRetrieve.req ->	
	The segment sends the generic attributes to any requestor:
	<- RMNRetrieve.rsp

10.2 *Distributed Recipe Namespace Recorder* — This section defines the operations supported by the *distributed recipe namespace recorder*.

10.2.1 *Object Services* — The *recorder specifier* is the object specifier of the *recorder*. A *recorder* is owned by the *agent* providing the *DRNS recorder* capabilities. When attached to a *DRNS manager*, it is also owned by that *manager*. An example of the object specifier for a *recorder* named Recorder182 provided by *agent* RecorderServer is

"Agent:RecorderServer>RNSDRecorder:Recorder182>".

10.2.1.1 *Attribute Read/Write* — The *DRNS distributed recipe namespace recorder* shall support the get attributes operation for its attributes. It shall deny attempts to set its attributes through the set attributes service.

10.2.1.2 *Object Create and Delete Operations* — The *recorder* may support both the create object and delete object pair of operations. The *authorized user* who invokes the create object operation shall assign a name to be used as its *name* ObjID. The *name* "Default" is prohibited.

Once *created*, the *recorder* shall be attached to a specific *manager* before it is ready to accept data. Once *created*, the *recorder* shall set its attributes other than ObjID to null or empty values.

The create and delete operations are not required if the *owner agent* that provides the *distributed recipe namespace recorder* capabilities provides an installed *distributed recipe namespace recorder* that cannot be deleted. In this case, a means of recreating the *recorder* shall be provided in the event the *recorder* becomes damaged. If either of these two operations is supported, both are required.

10.2.1.3 *Object Attachment Operations* — The *recorder* shall support the operations to attach and reattach to a *DRNS manager*, and the detach and attach set attributes when invoked by the *DRNS manager* to which it is attached.

The *recorder* attributes Namespace and Namespace-Manager are set by the attach and reattach operations.

The detach operation breaks the logical connection of the *recorder* to the *namespace* and *managers* by setting the *recorder* attributes Namespace and Namespace-Manager to *null values*.

NOTE: In the event that a *distributed recipe namespace* becomes damaged, its *recorder* should be left attached so that it may later be reattached to a new *manager*.

The reattach operation is used in rebuilding a *distributed recipe namespace*.

10.2.2 *Add Segment Record* — The **add segment record** operation adds a given *segment* (its *object specifier*) to the *DRNS recorder's* internal list of *DRNS segments*. A request to *add* a *DRNS segment* that is already in the list shall be denied.

The *add segment record* operation is invoked by the service RMDRAddSegRecord.

10.2.3 *Delete Segment Record* — The **delete segment record** operation deletes a given *segment specifier* from the *DRNS recorder's* internal list of *DRNS segments*. A request to *delete* a *segment* not in the current list shall be denied.

The *delete segment record* operation is invoked by the service RMDRDelSegRecord.

10.2.4 *Add Change Request Record* — The **add change request record** operation adds a *change request record* to the *DRNS recorder*. The *DRNS recorder* keeps, at most, one *change request record* per recipe at any time. This is intended to represent a change currently approved and *active* for that recipe. If the *DRNS recorder* already has a *change request record* for the specified recipe, the information in the new *change request* replaces the previous information.

The contents of the *change request record* are defined in Section 10.3.7.4.

The *add change request record* operation is invoked by the service RMDRAddChgRecord.

10.2.5 *Delete Change Request Record* — The **delete change request record** operation removes a *change request record* for a specified recipe.

The *delete change request record* operation is invoked by the service RMDRDelChgRecord.

10.2.6 *Get Change Request Record* — The **get change request record** operation returns the current *change request record* for a specified recipe or assigned *segment*.

The *get change request record* operation is invoked by the service RMDRGetChgRecord and is available to any service user.

10.3 *Distributed Recipe Namespace Management Operations* — Operations defined in Sections 8 and 9 shall be supported by the *DRNS manager*. This section defines the additional operations provided by the *DRNS manager*. Operations defined in Sections 8 and 9.4 are delegated by the *DRNS manager* to an attached *DRNS segment*.

10.3.1 *Object Services* — The *DRNS manager* is considered to own the *DRNS segments* and any *DRNS recorder* currently attached to the *distributed recipe namespace*. In addition to the object services required in Section 9, the *DRNS manager* shall support the get type and get attribute name operations for its attached objects. The *DRNS manager* shall support object services directed to any of its attached objects and to recipes stored by specific *DRNS segments*.

The *DRNS manager* is considered to own the recipes that are owned through delegation by any of its attached *DRNS segments*. The Get Attributes and Set Attributes operations for a recipe may be directed to the *distributed recipe namespace*.

The object specifier for an object owned by a *DRNS manager* is formed by concatenating the object type and identifier for either the *manager* or the *namespace*, followed by the object type and identifier of each owned object in the ownership hierarchy. An example of the object specifier for a recipe XYZ;3 stored by *DRNS segment* ABC_Etch_Seg within the *distributed recipe namespace* WetEtch003 would be:

"RNSD:WetEtch003>RNSDSegment:ABC_Etch_Seg>MRcp:XYZ;3"

If an *agent* or a *DRNS segment* is specified, then the *DRNS manager* shall delegate the operation to the that *segment*. Otherwise, the operation shall be delegated to a *master segment*.

A request to set one or more *read-write* attributes of a recipe is treated by the *DRNS manager* as a *change request*.

10.3.2 *Delete Distributed Recipe Namespace* — A *distributed recipe namespace* with attachments may not be deleted.

The *delete distributed recipe namespace* operation is invoked by the service RMNDeleteNS defined in Section 9.2.2.

10.3.3 *Attach and Detach Supervised Objects* — This section defines the support required for the *authorized user* to request a *DRNS manager* to attach or detach one or more *segments* or a *recorder*. The operations and services are defined in detail in SEMI E39 (OSS).

10.3.3.1 *Attach Supervised Object* — The **attach supervised object** operation is invoked by an *authorized user* to request the *DRNS manager* to attach a specified *unattached segment* or *recorder*.

When a request to attach a supervised object is accepted, the *DRNS manager* sends an attach or detach request to the specified object.

The *DRNS manager* shall have the capability of managing at least one attached *dedicated* and one attached *master segment* at a time. At most, one *recorder* shall be attached to a *DRNS manager* at any given time.

Once attached, the *segment* or *recorder* becomes a formal part of the *namespace* and is owned by the *manager*.

When adding attachments to a *DRNS manager*, the *recorder* should be added first, so that it may be used to record the *segments* as they are subsequently attached. When the *distributed recipe namespace manager* receives a request to attach a *segment*, it sends that request to the specified *segment*. If the operation is successful, and if a *recorder* is attached, the *manager* requests the *distributed recipe namespace recorder* to record the *segment specifier* (the object specifier for the segment). If the *agent* providing the *segment* is not already in the *namespace* attribute Members, it is added at this time.

The operation of attaching a *recorder* shall set the *distributed recipe namespace* attribute Recorder to the value of the *recorder's* attribute ObjID. The operation of attaching a *segment* shall add the *segment specifier* to the Segments attribute of the *distributed recipe namespace*.

When a *recorder* is attached, all subsequent operations that attach and detach *segments* shall update the *recorder* through its operations to add and remove a record of the *segment*.

Specifiers used in the *namespace* attributes Recorder and Segments, and *segment* specifiers stored in the *DRNS recorder*, shall use the form including the specifier for the *agent* providing the capability for the *recorder* or *segment*. This is required for identification outside the scope of the current *namespace*. For example, if it later becomes necessary to rebuild the *distributed recipe namespace*, then the *segment* must be located through its *agent* owner rather than through the *namespace*.

10.3.3.2 *Detach Supervised Object* — An attached *segment* or *recorder* may be detached at any time. The *manager* forwards the request to the specified object. When a *segment* is detached, if a *recorder* is attached, then the *manager* requests the *recorder* to remove the *segment* that is being detached.

The user may request a *DRNS manager* to detach an attached *recorder* or *segment* at any time. When a *recorder* is detached, the *distributed recipe namespace* attribute Recorder shall be set to a null value. When a *segment* is detached, its *specifier* is removed from any attached *recorder* and from the Segments attribute of the *distributed recipe namespace*.

10.3.4 *Change Request Management* — A *change request* occurs whenever the *DRNS manager* receives any request, from any source, to change a recipe or the contents of the *distributed recipe namespace* as a whole. This includes requests to change the recipe *identifier*, a *generic attribute*, an *agent-specific attribute*, or the body of an existing recipe. It also includes all changes that affect the set of *recipe identifiers* within the *distributed recipe namespace*.

Requests for changes may come from a source that is either internal or external to the *namespace*.

10.3.4.1 *External Change Requests* — The *DRNS manager* may receive a request, through recipe management services, to change a recipe, or to change the *namespace* (for example, to *store* a new recipe or *delete* an existing one), from an entity other than an attached *DRNS segment*. If the change involves a specified *agent* (for example, *verify* or *upload* requests), then the *DRNS manager* shall delegate the operation to the *DRNS segment* provided by that *agent*. Otherwise, operations are preferably delegated to a *DRNS master segment*.

10.3.4.2 *Internal Change Requests* — A *change request* may be initiated by a specific attached *segment*. For example, a local operator may want to change the *generic* attribute EditedBy (illustrated in Figure 10.3) or to rename a recipe. The *DRNS segment* then requests its *DRNS manager* for approval to make the specific type of change desired. The *DRNS manager*, upon receipt of the request, shall create a *change request record* (Section 10.3.4.4) for the recipe(s), specifying the *DRNS segment* that initiated the request, the type of change requested, and noting that the change was *segment*-initiated.

10.3.4.3 *Allowable Change Requests* — A *change request* may not be allowable. For example, a change to a *write-protected* recipe or a change to introduce a recipe *identifier* already in use may be denied immediately. If the change is allowed, then a *change request record* shall be created in non-volatile memory for each allowed *change request*.

Any operation that creates or changes a recipe body, a recipe attribute, or a recipe identifier, requires explicit *manager* approval. This includes the following operations: create, delete, modify (body), copy (new *identifier*), rename (new *identifier*), protect, verify, link, unlink, certify, de-certify, change read-write *generic attribute*, and change read-write *agent-specific attribute*.

The following requirements shall apply:

— A request to *create* a new recipe, or *copy* an existing recipe, with a specified *identifier* shall be granted only if that *identifier* is not in use for a *write-protected* recipe within the *namespace* as a whole (that is, no attached *DRNS segment* has a *write-protected* recipe using that *identifier*).

— A request from a *DRNS segment* to rename a recipe shall be granted only if no other *segment* has that recipe and the new *identifier* is not otherwise in use.

— A request from a *dedicated segment* to delete a recipe shall be denied only if the recipe is *write-protected*.

10.3.4.4 *Change Request Record Definition* — A **change request record**, as shown in Figure 5.7, consists of the following information:

— The *recipe identifier* (RecipeID),

— a *destination recipe identifier* (DestRecipeID) (used for copy and rename only, and otherwise null),

— the *segment specifier*, (Segment), of the *DRNS segment* that has requested a change or to which the change operation is or will be delegated,

— the specific type of change requested (ChangeType),

— a timestamp of when the request was received (Timestamp),

— an **operation identifier** (OperationID), an integer delegated by the *DRNS manager* that uniquely identifies a given *change request* within the *distributed recipe namespace* at large,

— a boolean (SegmentRequest) used to differentiate requests by attached *segments* from other requests (the *manager* responds differently in the two cases).

All of the above information, with the exception of the *segment specifier*, shall be determined at the time the *change request record* is created. In the case of externally initiated requests, delegation of a *segment specifier* may be postponed until the *change request* is **selected**.

The *operation identifier* is used to identify a specific change request by both the *namespace* and the delegated *DRNS segment*. It is passed to the *DRNS segment* when granting permission to make the requested change (Section 10.3.5) and when sending *segment change approval* to a *DRNS segment* (Section 10.1.2.2) for a previous *change request* made while the recipe was *locked*. It shall also be used for recipe management services defined in Section 12 that use an *operation identifier* (parameter RMOpID).

For *change requests* initiated by an attached *segment*, the boolean SegmentRequest is set to TRUE. Otherwise, it is FALSE.

The *change request record* shall be deleted when the requested change operation has been completed, whether successfully or unsuccessfully.

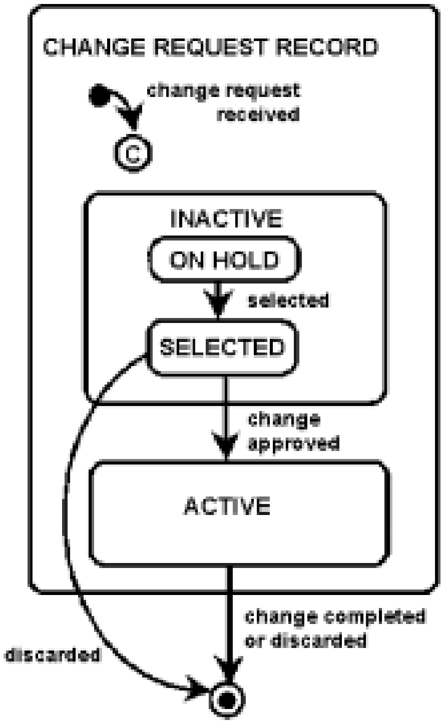

Figure 10.3

Change Request Record State Model

10.3.4.5 *Change Request Lifecycle* — This section describes the states of a *change request.*

A *change request* is received and examined. It is determined either to be allowed or not allowed.

If the requested change is allowed, then a *change request record* is created for the specified recipe by saving the information required. The *change request* is now INACTIVE and ON HOLD (see Figure 10.1). The *operations identifier* is set to a unique unsigned integer. If the change was initiated externally, a *segment* may or may not be designated until the *change request* is selected for approval. The remaining information is filled at this time. The *change request record* is placed in a queue for that recipe in non-volatile memory.

The *change request* remains **on hold** until the *DRNS manager* selects it as the next change and it becomes **selected**. If a *segment* has not already been designated, then one is determined at this time. The *selected* recipe may be discarded after evaluation due to changes in circumstances since it was originally put *on hold*. Otherwise, the *change request* becomes **active**, and the *change request record* is added to any attached *DRNS recorder*. The *manager* is ready to begin its negotiations with the designated *segment* or to approve a *segment*-initiated *change request* already in progress, at this point.

These stages may occur in rapid succession if the request is initiated by a *segment* and the recipe was not *locked*.

Selection occurs in one of two ways: either a *change request* is received when the specified recipe is *unlocked (Section 10.3.4.5)*, or else a currently *active change request* completes, and a new *change request* is *selected* from the queue of *change request records on hold* for that recipe. Rules for selection may vary and are beyond the scope of RMS. For example, rules could be sequence-oriented (first-in, first-out), or they might consider the types of operations specified. For example, requests for *verification* might be given precedence over requests to *link*.

When a *selected change request* becomes *active*, the *manager* adds the *change request record* to any attached *recorder* and begins negotiations with the delegated *segment*.

If the *change request* was *segment*-initiated (Section 10.3.5), the *segment change request* is approved. The *DRNS manager* shall initiate a *segment change approval* to the *DRNS segment* (Section 10.1.2.2).

There are three possible scenarios for the negotiations with the *segment*: an externally initiated request, an internally initiated request from a *segment* when the recipe specified was *unlocked*, and an internally initiated request from a *segment* when the recipe specified was *locked*. These three types of scenarios are illustrated in Table 10.5. NOTE: In both of the first two cases, the *segment* sends a request to make a change with RMDChangeRequest.req. However, in the first case, the initiation of that *change request* was external, and the *segment's* request is its required response to any change request that it receives.

Table 10.5 Active Change Request Negotiations

Manager	*Segment*
Externally Initiated Change Request	
An externally initiated change request becomes active. The manager requests the delegated segment to make the change:	
RMNAction.req ->	
	The segment responds that it will make the change and notify the requestor when done.
	<- RMNAction.rsp
	The segment requests approval to make the change:
	<- RMDChangeRequest.req
The manager approves the request immediately:	
RMDChangeRequest.rsp ->	
	The segment completes the change and notifies its manager:
	<- RMDComplete.nfy
	The segment notifies the requestor of the change (in this case, its manager) that the change is complete.
	<- RMNComplete.nfy
Segment-Initiated Change Request for Unlocked Recipe	
	The segment requests approval to make the change:
	<- RMDChangeRequest.req
The manager approves the request immediately:	
RMDChangeRequest.rsp ->	
	The segment completes the change and notifies its manager:
	<- RMDComplete.nfy
	The segment notifies the requestor of the change (in this case, its manager) that the change is complete.
	<- RMNComplete.nfy
	The segment notifies the initial requestor of the change that the change is complete:
	RMNComplete.nfy ->
Segment-Initiated Change Request for Locked Recipe	
	The segment requests approval to make a change: <- RMDChangeRequest.req
The manager puts the change request on hold:	
RMDChangeRequest.rsp ->	
The change request later becomes active. The manager now approves the segment's earlier request to change generic attributes:	
RMDSApproveAction.req ->	
	The segment responds that it intends to make the change:
	<- RMDSApproveAction.rsp
	The segment completes the change and notifies its manager:
	<- RMDComplete.nfy
	The segment notifies the initial requestor of the change that the change is complete:
	RMNComplete.nfy ->

10.3.4.6 *Change Request Completion* — The *DRNS manager* is informed of the completion of an approved change either immediately or through a later notification using the RMDComplete service.

There are two circumstances when a *DRNS segment* notifies its *manager* that it has completed an approved change, illustrated by Figures 10.1 and 10.2 (b) for the services RMDSegChange and RMDSApproveAction respectively.

Figure 10.2 (a) illustrates the case where the *manager* approves an earlier change request and the *segment* makes the change before responding. In this case, RMDComplete is not sent. However, if the *segment* responds before actually making the change, then it is required to send the notification RMDComplete when done.

When a requested change has been completed by the delegated *segment*, it notifies its *manager* by sending the notification RMDComplete as shown in Figures 10.1 and 10.2 (b). The type of change and results of the change operation dictate how the change shall be updated to the other attached *DRNS segments* of the *namespace*. After all affected *DRNS segments* have been properly updated, then the *change request record* corresponding to the completed change shall be removed from the queue. If there are still *inactive change requests*, the next *request* is selected and then made *active*.

All other *DRNS segments* with the same logical recipe shall be updated as appropriate. A change in *agent-specific datasets* only shall be updated to *master segments*. A change to attributes only shall cause only the attributes of other instances of that recipe to be updated. If the *logical recipe* was changed, then all *segments* having a copy of that *logical recipe* shall be updated.

When all necessary updates have been performed, the *DRNS manager* shall discard the *change request record*. It shall either request its *DRNS recorder* to remove the *change request* for that change or to add the next *change request* to be approved. Then the *DRNS manager* shall select another *inactive change request*. If no further *change requests* exist for that recipe, the *DRNS manager* shall remove the last *change request* from any attached *DRNS recorder*.

10.3.4.7 *Change Management Example* — As an example of change management, if an *operator* at Equipment A wants to *link* Recipe R;3 within the *distributed recipe namespace* D, the resulting changes to the recipe's *generic header* must be passed to all other attached *DRNS segments* within the *namespace* that contain Recipe R;3 before any other change is approved.

In this example, if a request from *segment* A to *link* Recipe R;3 is received by the *manager*, and no *inactive* requests exist, and if Recipe R;3 is not already both *linked* and *write-protected*, and if the request is to be approved, the *DRNS manager* creates a *change request record* for that recipe, which *locks* the recipe. The *DRNS manager* approves the request and denies subsequent requests until the approved change has been made and other *segments* with an *instance* of that recipe have been updated appropriately.

10.3.5 *Segment Change Request* — The **segment change request** operation is a request made by an attached *DRNS segment* to approve a specific type of change. The *DRNS manager* shall respond by either approving the request, denying it, or putting it on hold. When putting the requested change on hold, the *DRNS manager* shall return the *operation identifier* delegated in the corresponding *change request record*.

The *segment change request* operation is invoked with the service RMDSegChange sent by an attached *DRNS segment*.

10.3.6 *Segment Action Complete* — A *DRNS segment* that has requested and received permission to change a recipe shall notify the *DRNS manager* when the action is complete, whether normally or abnormally. Also, when the *manager* approves an earlier request made by a *segment*, and the *segment* makes the change after responding to the approval, the *segment* shall also notify its *manager* of the completion of the change. The notification allows the *DRNS manager* to request the updated recipe and send it to other *segments* as appropriate.

The *segment action complete* operation is invoked with the service RMDComplete, sent by an *attached segment*.

10.3.7 *Segment Notification* — A *dedicated segment* shall notify its *manager* of any change to an *agent-specific dataset*. These changes are pre-approved. They are not preceded by formal requests for change and do not generate change request records. Upon receiving notification of such a change, the *DRNS manager* shall update all *master segments* with the new *agent-specific dataset* values. An example of this case is illustrated in Table 10.6.

The *segment notification* operation is invoked with the service RMDNotify, sent by an attached *segment*.

Table 10.6 Notification of Change to an Agent-Specific Dataset

Manager	*Segment*
	Receives request from local operator to certify recipe.
	Local operator certifies recipe for this agent.
	The segment stores the generic attribute sent by its manager.
	<- RMDComplete.nfy
	The segment notifies its manager that the change has been made.
	<- RMNComplete.nfy
The manager requests the new set of agent-specific attributes:	
RMNRetrieve.req ->	
	The segment sends the generic attributes to any requestor:
	<- RMNRetrieve.rsp
The manager updates all master segments with the new agent-specific attributes for that agent and recipe.	

10.3.8 *Get Change Requests* — The **get change requests** operation returns a list of *active* and *inactive change requests* (in that order) for a *locked* recipe. If the recipe is not *locked*, an empty list is returned. Otherwise, where the *active change request* record is returned first in the list, followed by any *pending change requests*.

The *get change requests* operation is invoked with the service RMDGetChangeRequests.

10.3.9 *Rebuild Distributed Recipe Namespace* — The **rebuild distributed recipe namespace** operation is used to rebuild a previous *namespace* by *reattaching* all of its *attachments* to a different *namespace*.

The *DRNS manager* must first get a list of *DRNS segments* to be used. This list may be provided by either the service user or by a *DRNS recorder* specified by the service user. It then **reattaches** the *DRNS recorder* (where specified) and each of the specified *DRNS segments*. The reattach operation alerts the reattached object that the communication linkages to its *DRNS manager* may have changed and that its *inactive change requests* have been lost.

Next, the *DRNS manager* obtains the list of recipe *identifiers* stored by each *DRNS segment*. Finally, when a *DRNS recorder* has been provided, the *DRNS manager* completes the *rebuild* operation by checking the *DRNS recorder* for any *change request record* in progress at the time the original *namespace* was lost. The *DRNS manager* shall determine if the change was completed (through comparisons of recipe *descriptors*) and, if so, shall update the other *segments* as if it had just received a *segment change completion* notification.

Note that only the currently *active change request record* is retained. Other *inactive change requests* made while a recipe was *locked* have been lost with the original *DRNS manager*.

Note also the potential exists for *agent-specific datasets* stored by *dedicated segments* to be more recent than the corresponding *datasets* stored by *master segments*.

The *rebuild distributed recipe namespace* operation is invoked with the service RMDRebuild.

10.4 *Tables of Operations* — This section provides the operations defined for each object within the *distributed recipe namespace* capability. An additional column for the object authorized to invoke the operation is provided for tables in this section.

10.4.1 *Segment Operations Table* — Table 10.1 lists all the operations defined for *DRNS segment*.

Table 10.1 Distributed Recipe Namespace Segment Operations

Operation	*Invoked by*	*Description*	*Reqd*
Segment change approval	The *manager* of the attached *distributed recipe namespace segment.*	A change to a recipe requested earlier by a segment is now permitted.	Y

10.4.2 *Recorder Operations Table* — Table 10.2 lists all the operations defined *for distributed recipe namespace recorder*.

Table 10.2 Distributed Recipe Namespace Recorder Operations

Operation	*Invoked by*	*Description*	*Reqd*
add segment record	the *recorder's manager*	A *segment specifier* is added to the current list.	Y
delete segment record	the *recorder's manager*	A *segment specifier* is removed from the current list.	Y
add change request record	the *recorder's manager*	A currently active *change request record* is added for a specified recipe.	Y
delete change request record	the *recorder's manager*	An existing *change request record* is removed for a specified recipe.	Y
get change request records	any	The *change request records* for one or more recipes are requested.	Y

10.4.3 *Manager Operations Table* — Table 10.3 lists all the operations defined *for distributed recipe namespace manager*.

Table 10.3 Distributed Recipe Namespace Manager Operations

Operation	*Invoked by*	*Description*	*Reqd*
segment change request	an attached *segment*	A *segment* requests approval for a specified type of change on a specified recipe.	Y
segment change complete	an attached *segment*	A *segment's* notification that an approved change has been completed, either normally or abnormally.	Y
segment notification	an attached *dedicated segment*	A *dedicated segment's* notification that an *agent-specific dataset* has been changed.	Y
get change requests	any	A request for the list of existing change requests for a specified recipe.	Y
rebuild distributed namespace	an *authorized user*	A *manager* is requested to rebuild a *distributed recipe namespace* using a specified *recorder*.	Y

11 Recipe Executor Operations

The operations of the *recipe executor* defined by RMS are: **download and verify, verify, upload, rename, get available storage, delete, select, deselect,** and **change notification.** In addition, the *recipe executor* shall provide object services as described in Section 11.1.

Recipe executor operations may be invoked by an operator or through *recipe executor* services defined in Section 14. In most cases, service scenarios consist of a single message request from the service user and a corresponding response from the *recipe executor*. This case is illustrated in Section 14.1.

Scenarios are shown only for operations that differ from this typical case. For example, some operations may require more time to complete, such as *recipe verification* and the *select* operation that may be performed on more than one recipe and may require interactions with a *recipe namespace* to complete. In this case, the initial response to the message service request may only indicate the intent to perform the operation. The *recipe executor* informs the service user of the completion of each individual operation by sending the notification message RMEComplete.

In addition, in restricted circumstances, the *recipe executor* is required to inform a *namespace* that a recipe body originally downloaded from that *namespace* has been changed.

11.1 *Object Services Operations* — A *recipe executor* shall comply with Object Services Standard specifications for *fundamental requirements* and with the requirements for Owner Objects. Support for Filtering is optional.

A *recipe executor* owns the *execution recipes* that it stores, and it is *owned by* the *agent* that provides *recipe executor*. The owner relationships are used by Object Services to define a *recipe specifier*.

The *recipe executor* shall support operations for Get Attributes and Set Attributes for its own attributes. It shall support the operation of Get Attributes for the execution recipe. (Note that all attributes of the execution recipe are read-only and may not be set through the interface. It shall support the Get Type and Get Attribute Name operations for the object types of *recipe executor* and *execution recipe*.

11.1.1 *Execution Recipe Specifier* — The object specifier for an *execution recipe* includes the object type and *identifier* of the recipe executor, followed by the identifier of the recipe, including its *originating namespace*. For example, to specify an *execution recipe* "NS-MOM>PROCESS/ABC;5>" that is stored by a *recipe executor* named "RE-Etch" owned by "Agent-:Etch01", the object specifier would be

"Agent:Etch01>RcpExec:RE-Etch>NS-MOM>PROCESS/ABC;5>".

11.2 *Description of Operations* — This section describes the operations of the *recipe executor*.

11.2.1 *Recipe Download and Verify* — A recipe is **downloaded** when it is transferred (sent) to the *recipe executor*. *Downloaded* recipes that do not have the <u>Verified</u> attribute set to TRUE shall be immediately *verified*. Otherwise, it is not necessary to *re-verify* a recipe. Any *verification* errors shall be reported to the initiator of the *download* operation.

For further discussion of the *verification* operation, see Section 11.2.2.

Normally, if the *identifier* of the recipe *(namespace name, recipe class, recipe name, and version number)* is already assigned to an *execution recipe* already existing in storage, the *download* is refused. However, the initiator of the download operation may optionally request a **forced overwrite** of any such pre-existing recipe. In this case, if the existing recipe is not currently *selected*, the new recipe replaces the older one. A request to *delete or overwrite* a currently *selected* recipe shall be denied.

The body of a recipe currently being edited shall be protected from inadvertent change or overwriting by a recipe with the same identifier that is downloaded during this time. If the downloaded recipe is accepted (stored), the equipment shall require the operator either to save the edited recipe to a new (unused) identifier or to discard it.

The *download and verify recipe* operation is invoked with the RMEDnldVer service.

11.2.2 *Recipe Verify* — This is a required operation that *verifies* a specified *execution recipe*.

Verification requires reading the recipe's body. For a *source form* recipe, the *verification* operation checks the contents of the recipe for syntactical correctness. If supported, the *recipe executor* may also include one or more checks for semantic correctness as part of its *verification* operation. For recipes in *object form*, *verification* checks the format of the contents to achieve the same effect.

A *verified* recipe merely indicates that it is technically correct and can be executed. It does not indicate that it can be properly executed for the current hardware configuration. Checking to ensure a recipe will execute properly is called **validation** and shall only be performed at the time recipes are *selected* for execution.

A recipe that has syntactical or format errors fails the *verification* process. Information concerning errors shall be reported to the initiator of the *verification* process. This information is required for the user to be able to make appropriate corrections.

Information returned to the *namespace manager* at the conclusion of the *verification* process includes:

- *All* external references*, required for the <u>ExtRef</u> attribute of the* managed *recipe,*
- *All* variable parameter definitions*, required for the <u>Parameters</u> attribute of the* managed *recipe,*
- *The estimated or nominal time of the recipe, in seconds, used for the <u>EstRunTime</u> attribute of the* managed recipe *(optional).*

These items are not returned if the recipe fails *verification*. In this case, the *recipe executor* shall provide sufficient information to the user for identification of the type of error and where within the *body* it occurred, for at least the first error encountered.

The *external references* that are returned shall always include the *name* of the recipe referenced, and any referenced *namespace*, in the proper form for a *recipe identifier*. If the *external reference* specifies a *namespace* other than "Default" (Section 6.4), the *version* is required to be fully specified for *verification* to be successful. Otherwise, *version* shall be left exactly as specified in the *body*. Omission of version allows "the best version" to be determined by the *namespace* at a later stage.

The *verify* operation is invoked explicitly with the RMEVerify service. It may also be performed as part of the *download and verify* operation as discussed in Section 11.2.1.

11.2.2.1 *Derived Object Form Recipes* — For downloaded recipes that are to be stored, the *recipe executor* may wish to re-write or compress a *source form* recipe into a *derived object form* recipe (Section 3.2.2.1.2) as part of the *verification* process. (The rewritten form may be of any format and is typically **not** a form of "machine-executable code".)

Where downloaded recipes are converted to a *derived object* form prior to storage, a method of re-converting to *source form* is required. Note that the capability to retain user comments is desirable, but not required, where this process is adopted.

The new *derived object form* recipe inherits the attributes of the *source form* recipe with the following exceptions:

- *The* class *or* name *of the* object form *shall be changed in a systematic and documented manner that both makes clear the* object form *derivative and its heritage from the* source form *original. For example, the object form may add an extension to the* name *of the original recipe.*
- *The* BodyFormat *attribute shall be changed to reflect the* object form.
- *The attributes* ExecLength*,* ExecChgTime*,* BodyLength*, and* EditTime *shall be updated.*

If the attribute ExecChgCtrl requires the *originating namespace* to be notified of changes, then this request applies to the creation of the *derived object form recipe*, and the ChangedBody attribute is set to TRUE until the recipe has been *uploaded* successfully by the *namespace manager*.

The *source form recipe* from which the *derived object form* was obtained should not be deleted automatically.

11.2.2.2 *Verification ID* — The attribute VerificationID is used for *derived object form* recipes and is provided for the *recipe executor* **identification code**. This is a text string containing a unique and persistent "signature" or identifier for the *recipe executor*. This is used to detect *derived object form* recipes that were derived by earlier software versions of the *recipe executor*, or by versions used by other *agents*, that may have obtained different results.

The *identifier* of the *source form* recipe of the *derived object form* recipe is stored in the attribute SrcRcpID of the *derived object form* recipe.

11.2.3 *Recipe Upload* — **Recipe upload** is the operation that returns an *execution* recipe from the *recipe executor's* storage to the service user. It is required for *recipe executors* that are able to *originate* or modify recipes. *Recipe upload* allows recipes to be managed in a *recipe namespace.*

The *upload recipe* operation is invoked with the RMEUpload service.

11.2.4 *Recipe Rename* — The **recipe rename** operation causes a recipe to be assigned a new *identifier*. If the new *identifier* is already in use by a pre-existing *execution recipe*, or if the recipe to be *renamed* is currently *selected*, the request shall be denied. This is a required operation.

This service is provided to maintain synchronization between *execution recipes* and the *managed recipes* within an *originating namespace*.

The *rename recipe* operation is invoked by the message service RMERename.

11.2.5 *Get Available Storage* — The **get available storage** operation is used to determine the size of the remaining recipe storage capacity, in bytes. The value returned shall exclude any overhead requirements for storage of one *execution recipe*. That is, it shall be assumed that sufficient storage exists for a single recipe with a combined *attribute length* and *body length* less than or equal to the returned value. This is a required operation.

The *get available storage* operation is invoked by the message service RMESpaceInquire.

11.2.6 *Recipe Delete* — The **recipe delete** operation removes one or more recipes from the *execution recipe storage*. Any reusable (rewritable) storage used by a *deleted* recipe shall be made available for other recipes, and the *deleted* recipe shall be unavailable for all subsequent operations. This is useful to release storage for new recipes. This is a required operation.

Recipes stored in non-reusable storage that cannot be physically deleted shall be made unavailable for subsequent *selection*.

If the *recipe executor* does not have *execution recipe storage* (that is, if its sole storage is the *recipe execution area*), then the *delete* operation shall completely remove the specified recipes from the *recipe execution area*.

The *delete recipe* operation is invoked with the RMEDelete service. A request to *delete* a currently *selected* recipe shall be denied.

11.2.7 *Recipe Selection* — Recipe **selection** is the process of locating, *validating*, and preparing a recipe for execution within the *execution area*. Recipe *selection* is a required *operation* of the *recipe executor* that allows specification of initial (default) values of any *variable parameters* defined by the recipe. Initial parameter values specified at this time shall override the corresponding values contained in the ExecLinkParam attribute.

It shall be possible to explicitly specify a recipe for execution. It may also be possible to implicitly *select* a recipe, including initial *variable parameter* values, through other operations, such as within a higher-order "process job". Services for implicit methods and for starting execution itself are beyond the scope of RMS.

If the recipe class is omitted when specifying a recipe for *selection*, then the class "/PROCESS/" shall be assumed.

The request for *recipe selection* specifies one or more recipes to be *selected.* If a recipe cannot be located in the *recipe executor's* recipe storage area, then the *recipe executor* may optionally attempt to locate and *retrieve* it from the *originating namespace* specified.

Only a *linked* recipe (with the Linked attribute set to TRUE) may be specified by the service user. An attempt to *select* an *unlinked* recipe shall be denied. *Subrecipes* that are part of a *linked recipe set* are required only to be *verified* but not *linked*.

The *selection* process completes abnormally whenever an error is detected, including the failure to locate a specified recipe or to successfully store it, invalid parameter settings, an attempt to *select* an *unverified* recipe, and other *validation* errors.

The *select recipe* operation is invoked with the RMESelect service.

11.2.7.1 *Multiple Selection* — *Executing agents* that support *subclasses* of the PROCESS *class* shall provide at least one of two methods for the *selection* of multiple recipes: (1) they may either allow, or require, that a request for recipe *selection* explicitly specify a recipe from each of certain *subclasses*, and/or (2) they may either allow, or require, specification of required *subclasses* within a *linked* set of multi-part recipes. Such additional permissions and restrictions shall be included in the recipe management documentation.

For *executing agents* that support multi-part recipes (such as described in method 2 above), the *recipe executor* is responsible for *validating*, as a set, the *main* recipe and all its *subrecipes* listed in the LinkList attribute of the *main* recipe as a condition of execution.

If the *namespace* is specified as "Default", the *default namespace* is used. The *name* of this *namespace* is the value in the *recipe executor* attribute DefaultNamespace (see Section 6.4 and 6.7).

All recipes in the *linked recipe set* are considered to be *selected* if the *select* operation is successful.

11.2.7.2 *Validation* — **Validation** consists of type and range-checking of recipe settings and parameters, and of confirmation that the recipe is valid for the current hardware configuration. *Validation* shall occur as part of the process of *selection*. For *recipe executors* that require several different *classes* of recipe, *validation* may depend on the recipes that are *selected* as a set.

For example, a diffusion furnace may have a *class* of recipe that is used for the current gas configuration to map gases to valves. The furnace's normal process recipe that uses names of gases can only be *validated* in combination with the gas configuration table *selected* at the same time.

11.2.7.3 *Delegation* — If *delegated* recipes are specified in LinkList, it is the responsibility of the *recipe executor* to ensure that the designated recipe is accessible to the *recipe executor* of the *component agent* at the time it is *selected*. Otherwise, the *select* request shall be denied.

11.2.7.4 *Variable Parameters* — For recipes with *variable parameters*, new *initial values* for some or all of its *parameters* may be specified as part of the *selection* as a *parameter name* and *parameter initial value* pair. *Parameter values* specified as part of the *selection* take precedence over those *initial values* defined in the ExecLinkParam attribute. However, *parameter restrictions* may not be changed when *selecting* a recipe.

All *parameter values* that are set either prior to, or during[12], the execution of a recipe shall satisfy the conditions of the *parameter restriction.* If a *parameter restriction* is given in the ExecLinkParam attribute, then that *restriction* is used for all occurrences of the *parameter*.

11.2.7.5 *Message Scenarios* — There are two possible message flows between the *recipe executor* and the service user for the *select* service.

If the *recipe executor* is able to locate the recipes in its local storage, to *validate* them as a set, and to ready

12 RMS neither defines, nor prohibits, methods for changing parameter values during the execution process.

them for execution in a timely manner, then it may indicate the results of the *select* operation in the response message, as illustrated in Figure 11.1.

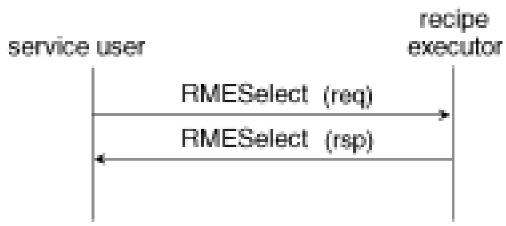

Figure 11.1

RMESelect Message Flow

Alternatively, the *recipe executor* may anticipate that the process of *selection* will require more time. In this case, it may send a response indicating the intent to perform the operation as soon as possible, prior to starting the operation. The notification message RMEComplete is sent when all specified recipes are *selected* or when a *selection* failure occurs. Exactly one notification message is sent, as illustrated in Figure 11.2.

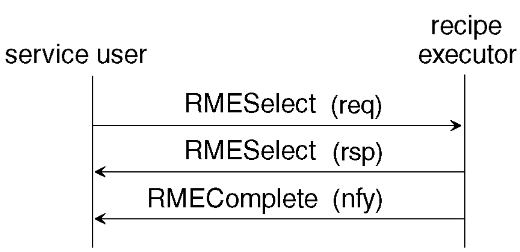

Figure 11.2

RMESelect with RMEComplete Notification

If all recipes are located and in local storage, the recipes are *validated* as a set.

11.2.7.6 *Selected Recipes* — Once a recipe and its associated *subrecipes* have been *selected*, they shall be fully protected from inadvertent (unintentional) change, including change through download, overwrite, deletion, and renaming operations.

The *recipe executor* attribute RecipeSelectID shall be set to the list of currently *selected* recipes, including all *main* recipes specified in the *select* request and all *subrecipes* within a *linked recipe set.*

The attribute RecipeSelectParam shall be set to the list of all *variable parameter definitions* currently in effect following *selection* and prior to the start of actual recipe execution.

11.2.7.6.1 *Select Errors* — If the *recipe executor* is unable to locate a recipe specified for *selection* in its storage, it is responsible for obtaining the recipe from the designated *namespace* included in the *recipe specifier*.

Possible errors resulting from the *select* operation include:

- *Failure to specify recipes from each of the* subclasses *that it requires,*
- *Failure to validate a recipe,*
- *Failure to locate a recipe in a specified* namespace*,*
- *Failure to locate a recipe, and*
- *An attempt by the user to* select *an* unlinked *recipe.*

The *select recipe* operation is invoked with the RMESelect service.

11.2.8 *Recipe Deselection* — A *selected* recipe is **deselected** by making it unavailable for execution for the next (subsequent) processing cycle, deleting its *identifier* from the RecipeSelectID attribute, and deleting its *parameter definitions* from RecipeSelectParam attribute. This is a required operation.

Only a *main* recipe that is currently *selected* may be specified for *deselection*. *Deselecting* a main recipe shall result in the simultaneous *deselection* of all of its *subrecipes.*

If a recipe is *deselected* during execution, this shall have no effect until the current process cycle has completed.

The *recipe executor* may have additional restrictions concerning *deselection*.

The *deselect recipe* operation is invoked with the RMEDeselect service.

11.2.9 *Get Execution Recipe Descriptor* — The **get execution recipe descriptors** operation returns the *descriptors* of a specified *execution* recipe: the *execution attribute descriptor*, the *generic attribute descriptor*, and the *body descriptor*, in that order. This is a required operation.

The *execution recipe descriptor* may be used to compare two *execution* recipes or a *managed* recipe and an *execution* recipe.

The *get execution recipe descriptor* operation is invoked with the RMEGetDescriptor service.

11.2.10 *Change Control* — It is important to the user to be able to control change for execution recipes. In addition, it may be important to store recipes that were *originated* by the *recipe executor* in the managed environment of a *recipe namespace.* The recipe attribute ExecChgCtrl is used to accomplish both purposes.

The ExecChgCtl attribute allows the user to control the modification of an existing *execution recipe* and its subsequent use. ExecChgCtrl is a binary value that specifies permission for behavior related to changes. ExecChgCtrl uses bit settings to indicate permission in order to facilitate the different possible combinations. Values given below are in decimal:

1 = permission to change the body of the *execution recipe*

2 = requirement to notify the *originating namespace* of permitted changes

4 = permission to select (including *re-selection* of an already *selected* recipe) a changed recipe

8 = permission to save the *last values* of *variable parameters* in the ExecParam attribute

11.2.10.1 *Changing Existing Recipes* — Whenever the body is changed, the attributes ExecAttrLength, ExecChgTime, BodyLength, and EditTime shall be updated. The attribute ChangedBody shall be set to TRUE and remain set until the recipe is uploaded successfully to the *originating recipe namespace.* The ChangedBody attribute is *reset* when the upload request is received. It is not included in the uploaded attributes. Note that the attributes ExecAttrLength and ExecChgTime are not kept in the *managed* recipe stored in the *namespace*, and that the attributes AttrLength and AttrChgTime are not maintained by the *recipe executor* and are recalculated for the *managed recipe* when stored.

If the ExecChgCtrl attribute permits both change and subsequent selection or *re-selection* (as for a currently *selected* recipe changed by the execution process itself), then the recipe's Linked attribute is not affected. Otherwise, if change is permitted but subsequent *selection* is not permitted, then the Linked attribute of the *main* recipe shall be *cleared* (set to FALSE) to prevent any subsequent *selection*, and the recipe shall be automatically *de-selected* at the end of any current processing cycle. It shall not be available for *selection* until it has been *uploaded*, *re-linked*, and *downloaded* again, with its changes, by the *originating namespace*.

11.2.10.2 *Creating New Recipes* — A new *execution recipe* may be *created* by various mechanisms. Such mechanisms are beyond the scope of RMS. However, all such recipes shall be assigned an *identifier* that is not already in use by an *execution recipe.* It is not required that an *originating namespace* be assigned immediately in all cases. However, it must be provided before the recipe can be *uploaded* and placed in the management system. New *identifiers* assigned automatically by the *recipe executor* shall use the next available *numeric version*, in conformance with Section 3.2.3.3.

A newly *created* recipe may not be executed. Its ChangedBody attribute shall be set to TRUE, and BodyFormat shall be set TRUE for non-text recipes. The attribute ExecChgCtrl shall be set to a value of 3 (1 plus 2) or higher. Other *non-mandatory* attributes shall be set to their default value. Since the Linked attribute is set to FALSE, the new recipe may not be *executed* as a *main* recipe. New recipes must be *uploaded* to a designated *originating namespace* for management purposes and subsequently *downloaded* after they have been *linked*.

11.2.10.3 *Building Derived Form Recipes* — A new recipe, with a new identifier, is also originated if recipe executor builds a *derived object form recipe* from an existing *source form recipe*. Requirements for the *derived object form recipe* are defined in Section 11.2.2.1.

The *manager* of the *originating namespace* shall be notified when a *derived object form* recipe is built from a *source form recipe* where ExecChgCtrl requires notification of change for the original *source form* recipe.

11.2.10.4 *Saving Last Value* — Saving the most recent settings specified by the user in the attribute ExecLink-Param is a protected activity requiring explicit permission in ExecChgCtrl. A *change notification* requirement in ExecChgCtrl applies to the change of this attribute.

Parameter values in ExecLinkParam are overridden by any parameter settings specified by the user at the time a recipe is *selected*. In this case, the last value of each parameter is stored in the appropriate *parameter definition* in the ExecLinkParam *attribute.* If *change notification* is specified, the *originating namespace* shall be notified of this change. The attributes ExecLength and ExecChgTime shall be updated whenever this change is made. The *body* of the recipe in *execution recipe storage* shall not be changed for this purpose.

11.2.10.5 *Change Notification* — If ExecChgCtrl requires that the *originating namespace* be notified of changes, the notification service RMEChange is sent to the specified *namespace* indicating the type of change that has occurred.

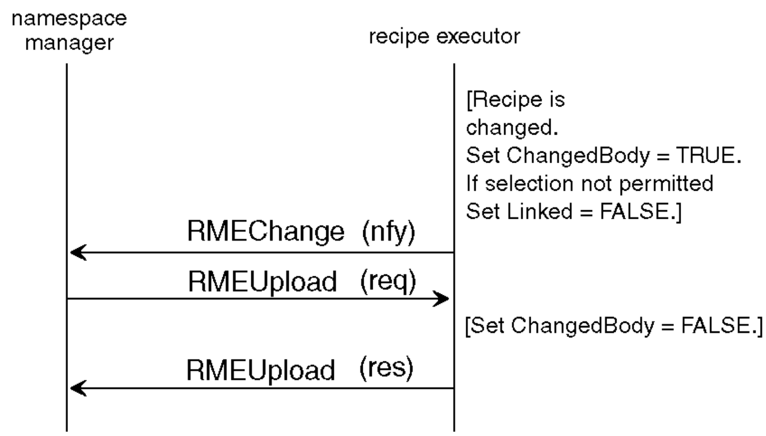

Figure 11.3
RMEChange Message Flow

The *recipe executor* may or may not have direct communication links with the *namespace* itself. However, in this case, the necessary links may be assumed to exist with the *supervisor* or other *owner* of the *recipe executor*, or it would not be possible for recipes to be *downloaded* in the first place.

The *originating namespace*, on receipt of a change notification, is responsible for uploading the changed recipe and for *synchronizing* through the service RMERename any change in *identifier* that might result from changing a *write-protected* recipe.

11.3 *Table of Operations* — Table 11.1 lists all the operations defined for recipes and *namespaces*.

The column labeled "Rqmt" indicates those operations that are required for *fundamental compliance* to the RMS *recipe execution resource.*

Table 11.1 Recipe Executor Operations

Operation	*Description*	*Rqmt*
Recipe download and verify	Transfer *execution recipe* to local storage. If the recipe is *unverified*, then *verify* it at this time.	Y
Recipe verify	*Verify* a stored *execution recipe.*	Y
Recipe unload	Transfer a recipe from local storage. Required if the execution process modifies an executed recipe or if the *recipe executor* is able to *create* recipes.	N
Recipe rename	Change the recipe's *identifier.*	Y
Get available storage	Calculate the amount of storage available for a single *execution recipe*, exclusive of formatting overhead.	Y
Recipe delete	Delete a recipe from local storage.	Y
Recipe select	*Select* recipes for execution.	Y
Recipe deselect	*Deselect* one or more recipes.	Y
Get recipe descriptor	Get the *descriptors* of a specified *execution recipe.*	Y
Change notification	Inform the *originating recipe* that a recipe has been *originated* or changed. Required if the *recipe executor* is able to make a change protected by ExecChgCtrl or to originate a recipe.	N

11.4 *Recipe Executor Events* — The *recipe executor* shall provide the Recipe Select and Recipe Deselect events. *Recipe executors* that are capable of *originating* a new *execution recipe* shall provide the New Execution Recipe event. *Recipe executors* that are capable of *changing* the body of an existing recipe shall provide an Execution Recipe Change Event. These events allow *service users* other than the *originating namespace* to receive notification whenever a new recipe is created or an existing recipe body is modified.

12 Recipe Namespace Services

This section defines *recipe management* and *namespace* services (see Table 12.1), which begin with a prefix of RMN. RMS services used by *distributed recipe namespaces* and by the *recipe executor* are defined in later sections.

Recipe management and *recipe namespace services* request that an operation be performed on a recipe within a *namespace* or on a *namespace*.

Recipe management operations that change recipe attributes are invoked with the RMNAction or RMNVarPar requests.

Certain activities that require extended time to complete may indicate the intent to comply in the response message and then provide confirmation with the RMNComplete message at the completion of each individual operation specified.

Table 12.1 Recipe Namespace Services

Message Service Name	*Type*	*Description*
RMNCreateNS	R	Create a new *namespace*.
RMNDeleteNS	R	Delete a *namespace*.
RMNRenameNS	R	Rename a *namespace* (assign a new *identifier*).
RMNSpaceInquire	R	Determine the available space for recipe storage.
RMNRcpStatInquire	R	Determine a recipe's *read-only* status.
RMNVersionInquire	R	Determine the best version of a recipe.
RMNCreate	R	Initialize new recipe with the specified body.
RMNUpdate	R	Transfer new recipe body.
RMNStore	R	Store a recipe.
RMNRetrieve	R	Retrieve a recipe and give to the requestor.
RMNCopy	R	*Copy* a recipe to a new recipe (originated).
RMNRename	R	*Rename* a recipe.
RMNAction	R	Perform an operation on a recipe (verify, link, unlink, …)
RMNVarPar	N	Modify *agent-specific variable parameter definition*.
RMNGetDescriptor	R	Get recipe *descriptors*.
RMNComplete	N	Notification that a requested action has completed.

12.1 *Recipe Management Message Parameter Dictionary* — Table 12.2 contains the definitions for message parameters, and their components, used by *namespace* services.

For purposes of transferring a recipe with its components, it is regarded as having three types of **sections**: a *section* containing the *generic* attributes, a *section* consisting of the *body*, and a *section* containing the attributes of the *agent-specific dataset*. The *generic section* is always transferred first, and the attributes AttrLength, AttrTimestamp, BodyLength, and EditTime are always sent first, in that order. This allows the length information to be immediately determined by the receiver. *Agent-specific dataset* sections are sent last, since the number of *agent-specific datasets* will vary.

Descriptors are also regarded as consisting of *sections* for the *generic descriptor*, the body *descriptor*, and zero or more *agent-specific descriptors*.

Each start of each *section* is identified with a text string reserved for that *section type*.

Table 12.2 Recipe Management Parameter Dictionary

Parameter	*Definition*	*Form*
AgentSpec_Desc	*Agent-specific dataset* descriptor.	Structure composed of AgentSpec_DescName, AgentSpec_DescLength, AgentSpec_DescTimestamp.
AgentSpec_DescName	Identifies start of *agent-specific dataset descriptor*.	Text = "ASDesc".
AgentSpec_DescLength	Value of AgentSpec_AttrLength.	Unsigned integer.
AgentSpec_DescTimestamp	Value of AgentSpec_AttrChgTime attribute.	Timestamp format: "YYYYMMDDHHMMSSCC".
AgentSpec_Section	A message section for an *agent-specific* dataset.	(List of) structures composed of AgentSpec_SectionName, AgentSpec_SectionData
AgentSpec_SectionData	*Agent-specific* attribute name/value pairs.	(List of) AttrSetting
AgentSpec_SectionName	Identifies start of *agent-specific* dataset.	Text = "ASDS".
AttrData	Value of attribute.	Varies with attribute.
AttrName	Name of attribute.	Text.
AttrSetting	Attribute name/value pair.	Structure composed of AttrName, AttrData.
BodyData	The recipe body contents.	Varies.
BodyDesc	Body descriptor section.	Structure composed of BodyDescName, BodyDescLength, BodyDescTimestamp.
BodyDescLength	Value of BodyLength *attribute*.	Unsigned integer.
BodyDescName	Identifies start of *body descriptor*.	Text = "BodyDesc".
BodyDescTimestamp	Value of EditTime *attribute*.	Timestamp format: "YYYYMMDDHHMMSSCC".
BodySection	The recipe *body* section.	Structure composed of BodySectionName, BodyData.
BodySectionName	Value of BodyName attribute.	Text = "Body".
ErrorCode	Contains the code for the specific error found.	Enumerated: unknown object type in specifier unknown object identifier in specifier unknown attribute name invalid attribute value access denied syntax error recipe not found verification error validation error agent not found
ErrorText	Text in support of the error code to provide additional information.	Text.
GenAttrSection	The *generic* attribute *section*.	Structure composed of GenAttrSectionName and (List of) AttrSettings for *generic* attributes.
GenAttrSectionName	Value of Gen_AttrName *attribute*.	Text ="Generic".
GenDesc	*Generic* attribute descriptor.	Structure composed of GenDescName, GenDescLength, and GenDescTimeStamp.
GenDescLength	Value of AttrLength *attribute*.	Unsigned integer.
GenDescName	Identifies start of *generic section*.	Text ="GenDesc".
GenDescTimestamp	Value of AttrChgTime attribute.	Timestamp format: "YYYYMMDDHHMMSSCC".
LinkID	In response or completion message, has the value of RMOpID in the request. Otherwise, set to zero if, and only if, no further completion messages will be sent.	Unsigned integer.
NSAck	Acknowledge code.	Enumerated: requested operation completed without errors

		requested operation completed with errors requested operation will be performed and notifications of results will be sent
NSStatus	Information concerning the outcome of the requested operations.	Structure composed of NSAck and Status.
RcpClass	Recipe *class*.	Formatted text.
RcpName	Recipe name.	Text.
RcpVersion	Recipe version.	Text.
RMAction	Identifies action performed on recipe.	Enumerated: *delete* *protect* *verify* *link* *unlink* *certify* *de-certify* *download* *upload*
RMAgent	Agent name (identifier).	Text.
RMChangeStatus	Indicates new status of recipe.	Enumerated: *no change* *created (new identifier)* *updated (modified)* *deleted* *copied (new identifier)* *renamed (new identifier)* *verified* *linked* *unlinked* *certified* *de-certified*
RMDestRcpID	Identifier of destination recipe.	Formatted text.
RMDesc	Recipe descriptor (timestamp and length attributes).	Structure composed of GenAttrDesc, BodyDesc, and (list of) AgentSpec_Desc
RMNewNS	New *namespace* name.	Text.
RMSpace	Amount of space available in *namespace*.	Unsigned integer.
RMNSSpec	Target *namespace specifier*.	Formatted text for object specifier.
RMOpID	Operation ID assigned by the service user in a request.	Unsigned integer.
RMParam	Parameter definition.	Structure composed of RMParamName, RMParamSetting, and RMParamRule.
RMParamName	Parameter name.	Text.
RMParamRule	Parameter definition restriction.	Formatted text.
RMParamSetting	The initial value to use for that parameter at execution time.	Varies with parameter definition and recipe language.
RMRcpID	Recipe identifier.	Formatted text.
RMRcpSpec	Target *recipe specifier*.	Formatted text for object specifier.
RMRcpStat	The status of a recipe.	Enumerated: Does not exist Unprotected Protected
RMSectionsCode	Indicates which recipe sections are requested.	Enumerated: All *generic attributes* and the body *Generic* attributes *Generic* and body *Agent-specific dataset* only All *agent-specific datasets*
RMSectionsRequested	Specification of recipe sections requested.	Structure composed of RMSectionsCode and

		RMAgent.
RMSectionsSent	Recipe attributes, recipe body, and attributes of *agent-specific* section(s).	Structure composed of GenAttrSection, BodySection, and (List of) AgentSpec_Section.
Status	Error Information.	Structure composed of ErrorCode and ErrorText.

12.2 *Message Flow* — The flow of messages defined in RMS, between the service user and the service provider, are of two types. The first type, illustrated in Figure 12.1, applies to most namespace operations. A request message is sent from the service user, and the *namespace manager* returns a response message containing the appropriate information.

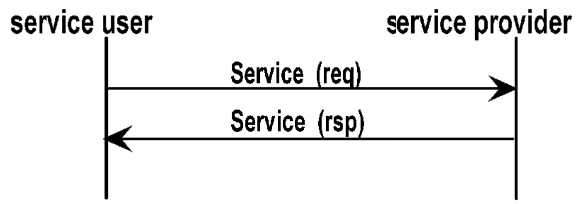

Figure 12.1

Basic Message Flow

The second type of message flow, illustrated in Figure 12.2, is used for messages that specify an operation to be performed that may require more time for completion than is allowed between a request and a response. In this case, the response to the request indicates an intent to complete the operation rather than actual completion. The operation is then performed on each of the specified recipes in turn, until each operation has completed, either successfully or with errors. Any errors that occurred are reported in the completion message.

The second type of message flow may be used for notifying the service user of RMNAction that individual operations on recipes have been completed. The first type of message flow is used for all other *namespace* services.

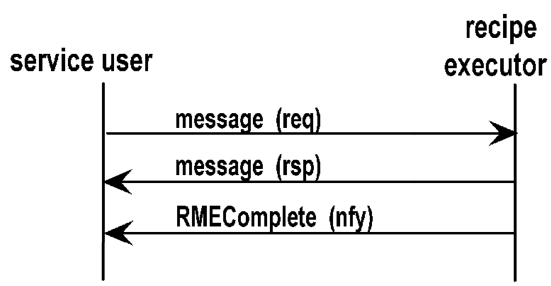

Figure 12.2

Message Flow with Completion Notification

The second type of message flow may be used for notifying the service user of RMNAction that individual operations on recipes have been completed. The first type of message flow is used for all other namespace services.

12.3 *RMNCreateNS* — The service user may request to *create* a new *namespace* and assign it a name (*identifier*). The request shall be denied if the *owner agent* already has a *namespace* with the new name.

The parameters for RMNCreateNS are listed in Table 12.3.

Table 12.3 RMNCreateNS

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
NSStatus	-	M	Information concerning the result of the requested operation.

12.4 *RMNDeleteNS* — The service user may request to delete a *namespace*. If the *namespace* contains recipes, the request shall be denied.

The parameters for RMNDeleteNS are listed in Table 12.4.

Table 12.4 RMNDeleteNS

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
NSStatus	-	M	Information concerning the result of the requested operation.

12.5 *RMNRenameNS* — The service user may request to rename a *namespace*. The request shall be denied if the owner agent already has a *namespace* with the new name.

The parameters for RMNRenameNS are listed in Table 12.5.

Table 12.5 RMNRenameNS Service

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
RMNewNS	M	M(=)	New *namespace* name *(identifier)*.
NSStatus	-	M	Information concerning the result of the requested operation.

12.6 *RMNSpaceInquire* — The service user may request the amount of space available for recipes.

The parameters for RMNSpaceInquire are listed in Table 12.6.

Table 12.6 RMNSpaceInquire

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
RMSpace	-	M	Amount of space available in target *namespace*.
NSStatus	-	M	Information concerning the result of the requested operation.

12.7 *RMNRcpStatInquire* — The service user may request the current write-protection status of a recipe and the next available numeric version for a recipe of the same class and name.

The parameters for RMNRcpStatInquire are listed in Table 12.7.

Table 12.7 RMNRcpStatInquire

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
RMRcpStat	-	M	Status of recipe.
RcpVersion	-	C	Next available numeric version. Required, except with the specified recipe does not exist.
NSStatus	-	M	Information concerning the result of the requested operation.

12.8 *RMNVersionInquire* — The service user may request the best version (highest) for a recipe with given qualifiers of *class*, *name*, and (optionally) *agent*.

The parameters for RMNVersionInquire are listed in Table 12.8.

Table 12.8 RMNVersionInquire

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
RcpClass	M	-	Qualifying recipe *class*.
RcpName	M	-	Qualifying recipe *name*.
RMAgent	C	C(=)	Certified agent. If omitted, agent qualification is not considered. If included, only recipes for which the *agent* is *certified* qualify.
RcpVersion	-	C	The best available *version* of the recipe. Omitted if no qualifying recipe is found.
NSStatus	-	M	Information concerning the result of the requested operation.

12.9 *RMNCreate* — A service user may request to initialize a new recipe in a namespace with a body created elsewhere. The requestor is required to supply the *attributes* of the recipe *body*. If the requested recipe *identifier* is used by a *read-only* recipe, the request shall be denied.

The parameters for RMNCreate are listed in Table 12.9.

12.10 *RMNUpdate* — The service user requests to replace an existing recipe *body* in a namespace with an *updated* body. If the requested recipe *identifier* is used by a *read-only* recipe, the request shall be denied.

The parameters for RMNUpdate are listed in Table 12.9.

Table 12.9 RMNCreate and RMNUpdate

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMRcpSpec	M	-	Recipe specifier.
(List of) AttrSetting	M	-	List of recipe attributes required for create/update.
BodySection	M	-	Recipe body.
NSStatus	-	M	Information concerning the result of the requested operation.

12.11 *RMNStore* — The service user may request to store a recipe in a *namespace*. If the recipe *identifier* is already in use by a *read-only* recipe in the *namespace,* or if the *namespace* has insufficient space for storing the recipe, request shall be denied.

The parameters for RMNRetrieve are listed in Table 12.10.

Table 12.10 RMNStore

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMRcpSpec	M	-	The *recipe specifier.*
RMSectionsCode	M	-	Indicates which sections sent.
RMSectionsSent	M	-	Contents of all sections to be sent.
NSStatus	-	M	Information concerning the result of the requested operation.

12.12 *RMNRetrieve* — The service user may request to receive a recipe in its entirety (including all *agent-specific datasets*), the *generic* attributes with or without the *body* but without *agent-specific* datasets, a particular *agent-specific dataset*, or all *agent-specific datasets*.

The parameters for RMNRetrieve are listed in Table 12.11.

Table 12.11 RMNRetrieve

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMRcpSpec	M	-	The *recipe specifier.*
RMSectionsRequested	M	-	Indicates which sections are requested.
RMSectionsSent	-	M	Contents of all sections to be sent.
NSStatus	-	M	Information concerning the result of the requested operation.

12.13 *RMNCopy* — The service user may request to copy a recipe in a *namespace* to another recipe within the same *namespace*. If a *read-only* recipe with the specified Destination ID exists, an Access Denied error shall be returned.

The parameters for RMNCopy are listed in Table 12.12.

12.14 *RMNRename* — The service user may request to rename a recipe in a *namespace* if the recipe is not *write-protected.* If the recipe is *write-protected*, then an Access Denied error shall be returned.

The parameters for RMNRename are listed in Table 12.12.

Table 12.12 RMNCopy, RMNRename

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMRcpSpec	M	-	*Specifier* of the recipe to be copied or renamed (source).
RMDestRcpID	M	-	The identifier for the recipe to be originated (destination).
NSStatus	-	M	Information concerning the result of the requested operation.

12.15 *RMNAction* — RMNAction is used to request the performance of one of the following actions (operations) on one or more recipes: delete, protect, verify, link, unlink, certify, de-certify, download to a specified *agent*, and upload from a specified *agent*. Where more than one recipe is specified, operations shall be performed on each recipe in the requested order.

If performance of the requested action is likely to take more time to complete than is normally allowed between a request message and the corresponding response, then the *namespace manager* should respond with an intent to comply at the earliest opportunity before it begins the requested operation. Immediately following the completion of the operation on each of the specified recipes, the *manager* shall send a notification message RMNComplete to the service requestor, providing the results of that operation together with information concerning any errors causing abnormal completion of the operation. Error information is important for diagnosis and correction of problems. Figure 12.2 in Section 12.2 shows an example of the message flow for the download operation performed on two recipes.

The parameter LinkID is set to a zero value in the response if the operations have been completed and no notifications will be sent. Otherwise, it is set to a non-zero value, and the value set in the parameter RMOpID shall be retained for use in RMNComplete.

The parameters for RMNAction are listed in Table 12.14.

Table 12.14 RMNAction

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
RMAction	M	M(=)	Action.
RMOpID	C	C(=)	Operation ID, used where multiple confirmations may occur. May be null or omitted where the service initiator does not request a new service until all confirmations for the outstanding service have been received.
(List of) RMRcpID	M	-	Identifier of the target recipe.
RMAgent	C	C(=)	Omitted, except for certify, de-certify, download, upload.
RMLinkID	-	M	LinkID is set to zero if, and only if, no further completion messages will be required.
NSStatus	-	M	Information concerning the result of the requested operation.

12.16 *RMNVarPar* — The service user may request to set *agent-specific variable parameter definitions*. NOTE: Modification of the *parameter restrictions* in a *variable parameter definition* shall reset the Certified *attribute* for that *agent*.

The parameters for RMNVarPar are listed in Table 12.15.

Table 12.15 RMNVarPar

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMRcpSpec	M	-	*Specifier* of the target recipe.
RMAgent	M	-	Agent name (identifier).
(List of) RMParam	M	-	Variable parameter definition.
NSStatus	-	M	Information concerning the result of the requested operation.

12.17 *RMNGetDescriptor* — The service user may request the descriptors of one or more recipes.

The parameters for RMNGetDescriptor are listed in Table 12.13.

Table 12.13 RMNGetDescriptor

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMNSSpec	M	-	Target *namespace specifier*.
(List of) RMRcpID	M	-	Identifier of the target recipe.
(List of) RMDesc	-	M	Requested *recipe descriptor(s)* in the same order as requested.
NSStatus	-	M	Information concerning the result of the requested operation.

12.18 *RMNComplete* — The service provider notifies the service user that an action requested by the service user has completed.

The parameter RMOpID is retained from the initial request message RMNAction.

The parameter LinkID is set to a non-zero value for all notifications except the notification of completion of the last operation performed. A zero value indicates that no further notifications will be sent.

The parameters for RMNComplete are listed in Table 12.16.

Table 12.16 RMNComplete

Parameter	*Req/ Ind*	*Rsp/ Conf*	*Description*
RMOpID	C(=)	-	Operation ID, used where multiple completion messages may occur, corresponding to the value in the original request. May be null or omitted where the service initiator does not request a new service until all confirmations for the outstanding service have been received.
RMLinkID	M	-	LinkID is set to zero if, and only if, no further completion messages will be required.
RMRcpSpec	-	C	*Specifier* of the changed recipe. Indicates *namespace* and recipe *identifiers*.
RMChange Status	M	-	State of the changed recipe.
(List of) AttrSettings	C	-	Attributes of particular interest to the result. Varies with action.
NSStatus	M	-	Information conerning the result of the requested operation.

13 Distributed Recipe Namespace Services

This section defines the new message services required for implementation of *distributed recipe namespace* services. Table 13.1 lists the messages, the type of each message (request or notification), and provides a brief description.

Table 13.1 Distributed Recipe Namespace Services

Message Service Name	*Type*	*Description*
DRNS Segment Services		
RMDSApproveAction	R	A *segment's manager* approves an earlier *change request*.
DRNS Recorder Services		
RMDRAddSegRecord	R	A *manager* requests a *recorder* to add a *segment specifier* to its Segments attribute.
RMDRDelSegRecord	R	A *manager* requests a *recorder* to delete a *segment specifier* from its Segments attribute.
RMDRAddChgRecord	R	A *manager* requests a *recorder* to add a *change request record* for a specified recipe.
RMDRDelChgRecord	R	A *manager* requests a *recorder* to delete a *change request record* for a specified recipe.
RMDRGetChgRecord	R	A *service user* requests *change request* for a recipe or segment.
DRNS Manager Services		
RMDComplete	N	An attached *segment* notifies its *manager* that an approved change has been completed.
RMDNotify	N	An attached *dedicated segment* notifies its *manager* that an *agent-specific dataset* has been changed.
RMDGetChgRequest	R	A request is made for *change request* information for a recipe.
RMDSegChange	R	An attached *segment* requests approval for a specified type of change to a recipe.
RMDRebuild	R	A request is made for a new *manager* to rebuild an existing *distributed namespace*.

13.1 *Distributed Recipe Namespace Message Parameter Dictionary* — This section defines, in alphabetical order, the parameters that are used in *distributed recipe namespace* services and are not already defined in Table 12.2 in Section 12.

Table 13.2 contains the definitions for message parameters.

Table 13.2 Distribute Recipe Namespace Parameter Dictionary

Parameter	*Definition*	*Form*
AttrData	Value of attribute.	Varies with attribute.
AttrName	Name of attribute.	Text.
AttrSetting	Attribute name/value.	Structure composed of AttrName, AttrData.
Attach Token	Attach token provided by an object at the time it is attached or reattached and used by the manager as identification.	Unsigned integer.
ChgRequest	The information provided in a change request.	Structure composed of: RMRcpID, DestRcpID, RMSegSpec, RMChgType, RMOpID, RMTimestamp, RMRequestor
NSAck	Acknowledge code.	Enumerated: no request for this action exists requested operation completed without errors requested operation completed with errors requested operation will be performed and notification of results will be sent

NSStatus	Information concerning the outcome of the requested operation.	Structure composed of NSAck and Status.
ObjID	Object identifier.	Text.
ObjSpec	Object specifier.	Formatted text for object specifier.
ObjType	Object type.	Text.
RMChgType	Type of change requested.	Enumerated: create update delete copy rename verify link unlink certify de-certify change generic attributes(s) change agent-specific attribute(s) store
RMManagerSpec	Object specifier for a *DRNS manager*.	Formatted text.
RMOpID	Operation ID assigned by the *distributed recipe namespace manager*.	Unsigned integer.
RMPermit	Approval for a requested change.	Enumerated: change request approved change request denied change request on hold
RMRcpID	Recipe identifier.	Formatted text.
RMRecorderSpec	Recorder specifier.	Formatted text for object specifier.
RMRequestor	Indicates if the initiator of a change request was an *attached segment* (TRUE) or an external user (FALSE).	Boolean.
RMSegSpec	Segment specifier.	Formatted text for object specifier.
RMTimestamp	Date and time a *change request* was first received.	Timestamp format: "YYYYMDDhhmmsscc".
TargetSpec	Object specifier of target object.	Formatted text for object specifier.

13.2 *Distributed Recipe Namespace Segment Services*

13.2.1 *RMDSApproveAction* — A *distributed recipe namespace manager* may approve or deny a *change request* that the *segment* requested at an earlier time.

Parameters for RMDSApproveAction are listed in Table 13.3.

Table 13.3 RMDSApproveAction Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMSegSpec	M	-	The segment specifier.
Attach Token	M	-	Segment attach token.
RMPermit	M	-	Approval is granted or denied by the *manager*.
RMOpID	M	-	An *operation identifier* assigned by the *manager* for the change.
RMRcpID	M	-	The *identifier* of the recipe for which a change was requested.
RMChgType	M	-	The type of change requested.
NSStatus	-	M	Information concerning the result of the requested operation.

13.3 *Distributed Recipe Namespace Recorder Services*

13.3.1 *RMDRAddSegRecord* — A *recorder's manager* may request the *recorder* to add a *segment record*. Parameters for RMDRAddSegRecord are listed in Table 13.4.

Table 13.4 RMDRAddSegRecord Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRecorderSpec	M	-	The *recorder specifier*.
RMSegSpec	M	-	The *specifier* of the *segment* to add.
Attach Token	M	-	The recorder's attach token.
NSStatus	-	M	Information concerning the result of the requested operation.

13.3.2 *RMDRDelSegRecord* — A *recorder's manager* may request the *recorder* to delete a *segment record*. Parameters for RMDRDelSegRecord are listed in Table 13.5.

Table 13.5 RMDRDelSegRecord Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRecorderSpec	M	-	The *recorder specifier*.
RMSegSpec	M	-	The *specifier* of the *segment* to add.
Attach Token	M	-	The recorder's attach token.
NSStatus	-	M	Information concerning the result of the requested operation.

13.3.3 *RMDRAddChgRecord* — A *recorder's manager* may request the *recorder* to add a *change request record*. Parameters for RMDRAddChgRecord are listed in Table 13.6.

Table 13.6 RMDRAddChgRecord Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRecorderSpec	M	-	The *recorder specifier*.
ChgRequest	M	-	Change request record.
Attach Token	M	-	The recorder's attach token.
NSStatus	-	M	Information concerning the result of the requested operation.

13.3.4 *RMDRDelChgRecord* — A *recorder's manager* may request the *recorder* to delete a *change request record*. Parameters for RMDRDelChgRecord are listed in Table 13.7.

13.7 RMDRDelChgRecord Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRecorderSpec	M	-	The *recorder specifier*.
RMRcpID	M	-	The *identifier* of the recipe to be changed.
Attach Token	M	-	The recorder's attach token.
NSStatus	-	M	Information concerning the result of the requested operation.

13.3.5 *RMDRGetChgRecord* — A service user may request an attached *recorder* to return the current *change request record(s)* for a recipe or an attached *DRNS segment*.

Parameters for RMDRGetChgRecord are listed in Table 13.8.

Table 13.8 RMDRGetChgRecord Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRecorderSpec	M	-	Recorder specifier.
TargetSpec	M	-	Recipe identifier or segment specifier.
Attach Token	M	-	The recorder's attach token.
(list of) ChangeRequest	-	C	List of change request information. Omitted if no change requests exist for specified recipe/segment.
NSStatus	-	M	Information concerning the result of the requested operation.

13.4 *Distributed Recipe Namespace Manager Services*

13.4.1 *RMDComplete* — An attached *segment* notifies its *manager* when it has completed an approved change to a recipe.

The parameter RMOpID is retained from the initial request message RMNAction.

The parameter LinkID is set to a non-zero value for all notifications except the notification of completion of the last operation performed. A zero value indicates that no further notifications will be sent.

Parameters for RMDComplete are listed in Table 13.9.

Table 13.9 RMDComplete

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMOpID	C(=)	-	Operation ID, used where multiple completion messages may occur, corresponding to the value in the original request. May be null or omitted where the service initiator does not request a new service until all confirmations for the outstanding service have been received.
RMLinkID	M	-	LinkID is set to zero if, and only if, no further completion messages will be required.
RMRcpSpec	M	-	*Specifier* of the changed recipe. Indicates *namespace* and recipe *identifiers*.
RMChangeStatus	M	-	State of the changed recipe.
(List of) AttrSettings	C	-	Attributes of particular interest to the result. Varies with action.
NSStatus	-	C	Information concerning the result of the requested operation.

13.4.2 *RMDNotify* — An attached *dedicated segment* notifies its *manager* that it has changed an *agent-specific dataset* and provides the attribute AgentSpec_Agent and all updated attributes.

Parameters for RMDNotify are listed in Table 13.10.

Table 13.10 RMDNotify

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRcpSpec	M	-	*Specifier* of the changed recipe. Indicates *namespace* and recipe *identifiers*.
RMChangeStatus	M	-	State of the changed recipe.
(List of) AttrSettings	C	-	Changed *agent-specific attributes*.
NSStatus	-	C	Information concerning the result of the requested operation.

13.4.3 *RMDSegChange* — An *attached segment* may request its *manager*'s approval to make a change. The recipe specifier RMRcpSpec shall include the requesting *segment's* object type and name to identify the requestor and the specific instance of the logical recipe to be changed first.

Parameters for RMDSegChange are listed in Table 13.11.

Table 13.11 RMDSegChangeService

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMRcpSpec	M		Recipe specifier.
RMDestRcpID	C		Destination recipe identifier (copy/rename only).
RMChgType	M	M	Type of change requested.
RMPermit		M	Grants or denies permission.
RMOpID		M	A non-zero value returned when the change is completed.

13.4.4 *RMDGetChangeRequests* — A service user may request that all existing *change requests* for a recipe be returned. The first item returned is the *active change request*.

Parameters for RMDGetChangeRequests are listed in Table 13.12.

Table 13.12 RMDGetChangeRequests Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMNSSpec	M	-	The object specifier of the *distributed recipe namespace*.
RMRcdID	M	-	The *recipe specifier*.
(list of) ChangeRequest	C	-	Omitted if no *change requests* exist for the specified recipe.
NSStatus	-	M	Information concerning the result of the requested operation.

13.4.5 *RMDRebuild* — A service user may request a *distributed namespace manager* to rebuild a *distributed namespace*.

Parameters for RMDRebuild are listed in Table 13.13.

Table 13.13 RMDRebuild Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RMManagerSpec	M	-	The object specifier of the new *distributed namespace manager*.
RMNSSpec	M	-	The specifier of the *distributed namespace*.
RMRecorderSpec	C	-	The *recorder specifier*. Omitted only if list of segments provided.
(list of) RMSegSpec	C	-	List of specifiers of attached *segments*. Omitted if *recorder specifier* provided.
NSStatus	-	M	Information concerning the result of the requested operation.

14 Recipe Executor Services

This section defines *recipe executor services*. *Recipe executor services* request that an operation be performed by the *recipe executor* and begin with the prefix RME.

Certain activities that may require extended time to complete shall provide confirmation with the RMEComplete message at the completion of each individual operation specified.

Table 14.1 Recipe Executor Services

Message Service Name	*Type*	*Description*
RMEDnldVer	R	Receive a recipe, verify it, and put it into storage.
RMEVerify	R	Verify one or more recipes.
RMEUpload	R	Retrieve a recipe from storage.
RMERename	R	Change a recipe's *identifier*.
RMESpaceInquire	R	Determine the available space for recipe storage.
RMEDelete	R	Delete a recipe from storage.
RMESelect	R	*Select* recipes for execution.
RMEDeselect	R	*Deselect* a recipe to prevent its execution.
RMEGetDescriptor	R	Get recipe descriptor.
RMEChange	N	Notification that a permitted change has occurred.
RMEComplete	N	Notification that a requested action is complete.

14.1 *Recipe Executor Message Parameter Dictionary* — For purposes of transferring a recipe, it is regarded as having two types of *sections:* an *attribute section* containing the recipe's attributes, and a **body section** consisting of the *body*. The *attribute section* is always transferred first, and the attributes ExecAttrLength, ExecAttrChgTime, AttrLength, AttrTimestamp, BodyLength, and EditTime are always sent first, in that order. This allows the length information to be immediately determined by the receiver.

Descriptors are also regarded as consisting of *sections* for the *attribute descriptor*, the *generic attribute descriptor*, and the *body descriptor*.

Each start of each *section* is identified with a text string reserved for that *section type*.

Table 14.2 contains the definitions for message parameters.

Table 14.2 Recipe Executor Parameter Dictionary

Parameter	*Definition*	*Form*
AttrName	Name of attribute.	Text.
AttrData	Value of attribute.	Varies with attitude.
AttrSetting	Attribute name/value pair.	Structure composed of AttrName, AttrData.
BodyData	The recipe *body* contents.	Varies.
BodyDesc	*Body descriptor.*	Structure composed of BodyDescName, BodyDescLength, BodyDescTimestamp.
BodyDescLength	Value of BodyLength.	Unsigned integer.
BodyDescName	Identifies the start of the *body descriptor*.	Text ="BodyDesc".
BodyDescTimestamp	Value of EditTime.	Timestamp format: "YYYYMMDDhhmmsscc".
BodySection	The recipe *body section.*	Structure composed of BodySectionName, BodyData.
BodySectionName	Identifies the start of the *body section.*	Text ="Body".
ErrorCode	Contains the code for the specific error found.	Enumerated: unknown object type unknown object identifier unknown attribute name unknown attribute value access denied recipe not found syntax error validation error verification error recipe select error: unlinked recipe recipe approval level too low recipe certification level too low
ErrorText	Text in support of the error code to provide additional information.	Text.
GenDesc	*Generic attribute* descriptor.	Structure composed of GenDescName, GenDescLength, and GenDescTimestamp.
GenDescLength	Value of AttrLength.	Unsigned integer.
GenDescName	Identifies start of *generic descriptor.*	Text ="GenDesc".
GenDescTimestamp	Value of AttrChgTime.	Timestamp format: "YYYYMMDDhhmmsscc".
LinkID	In response or completion message, has the value of REOplD in the request, or is set to zero if, and only if, no further completion messages will be sent.	Unsigned integer.
RcpDerivedID	Identifier of derived object form recipe.	Structure composed of text "DerivedID" and REDerivedID.
RcpEstRunTime	EstRunTime attribute.	Structure composed of text "EstRunTime" and REEstRunTime.
RcpExtRef	ExtRef attribute of *managed* recipe.	Structure composed of text "ExtRef" and (list of) REExtRef.

Parameter	*Definition*	*Form*
RcpParameters	Parameters attribute of *managed* recipe.	Structure composed of text "Parameters" and (list of) REParam.
RcpVerificationID	VerificationID attribute of a *verified* recipe.	Structure composed of text "VerificationID" and REVerID.
REAck	Acknowledge code.	Enumerated: unknown object type unknown object identifier unknown attribute name invalid attribute value access denied recipe not found invalid parameter settings
REAttrDesc	The descriptor of the *execution* recipe attributes.	Structure composed of REAttrDescName, REAttrDescLength, REAttrDescTimestamp.
REAttrDescLength	The value of ExecAttrLength.	Unsigned integer.
REAttrDescName	Identifies the start of the *attribute descriptor*.	Text ="REAttrDesc".
REAttrDescTimestamp	Value of ExecAttrChgTime.	Timestamp format: "YYYYMMDDmmhhsscc".
REAttrSection	Recipe attributes section.	Structure composed of REAttrSectionName and REAttrSectionData.
REAttrSectionData	Recipe attributes name/value pairs.	(List of) AttrSetting.
REAttrSectionName	Identifies recipe attribute section.	Text ="Attributes".
REChangeStatus	Indicates new status of recipe.	Enumerated: stored deleted selected de-selected created changed body updated last value derived object form
REDerivedID	The *identifier* of a *derived form recipe.*	Formatted text.
REDesc	*Descriptor* of the *execution* recipe.	Structure composed of REAttrDesc, GenDesc, and BodyDesc.
REEstRunTime	Estimated run time of recipe, in seconds. Value of EstRunTime attribute.	Unsigned integer.
REExRef	A reference to an external recipe, in the form of a *recipe specifier.*	Formatted text.
REDestRcpID	The new *identifier* of a renamed recipe.	Formatted text.
REOpID	Operation ID assigned by the service user in a request.	Unsigned integer.
REOWCode	Indicates a forced overwrite of any pre-existing recipe of the same *identifier.*	Boolean: If FALSE or omitted, a pre-existing recipe with the same identifier is not overwritten and will cause a download error. If TRUE, any pre-existing recipe with the same *identifier* is effectively overwritten.
REParam	Parameter definition.	Structure composed of REParamName, REParamSetting, and REParamRule.
REParamName	Parameter name.	Text.
REParamSetting	The *initial value* to use for a parameter at execution time.	Varies with parameter definition and recipe language.
RERcpID	Recipe *identifier*.	Formatted text.
RERcpSpec	Recipe specifier[a].	Formatted text.

Parameter	*Definition*	*Form*
RERecipe	*Execution* recipe.	Structure composed of REAttrSection, BodySection.
RESelect	Recipe specifier with option parameter setting.	(List of) Structure composed of RERcpSpec and (list of) RESelectParam.
RESelectParam	*Variable parameter name* and *initial value*.	Structure composed of REParamName and REParamSetting.
RESpace	Amount of available storage, in bytes.	Unsigned integer.
RESpec	The specifier of the *recipe executor.*	Formatted text.
REStatus	Information regarding the success or failure of the request.	Structure composed of REAck and (List of) Status.
REVerData	Information concerning a successfully *verified* recipe.	Structure composed of RcpExtRef, RcpParameters, RcpEstRunTime (optional), RcpVerificationID (optional), and (where applicable) RcpDerivedID.
REVerID	Contents of VerificationID attribute.	Text.
Status	Error information.	Structure composed of Error Code and ErrorText.

a. A recipe specifier may reference a recipe that is in a namespace and not in the recipe executor's storage.

14.2 *Message Flow* — The flow of messages defined in RMS, between the service user and the service provider, are of three types. The first type, illustrated in Figure 14.1, is the most common and applies to all *recipe executor* operations except for cases of RMEDnldVer, RMEVerify, and RMESelect. A request message is sent from the service user, and the *recipe executor* returns a response message containing the appropriate information. All activities that occur as a result of the request are completed before the response message is sent.

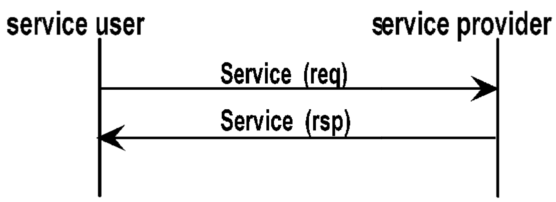

Figure 14.1

Basic Message Flow

The second type of message flow, illustrated in Figure 14.2, is used for messages that specify an operation to be performed that may require more time for completion than is allowed between a request and a response. In this case, the response to the request indicates an intent to complete the operation rather than actual completion. The operation is then performed on each of the specified recipes in turn, until each operation has completed, either successfully or with errors. Any errors that occurred are reported in the completion message.

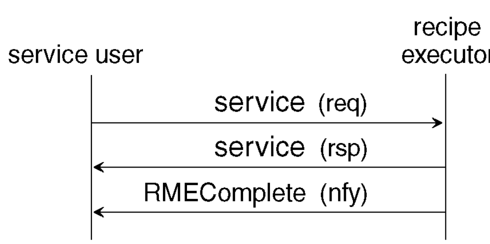

Figure 14.2

Message Flow with Completion Notification

The second type of message flow may be used for notifying the service user of RMEDnldVer, RMEVerify, and RMESelect that individual operations on recipes have been completed.

A third type of message flow consists of a single notification message, shown in Figure 11.3, sent by the *recipe executor* to inform the *originating namespace* of a new or changed *execution* recipe. (See Section 11.2.10.)

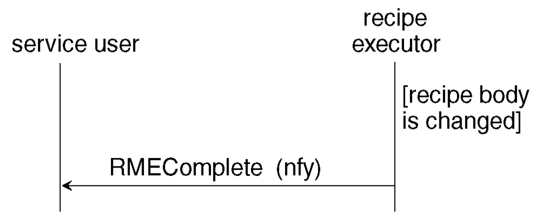

Figure 14.3
Change Notification Message Flow

14.3 *RMEDnldVer* — The service user may request the *recipe executor* to download and *verify* an *execution* recipe. All *unverified* downloaded recipes are *verified* automatically. The service user may optionally specify a *forced overwrite* of any pre-existing *unselected* recipe with the same *identifier.* A currently *selected* recipe shall not be overwritten. If forced *overwrite* is not specified and a recipe with the same *identifier* is already in storage, the request to *download* is denied and the recipe is discarded.

If the *recipe executor* performs a *verification* of the *downloaded* recipe, and if the *verification* is successful, then it shall return the information provided by the conditional parameters.

Parameters for RMEDnldVer are listed in Table 14.3.

Table 14.3 RMEDnldVer Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RERcpSpec	M	-	Destination *specifier* of the *execution* recipe.
REOWCode	M	-	Indicates if a forced overwrite is requested.
RERecipe	M	-	The *execution* recipe.
REVerData	-	C	Information concerning the successfully *verified* recipe. Omitted if recipe has no external references or fails *verification.*
REStatus	-	M	Information concerning the results of the operation.

14.4 *RMEVerify* — The service user may request the *recipe executor* to *verify* an *execution* recipe. If the *verification* is successful, then it shall return the information provided by the conditional parameters.

Parameters for RMEVerify are listed in Table 14.4.

Table 14.4 RMEVerify Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RESpec	M	-	*Specifier* of the target recipe executor.
(List of) RERcpID	M	-	*Identifier* of the recipe.
REOpID	C	C(=)	Operation ID, used where multiple confirmations may occur. May be null or omitted where the service initiator does not request a new service, until all confirmations for the outstanding service have been received.
LinkID	-	M	LinkID is set to zero if, and only if, no further completion messages will be required.
(List of) REVerData	-	C	Information concerning the successfully *verified* recipe. Omitted if recipe has no external references or fails *verification.*
REStatus	-	M	Information concerning the results of the operation.

14.5 *RMEUpload* — RMEUpload retrieves a recipe from local storage and sends it to the service user.

Parameters for RMEUpload are listed in Table 14.5.

Table 14.5 RMEUpload Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RERcpSpec	M	M(=)	Specifier.
RERecipe	-	M	The *execution* recipe.
REStatus	-	M	Information concerning the results of the operation.

14.6 *RMERename* — RMERename changes the *identifier* of an *execution recipe* through changing one or more of its *identification* attributes. If the new *identifier* is already in use by an *execution recipe*, or if the recipe is currently *selected*, permission to rename the recipe shall be denied.

Parameters for RMERename are listed in Table 14.6.

Table 14.6 RMERename Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RERcpSpec	M	-	*Specifier* of the *execution* recipe.
REDestRcpID	M	M(=)	The new recipe *identifier*.
REStatus	-	M	Information concerning the results of the operation.

14.7 *RMESpaceInquire* — The service user may request the amount of space available for recipes. The parameters for RMESpaceInquire are listed in Table 14.7.

Table 14.7 RMESpaceInquire

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RESpec	M	-	Target *recipe executor specifier*.
RESpace	-	M	Amount of space available in target *namespace*.
REStatus	-	M	Information concerning the results of the requested operation.

14.8 *RMEDelete* — RMEDelete removes one or more recipes from local storage and frees any reusable storage area for new recipes. If the recipe is currently *selected*, permission to delete the recipe shall be denied.

Parameters for RMEDelete are listed in Table 14.8.

Table 14.8 RMEDelete Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RESpec	M	-	*Specifier* of the recipe executor.
(List of) RERcpID	M	C	Identifier of the recipe to be deleted. Response returns identifiers of successfully deleted recipe(s) only.
REStatus	-	M	Information concerning the results of the operation.

14.9 *RMESelect* — The service user may specify one or more recipes to be *selected* for *execution*. RMESelect is the only service of the *recipe executor* that allows the service user to specify more than one recipe in a single request.

Parameters for RMESelect are listed in Table 14.9.

Table 14.9 RMESelect Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RESpec	M	-	*Specifier* of the recipe executor.
(List of) RESelect	M	-	Recipe *specifiers* with (optionally) one or more associated parameter names/values per recipe.
REOpID	C	C(=)	Operation ID, used where multiple confirmations may occur. May be null or omitted where the service initiator does not request a new service, until all confirmations for the outstanding service have been received.
LinkID	-	M	LinkID is set to zero if, and only if, no further completion messages will be required.
REStatus	-	M	Indicates the results of the operation.

14.10 *RMEDeselect* — The service user may deselect a recipe to prevent its *re-execution*.

Parameters for RMEDeselect are listed in Table 14.10.

Table 14.10 RMEDeselect Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RESpec	M	-	*Specifier* of the recipe executor.
(List of) RERcpID	M	-	Identifier of the recipe.
REStatus	-	M	Information concerning the results of the operation.

14.11 *RMEGetDescriptor* — The service user may request the descriptors of one or more recipes.

Parameters for RMEGetDescriptor are listed in Table 14.11.

Table 14.11 RMEGetDescriptor

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RESpec	M	-	*Specifier* of the recipe executor.
(List of) RERcpID	M	-	Identifier of the recipe.
(List of) REDesc	-	M	Requested *recipe descriptor(s)* in the same order as requested.
REStatus	-	M	Information concerning the results of the operation.

14.12 *RMEChange* — The service provider informs an *originating namespace* that a permitted change has occurred.

Parameters for RMEChange are listed in Table 14.12.

Table 14.12 RMEChange Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
REOpID	C	-	Operation ID, used where multiple completion messages may occur, corresponding to the value in the original request. May be null or omitted where the service initiator does not request a new service using REOpID, until the confirmation for the outstanding service has been received.
RERcpID	M	-	*Identifier* of the recipe of interest. Equivalent to *specifier* of corresponding *managed recipe*.
REChangeStatus	M	-	State of the changed recipe.
(List of) AttrSettings	C	-	Attributes of particular interest to the result. Varies with action.
REStatus	M	-	Information concerning the results of the operation.

14.13 *RMEComplete* — The service provider notifies the service user that an action requested by the service user has completed.

Parameters for RMEComplete are listed in Table 14.13.

Table 14.13 RMEComplete Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
REOpID	C	-	Operation ID, used where multiple completion messages may occur, corresponding to the value in the original request. May be null or omitted where the service initiator does not request a new service using REOpID, until the confirmation for the outstanding service has been received.
RERcpID	M	-	*Identifier* of the recipe of interest. Equivalent to *specifier* of corresponding *managed recipe*.
REChangeStatus	M	-	State of the changed recipe.
(List of) AttrSettings	C	-	Attributes of particular interest to the result. Varies with action.
REStatus	M	-	Information concerning the results of the operation.

15 Recipe Management Compliance

This section gives a centralized reference location for compliance for RMS objects. It provides references to other sections of the standard where detailed requirements are located. This section also defines standard terminology and documentation related to RMS compliance that can be used by *agent* suppliers and device manufacturers to describe compliance with this standard.

Each object defined by RMS has both *fundamental requirements* and *additional capabilities*. *Fundamental requirements* shall be met by all instances of an RMS-compliant object as specified in cited sections. Additional capabilities consist of those features that are optional. However, for RMS compliance, where features providing the same or similar capabilities are implemented, they shall be implemented according to RMS specifications.

Except where one or more subsections are specifically excluded, section references include all subsections of the referenced section.

The following table format is used in this section to specify fundamental and additional (optional) capabilities. Fundamental capabilities have a "Y" in the column labeled "Fund." Otherwise, the capability is optional.

Capability	*Reference*	*Fundamental*
Name of capability	Sections in SEMI E42	Y or N

15.1 *Areas of Compliance* — There are seven areas of RMS compliance, as follows:

a. Managed Recipe

b. Recipe Namespace Management

c. Distributed Recipe Namespace Management

e. Distributed Recipe Namespace Recorder

d. Distributed Recipe Namespace Segment

f. Execution Recipe

g. Recipe Executor

15.2 *Managed Recipe* — This section defines RMS compliance for the *managed recipe*.

A *managed recipe* has attributes, a body, and is capable of supporting at least one agent-specific dataset. An RMS-compliant *managed recipe* reflects its compliance (a) through its attributes and (b) through its structure when it is transferred.

In some cases, a capability is represented by a single attribute. In other case, support of an additional capability requires several attributes that are required as a set.

Table 15.1 describes the requirements for compliance to the *managed recipe*.

Table 15.1 Section References for Managed Recipe Capabilities

Capability	*Reference*	*Fundamental*
Recipe identifier (class, name, version)	3.2.3	Y
/PROCESS/ recipe class	3.2.3.2	Y
Mandatory and required generic attributes	3.2.5, 3.4.1, 3.4.2	Y
Mandatory and required agent-specific dataset attributes	3.4.2.2	Y
Recipe State Model	8.3, Table 8.1	Y
/PROCESS/ recipe subclass(es)	3.2.3.2	N
Non-process recipe class(es)	3.2.3.2	N
Multi-part recipe (ExtRef, LinkList)	3.2.3.1, 3.4.2.1	N
Variable parameters (Parameters, LinkParam)	3.2.4.2, 3.4.2.1	N
Approval level (ApprovalLevel)	3.4.2.1, 3.4.2.1	N
Certification Certified	3.4.2.1	N
Source Form recipe body	3.2.2.1.1	N*
Object Form recipe body	3.2.2.1.2	N*

* At least one of the two forms is required.

15.3 *Managed Recipe Compliance Table* — Table 15.2 provides a statement of compliance for the *managed recipe*.

Table 15.2 Recipe Namespace Management Compliance Table

Manual Recipe Compliance Table		
Fundamental RMS Requirements	*Implemented*	*RMS Compliant*
Recipe identifier (class, name, version)	❒ Yes ❒ No	❒ Yes[1] ❒ No
/PROCESS/ recipe class	❒ Yes ❒ No	
Mandatory and required generic attributes	❒ Yes ❒ No	
Mandatory and required agent-specific dataset attributes	❒ Yes ❒ No	
Recipe State Model	❒ Yes ❒ No	
Additional Capabilities	*Implemented*	*RMS Compliant*[2]
/PROCESS/ recipe subclass(es)	❒ Yes ❒ No	❒ Yes ❒ No
Non-process recipe class(es)	❒ Yes ❒ No	❒ Yes ❒ No
Multi-part recipe (ExtRef, LinkList)	❒ Yes ❒ No	❒ Yes ❒ No
Variable parameters (Parameters, LinkParam)	❒ Yes ❒ No	❒ Yes ❒ No
Approval level (ApprovalLevel)	❒ Yes ❒ No	❒ Yes ❒ No
Agent-specific dataset mandatory and required attributes	❒ Yes ❒ No	❒ Yes ❒ No
Certification Certified	❒ Yes ❒ No	❒ Yes ❒ No
Source Form recipe body	❒ Yes ❒ No	❒ Yes ❒ No
Object Form recipe body	❒ Yes ❒ No	❒ Yes ❒ No

[1] Do not mark YES unless all fundamental RMS requirements are implemented.

[2] Additional capabilities may not be marked RMS compliant unless all fundamental RMS requirements are implemented.

15.4 *Recipe Namespace Management* — Recipe Namespace Management requires compliance to specifications for the *managed recipe*, the *recipe namespace*, and the *recipe namespace manager*.

15.4.1 *Recipe Namespace* — This section defines RMS compliance for the *recipe namespace* object. A *recipe namespace* exhibits RMS compliance through its attributes and access to managed recipes.

NOTE: Operations and services are performed by the *recipe manager*.

Table 15.3 describes the requirements for compliance to the *recipe namespace*.

Table 15.3 Section References for Recipe Namespace Capabilities

Capability	*Reference*	*Fundamental*
Fundamental compliance to *managed recipe*	15.2, Table 15.2	Y
Basic requirements	4.3, 4.4, 4.6, 8.2.1	Y

15.4.2 *Recipe Namespace Manager* — Table 15.4 describes RMS compliance for the *recipe namespace manager*.

Table 15.4 Section References for Recipe Namespace Manager Capabilities

Capability	*Reference*	*Fundamental*
Basic requirements	4.3, 4.6 (Table 4.2), 8.2.1	Y
OSS services	9.1, 9.1.1–9.1.2	Y
Create recipe (RMNCreate)	8.2.2, 8.2.2.1, 9.4.1, 12.9	Y
Update recipe (RMNUpdate)	8.2.2.2, 9.4.2, 12.10	Y
Verify recipe (RMNAction)	8.2.3.1, 9.4.7, 12.15	Y
Link recipe (RMNAction)	8.2.3.2, 12.15	Y
Get recipe descriptor (RMNGetDescriptor)	8.2.7.1, 12.17	Y
Get available space (RMNSpaceInquire)	9.3.1, 12.6	Y
Check recipe status (RMNRcpStatInquire)	9.3.2, 12.7	Y
Get best version (RMNVersionInquire)	9.3.3, 12.8	Y
Store recipe (RMNStore)	9.4.3, 12.11	Y
Download *execution* recipe (RMNAction)	6.3.2, 9.4.8, 12.15	Y
Retrieve recipe (RMNRetrieve)	9.4.4, 12.12	Y
Recipe Namespace Change Event	9.6	Y
Action complete notification (RMNComplete)	12.18	Y
Upload *execution* recipe (RMNAction)	9.4.9, 12.15	N
Unlink recipe (RMNAction)	8.2.3.3, 12.15	N
Approve recipe (RMNAction)	8.2.4.1, 12.15	N
Protect recipe (RMNAction)	8.2.5, 12.15	N
Unprotect recipe (RMNAction)	8.2.6, 12.15	N
Certify recipe (RMNAction)	8.2.4.2, 8.2.7, 12.15	N
Decertify recipe (RMNAction)	8.2.8, 12.15	N
Create namespace (RMNCreate)	9.2.1, 12.3	N
Delete namespace (RMNDeleteNS)	9.2.2, 12.4	N
Rename namespace (RMNRename)	9.2.3, 9.4.6, 12.5	N
Copy recipe (RMNCopy)	9.4.5, 12.13	N
Upload recipe (RMNAction)	9.4.9, 12.15	N
Modify recipe variable parameters (RMNVarPar)	8.2.3.4, 12.16	N
Recipe synchronization	9.5	N

15.4.3 *Recipe Namespace Management Compliance Table* — Table 15.5 provides a statement of compliance for recipe namespace management.

Table 15.5 Recipe Namespace Management Compliance Table

RMS Recipe Namespace Management	*Compliance Statement*	
Fundamental RMS Requirements	*Implemented*	*RMS Compliant*
Managed Recipe Object	❐ Yes ❐ No	
Recipe Namespace Object	❐ Yes ❐ No	❐ Yes[3]

3 Do not mark YES unless all fundamental RMS requirements are implemented.

4 Additional capabilities may not be marked RMS compliant unless all fundamental RMS requirements are implemented.

15.5 *Compliance for Distributed Recipe Namespace Management* — Compliance for distributed recipe management requires compliance to the following objects:

- *managed recipe*
- *recipe namespace*
- *distributed recipe namespace*

15.5.1 *Distributed Recipe Namespace* — Table 15.6 describes the requirements for compliance for the *distributed recipe namespace*.

Table 15.6 Section References for Distributed Recipe Namespace Capabilities

Capability	*Reference*	*Fundamental*
Recipe namespace fundamental requirements	15.x, Table 15.x	Y
Basic requirements	5.11.3, Table 5.4	Y
OSS services	5.3.1, 10.1, 10.1.1.1–10.1.1.3	Y
Logical recipes	5.3.2	Y

15.5.2 *Distributed Recipe Namespace Manager* — Table 15.7 describes the requirements for compliance to the *distributed recipe namespace manager*.

Table 15.7 Section References for Distributed Recipe Namespace Manager Capabilities

Capability	*Reference*	*Fundamental*
Recipe namespace manager	15.x, Table 15.x	Y
Basic requirements	5.8, 5.8.1, 5.11.4, 10.3	Y
OSS services	10.3.1	
Attachment and detachment	10.3.3 (all)	Y
Attached segment read-only level	5.4.2	Y
Delete *distributed namespace*		Y
Change request management	10.3.4 (all)	Y
Segment change request (RMDSegChange)	10.3.5, 13.4.3	Y
Segment action complete (RMDComplete)	10.3.6?, 13.4.1	Y
Segment action complete (RMDNotify)	10.3.6?, 13.4.2	Y
Get change request (RMDGetChangeRequest)	10.3.8, 13.4.4	Y
Rebuild *distributed recipe namespace* (RMDRebuild)	5.10, 10.3.9, 13.4.5	Y

15.5.3 *Distributed Recipe Namespace Management Compliance Table* — Table 15.8 provides a statement of compliance for *distributed recipe namespace* management.

Table 15.8 Distributed Recipe Namespace Management Compliance Table

RMS Compliance Statement		
Fundamental RMS Requirements	*Implemented*	*RMS Compliant*
Managed Recipe Object	❐ Yes ❐ No	❐ Yes[5] ❐ No

[11] Do not mark YES unless all fundamental RMS requirements are implemented.

[12] Additional capabilities may not be marked RMS compliant unless all fundamental RMS requirements are implemented.

16 Glossary of Terms

The list of terms in this section is intended only as a guide. Formal definitions are provided in the main body of the document.

agent — A type of *resource* system in a factory that includes both hardware and software components, at least some of which are also *resources*.

Examples of *agents* include recipe namespace servers, cells, stations, clusters, attached cluster modules, equipment, and smart equipment subsystems. *Agents* are associated with a physical system or a collection of physical systems, including computer platforms.

agent-specific attribute — A recipe attribute that applies only to a specific agent.

agent-specific parameter — A *variable parameter* that has been "tuned" for a specific *agent* by modifying its original initial value and/or restrictions and placing the result in the *agent-specific attribute* AgentSpecific LinkParam.

agent-specific recipe — A recipe stored in the *default namespace* of a specific *agent*.

agent-specific dataset — The recipe component containing the set of agent-specific attributes that have been set for that recipe for a specific *agent*.

approve — The operation that sets a recipe's ApprovalLevel attribute to a non-zero value.

approved — A recipe is *approved* whenever its ApprovalLevel attribute is non-zero.

approval level — (1) Used to reflect different degrees of recipe development and qualification; (2) The value of the attribute ApprovalLevel.

attribute — Information concerning an *object* that may be used either for internal or external purposes.

attribute length — The length of an individual attribute, calculated as the sum of the lengths of the *attribute name* and the *attribute value*, exclusive of formatting information.

attribute length attribute — An attribute that contains the sum of the lengths of the attributes. A *managed recipe, agent-specific dataset,* and *execution recipe* each have their own *attribute length* attribute.

attribute timestamp attribute — The *timestamp* of the last change to any of a recipe's attributes.

authorized user — A user who is able to identify him or herself to the host or equipment as having the level of authority required for a particular activity, such as *certifying* a recipe for that equipment.

body — See *recipe body*.

centralized namespace — A *recipe namespace* that is not distributed.

certification-level — The value of the attribute Certified.

certified — (1) Factory-level approval that a recipe produces the expected results on a particular instance of equipment; (2) A recipe for which the Certified attribute is defined and given a non-zero value for a specific *agent*.

certify — The operation of changing the *certification-level* of a recipe for an installation of equipment.

class — See *recipe class*.

clear — An attribute is *cleared* (reset) by setting its value to its *default value*.

component agent — A subordinate *agent* that provides services to a *supervisory agent*.

copy — Originate a recipe by the internal operation of duplicating a recipe and assigning a new *identifier*.

create — The operation of entering a recipe *body* into a *namespace* and assigning it a new (unused) *identifier*.

de-certify — The operation of *clearing* the *certification level* (Certified attribute) for a specific *agent*.

dedicated namespace — A *recipe namespace* with exactly one *member*.

default namespace — A *dedicated, centralized namespace* that is used by standalone equipment and/or for hardware-specific *(agent-specific)* recipes.

default value — A pre-defined value. All non-mandatory recipe attributes are assigned a *default value* as part of their definition. An attribute set to its *default value* may be omitted when a recipe is transferred.

delegate — An *agent's supervisor* **delegates** a recipe that is *executed* by its component *agent*. The *delegating agent* is responsible for ensuring that the *component* has access to a current copy of the recipe and that the recipe is *selected*, started, and *deselected* at the proper time.

delete — A recipe is *deleted* by removing its *identifier*, preventing further access, and freeing its storage.

derived object form — An *object form* of a recipe that is based upon a recipe in *source form* and that represents a more efficient format for execution purposes. Typically, but not by definition, this is a "tokenized" form and requires less storage.

descriptor — (1) The *length* and *timestamp* attributes of a recipe's attributes or of one of its components; (2) The set of all of the individual *descriptors* of a recipe.

deselect — The operation that **prevents a selected** recipe from subsequent execution without its first being *selected* again.

distributed recipe namespace — A namespace that is capable of using *namespace segments* provided by multiple *agents*.

download — To send a recipe to the *recipe executor*.

edit — An operation which *creates* a new recipe *body* or changes the *body* of an existing recipe.

editor — A service which allows a *user* to *create* or modify the contents of the recipe *body*. *Editors* are not defined by RMS and are generally considered as external to a *namespace*.

eol — The ASCII line-feed character ($0A_{16}$) signifying the end of a line of text.

empty — An attribute with a *binary*, list, or text format with no content.

end of line character — See *eol*.

equipment — An *agent* with associated hardware that provides, at a minimum, *recipe execution* services.

event — A detectable occurrence of interest to a *service user*.

exception — An irregular event that indicates some abnormal or unacceptable condition that requires attention but does not constitute a safety hazard. Within RMS, *exceptions* indicate the abnormal completion of an *operation*.

execute — An *agent* **executes** a recipe by reading the recipe contents and implementing its instructions, process parameters, or other information required for its own processing.

executing agent — The *agent* that is capable of *executing* a specific recipe.

execution area — The storage location of the recipe(s) currently *selected* (ready) for *execution*.

executable copy — A selected recipe, or “copy” of a selected recipe, which is in the *execution area*.

execution recipe — The subtype of recipe that is stored by the *recipe executor*.

execution recipe descriptor — Consists of the *execution attribute description*, the *generic attribute description*, and the *body descriptor*, in that order.

execution recipe storage — Storage for recipes provided by the *recipe executor* for recipes that are not currently *selected*.

external reference — (1) The reference which a recipe makes to another recipe; (2) The list of *subrecipes* referenced by a *parent* recipe.

forced overwrite — The replacement of an existing *execution recipe* with a *downloaded* recipe with the same *identifier*.

fundamental requirements — The requirements for information and behavior that must be satisfied for compliance to the Recipe Management Standard. *Fundamental requirements* apply to specific areas of application or objects.

generic attribute — A recipe *attribute* that applies to all *agents* capable of *executing* a specific recipe.

get available storage — The operation that calculates the amount of remaining recipe storage capacity, in bytes, exceeding overhead requirements.

header length — The sum of the lengths of the *attributes* the *header* contains at the time the calculation is performed.

host — A *supervisory agent* that represents the factory to its subordinates.

identification attribute — An attribute that is used to identify a specific object and that is not included in a recipe section when a recipe is transferred.

identification code — A text string containing a unique and persistent “signature” for the *recipe executor* that last performed verification on a recipe.

identifier — One or more attributes of an object that uniquely identify it within a specific context.

last value — The setting for a *variable parameter* specified by the *user* when the recipe was last *selected* for execution.

link — The operation performed on a main recipe that collects and resolves external references, and collects variable parameter definitions, for that recipe and all referenced recipes.

linked recipe set — The set of recipes identified by the *link* operation and specified by the attribute LinkList.

logical recipe — A recipe with a particular set of attributes and a particular *body* considered independently from its physical location. A *logical recipe* may have multiple instances or copies.

main recipe — (1) The recipe, within a set of one or more recipes to be *linked* together, which is not a *subrecipe*; (2) The starting recipe or “entry point” for a set of recipes.

managed recipe — A recipe that is stored with a *recipe namespace*.

mandatory attribute — A required attribute that always exists and has a *non-default value*.

modify variable parameters — An operation that modifies the *variable parameter definitions* applied to a specific agent.

name — A text-based attribute of an object that may be used as all or part of an identifier. Certain restrictions on its characters exist. (See SEMI E39.)

namespace — A domain within which object identifiers are unique. Also see *recipe namespace*.

namespace specifier — An object specifier applied to a *recipe namespace*.

non-numeric parameter — Any *variable parameter* that is not a *numeric parameter*.

non-shared namespace — A *recipe namespace* that has at most one *member*.

notification service — A *service* that does not expect a response.

numeric parameter — Any *variable parameters* that can take on any *numeric value* for their *format type*, between a *parameter low limit* and a *parameter high limit*. These *limits* shall not exceed absolute minimum and maximum limits set for that *parameter* by the *agent's* supplier.

numeric version — See *version number*.

object form — (1) Any recipe not in text form; (2) The *body* of a recipe which has been compressed from the *source form*. (See also the generic attribute BodyFormat.)

object specifier — A logical pointer to a remote object. See SEMI E39 (OSS).

operator — The user who interacts locally with *agent* through the *agent's* human interface.

originate — Any operation which produces a new recipe *identifier*, including *copying, renaming, creating, editing* a *read-only* recipe, and *downloading* a new version.

originating namespace — The *recipe namespace* from which an *execution recipe* was originally *downloaded* and/or to which it is to be *uploaded*.

parameter — A control value that affects the *agent's* process. Also see *variable parameter*.

parameter definition — A formal declaration of a *variable parameter* that specifies the *parameter's name*, *initial value*, and *restrictions*.

parameter domain — The set of all possible values for a given *form* that fulfill the conditions of the *parameter restriction* (if any).

parameter restriction — A required part of a *parameter definition* specifying one or more conditions that any *value* assigned to that *parameter* is required to satisfy to be valid.

parent recipe — Any recipe with *external references* to *subrecipes*.

primary class — A recipe *class* which is not a *subclass* of another *class*.

PROCESS class — The required *primary class* for all recipes used for the *agent's* normal process.

protect — The operation of changing the *approval level* of an individual recipe to that of the RecipeRead-OnlyLevel attribute of the *recipe namespace*.

read-only recipe — A recipe that is *protected*. A recipe with an *approval-level* greater than, or equal to, the value of the *namespace* attribute RecipeRead-OnlyLevel cannot be changed by *updating, deleting, renaming, unlinking,* or *re-linking*.

recipe — (1) The pre-planned and reusable portion of the set of instructions, *settings,* and parameters under control of the *agent* that determine the processing environment seen by the manufactured object and that may be subject to change between runs or processing cycles; (2) The aggregation composed of a *generic header*, zero or more *agent-specific headers*, and a recipe body.

recipe attribute — Structured information concerning a recipe within the recipe *header*.

recipe body — The contents of the recipe containing the data used for execution purposes.

recipe class — A formal grouping of recipes with a common language syntax and functionality.

managed recipe descriptor — Consists of the *generic attribute descriptor* and the *body descriptor*, followed by *descriptors* for any *agent-specific* datasets.

recipe execution area — Storage used for currently *selected* recipes (i.e., for the current process cycle).

recipe executor — The component of an *executing agent* responsible for understanding and *verifying* the syntax and semantics of a recipe, for *validating* it, and for *executing* it.

recipe identifier — Consists of the recipe's *class, name,* and *version*.

recipe name — A user-defined text string used in the recipe *identifier*. The *name* corresponds to PPID in Stream 7 implementations.

recipe namespace — A logical management domain for (1) the storage and management of recipes, and (2) the insurance of the uniqueness of recipe *identifiers* within that domain.

recipe namespace manager (manager) — The component of an *agent* that manages the *recipe namespace* and that represents the interface for the *namespace* to the external world.

recipe namespace segment (segment) — The component of a *namespace* that represents the internal storage and actual manipulation of recipes.

recipe section — A partition of the recipe for purposes of transferring it through an RMS service. All recipes have a section containing the *generic* attributes and a section containing the body. Some recipes also have a section containing the *agent-specific* attributes.

recipe specifier — An object specifier applied to a recipe.

recipe storage area — A storage area for recipes.

rename — The operation of assigning a new *identifier* to a recipe or to a *recipe namespace*.

request service — A *service* that requires a response.

SERVICE class — An optional *primary class* used for recipes whose purpose is to maintain, prepare, calibrate, or test the operation of *equipment*.

reset — See *clear*.

resource — An owned entity that has an active role in factory operations.

select — The act of preparing a recipe, or a linked recipe set, for execution. This includes confirmation that all specified *subrecipes* are available, that the attributes of the *main* recipe and all its referenced *recipes* meet *execution* requirements, that the recipes are *validated* as a set, and that all other steps that may be necessary for the proper *execution* of the recipe have been performed.

service — A **service** (or **message service**) represents a function offered to a user by a provider. A *service* is one of two types: a *request* or a *notification*.

service resource — A set of services within a particular area of specialization, such as a *recipe namespace resource* or a *recipe execution resource*.

setting — A static value accessible to the *user*, through one or more methods, that is used by *agent* to control its process. *Settings* include, but are not limited to, setpoint values. *Settings* typically may be specified within a recipe.

shared namespace — A *namespace* with more than one *member*.

source form — A recipe *body* which consists of one or more lines of text and which conforms to a formally defined recipe language.

storage area — An area where objects and data are stored. See also *recipe storage area*.

stored recipe attribute — An attribute of a recipe, a *recipe header*, or a *recipe body*, that is stored as a name/value pair within a recipe *header* whenever the recipe is transferred.

subclass — A *class* of recipes within a larger *class*.

subrecipe — Any recipe which is referenced by another recipe within the same *namespace*.

supervisory agent — An *agent* with supervisory responsibilities for one or more subordinate *agents*. Examples include a *host* manufacturing system and a cluster controller.

timestamp — (1) The notation of the date and time of the occurrence of an event; (2) An attribute of a *recipe header* or *recipe body* that contains the date and time the particular section was last changed. This attribute is a text string of the form "yyyymmddhhmmsscc" for the year yyyy, the month mm, the day dd, the hour hh, the minutes mm, and the seconds ss.

unlink — An operation that *clears* all attributes set by a *link* operation.

unprotect — An operation that resets a recipe's ApprovalLevel attribute. (Set it to zero.)

update — The operation of replacing the *body* of an existing recipe.

upload — To transfer a recipe body from the *recipe executor*.

user — A person interacting with an *agent* directly through the *agent's* human interface or indirectly through the *agent's supervisor*.

validate — The action of checking a recipe to ensure that the recipe and its parameters' type and range are valid for the *agent's* configuration at the time the recipe is *selected* for execution. [A recipe may be syntactically correct and yet may contain statements that cannot be executed under all configurations of the *agent*.]

variable parameter — A formally defined variable *(setting)* defined in the body of a recipe (1) With a specified default value, boundaries or conditions for replacement values, and (where applicable) units, and which is placed in the Parameters attribute of the recipe when it is *verified*; (2) Permitting the actual value to be supplied externally by a parent recipe, or at the time the recipe is selected for execution by the *supervisor* or the *operator*.

verification area — Optional temporary storage provided for unverified downloaded recipes.

verify — The operation of (1) ensuring that a recipe is syntactically correct, and (2) identifying *variable parameters* and *external references*.

version — A text string that is part of a recipe's *identifier*.

version number — A version consisting only of the digits “0” through “9” and one decimal point character “.” that can be translated to a pure number. Only whole numbers (with no decimal point) and numbers with a decimal point that do not begin or end with a “0” may be used.

whitespace — In ASCII, the space (20_{16}), tab (9_{16}), carriage return ($0D_{16}$), and form feed ($0C_{16}$) characters.

write-protect — See *protect*.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E42 and is not intended to modify or supersede the official standard. Rather, these notes are auxiliary information provided as background or examples of possible application and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

R1-1 RMS Standardized Objects

The *standardized objects* defined by RMS are shown in Table R1-1.

Table R1-1 Standardized Objects

Object Type	*ObjType*	*Section Reference*
Managed Recipe	MRcp	3.4.2.1
Agent-Specific Dataset	MRcpASDS	3.4.2.2
Execution Recipe	ERcp	3.5.4
Recipe Namespace	RNS	4.6
Recipe Namespace Manager	RNS_Mgr	4.6
Recipe Executor	RcpExec	6.8
Agent	Agent	7.3

R1-2 RMS Requirements/Concepts Map

Table R1-2 provides the specific RMS concepts that address each of the requirements from Table 2.1.

Table R1-2 RMS Requirements/Concepts Map

Requirement	*Concept*
Uniquely store, identify, and select recipes in a system.	Namespace
Share recipes among different agents.	
Synchronize the change of shared recipes among agents.	
Share recipes among different installations of the same type of *equipment* by adjusting individual differences.	
Ability to execute recipes with or without a communication link.	Default Namespace
Ability to change recipes managed by another agent when the communication link has failed or before it is established.	
Formal differentiation of, and recognition of, recipes of different types.	Recipe Class
Allow a recipe name to retain its base identity across a series of modifications.	Version Number
Allow shared recipes to be adjusted for individual pieces of *equipment*.	Variable Parameters
Allow a recipe's parameters to be adjusted within specified limits without requiring the recipe body to be changed.	
Support feedback/feed forward control.	
Ensure the recipe is syntactically correct.	Verification
Manage the approval level of specific recipes with respect to process development and production-worthiness.	Approval
Allow management of equipment qualified for specific recipes.	Certification
Change the recipe while it is running.	Protection of execution area from inadvertent change

R1-3 Background

The material in this section provides a context for the Recipe Management Standard and is intended for background information only.

In a complex environment, *equipment* and *host* become relative terms indicating roles of two independent *agents* with respect to each other. In general, both *equipment* and *host* may provide services to one another, and some services may be provided by both. In certain cases, one may provide services to its partner that the other does not. With respect to recipes, *equipment* refers to the recipe's executor, whereas *host* represents a *supervisory agent* who may *delegate* recipes which will be executed by the *equipment*.

For clusters, cells, and local-area stations, where a mid-level controller communicates both to lower-level *components* and to a higher level factory system, that controller may alternately take the role of *host* to its *components* and of *equipment* to the factory system.

Where role is significant, the terms *equipment* and *host* are used in this section to indicate the relationship of the two *agents* to one another.

R1-3.1 *Traceability* — A main management objective in both a Development Fab and a Production Fab is traceability of manufacturing conditions to the final device characteristics. This traceability is required in a Development Fab to support the analysis and characterization of the process under development. Certain customers of a Production Fab require this traceability in order to do business. Even without such a customer requirement, traceability is important for process control and postmortem analysis of unexpected device characteristics.

The recipe is the primary specification of manufacturing conditions to the *equipment*; therefore, the management of recipes is critical to this traceability.

R1-3.2 *Recipe Life Cycle* — The lifetime of a recipe in a Fab typically has several phases, as illustrated in Figure R1-1. While being developed, it may contain errors, or it may not produce the desired results. The recipe may be edited several times during its initial development. At some point, the recipe enters the test phase, where it will be executed and its results evaluated. A check for syntax correctness occurs at or before the time the equipment prepares it for execution. Still further changes may be made to fine-tune the process to achieve a particular result. During this process, it is still desirable to be able to protect it from inadvertent change or deletion. Finally, the recipe is ready for production and goes through a series of signoffs which constitutes a formal authorization procedure. In many factories, only recipes which have been approved as production-worthy may be used in production runs.

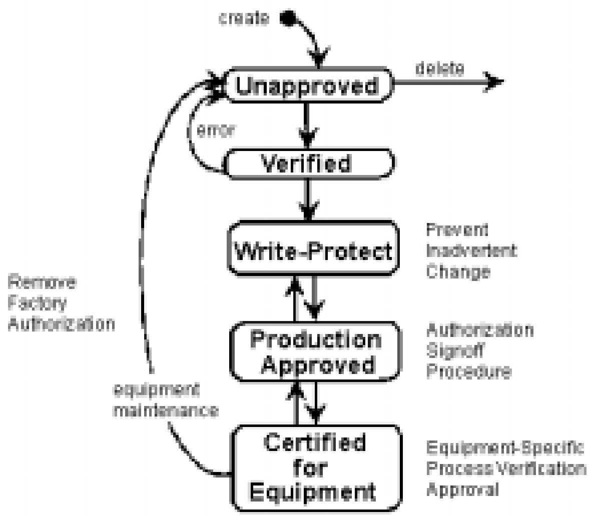

Figure R1-1
Typical Recipe Life Cycle

Also, because results may vary between different installations of *equipment*, an additional level of authorization may be required that certifies individual *equipment* for a given approved recipe.

A factory change control system must accommodate different levels of protection for recipes in different phases of their life cycle. To accomplish this, *equipment* must recognize and support the different requirements for each phase.

R1-3.3 *Recipe Editing* — Traditionally, recipes are developed on the *equipment* that runs them. Besides requiring time on the target machine (a potentially scarce and expensive resource), this requires the person defining the recipe to be inside a clean area. A potential solution is for *equipment* manufacturers to provide versions of their dedicated recipe editors that can be integrated into the factory manufacturing systems. Aside from the difficulty of the *equipment* manufacturer supporting the variety of platforms currently in use internationally, even in a distributed factory environment, a proliferation of different dedicated recipe editors required for the different types of *equipment* is not considered a good solution.

A better solution is to permit editing external to the cleanroom and then to transmit the completed recipe to the *equipment* for verification. This can be achieved by providing a text form of the *equipment* manufacturer's recipe language which can be created and modified with any standard text editor. This may not be possible with some types of recipes (e.g., pattern recognition programs for vision systems), but this restriction may be removed when the technology advances.

Editing on the *equipment* may still be desirable, particularly in a Development Fab. When the *equipment* permits a recipe to be changed, the *equipment* must provide reporting mechanisms that inform the *host* of changes and allow the *host's* change control system to operate.

R1-3.4 *Recipe Sharing* — A Fab may have several installation of the same type of equipment (equipment with the same functionality and the same recipe language). Therefore, where possible, the same recipe should be able to be shared between different equipment of this same type.

R1-3.5 *Protection and Process Control* — The primary goal of process control is to ensure that the final result of the manufacturing process does not change over time. This may be accomplished by both feedback and feedforward methods. These methods modify the settings used in the process. This requires two capabilities that seem to be in conflict:

- The definition of the process settings (the recipe) should not change.
- The process settings should change to counter the drift inherent in real processes.

The first capability is particularly important in a Production Fab. Most Fab policies prohibit processes from changing after they have been approved for production. This is easy to build into a change control system on the *host*. However, if the *equipment* allows local editing, then it must also enforce this policy.

Wholesale changes in a recipe are never necessary for the second purpose. Usually only a few parameter values are modified in small increments to effect control of the process. A well-defined process specifies the parameters that vary and their range of variation. For any given recipe, it must be possible for the *host* to specify different values of such parameters for each piece of *equipment* so that the recipe may be "tuned" for that *equipment* to produce uniform results. In addition, the process control *agent*, on the *equipment* or the *host*, may need the ability to calculate the parameter value changes for each run and to inform the *equipment* of the new values. Mechanisms are provided to support such interactions.

R1-3.6 *Recipe Selection* — Typical operation of *equipment* requires an *operator* or the *host* to initially *select* the recipe to be run. Recipe *selection* may be specified implicitly within the definition of a higher order "process job". In either case, the specification of a recipe is accomplished by referring to its recipe *identifier* (i.e., the *identifier* used by the change control system) and, where needed to resolve ambiguity, its location. Once *selected*, a recipe is initiated by an appropriate start command, which may be explicitly given by the *operator* or *host* or implicitly given by the *equipment* when executing a higher order process job. Repeated runs of the same recipe may be accomplished via subsequent start commands without the necessity of formal recipe re-selection.

R1-4 Example of a Factory Implementation of Approval Levels

A factory might implement different levels of approval by regulating the following levels of recipe *approval* on the equipment:

```
   Approval Level                                  FACTORY POLICY

   Level 0                                         "Unapproved"
   Level 1                                         "In Test"
   Level 2                                         "Non-Production"
   Level 3                                         "Ready for Release"
   Level 4                                         "Released for Production"
with
   RecipeReadOnlyLevel = 2                         Level 2 = read-only
```

R1-5 Examples of Variable Parameters

The recipe *body* may have statements that allow parameters to be changed within fixed limits. For example, recipe BAKE;2.3 may contain statements such as:

```
   Parameter BakeTime of TIME                      default = 200 seconds
                                                   minimum = 100 seconds
                                                   maximum = 300 seconds;
  or
   TIME BakeTime • (200,100,300,"s")                  /* default,min,max,units */
```

that define the process parameter "BakeTime", its *initial value* and *restrictions*. The BAKE;2.3 recipe may use the BakeTime *parameter* in further internal statements to determine the length of time a wafer is processed, such as:

```
      wait for TIME BakeTime;
```

This parameter may then be set by a *parent* recipe as in Example (1) below or from the EqpSpec_PARAM *attribute* (see 5.3.1.4) or with a "Select Recipe" command from the *host* or *operator*.

For example, a recipe "BAKE;2.3" may *define* a *variable* "BakeTime", while a recipe "RAMP;1,0" may *define* a *variable* "RampSetPoint". A *parent* recipe "XYZ" might contain *external references* in the text of the *source form* such as:

```
(1)    RUN RAMP;1                               // use default for RampSetPoint
       RUN BAKE;2.3 with BakeTime=10            // bake for 10 seconds
```

or

```
(2)    set RampSetPoint to 500;                 /* ramp up to 500 degC */
       do RAMP(RampSetPoint);
       set Baketime to 120;                     /* 120 sec (2 min.) bake */
       do BAKE;2.3(BakeTime);
```

or

```
(3)    RAMP(RampSetPoint:=500)
       BAKE;2.3(BakeTime:=Time_A)               /* 1st bake time may vary */
       RAMP(RampSetPoint:=650)
       BAKE;2.3(BakeTime:=Time_B)               /* 2nd bake time may vary*/
       RAMP(RampSetPoint:=800)
       BAKE;2.3(BakeTime:=Time_B+50)            /* 2nd bake plus 50 sec */
```

where "Time_A" and "Time_B" were both formally defined within XYZ.

In example (1), no *initial* value is specified for RampSetPoint. In this case, when the *main* recipe is selected, the *initial value* specified either in EqpSpec_LinkParam or in Gen_LinkParam (that is the same as the *definition* in RAMP;2.3) is used. However, in this example, the *parameter* BakeTime is assigned a value by the *parent* recipe, and this supersedes any *value* from a recipe *attribute* or a "Select Recipe" command from the *host* or *operator*. In the example given, BakeTime is assigned a value outside of the declared *domain*. This should create an error when the recipe is *verified*.

Examples (2) and (3) illustrate how *subrecipes* RAMP and BAKE may be referenced multiple times by a *parent* recipe, and the *parent* may provide different *values* with each reference (Example 2) or may *define* new *parameters* to use with different *references* (Example 3).

In the above examples, PARAMETERS (set when each individual recipe is *verified*) and Gen_LinkParam (set when XYZ is *linked*) will contain *parameter definitions* as follows:

Recipe	PARAMETERS	n_LinkParam
XYZ;0.8	Time_A	Time_A
	Time_B	Time_B
		RampSetPoint
		BakeTime
RAMP;1.0	RampSetPoint	undefined for *unlinked* recipe
BAKE;2.3	BakeTime	undefined for *unlinked* recipe

R1-6 Applications of Object Services

Object Services are defined in SEMI E39 (Object Services Standard (OSS): Concepts, Behavior, and Services). This section provides a description of how these services may be applied for RMS.

R1-6.1 *Scope* — Scope may be used to specify the *namespace* of interest. It may also be used to specify a *namespace* or *recipe execution resource* belonging to a *component agent* of the service provider. For example, scope allows a factory host to ask a cluster tool for the attributes of a cluster module.

Scope may be used to point to one of several namespaces supported by an agent.

R1-6.2 *Filter* — A filter may be used when asking a *namespace* for a list of recipe *identifiers* to limit the number of *identifiers* returned. For example, the service user may ask a *namespace* for a list of recipe *identifiers* that were edited by “Tom” (Attribute name = “EditedBy”, Attribute value = “Tom”, Attribute Relation = “is equal to”) and that are *linked* (Attribute name = “Linked”, Attribute value = “TRUE”, Attribute Relation = “is equal to”).

R1-6.3 *Complex Attributes* — Object Services do not provide a way to change individual elements in an attribute with a structure or list form. To add, delete, or modify items in a list or structure, it is necessary to first get the current attribute value for the object of interest using the GetAttr service, to make the desired changes externally to the value, and then to write the new value using the SetAttr service.

R1-7 Examples of RMS Application

Figure R1-2 illustrates possible interactions between a *namespace* and *namespace manager* implemented on a factory system, a diskless equipment with a *recipe executor*, and an *operator*.

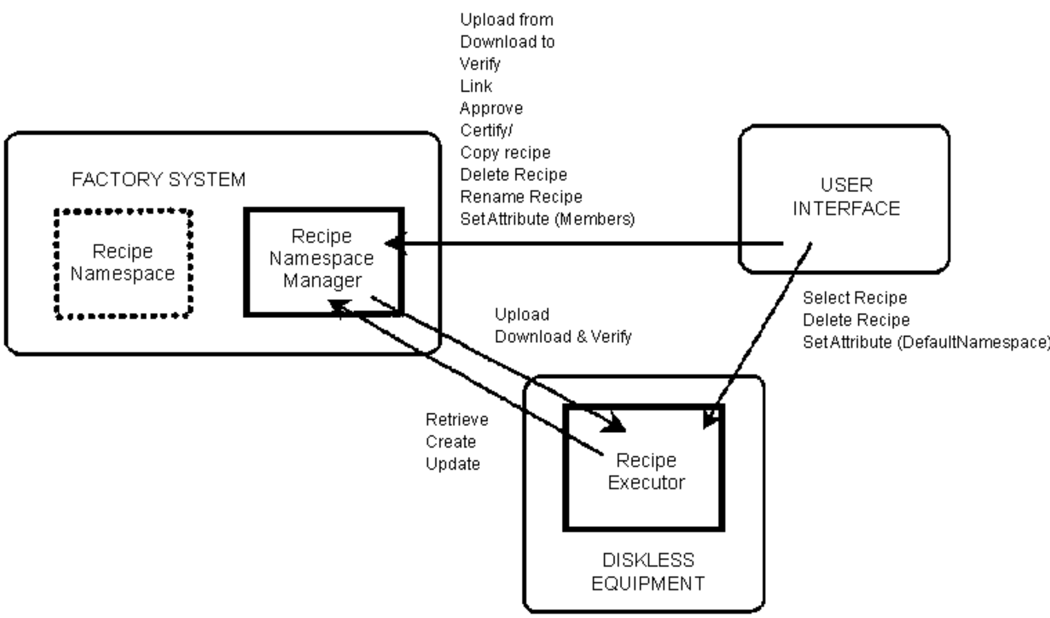

Figure R1-2
Example of RMS Applications

Other examples would be similar. Interactions are primarily with external service users of *namespace* and *recipe execution* capabilities, and between *namespace managers* and *recipe executors*.

Namespaces do not interact with one another. To copy a recipe from one *namespace* to another, an intermediary is required. This is not covered by RMS.

SEMI E42.1-0997
STANDARD FOR SECS-II PROTOCOL FOR RECIPE MANAGEMENT STANDARD (RMS)

1 Purpose

1.1 This document maps the services and data of the parent document to SECS-II streams and functions and data definitions.

2 Scope

2.1 This document applies to all implementations of Recipe Management that use the SECS-II message protocol (SEMI E5).

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E42 — Recipe Management Standard: Concepts, Behavior, and Message Services

4 Terminology

None.

5 Service Mapping

5.1 Table 1 shows the specific SECS-II streams and functions that shall be used for SECS-II implementations of the services defined in RMS.

5.2 Request and notification messages are mapped to primary (odd-numbered) SECS-II functions and response messages are mapped to secondary (even-numbered) SECS-II functions.

5.3 In several cases, a common set of parameters allows more than one RMS services to be mapped to a single stream and function, with an additional SECS-II data item used to differentiate between the two services. RMNCreateNS and RMNDeleteNS both map to S15,F3/F4, RMNCreate and RMNUpdate both map to S15,F13/14, and RMNCopy and RMNRename both map to S15,F19/20.

5.4 In addition, the notification messages RMNComplete, RMEComplete, RMEChange, RMDComplete, and RMDNotify all map to S6,F25/F26.

Table 1 Services Mapping Table

Message Name	*Stream, Function*	*SECS-II Name*
RMNCreateNS	S15,F3/F4	Recipe Namespace Action Request/Acknowledge
RMNDeleteNS	S15,F3/F4	Recipe Namespace Action Request/Acknowledge
RMNRenameNS	S15,F5/F6	Recipe Namespace Rename Request/Acknowledge
RMNSpaceInquire	S15,F7/F8	Recipe Space Request/Data
RMNRcpStatInquire	S15,F9/F10	Recipe Status Request/Data
RMNVersionInquire	S15,F11/F12	Recipe Version Request/Data
RMNCreate	S15,F13/F14	Recipe Create Request/Acknowledge
RMNUpdate	S15,F13/F14	Recipe Create Request/Acknowledge
RMNStore	S15,F15/F16	Recipe Store Request/Acknowledge
RMNRetrieve	S15,F17/F18	Recipe Retrieve Request/Data
RMNCopy	S15,F19/F20	Recipe Rename Request/Acknowledge
RMNRename	S15,F19/F20	Recipe Rename Request/Acknowledge
RMNAction	S15,F21/F22	Recipe Action Request/Acknowledge
RMNGetDescriptor	S15,F23/F24	Recipe Descriptor Request/Data
RMNVarPar	S15,F25/F26	Recipe Parameter Update Request/Acknowledge
RMNComplete	S6,F25	Notification Report Send
RMEDnldVer	S15,F27/F28	Recipe Download
RMEVerify	S15,F29/F30	Recipe Verify
RMEUpload	S15,F31/F32	Recipe Upload
RMESpaceInquire	S15,F7/F8	Recipe Space Request/Data
RMERename	S15,F19/F20	Recipe Rename Request/Acknowledge

Message Name	*Stream, Function*	*SECS-II Name*
RMEDelete	S15,F35/F36	Recipe Delete Request/Acknowledge
RMESelect	S15,F33/F34	Recipe Select Request/Acknowledge
RMEDeselect	S15,F35/F36	Recipe Deselect Request/Acknowledge
RMEGetDescriptor	S15,F23/F24	Recipe Descriptor Request/Data
RMNAction	S15,F21/F22	Recipe Action Request/Acknowledge
RMEChange	S6,F25	Notification Report Send
RMEComplete	S6,F25	Notification Report Send
RMDSApproveAction	S15,F37/F38	DRNS Segment Approve Action Request/Acknowledge

RcpDerivedID	RCPID
REAck	RMACK
REAttrDescLength	RCPDESCLTH
REAttrDescName	RCPDESCNM = “REAttrDesc”
REAttrDescTimestamp	RCPDESCTIME
REAtrSectionName	RCPSECNM = “Attribute”
REChangeStatus	CHGCODE
REDerivedID	RCPID
REDestRcpID	RCPNEWID
REOpID	OPID
REWOCode	REOWCODE
REParamName	PARAMNAME
REParamSetting	PARAMVALUE
RERcpID	RCPID
RERcpSpec	RCPSPEC
RESpace	RMSPACE
RESpec	RESPEC
AttachToken	OBJTOKEN
RMChgType	RMCHGTYPE
RMManagerSpec	OBJSPEC
RMPermit	RMGRNT
RMRecorderSpec	OBJSPEC (S15,F43) and RMRECSPEC otherwise
RMRequestor	RMREQUESTOR
RMSegSpec	RMSEGSPEC
RMTimestamp	TIMESTAMP
TargetSpec	TARGETSPEC

6.2 There are also several data items that are used in the SECS-II messages which do not map to specific services parameters. Services with the same set of parameters are mapped to the same SECS-II message by adding an additional data item to differentiate between the services. In addition, SECS-II restrictions require multi-block primary messages to be preceded by a multi-block inquire/grant transaction defined within the same stream. For RMS messages, this requirement is satisfied with the S15,F1 and F2 messages. Data items defined for these two messages have no counterpart in RMS service parameters.

6.3 Table 3 contains the SECS-II data items that have no corresponding RMS service parameter:

Table 3 Additional Data Item Requirements Table

Function	*SECS-II Data Item*
Used to satisfy SECS-II conventions for linking a multi-block inquiry with a subsequent multi-block message.	DATAID
Used for the name of any *non-identifier* recipe attribute.	RCPATTRID
Used for the value of any *non-identifier* recipe attribute.	RCPATTRDATA
Used by S15,F19 to differentiate between RMNCopy and RMNRename services.	RCPRENAME
Used to satisfy SECS-II multi-block requirements.	RMGRNT
Used by S15,F3 to differentiate between RMNCreateNS and RMNDeleteNS services. Used by S15,F39 to differentiate between RMDRAddSegRecord and RMDRDelSegRecord. Used by S15,F41 to differentiate between RMDRAddChgRecord and RMDRDelChgRecord.	RMNSCMD
Used to satisfy SECS-II multi-block requirements. Neither required nor specified by RMS.	RMDATASIZE
Used by S15,F13 to differentiate between RMNCreate and RMNUpdate services.	RCPUPDT
Used by S15,F35 to differentiate between RMEDelete and RMEDeselect services.	RCPDEL
Used by S15,Fy to differentiate between A and B services.	RCPDEL

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E42.1 and is not intended to modify or supercede the official standard. Publication was authorized by full letter ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 RMS-Compliant Equipment with a Stream 7 Host

Semiconductor manufacturers with legacy systems, capable of communicating using Stream 7 messages only, may still take advantage of many of the Recipe Management concepts when used with equipment that is Recipe Management-compliant. This section contains guidelines and examples for maintaining recipe attributes within the body of a Stream 7 process program.

R1-1.1 *Recipe Identifier* — Both the process program identifier PPID and the object identifier, including the recipe identifier, have a maximum length of 80 characters. Recipe class, name, and version number may be encoded into the data item PPID using the format required for the recipe identifier.

"/$CLASS_1$/$CLASS_2$/.../$CLASS_n$/NAME;VERSION"

It is recommended that recipe class names be unique, allowing use of the form

"/CLASS/NAME;VERSION"

to ensure the length conforms to the maximum allowed in SECS-II.

R1-1.2 *Recipe Sections* — All sections of the recipe are transferred together as the data item PPBODY. This allows all non-default values of recipe attributes to be preserved when a recipe is uploaded to the host and later downloaded back to equipment.

There are two potential methods for formatting PPBODY. If the recipe body is a text file, it is recommended that all attribute values are translated into text, including numeric and boolean values, with boolean values represented by the strings ".T." or ".F.". The second recommended method, applicable to both source and object forms, uses the structure of one of the SECS-II messages containing the managed recipe, as illustrated in Figure 1, or of an execution recipe. A cluster tool supporting shared *namespaces*, for example, might require multiple agent-specific data sets, while single-process equipment types would not.

R1-1.2.1 *Structuring PPBODY Using Text* — For purposes of transfer, recipes are regarded as composed of sections: The generic section, the body section, and zero or more agent-specific data-set sections (RMS, Section 12.1). This convention should also be maintained within PPBODY. The SECS-II messages used to transfer recipes (Stream 15, Functions 15 and 18) transfer the data-set sections last, because they are variable in number and are not always present. However, in a text format within PPBODY, it is generally easier to put all attributes before the body.

Since RMS uses the end-of-line character for source form recipes, this convention is recommended to separate the logical components of the sections containing attributes as well. A few reserved keywords are sufficient as tags to identify significant components: SECTION, ATTRIBUTE, LIST, PARAMNAME, PARAMSETTING, and PARAMRULE are recommended for consistency. Keywords are in uppercase for visual impact and are not delimited except for use of whitespace and the line-feed character ($0A_{16}$) used as the end-of-line (eol) character.

Whitespace is used to separate fields within a line. The symbol ⎵ is used here to represent whitespace, which is used both as a delimiter to separate fields within a line and also for optional visual effect.

Each section begins with a section declaration of the form

SECTION⎵"text"(eol)

where text is a section name, one of "Generic", "ASDS", "Body". Two sections are separated with two eol characters together. The eol convention within the body section, however, must conform to the recipe language specifications provided by the equipment manufacturer.

Each attribute begins with

ATTRIBUTE⎵AttributeName

followed by the attribute value, which may be a single item, a list of single items, or a list of complex items, such as variable parameters. If a list, the keyword LIST precedes the values, each item in the list terminated with either a comma or, for the last item, the eol character.

This becomes

ATTRIBUTE␣AttributeName␣ “text”(eol)   (single-value attributes)

or

ATTRIBUTE␣AttributeName␣LIST␣“text”, ␣“text”,...(eol)

for attributes consisting of lists of single items (e.g., LinkList or ExtRef).

If the keyword LIST if followed by eol, this indicates a list of complex items. The eol character, in this case, also is used to terminate the individual items in the high-order list. An attribute consisting of a list of complex items should identify the individual fields of each complex item. Those attributes containing variable parameters (e.g., Parameters) are of the form

ATTRIBUTE␣AttributeName␣LIST(eol)

␣PARAMNAME␣“text”, ␣PARAMSETTING␣“text”, ␣PARAMRULE␣“text”(eol)
␣PARAMNAME␣“text”, ␣PARAMSETTING␣“text”, ␣PARAMRULE␣“text”(eol)

...

␣PARAMNAME␣“text”, ␣PARAMSETTING␣“text”, ␣PARAMRULE␣“text”(eol)

Each individual field within a complex attribute value is delimited with the quotation mark (“) character. The eol character is used to terminate a section declaration, an attribute declaration, and a complex item within an attribute.

The recipe body is preceded with

SECTION “Body”(eol)

followed by the recipe body in the form normally used by the equipment.

In comparison of the two suggested formats, the advantage of the text form described in this section is that the attributes are human-readable and printable and therefore the user is able to modify those attributes that are not designated as read-only with a standard text editor.

The advantage of the SECS-II form (Figure 1) is that the equipment is more easily able to support a host that is only capable of using Stream 7.

R1-2 RMS-Compliant Recipe Management with Stream 7 Equipment

For RMS-Compliant Recipe Management applications dealing with legacy Stream 7 equipment, the situation is more restricted. While an RMS-compliant equipment may preserve attributes by bundling them inside the PPBODY of a process program, this option is not available when the situation is reversed because the equipment determines the permissible format(s) within the recipe. Therefore, all attributes of the recipe must be completely maintained by the host. The host in this situation may provide a recipe namespace that is dedicated either to an individual equipment installation, to a group of equipment capable of sharing the same process programs, or both.

If the equipment is compliant to Process Program Management as defined in SEMI E30 (GEM), then it will provide a collection event when the process program is created, changed, or deleted. Hosts that provide a dedicated recipe namespace for non-RMS equipment are able to use this event to trigger a process program upload and update the corresponding recipe.

Most Stream 7 equipment use only a single type of process program. This defaults to the recipe class PROCESS. The equipment is unaware of the internal fields used by the recipe identifier. If it preserves the contents of PPID and does not impose its own restrictions, it may be desirable to use the format of the recipe identifier, in particular the version component. This would allow version control at the host.

Some equipment maintains more than one type of process program and may distinguish between the different types either through providing additional Stream 7 messages, through naming conventions such as a ".ext" extension, through program length, or other devices.

Downloading a process program in Stream 7 is equivalent to both the operation of "sending" a recipe to a different namespace (at the equipment) and to downloading a recipe to the recipe executor for execution.

R1-2.1 *Structuring PPBODY Using SECS-II Message Format* — The second method of sending attributes within PPBODY is to use a SECS-II message structure that is used to send and receive recipes. Figure 1 illustrates using the structure of a managed recipe form S15,F13 and F16.

Note that cluster tools may provide full recipe namespace capabilities for its modules, including shared namespaces for modules of a specific type. In this case, a cluster recipe may contain multiple agent-specific datasets (m > 1). Other equipment may be able to use the structure for the *execution recipe*.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E53-1296
EVENT REPORTING

1 Purpose

Access to process data in equipment is crucial for effective process monitoring and control in a semiconductor manufacturing facility. This standard addresses the communication needs of semiconductor equipment and other factory objects, such as cell controllers or recipe servers, with respect to the timely collection and reporting of such data.

The purpose of this standard is to provide a general purpose set of event reporting services that may be offered by equipment suppliers. This document may be referenced, in whole or in part, by other standards addressing higher level application domains.

The communications services defined here will enable standards based inter-operability of independent systems. They shall allow application software to be developed which can assume the existence of these services and allow software products to be developed which offer them.

2 Scope

This standard is applicable to any stand-alone equipment, cluster module, cluster tool, or cell of automation in a factory. As such it addresses event reporting at all levels in the factory and equipment control hierarchy.

This standard requires significant communication and computational resources and is therefore not applicable at or below the level of I/O distribution (e.g., sensor bus) within the equipment.

This standard covers the reporting of data periodically and/or in response to events. Reports may also be requested on demand.

This standard presents a solution from the concepts and behavior down to the messaging services. It does not define the messaging protocol.

A messaging service includes the identification that a message shall be exchanged and definition of the data which is contained in that message. It does not include information on the structure of the message, how the data is represented within the message, or how the message is exchanged. This additional information is contained with the message protocol. The defined services may be applied to multiple protocols. Information on the mapping of these services to special protocols (e.g., SECS II) are added as adjunct standards.

The services assume a communications environment in which a reliable connection has been established between the user and the provider of the services. Establishing, maintaining, and releasing a connection is beyond the scope of this standard.

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS II)

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E38 — Cluster Tool Module Communications (CTMC)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E40 — Standard for Processing Management

4 Terminology

4.1 The following definitions are arranged in alphabetical order. Some terms are defined using terms defined elsewhere within this section. Other terms may be defined within SEMI's Compilation of Terms.

4.1.1 *attribute* — a data item associated with an object. An attribute may be referenced by zero or more data reports.

4.1.2 *behavior* — the manner in which something functions; how an object acts and reacts, in terms of its state changes and message passing.

4.1.3 *collection event* — an event that may be used to initiate the collection and reporting of data. A collection event may trigger an event report. A collection event may also start or stop one or more trace reports.

4.1.4 *data report* — a data report is a list of attribute names for a single object. Data reports may be pre-defined by a factory object or defined dynamically by the service user.

4.1.5 *default object* — the object assumed when no object specifier is supplied.

4.1.6 *event* — represents the occurrence of a change in the condition of a system (e.g., lot complete, temperature over range).

4.1.7 *event report* — a class of objects that has information related to an event and can be linked to user defined data reports and can send messages containing this information to a service user.

4.1.8 *factory object* — any identifiable object within the factory information and control architecture. Examples include equipment, a cluster process module, a cell controller, a recipe namespace server.

4.1.9 *object* — defined in the Object Services (SEMI E39).

4.1.10 *object specifier* — defined in the Object Services (SEMI E39).

4.1.11 *services* — a set of closely related messages.

4.1.12 *service provider* — a service provider is an application responsible for providing services to service users.

NOTE 1: There may be one or more service users concurrently accessing a single service provider. It is the responsibility of the service provider to provide its services transparently to each service user.

4.1.13 *service user* — a service user is any application that uses the services.

4.1.14 *trace report* — a class of objects which provides to a service user a means for collecting periodic readings of selected attributes of a system.

4.2 *Data Types*

4.2.1 *form* — type of data: float, positive integer, unsigned integer, integer, enumerated, boolean, text, formatted text, structure, list, ordered list.

4.2.2 *float* — a number represented by a mantissa and an exponent. It is used to represent numeric data which is continuous in value.

4.2.3 *positive integer* — May take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

4.2.4 *unsigned integer* — May take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

4.2.5 *integer* — May take the value of any negative or unsigned number. Messaging protocol may impose a limit on the range of possible values.

4.2.6 *enumerated* — May take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

4.2.7 *boolean* — May take on one of two possible values; TRUE or FALSE.

4.2.8 *Text* — A text string. Messaging protocol may impose restrictions, such as length or ASCII representation.

4.2.9 *formatted text* — a text string with an imposed format. This could be by position, by use of special characters, or both.

4.2.10 *structure* — a complex structure consisting of a specific set of items, of possibly mixed data types, in a specific arrangement.

4.2.11 *list* — set of one or more items that are all of the same form (one of the above forms).

4.2.12 *ordered list* — s list for which the order in which the items appear is significant.

5 Conventions

5.1 *Harel State Model* — This document uses the Harel State Chart notation to describe the dynamic behavior of the objects defined. An overview of this notation is presented in an appendix of SEMI E30. The formal definition of this notation is presented in Science of Computer Programming 8, "Statecharts: A Visual Formalism for Complex Systems," by D. Harel, 1987.

Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition contains columns for transition #, current state, trigger, new state, action(s). The "trigger" (column 3) for the transition occurs while in the "current" state. The "actions" (column 5) include a combination of; 1) actions taken upon exit of the current state, 2) actions taken upon entry of the new state, and 3) actions taken which are most closely associated with the transition. No differentiation is made.

5.2 *OMT Object Information Model* — The object models are presented using the Object Modeling Technique developed by Rumbaugh, James, et al, in "Object-Oriented Modeling and Design," Prentice Hall, Englewood Cliffs, NJ, ©1991. Overviews of this notation are provided in an appendix of the Object Services SEMI E39.

5.3 *Object Attribute Representation* — The object information models for standardized objects will be supported by an attribute definition table with the following column headings:

Attribute	*Definition*	*Rqmt*	*Access*	*Form*
The formal text name of the attribute	Description of the information contained	Y or N	RO or RW	(see below)

The access column uses RO (read only) or RW (read and write) to indicate the access that users of object services have to the attribute.

A ‘Y’ or ‘N’ in the requirement (rqmt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

The form column is used to indicates the format of the attribute. See Section 4.2 for definitions.

5.4 *Service Message Representation*

5.4.1 *Service Resource Definition* — The service resource definition table defines the specific set of messages for a given service group, as shown in the following table:

Service	*Type*	*Description*
Message name	N or R	The intent of the service

Type can be either notification (N) or request (R). Notification messages are initiated by the service provider. No response is expected. Request messages are initiated by the service user. Request messages ask for data or for an operation to be performed. Request messages expect a specific response (no presumption on the message content).

5.4.2 *Service Parameter Dictionary* — Each parameter should relate to either attributes from the object model or events of the dynamic model (Harel State Chart). All parameters to the services are listed in a single table or dictionary. The column headings for this parameter dictionary are as follows:

Parameter	*Description*	*Form*
Parameter X	Data type	A parameter

A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and the contents of the parameter.

The description column describes the meaning of the parameter and interrelationships with other parameters.

The form column is used to indicate the type of data contained in the parameter (see Section 4.2 for definitions) and the possible values it may take on.

To prevent definition of numerous parameters named “XxxList,” this document adopts the convention of referring to the list as “(list of) Xxx.” In this case, the definition of the parameter “Xxx” will be given, not of the list. Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element unless zero elements are specifically allowed.

5.4.3 *Service Message Definition* — There is a table for each service showing the parameter detail. The column headings for the service detail are as follows:

Parameter	*Req/ Ind*	*Rsp/ Cnf*	*Comment*
Parameter X	(see below)	(see below)	A description of the service

The columns labeled req/ind and rsp/cnf link the parameters to the direction of the message. The message sent by the initiator is called the “request” (req). The receiver terms the message the “indication” (ind). The receiver may then send a “response” (rsp), which the original sender terms the “confirmation” (cnf).

The request (req/ind) and response (rsp/cnf) entries can take on the following values:

“M”	**Mandatory parameter** — Must be given a valid value.
“C”	**Conditional parameter** — May be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of another parameter.
“U”	**User-defined parameter**
“-”	The parameter is not used.
“=”	The entries M and C in the response can be modified with (=) to indicate that the value in the response must match the request.

6 Overview

Event reporting provides a dynamic and flexible means by which the service user can receive notification of events and data relating to objects defined here and in other SEMI standards.

Figure 1 illustrates a simple event reporting situation.

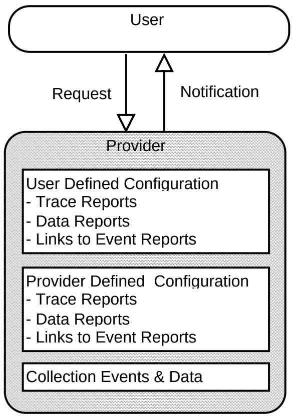

Figure 1
Simple Event Reporting

Event and variable identifiers may be defined by another standard with which equipment or an object complies. In either case, the definitions must be included in the documentation from the supplier.

The service user may define and access data reports using the event reporting request services. Data reports are sampled and sent by the service provider using the event reporting notification services.

Data reports may be pre-defined by the supplier. Such reports cannot be deleted and their report identifiers may not be used for dynamically created reports.

6.1 *Multiple Service Users* — In a more complex situation, several service users may require simultaneous access to the event reporting services (ERS). In this case, the service provider manages data report definitions independently for each service user as shown in Figure 2. A copy of each pre-defined report is made for each service user. Support for more than one simultaneous service user is optional.

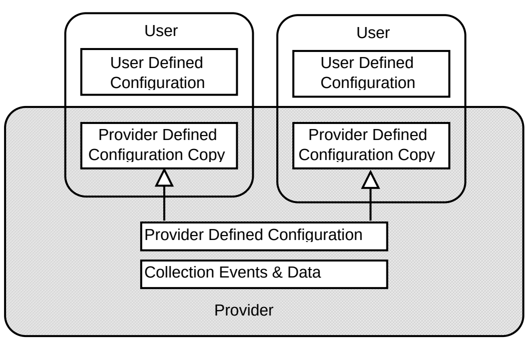

Figure 2
Multiple Service Users

6.2 *Using Object Services* — An event reporting service user can create reports dynamically by accessing attribute information using the object services (see SEMI E39) when they are provided (see Figure 3).

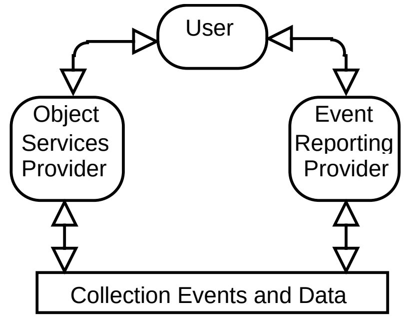

Figure 3
Using Object Services

7 Concepts

7.1 *Objects and Identifiers* — Much of the discussion and specification for event reporting services relies on an understanding of object technology and modeling techniques. The use of object technology for ERS implementations is not required. Further, it is not required that ERS implementations be compliant to the Object Services Standard (OSS). This standard does specifiy mechanisms by which ERS can take advantage of OSS when those services are provided.

Events are associated with an object and data is stored in object attributes. To uniquely identify an event or an attribute the object to which it relates must first be identified.

An object may be a physical entity such as stand-alone process equipment, a cluster tool or a cluster module. An object may be an abstraction such as a recipe, a process job or a transfer job. An object may be defined by the equipment supplier, or by a standard with which the equipment complies. An example of a cluster tool, containing process modules, is used in this section as the service provider. This example is for illustration purposes only. The same concepts apply for all factory objects as defined above.

Objects may be part of an object hierarchy or contained in other objects. The default object is the object which provides the service connection. In the case for batch processing equipment which is compliant to GEM, SEMI E30, the connection to the host is provided by the equipment and the equipment is the default object. Also, a cluster controller would be the default object of equipment containing process modules. However, from the point of view of the cluster controller, each connection to the service providers in each connected module would be the default object. For example, the processing management service of PM:ETCH would be a default object for that module connection. But, the cluster controller would have differernt default objects on each of its other service connections.

An object specifier, (see SEMI E39), identifies an object within the scope of the service provider. An object specifier consists of one or more object type and object instance identifier pairs. For example, “PM:ETCH>” might be the object specifier of a process module (type=PM, identifier=ETCH) within a cluster tool. If the object specifier is omitted, then the default object is assumed.

Objects are considered local to the service provider even if they exist on a remote module. That means the service provider is responsible for detecting events and accessing data from those objects in a timely manner, by whatever means, to provide the specified services.

Equipment which implements OSS-compliant event reporting services allows the service user to reference equipment components by an object specifier; for example, “PM:ETCH>MFC:CCL4.”

7.2 *Event Report Object Model* — Figure 4 shows the objects, attributes (variables), and relationships involved in event reporting. The notation used is defined in Section 5. The diagram illustrates the relationships between the service’s messages and attributes (variables). The objects and their attributes are defined Section 8. Only the trace, data report, collection event, and data source objects’ attributes and behaviors are standardized in that section. Note that this model presents a view of event reporting services from the perspective a single user. It is optional for the service provider to support simultaneous access from multiple service users. But for that option the provider shall present this view to each user independently.

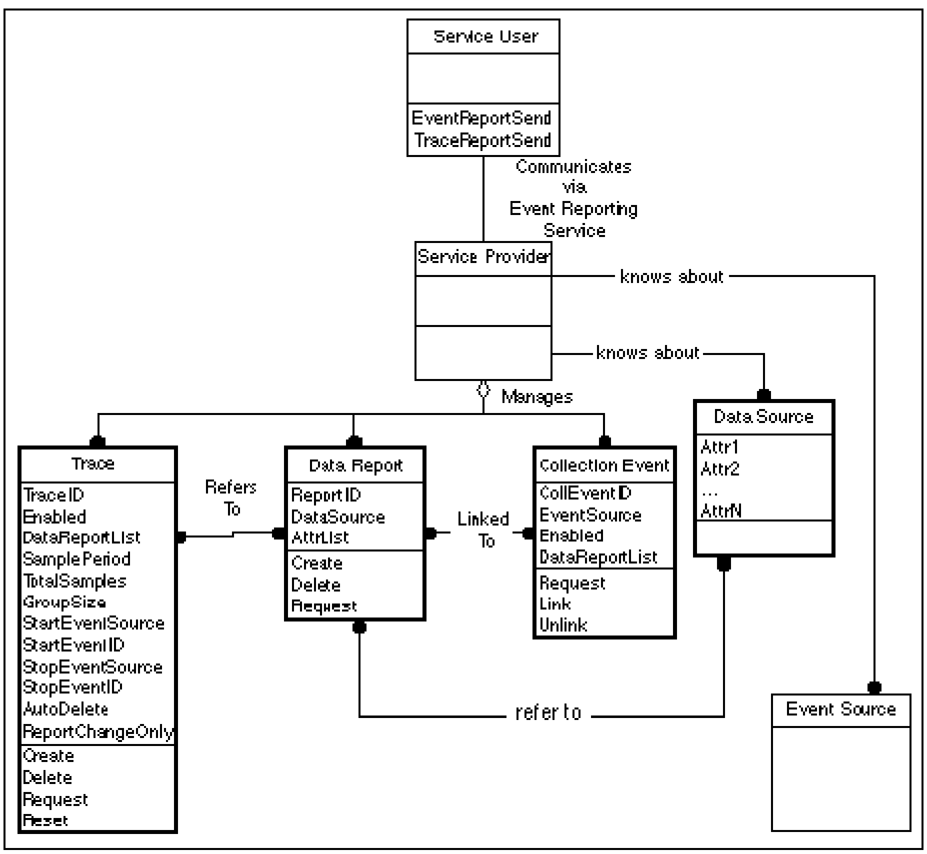

Figure 4
Event Report Object Model

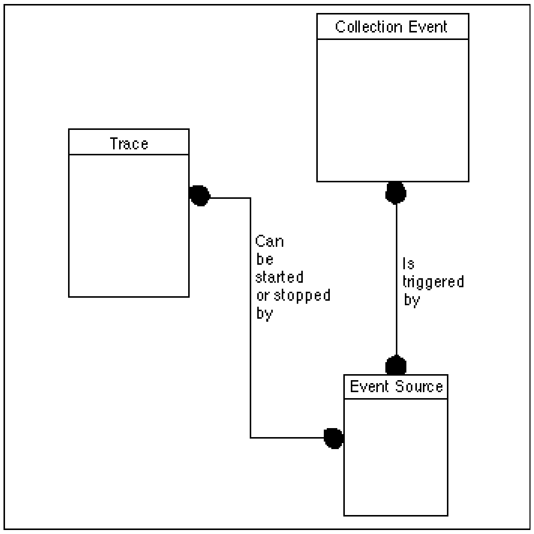

Figure 5
Trace Object Information Model

7.2.1 *Service Provider Object* — The service provider is responsible for compiling report samples according to each service user setup. It detects collection events, provides trace timing and accesses the value of data source object attributes (variables) in order to compile the data reports. ERS does not specify the attributes or behavior of this object. It is included in the event report object model to provide context for other objects within ERS.

7.2.2 *Service User Object* — The service user is responsible for configuring its own event reporting setup and receives reports from the service provider according to that setup. ERS does not specify the attributes or behavior of this object. It is included in the event report object model to provide context for other objects within ERS. However, the service user object shall be able to receive the event report send and trace report send messages from the service provider.

7.2.3 *Collection Event Object* — This object type or class is responsible to provide all the collection event identifiers for which event reports can be generated. Other factory services and objects may provide event notification messages which are important in the context of a service or functionality that they provide. But, in general, these notifications do not provide mechanisms to report information beyond their domain boundaries. For example, Processing Management, SEMI E40, includes an event notification for process complete (PRJobAlert (Milestone)). In order to collect data associated with this event, it must be "known" to the collection event object type. When it is "known" by the collection event object, then event reports can be generated using data or attributes from the data sources which are "known" by the event reporting service provider. A data source could provide information on process chamber pressure and temperature, which are attributes or variables important to the process but which are not known to the processing management service.

7.2.4 *Event and Data Source Objects* — The use of the event source and data source objects provides extensive capability to access the attributes of objects in a distributed environment. Where the event services provider has a domain which extends over multiple resources, such as a cell controller for a furnace bay or a cluster tool controller, these objects provide an unambiguous mechanism for addressing the data that the service user wishes to access.

The event and data source objects are to the event reporting services what directory object is in a file system of a computer's operating system. They should be thought of as containers of information which provide pointers (or names) of objects that are the actual sources of events or data.

The event source object is not directly accessible to the service user. Knowledge of events and event sources can be accumulated by interrogation of the collection event object using OSS.

Collection event identifiers shall be determined by either of two possible methods. One, the equipment supplier may define and supply with the equipment a list of collection event IDs (identifiers). Two, the equipment's collection event object can be interrogated with object services requests for collection event sources and identifiers. For example, using the second method, one could use object services to ask the collection event object for a list of collection event sources, which might include objects such as "PM:Etch>MFC:CCL4" or "TM>Aligner." Then using OSS, the collection event object can be queried for events associated with these sources. For the MFC a list of events might include "preslow," "overlimit," "valvemax," etc..

7.2.5 *Data Report Object* — A data report defines the variables (or attributes) of a specific object (data source) which are to be sampled. Data reports are either pre-defined or defined dynamically by the service user. A data report sample is a set of data containing the values of the variables defined for the data report. To sample a data report means that the current values of the variables at their data source object should be recorded. Data reports may be sampled and sent either with an event report and/or with a trace report. The service user may request:

- To sample an individual data report.
- Create a data report.

- Delete a data report.

7.2.6 *Event Report* — Event reports may be sent as messages to the service user whenever the associated collection event occurs. The collection event object is the source of the event report message. Event reporting is initially disabled. If the data to be sent with an event report has more than one data source, then there must be at least one data report for each data source to be included in the event report link definition. The service user may request:

- Event reporting to be enabled.
- Event reporting to be disabled.
- One or more data reports to be to linked (included in) the event report.

7.2.7 *Trace Report* — Trace reports are messages which are sent to the service user periodically. The trace report will contain the value(s) of the data item(s) specified in the data report(s) referred to by the trace object which is the source of the trace report.

The trace object contains the description of what to include in the trace report and trace objects are either pre-defined or defined dynamically by the service user. The service user may request:

- Trace reporting to be enabled.
- Trace reporting to be disabled.
- One or more trace reports to be reset at any time to their initial state.
- One or more trace reports to be deleted at any time.

When the enabled attribute of the trace object is set, then trace reporting may be started or in response to a start event. When the trace reporting starts, the sample count is reset to zero. A trace report may be stopped when a certain number of samples have been reported or when a stop event occurs.

The service user may specify a trace object to be automatically deleted once it has been stopped by whichever mechanism. Otherwise, the trace reporting simply stops. If no start event is defined, then the trace is restarted immediately. Otherwise, the next start event will restart the trace. Disabling or deleting a trace report stops reporting immediately.

7.3 *Scenarios* — The communications involved in event reporting are introduced below in the form of some representative scenarios. The full behavior and message set are covered in Sections 8.2 and 8.3 respectively.

7.3.1 *Event Reporting* — Figure 6 shows a scenario in which a data report is created by the service user and linked to an event report. Event reporting is then enabled. Subsequently, an event report is sent with the data reports attached whenever the collection event occurs. The service user then disables event reporting, preventing subsequent collection events from triggering the report. Data reports and links to event reports may be pre-defined by the equipment in which case the DataReportCreate and LinkCreate messages are omitted.

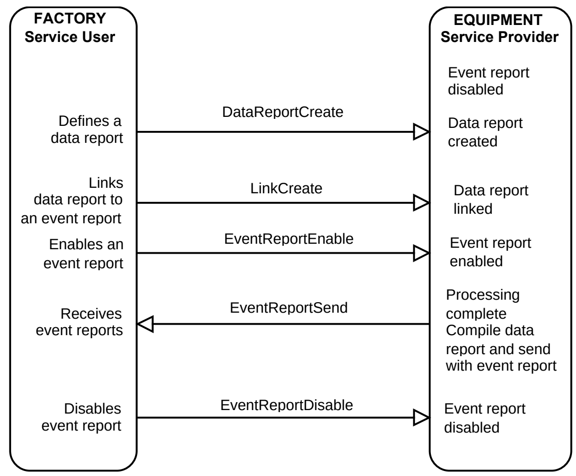

Figure 6
Event Reporting Scenario

7.3.2 *Trace Reporting* — Figure 7 shows a scenario in which a trace object is created with enabled and AutoDelete both set to TRUE. Since the trace object is enabled and there is no start event defined the data reports assigned to the trace object are sampled and sent immediately as a trace report message. The trace object timer is started and the sample counter set to zero. Each time the sample period elapses thereafter, a new trace report is sent, and the sample counter incremented. When the sample counter reaches the total samples parameter, then the trace report is automatically deleted.

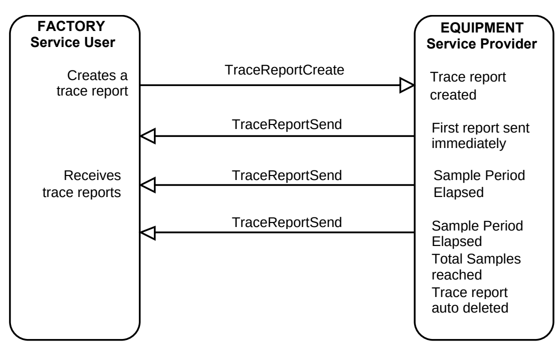

Figure 7
Trace Reporting Scenario

7.3.3 *Trace Reporting with Event Control* — Figure 8 shows a scenario in which a trace object is created with enabled and AutoDelete both set to FALSE. There is also a start event (ProcessingStarted) and a stop event (ProcessingComplete) defined. When the start event occurs, the data reports assigned to the trace are sampled and sent, the trace timer is started and the sample counter set to zero. Each time the sample period elapses thereafter, a report is sent and the sample counter incremented. Since a total samples parameter was not specified, the trace report stops only when the stop event occurs. Once the stop event has occurred, the service user disables the trace report preventing it from restarting when the next start event occurs.

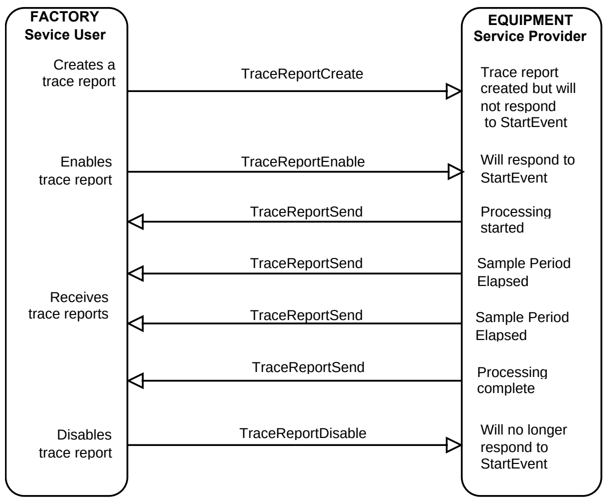

Figure 8
Trace Reporting with Event Control

8 Specification

8.1 *Object Definitions*

8.1.1 *Collection Event Object* — A collection event object generates an event report each time it is triggered by a collection event from an event source. An event report contains the data samples from zero or more data reports to which it is linked by the collection event object.

Table 1 Collection Event Object Attribute Definitions

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	Specification of the Object Type of "Collection Event."	Y	RO	Text = "COLLEVENT"
ObjID	Object Identifier, within the scope of the event source object, for the Collection Event which is the trigger for the generation of an event report.	Y	RO	Text
EventSource	The object specifier which is the source of the event, see Section 7.1 and SEMI E39 (Object Services Standard).	N	RO	Formatted Text
DataReportList	Ordered list of data report object identifiers (text) to be sampled and sent with the event report.	Y	RO	List
Enabled	If this flag is cleared or false, then event reports will not be generated and sent when the associated Collection Event is detected.	Y	RW	Boolean

8.1.2 *Data Report Object* — The data report is part of the event reporting setup. It references zero or more attributes of a data source object and may be linked to zero or more event reports or trace reports.

Table 2 Data Report Object Attribute Definitions

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	Specification of the Object Type of "Data Report."	Y	RO	Text="DATARPT"
ObjID	The object identifier of a pre-defined data report or one defined dynamically by the service user. ReportIDs are unique for eachservice user.	Y	RO	Text
DataSource	The object specifier of the object which has the attributes to be reported, see Section 7.1.	N	RO	Formatted Text
AttrList	An ordered list of attribute names from the Data Source object which will be sampled for inclusion in the data report.	Y	RW	List

8.1.3 *Trace Object* — The trace object generates trace reports based on the settings of its attributes. Trace object activities may be started and stopped by a collection event and may refer to one or more data reports.

Table 3 Trace Report Object Attribute Definitions

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	Specification of the Object Type.	Y	RO	Text="TRACE"
ObjID	The identifier of a Trace Object. Trace reports contain this parameter to be used for reference purposes.	Y	RO	Text
Enabled	If this flag is cleared or false, then trace reports will not be generated and sent.	Y	RW	Boolean
DataReportList	Ordered list of data report object identifiers (text) to be sampled and sent with trace report.	Y	RO	List
SamplePeriod	The time delay between samples in seconds. Resolution may be in fractions of a second and should be specified by the service provider. The resolution available may also vary depending on the Data Source.	Y	RO	Float
TotalSamples	The number of samples to be taken before trace reporting stops automatically.	N	RO	Positive Integer
GroupSize	The number of samples taken before the report is sent to the service user.	N	RO	Positive Integer
StartEventSource	The object specifier of the object which is the source of the event which starts the trace reporting.	N	RO	Formatted Text
StartEventID	The event within the event source object which starts the trace reporting.	N	RO	Text
StopEventSource	The object specifier of the object which is the source of the event which stops the trace reporting.	N	RO	Formatted Text
StopEventID	The event within the event source object which stops the trace reporting.	N	RO	Text
AutoDelete	Specifies if trace report automatically deletes itself when its reporting cycle is complete.	N	RO	Boolean
ReportChangeOnly	If TRUE, then only those data reports linked to the trace report which have changed since the last sample will be sent with the trace report. Otherwise, all data reports will be sent with the trace report.	N	RO	Boolean

8.1.4 *Data Source Object* — The data source is an entity, accessible to the service provider, which contains data (attributes) that may be of interest to the service user. The event reporting service can be composed of one or more data sources. In the case of only one data source, the use of its identifier in messages can be dropped. In this case, the data source is the default object. The attributes of a data source may be referenced by zero or more data reports.

Table 4 Data Source Object Attribute Definitions

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	The specification of the name for object type of "Data Source."	N	RO	Text = "DATASRC"
ObjID	The identifier of a Data Source Object. (This identifier is used in the object specifier when defining Data Report.)	N	RO	Text
AttrList	A list of the data source object attribute names. Names from this list may be used when defining a data report.	Y	RO	List

8.1.5 *Event Source Object* — This object represents components within a system that generate collection events. The service provider supplies mechanisms such that the when collection events are generated by the event source, then the collection event object, if enabled, will be triggered to generate an event report. ERS does not specify the attributes or behavior of the event source object. It is included in the event report object model to provide context for other objects within ERS.

8.2 *Object Behaviors* — This section specifies the behavior of the three objects in the information model which have standardized behaviors. The message detail for the service is addressed in a later section. Message flow diagrams presented in the previous section are useful to show simple situations. The data report, event report and trace report state models presented in this section provide the information necessary to extrapolate the message flow diagrams for all situations within the scope of this standard.

8.2.1 *Event Reporting State Models* — The behavior required for event reporting is fully specified by the service provider state model. All required service user behavior is inferred by this model.

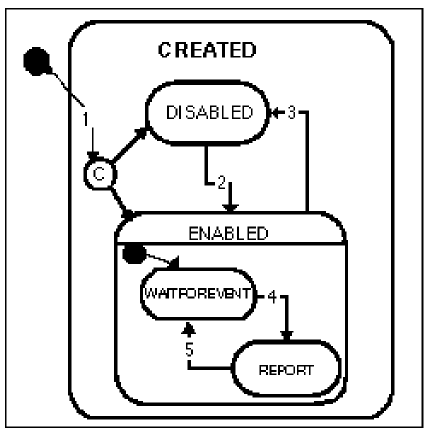

Figure 9
Collection Event Object State Diagram

Figure 9 shows the state diagram for a collection event object. The Harel State Model Notation used is described in Section 5.

Table 5 Collection Event Object State Definitions

State	*Definition*
CREATED	Each collection event is associated with a unique Collection Event ID.
ENABLED	The Service User will be notified by the sending of an event report when the collection event occurs.
DISABLED	Event reports will not be sent to the Service User.
WAITFOREVENT	The object is waiting for its associated Collection Event to occur.
REPORT	Send an Event Report to a Service User, sample Data Reports which have been linked.
notExist	User view of Collection Event Objects prior to connection (establishment of communications).

Table 6 Event Report Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*
1		Service user establishes connection.	CREATED and ENABLED or DISABLED	A Collection Event Object is created on behalf of the service user for every collection event. The event reporting Enable attribute setting is conditional. It may get its value from stored configuration information.
2	DISABLED	Enable attribute set to TRUE	ENABLED	Event reporting is enabled for a specific collection event.
3	ENABLED	Enable attribute set to FALSE	DISABLED	Event reporting is disabled for a specific collection event.
4	WAITFOREVENT	Collection Event occurs	REPORT	Sample linked data reports. Send event report with linked data reports.
5	REPORT	Reporting Complete	WAITFOREVENT	The object waits for the collection event.

8.2.2 *Data Report Object State Model* — Each data report shall follow the transitions as specified in Figure 10. Multiple instances of data report are managed by the event services. There are two basic types of data reports; pre-defined and user defined.

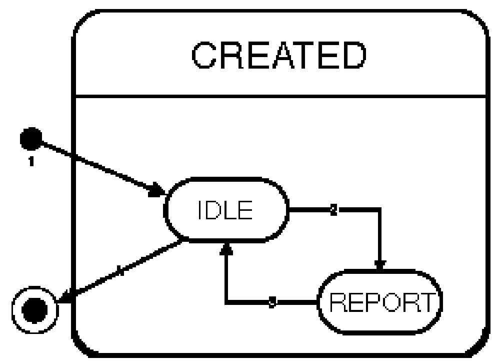

Figure 10
Data Report Object State Chart

Table 7 Data Report Object State Definitions

State	*Definition*
notExist	The state from which the service provider creates reports. NOTE: Some reports may be predefined, that is, they are not created by a user request.
IDLE	Reports are sampled and generated only when requested from an external source such as the Trace or Event Report object or the Service User directly.
CREATED	This is the super-state of Idle and Report. Variables and/or attributes to be sampled are defined.
REPORT	The variables or attributes specified in the Data Report Object are sampled and then sent to the report requestor.

Table 8 Data Report State Transition

#	*Current State*	*Trigger*	*New State*	*Action(s)*
1		CreateRequest	CREATED and IDLE	New ReportID is defined. Wait for an actionable event.
2	IDLE	ReportRequest	REPORT	Sample data in report definition
3	REPORT	SamplingComplete	IDLE	Send data to report requestor
4	IDLE	DeleteRequest and not pre-defined	notExists	ReportID is no longer valid

8.2.3 *Trace Object State Model* — Figure 11 shows the state diagram for a trace object. The Harel State Model Notation used is described Section 5. The state transition table is shown in Table 10.

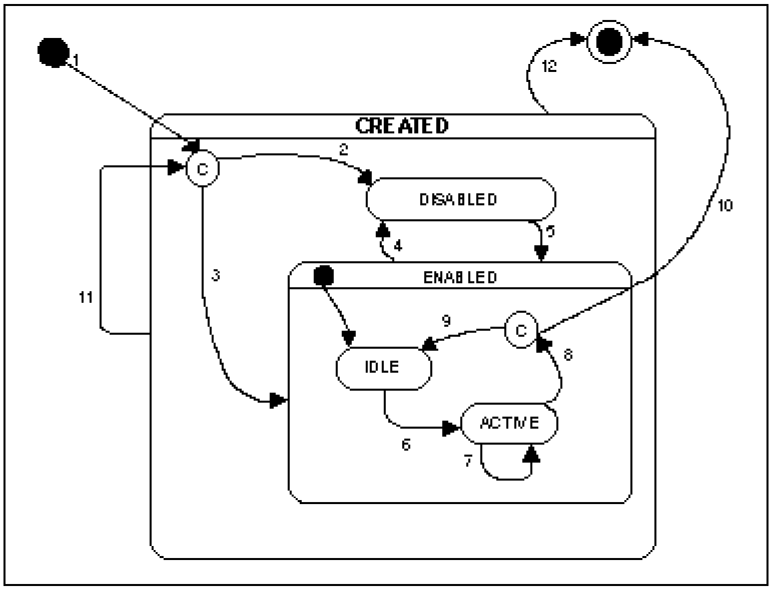

Figure 11
Trace Object State Diagram

Table 9 Trace Object State Definitions

State	*Definition*
CREATED	The Trace Object is created and ready to be accessed.
DISABLED	Trace report is created but will not be sampled or sent.
ENABLED	Trace object may begin generation of trace reports. See sub-states IDLE and ACTIVE.
IDLE	Trace reports are not being generated.
ACTIVE	The trace reports are being generated and sent periodically.

Table 10 Trace Report Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*
1	(deleted)	Trace Object Create	(condition)	A Trace Object is created with Report ID, Enabled, Group Size, Total Samples, Sample Period, Start Event, Stop Event, and Auto Delete parameters.
2	(condition)	Enabled was initially FALSE.	DISABLED	Trace reporting is disabled.
3	(condition)	Enabled was initially TRUE.	ENABLED	Trace reporting is enabled.
4	ENABLED	Trace Report Disable	DISABLED	Trace reporting is disabled.
5	DISABLED	Trace Report Enable	ENABLED	Trace reporting is enabled.
6	IDLE	Start Event is not defined or Start Event is defined and occurs.	ACTIVE	Sample Data Reports and send. Start sample timer. Reset sample counter. Reset group counter. Wait for sample timer to elapse.
7	ACTIVE	Sample period elapses.	ACTIVE	Sample data reports into a trace report. If group sample counter equals group size, then send the trace report and reset group counter. Then prepare to generate the next trace report. Start sample time and wait for it to elapse.

#	*Current State*	*Trigger*	*New State*	*Action(s)*
8	ACTIVE	Stop Event is defined and occurs or… Total Samples > 0 and sample counter equals Total Samples.	(condition)	Sample data reports into a trace report. Send the trace report.
9	(condition)	Auto Delete is FALSE	IDLE	(none)
10	(condition)	Auto Delete is TRUE	(deleted)	Delete Trace Report Object.
11	CREATED	Event Report Reset	(condition)	Reset Trace Report Object state back to initial state when it was first created.
12	CREATED	Event Report Delete	(deleted)	Delete Trace Report Object.

8.3 *Messaging Services Detail* — This section specifies the messages required to implement the event reporting service. The messages were introduced in Section 7.3.1. These services are independent of the messaging protocol used.

The specification includes a list of required messages, the definition of the parameters contained within the messages, and data type of the parameters. Not defined here is the internal structure of the actual messages as transferred, including order of the parameters and how various data structures and data types are represented.

The service message notation used in the tables below is described in the Conventions, Section 5.4.

8.3.1 *Service List*

Table 11 Event Reporting Services

Service	*Type*	*Description*
Event Report Request	R	Requests the specified event report, and the data reports linked to it, to be sampled and returned to the service user.
Event Report Send	N	Notifies the service user of the occurrence of an event with a time stamp indicating when the event occurred. Any data reports linked to the event report are sampled and attached to the event report sent to the service user.
Data Report Create	R	Creates a data report which defines a set of attributes of an object to be reported.
Data Report Delete	R	Deletes one or more data report definitions.
Data Report Request	R	Requests the specified data report to be sampled and returned to the service user.
Collection Event Link	R	Request a Collection Event Object to link a Data Report. All Data Reports linked to an enabled Collection Event Object are sampled and sent with the event report when the collection event occurs.
Collection Event Unlink	R	Unlinks one or more Data Reports from the Collection Event Object.
Trace Report Create	R	Creates a trace report which defines the sample period, group size, start and stop events, auto delete, report change only, and the initial state (enabled or disabled).
Trace Report Delete	R	Deletes one or more trace report definitions.
Trace Report Request	R	Requests that the data reports assigned to the trace report be sampled and returned to the service user.
Trace Report Send	N	Notifies the service user of trace report samples taken. Group size samples are taken before the service user is notified. After notifying the service user, the group counter is reset to zero. A trace report sample is taken either when the start event occurs or the sample period elapses.
Trace Report Reset	R	Resets one or more trace reports back to their initial state when created regardless of the current state of the trace report. All reports may be reset at once providing a simple way to re-establish the event reporting setup after modifications have been made.

8.3.2 *Use Object Services* — Attributes of the standardized objects listed in Table 12: SEMI E39 shall be accessed by using the GetAttr and SetAttr messages as defined in SEMI E39.

Table 12 SEMI E39 Access

Object	*Attribute*	*Comment*
Collection Event	Enabled	When set to TRUE, a Collection Event Report will be sampled and sent when the Collection Event occurs. When FALSE, Collection Event Reports are not sampled and sent.
Trace	Enabled	When set to TRUE, a Trace Report will be sampled and as described by the Trace Report definition. When FALSE, Trace Reports are not sampled and sent.
Data Source	AttrList	Use GetAttr to get the names of the attributes of a data source. These names can be used in the Data Report Create message.
Data Report	AttrList	Use GetAttr and SetAttr to change the variables included in a data reportdefinition.

8.3.3 *Parameter Dictionary*

Table 13 Event Reporting Parameters

Parameter	*Definition*	*Form*
EvtSrcSpec	The object specifier of the Event Source Object.	Formatted text
CollEventID	References the Object Identifier of the collection event, within the scope of the event source object, that triggers an event report to be sent.	Text
Enabled	Specifies whether an Event or Trace Report is enabled.	Boolean: TRUE – Successful FASLE – Unsuccessful
DatSrcSpec	The object specifier of the data source object.	Formatted text
(list of) AttrName	An ordered list of attribute names from the data source object which specify the samples to be included in a data report. Maximum must be documented by supplier.	Text
ReportID	References the Object Identifier of a data report, either pre-defined by the service provider or specified by the service user.	Text
TraceID	References the Object Identifier of a trace report specified by the service user.	Text
(list of) ReportID	A list of data reports to be linked to a trace. Maximum must be documented by supplier.	Text
SamplePeriod	The time delay between samples. Minimum and maximum must be documented by supplier.	Float
TotalSamples	The number of samples to be taken before trace data reporting stops automatically.	Positive Integer
GroupSize	The number of trace report samples made before the report is sent to the service user. Maximum group size must be documented by supplier.	Positive Integer
StartEvtSrcSpec	The object which is the source of the event which starts the trace reporting.	Text
StartEventID	The Collection Event Object Identifier within the event source object which starts the trace reporting.	Text
StopEvtSrcSpec	The object which is the source of the event which stops the trace reporting.	Text
StopEventID	The Collection Event Object Identifier within the event source object which stops the trace reporting.	Text
AutoDelete	Specifies if trace report automatically deletes itself when its reporting cycle is complete.	Boolean: TRUE – Successful FASLE – Unsuccessful
ReportChangeOnly	If TRUE, then only data reports linked to the trace report which have changed since the last sample will be sent with the trace report. Otherwise, all data reports will be sent with the trace report.	Boolean: TRUE – Successful FASLE – Unsuccessful

Parameter	*Definition*	*Form*
(list of) DataReportSample	A list of data reports. Each data report sample contains the values of the variables specified in the data report at the time at which the sample was taken (see TimeStamp).	Structure
(list of) TraceReportSample	Trace report data. Each trace report contains a set of data report samples taken at a single point in time. This parameter is used when several trace report samples are made before notifying the service user (see Group Size).	Structure
ERAck	Indicates whether the activity was successful.	Boolean: TRUE – Successful FALSE - Unsuccessful
ErrorCode	Identifies errors that may arise.	Enumerated: Unknown event Unknown attribute Unknown data report Duplicate Report ID Data report not linked Unknown trace report Duplicate Trace ID Cannot delete predefined Too many data reports Sample period out of range Group size too large text
ErrorText	Text in support of Error code.	Text
ERStatus	Reports the acceptance or rejection of a requested operation.	Structure Composed of: ERAck (list of) Status
Status	Reports any errors found.	Structure Composed of: ErrorCode ErrorText

Table 14 Data Report Sample Parameter Detail

Parameter	*Definition*	*Form*
ReportID	Unique identifier of a data report.	Text
TimeStamp	Records time at which report sample values were recorded.	Formatted text: YYYMMDDhhmmsscc
(list of) AttributeValue	An ordered list of attribute values that match the (list of) AttrName in the data report.	(depends on attribute)

Table 15 Trace Report Sample Parameter Detail

Parameter	*Definition*	*Form*
(list of) DataReportSample	Samples of data reports assigned to the trace report.	Structure

8.3.4 *Service Detail*

8.3.4.1 *Event Report Request* — When the event object receives this message, it immediately generates and sends an event report to the service user.

Table 16 Event Report Request Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
EvtSrcSpec	C	C(=)	Source object for requested event report. If omitted, then the default object is assumed.
CollEventID	M	M(=)	Identifies requested Event Report. If not recognized, then the error code “unknown event” is returned.
TimeStamp	-	C	Time at which request was received. Parameter is omitted if Event ID is not recognized.
(list of)DataReportSample	-	C	Samples of data reports linked to the event. Parameter is omitted if Event ID is not recognized.
ERStatus	-	C	Possible errors: Unknown event

8.3.4.2 *Event Report Send* — This is a notification message to the service user. It contains the event report for the collection event which has triggered this action.

Table 17 Event Report Send Service Detail

Parameter	*Req/Ind*	*Comment*
EvtSrcSpec	C	Source object for event report to be sent. If omitted, then the default object is assumed.
CollEventID	M	Event Report being sent.
TimeStamp	M	Time at which Collection Event occurred.
(list of)DataReportSample	M	Samples of data reports linked to the event. An empty list can be sent by the service prvider when there are no data reports linked to the Collection Event.

8.3.4.3 *Data Report Create*

Table 18 Data Report Create Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
DatSrcSpec	C	-	Source object for data report to be created. If omitted, then the default object is assumed.
AttrList	M	-	Attributes of data source object to be included in data report. If an AttrName is not recognized, then the error code “unknown attribute” is returned.
ReportID	C	M(=)	If ReportID is not specified in the request, then the provider will return a unique ID to the user. If the user specifies ReportID, then the user must be responsible for making it unique, otherwise, the ReportID already identifies a Data Report, then that Report definition will be overwritten.
ErrorCode	-	C	Possible errors: Unknown Data Source Unknown Attribute

8.3.4.4 *Data Report Delete*

Table 19 Data Report Delete Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
(list of) Report ID	C	C	Identifies data report(s) to be deleted. If data report ispre-defined, then the error code “Cannot delete pre-defined” is returned. If a ReportID is not recognized, then the error code “unknown data report” is returned. If parameter is omitted in the request, then all data reports are deleted. In all cases, the (list of) ReportID that are deleted, if any, is returned in the response.
ERStatus	-	C	ERAck is set to FALSE if any requested ReportID cannot be deleted. ErrorCodes: Unknown data report Cannot delete predefined ErrorText shall be set to the ReportID of reports which could not be deleted.

8.3.4.5 *Data Report Request* — Message asking the service provider to sample the data report and send the resulting report.

Table 20 Data Report Request Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
ReportID	M	C(=)	Identifies requested Data Report to sample. If Report ID is not recognized then the error code “unknown data report” is returned. Parameter is omitted in the response when the ReportID is recognized by the service provider.
DataReportSample	-		Parameter is omitted if ReportID is not recognized.
ERAck	-	C	In the case where no Data Report can be returned then this value is returned set to FALSE. This informs the service requestor that the message was received but that for some reason, the report could not be sampled. The most likely reason is the ReportID was not recognized.

8.3.4.6 *Collection Event Link*

Table 21 Collection Event Link Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
EvtSrcSpec	C	C(=)	Source object for event report to be linked. If omitted, then the default object is assumed.
CollEventID	M	M(=)	Identifies Collection Event Object to be linked. If CollEventID is not recognized, then the error code “unknown event” is returned. This error takes precedence over other errors.
(list of) ReportID	M	-	Identifies Data Report(s) to be linked to an Event Report for this Collection Event Object. If ReportID is not recognized, then the error code “unknown data report” is returned.
ERStatus	-	C	ERAck is set to FALSE if any ReportID cannot be linked. ErrorCodes: Unknown event Unknown data report ErrorText shall be set to the ReportID of reports which could not be linked.

8.3.4.7 *Collection Event Unlink*

Table 22 Collection Event Unlink Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
EvtSrcSpec	C	C(=)	Source object for event report to be unlinked. If omitted, then the default object is assumed.
CollEventID	M	M(=)	Identifies Collection Event to be unlinked. If the ID is not recognized, then the error code “unknown event” is returned. This error takes precedence over other errors.
(list of) ReportID	M	-	Identifies data report to be unlinked. If link is pre-defined, then the error code “Cannot delete predefined” is returned. If ReportID is not recognized, then the error code “unknown data report” is returned. If data report is not linked to the specified event, then the error code “data report not linked” is returned.
ERStatus	-	C	ERAck is set to FALSE if any ReportID cannot be unlinked. ErrorCodes: Unknown event Unknown data report Data report not linked Cannot delete predefined ErrorText shall be set to the ReportID of reports which could not be unlinked.

8.3.4.8 *Trace Create*

Table 23 Trace Report Create Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
TraceID	C	M(=)	Identifier of Trace Object to be created. The service user can be responsible for the uniqueness of the Trace ID. If duplicate ID is used, then the current Trace Object definition overwritten. If omitted in the request, then the Service Provider will generate a unique identifer.
Enabled	M	-	If TRUE, then the initial state of trace report is enabled and will start reporting when the next Start Event occurs, if one is defined, or immediately otherwise.
(list of) ReportID	M	-	Data reports to be linked to trace report.
SamplePeriod	M	-	A Sample Period outside the range supported by the service provider will return the error code “Sample period out of range.”
TotalSamples	C	-	If this is equal to zero or is omitted, then the trace reporting will continue until it is stopped by some other means (i.e., by Stop Event, by Trace Report Disable or by Trace Report Delete).
GroupSize	C	-	If this is omitted, then every sample is immediately reported.
StartEvtSrcSpec	C	-	The object which is the source of the event which starts the trace reporting. If omitted, then the default object is assumed.
StartEventID	C	-	The event within the event source object which starts the trace reporting. If this is omitted, then trace reporting begins as soon as it is enabled.
StopEvtSrcSpec	C	-	The object which is the source of the event which stops the trace reporting. If omitted, then the default is assumed.
StopEventID	C	-	The event within the event source object which stops the trace reporting. If this is omitted, then trace reporting must be stopped by some other means (i.e., by Total Samples, or by Trace Report Delete).
AutoDelete	C	-	If this is omitted, then AutoDelete is assumed to be TRUE.
ReportChangeOnly	C	-	If this is omitted, then ReportChangeOnly is assumed to be FALSE.
ErrorCode	-	C	Possible errors: Duplicate trace ID Too many data reports Sample period out or range Group size too large Unknown event

8.3.4.9 *Trace Delete*

Table 24 Trace Report Delete Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
(list of) Trace ID	C	C	Identifies Trace Object(s) to be deleted. If a Trace Object ispre-defined, then the error code "Cannot delete predefined" is returned. If a TraceID is not recognized, then the error code "unknown trace report" is returned. If parameter is omitted in the request, then all trace reports are deleted. In all cases, the (list of) Trace ID that are deleted, is returned in the response.
ERStatus	-	C	ERAck is set to false if any requested TraceID cannot be deleted. ErrorCodes: Unknown trace report Cannot delete predefined ErrorText shall be set to the TraceID of reports which could not be deleted.

8.3.4.10 *Trace Report Request* — Request the data reports specified by the trace object ID be sampled and sent to the service user.

Table 25 Trace Report Request Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
TraceID	M	M(=)	Identifies requested trace report.
TimeStamp	-	C	Time at which request was serviced and data report samples taken. Parameter is omitted if Trace ID is not recognized.
(list of) DataReportSample	-	C	Samples of data reports assigned to the trace report. Parameter is omitted if Trace ID is not recognized.
ERAck	-	C	If the Data Report Samples cannot be sent, then this item shall be returned with its Boolean value set to false. The most likely cause of this would be that the TraceID was undefined.

8.3.4.11 *Trace Report Send* — The notification message sent by the service provider to the service user when the trace object has prepared a trace report according to its definition.

Table 26 Trace Report Send Service Detail

Parameter	*Req/Ind*	*Comment*
TraceID	M	Identifies trace report.
(list of) TraceReportSample	M	Number of samples in list is determined by Group Size parameter in TraceReportCreate.

8.3.4.12 *Trace Report Reset*

Table 27 Trace Report Reset Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
(list of) TraceID	C	M	Identifies trace report(s) to be reset. If a Trace ID is not recognized, then the error code "unknown trace report" is returned. If parameter is omitted in the request, then all trace reports are reset. In all cases, the (list of) TraceID that are reset is returned in the response.
ERStatus	-	C	ERAck is set to false if any requested TraceID cannot be reset. ErrorCodes: Unknown trace report ErrorText shall be set to the TraceID of reports which could not be reset.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E53.1-1296
SECS-II SUPPORT FOR EVENT REPORTING STANDARD

1 Purpose

This document maps the services and data of its prime document, SEMI E53, to SECS-II streams and functions and data definitions.

2 Scope

This is the standard way to implement the Event Reporting, which provides event-based reporting using the SECS-II message format.

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E39.1 — SECS-II Protocol for Object Services Standard (OSS)

SEMI E53 — Event Reporting

4 Terminology

None.

5 Mapping of Event Reporting Messages

Table 1 Event Messages Mapping

Service Message Name	*Stream, Function*	*SECS-II Name*
Event Report Send	S6F11,F12,F13,F14	Event Report Send/Acknowledge Annotated Event Report Send/ Acknowledge
Event Report Request	S6F15,F16	Event Report Request/Data
Data Report Request	S6F19,F20	Individual Report Request/Data
Collection Event Link Request	S17F9,F10	Collection Event Link Request/Acknowledge
Collection Event Unlink Request	S17F11,F12	Collection Event Unlink Request/Acknowledge
Data Report Create	S17F1,F2	Data Report Create Request/Acknowledge
Data Report Delete Request	S17F3,F4	Data Report Delete Request/Acknowledge
Trace Create Request	S17F5,F6	Trace Create Request/Acknowledge
Trace Delete Request	S17F7,F8	Trace Delete Request/Acknowledge
Trace Report Send	S6F27,F28	Trace Report Send/ Acknowledge
Trace Report Reset Request	S17F13,F14	Trace Report Reset Request/Acknowledge
Trace Report Request	S6F29,F30	Trace Report Request/Data

6 Event Parameters Mapping

Table 2 Event Service Parameter Mapping

Parameter	*SECS-II Data Item or Object Attribute*
ErrorCode	ERRORCODE
ErrorText	ERRTEXT
ReportID	RPTID
DataSrcSpec	DATASRC
CollEventID	CEID
EvtSrcSpec	EVNTSRC
Enabled	CEED

Parameter	*SECS-II Data Item or Object Attribute*
(list of) AttrName	(list of) VID
ReportChangeOnly	RPTOC
TraceID	TRID
SamplePeriod	TRSPER
TotalSamples	TOTSMP
GroupSize	REPGSZ
StartEventID	CEID
StopEventID	CEID
AutoDelete	TRAUTOD

7 Implementation Details

Many of the messages of the Event Reporting Standard are implemented with currently defined SECS-II messages. Certain restrictions must be applied to their usage. These restrictions are specified in this section.

7.1 To be OSS-compliant, the following data items must use the format 20 specification:

RPTID

CEID

TRID

VID

The format of the ASCII strings shall conform to the Object identifier specifications in the Object Services Standards, document SEMI E39 and SEMI E39.1.

7.2 Each Data Report sample, whether stand alone or as part of an Event or Trace report, will report TIMESTAMP as the first item in its list of report variables and/or object attributes. This means for reports defined by the service user, the user should define TIMESTAMP as the first VID in the report definition. Further, all of the service provider's predefined reports shall deliver the value of TIMESTAMP in the first V.

7.3 Serveral capabilities of the Event Reporting Standard are accessed through the Object Services Standard. When an instance of a report (Report, Event, or Trace) object has been created, then its attributes can be read and written using the Object Service's GetAttr and SetAttr messages.

7.3.1 Object Services shall be used to set RPTOC and to get CHGND.

7.3.2 Object Services shall be used to set or clear CEED.

7.3.3 EVNTSRC shall be provided in supplier documentation or as a list of Event Sources obtained by using Object Services to interrogate the Collection Event Object, COLLEVENT, with the GetAttrName request message.

7.4 Event Reporting Services is protocol independent and therefore, makes no mention of SECS-II multi-block access and grant messages. When the Event Reporting Services use the SECS-II protocol, then S6F11,F13 shall be preceded by S6F5 if a report will be multi-block. Trace Report Send, S6F27 shall also use the multi-block access/grant transaction if the report will be multi-block.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E54-0997
SENSOR/ACTUATOR NETWORK STANDARD

NOTE: The document that was previously designated as SEMI E54 (Standard for Sensor/Actuator Network Common Device Model) has been redesignated as SEMI E54.1. Because the Sensor/Actuator Network Standard is the parent document, it has been designated as SEMI E54.

1 Purpose

1.1 This specification provides the structure of SEMI's Sensor/Actuator Network (SAN) standard. It provides the definition for interoperability with respect to SEMI SAN standard-compliant Sensor/Actuator devices.

2 Scope

2.1 This standard specifies how devices interoperate on a network as part of the control system for equipment.

2.2 This specification, which is the root of the SAN standard, defines the relationships of each of the other specifications that are components of the SEMI SAN standard.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E54.1 — Standard for Sensor/Actuator Network Common Device Model

3.2 *Other Documents*

ISO 7498[1] — Basic Reference Model for Open Systems Interconnection (OSI)

James Rumbaugh, Michael Blaha, William Premerlani, Frederic Eddy, William Lorensen, *Object-Oriented Modeling and Design*, Englewood Cliffs, New Jersey: Prentice-Hall, 1991.

4 Terminology

4.1 *Abbreviations & Acronyms*

4.1.1 *API* — Applications Programming Interface

4.1.2 *CDM — Common Device Model.* The root object application model for devices on the sensor bus.

4.1.3 *DM* — DeviceManager. An object specified in SEMI E54.1 (Standard for Sensor/Actuator Network Common Device Model).

4.1.4 *IDL* — Interface Definition Language. A programming language-independent notation for specifying interfaces.

4.1.5 *ISO* — International Organization for Standardization.

4.1.6 *NCS* — Network Communication Standard. Provides the specification for mapping the CDM and SDM to specific network technologies. These standards will be incorporated as parts of the SEMI SAN standard.

4.1.7 *OEM* — Original Equipment Manufacturer. They are usually the control system developer, but in any case they are almost always responsible for the control system.

4.1.8 *OMT* — Object Modeling Technique. A methodology developed by James Rumbaugh, et al. for using objects to model systems.

4.1.9 *OSI* — Open System Interconnection. A seven-layer model for communications developed by ISO.

4.1.10 *OSS* — Object Services Standard. SEMI E39.

4.1.11 *SAN* — Sensor/Actuator Network. It is frequently used to reference this standard.

4.1.12 *SDM* — Specific Device Model. This is an application model for a specific type of sensor, actuator, or entity.

1 International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211, Geneva 20, Switzerland. Available in the US from American National Standards Institute, 11 West 42nd Street, 13th Floor, New York, NY 10036.

4.2 *Definitions*

4.2.1 *application* — for software, this is a working series of computer instructions that provide end user services.

4.2.2 *applications model* — a formal description of the software elements and interactions that perform an end user task.

4.2.3 *entity* — in software engineering, this is something that is recognizable as distinct and particular from the other things that make up a software system or program.

4.2.4 *interface* — in information modeling, it is the boundary between two entities from which information will flow.

4.2.5 *user layer* — in communications, this is a set software function connected to the communication protocol's top layer, usually called the applications layer, from the user's application environment. It typically allows the user application to be protocol-independent.

5 Overview

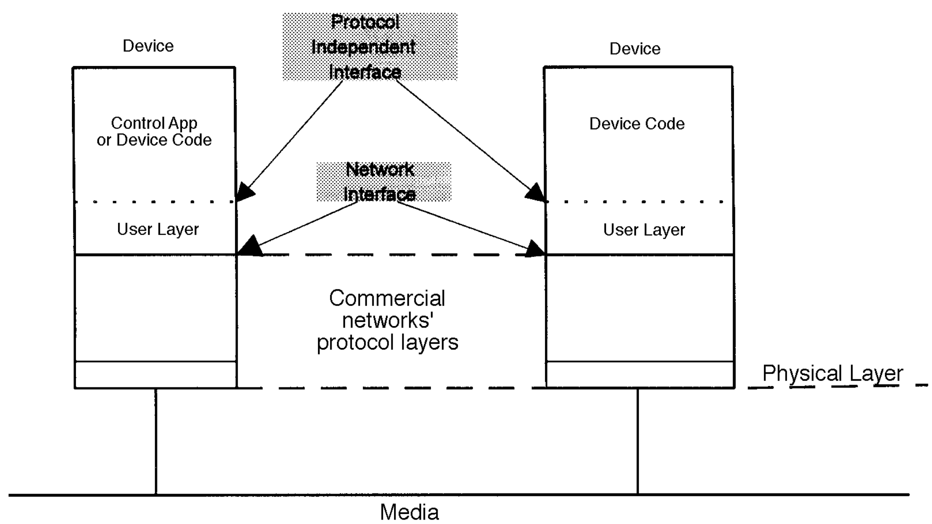

Figure 1
SEMI SAN Protocol Layers

5.1 Referring to Figure 1, the SAN standards specify a complete communications solution covering all the layers of the OSI reference model. The CDM and SDM together specify a protocol-independent set of application services, attributes, and behavior for a device that must be supported by the user layer as shown in Figure 1. An NCS completes the specification of the user layer by specifying a mapping to a network technology's interface. The NCS must specify its capabilities referenced against the ISO OSI Reference Model. An NCS may utilize an open or commercial solution. In any case, the NCS will provide references to those solution's specifications.

5.2 Generally, the functionality of a software layer is embodied by the definition of the services it provides. Its services are the set of messages it generates and to which it responds, and its subsequent behavior upon receipt of any particular message. The CDM and an SDM provide a complete user layer specification in a platform and language-neutral form (dotted line in Figure 1). The goal being to provide device interoperability at the applications level. The NCS will guarantee interoperability at the network level (i.e., across a single type of network). The SAN standard does not require implementation of the top interface to the user layer, as specified by the CDM and an SDM. The CDM and an SDM provide the information needed to develop an NCS, which defines the interface requirement between the user layer and a specific network technologies communication layer (the solid line labeled as Network Interface). This means that the SAN standard allows user applications, whether from the device or the controller side implementation viewpoint, to interact directly with a network technologies interface.

5.3 *Network Technology Supplier View* of *the SAN Standard*

5.3.1 The CDM and an SDM together specify the messages, behavior, and attributes of a device type that will be visible over the network. In Figure 1, this is the area above the line that indicates the protocol-independent interface. Network suppliers will map this information to the top layer of their protocol. They do this by helping to develop and extend their NCS.

5.3.2 Most network suppliers have an application layer already defined for their protocol. In that case, the user layer as specified in a SEMI SAN NCS is quite thin. In fact, it is just a simple mapping of SDM interface to messages and data (attributes) provided by the network. Thus, an NCS (one for each supported network) specifies a user layer that sits on top of the network supplier's protocol.

5.4 *Device Supplier View of the SAN Standard*

5.4.1 Device suppliers are not required to implement designs illustrated in the specific device model (SDM) specifications. The designs are presented using an object-modeling notation as a means to clearly specify the devices interface. An SDM provides a model of a device, it is not a design for the device. Device suppliers are not expected to provide an object-oriented implementation. However, in order to ensure that a device interface responds as expected, it is necessary for the device supplier to not only provide the support for the services and attributes specified, but to ensure that the code that is implemented on the device behaves as specified by the applications model for a specific device type.

5.5 *Equipment Supplier View of the SAN Standard*

5.5.1 The OEM's have the largest task in adopting the SAN standard. They have to implement applications that use the interfaces defined for the many devices that make up the typical equipment control system. They have to be familiar with the interfaces of a large number of the SDMs. On the other hand, they will become insulated from the inner workings of many devices, and from the code that they used to write to support those inner workings. In many cases, they may have to implement more than one Network Communication Standard.

5.5.2 During early adoption, OEM's may look to the SAN to act as a replacement for memory mapped discrete wired IO. With this type of adoption, the OEM will not lessen his burden of control code.

5.5.3 As Sensor Bus becomes more broadly adopted, OEM's may take advantage of the distributed processing capability offered by intelligent devices to reduce the complexity of their control software.

5.6 *The SAN Standard Structure*

5.6.1 A SAN employs devices from numerous suppliers. The SEMI SAN standard provides a framework to ensure interoperability of these devices within a network. The standard enables device suppliers and equipment control system developers to achieve that end. The SAN standard comprises five specifications.

5.6.2 The first specification is this document, which is the root document and specifies the connection between the other documents of the standard. It also specifies the construction for each of the other documents.

5.6.3 The next specification is the Common Device Model Specification. Each device on the SAN must comply with this specification.

5.6.4 The third specification defines the templates for creating ballots for specific device models and additions to the NCS.

5.6.5 The fourth specification is Specific Device Models standard. These standards contain models for various types of sensors, actuators, and entities. For instance, a model of a mass flow controller, a manometer, and a thermocouple will be specified.

5.6.6 The fifth type of specification is the Network Communication Standards. Each network technology has its own standard as an ancillary specification to the SAN standard.

5.6.7 Applications notes may accompany a number of the standards documents and are intended to guide implementors in the application of the standard.

6 Concepts

6.1 *Minimal device* — The SAN specifications allow simple and complex devices to be built compliant to the standard. This is done by specifying a minimum of required attributes, services, and behaviors in an SDM. The SDMs may also provide optional service definitions that must be followed if extended capabilities are to be built into a device. Devices that do not implement the extended capabilities must respond to extended service or access requests with an appropriate response code rather than failing to respond or issuing an exception or alarm message.

6.2 Many of the SAN NCS specifications rely on commercial technology. A significant number of network technologies are available off-the-shelf. The standards do not prescribe a choice. Once a technology described in an NCS is chosen, the NCS specifies how it is to be applied. The SAN standard is easily extensible for future technologies.

6.3 A device supplier must be able to use the standard to describe a device with little or no ambiguity for the device users. For the user, this means that he can select a device with confidence and that it can be easily integrated with his control system. The user must understand the electrical interface, the capabilities, and messages which a device supports based on the supplier's description of how this standard is supported by the device.

7 Requirements

7.1 *Organization of the SAN Specifications* — Figures 2 and 3 are intended to assist in understanding the document relationships that are specified in the following subsections. In these figures, all specifications that are standards are drawn as rounded rectangles. In Figure 3, the shadowed rectangles indicate the standards that contain requirements for implementing devices that are compliant to this standard.

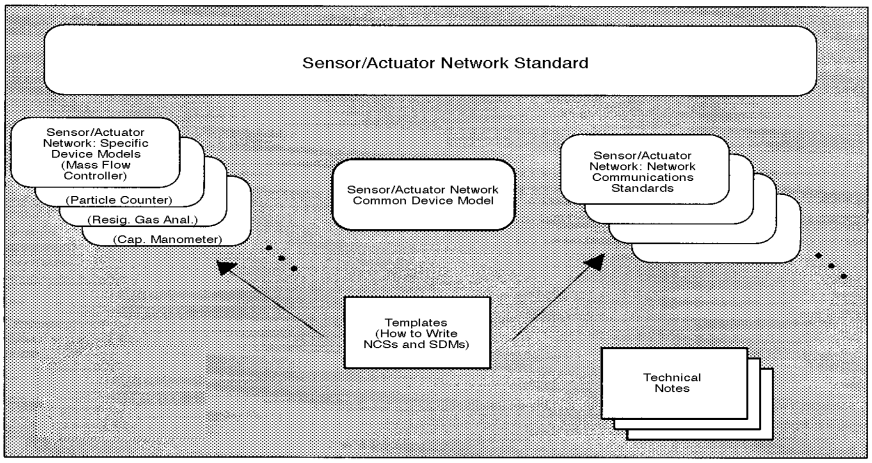

Figure 2
Organization of SAN Specification

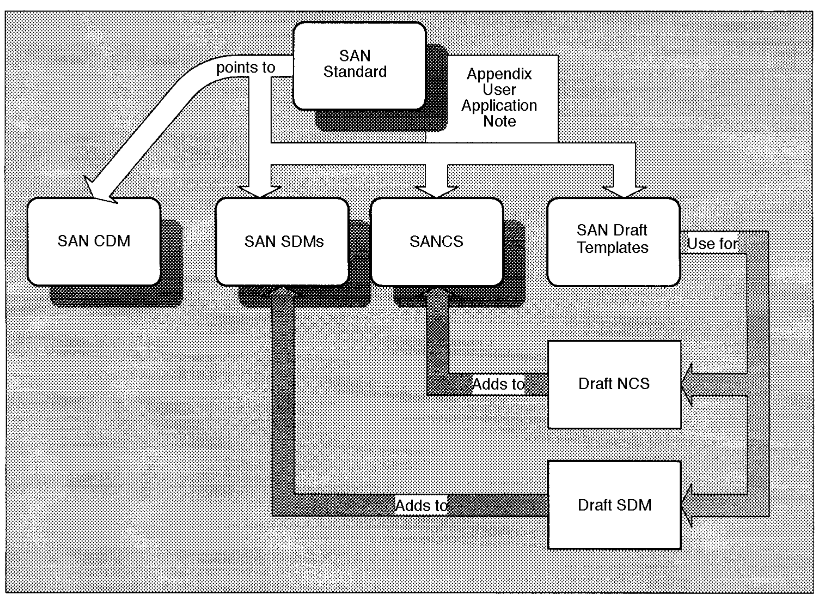

Figure 3
SAN Standard Relationships

7.1.1 The CDM specification is the first ancillary document of the SAN suite.

7.1.2 A second ancillary specification to the SAN standard provides templates that are guides to adding specific device models and network communication mappings to the SAN standard.

7.1.3 Specifications for specific device models for all types of devices are included as additional ancillary specifications of the SEMI SAN standard. Specific device models are added in the order they are developed and passed SEMI's ballot procedure.

7.1.4 Each network technology's user layer specification is included as an ancillary standard (see Figure 3). These *Network Communication Standards (NCS)* provide the mapping for each of the approved specific device models. Therefore, each NCS is also a specification that grows over time. As new device models are developed and approved, a mapping of the model to a network technology is added to a NCS.

7.1.5 *Auxiliary Information* — Auxiliary information may be included with the standard in the form of appendices or technical notes. Generally, this information is not balloted, but is included as provided by the SEMI Standards Program regulations. Auxiliary information shall always be noted as such when it accompanies a specification or ballot.

7.2 *Interoperability*

7.2.1 *At the Applications Level* — The SDMs are used to derive the definitions for attributes, services, and behavior that are unique to each device type. A model may discuss relationships internal to a device to provide additional meaning to the services and attributes that can be manipulated over the network. Applications written to these models can operate a device independent of the network on which they communicate. The models shall assure that devices of different types can operate cooperatively at the applications level.

7.2.2 *Below the User Layer* — The various SANCS specifications describe the method by which a device communicates over a specific network such that it can meet the requirements of its type. All devices described within an NCS shall operate cooperatively on that specific network technology below the user layer.

7.2.3 The SEMI SAN standard does not address methods for internet-working below the applications layer, as described herein. An application entity may connect to more than one network. This could be typical of the application entities on the equipment controller. While the SAN standard allows that application entities could exist at any network node, it requires no mechanism for a message that begins on one network to be routed to another network.

7.3 *SEMI SAN Compliance* — To fully describe the characteristics of a network capable device, its compliance shall be specified by reference to the SAN ancillary standards. Thus, a device indicates both its type and network technology for its SDM and a NCS.

7.3.1 For a device to be compliant to the SAN standard, it shall implement all of the required attributes, behavior, and services as described in the SAN CDM.

7.3.2 *Type or Applications Model Specification* — The SDM of a device (which is its type, e.g., MFC or thermocouple) shall be denoted by SEMI E54.y, where "y" indicates the SDM ancillary standard.

7.3.3 Network Communication Specification Communication (protocol) compliance specification of a device is denoted by SEMI E54.x, where "x" is the network communications ancillary specification.

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: The material contained in these Application Notes is not an official part of SEMI E54 and is not intended to modify or supersede the official standard. Rather, these notes are auxiliary information included as reference material for implementers of the standard. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of this material for any particular purpose is solely the responsibility of the user.

R1-1 Implementing a SAN Standard-Compliant Device

This Related Information section describes how the SAN standard is used by a device supplier who wishes to offer SEMI SAN-compliant devices to the market.

R1-1.1 While the SAN standard may appear overwhelming on first viewing, it is actually built from independent components. It is not necessary to understand or 'know' the entire standard. It can be dealt with in small pieces. For device suppliers, only the pieces that deal with their particular device type need to be considered. The specifications to implement a specific device are typically less than thirty pages of text. The standard is structured such that it is extensible while providing the ability to specify a device by reference to the standard.

R1-1.2 *Synopsis of Device Operation* — All devices on a SAN have a similar operational profile. That profile is specified in SEMI E54.1 (Standard for Sensor/Actuator Network Common Device Model) and in the Common Device Model support section of each NCS.

Table R-1 explains where to find specifications for various device operations.

Table R-1

Operation	*Spec.*
Power applied	CDM
Enable SAC	CDM
Enable DM	CDM
Enable Communications	NCS
Establish Communication	NCS
Send Events	CDM
Receive messages/answer	CDM
Send messages/accept	CDM

R1-1.3 *Device Type* — Each type of device is specified in the SDM specifications. One SDM is devoted to each device type. An SDM is always a specialization of the CDM. The SDM provides services, behavior, and attributes that are in addition to those specified in the CDM. For example, the SDM of a manometer might specify attributes for current pressure and alarm bands. It might have services needed for performing calibration.

R1-1.4 *Network Technology* — How a network technology is used by the SAN standard is specified in an NCS. The NCS for a technology provides a mapping of the CDM and SDM of a device type to a specific network protocol.

R1-1.4.1 It is only necessary for a device to support an NCS and the section for its type within that NCS. The NCS provides all that is needed to ensure that a device can communicate and interoperate across a given network technology. The point is that from the other side of the wire, the network-independent interface is not visible. That interface is implied by the behavior of the network interface.

R1-1.5 *Network Independence* — Device suppliers have the option of supplying an interface at the protocol-independent applications layer, as indicated in Figure 1. While this requires more implementation work for the device supplier, it speeds the integration of sensors and actuators for the OEM.

R1-1.5.1 In this case, it is still necessary for the device to support the NCS to ensure that their device will interoperate with other devices on the network.

R1-1.5.2 To supply this option, a device supplier would provide a device driver-like interface (software) to the OEM.

R1-1.5.3 Devices that supply a protocol-independent API that is compliant to the SEMI SAN standard provide advantages to both device and control system suppliers. The device supplier can assure that his device receives syntactically correct messages at his network interface layer. Control applications written to the protocol-independent interfaces have the advantage that they would not have to be rewritten in order to change to another network. To achieve this, device suppliers would have to ship software, in the form of 'device drivers', that would be installed on the control supplier's platform.

NOTE: Standards for these 'device drivers' may be developed at a later time as they do not currently exist. However, most operating systems used by control systems suppliers support installable device drivers.

R1-1.6 *Recommendations on Optional and Extended Device Capabilities* — It is expected that device suppliers would not compete based on their network interface. Devices traditionally compete based on cost, service, stability, reliability, accuracy and repeatability, and relevant dynamic attributes. From a network perspective, all devices have these common characteristics: periodic reporting, polled reporting, asynchronous event reporting, calibration, health, and diagnostic reporting. Access and control over the common characteristics should be implemented based on the SAN standard. Access and control of the competitive characteristics of devices may be implemented with supplier-specific interface extensions. However, the device supplier is strongly cautioned in the use of these extensions. Heavy use of extensions could be a serious competitive disadvantage unless the supplier is the clear winner in all the competitive characteristics. A locked door could lock one in, it could also lock one out. Device suppliers will usually find that their extensions can be implemented using the optional features of the CDM and SDM.

NOTE: Network interfaces could be a competitive factor during the early technology adoption phase.

R1-1.7 *The Controller Side Usage of the SAN Standard* — The control system supplier (in many cases this is the OEM) evolves a different view of SEMI's SAN standard. They are not as concerned with the network technology as with utilizing the applications capabilities as specified by the CDM and SDMs. It is strongly recommended that control applications not be network aware. This may produce some operating overhead, but for most applications, this is a good trade-off to gain flexibility provided by a protocol-independent interface. Many network devices may be supplied without any user layer (device driver) application side software. For these devices, the control system supplier would have to do some system's programming to provide a device driver for the application interface. Over time, it is likely that most devices will be delivered with a device driver. (Similar to the way printers are sold with Windows (TM) device drivers. This is what allows Windows applications to use a printer of the end users choosing.)

R1-1.7.1 The standards as of 1996 do not provide all the specifications needed to uniquely define how device drivers would be installed in the controller side of the API. This may become a future area of standardization, if OEMs decide to invest in the standard's development time.

R1-1.8 *Device Intelligence* — This varies considerably between device types and between devices of the same type. SEMI SAN specifications attempt to allow a range of intelligence to devices without forcing them to be 'highly' intelligent. To this end, the applications models specify a required minimum set of capabilities that must be supported for a device. Optional capabilities generally require more intelligent device operation. Devices that are not capable of supporting these extended capabilities provide a "not implemented" indication if access to those capabilities is requested.

R1-1.8.1 The following subsections describe device capabilities in order of increasing intelligence. A device's I/O direction is defined relative to the control application entity. Therefore, a sensor is an input, even though from the sensor's point of view it supplies output values.

R1-1.8.2 Polled input is the simplest sensor device requirement. All sensing devices should meet this requirement. In this mode of operation, a device only reports its value(s) when requested. This mode potentially provides the biggest burden on network bandwidth. However, it is the capability level that is most compatible with current control system architectures.

R1-1.8.3 Strobed output is the simplest actuator device requirement. All actuating devices should meet this requirement. This device only changes to a new state at the time of receipt of a specific message to do so.

R1-1.8.4 Periodic input is the capability to program the input device so that it sends its value(s) on a scheduled or periodic basis. Network bandwidth burden is reduced because it is not required to send a request each time an update for the input value is needed.

R1-1.8.4.1 This is also very compatible with current control architectures.

R1-1.8.5 Asynchronous input provides a capability for a sensing device to supply its value(s) when an event is detected. These events are usually programmed into the device. Examples of programmable events include threshold crossing of a value, value rate of change, measurement complete.

R1-1.8.5.1 Devices with this capability can significantly reduce network bandwidth burden, because they only need the network when some event has occurred. Equipment control architectures developed before 1990 may not be able to utilize this type of capability.

R1-1.8.6 Programmed output provides the capability for actuating devices to follow a programmable sequence of operations. For instance, an analog output could be given a ramp profile to follow as it moves between set points.

R1-1.8.6.1 This is another capability which can greatly reduce network bandwidth requirements. But, it is also a capability that 1990 vintage and earlier control systems may not be able to utilize easily.

R1-1.8.7 Devices with distributed processing capabilities are able to support features such as monitoring their health, providing diagnostics, and programmable preprocessing of data.

R1-1.8.7.1 These capabilities can have an impact on network burden, but more importantly may improve equipment reliability and maintainability. Again, this is a capability that is not readily utilized by control architectures developed prior to 1990.

R1-1.8.8 Devices with distributed control capabilities are capable of being programmed to create peer relationships with other devices on the network. Within these relationships, it is possible for one or more of the peers to control or regulate a subsystem within the equipment. For instance, a butterfly valve and manometer with these capabilities could be programmed to hold a particular pressure.

RELATED INFORMATION 2
INDEX FOR SENSOR/ACTUATOR STANDARDS

NOTE: This related information is not an official part of SEMI E54 and is not intended to modify or supercede the official standard. After approval of this document, publication of this Related Information was authorized by the committee chairs solely to aid in identifying the relationships between the current Sensor Bus standards and documents in process. Determination of the suitability of the material is solely the responsibility of the user.

R2-1 Scope

The table below is based on Figure 1 in SEMI E54.1, and is intended to show the relationships between standards that are currently published, as well as describe documents in process in SEMI Standards that, if approved, will be added to SEMI E54.

There are five categories:

Main Document
Templates
Specific Device Model
Common Device Model
Network Communication Standards

Standard titles with a designation number are published documents, and descriptors without designation numbers are documents in process.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E54.1-1000
STANDARD FOR SENSOR/ACTUATOR NETWORK COMMON DEVICE MODEL

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on July 14, 2000. Initially available at www.semi.org August 2000; to be published October 2000. Originally published in 1996; previously published February 1999.

NOTE: This document was previously designated SEMI E54. Because this document is part of a suite of documents, its designation has been reassigned for ease of reference.

1 Purpose

This standard defines a model comprised of device objects which are common to all devices on a semiconductor equipment sensor/actuator communications network.

2 Scope

2.1 This document describes common device structure and behavior (i.e., the minimum data structure and behavior all devices must support to operate on the network). These devices may range from simple sensors and actuators through hosts, masters, or controllers.

2.2 The model specified in this document is used in conjunction with a sensor/actuator network specific device model which describes the data structure and behavior characteristic of the specific device. Together, these two models are sufficient to completely describe a device as it appears from the network interface.

2.3 This standard, together with a sensor/actuator network interoperability guideline, a sensor/actuator network communication specification, and one or more specific device model specifications, form a complete interoperability specification. The sensor/actuator network document architecture is shown in Figure 1.

2.4 To comply with this standard, a device must implement and support instances of the objects, object attributes, object services, and object behaviors identified in this document, unless explicitly stated otherwise.

3 Limitations

3.1 This standard is a companion to a suite of sensor/actuator network communication network specifications. Therefore, using portions of this standard that relate to network communications necessarily requires an understanding of the associated network specification.

3.2 As this document is a standard for a *common* device model, it does not contain any information (e.g., object, attribute, services, or behavioral descriptions) that relates to a specific device or device type.

3.3 While the standards depicted in Figure 1 are sufficient to completely describe a device as it appears from the network, they do not fully describe behavior of the device which is not visible from the network. Some of the behavior detail within standard objects is intentionally left to the manufacturer to define. This allows flexibility for product differentiation and creates room for technology evolution. Manufacturer-specific objects may be defined by the manufacturer as appropriate, but are by definition outside the scope of this standard.

3.4 This standard is compatible, but not compliant, with SEMI E39. This means that although this standard does not require compliance with SEMI E39, it is extensible such that implementations may be developed that are fully compliant with both standards. Note that the concepts and terminology of this standard are compatible with those of SEMI E39. However, SEMI E39 has specific requirements that are intended for higher level applications and thus are not applied to the Common Device Model.

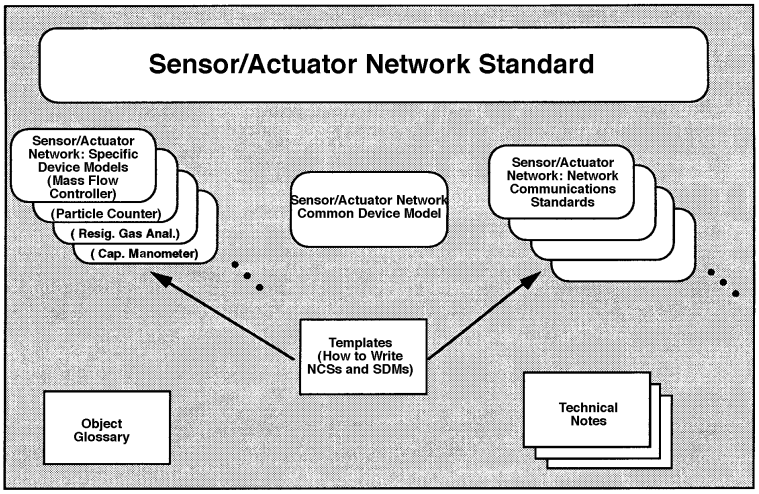

Figure 1
Sensor/Actuator Network-Related Documents

5 Terminology

Terminology may be reproduced here which is defined in other SEMI documents.

5.1 *Device Component Terminology*

5.1.1 *attribute* — Externally visible information concerning an object.

5.1.2 *behavior* — A specification of how an object acts. Actions result from different events the object detects, such as receiving service request, detecting internal faults, or elapsing timers.

5.1.3 *class* — A specific type or classification of objects.

5.1.4 *device* — A tangible thing consisting of: (1) at least one sensor and/or actuator and/or controller, (2) a communications controller which supports a single point of access to a network as specified in this document, and (3) interconnection and management hardware and software that provides for the consolidation of (1) and (2) into a system that has the capability to comply with the specification detailed in this document. Examples of devices are given in Figure 2.

5.1.5 *device model* — An abstraction of a device for the purpose of understanding it before building it or using it.

5.1.6 *embedded object* — An embedded object is similar in functionality or purpose to the object in which it is embedded, or supports the functionality of the object in which it is embedded. The embedding construct is utilized solely for purposes of documentation structure and understanding. As such, it does not imply any direct relationship, inheritance, similarity in structure, or connectivity in addressing scheme between the embedded object and the object in which it is embedded.

5.1.7 *instance* — A specific and real occurrence of an object.

5.1.8 *manufacturer* — In the context of this document, this refers to the manufacturer of the device.

5.1.9 *object* — An entity with a specific set of data and behaviors. Objects may be physical or conceptual. An object may be described in terms of its attributes, services it provides, and behavior it exhibits.

5.1.10 *service* — A function offered or supported by an object. A service consists of a sequence of service primitives, each described by a list of parameters. A service excludes definition of message structure and protocol.

5.1.11 *state diagram* — A means of representing state transitions, where the boxes represent states and the arrows represent transitions between states.

5.2 *Data Type Terminology* — Unless otherwise noted, data type terminology defined in SEMI E39 will be used in this document. The following terminology will also be used:

5.2.1 *Boolean (BOOL)* — A binary bit representing 0 and 1 corresponding to FALSE and TRUE or DISABLE and ENABLE respectively.

5.2.2 *byte* — A string of eight adjacent bits, interpreted as a unit and often representing a character.

5.2.3 *character* — A text symbol, letter, digit, or mark used to represent, control, or organize information that is one byte in length.

5.2.4 *character string* — A text string.

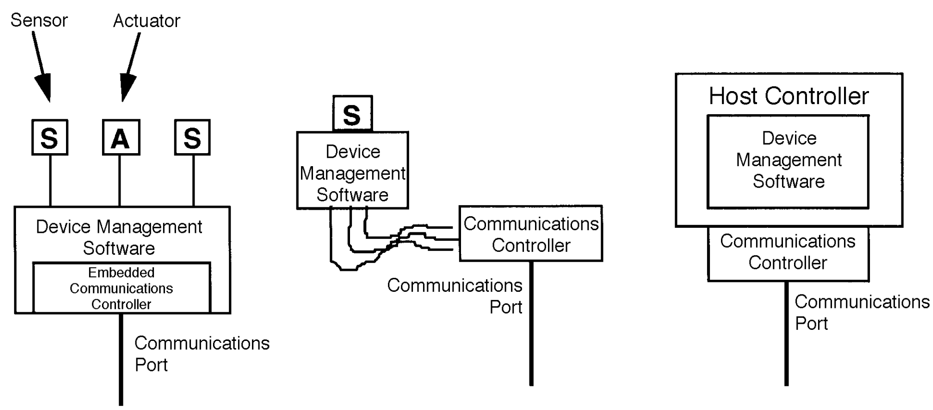

Figure 2
Examples of Devices

5.2.5 *data type* — An unsigned short integer formatted as an enumerated byte to specify attribute data format. The intended use of this attribute type is in cases where an attribute, or set of attributes, may be defined, allowing for more than one level of support (e.g., INT or REAL). The following values are defined:

0=INT

1=REAL

2=USINT

3=SINT

4=DINT

5=LINT

6=UINT

7=UDINT

8=ULINT

9=LREAL

10–99=reserved for CDM

100–199=reserved for SDMs

200–255=manufacturer-specified

5.2.6 *data units* — An unsigned integer enumerated to specify attribute data units. The intended use of this attribute type is in cases where an attribute, or set of attributes, may be defined, allowing for more than one unit's context. The values are defined in Appendix 1 of this document.

5.2.7 *date* — A data structure of four bytes used to represent a calendar date. Table 1 defines the format of the date data type.

Table 1 Date Format

Data #	*Description*	*Range*
0–1	Year	Unsigned Integer < 65,536
2	Month	Unsigned Integer (range of 1 to 12)
3	Day	Unsigned Integer (range of 1 to 31)

5.2.8 *Double Integer (DINT)* — An integer, four bytes long, in the range -2^{31} to $2^{31}-1$.

5.2.9 *enumerated byte* — A byte with assigned meaning to the values 0 through 255. May take on one of a limited set of possible values.

5.2.10 *full scale range* — The defined 100% value of an attribute in its assigned units. This value is not necessarily the maximum value for the attribute. As an example, the indicated flow attribute value may attain 120% of the full scale range.

5.2.11 *Last Valid Value (LVV)* — The most recent value successfully assigned to an attribute.

5.2.12 *Long Integer (LINT)* — An integer, eight bytes long, in the range -2^{63} to $2^{63}-1$.

5.2.13 *Long Real (LREAL)* — A double floating point number, 8 bytes long, as defined by IEEE 754.

5.2.14 *nibble* — A string of four adjacent binary bits.

5.2.15 *null character* — A byte with a value of zero.

5.2.16 *Real (REAL)* — A floating point number, 4 bytes long, as defined by IEEE 754.

5.2.17 *Short Integer (SINT)* — An integer, one byte long, in the range -128 to 127.

5.2.18 *Signed Integer (INT)* — An integer, 2 bytes long, in the range -32768 to 32767.

5.2.19 *text string* — A string of one byte characters.

5.2.20 *Unsigned Double Integer (UDINT)* — An unsigned integer, four bytes long, in the range 0 to 2^{32}-1.

5.2.21 *Unsigned Integer (UINT)* — An integer, 2 bytes long, in the range 0 to 65535.

5.2.22 *Unsigned Long Integer (ULINT)* — An unsigned integer, eight bytes long, in the range 0 to 2^{64}-1.

5.2.23 *Unsigned Short Integer (USINT)* — An integer, 1 byte long, in the range 0 to 255.

6 Conventions

6.1 *Harel State Model* — This document uses the Harel State Chart notation to describe the dynamic behavior of the objects defined. An overview of this notation is presented in an appendix of SEMI E30. The formal definition of this notation is presented in *Science of Computer Programming 8*, "Statecharts: A Visual Formalism for Complex Systems," by D. Harel, 1987.

Transition tables (referred to in this document as "state transition matrices") are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. Each transition table contains columns for Transition #, Current State, Trigger, New State, Action(s). The "trigger" (column 3) for the transition occurs while in the "current" state. The "actions" (column 5) include a combination of: 1) actions taken upon exit of the current state, 2) actions taken upon entry of the new state, and 3) actions taken which are most closely associated with the transition. No differentiation is made.

6.2 *OMT Object Information Model* — The object models are presented using the Object Modeling Technique developed by Rumbaugh, James, et al, in "Object-Oriented Modeling and Design," Prentice Hall, Englewood Cliffs, NJ, ©1991. Overviews of this notation are provided in an appendix of SEMI E39.

6.3 *Object Attribute Representation* — The object information models for standardized objects will be supported by an attribute definition table with the following column headings:

Attribute	*Definition*	*Access*	*Rqmt*	*Form*
The formal text name of the attribute.	Description of the information contained.	RO or RW	Y or N	(see below)

The access column uses RO (Read Only) or RW (Read and Write) to indicate the access that users of Object Services have to the attribute. Note that, in this document, the access column is used only to indicate user access via the network; no indication is made as to local access as this level of specification is considered to be implementation-specific. Thus, in the context of this document, a RW attribute is a network-settable attribute (i.e., an attribute whose value can be altered from the network), while a RO attribute is a non-network-settable attribute.

A 'Y' or 'N' in the requirement (Rqmt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

The Form column is used to indicate the format of the attribute.

6.4 *Service Message Representation*

6.4.1 *Service Resource Definition* — The service resource definition table defines the specific set of messages for a given service group, as shown in the following table:

Service	*Type*	*Description*
Message name	N or R	The intent of the service.

Type can be either Notification (N) or Request (R). Notification messages are initiated by the service provider. No response is expected. Request messages are initiated by the service user. Request messages ask for data or for an operation to be performed. Request messages expect a specific response (no presumption on the message content).

6.4.2 *Service Parameter Dictionary* — Each parameter should relate to either attributes from the object model or events of the dynamic model (Harel State Chart). All parameters to the services are listed in a single table or dictionary. The column headings for this parameter dictionary are as follows:

Parameter	*Form*	*Description*
Parameter X	Data type	A parameter

A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and the contents of the parameter.

The form column is used to indicate the type of data contained in the parameter and the possible values it may take on.

The description column describes the meaning of the parameter and interrelationships with other parameters.

6.4.2.1 *Service Message Definition* — There is a table showing the parameter detail for each service in which parameters are explicitly specified. The column headings for the service detail are as follows:

Parameter	*Req/Ind*	*Rsp/Cnf*	*Description*
Parameter X	(see below)	(see below)	A description of the service.

The columns labeled Req/Ind and Rsp/Cnf link the parameters to the direction of the message. The message sent by the initiator is called the "Request" (Req). The receiver terms the message the "Indication" (Ind). The receiver may then send a "Response" (Rsp), which the original sender terms the "Confirmation" (Cnf).

The request (Req/Ind) and response (Rsp/Cnf) entries can take on the following values:

"M" **Mandatory parameter** — Must be given a valid value.

"C" **Conditional parameter** — May be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of another parameter.

"U" **User-defined parameter**

"-" The parameter is not used.

"=" The entries M and C in the response can be modified with (=) to indicate that the value in the response must match the request.

7 Device High Level Structure

The high level object view of a device aggregation is shown in Figure 3. A device is depicted as consisting of a sensor/actuator/controller (SAC) object, a device manager (DM) object, and at least one active element object (i.e., sensor or actuator or controller object). Each of these objects by definition has attributes, services, and behavior. Note that the "Device" object is depicted in Figure 3 only for purposes of illustrating a high level view of the device and its component objects; in the context of this document, the "Device" object is not addressable, does not have addressable attributes or accessible services, and has no behavior defined.

This document defines in detail only the DM object. The SAC, Sensor, Actuator, and Controller objects are defined here only in terms of characteristics common to all devices. A complete definition of a SAC object includes an appropriate sensor/actuator network specific device model. This companion model could also complete the definition of sensor, actuator, and controller objects as appropriate to specify a device model.

7.1 *General Requirements* — Objects are defined in terms of their object name and instance identifier. Identifiers for all objects described in this document are summarized in Table 2. Note that these identifiers may be used for remote interrogation of an object instance via the sensor/actuator network (see appropriate sensor/actuator communications specification). Also note that, in Table 2, many of the objects specified in this document have exactly one instantiation per device.

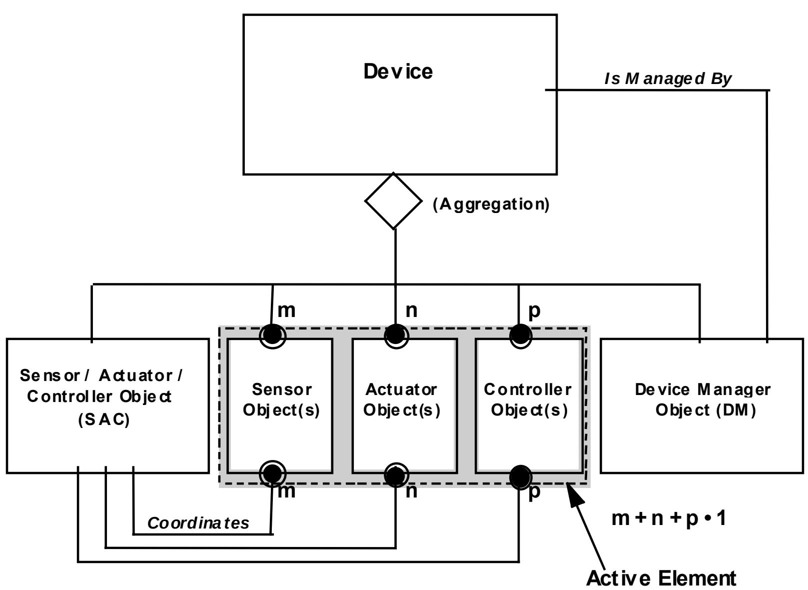

Figure 3
High Level Object View of a Device

Table 2 Device Objects and Identifiers

Object Name	*Object Identifier (tag)*	*Support Required in a Device*	*Comment*
Sensor/Actuator/Controller	SacI0*	Yes	Only one instance per device allowed.
Sensor	SenIn**	No	Zero or more instances per device allowed.***
Actuator	ActIn**	No	Zero or more instances per device allowed.***
Controller	CntIn**	No	Zero or more instances per device allowed.***
Device Manager	DmI0*	Yes	Only one instance per device allowed.

* Only one object instance per device; identifier uses “I0” to specify “instance zero.”

** “In” is used to indicate the instance number of the object; “n” is a non-negative integer.

*** The specification of the number of sensor, actuator, and/or controller object instances allowed per device may be further constrained by the appropriate sensor/actuator network specification.

The objects described in this document collectively define a device’s capabilities, including how it has been configured for network interoperability. The information in the attributes of these object instances must be accessible over the network and stored at the device.

Character strings described in this document have a prescribed maximum length. If the contents of the string are shorter than the prescribed length, the string must be terminated with the null character: a byte whose value is 00h. Note that this specification of null termination does not indicate that a sensor/actuator network protocol implementation communicating a character string over a network must send the null termination; the presentation of character string data over a network is sensor/actuator network communication protocol-specific.

7.2 *Sensor/Actuator/Controller (SAC) Object* — The SAC object is the device component responsible for coordinating the interaction of the device with the sensory/actuation/control environment. A view of the SAC object is shown in Figure 4. The SAC object coordinates operation of one or more sensor, actuator, and/or control object instances that collectively form the sensory/actuation/control portion of the device, so as to enable desired device behavior. For example, it could coordinate the operation of the device sensor, actuator, and/or control elements to enable device level data reporting or actuation, alarming detection and servicing, status reporting, device self-testing, device shutdown, etc. The number of sensor, actuator, and/or controller object instances allowed per device may be specified by the appropriate sensor/actuator network specific device model. An operating device shall contain exactly one instance of a SAC object.

The SAC object has embedded in it other objects that address specific tasks associated with coordinating the interaction of the device with the sensor/actuation/control environment. These objects are listed in Table 3. Note that although only one instance of the SAC object is allowed per device, a device can have multiple instances of embedded objects. These objects are described in Section 7.2.4.

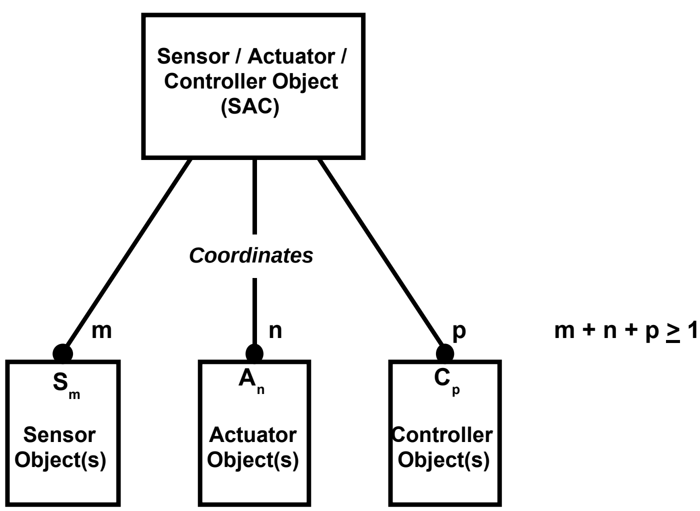

Figure 4
Detailed View of the Sensor/Actuator/Controller Object

Table 3 Objects Embedded in SAC Object and Identifiers

Object Name	*Object Identifier (tag)*	*Support Required in a Device*	*Comment*
Assembly	AsmIn*	No	Zero or more instances per device allowed.**
Local Link	LnkIn*	No	Zero or more instances per device allowed.**

* "In" is used to indicate the instance number of the object; "n" is a non-negative integer.

** The specification of the number of Assembly or Local Link object instances allowed per device may be further constrained by the appropriate sensor/actuator network specification.

7.2.1 *SAC Object Attributes* — All required and "common optional" SAC object attributes are listed in Table 4. Note that many of the attributes are in text "human-readable" forms. Information provided in this table includes, for each attribute: (1) an attribute identifier tag; (2) an indication of user access (via the network) to the attribute, (i.e., an indication of whether the attribute is network-settable); and (3) an attribute type. Required attributes must be supported in all SAC object instantiations. Optional attributes may or may not be supported; a further specification of the requirement of support for these optional attributes can be found in Section 7.2.3 and in an appropriate sensor/actuator network specific device model specification.

Table 4 SAC Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Last Calibration Date	SacA1	RW	No	date
Next Calibration Date	SacA2	RW	No	date
Expiration Timer	SacA3	RW	No	signed integer
Expiration Warning Enable	SacA4	RW	No*	Boolean
Run Hours	SacA5	R	No	unsigned integer
Reserved	SacA7-SacA64	—	—	Reserved for future expansion.

* The Expiration Warning Enable attribute is required if the Expiration Timer attribute is supported.

7.2.1.1 *Last Calibration Date* (Optional) — An attribute which identifies the date the device was last calibrated. The attribute is formatted as a date defined in Section 5.2.

7.2.1.2 *Next Calibration Date* (Optional) — An attribute which identifies the date the device is scheduled for the next calibration. The attribute is formatted as a date defined in Section 5.2.

7.2.1.3 *Expiration Timer* (Optional) — An attribute which identifies the number of run hours remaining until the next recommended calibration. The attribute is an unsigned integer with a resolution of 1 hour.

7.2.1.4 *Expiration Warning Enable* (Optional) — An attribute which specifies whether the calibration expiration timer will set a specific warning status bit in the exception status attribute of the DM object instance (specifically the "calibration expiration" exception bit — see Section 7.3.1.14).

The expiration warning enable attribute is Boolean and can take on one of the following values:

0 = Disable

1 = Enable

7.2.1.5 *Run Hours* (Optional) — An attribute which identifies the number of hours that the device has been powered ON. The attribute is an unsigned integer with a resolution of 1 hour.

7.2.1.6 *Initial and Default Values* — The initial and default values for relevant SAC attributes are given in Table 5:

Table 5 SAC Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Last Calibration Date	LVV	0,0,0*	
Next Calibration Date	LVV	0,0,0	
Expiration Timer	LVV	0	
Expiration Warning Enable	LVV	0	
Run Hours	LVV	0	

* Corresponding to year, month, and day; see Section 5.2.

7.2.2 *SAC Object Services* — All SAC object instances must provide the services listed in Table 6 (the SAC object is the "service provider" of these services). SAC services are identified with a service identifier of the form "SacSn", where "n" is a positive decimal number. SAC service identifiers SacS1 through SacS3 are used by this common device model standard. SAC service identifiers SacS4 through SacS32 are reserved.

Table 6 SAC Services

Service	*Service Identifier*	*Required*	*Type*	*Description*
Reset	SacS1	Yes	R	Used to place object in INITIALIZING state.
Abort	SacS2	Yes	R	Used to place object in ABORT state.
Recover	SacS3	Yes	R	Used to move object from ABORT state to RECOVERING state.
Get Attribute	SacS4	Yes	R	Used to read object attribute.
Set Attribute	SacS5	Yes	R	Used to modify object attribute.
Operate	SacS6	Yes	R	Used to move object to the OPERATING state from INITIALIZING or RECOVERING state.
Restore Default	SacS7	No	R	Used to restore object attributes to their default values.
Publish Attribute	SacS8	No	N	Used to proactively report an object attribute value.
	<SacS32	–	–	Reserved for future extensions of the CDM.

7.2.2.1 *Reset (Service Identifier: SacS1)* — Used to place the SAC object in its INITIALIZED state. The description of this state is device-specific. There are no parameters specified for this service.

7.2.2.2 *Abort (Service Identifier: SacS2)* — Used to place the SAC object in its ABORT state. The description of this state is device-specific. There are no parameters specified for this service.

7.2.2.3 *Recover (Service Identifier: SacS3)* — Used to move the SAC object from an ABORT state to its RECOVERED state. The description of this state is device-specific. There are no parameters specified for this service.

Additional services and/or service parameters may be provided by a SAC object that are device-specific and/or implementation-specific. These services may be Notification or Request type services (see Section 6.4.1). A complete definition of additional services and service parameters that are device-specific may be found in an appropriate sensor/actuator network specific device model specification.

7.2.2.4 *Get Attribute* — This service is used to read the value of an object instance attribute over the network. Table 7 describes the parameters specified for this service.

Table 7 SAC Object Get Attribute Parameter Definition

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
Attribute ID	M	C	Network-Specific	Attribute Identifier of the attribute whose value is being requested.
Attribute Value	–	M	Context-Specific	Value of the attribute requested.

7.2.2.5 *Set Attribute* — This service is used to modify the value of an object instance attribute over the network which has been identified as modifiable. Table 8 describes the parameters specified for this service.

Table 8 SAC Object Set Attribute Parameter Definition

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
Attribute ID	M	C	Network-Specific	Attribute Identifier of the attribute whose value is being modified.
Attribute Value	M	C	Context-Specific	Value of the attribute to modify.

7.2.2.6 *Operate* — This service is used to move the object instance to the OPERATING state from the INITIALIZING or RECOVERING state There are no parameters specified for this service. Operate requests are issued to all S, A, and C objects.

7.2.2.7 *Restore Default* (Optional) — This service is used to restore attributes of this object instance to their default values. Table 9 describes the parameters specified for this service. For Restore Default Conditions = 2, a Restore Default Condition = 1 request is issued to all S, A, and C objects.

Table 9 SAC Object Restore Default Parameter Definition

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
Restore Conditions	M	C	byte, enumerated	0 = Restore specific attribute of this object 1 = Restore this object 2 = Restore all objects of this device
Attribute ID	C	C	Network-Specific	Attribute ID of the attribute whose value is being restored. This parameter is only used for Restore Conditions = 0.

7.2.2.8 *Publish Attribute* (Optional) — Used to proactively communicate a SAC object attribute. Table 10 describes parameters specified for this service.

Table 10 SAC Publish Attribute Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf**	*Description*
Attribute ID	M	–	Attribute Identifier of the attribute whose value is being reported.
Attribute Value	M	–	Value of attribute being reported.

*The utilization of a service response message and its format is outside the scope of this document.

7.2.3 *SAC Instance Behavior* — SAC object instance behavior that is common to all devices is illustrated in Figure 5. Associated states and state transitions are described in Tables 11 and 12. The following also applies to SAC object behavior:

A SAC object service may be requested internally by the SAC object.

Upon SAC object instantiation or upon receipt of a reset request, the SAC responds by entering or staying in its INITIALIZED state.

Upon receipt of an abort request, the SAC object responds by entering or staying in its ABORT state.

Upon receipt of a recover request, the SAC object responds by transitioning to its RECOVERED state if and only if it is currently in its ABORT state. Otherwise, it responds with an error indication.

Additional behavior may be exhibited by a SAC object that is device-specific. A complete definition of this additional SAC object behavior may be found in an appropriate sensor/actuator network specific device model specification.

All SAC services have the same behavior associated with invalid service requests unless otherwise indicated. Common service error responses are listed in Appendix 2.

If a Set Attribute request is received over the network for an attribute that is not network-settable, or if the value in the SetAttribute request is beyond the specified range allowed for the value of the specified attribute, the attribute value is not changed and an error service response is generated.

When the SAC object instance is INITIALIZED, all attributes are set to their appropriate initial values (as indicated in their associated object instance attribute descriptions). Initial values could correspond to those retrieved from the device's non-volatile memory and reflect, in large part, the values set in a previous NORMAL OPERATING state.

Additionally, whenever the SAC object instance enters the INITIALIZED state, it must issue a Reset service request to all Sensor, Actuator, and Controller object instances. Each object instance must then respond with a Pass or Fail response indication upon completion of its respective INITIALIZING application process. The SAC object instance must coordinate these responses in order to determine whether the device is qualified to enter the OPERATING state. If qualified, an Execute service request is issued to the DM object instance. If not qualified, an exception condition is reported to the DM object instance (see Section 7.3).

When the SAC object instance is recovering from an ABORT state, all attributes are set to their appropriate values (as determined by the associated object instance recovering application process defined by the manufacturer). Additionally, the SAC object instance must issue a Recover service request to all Sensor, Actuator, and Controller object instances. Each object instance must then respond with a Pass or Fail response indication upon completion of its respective recovering application process. The SAC object instance must coordinate these responses in order to determine whether the device is qualified to enter the OPERATING state. If qualified, an Execute service request is issued to the DM object instance. If not qualified, an exception condition is reported to the DM object instance.

The SAC object optionally includes an Expiration Timer attribute. The value of this attribute is decremented at a rate described by the "ExpirationTimer" attribute format definition. Whenever the "ExpirationTimer" attribute is less than or equal to zero, a warning exception condition exists and is reported to the DM object instance (utilizing the PublishAttribute service) provided the "ExpirationWarningEnable" attribute is set to Enable. When the "ExpirationWarningEnable" attribute is set to Disable, the "ExpirationTimer" attribute continues to decrement; however, a warning exception condition will not be reported to the DM object instance.

The "ExpirationTimer" attribute will continue to be decremented to values less than zero. Therefore, a negative number indicates an elapsed time past expiration. When this attribute reaches its most negative value, it maintains this value and no longer decrements.

The "ExpirationTimer" is also maintained by the object while in the ABORT state. In the RECOVERING state, the current status of the device is evaluated and any exception conditions that exist are reported to the DM object instance.

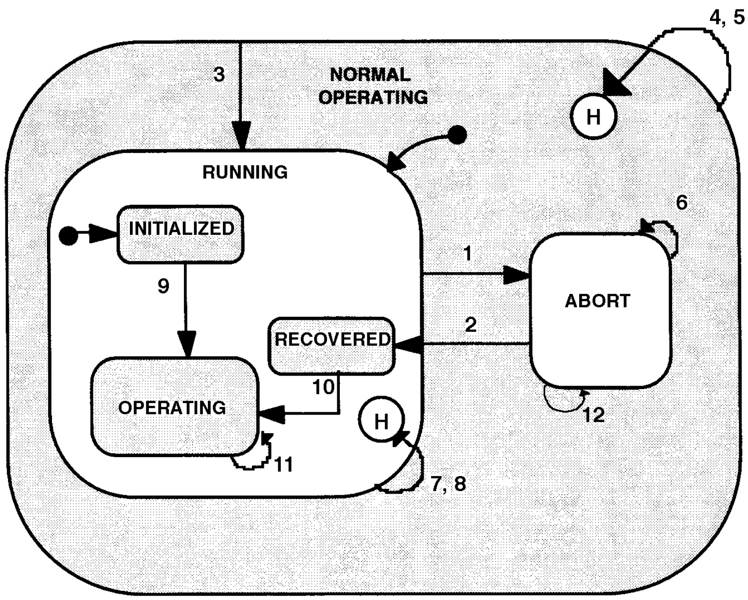

Figure 5
SAC Object Instance Behavior*

NOTE: Only generic behavior is indicated in this chart. A complete state chart necessarily requires the inclusion of device-specific behavior.

* Transitions 4 through 8, 11, and 12 are recursive (i.e., the New State is the same as the Current State (including all nested sub-states)).

Table 11 SAC Object Instance Behavior State Description

State	*Description*
NORMAL OPERATING	Object instance exists. Object services can be processed.
RUNNING	This is the entry sub-state to NORMAL OPERATING. Object instance is not in its ABORT state.
INITIALIZED	This is the entry sub-state to NORMAL OPERATING and RUNNING. Object instance exists and has been initialized. All attributes set to appropriate initial values (as indicated in an appropriate sensor/actuator network specific device model specification).
RECOVERED	Object instance is in an abort recovered state.
OPERATING	This represents the entire collection of sub-states within RUNNING except INITIALIZED and RECOVERED. The further delineation of this sub-state and transition into this sub-state is outside the scope of this document.
ABORT	Object instance is in an aborted state; a detailed description of this state is outside the scope of this document.

Table 12 SAC Object Instance Behavior State Transition Matrix*, **

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	RUNNING	Abort request.	ABORT	Abort. Abort response.	ABORT state is device-specific.
2	ABORT	Recover request.	RECOVERED	Recover. Recover response.	RECOVERED state is device-specific.
3	NORMAL OPERATING	Reset request.	RUNNING	Reset. Reset response.	Valid for all sub-states of NORMAL OPERATING. Move to RUNNING/INITIALIZED.
4	NORMAL OPERATING	Invalid service request.	NORMAL OPERATING	Error response.	Valid for all substates of NORMAL OPERATING.

5	NORMAL OPERATING	GetAttribute, SetAttribute, or RestoreDefault request.	NORMAL OPERATING	Get or Set appropriate attribute or restore defaults.	Valid for all substrates of NORMAL OPERATING.
6	ABORT	Abort request, Operate request.	ABORT	Error response.	Invalid request in this state.
7	RUNNING	Recover request.	RUNNING	Error response.	Recover service can only be invoked while in ABORT state.
8	RUNNING	PublishAttribute.	RUNNING	Attribute identified by attribute ID in PublishAttribute service is published.	Notification service.
9	INITIALIZED	Operate request or Device-specific.	OPERATING	Device-specific.	Behavior associated with this transition may be further specified in an appropriate sensor/actuator network specific device model specification.
10	RECOVERED	Operate request or Device-specific.	OPERATING	Device-specific.	Behavior associated with this transition may be further specified in an appropriate sensor/actuator network specific device model specification.
11	OPERATING	Operate request.	OPERATING	Error response.	Invalid request in OPERATING state.
12	ABORT	PublishAttribute.	ABORT	None.	Attributes cannot be published while in ABORT state.

* Transitions 4 through 8, 11, and 12 are recursive (i.e., the New State is the same as the Current State (including all nested sub-states)).

** Note: Only generic behavior is indicated in this table.

7.2.4 *Objects Embedded in SAC Object* — The object types that are embedded in the SAC object are listed in Table 3. The structure and behavior of instances of these object types are detailed in the remainder of this section.

7.2.4.1 *Assembly Object* — Assembly object instances may be used to provide a mechanism for grouping more than one attribute from one or more object instances in a device into a single data structure for communication over the network.

7.2.4.1.1 *Assembly Object Attributes* — All required and "common optional" Assembly object attributes are listed in Table 13.

Table 13 Assembly Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Data	AsmA1	Context-Specific	Yes	Context-Specific

7.2.4.1.1.1 *Data* — An attribute which contains the assembled data. The structure of this data is context-specific.

7.2.4.1.2 *Assembly Object Services* — The Assembly object instance provides two services: GetAttribute and SetAttribute.

7.2.4.1.2.1 *Get Attribute* — This service is used to read the value of an object instance attribute over the network. Table 14 describes the parameters specified for this service.

Table 14 Assembly Object Get Attribute Parameter Definition

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
Attribute ID	M	C	Network-Specific	Attribute Identifier of the attribute whose value is being requested.
Attribute Value	—	M	Context-Specific	Value of the attribute requested.

7.2.4.1.2.2 *Set Attribute* — This service is used to modify the value of an object instance attribute over the network which has been identified as modifiable. Table 15 describes the parameters specified for this service.

Table 15 Assembly Object Set Attribute Parameter Definition

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
Attribute ID	M	C, =	Network-Specific	Attribute Identifier of attribute whose value is to be modified. Inclusion of Attribute in Rsp/Conf. is optional.
Attribute Value	M	C	Context-Specific	Value to which the attribute is to be modified. Inclusion of Attribute in Rsp/Conf. is optional. Conditions under which the value may differ from that supplied in the associated Req/Ind. message (e.g., negative response) are not defined in this document.

Additional services and/or service parameters may be provided by an Assembly object instance that are device-specific and/or implementation-specific. These services may be Notification or Request type services (see Section 6.4.1). A complete definition of additional services and service parameters that are device-specific may be found in an appropriate sensor/actuator network specific device model specification.

7.2.4.1.3 *Assembly Object Behavior* — The behavior exhibited by the Assembly object instance is in support of the GetAttribute and SetAttribute services. That is, when a GetAttribute service request is received for the attribute "Data", the response contains the "Data" attribute value. Similarly, when a SetAttribute service request is received for the attribute "Data", the value of "Data" is modified, if indeed the attribute is modifiable, and a successful service response is returned; otherwise, a service not successful is returned.

7.2.4.2 *Local Link Object* — Local Link object instances may be used to "link" an attribute of one object instance to an attribute of another object instance.

7.2.4.2.1 *Local Link Object Attributes* — All required and "common optional" Local Link object attributes are listed in Table 16.

Table 16 Local Link Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Source Object Class	LnkA1	Context-Specific	N	Context-Specific
Source Object Instance	LnkA2	Context-Specific	N	Context-Specific
Source Object Attribute	LnkA3	Context-Specific	Y	Context-Specific
Destination Object Class	LnkA4	Context-Specific	N	Context-Specific
Destination Object Instance	LnkA5	Context-Specific	N	Context-Specific
Destination Object Attribute	LnkA6	Context-Specific	Y	Context-Specific
Commit	LnkA7	Context-Specific	N	Boolean

7.2.4.2.1.1 *Source Object Class* — Where applicable, the class of the object instance from which the source attribute is to be linked.

7.2.4.2.1.2 *Source Object Instance* — The instance number of the object from which the source attribute is to be linked.

7.2.4.2.1.3 *Source Object Attribute* — The attribute ID of the source attribute to be linked.

7.2.4.2.1.4 *Destination Object Class* — Where applicable, the class of the object instance to which the destination attribute is to be linked.

7.2.4.2.1.5 *Destination Object Instance* — The instance number of the object to which the destination attribute is to be linked.

7.2.4.2.1.6 *Destination Object Attribute* — The attribute ID of the destination attribute to be linked.

7.2.4.2.1.7 *Commit* — An attribute that indicates whether the Link object will perform the link function (the link function is described in Section 7.2.4.2.3). When this attribute is FALSE, the object cannot perform the link function.

7.2.4.2.2 *Local Link Object Services* — There are no common Local Link object services specified. Services and service parameters may be provided by a Local Link object instance that are device-specific and/or implementation-specific. These services may be Notification or Request type services (see Section 6.4.1). A complete definition of additional services and service parameters that are device-specific may be found in an appropriate sensor/actuator network specific device model specification.

7.2.4.2.3 *Local Link Object Behavior* — Local Link object instance behavior common to all instances is as follows. When instantiated, this object performs the link function. That is, it first uses the GetAttribute service capability of the source object instance identified by the Source Object Instance and (possibly) Source Object Class attributes to retrieve the attribute value of the attribute identified by the Source Object Attribute. If the Commit attribute value is TRUE, the object then uses the SetAttribute service capability of the destination object instance identified by the Destination Object Instance and (possibly) Destination Object Class attributes to set the attribute value of the attribute identified by Destination Object Attribute to the (retrieved) value of Source Object Attribute. The object shall also perform the link function any time the Commit attribute value transitions to TRUE. The object shall not write to the destination object instance whenever the value of the Commit attribute is set to FALSE. Issues such as frequency of this link update behavior (while the Commit attribute is set to TRUE, or when the Commit attribute does not exist), type matching of Source and Destination attributes, etc., are beyond the scope of this document.

7.3 *Device Manager (DM) Object* — The DM object is the device component responsible for managing and consolidating the device operation. The DM object houses information about the device (e.g., serial number, device type) so that the device may be uniquely identified remotely via a sensor/actuator network. The DM object is also responsible for providing details of the device status. As such, the responsibility of the DM object includes managing the reporting of exceptions to normal processing as alarms or warnings. Note that it is outside the scope of this document to specify the detailed conditions which initiate alarms and warnings. Exception handling that is common to all devices on the network is described here. This behavior and structure may be extended to handle exceptions which are specific to certain devices or are proprietary to individual manufacturers. Extensions for specific devices would be described in a sensor/actuator network specific device model for those devices.

A device shall contain exactly one instantiation of a DM object.

7.3.1 *DM Object Attributes* — All required and "common optional" DM object attributes are listed in Table 17. Note that many of the attributes are in text "human-readable" forms. Information provided in this table includes, for each attribute: (1) an attribute identifier tag; (2) an indication of user "write" access (via the network) to the attribute, (i.e., an indication of whether the attribute is network-settable); and (3) an attribute type and maximum length. (Note that in many cases it may be desirable to limit the length of these attributes.) Required attributes must be supported in all DM object instantiations. Optional attributes may or may not be supported; a further specification of the requirement of support for these optional attributes can be found in Section 7.3.3 and in an appropriate sensor/actuator network specific device model specification. DM attributes are identified with an attribute identifier of the form "DmAn" where "n" is a positive decimal number. DM attribute identifiers DmA1 through DmA14 are used in this common device model standard. DM attribute identifier numbers DmA15 through DmA64 are reserved.

Table 17 Device Manager Instance Attributes*

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Device Type	DmA1	RO	Y	Text, 8 characters maximum
Standard Revision Level	DmA2	RO	Y	Text, 10 characters maximum
Device Manufacturer Identifier	DmA3	RO	Y	Text, 20 characters maximum
Manufacturer Model Number	DmA4	RO	Y	Text, 20 characters maximum
Software or Firmware Revision Level	DmA5	RO	Y	Text, 8 characters maximum
Hardware Revision Level	DmA6	RO	Y	Text, 8 characters maximum
Serial Number (optional)	DmA7	RO	N	Text, 30 characters maximum
Device Configuration (optional)	DmA8	RO	N	Text, 50 characters maximum
Device Status	DmA9	RO	Y	unsigned integer, enumerated, see text
Reporting Mode	DmA10	RW	Y	Formatted byte, see text
Exception Status Report Interval (optional)	DmA11	RW	N	unsigned integer, < 65,536

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Exception Status	DmA12	RO	Y	Formatted byte, see text
Exception Detail Alarm (optional)	DmA13	—	N	Structure of
Common Exception Detail	—	—	—	Structure of
Size	—	RO	—	unsigned integer, < 256
Detail	—	RO	—	Ordered list of bytes, see text
Device Exception Detail	—	—	—	Structure of
Size	—	RO	—	unsigned integer, < 256

Visual Indicator	DmA15	RW	N	Byte, enumerated
Alarm Enable	DmA16	RW	N	Boolean
Warning Enable	DmA17	RW	N	Boolean
Exception Detail Type	DmA18	RW	N	Byte, enumerated
Exception Detail Alarm Queue	DmA19	R	N	Ordered list of type Exception Detail Alarm.
Exception Detail Warning Queue	DmA20	R	N	Ordered list of type Exception Detail Warning.
Date and Time	DmA21	RW	N	See Section 7.3.1.23
Date and Time Type	DmA22	RW	N	Enumerated USINT
Reserved for CDM	< DmA32	—	—	Reserved for future CDM DM attribute definitions.

* A “Definition” column is not included. For attribute definitions, see text.

** A value of 00 indicates that this timer is disabled.

*** Same as Exception Detail Alarm.

7.3.1.1 *Device Type* — An attribute which identifies the type of the device on the sensor/actuator network. It is formatted as a text string with a maximum length of 8 characters. The exact content may be defined in an appropriate sensor/actuator network specific device model specification. For example, “MFC” = mass flow controller, “CDG” = capacitance diaphragm gauge.

7.3.1.2 *Standard Revision Level* — An attribute which identifies the most recent version of the sensor/actuator network specific device model to which the device adheres. It is formatted as a text string with a maximum length of 9 characters as “ENNNNNNYY,” where “E” is a constant defined by SEMI, “NNNNNN” is the number of the standard, and “YY” is the last two digits of the year in which the standard/revision was published. If there is no relevant standard or the device is not compliant to the standard, then “NNNNNN” is zero length and “YY” is set to “00” (thus, the attribute is set to “E00”).

7.3.1.3 *Device Manufacturer Identifier* — An attribute which designates the manufacturer of the device. Each manufacturer is responsible for defining this variable for their products in a way which will be unique to that manufacturer and which must be the same for all devices they provide. Formatted as a text string with a maximum length of 20 characters, it will usually be the company name, as in “Acme Instrument Co.”

7.3.1.4 *Manufacturer Model Number* — An attribute which designates the basic model identification number, defined by the manufacturer. It is formatted as a text string with a maximum length of 20 characters.

7.3.1.5 *Device Software or Firmware Revision Level* — An attribute which designates the version of microprocessor code which is contained in the device, defined by the manufacturer. It is formatted as a text string with a maximum length of 5 characters.

7.3.1.6 *Hardware Revision Level* — An attribute which designates the version of the device, excluding the microprocessor code, defined by the manufacturer. It is formatted as a text string with a maximum length of 5 characters.

7.3.1.7 *Serial Number (optional)* — An attribute which designates the number defined and assigned by the manufacturer that uniquely identifies each individual device produced. It is formatted as a text string with a maximum length of 30 characters.

7.3.1.8 *Device Configuration (optional)* — An attribute which designates a manufacturer-defined device configuration (beyond model number). It is formatted as a text string with a maximum length of 50 characters.

7.3.1.9 *Device Status* — An attribute which designates the state of the DM object. The attribute (unsigned integer) values and corresponding object states specified by this attribute are enumerated in Table 18.

Table 18 Device Status Attribute Values

Attribute Value	*DM Object State*
0	Unknown
1	INITIALIZED/SELF TESTING
2	IDLE
3	SELF TEST EXCEPTION
4	EXECUTING
5	ABORT FROM IDLE OR EXECUTING
6	ABORT FROM INITIALIZED/SELF TESTING OR SELF TEST EXCEPTION
7 – 255	Reserved

This attribute is set and updated internally by the DM object as part of the object behavior associated with transition between the various states (see Section 7.3.3 and Figure 6).

7.3.1.10 *Reporting Mode* — A network-settable attribute defined as a single byte containing two nibbles: A low nibble (bits 0 – 3) and a high nibble (bits 4 – 7). The high nibble contains the value for alarm conditions. The low nibble contains the value for warning conditions. The value assigned to each nibble indicates how the alarm/warning status variable is to be reported. The possible attribute values and corresponding reporting modes specified by this attribute are enumerated in Table 19.

Table 19 Reporting Mode Attribute Values for Alarms and Warnings

Reporting Mode	*Attribute High Nibble Value (Alarm)*	*Attribute Low Nibble Value (Warning)*
Request	0	0
RequestLatched (optional)	1	1
EventTriggeredOn (optional)	2	2
EventTriggeredOn/Off (optional)	3	3
TimeTriggered (optional)	4	4
EventOnOrTimeTriggered (optional)	5	5
EventOn/OffOrTimeTriggered (optional)	6	6

The behavior of the DM object associated with this attribute and each of these reporting modes is described in Section 7.3.3.

7.3.1.11 *Exception Status Report Interval (optional)* — A network-settable attribute which specifies the time interval for periodic exception status reporting (when a time-triggered reporting mode is indicated, see definition of Reporting Mode attribute and Section 7.3.3). It is formatted as an unsigned integer whose least significant bit corresponds to a value of 1/100 second. The requirement to store this attribute in non-volatile memory (so that the value upon “power-up” is the last value active) is device-specific. Note that a value of 0.00 indicates that this timer, and thus time-triggered exception reporting, is not enabled (see also Section 7.3.3).

7.3.1.12 *Exception Status* — A single-byte attribute whose value indicates the status of the alarms and warnings for the device (see Table 19). This indication may be provided in one of two methods: Basic or Expanded. In the Basic method, bit seven of the Exception Status attribute is set to zero; all exceptions are reported exclusively through communication of this Exception Status attribute. The format of bits zero through six in this mode is device-specific; the format may be further specified in an appropriate sensor/actuator network specific device model specification; if it is not specified, then the format of bits zero through six is equivalent to that specified in the expanded mode. In the Expanded method, bit seven of Exception Status attribute is set to one; exceptions are reported through the communication of this Exception Status attribute, formatted as specified in Table 20, and exception detail attributes as indicated by the Exception Status attribute.

Table 20 Exception Status Attribute Value*

	Exception Status Bit Map, Bit 7 set to 0	*Exception Status Bit Map, Bit 7 set to 1*
bit	*Function*	*Function*
0	Device-Specific	ALARM/device-common**
1	See sensor/actuator network specific device model for further specification	ALARM/device-specific
2		ALARM/manufacturer-specific
3		reserved
4		WARNING/device-common**
5		WARNING/device-specific
6		WARNING/manufacturer-specific
7	0 == Basic Method	1 == Expanded Method

* Behavior associated with the reporting of exception status attribute values is described in Section 7.3.3.

** The alarm or warning is not specific to the device type or device type manufacturer.

7.3.1.13 *Exception Detail Alarm and Exception Detail Warning (optional)* — Attributes that relate the detailed status of the alarms or warnings associated with the device. Each attribute is a structure containing three members; these three members respectively relate the detailed status of exceptions that are device-common (i.e., not device-specific), device-specific but not manufacturer-specific, and manufacturer-specific. Each of the three structure members is defined as a structure containing an ordered list (i.e., array) of bytes of length SIZE, and an unsigned integer whose value is SIZE. Each of the bytes in each array has a specific mapping. This mapping is formatted as 8 bits representing 8 independent conditions, whereas a value of 1 indicates that the condition is set (or present), and a value of 0 indicates that the condition is cleared (or not present). Note that if a device does not support an exception detail, the corresponding bit is never set. The bitmaps for alarms and warnings in the corresponding attributes are structured in parallel so that a condition may have either alarm or warning set, depending on severity. If a condition inherently cannot be both alarm and warning, then the parallel bit position corresponding to the other state will remain “0.”

The existence of an exception detail variable structure is dependent on the value of the Exception Status Attribute; the existence of an exception detail variable structure is only required if bit seven of the Exception Status attribute is set to 1 (indicating Expanded mode reporting) and the bit (among bits zero through six) of the Exception Status attribute corresponding to the particular exception type is also set to 1 (see Table 20).

7.3.1.14 *Common Exception Detail (optional)* — This structure relates exception conditions (i.e., alarms or warnings) which are common to all devices on the network. The Detail element of the structure is an ordered list (i.e., array) of bytes of length [SIZE] which is the value of the structure element Size. For each byte in the Detail field, all bits which are not identified are reserved for future standardization. The first byte in this attribute is CommonExceptionDetail[0]. Additional exception details, if provided, are named CommonExceptionDetail[1], CommonException Detail[SIZE]. The specific exception associated with each of the bitmaps is given in Table 21. The criteria details for each exception condition are outside the scope of this document.

Table 21 Common Exception Detail Attribute Value

	*Common Exception Detail**
bit	*Detail[0]*
0	internal diagnostic exception
1	microprocessor exception
2	EPROM exception
3	EEPROM exception
4	RAM exception
5	communications exception
6	internal real-time exception
7	calibration expiration

	*Common Exception Detail**
bit	*Detail[1]*
0	power supply overcurrent
1	reserved power supply
2	power supply output voltage
3	power supply input voltage
4	routine maintenance due
5	notify manufacturer
6	reset exception
7	reserved

* Note that if a device does not support an exception detail, the corresponding bit is never set.

7.3.1.15 *Device Exception Detail (optional)* — This structure, similar in form to Common Exception Detail, relates exception conditions which are specific to individual devices on the network and are defined in their respective device model documents. The Detail element of the structure is an ordered list (i.e., array) of bytes of length [SIZE] which is the value of the structure element size. For a detailed description of this attribute, consult the appropriate specific device model documentation.

7.3.1.16 *Manufacturer Exception Detail (optional)* — This structure, similar in form to Common Exception Detail, relates exception conditions which are specific to the manufacturers of individual devices on the network and are defined by them in their product documentation. The Detail element of the structure is an ordered list (i.e., array) of bytes of length [SIZE] which is the value of the structure element size. For a detailed description of this attribute, consult the appropriate specific device manufacturer documentation.

Additional attributes may be supported by a DM object that are device-specific. A complete definition of any additional attributes may be found in an appropriate sensor/actuator network specific device model specification.

7.3.1.17 *VisualIndicator* (Optional) — An attribute which defines the behavior of a visual indicator allowing the device to be visually located. This attribute is an enumerated byte that can take on one of the following values:

0 = Visual Indicator OFF

1 = Visual Indicator ON

2–63 = Reserved

64–255 = Manufacturer-Specified

For values visual indicator OFF and visual indicator ON, the visual indicator is defined to be a Light Emitting Diode (LED). When the value is visual indicator ON, the device is expected to flash the LED at a frequency of approximately 0.5 to 1.5 Hz at a duty cycle of approximately 30 to 70 percent. The location and labeling of the LED are manufacturer-specified.

7.3.1.18 *AlarmEnable* (Optional) — An attribute which defines whether or not the object will report alarms (as indicated by the ReportingMode, ExceptionStatus, ExceptionDetailType, and ExceptionDetailAlarm attributes). When this attribute is set to TRUE, then alarming is enabled. When this attribute is set to FALSE, all DM exception attributes are set and maintained at values that indicate a no alarm state. Thus bits 0 through 2 of the ExceptionStatus attribute are set and maintained at zero, and any ExceptionDetailAlarm attribute bytes are set and maintained at a value of zero.

7.3.1.19 *WarningEnable* (Optional) — An attribute which defines whether or not the object will report warnings (as indicated by the ReportingMode, ExceptionStatus, ExceptionDetailType, and ExceptionDetailWarning attributes). When this attribute is set to TRUE, then warning exception reporting is enabled. If this attribute is set to FALSE, all DM exception attributes are set and maintained at values that indicate a no warning state. Thus, bits 4 through 6 of the ExceptionStatus attribute are set and maintained at zero, and any ExceptionDetailWarning attribute bytes are set and maintained at a value of zero.

7.3.1.20 *ExceptionDetailType* (Optional) — An attribute consisting of two enumerated nibbles that designate the method of alarm and warning detail reporting respectively that is supported. The possible attribute values and corresponding reporting mode support indications are enumerated in Table 22. Note that if this attribute is not supported, the reporting mode is either zero (basic) or one (expanded) as indicated in bit seven of the ExceptionStatus attribute.

Table 22 ExceptionDetailType Attribute Values for Alarm and Warning Reporting Methods

Reporting Method	*Attribute High Nibble Value (Alarm)*	*Attribute Low Nibble Value (Warning)*
Basic	0	0
Expanded	1	1
Queued	2	2
Reserved for Future Extension of CDM	3 – 15	3 – 15

7.3.1.21 *ExceptionDetailAlarmQueue* (Optional) — An attribute consisting of an ordered list of alarm events; the data structure of the individual alarm events (i.e., queue elements) is determined by the values of the ExceptionStatus attribute; if bit 7 of the ExceptionStatus attribute indicates a Basic Mode reporting data format then each queue element is of the same data type as ExceptionStatus; if bit 7 of the ExceptionStatus attribute indicates an Expanded Mode reporting data format then each queue element is of the same data type as ExceptionDetail (Alarm/Warning). The behavior of this queue in storing and reporting alarms is described in Section 7.3.3.

7.3.1.22 *ExceptionDetailWarningQueue* (Optional) — An attribute consisting of an ordered list of warning events; the data structure is determined as described in Section 7.3.1.21. The behavior of this queue in storing and reporting warnings is described in Section 7.3.3.

7.3.1.23 *Date and Time* — A structure that relates the current time as perceived by the device. The form of the structure depends on the value of the *Data and Time Type* attribute as follows:

Date and Time Type	*Date and Time Structure*	*Semantics*
0 [default]	Struct of: UDINT UINT	{*Standard Time and Date*} (6 Bytes) Number of milliseconds since midnight Number of days since 01 January, 1972
1	Struct of: UDINT UINT INT	{*Standard Time and Date with Offset*} (8 Bytes) Number of milliseconds since midnight Number of days since 01 January, 1972 Number of minutes displacement from the Greenwich Meridian
2	Struct of: LINT	{*Universal Time Coordinated* (UTC)} (8 Bytes) Number of 100 nanoseconds since 15 October, 1582, 00:00:00
3	Struct of: LINT INT	{*UTC with Time Displacement Factor*} (10 Bytes) Number of 100 nanoseconds since 15 October, 1582, 00:00:00 Number of minutes displacement from the Greenwich Meridian
4 - 63	Reserved	
64 - 127	Specific Device Model definitions as required	
128 - 255	Manufacturer specified as required	

7.3.1.23.1 If the *Date and Time Type* attribute is not supported, the default value of zero (0) is assumed.

7.3.1.23.2 The *Standard Time and Date* (Type 0) uses 32 bits to represent the number of milliseconds since midnight followed by 16 bits to represent the number of days since 01 January, 1972. The reference for this format is either Greenwich Mean Time or Local Time as defined by the user. This format has a range of 01 January, 1972 to 06 June, 2151.

7.3.1.23.3 The *Standard Time and Date with Offset* (Type 1) uses the above format followed by 16 bits to represent the number of minutes displacement from the Greenwich Meridian. Meridians to the East are positive, while those to the West are negative.

7.3.1.23.4 The *Universal Time Coordinated* (UTC) (Type 2) is based on the format used by the WWV radio station of NIST. It uses 64 bits to represent the number of 100 nanoseconds since 15 October, 1582, 00:00:00. The reference for this format is always Greenwich Mean Time. This format has an approximate range of BC 27,000 to AD 30,000.

7.3.1.23.5 The *UTC with Time Displacement Factor* (TDF) (Type 3) uses the above format followed by 16 bits to represent the number of minutes displacement from the Greenwich Meridian. Meridians to the East are positive, while those to the West are negative.

7.3.2 *DM Object Services* — All DM object instances must provide the services listed in Table 23. (The DM object is the "service provider" of these services.) Note that all of these services are Request services, with the exception of the PublishAttribute service (which is a notification service). DM services are identified with a service identifier of the form "DmSn", where "n" is a positive decimal number. Dm service identifiers DmS1 through DmS8 are used by this common device model standard. DM service identifiers DmS9 through DmS32 are reserved. Service parameters that are specified in this standard are summarized in Table 24.

Table 23 DM Object Service Resource Definition

Service	*Service Identifier*	*Required*	*Type*	*Description*
Reset	DmS1	Y	R	Used to place object in INITIALIZED state.
Abort	DmS2	Y	R	Used to place object in ABORT state.
Recover	DmS3	Y	R	Used to move object from ABORT state to RECOVERED state.
GetAttribute	DmS4	Y	R	Used to read object attribute.
SetAttribute	DmS5	Y	R	Used to modify object attribute.
Execute	DmS6	Y	R	Used to move object from IDLE state to EXECUTING state.
PerformDiagnostics	DmS7	Y	R	Used to instruct object to perform diagnostic test.
PublishAttribute	DmS8	N	N	Used to proactively report exception status attribute.
Lock	DmS9	N	R	Used to restrict access to READ only attributes.
Unlock	DmS10	N	R	Used to make READ only attributes modifiable.
Get Exception Queue	DmS11	N	R	Used to retrieve all, or a specified number of, exception events from the front of the ExceptionDetailAlarm/WarningQueue.
Clear Exception Queue	DmS12	N	R	Used to clear all exception events from the ExceptionDetail Alarm or WarningQueue.
Reserved by CDM	DmS13 – DmS32	—	—	Reserved for CDM expansion.

Table 24 DM Object Service Parameter Dictionary

Parameter	*Form*	*Description*
AttributeID	Enumerated	DM object attribute identifier (see Table 17)
AttributeValue	Context-specific (see Table 17)	Value of DM object attribute.
TestID	Non-negative integer, < 256	Type and possibly detail of diagnostic test to be performed.

A detailed description of these services follows.

7.3.2.1 *Reset (Service Identifier: DmS1)* — Used to place the DM object in its INITIALIZED state. There are no parameters specified for this service.

7.3.2.2 *Abort (Service Identifier: DmS2)* — Used to place the DM object in its ABORT state. There are no parameters specified for this service.

7.3.2.3 *Recover (Service Identifier: DmS3)* — Used to move the DM object from its ABORT state to a recovered state (which is the IDLE state for this object). There are no parameters specified for this service.

7.3.2.4 *GetAttribute (Service Identifier: DmS4)* — Used to read a DM object attribute.

GetAttribute Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
AttributeID	M	C**, =	Attribute Identifier of attribute whose value is being requested. Inclusion of attribute in Rsp/Conf. is optional.
AttributeValue	—	M	Value of attribute requested.

* See Section 6.4.3 for a further description of terminology used in this table.

** The determination of whether Attribute ID is supplied in the service response/confirm is outside the scope of this document.

7.3.2.5 *SetAttribute (Service Identifier: DmS5)* — Used to modify a DM object attribute.

Set_Attribute Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
AttributeID	M	C, =	Attribute Identifier of attribute whose value is to be modified. Inclusion of Attribute in Rsp/Conf. is optional.
AttributeValue	M	C	Value to which the attribute is to be modified. Inclusion of Attribute in Rsp/Conf. is optional. Conditions under which the value may differ from that supplied in the associated Req/Ind. message (e.g., negative response) are not defined in this document.

* See Section 6.4.3 for a further description of terminology used in this table.

7.3.2.6 *Execute (Service Identifier: DmS6)* — Used to move the DM object from its IDLE state to its EXECUTING state. Note that this service may be internally generated by the DM object. There are no parameters specified for this service.

7.3.2.7 *PerformDiagnostics (Service Identifier: DmS7)* — Used to instruct the DM object to perform a diagnostic test. A diagnostic test is either of type “common” or “device-dependent.” “Common” diagnostic tests could include: RAM, EPROM, non-volatile memory, and communications. The structure of “common” type diagnostic tests is implementation-specific. All detail of “device-dependent” diagnostics is outside the scope of this document. The following table describes parameters specified for this service.

Perform_Diagnostics Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
TestID	M	C, =	Indicates the type and possibly detail of the test to be performed.

* See Section 6.4.3 for a further description of terminology used in this table.

Additional services and/or service parameters that are device-specific and/or implementation-specific may be provided by a DM object. These services may be Notification or Request type services (see Section 6.4.1). A complete definition of additional services and service parameters that are device-specific may be found in an appropriate sensor/actuator network specific device model specification.

7.3.2.8 *PublishAttribute (Optional — Service Identifier: DmS8)* — Used to proactively communicate a DM object attribute. The following table describes parameters specified for this service.

PublishAttribute Service Message Definition Table*

Parameter	*Ind*	*Description*
AttributeID	M	Attribute Identifier of attribute whose value is being reported.
AttributeValue	M	Value of attribute being reported.

* The utilization of a service response message and its format is outside the scope of this document.

7.3.2.9 *Lock* (Optional) — This service is used to restrict network access to all READ only attributes of all objects of this device. This service guarantees that the READ only attributes of this device are not modified over the network. There are no parameters specified for this service.

7.3.2.10 *Unlock* (Optional) — This service is used to make READ only attributes of objects of this device modifiable over the network. Not only is support of this object optional, but the degree to which it is supported is also specified by the manufacturer (i.e., only some attributes may become "unlocked"). Table 25 describes the parameters specified for this service.

Table 25 DM Object Unlock Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
Password Key	C	C	Manufacturer-Specific	Password may be specified to restrict access or to provide a manufacturer-specified security scheme.

7.3.2.11 *GetExceptionQueue* (Optional) — This service is used to read all or portions of the AlarmQueue and WarningQueue elements. Table 26 describes the parameters specified for this service.

Table 26 DM Object GetExceptionQueue Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
ExceptionType	M	C**, =	Byte, enumerated0 = Alarm1 = Warning	Used to indicate which exception queue is being queried.
ElementNumb	M	M	unsigned integer < 65,536	Used to indicate the number of Exception queue events to be returned with the service response. A zero value implies that all elements in the queue should be returned.
ExceptionList	—	M	List of elements; element data type. Dependent on the Reporting Mode (Basic or Expanded — See Sections 7.3.1.12, 7.3.1.19, 7.3.1.20, and 7.3.3).	An array of exception queue events of size ElemNumb returned with the response.
Clear	M	C	Boolean	Used to indicate whether or not the exceptions are to be removed from the exception queue upon reporting.

7.3.2.12 *ClearExceptionQueue* (Optional) — This service is used to clear all elements out of either the AlarmQueue or WarningQueue. Table 27 describes the parameters specified for this service. If the ExceptionType attribute is set to 0, 1, or 2 with the service request, the Alarm, Warning, or both queues respectively are cleared completely of their members.

Table 27 DM Object Clear ExceptionQueue Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Form*	*Description*
ExceptionType	M	C**, =	Byte, enumerated 0 = Alarm 1 = Warning 2 = Both	Used to indicate which exception queue(s) is/are to be cleared.

7.3.3 *DM Object Behavior* — The DM object behavior is illustrated in Figure 6 and in Tables 28 and 29.

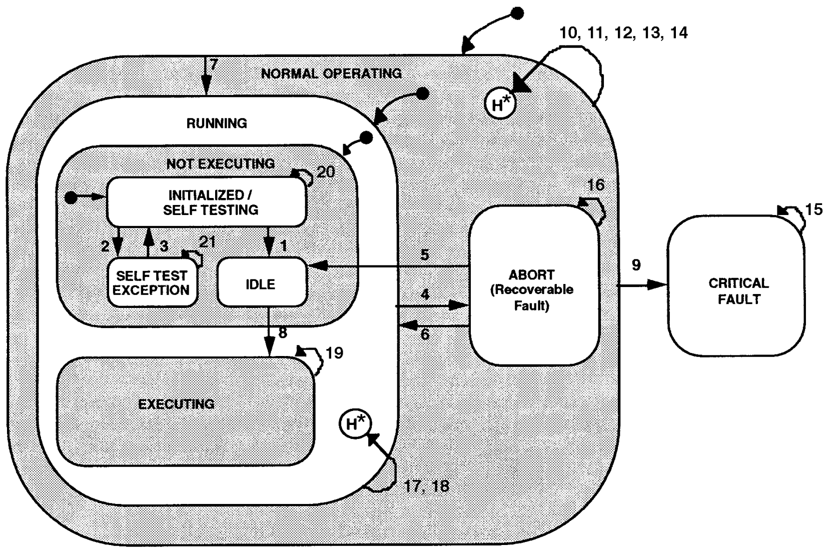

Figure 6
DM Object Instance Behavior*

*Transitions 10 through 21 are recursive (i.e., the New State is the same as the Current State (including all nested sub-states)).

Table 28 DM Instance Behavior State Description

State	*Description*
NORMAL OPERATING	Object instance exists. Object services can be processed.
RUNNING	This is the entry sub-state to NORMAL OPERATING. Object instance is not in an aborted state. Object is capable of reporting attribute values, including exceptions.
NOT EXECUTING	Device is not executing (e.g., it is not performing its device-specific function). A detailed description of this state is outside the scope of this document.
	This state may be further specified in an appropriate sensor/actuator network specific device model specification.
EXECUTING	Device is executing (e.g., it is performing its device-specific function). A detailed description of this state is outside the scope of this document.
	This state may be further specified in an appropriate sensor/actuator network specific device model specification.
INITIALIZED/SELF TESTING	This is the entry sub-state to NORMAL OPERATING and RUNNING.
	Object instance exists and has been initialized; all attributes have appropriate initial values(as indicated herein and in an appropriate sensor/actuator network specific device model specification).
	Device is performing device-specific and device type-specific tests to determine if it is qualified to be running.
	Note that as this is a sub-state of RUNNING, object is not initialized unless it is capable of reporting attribute values, including exceptions.
SELF TEST EXCEPTION	Object has detected an exception condition during self testing. The details of the exception are stored in the appropriate attribute values of the DM object.
IDLE	Object and device have been initialized and have successfully completed self testing.
ABORT	Object instance is in an aborted state; a detailed description of this state is outside the scope of this document. The object will not initiate communication over the network while in this state.
CRITICAL FAULT	The object (and device) are in a fault state from which there is no recovery. Object services cannot be processed. The conditions required for exit from a critical fault are outside the scope of this document.

Table 29 DM Instance Behavior State Transition Matrix*

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	INITIALIZED/ SELF TESTING	DM Object determines internally that the device is initialized and self test passed.	IDLE	Set Device Status attribute to appropriate value.	Device is in an idle state.
2	INITIALIZED/ SELF TESTING	One or more exceptions reported as a result of device testing.	SELF TEST EXCEPTION	Report exceptions through appropriate attribute settings in DM object. Set Device Status attribute to appropriate value.	Conditions resulting in the reporting of a self test exception are device-specific.
3	SELF TEST EXCEPTION	Exception condition cleared.	INITIALIZED/ SELF TESTING	Set Device Status attribute to appropriate value. Initiate self testing procedure from beginning.	Enter RUNNING/NOT EXECUTING/INITIALIZ ED/SELF TESTING.
4	RUNNING	Abort request.	ABORT	Abort response. Set Device Status attribute to appropriate value.	Abort request may be generated internally (e.g., as a result of Self Test catastrophic failure).
5	ABORT	Recover request; Device Status attribute value == ABORT FROM IDLE OREXECUTING.	IDLE	Recover response. Set Device Status attribute to appropriate value.	Enter IDLE state.
6	ABORT	Recover request; Device Status attribute value == ABORT FROM INITIALIZED/ SELF TESTING OR SELF TEST EXCEPTION.	INITIALIZED/S ELF TESTING	Recover response. Initiate self testing procedure from beginning. Set Device Status attribute to appropriate value.	Enter RUNNING/NOT EXECUTING/ INITIALIZED/SELF TESTING.
7	NORMAL OPERATING	Reset request.	RUNNING	Reset response. DM Object is initialized. Set Device Status attribute to appropriate value.	Valid for all sub-states of NORMAL OPERATING. Move to RUNNING/NOT EXECUTING/ INITIALIZED/SELF TESTING.
8	IDLE	Execute service request (this service request may be internally generated).	EXECUTING	Execute response. Set Device Status attribute to appropriate value.	Device is now executing.
9	NORMAL OPERATING	Critical Fault detected.	CRITICAL FAULT	The object (and device) is in a fault state from which there is no recovery. Object services generally cannot be processed.	The mechanism for exit from a critical fault is device-specific.
10	NORMAL OPERATING	GetAttribute or Set Attribute request.	NORMAL OPERATING	Get or Set Attribute appropriate response.	Valid for all sub-states of NORMAL OPERATING.
11	NORMAL OPERATING	PerformDiagnostics request.	NORMAL OPERATING	PerformDiagnostics response. Diagnostic is performed if possible. Exceptions are set within DM object as necessary.	Conditions which are deemed exceptions are device-specific.
12	NORMAL OPERATING	Lock or Unlock request.	NORMAL OPERATING	Adjust write access to READ only attributes of all device objects as appropriate. Lock or Unlock service response.	The mechanism for exit from a critical fault is device-specific.
13	NORMAL OPERATING	GetExceptionQueue or Clear Exception Queue request.	NORMAL OPERATING	GetExceptionQueue response with appropriate exception queue data. Clear appropriate	Valid for all substates of NORMAL OPERATING.

				exception queue and send service response.	
14	NORMAL OPERATING	Invalid service request.	NORMAL OPERATING	Error response to appropriate request.	Valid for all sub-states of NORMAL OPERATING.
15	CRITICAL FAULT	Any service request.	CRITICAL FAULT	none	Object services generally cannot be processed.
16	ABORT	Abort or Execute request.	ABORT	Error response.	Not valid requests in this state.
17	RUNNING	Recover request.	RUNNING	Error response.	Recover request only valid while in ABORT state.
18	RUNNING	Internally generated PublishAttribute Notification Service.	RUNNING	Attribute Identified by Attribute ID in PublishAttribute Service is Published.	Notification only occurs if specific conditions are met (see Section 7.3.3).
19	EXECUTING	Execute Request.	EXECUTING	Error response.	Not a valid request in this state.
20	INITIALIZED/ SELF TESTING	Execute service request.	INITIALIZED/ SELF TESTING	Error response.	Not a valid request in this state.
21	SELF TEST EXCEPTION	Execute service request.	SELF TEST EXCEPTION	Error response.	Not a valid request in this state.

* Transitions 10 through 21 are recursive (i.e., the New State is the same as the Current State (including all nested sub-states)).

The following also applies to DM behavior:

A DM instance service may be requested internally by the DM object.

If a SetAttribute request is received over the network for an attribute that is not network-settable, the attribute value is not changed and an error service response is generated.

When processing an Abort, Recover, or Reset service request, the DM object issues a corresponding Abort, Recover, or Reset service request to the SAC object.

While in the Abort state, the DM object will not initiate communications over the network (e.g., it will not initiate communication of exceptions over the network). It may, however, communicate over the network in response to service requests.

All DM services have the same behavior associated with invalid service requests unless otherwise indicated. Common service error responses are listed in Appendix 2.

The following identifies additional behavior associated with specific values of DM object attributes:

The Device Status attribute value indicates the state of the DM object (see Table 18). It is updated on appropriate state transitions within the DM object (see Table 29). Attribute values 1 through 6 represent valid states. A value of zero indicates that the DM state is unknown; conditions under which a zero value may occur are outside the scope of this document.

The Reporting Mode attribute determines five different conditions under which alarms and warnings are reported through communication of the Exception Status attribute (see Table 19). Both warnings and alarms have separate values within Reporting Mode. This allows alarms to be reported more aggressively than warnings because alarms are presumably more time-critical. The behavior associated with the five Reporting Mode conditions which are used for both alarms and warnings is described in the following paragraphs. Optionality indicates that the mode may or may not be supported; this optionality may be further specified in a sensor/actuator network specific device model and/or device manufacturer specification.

_ *Request* — When a bit in the status attribute transitions from cleared to set, the device will not report until requested. When the exception condition no longer exists, both the exception status bit and the specific bit in the exception detail attribute are cleared. In this mode, a device may go in and out of an exception condition without ever reporting the condition because there has been no request. The device must always respond to a request for exception conditions, regardless of Reporting Mode state.

_ Optional *RequestLatched* — When a bit in the status attribute transitions from cleared to set, the device will not report until requested. When the exception condition no longer exists, the exception status bit and the specific bit in the exception detail attribute are not cleared until they have been requested and reported. This mode guarantees that a brief occurrence of an exception condition will always be reported, barring an unrecoverable communications error. Within each exception variable, active bits will be cleared as they are reported.

_ Optional *EventTriggeredOn* — When a bit in the status attribute transitions from cleared to set, the device will automatically report the exception status attribute. When the exception condition no longer exists, both the exception status bit and the specific bit in the exception detail variable are cleared.

_ Optional *EventTriggeredOn/Off* — When a bit in the status attribute transitions from cleared to set, the device will automatically report the exception status attribute. When the exception condition no longer exists, both the exception status bit and the specific bit in the exception detail attribute are cleared, and the device will again automatically report the exception status attribute.

_ Optional *TimeTriggered* — If this mode is supported, the Exception Status Timer attribute value indicates the time interval for periodic status reporting. When the indicated time period expires, the device will automatically report the exception status attribute. When the exception condition no longer exists, both the exception status bit and the specific bit in the exception detail attribute are cleared.

_ Optional *EventOnOrTimeTriggered* — This is a logical "or" of EventTriggeredOn mode and TimeTriggered mode. When the exception condition no longer exists, both the exception status bit and the specific bit in the exception detail attribute are cleared.

_ Optional *EventOn/OffOrTimeTriggered* — This is a logical "or" of EventTriggeredOn/Off mode and Time-Triggered mode. When the exception condition no longer exists, both the exception status bit and the specific bit in the exception detail attribute are cleared.

The Reporting Mode attribute value defaults to zero upon object initialization (i.e., request mode), unless otherwise specified in an appropriate sensor/actuator network specific device model specification.

The Reporting Mode attribute is defined as network-settable; however, it is only settable to (valid) values corresponding to supported reporting modes (see Table 19, appropriate sensor/actuator network specific device model specification, and device manufacturer specification). Note that at least one reporting mode, Request, must be supported. If an attempt is made, via a Set_Attribute service request, to set the Reporting Mode attribute to an invalid value, an error service response is returned.

All exceptions are communicated through reporting the values of the Exception Status and, conditionally, the Exception Detail Alarm and Exception Detail Warning attributes. An Exception Detail attribute may only be reported if both bit 7 and the corresponding exception bit of the Exception Status variable are set to 1.

If the Reporting Mode attribute indicates a reporting mode of TimeTriggered, EventOnOrTimeTriggered, or EventOn/OffOrTimeTriggered, the time interval for reporting is the value of the Exception Status Report Interval attribute. Time zero is defined as the time at which the Reporting Mode attribute is last modified utilizing the SetAttribute service. The first report is generated at time zero (not after the first time interval). If this value of the Exception Status Report Interval attribute is zero, then time triggered exception reporting is disabled.

If the Reporting Mode attribute indicates a reporting mode of EventOnOrTimeTriggered, or EventOn/OffOrTimeTriggered, the reporting associated with the occurrence of the appropriate event and the reporting associated with the report interval are independent (e.g., the occurrence of reporting due to an event does not impact the timing associated with reporting according to a specified time interval).

The Exception Status Report Interval attribute value defaults to 0.0 seconds upon object initialization, unless otherwise specified in an appropriate sensor/actuator network specific device model specification.

Additional behavior may be provided by a DM object that is device-specific. A complete definition of this additional behavior may be found in an appropriate sensor/actuator network specific device model specification.

The PublishAttribute service would be used for automatic reporting of the DM object exception status attribute when (1) an exception exists, (2) an automatic reporting mode is indicated by the Reporting Mode attribute (see Section 7.3.1), and (3) the indicated reporting mode is supported by the device (in its current state).

Behavior associated with the AlarmEnable and WarningEnable attributes is as follows. If the alarm/warning attribute is TRUE or if the attribute is not supported, alarm/warning reporting behavior as described elsewhere in this section is not impacted by this attribute. If the alarm/warning attribute is set to FALSE, all alarm/warning DM exception attributes are set and maintained at values that indicate a no alarm state. Thus, bits 0 through 2 of the ExceptionStatus attribute (alarms) or bits 4 through 6 (warnings) are set and maintained at zero, and any ExceptionDetail Alarm/Warning attribute bytes are set and maintained at a value of zero. When the Alarm/WarningEnable is toggled to TRUE, the device immediately determines its alarm/warning state, updates the appropriate DM attributes as necessary, and reports any alarms/warnings according to the mode defined by the ReportingMode attribute.

Behavior associated with the (Alarm and Warning) Exception Queues (see Sections 7.3.1.21 and 7.3.1.22), if supported, is as follows: Upon device initialization (start-up) or reset, both exception queues are cleared. The data type of queue elements is determined by the value of bit 7 of the status attribute (as explained in Section 7.3.1.21). As alarm events are issued to the DM object, the appropriate exception parameters are set (ExceptionStatus and ExceptionDetailAlarm/Warning) and the events are also logged onto the appropriate Alarm or Warning Exception Queue on a first-in, first-out basis. Any alarm or warning clear events are also logged onto these queues in the same manner; these events are logged in the same data format as the exception, but with the data value indicating that the exception no longer exists. The maximum number of elements that are retained by the queue is application-specific. Once the maximum queue length is reached, new exception events depose the oldest exception event from the queue in a first-in, first-out fashion (similar to a shift register). The GetExceptionQueue service may be used to retrieve any number or all exception events from either (alarm or warning exception) queue. If the value of the Clear attribute is TRUE, retrieved events are deposed from the queue; otherwise, they are left in the queue.

Behavior associated with the optional “Date and Time” attribute is as follows. This attribute indicates the current date and time as perceived by the device whenever it is reported. The resolution of the “Time of Day” reported shall be milliseconds unless the “Date and Time Type” attribute is supported and it indicates a resolution other than milliseconds.

7.4 *Sensor, Actuator, and Controller Objects* — The Sensor (S), Actuator (A), and Controller (C) objects are the model components that model the high level sensory, actuation, and/or control element capabilities of the device as viewed from the network. Although the structure and behavior of these elements can vary widely from device to device, there are common aspects of structure and behavior that can be identified. Specifically, there are structure and behavior characteristics common to all active elements (i.e., all S, A, and C objects), common to all elements of an element type (i.e., all S objects, A objects, or C objects), or common to all elements of an element sub-type (e.g., all analog input sensor objects). This commonality of structure and behavior among these object types is depicted in the class generalization hierarchy of Figure 7. With this generalization hierarchy in place, objects inherit structure and behavior from their parent object classes, thus reducing the level of redundancy in description. For example, object instances of the Sensor-AI class inherit (i.e., also have) the attributes, services, and behavior of the Sensor and Active Element parent classes.

Note that the only classes from which accessible object instances can be created in this hierarchy exist at the lowest level (i.e., Sensor-AI, Sensor-BI, Actuator-AO, Actuator-BO, and Controller objects). Also note that the object identifiers for these object instances are designated as indicated in Table 1 (e.g., a Sensor-AI object instance has an Object Identifier of SenI’n’, where ‘n’ is the instance number of the sensor object for the device).

In the following sub-sections, the attributes, services, and behavior at each level of the active element class generalization hierarchy are identified and defined. Note that the specific device model would complete the definition of each sensor, actuator, and controller element of a specific device type through definition of additional structure and behavior for the S, A, and C object instances that collectively realize the sensory/ actuation/control capability portion of the device model.

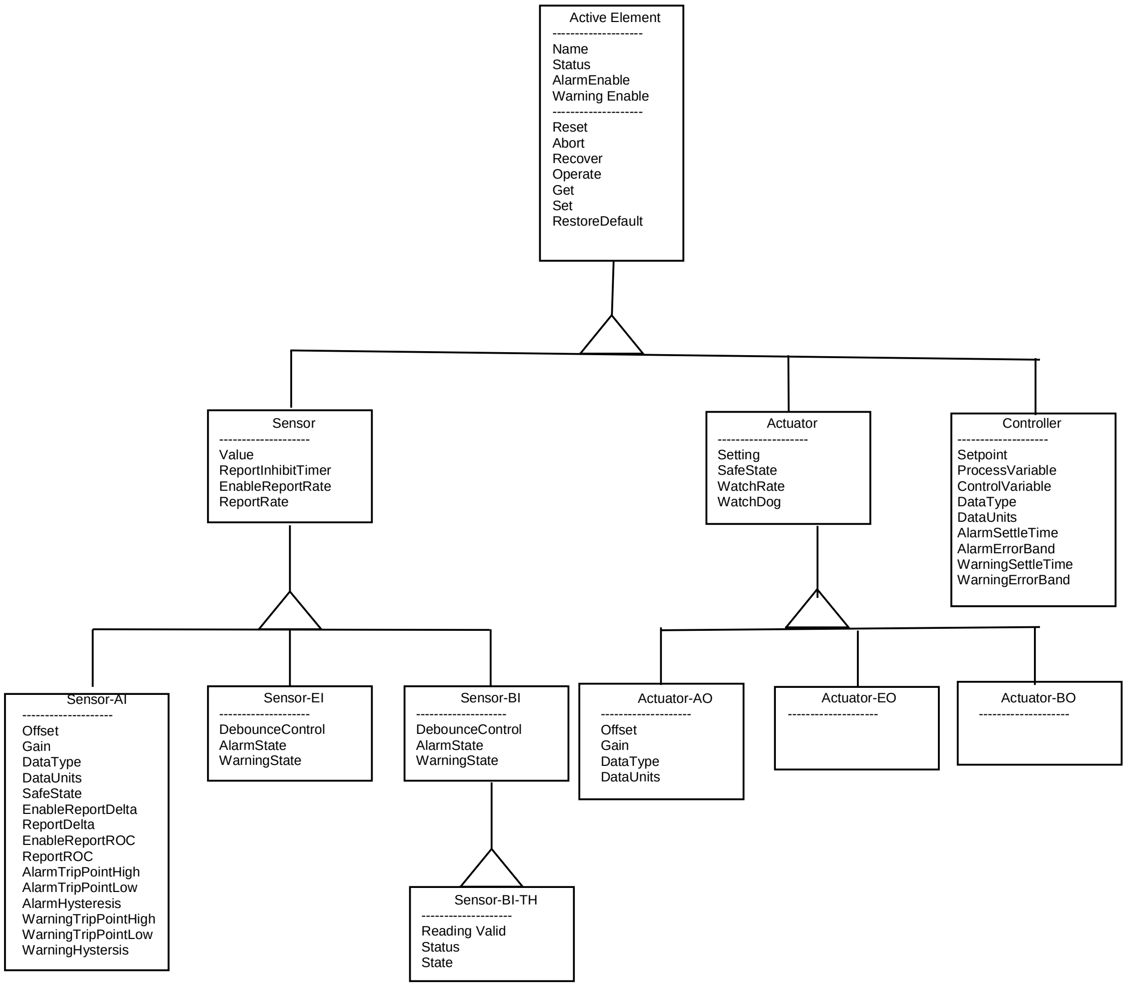

Figure 7
Active Element Class Generalization Hierarchy

7.4.1 *Active Element (AE) Class* — The AE class at the top of the active element generalization hierarchy contains structure and behavior common to all active element instances in a device.

7.4.1.1 *Active Element Class Attributes* — All required and "common optional" AE class attributes are listed in Table 30 and described below. For an explanation of the table format, see Section 7.3.1.

Table 30 AE Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Name	nA1**	RO	N	Text, 16 characters maximum
Status	nA2	RO	Y	Context-specific
AlarmEnable	nA3	RW	N	Boolean
WarningEnable	nA4***	RW	N	Boolean

* A "Definition" column is not included. For attribute definitions, see text.

** Where 'n' is the type of the object instance to which the particular attribute is associated (e.g., Sai, Sbi, Aao, Ado, or C), see Sections 7.4.4 through 7.4.8.

*** ID's nA5 through nA15 are reserved for future AE class attribute definition.

7.4.1.1.1 *Name* — A label used to identify the active element associated with the object instance.

7.4.1.1.2 *Status* — An indication of the state of the active element associated with the object instance. The form and interpretation of the value of this attribute is context-specific.

7.4.1.1.3 *AlarmEnable* — An attribute which specifies whether alarm exception conditions of the active element associated with the object instance are to be reported. Reporting is enabled if this variable is set to TRUE. The method of reporting is beyond the scope of this document.

7.4.1.1.4 *WarningEnable* — An attribute which specifies whether warning exception conditions of the active element associated with the object instance are to be reported. Reporting is enabled if this variable is set to TRUE. The method of reporting is beyond the scope of this document.

7.4.1.2 *Active Element Class Services* — All Active Element common services are listed in Table 31 (the specific AE object is the "service provider" of these services). Note that all of these services are Request services. Service parameters that are specified in this standard are summarized in Table 32.

Table 31 AE Class Service Resource Definition

Service	*Service ID*	*Type*	*Description*
Reset	nS1*	R	Used to place object in INITIALIZED state.
Abort	nS2	R	Used to place object in ABORT state.
Recover	nS3	R	Used to move object from ABORT state to RECOVERED state.
Operate	nS4	R	Used to move object to the operating state from INITIALIZING, or RECOVERING state.
GetAttribute	nS5	R	Used to read object attribute.
SetAttribute	nS6	R	Used to modify object attribute.
RestoreDefault	nS7**	R	Used to restore object attributes to their default values.

* Where 'n' is the type of the object instance to which the particular service is associated (e.g., Sai, Sbi, Aao, Ado, or C), see Sections 7.4.4 through 7.4.8.

** ID's nS8 through nS15 are reserved for future AE class service definition.

Table 32 AE Class Service Parameter Dictionary

Parameter	*Form*	*Description*
AttributeID	Positive Integer	Object instance Attribute Identifier.
AttributeValue	Context-specific	Value of object instance attribute.
RestoreConditions	Byte enumerated	Level of restore requested.

A detailed description of these services follows:

7.4.1.2.1 *Reset* — Used to place the object instance in its INITIALIZED state. There are no parameters specified for this service.

7.4.1.2.2 *Abort* — Used to place the object instance in its ABORT state. There are no parameters specified for this service.

7.4.1.2.3 *Recover* — Used to move the object instance from its ABORT state to a RECOVERED state. There are no parameters specified for this service.

7.4.1.2.4 *Operate* — Used to move the object instance to the OPERATING state from the INITIALIZING or RECOVERING state. There are no parameters specified for this service.

7.4.1.2.5 *GetAttribute* — Used to read a value of an object instance attribute over the network. The following table describes the parameters specified for this service.

GetAttribute Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf*	*Form*	*Description*
AttributeID	M	C**, =	Network-Specific	Attribute Identifier of attribute whose value is being requested. Inclusion of attribute in Rsp/Conf. is optional.
AttributeValue	-	M	Context-Specific	Value of attribute requested.

* See Section 6.4.3 for further description of terminology used in this table.

** The determination of whether Attribute ID is supplied in the service response/confirm is outside the scope of this document.

7.4.1.2.6 *SetAttribute* — Used to modify the value of an object instance attribute over the network which has been identified as modifiable. The following table describes the parameters specified for this service.

SetAttribute Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf*	*Form*	*Description*
AttributeID	M	C, =	Network-Specific	Attribute Identifier of attribute whose value is to be modified. Inclusion of Attribute in Rsp/Conf. is optional.
AttributeValue	M	C	Context-Specific	Value to which the attribute is to be modified. Inclusion of Attribute in Rsp/Conf. is optional. Conditions under which the value may differ from that supplied in the associated Req/Ind. message (e.g., negative response) are not defined in this document.

* See Section 6.4.3 for further description of terminology used in this table.

7.4.1.2.7 *RestoreDefault* — Used to restore attributes of this object instance to their default values. The following table describes the parameters specified for this service.

RestoreDefault Service Message Definition Table*

Parameter	*Req/Ind*	*Rsp/Conf*	*Form*	*Description*
Restore Conditions	M	C	byte, enumerated	0 = Restore specific attribute of this object 1 = Restore all attributes of this object 2 – 63 = Reserved 64 – 255 = Application-Defined
AttributeID	C	C	Network-Specific	Attribute ID of the attribute whose value is being restored.

* See Section 6.4.3 for further description of terminology used in this table.

7.4.1.3 *Active Element Class Behavior* — The AE class behavior is illustrated in Figure 8. Associated states and state transitions are described in Tables 33 and 34. The following also applies to AE class behavior:

An AE class service may be requested internally by the AE object instance.

Note that the behavior associated with the Reset, Abort, Recover, Operate, and Restore Default services differs from the SAC object instance behavior in that no service requests are necessarily issued to any other object instances.

Upon instantiation or upon receipt of a reset request, an AE object instance responds by entering or staying in its INITIALIZED state.

The object INITIALIZING application process is described as follows: When a request to initialize is received (e.g., through a Reset service request), all object instance attributes are restored to their initial value; the interpretation of these values and how they are stored/retrieved is beyond the scope of this document. The object performs any manufacturer-specified self tests and diagnostics to determine if it is qualified to enter the OPERATING state. Upon completion of these tests, the appropriate Pass or Fail service response is reported to the requesting object instance. The content, format, and protocol of this service response are specified by the network for requests made over the network.

Upon receipt of an abort request, an AE object instance responds by entering or staying in its ABORT state.

Upon receipt of a recover request, an AE object instance responds by transitioning to its RECOVERED state if, and only if, it is currently in its ABORT state. Otherwise, it responds with an error indication.

The object RECOVERING application process is described as follows: Upon receipt of a Recover service request, the object performs any manufacturer-specified self tests and diagnostics to determine if it is qualified to enter the OPERATING state.

Upon completion, the appropriate Pass or Fail service response is reported to the requesting object instance. The content, format, and protocol of this service response are specified by the network for requests made over the network.

The AlarmEnable attribute determines whether or not alarms are reported through the ExceptionStatus and ExceptionDetail attributes of the DM object (see Section 7.3). If the AlarmEnable attribute is set to the enabled state, then any alarm is reported to the DM object instance upon its occurrence. The WarningEnable attribute works analogously with respect to reporting a warning.

Additional behavior may be exhibited by an AE object instance that is defined elsewhere in its class generalization hierarchy, or is device-specific. A complete definition of AE object type instance behavior includes the appropriate sensor/actuator network specific device model specification.

Behavior associated with receipt of an invalid service request identified in this document applies to all services required for this class. Unless otherwise specified (e.g., in an appropriate sensor/actuator network specific device model specification), behavior associated with the receipt of an invalid service request for additional services defined (elsewhere) for this class shall be the same as that for required services.

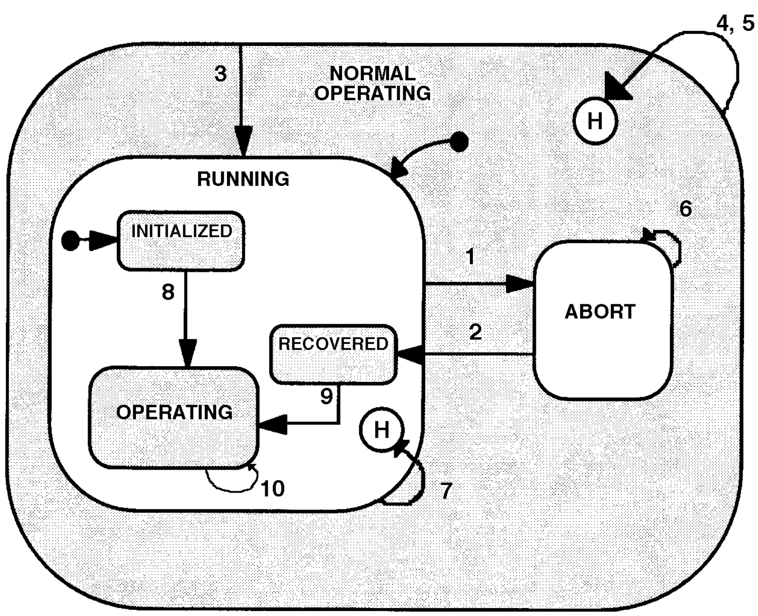

Figure 8
AE Class Behavior

NOTE: Only generic behavior is indicated in this chart. A complete state chart necessarily requires the inclusion of device-specific behavior.

Table 33 AE Class Behavior State Description

State	*Description*
NORMAL OPERATING	Object instance exists. Object services can be processed.
RUNNING	This is the entry sub-state to NORMAL OPERATING. Object instance is not in its ABORT state.
INITIALIZED	This is the entry sub-state to NORMAL OPERATING and RUNNING. Object instance exists and has been initialized. All attributes set to appropriate initial values (as indicated in an appropriate sensor/actuator network specific device model specification).
RECOVERED	Object instance is in an abort recovered state.
OPERATING	This represents the entire collection of sub-states within RUNNING except INITIALIZED and RECOVERED. The further delineation of this sub-state and transition into this sub-state is outside the scope of this document.
ABORT	Object instance is in an aborted state and is not running any application process; a detailed description of this state is outside the scope of this document.

Table 34 AE Class Behavior State Transition Matrix*

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	RUNNING	Abort request.	ABORT	Abort. Abort response.	ABORT state is device-specific.
2	ABORT	Recover request.	RECOVERED	Recover. Recover response.	RECOVERED state is device-specific.
3	NORMAL OPERATING	Reset request.	RUNNING	Reset. Reset response.	Valid for all sub-states of NORMAL OPERATING. Move to RUNNING/ INITIALIZED.
4	NORMAL OPERATING	GetAttribute, SetAttribute, RestoreDefault.	NORMAL OPERATING	Get Attribute, Set Attribute, Restore Defaults. Appropriate Response.	Valid for all sub-states of NORMAL OPERATING.
5	NORMAL OPERATING	Invalid service request.	NORMAL OPERATING	Error response.	Valid for all substates of NORMAL OPERATING.
6	ABORT	Abort request, Operate request.	ABORT	Error response.	Invalid request in this state.
7	RUNNING	Recover request.	RUNNING	Error response.	Recover service can only be invoked while in ABORT state.
8	INITIALIZING	Operate request.	OPERATING	Device-specific.	Behavior associated with this transition may be further specified in an appropriate sensor/ actuator network specific device model specification.
9	RECOVERED	Operate request.	OPERATING	Device-specific.	Behavior associated with this transition may be further specified in an appropriate sensor/actuator network specific device model.
10	OPERATING	Operate request.	OPERATING	Operate response.	Object remains in the OPERATING state. Additional behavior associated with this transition may befurther specified in an appropriate sensor/actuator network specific device model.

* NOTE: Only generic behavior is indicated in this table.

7.4.2 *Sensor (S) Class* — The S class at the second level of the active element generalization hierarchy contains structure and behavior common to all sensing element instances in a device.

7.4.2.1 *Sensor Class Attributes* — All required and "common optional" S class attributes are listed in Table 35 and described below. For an explanation of the table format, see Section 7.3.1. Note that the S class also inherits all AE class attributes.

Table 35 S Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Value	nA16**	RO	Y	Context-Specific
ReportInhibitTimer	nA17	RW	N	Context-Specific
EnableReportRate	nA18	RW	N	Boolean
ReportRate	nA19***	RW	N	Context-Specific

* A "Definition" column is not included. For attribute definitions, see text.

** Where 'n' is the type of the object instance to which the particular attribute is associated (e.g., Sai or Sbi), see Sections 7.4.4 through 7.4.8.

*** ID's nA20 through nA63 are reserved for future S class attribute definition.

7.4.2.1.1 *Value* — The value of the sensor (associated with the object instance) that is to be conveyed. The form and content of this attribute is context-specific.

7.4.2.1.2 *ReportInhibitTimer* — An attribute which is used to identify the absolute minimal time interval (i.e., maximum rate) for reporting the attribute "Value"; expressed in seconds. A value of zero indicates that there is no minimal time interval.

7.4.2.1.3 *EnableReportRate* — An attribute which enables the reporting of the attribute "Value" based on the "ReportingRate" attribute value; a value of TRUE signifies that the reporting at the "ReportingRate" is enabled.

7.4.2.1.4 *ReportRate* — An attribute which defines the time interval at which the attribute "Value" will be reported; expressed in seconds.

7.4.2.2 *Sensor Class Service*s — No S class common services are defined. Note that the S class inherits all AE class services.

7.4.2.3 *Sensor Class Behavior* — The following applies to S class behavior:

Some form of measurement or other sensory activity is made by the active sensory element. This measurement is converted into the appropriate data and becomes the value of the "Value" attribute. The method of conversion is beyond the scope of this document.

No other S class common behavior is defined. Note that the S class inherits all AE class-defined behavior.

7.4.3 *Actuator (A) Class* — The A class at the second level of the active element generalization hierarchy contains structure and behavior common to all actuator element instances in a device.

7.4.3.1 *Actuator Class Attributes* — All required and "common optional" A class attributes are listed in Table 36 and described below. For an explanation of the table format, see Section 7.3.1. Note that the A class also inherits all AE class attributes.

Table 36 A Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Setting	nA16**	RW	Y	Context-Specific
SafeState	nA17	RW	N	Context-Specific
WatchRate	nA18	RW	N	Unsigned Integer < 65,536
WatchDog	nA19***	RW	N	Boolean

* A "Definition" column is not included. For attribute definitions, see text.

** Where 'n' is the type of the object instance to which the particular attribute is associated (e.g., Aao or Ado), see Sections 7.4.4 through 7.4.8.

*** ID's nA20 through nA63 are reserved for future A class attribute definition.

7.4.3.1.1 *Setting* — Specifies the value that is to be actuated by the actuator associated with the object instance. The form and content of this attribute is context-specific.

7.4.3.1.2 *SafeState* — Specifies the state in which the actuator will be placed for ABORT and INITIALIZING states. Unless otherwise specified, this attribute is a Boolean type corresponding to Zero (or "no output") or One (or "full output").

7.4.3.1.3 *WatchRate* — Specifies the rate at which the "Setting" attribute is to be refreshed (i.e., set externally). If the "Setting" attribute is not refreshed at this rate, it reverts to its default value; expressed in (integer/100) hertz.

7.4.3.1.4 *WatchDog* — Enables or disables the capability of setting the "Setting" attribute to its default value due to a refresh rate lower than specified by the "WatchRate" attribute value; a value of TRUE signifies that the WatchRate functionality is enabled.

7.4.3.2 *Actuator Class Services* — No A class common services are defined. Note that the A class inherits all AE class services.

7.4.3.3 *Actuator Class Behavior* — The following applies to A class behavior:

Some form of actuation activity is made by the active actuation element. The value of the "Setting" attribute is converted into the appropriate signal to cause the desired actuation.

A class-defined behavior associated with the "WatchRate" and "WatchDog" attributes is defined in Section 7.4.3.1 (above). No other A class common behavior is defined. Note that the A class inherits all AE class-defined behavior.

7.4.4 *Controller (C) Class* — The C class at the second level of the active element generalization hierarchy contains structure and behavior common to all controller element instances in a device. Note that, as discussed in Section 7.4, since this is the lowest level of class description in the generalization hierarchy for this device type (see Figure 7), object instances can be created as instances of this class type.

7.4.4.1 *Controller Class Attributes* — All required and "common optional" C class attributes are listed in Table 37 and described below. For an explanation of the table format, see Section 7.3.1. Note that the C class also inherits all AE class attributes.

Table 37 C Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Setpoint	CA16	RW	Y	Context-Specific
ProcessVariable	CA17	RW	N	Context-Specific
ControlVariable	CA18	RW	N	Context-Specific
DataType	CA19	RW	N	Context-Specific
AlarmSettleTime	CA21	RW	N	Context-Specific
AlarmErrorBand	CA22	RW	N	Context-Specific
WarningSettleTime	CA24	RW	N	Context-Specific
WarningErrorBand	CA25	RW	N	Context-Specific

* A "Definition" column is not included. For attribute definitions, see text.

** ID's CA27 through CA63 are reserved for future C class attribute definition.

7.4.4.1.1 *Setpoint* — This attribute specifies the value to which the Process Variable will be controlled via the Control Variable. This is one of the inputs of a classic single-stage closed-loop controller. The setpoint attribute value is expressed in units identified by the "DataUnits" attribute.

7.4.4.1.2 *ProcessVariable* — This attribute value is the measurement of the process being controlled. This is one of the inputs of a classic single-stage closed-loop controller.

7.4.4.1.3 *ControlVariable* — This attribute value is the control signal being sent to the process controlling element. This is the output of a classic single-stage closed-loop controller.

7.4.4.1.4 *DataType* — An attribute which defines the format of the data associated with "Value" attribute (inherited) of the object instance.

7.4.4.1.5 *DataUnits* — An attribute which defines the current units associated with "Value" attribute (inherited) of the object instance.

7.4.4.1.6 *AlarmSettleTime* — An attribute which specifies a time used in the determination of a Controller object instance alarm exception condition. This value is expressed in units of seconds. The minimum allowable value for this attribute is specified by the manufacturer. An out-of-range error will result from an attempt to set this attribute to a value lower than that specified as the minimum allowable.

7.4.4.1.7 *AlarmErrorBand* — An attribute which specifies an amount by which the process variable may not equal the setpoint used in the determination of a Controller object instance alarm exception condition. This value is expressed in units identified by the "DataUnits" attribute and in a format specified by the "DataType" attribute.

7.4.4.1.8 *WarningSettleTime* — An attribute which specifies a time used in the determination of a Controller object instance warning exception condition. This value is expressed in units of seconds. The minimum allowable value for this attribute is specified by the manufacturer. An out-of-range error will result from an attempt to set this attribute to a value lower than that specified as the minimum allowable.

7.4.4.1.9 *WarningErrorBand* — An attribute which specifies an amount by which the process variable may not equal the setpoint used in the determination of a Controller object instance warning exception condition. This value is expressed in units identified by the "DataUnits" attribute and in a format specified by the "DataType" attribute.

7.4.4.2 *Controller Class Services* — No C class common services are defined. Note that the C class inherits all AE class services.

7.4.4.3 *Controller Class Behavior* — The following applies to C class behavior:

The controller element uses the value of the Process-Variable and Setpoint attributes and determines the error signal. It then adjusts the ControlVariable attribute value as necessary and appropriate to minimize this error signal. The method of, and conditions for, adjustment are beyond the scope of this document.

Note that the C class inherits all AE class-defined behavior.

7.4.5 *Sensor-Analog Input (SAI) Class* — The SAI class at the third level of the active element generalization hierarchy contains structure and behavior common to all analog input sensor element instances in a device. Note that, as discussed in Section 7.4, since this is the lowest level of class description in the generalization hierarchy for this device element type (see Figure 7), object instances can be created as instances of this class type.

7.4.5.1 *Sensor-Analog Input Class Attributes* — All required and "common optional" SAI class attributes are listed in Table 38 and described below. For an explanation of the table format, see Section 7.3.1. Note that the SAI class also inherits all AE and S class attributes.

Table 38 SAI Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Offset	SaiA64	RW	N	Context-Specific
Gain	SaiA65	RW	N	Context-Specific
DataType	SaiA66	RW	N	Context-Specific
DataUnits	SaiA67	RW	N	Context-Specific
SafeState	SaiA68	RW	N	Enumerated Byte
EnableReportDelta	SaiA69	RW	N	Boolean
ReportDelta	SaiA70	RW	N	Context-Specific
EnableReportROC	SaiA71	RW	N	Boolean
ReportROC	SaiA72	RW	N	Context-Specific
AlarmTripPointHigh	SaiA73	RW	N	Context-Specific
AlarmTripPointLow	SaiA74	RW	N	Context-Specific
AlarmHystersis	SaiA75	RW	N	Context-Specific
WarningTripPointHigh	SaiA76	RW	N	Context-Specific
WarningTripPointLow	SaiA77	RW	N	Context-Specific
WarningHystersis	SaiA78**	RW	N	Context-Specific

* A "Definition" column is not included. For attribute definitions, see text.

** ID's SaiA78 through SaiA127 are reserved for future Sai class attribute definition.

7.4.5.1.1 *Offset* — An attribute which specifies the amount of offset correction being applied to derive the value of the “Value” attribute (inherited) of the object instance. It is expressed in terms of the units specified by the “DataUnits” attribute.

7.4.5.1.2 *Gain* — An attribute which is used to define the range of the “Value” attribute (inherited) of the object instance. The method of conveying this range with this attribute is beyond the scope of this document.

7.4.5.1.3 *DataType* — An attribute which defines the format of the data associated with “Value” attribute (inherited) of the object instance.

7.4.5.1.4 *DataUnits* — An attribute which defines the current units associated with “Value” attribute (inherited) of the object instance.

7.4.5.1.5 *SafeState* — An attribute which defines the Value (inherited attribute) to be reported by the object instance when it is in a non-OPERATING state. The enumeration of the SafeState attribute is given in Table 39.

Table 39 SafeState Attribute Values

Attribute Value	*DM Object State*
0	Zero
1	Full-Scale
2	LVV
3	Undefined
4 – 63	Reserved
64 – 255	Open

7.4.5.1.6 *EnableReportDelta* — An attribute which enables the reporting of the attribute “Value” based on the “ReportDelta” attribute value (see below); a value of TRUE signifies that reporting using the “ReportDelta” method is enabled.

7.4.5.1.7 *ReportDelta* — The value of this attribute indicates the amount by which the sensor value (indicated by the “Value” attribute (inherited)) must change before it is published. When the value of the EnableReportDelta attribute indicates that this method of reporting is “enabled”, and when the value of the “Value” attribute changes by an amount in excess of the amount indicated by the ReportDelta attribute value, the object will publish the Value attribute.

7.4.5.1.8 *EnableReportROC* — The Enable ReportROC (rate of change) attribute enables the reporting of the attribute “Value” based on the “ReportROC” attribute value (see below); a value of TRUE signifies that reporting using the rate of change method is enabled.

7.4.5.1.9 *ReportROC* — The value of this attribute indicates the rate by which the sensor value (indicated by the “Value” attribute (inherited)) must change before it is published. The attribute value context is DataUnits/Time; the specific context of DataUnits is defined in the DataUnits attribute, while the unit of Time is context-specific. When the value of the EnableReportDelta attribute indicates that this method of reporting is “enabled”, and when the value of the “Value” attribute changes at a rate in excess of the amount indicated by the ReportDelta attribute value, the object will publish the Value attribute.

7.4.5.1.10 *AlarmTripPointHigh* — An attribute which specifies the value above which the object instance “Value” attribute (inherited) value must be to generate an alarm status indication. The behavior associated with the generation of an alarm status indication (beyond that described in Section 7.4.1.3) is beyond the scope of this document.

7.4.5.1.11 *AlarmTripPointLow* — An attribute which specifies the value below which the object instance “Value” attribute (inherited) value must be to generate an alarm status indication. The behavior associated with the generation of an alarm status indication (beyond that described in Section 7.4.1.3) is beyond the scope of this document.

7.4.5.1.12 *AlarmHysteresis* — An attribute which specifies the amount of hysteresis to be applied in the clearing of an alarm condition. For example: a Trip Point High value of 100 with a hysteresis value of 2 will result in an exception condition being set when the Value attribute exceeds 100 in the positive direction and cleared when the Value attribute exceeds 98 in the negative direction. Similarly, a Trip Point Low value of 100 with a hysteresis value of 2 will result in an exception condition being set when the Value attribute exceeds 100 in the negative direction and cleared when the Value attribute exceeds 102 in the positive direction. The behavior associated with the generation and clearing of exception conditions is beyond the scope of this document.

7.4.5.1.13 *WarningTripPointHigh* — An attribute which specifies the value above which the object instance “Value” attribute (inherited) value must be to generate a warning status indication. The behavior associated with the generation of a warning status indication is beyond the scope of this document.

7.4.5.1.14 *WarningTripPointLow* — An attribute which specifies the value below which the object instance “Value” attribute (inherited) value must be to generate a warning status indication. The behavior associated with the generation of a warning status indication is beyond the scope of this document.

7.4.5.1.15 *WarningHysteresis* — An attribute which specifies the amount of hysteresis to be applied in the clearing of an alarm condition (see Section 7.4.5.1.12). The behavior associated with the generation and clearing of exception conditions is beyond the scope of this document.

7.4.5.2 *Sensor-Analog Input Class Services* — No SAI class common services are defined. Note that the SAI class inherits all AE and S class services.

7.4.5.3 *Sensor-Analog Input Class Behavior* — No SAI class common behavior is defined. Note that the SAI class inherits all AE and S class-defined behavior.

7.4.6 *Sensor-Binary Input (SBI) Class* — The SBI class at the third level of the active element generalization hierarchy contains structure and behavior common to all binary input sensor element instances in a device. Note that, as discussed in Section 7.4, since this is the lowest level of class description in the generalization hierarchy for this device element type (see Figure 7), object instances can be created as instances of this class type.

7.4.6.1 *Sensor-Binary Input Class Attributes* — All required and "common optional" SBI class attributes are listed in Table 40 and described below. For an explanation of the table format, see Section 7.3.1. Note that the SBI class also inherits all AE and S class attributes.

Table 40 SBI Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
DebounceControl	SbiA64	RW	N	Context-specific
AlarmState	SbiA65	RW	N	Boolean
WarningState	SbiA66**	RW	N	Boolean

* A "Definition" column is not included. For attribute definitions, see text.

** ID's Sbi67 through SbiA127 are reserved for future Sbi class attribute definition.

7.4.6.1.1 *DebounceControl* — This attribute is used to control sensitivity to 'false' transitions. The method of utilization of this attribute for debounce control is application-specific.

7.4.6.1.2 *AlarmState* — The value of the Value attribute (i.e., TRUE or FALSE) that will cause an alarm condition.

7.4.6.1.3 *WarningState* — The value of the Value attribute (i.e., TRUE or FALSE) that will cause a warning condition.

7.4.6.2 *Sensor-Binary Input Class Services* — No SBI class common services are defined. Note that the SBI class inherits all AE and S class services.

7.4.6.3 *Sensor-Binary Input Class Behavior* — No SBI class common behavior is defined. Note that the SBI class inherits all AE and S class-defined behavior.

7.4.6.4 *Sensor-Enumerated Input Class Services* — No SEI class common services are defined. Note that the SEI class inherits all AE and S class services.

7.4.6.5 *Sensor-Enumerated Input Class Attributes* — All required and "common optional" SEI class attributes are listed in Table 41 and described below. For an explanation of the table format, see Section 7.3.1. Note that the SEI class also inherits all AE and S class attributes.

Table 41 SEI Class Attributes*

Attribute Name	*Attribute Identifier*	*Access Network*	*Rqmt*	*Form*
DebounceControl	SeiA64	RW	N	Context-Specific
AlarmState	SeiA65	RW	N	Enumerated
WarningState	SeiA66	RW	N	Enumerated

* A "Definition" column is not included. For attribute definitions, see text.

7.4.6.5.1 *DebounceControl* — This attribute is used to control sensitivity to 'false' transitions. The method of utilization of this attribute for debounce control is application-specific.

7.4.6.5.2 *AlarmState* — The value of the Value attribute that will cause an alarm condition.

7.4.6.5.3 *WarningState* — The value of the Value attribute that will cause a warning condition.

7.4.7 *Actuator-Analog Output (AAO) Class* — The AAO class at the third level of the active element generalization hierarchy contains structure and behavior common to all analog output actuator element instances in a device. Note that, as discussed in Section 7.4, since this is the lowest level of class description in the generalization hierarchy for this device element type (see Figure 7), object instances can be created as instances of this class type.

7.4.7.1 *Actuator-Analog Output Class Attributes* — All required and "common optional" AAO class attributes are listed in Table 42 and described below. For an explanation of the table format, see Section 7.3.1. Note that the AAO class also inherits all AE and A class attributes.

Table 42 AAO Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Offset	AaoA64	RW	N	Context-specific
Gain	AaoA65	RW	N	Context-specific
DataType	AaoA66	RW	N	Context-specific
DataUnits	AaoA67**	RW	N	Context-specific

* A "Definition" column is not included. For attribute definitions, see text.

** ID's AaoA68 through AaoA127 are reserved for future Aao class attribute definition.

7.4.7.1.1 *Offset* — An attribute which specifies the amount of offset correction being applied to derive the value of the "Value" attribute (inherited) of the object instance. It is expressed in terms of the units specified by the "DataUnits" attribute.

7.4.7.1.2 *Gain* — An attribute which is used to define the range of the "Value" attribute (inherited) of the object instance. The method of conveying this range with this attribute is beyond the scope of this document.

7.4.7.1.3 *DataType* — An attribute which defines the format of the data associated with "Value" attribute (inherited) of the object instance.

7.4.7.1.4 *DataUnits* — An attribute which defines the current units associated with "Value" attribute (inherited) of the object instance.

7.4.7.2 *Actuator-Analog Output Class Services* — No AAO class common services are defined. Note that the AAO class inherits all AE and A class services.

7.4.7.3 *Actuator-Analog Output Class Behavior* — No AAO class common behavior is defined. Note that the AAO class inherits all AE and A class-defined behavior.

7.4.8 *Actuator-Binary Output (ABO) Class* — The ABO class at the third level of the active element generalization hierarchy contains structure and behavior common to all binary output actuator element instances in a device. Note that, as discussed in Section 7.4, since this is the lowest level of class description in the generalization hierarchy for this device element type (see Figure 7), object instances can be created as instances of this class type.

7.4.8.1 *Actuator-Binary Output Class Attributes* — No ABO class common attributes are defined. Note that the ABO class inherits all AE and A class attributes.

7.4.8.2 *Actuator-Binary Output Class Services* — No ABO class common services are defined. Note that the ABO class inherits all AE and A class services.

7.4.8.3 *Actuator-Binary Output Class Behavior* — No ABO class common behavior is defined. Note that the ABO class inherits all AE and A class-defined behavior.

7.4.9 *Actuator-Enumerated Output (AEO) Class* — The AEO class at the third level of the active element generalization hierarchy contains structure and behavior common to all Enumerated output actuator element instances in a device. Note that, as discussed in Section 7.4, since this is the lowest level of class description in the generalization hierarchy for this device element type (see Figure 7), object instances can be created as instances of this class type.

7.4.9.1 *Actuator-Enumerated Output Class Attributes* — No AEO class common attributes are defined. Note that the AEO class inherits all AE and A class attributes.

7.4.9.2 *Actuator-Enumerated Output Class Services* — No AEO class common services are defined. Note that the AEO class inherits all AE and A class services.

7.4.9.3 *Actuator-Enumerated Output Class Behavior* — No AEO class common behavior is defined. Note that the AEO class inherits all AE and A class-defined behavior.

7.4.10 *Sensor-Binary Input-Threshold (SBITH) Class* — The SBITH class at the fourth level of the active element generalization hierarchy contains structure and behavior common to all binary input threshold sensor element instances in a device.

7.4.10.1 *Sensor-Binary Input Threshold Class Attributes* — All required and "common optional" SBITH class attributes are listed in Table 43 and described below. For an explanation of the table format see Section 7.3.1. Note that the SBITH class also inherits all AE, S, an SBI class attributes.

Table 43 SBITH Class Attributes*

Attribute Name	*Attribute Identifier*	*Access (Network)*	*Rqmt*	*Form*
Reading Valid	SbithA64	R	N	Enumerated, Byte
State	SbithA65	R	N	Enumerated, Byte
Status	SbithA66	R	N	Enumerated, Byte

* A "Definition" column is not included. For attribute definitions, see text.

** ID's Sbith67 through Sbith127 are reserved for future Sbith class attribute definition.

7.4.10.1.1 *Reading Valid* — This attribute is used to specify the validity of the "*Value*" attribute of the SBITH object. The method of utilization of this attribute is application specific.

7.4.10.1.2 *State* — This attribute is used to record the current state of the SBITH object. The method of utilization of this attribute is application specific.

7.4.10.1.3 *Status* — This attribute is used to record the current active reporting status of the SBITH object. The method of utilization of this attribute is application specific.

7.4.10.2 *Sensor-Binary Input-Threshold Class Services* — No SBITH class common services are defined. Note that the SBITH class inherits all AE, S, and SBI class services.

7.4.10.3 *Sensor-Binary Input-Threshold Class Behavior* — No SBITH class common behavior is defined. Note that the SBITH class inherits all AE, S, and SBI class behavior.

APPENDIX 1
DATA UNIT ENUMERATION

NOTE: This appendix was approved as an official part of SEMI E54.1 by full letter ballot procedure.

The Data Units data type term is defined in Section 5.2. The following is a partial enumeration of that data type; further enumeration may be provided in an application-specific context.

Table A1-1 General

Data Units	*Description*
0	Counts
1	Counts per Second
2	Counts per Millisecond
3	Counts per Microsecond
4	Counts per Minute
5	Counts per Hour
6	Counts per Day
7	Percent
8–191	Reserved
192–255	Open

Group 1 — Time and Frequency (256–511)

Table A1-2 Time and Frequency

Data Units	*Description*
256	Seconds
257	Milliseconds
258	Microseconds
259	Minutes
260	Hours
261	Days
262	Hertz
263	KiloHertz
264	MegaHertz
265	GigaHertz
266–447	Reserved
448–511	Open

Group 2 — Temperature (512–767)

Table A1-3 Temperature

Data Units	*Description*
512	Centigrade/Celsius
513	Fahrenheit
514	Kelvin
515–703	Reserved
704–767	Open

Group 3 — Pressure (768–1023)

Table A1-4 Pressure

Data Units	*Description*
768	PSI
769	Torr
770	MilliTorr
771	mm Hg (0°C)
772	inches Hg (0°C)
773	cm H_2O (25°C)
774	inches H_2O (25°C)
775	Bar
776	MilliBar
777	Pascal
778	KiloPascal
779	Atmosphere
780–959	Reserved
960–1023	Open

Group 4 — Flow (1024–1279)

Table A1-5 Flow

Data Units	*Description*
1024	SCCM
1025	SLM
1026	CFM
1027	Pa-m^3/s
1028–1215	Reserved
1216–1279	Open

Group 5 — Electrical (1280–1535)

Table A1-6 Electrical

Data Units	*Description*
1280	Volts
1281	MilliVolts
1282	MicroVolts
1283	NanoVolts
1284	PicoVolts
1285	FemtoVolts
1286	KiloVolts
1287	MegaVolts
1288	GigaVolts
1290	Amps
1291	MilliAmps

1292	MicroAmps
1293	NanoAmps
1294	PicoAmps
1295	FemtoAmps
1296	KiloAmps
1297	MegaAmps
1298	GigaAmps
1300	Ohms
1301	MilliOhms
1302	MicroOhms
1303	NanoOhms
1304	PicoOhms
1305	FemtoOhms
1306	KiloOhms
1307	MegaOhms
1308	GigaOhms
1310	Farads
1311	MilliFarads
1312	MicroFarads
1313	NanoFarads
1314	PicoFarads
1315	FemtoFarads
1320	Henries
1321	MilliHenries
1322	MicroHenries
1323	NanoHenries
1324	PicoHenries
1325	FemtoHenries
1326–1471	Reserved
1472–1535	Open

APPENDIX 2
ERROR RESPONSES

NOTE: This appendix was approved as an official part of SEMI E54.1 by full letter ballot procedure.

The following is a listing of common service error responses. The details of presentation of these responses over the network (such as response codes) are network-specific and, thus, are not part of this document. Also, note that there may be additional service error responses delineated in the appropriate SDM specification or manufacturer specification.

A2-1 Error Responses

A2-1.1 *Resource Unavailable* — Resources needed for the object to perform the requested service are unavailable.

A2-1.2 *Service Not Supported* — The requested service is not implemented or is not defined for this Object Class/Instance.

A2-1.3 *Invalid Attribute Value* — Invalid attribute data detected.

A2-1.4 *Already in Requested Mode/State* — The object is already in the mode/state being requested by the service.

A2-1.5 *Object State Conflict* — The object cannot perform the requested service in its current mode/state.

A2-1.6 *Attribute Not Settable* — A request to modify a non-modifiable attribute was received.

A2-1.7 *Device State Conflict* — The device's current mode/state prohibits the execution of the requested service.

A2-1.8 *Service Parameter Data Not Complete* — Not enough data supplied with the service request.

A2-1.9 *Attribute Not Supported* — The attribute specified in the request is not supported.

A2-1.10 *Too Much Data for Service Parameters* — The service supplied more data than was expected.

A2-1.11 *Object Does Not Exist* — The object specified does not exist in the device.

A2-1.12 *Vendor-Specific Error* — Vendor-specific error.

A2-1.13 *Invalid Service Parameter* — A parameter associated with the request was invalid.

SEMI E54.2-0698
GUIDE FOR WRITING SENSOR/ACTUATOR NETWORK (SAN) STANDARD BALLOTS

1 Purpose

1.1 This guide recommends the method, form, and content for adding specific device models and associated Sensor Actuator Network Communications Standard (SANCS) extensions to the SEMI Sensor Actuator Network (SAN) standard. This guide facilitates consistency of these ballots, leading to better consistency and clarity of the resulting specifications and to easier development of SAN standard-conformant devices that achieve a high level of interoperability.

2 Scope

2.1 This guide provides written templates for ballots that will add either a specific device model (SDM), an SANCS ancillary standard, or SANCS extensions to support an SDM to the SEMI SAN standards. The guide provides directions for using the templates.

2.2 Physical devices will not be compliant with this guide; they will be compliant to standards which are spawned from the templates specified herein.

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E54 — Sensor/Actuator Network Standard

SEMI E54.1 — Standard for Sensor/Actuator Network Common Device Model

SEMI E54.3 — Standard for Sensor/Actuator Network Specific Device Model for Mass Flow Device

4 Terminology

4.1 Acronyms

4.1.1 *A* — Actuator (a CDM class definition)

4.1.2 *AE* — Active Element (a CDM class definition)

4.1.3 *C* — Controller (a CDM class definition)

4.1.4 *CDM* — (SEMI) Common Device Model

4.1.5 *DM* — Device Manager (a CDM class definition)

4.1.6 *ISO-OSI* — International Organization for Standardization - Open Systems Interconnect (model)

4.1.7 *NCS* — Network Communications Standard

4.1.8 *OMT* — Object Modeling Technique

4.1.9 *S* — Sensor (A CDM object)

4.1.10 *SAC* — Sensor/Actuator/Controller (a CDM class definition)

4.1.11 *SAN* — Sensor/Actuator Network (or Sensor Bus)

4.1.12 *SANCS* — Sensor/Actuator Network Communications Standard, frequently abbreviated to NCS

4.1.13 *SDM* — (SEMI) Specific Device Model

4.2 *Definitions*

4.2.1 *connection oriented* — a situation between communicating objects wherein they are connected in a mode analogous to a two-way phone conversation.

4.2.2 *specific device model (SDM)* — a model used to specify each type of device, such as a Mass Flow Controller or Thermocouple.

5 Background

The SEMI sensor bus (SAN) communications model consists of three components: a CDM, an SDM, and an SANCS (NCS). The following subsections provide a brief description of the specifications which define these components:

5.1 *Network Communications Standard Specification* — An NCS specification is required for each network technology. Each one consists of two major parts:

5.1.1 *Part 1, Enabling Protocol and CDM Object Presentation* — This part of an SANCS specification should achieve the following goals:

- provide an ISO-OSI layered specification of the protocol, specifying the protocol requirements at each layer,
- specify the object oriented communication environment, including object representation and addressing, attributes and services addressing, etc.,
- specify how CDM objects are represented and addressed to/from the network, and

- specify how AE class and subclass objects, defined in the CDM and the SDMs, are represented and addressed to/from the network.

5.1.2 *Part 2, Enabling Specific Device Models* — This part provides a mapping of SDM objects for the SANCS specification. There should be a section for each SDM which identifies specific objects that must be supported to enable the SDM and how the SDM structure fits into the protocol application layer foundation.

5.2 *Common Device Model* — Each device's functions on a network should comply with the specifications of the Common Device Model, SEMI E54.1. Three types or classes of objects may be combined to create models of real devices. The types are Active Element (AE) and its subclasses, Sensor/Actuator Controller (SAC) and its embedded objects, and the Device Manager (DM).

NOTE: The CDM specifies the relationship between these objects. It specifies some of the structure and behavior for the DM and SAC objects. The subclasses of the AE object provide capabilities which are useful to most devices.

5.3 *Specific Device Model*

5.3.1 Specific Device Models are defined in the SEMI SAN SDM (SEMI E54.3). Each SDM is added as a separate new section (similar to the way a new section is added to SEMI E5 when a new stream is added).

5.3.2 The Specific Device Models (SDM's) should be a specialization of the CDM and may extend the attributes, services, and behavior of any of the Sensor, Actuator, or Controller (subclasses of the AE class) objects of which they are made. SDM's may add to the attributes, services, and behavior of the SAC object.

6 Ballot Preparation

6.1 *The Cover Letter* — All ballots are submitted with a cover letter. The cover letter sets the context for the ballot. The Ballot Cover Letter Template provides guidance to prepare the cover letter.

6.2 *Specific Device Model Ballots* — A ballot to add an ancillary specification for a new SDM should be prepared as defined in the template in the section titled Template for SDM Ballot Proposals.

SEMI E39 is the basis for the tables and figures called out in the template. Refer to SEMI E39 for clarifications on using and defining object models. General instructions for using the template are contained in the subsections of this section. Specific instructions are included within the templates.

6.2.1 Device application models should be presented using Rumbaugh's Object Modeling Technology notation for information models. (See SEMI E39 for details on using object notation for defining standards.)

6.2.2 The behavior of objects should be defined using Harel State charts, state definition tables, and state transition tables. A discussion of the notation may be found in Appendix A.5 of SEMI E30. An alternative table, Object Behavior State Transition Matrix, may be used in place of the more traditional (State) Transition Table. Cells in the Transition Matrix indicate the transition action which is taken for an event for any of the states in which it can be detected. This can be particularly useful for describing the variation in device response depending on a sub-state when the parent state detects an event.

6.2.3 The set of tables which define the device's interfaces are the only testable parts of the specification for the application models. The interface for each device model should be defined in a series of tables, as follows:

6.2.3.1 *Attribute Tables* — For each object defined as an element of a device, a table which defines its network visible attributes should be specified. Each attribute is named and tagged. Its network access type (read only or read/write) and storage class (volatile, non-volatile, or constant) are also specified. The table should also indicate which attributes have standardized values and which are device supplier reserved. The definition or description of an attribute can either be included in the table or else should immediately follow the table. The "Required" column indicates if the attribute must be supported for a device to be SDM-compliant. Use the letter "Y" to indicate yes and the letter "N" to indicate no. The form field is used to indicate the data type of the attribute, such as integer, floating point, array of characters, etc. Actual format of these data types is network-dependent.

6.2.3.2 *Optional Service Parameter Table* — If this table is included in the specification of an SDM, the parameters, which are used by the device's services, are defined in it, including the data type and length.

6.2.3.3 *Service Definition Table* — Each service and its parameters are defined in a table. If the optional parameter table is not used in the SDM specification, then the form field should be included in the service definition table.

6.3 *SANCS Ballots* — A ballot to add an ancillary specification for a new SANCS should be prepared as defined by the template in the section titled Template for Part 1 of an SANCS Ancillary Standard.

When a new SDM is added to the SAN standard, an update to Part 2 of the ancillary SANCS specifications is needed. A ballot should be prepared as defined in the template in the section titled Template for an SANCS ballot to support an SDM.

The nature of the Template for an SANCS ballot to support an SDM is that it adds SDM information to only one SANCS specification at a time. Additions and changes to support each new SDM are balloted separately for each SANCS specification.

6.3.1 *Coordination with Industry User Groups* — Most of the network technologies are supported by an industry user group or association. These groups are responsible for the assignment (i.e., mapping) of identifiers to the variables or attributes, parameters, and messages/services that will be managed by their protocol. When the SEMI SAN standards require new identifiers, they should be requested from the appropriate industry group.

6.3.1.1 *Technical Notes* — SEMI will make technical notes available, for each protocol supported by the SEMI SAN standards, that list the protocol's identifiers.

6.4 *Template Conventions*

6.4.1 Instructions or text that is meant to be replaced with ballot-specific information are included within the templates in italics. Non-italicized text and tables are intended to be included in the ballot as depicted in the template.

6.4.2 Section, figure, and table numbers specified using letters are meant to indicate structure and format. Specific numbers should be generated by the ballot author. Ballots which require adding to or modifying existing SAN standards will be edited by SEMI for consistency with the existing standard where necessary.

7 Ballot Cover Letter Template

Each ballot is accompanied by a cover letter which includes the following sections:

7.1 *Proposal* — Provide a brief description, typically one or two sentences, of the content of the ballot proposal.

7.2 *Background* — In 1–3 paragraphs, give the readers the background they need to understand the content and value of the proposed standard.

7.3 *Impact* — Use one or two paragraphs to describe how this standard affects the SEMI community.

7.4 *Ballot Description* — Describe the form of the ballot proposal. Use one or two paragraphs.

Note that SDM ballots are additions to the SEMI SAN SDM Specification (SEMI E54.3). This is a parent document which already has sections for overall purpose, scope, terminology, conventions, etc. for SDMs. Each individual SDM ballot should include only device-specific purpose, scope, and terminology. Items that are used in multiple SDMs should be balloted as updates to the SEMI E54.3 parent document.

8 Template for SDM Ballot Proposals

SEMI Document Number

Title

1 Purpose

Describe the purpose of the document. This is typically to provide a network-independent application model for the specific device - NamedDevice.

2 Scope

Describe the scope of the document.

3 Referenced Documents

List documents referenced from within this specification.

4 Terminology

Define terms used within this document. This is only for terms that are used within this document and not defined elsewhere (in the SEMI E54.3 parent document or other referenced documents).

5 NamedDevice High Level Structure

5.1 *General Description* — Describe what this device does, how it is used, etc.

5.1.1 *NamedDevice Description* — Provide a description of NamedDevice, including information model(s) in figure(s) that use a Rumbaugh OMT (see SEMI E39 Appendix A1-2) diagram.

NOTE 3: The device may actually consist of multiple devices (e.g., Mass Flow Device includes a Controller device and a Meter device), in which case multiple sections should be created - one per device.

5.1.x *General Requirements*

5.1.x.1 *Device Objects* — All objects are defined in terms of their object name and instance identifier. Identifiers for all objects described in this document are summarized in Table m.

Table m NamedDevice Device Objects

Referenced Document Section	*Object Name*	*Object Identifier*	*Minimum Instances*	*Maximum Instances*

All parameters used by the device's services can be summarized using the table (Table n). This is optional, as the parameters are further defined in association with specific objects (see 5.x.2).

Table n Parameter Definition Table

Parameter Name	*Data Type*	*Tag*	*Description*

For each Object in Table m, a section (5.x) is created as below, beginning with 5.2.

5.x *Name1 Object*

5.x.1 *Name1 Object Attributes* — Provide the object attribute information using the table (Table o) below.

Table o Object Name1 Attributes

Attribute Name	*Definition**	*Attribute Identifier*	*Network Access*	*Form*	*Storage Class*	*Required*

* The definition column can be omitted if the definitions immediately follow the table. The definitions can be provided as subsections.

Where appropriate, provide initial and default values for object attributes. This can be done as a table.

5.x.2 *Name1 Object Services* — Describe the services provided by this object using the following table (Table p) to list the services:

Table p Object Name1 Services

Service	*Service Identifier*	*Type*	*Description*

Provide a detailed description of each service, including a definition of the parameters for the service. The parameters can be defined using the following table (Table q) format:

Table q Service1 Service Parameter Definitions

Parameter	*Request/Indication*	*Response/Confirmation*	*Data Type**	*Description*

* This column can be removed if there is an overall parameter definition table (Table n) included in the specification.

5.x.3 *Name1 Object Behavior* — Describe the object states and sub-states as needed with a Harel State Diagram(s):

Figure

Harel State Diagram

Provide a state definition table as given in Table r. More than one state table could be added if a device is sufficiently complex. Put in any text needed to explain object states.

Table r Name1 Object Behavior State Descriptions

State Name	*Description*

Describe the state transitions using a table as given in Tables s or t. More than one table could be needed.

Table s Name1 Object Behavior State Transition Table

Event or Transition #	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comments*

Table t Name1 Object Behavior State Transition Matrix

Event Number	*State 1*	*State 2*	*State 3*	
			Sub A	*Sub B*
1				
2				
3				
4				

9 Template for Part 1 of an SANCS Ancillary Standard

The body of the ballot should then contain the following sections:

1 Purpose

This section contains wording describing the purpose with customization for the specific protocol. A "Background and Motivation" subsection could be included to generally describe the protocol.

2 Scope

This section contains wording describing the scope with customization for the specific protocol.

3 Limitations

This section contains wording describing the limitations customized for the specific protocol. Any limitations of CDM or SDMs support, due to the protocol, should be identified.

4 Referenced Documents

This section contains wording describing the referenced documents with additional references to protocol specification documentation and any support documentation as required for complete specification of the protocol (two subsections). A clearly defined mechanism is specified for obtaining any documentation that is not publicly available or available from SEMI.

5 Terminology

The various protocols and the CDM invariably use different terminology. A mapping is made between the CDM terminology and the terminology used in discussing the protocol. For example, a CDM Service implementation may be defined as an Action in the NCS. This terminology mapping is explicitly covered completely in the "Terminology" section. A mapping table is desirable that contains a column listing of the CDM terms in the same order as defined in the CDM document, mapped to terminology used in the NCS document. This NCS terminology and any additional terminology is defined in a subsection (e.g., Section 5.2).

6 Communication Protocol High Level Structure

A basic description of the protocol is provided in Section 6. The main purpose of Section 6 is to give the reader a general understanding of what will be specifically presented in the remainder of the subsections in Section 6.

The rest of the subsections in Section 6 should be devoted to describing the communications standard in terms of the OSI seven-layer model (one subsection for each layer) and any network management services.

Each of the OSI seven layers should be addressed and specified either directly or through reference; for each:

- If an OSI layer is not supported/defined, this is stated explicitly.
- Choices among protocol options are made, specified, and explained where appropriate. A complete summary of protocol choices specified and protocol options allowed should be summarized in a subsection of this section of the specification.

The Physical layer is specified either directly or through reference (signaling, bus arbitration, baud rate, transceivers, cabling, connectors, etc.).

The Data link layer is specified either directly or through reference (packet/frame specification and node addressing).

The Network layer is optional.

The Transport layer elements are specified either directly or through reference; message segmentation and reassembling should be supported as no message length limits are indicated in CDM or SDM's. This support should be provided as a transport layer service. Note that this functionality may alternatively be provided at the application layer by protocols unable to support it at the transport layer; if this is the case, it is explicitly stated in the description of transport layer support. Connection support would be specified here as appropriate.

The Session layer is optional.

The Presentation layer is optional.

The Application layer is specified. The document defines (explicitly or through reference) how objects are structured, identified, and addressed. Thus, it should also define how object attributes are addressed and how object request and notify services are addressed and communicated. This section also defines the application object to object communication mechanism which should include or reference a communication state model. This communication model should clearly indicate whether or not the protocol is connection oriented.

Network Management Services may be defined in a separate subsection.

7 Required Object Types

This section identifies specific objects that must be supported to enable the CDM. The document should identify how the CDM structure (Objects and relations) fits into the protocol application layer foundation. Any identifiable protocol object hierarchy should be introduced here. Specifically, the following are defined:

- The implementation of all CDM objects (DM, SAC, AE, and all subclasses) defined to the extent that these objects are defined in CDM documentation.
- Specific addressing/referencing for CDM objects (attributes, services, etc.) defined as necessary so as to specify access to CDM objects as required by the CDM standard specification. Attributes and services are further specified as necessary so that the protocol required to access specific attributes and services is fully defined. For example, a CDM service may be defined as a “new” SANCS service or mapped to an existing SANCS service (if an appropriate candidate has already been defined in the protocol specification).
- Any limitations among CDM object options are identified.
- Any additional capabilities required of, or optional for, CDM objects (e.g., attributes, services, and/or behavior) are identified.
- Any additional required objects (e.g., network management object) identified and their interaction with the CDM objects (e.g., connection management object) should be specified.

8 Protocol Compliance

This section should specify a method or reference for testing protocol compliance. It should contain in subsection 8.1 a “protocol specification sheet” that lists all protocol options that have been specified in the document or must be resolved by the user in order to achieve interoperability.

10 Template for an SANCS Ballot to Support an SDM

Section 1 Table of Contents

Request that the table of contents for the SANCS be updated to contain a pointer to the paragraphs which specify the SDM mappings which are being added by the ballot.

Section 2 <SDM> Object Mapping

Each of the subsections within this section should identify specific objects that must be supported to enable the SDM and should identify how the SDM structure (objects and relations) fits into the protocol application layer foundation.

Specifically, the following issues are addressed:

Terminology

- A mapping is made between the SDM terminology and the terminology used in discussing the protocol. This is explicitly covered in a “Terminology” section. A mapping table is desirable that contains a column listing of the SDM terms in the same order as defined in the CDM document, mapped to terminology used by the network technology.

Required Object Types

- Address implementation of all SDM objects to the extent that they are defined in SDM documentation.

- Identify and map the specific addressing/referencing for SDM object attributes, services, and parameters to the protocol. Note that, for example, this may be achieved by fully specifying a SDM service as a “new” NCS service or by mapping the service to an existing NCS service.

Protocol Compliance

- Provide methods or references (in addition to those identified in the section titled Template for Part 1 of an SANCS Ancillary Standard, Section 8) for testing protocol compliance of the SDM.

SEMI E54.3-0698
SPECIFICATION FOR SENSOR/ACTUATOR NETWORK SPECIFIC DEVICE MODEL FOR MASS FLOW DEVICE

1 Purpose

1.1 This specification is part of a suite of standards which specify the implementation of SEMI standards for the Sensor/Actuator Network. The specific purpose of this specification is to describe a network-independent application model comprised of device objects which are common to all Mass Flow Devices on a semiconductor equipment Sensor/Actuator communications network.

2 Scope

2.1 This specification specifically addresses the minimum attributes, services, and behavior a Mass Flow Controller (MFC) and Mass Flow Meter (MFM) device must support to be interoperable on the Sensor/Actuator Network.

2.2 This specification is intended to ensure a high-degree of device interoperability on the Sensor/Actuator Network, while still allowing flexibility for product differentiation and technology evolution.

2.3 The model specified in this specification is used in conjunction with the Sensor/Actuator Network Common Device Model (CDM) to completely describe the MFC or MFM as it appears from the network interface.

2.4 This specification, together with the Sensor/Actuator Network Standard, the Sensor/Actuator Network Common Device Model, and a Sensor/Actuator Network Communication Specification, form a complete interoperability specification for the MFC and MFM.

2.5 To comply with this specification, a device must implement and support, at a minimum, the required attributes, services, and behavior identified in these documents. Support for **optional** attributes, services, and behavior are not required to be compliant to this specification. Optional attributes, services, and behavior are specified in these documents to promote further device interoperability as features evolve and are adopted by more manufacturers. If optional attributes, services, and behavior are implemented for this device, they must be implemented as identified in this document.

3 Limitations

3.1 This specification is a companion to a suite of specifications which together make up the Sensor/Actuator Network Communication standard. Therefore, using portions of this specification that relate to network communications necessarily requires an understanding of the associated network specification.

3.2 As this document is a specification for the Mass Flow Device Model, it does not contain any definition of objects, attributes, services, or behavioral descriptions that are already defined in the Sensor/Actuator Network Common Device Model (CDM). Additional attributes, attribute assignments, services, and/or service parameters that are Mass Flow Device-specific and/or implementation-specific are contained in this specification.

3.3 While this specification is sufficient to completely describe the MFC or MFM as it appears from the network, it does not fully describe behavior of the MFC or MFM which is not visible from the network. This allows flexibility in implementation techniques and product differentiation between manufacturers. Manufacturer-specific objects may be defined by the manufacturer, but are, by definition, outside the scope of this standard.

3.4 This specification is compatible, but not compliant, with SEMI E39. This means that although this specification does not require compliance with SEMI E39, it is extensible such that implementations may be developed that are fully compliant with both standards. Note that the concepts and terminology of this specification are compatible with those of SEMI E39. However, SEMI E39 has specific requirements that are intended for higher level applications and, thus, are not applied to the Mass Flow Device Model.

3.5 Operation over the entire range specified for an attribute within a specific object instance is not a requisite for compliance with this specification.

4 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI E12 — Standard for Standard Pressure, Temperature, Density, and Flow Units Used in Mass Flow Meters and Mass Flow Controllers

SEMI E18 — Guideline for Temperature Specifications of the Mass Flow Controller

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E52 — Practice for Referencing Gases Used in Digital Mass Flow Controllers

SEMI E54.1 — Standard for Sensor/Actuator Network Common Device Model

4.2 *IEEE Document*[1]

IEEE 754 — Floating Point Definition

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Terminology Defined in Standard for Sensor/Actuator Network Common Device Model (SEMI E54.1)*

5.1.1 Attribute

5.1.2 Behavior

5.1.3 Byte

5.1.4 Character

5.1.5 Device

5.1.6 Device Manager (DM) Object

5.1.7 Device Model

5.1.8 Instance

5.1.9 Nibble

5.1.10 Object

5.1.11 S, A, and C Objects

5.1.12 Sensor Actuator Controller (SAC) Object

5.1.13 Service

5.1.14 State Diagram

5.2 *Definitions*

5.2.1 *boolean (BOOL)* — a binary bit representing 0 and 1 corresponding to FALSE and TRUE or DISABLE and ENABLE respectively.

5.2.2 *common device model (CDM)* — refers to Sensor/Actuator Network Common Device Model (SEMI E54.1).

5.2.3 *data type* — an unsigned short integer formatted as an enumerated byte to specify attribute data format. The intended use of this attribute type is in cases where an attribute, or set of attributes, may be defined, allowing for more than one level of support (e.g., INT or REAL). The following values are defined:

0 = INT

1 = REAL

2 = USINT

3 = SINT

4 = DINT

5 = LINT

6 = UINT

7 = UDINT

8 = ULINT

9 = LREAL

10–99 = reserved for CDM

100–199 = reserved for SDMs

200–255 = manufacturer-specified

5.2.4 *data units* — an unsigned integer formatted as an enumerated byte to specify attribute data units. The intended use of this attribute type is in cases where an attribute, or set of attributes, may be defined, allowing for more than one unit's context. The values are defined in an appendix of this document.

5.2.5 *date* — a data structure of four bytes used to represent a calendar date. Table 1 defines the format of the date data type.

Table 1 Date Format

Data #	*Description*	*Range*
0–1	Year	Unsigned Integer
2	Month	Unsigned Short Integer(range of 1 to 12)
3	Day	Unsigned Short Integer(range of 1 to 31)

5.2.6 *double integer (DINT)* — an integer, four bytes long, in the range -2^{31} to $2^{31} - 1$.

5.2.7 *enumerated byte* — a byte with assigned meaning to the values 0 through 255. May take on one of a limited set of possible values.

5.2.8 *full scale range* — the defined 100% value of an attribute in its assigned units. This value is not necessarily the maximum value for the attribute. As an example, the *indicated flow* attribute value may attain 120% of the full scale range.

1 Institute of Electrical and Electronics Engineers, Inc., 345 East 47th Street, New York, NY 10017

5.2.9 *gas calibration* — a reference to a set of parameters or methods which are used to calibrate or correct the device for a particular gas type, range, and units.

5.2.10 *gas standard number* — a number that references a gas type. The number and its referenced gas type are defined in SEMI E52.

5.2.11 *gas standard symbol* — a text symbol that references a gas type. The symbol and its referenced gas type are defined in SEMI E52.

5.2.12 *last valid value (LVV)* — the most recent value successfully assigned to an attribute.

5.2.13 *long integer (LINT)* — an integer, eight bytes long, in the range -2^{63} to $2^{63}-1$.

5.2.14 *long real (LREAL)* — a double floating point number, eight bytes long, as defined in IEEE 754.

5.2.15 *manufacturer* — in the context of this document, this refers to the manufacturer of the device.

5.2.16 *mass flow controller (MFC)* — a self-contained device, consisting of a mass flow transducer, control valve, and control and signal-processing electronics, commonly used in the semiconductor industry to measure and regulate the mass flow of gas.

5.2.17 *mass flow device (MFD)* — a device which is either a mass flow controller or mass flow meter.

5.2.18 *mass flow meter (MFM)* — a self-contained device, consisting of a mass flow transducer and signal-processing electronics, commonly used in the semiconductor industry to measure the mass flow of gas.

5.2.19 *null character* — a byte with a value of zero.

5.2.20 *programmed gas calibration* — a reference to a particular gas type, range, and units for which the device is currently calibrated.

5.2.21 real (REAL) — a floating point number, four bytes long, as defined by IEEE 754.

5.2.22 *short integer (SINT)* — an integer, one byte long, in the range -128 to 127.

5.2.23 *signed integer (INT)* — an integer, two bytes long, in the range -32768 to 32767.

5.2.24 *text string* — a string of one-byte characters. See Section 5.1 for a definition of a character.

5.2.25 *unsigned integer (UINT)* — an integer, two bytes long, in the range 0 to 65535.

5.2.26 *unsigned short integer (USINT)* — an integer, one byte long, in the range 0 to 255.

6 Requirements

6.1 In order to implement this standard in a Mass Flow Device, it is necessary to also implement SEMI E54.1 and one of the Sensor/Actuator Network Communication standards. See Section 2 for more information on a complete interoperability standard.

7 Conventions

7.1 This document embraces the Harel State Chart notation, the transition table definition format, the object attribute representation formats, service message definition formats, and behavior definition formats as specified in SEMI E54.1.

7.2 Figure 1 describes the convention for object representation used throughout this specification.

```
OBJECT NAME
-------------------------
Attributes

-------------------------
Services
```

Figure 1
Object Representation

8 Device High Level Structure

8.1 *General Description* — The high level object view of a Mass Flow Meter (MFM) device and a Mass Flow Controller (MFC) Device is shown in Figure 2.

Note that the "MFM" and the "MFC" objects are depicted in Figure 2 only for the purposes of illustrating a high level view of the device and its component objects. In the context of this document, these objects are not addressable, do not have addressable attributes, do not have accessible services, nor do they exhibit any defined behavior. These objects are only included in the figures to aid in the visualization of the device.

This document defines in detail all of the component objects unique to the MFC and the MFM devices. References, rather than definitions, are included for the DM, the SAC, and other objects defined in SEMI E54.1.

Many of the objects defined in this document inherit properties from other objects. The properties inherited include attribute, service, and behavior definitions. These other objects are specified here or in SEMI E54.1.

This document provides for future extensions, as well as manufacturer-specific enhancements, by reserving object attribute identifiers and object service identifiers. Specifically, all object definitions in this document specify or reserve the first 64 attribute identifiers (A1 through A64) and the first 64 service identifiers (S1 through S64), allowing manufacturers to specify identifiers beyond these ranges. Additionally, byte-enumerated attributes are specified or reserved from 0 to 63, allowing manufacturers to specify enumerations beyond this range (64 to 255).

8.1.1 *Mass Flow Meter (MFM) Device Description* — A Mass Flow Meter device profile is composed of the component objects and object relationships shown in Figure 2.

8.1.2 *Mass Flow Controller (MFC) Device Description* — A Mass Flow Controller device profile is composed of (1) all of the component objects and object relationships of the Mass Flow Meter Device in addition to (2) the component objects and object relationships as shown in Figure 2.

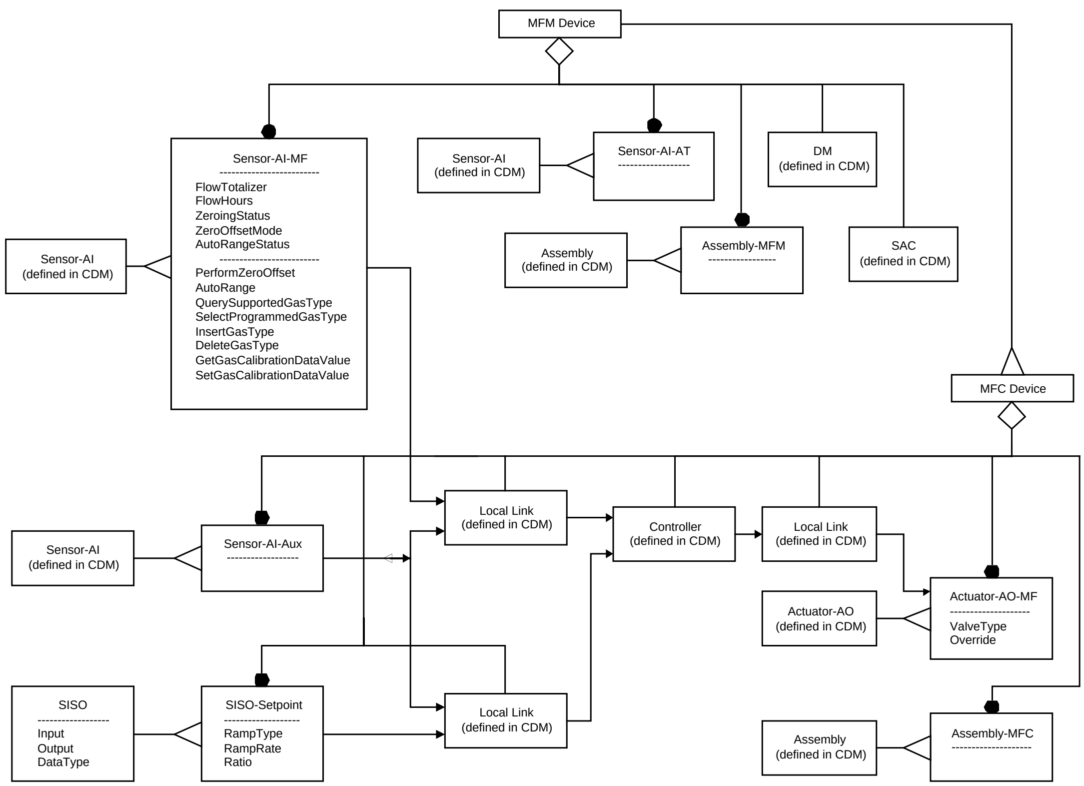

Figure 2
Mass Flow Meter Device and Mass Flow Controller Device High Level Structure

8.1.3 *General Requirements*

8.1.3.1 *Device Objects* — All objects are defined in terms of their object name and instance identifier. Identifiers for all objects described in this document are summarized in Table 2.

Table 2 Mass Flow Device Objects

Referenced Document Section	*Object Name*	*Object Identifier*	*MFC Minimum Instances*	*MFM Minimum Instances*	*Maximum Instances*
8.2	Device Manager (DM)	MFD1	1	1	1
8.3	Sensor Actuator Controller (SAC)	MFD2	1	1	1
8.4	Sensor-AI-MF	MFD3	1	1	Manufacturer-Specified
8.5	Sensor-AI-AT	MFD4	0	0	Manufacturer-Specified
8.6	Assembly-MFM	MFD5	0	0	1
8.7	Sensor-AI-Aux	MFD6	0	0	Manufacturer-Specified
8.8	Actuator-AO-MF	MFD7	1	0	Manufacturer-Specified
8.9	Controller	MFD8	1	0	1
8.10	Local Link	MFD9	2	0	Manufacturer-Specified
8.11	SISO	MFD10	0	0	Manufacturer-Specified
8.12	SISO-Setpoint	MFD11	0	0	Manufacturer-Specified
8.13	Assembly-MFC	MFD12	0	0	Manufacturer-Specified
—	Reserved	MFD13–MFD64	–	–	—
—	Manufacturer-Specified	> MFD64	–	–	—

8.1.3.2 *Object Services* — Not all object services listed in this document can necessarily be requested over the network. They are included in this document because their behavior may generate network activity.

8.1.3.3 *Object Behavior* — For all service requests received over the network that are unsupported by the object, or contain a parameter value which is beyond the supported range, or which is otherwise invalid, a network-specific service error response is generated as specified in SEMI E54.1.

8.2 *Device Manager Object (DM)*

8.2.1 The Device Manager object instance is the device component responsible for managing and consolidating the device operation as specified in SEMI E54.1. The following sections specify the components of the DM object that are not specified in the Common Device Model.

8.2.2 *Device Manager Object Attributes* — Required and optional DM object instance attributes are listed in Table 3.

Table 3 DM Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Device Type	A1	R	Yes	Refer to CDM (SEMI E54.1).
Exception Detail Alarm	A13	R	No	Refer to CDM (SEMI E54.1).
Exception Detail Warning	A14	R	No	Refer to CDM (SEMI E54.1).
Reserved	A33–A64	—	—	Reserved for SDM future expansion.
Manufacturer-Specified	> A64	—	—	Manufacturer-Specific attributes

8.2.2.1 *Device Type* — An attribute which uniquely identifies the type of the device on the network. The device type attribute is assigned as follows:

Mass Flow Controller Device = “MFC”

Mass Flow Meter Device = “MFM”

8.2.2.2 *Exception Detail Alarm (Optional)* — An attribute which identifies the detailed alarm status of the device. Table 4 defines the bit assignments associated with the alarm exception detail.

Table 4 Exception Detail Alarm Bit Assignments

Bit	*Device-Specific Alarm [0]*
0	Reserved
1	Indicated Flow High
2	Indicated Flow Low
3	Flow Controller
4	Flow Valve Actuator
5	Reserved
6	Reserved
7	Reserved

8.2.2.3 *Exception Detail Warning (Optional)* — An attribute which identifies the detailed warning status of the device. Table 5 defines the bit assignments associated with the warning exception detail.

Table 5 Exception Detail Warning Bit Assignments

Bit	*Device-Specific Warning [0]*
0	Reserved
1	Indicated Flow High
2	Indicated Flow Low
3	Flow Controller
4	Flow Valve Actuator
5	Reserved
6	Reserved
7	Reserved

8.2.2.4 *Initial and Default Values*

Table 6 DM Object Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Device Type	MFC, MFM	MFC, MFM	MFM = Mass Flow Meter Device MFC = Mass Flow Controller Device
Exception Detail Alarm	0	0	
Exception Detail Warning	0	0	

8.3 *Sensor Actuator Controller Object (SAC)* — The Sensor Actuator Controller object instance is the device component responsible for coordinating the interaction of the mass flow device with the sensory/actuation/control environment as specified in SEMI E54.1.

8.4 *Sensor-AI-MF Object* — The Sensor-AI-MF object inherits the attributes, services, and behavior of the Sensor-AI as defined in SEMI E54.1. The Sensor-AI-MF object instance is the device component responsible for retrieving a reading from a physical flow sensor, optionally correcting the reading with a manufacturer-specified algorithm, or algorithms, then making the value available to feed the Controller object instance via a Local Link object instance.

8.4.1 *Sensor-AI-MF Object Attributes*

Table 7 Sensor-AI-MF Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Flow Totalizer	A1	RW	No	REAL
Flow Hours	A2	R	No	ULINT
Zero Offset Mode	A5	RW	No	Enumerated Byte
Zeroing Status	A6	R	No	Enumerated Byte
Autorange Status	A7	R	No	Enumerated Byte
Reserved	A8–A64	—	—	Reserved for future expansion
Manufacturer-Specified	> A64	—	—	Manufacturer-Specific attributes

8.4.1.1 *Flow Totalizer (Optional)* — An attribute that maintains the volume of gas in standard cubic centimeters (SCC) that has flowed through the device since the last time the flow *totalizer* attribute value was set to zero.

8.4.1.2 *Flow Hours (Optional)* — An attribute which identifies the number of hours that the device has been flowing gas since the last time the *flow hours* attribute value was set to zero, as specified by the manufacturer. The attribute is an unsigned long integer with a resolution of 1 hour.

8.4.1.3 *Zero Offset Mode (Optional)* — An attribute which specifies the zero offset formula to be applied to produce the value attribute. This attribute is an enumerated byte that can take on one of the following values:

0 = Disable
1 = Enable Application of Formula
2 = Enable Automatic Zeroing
3–63 = Reserved
64–255 = Manufacturer-Specified

8.4.1.4 *Zeroing Status (Optional)* — An attribute which specifies whether the object is in the ZEROING substate. This attribute is an enumerated byte that can take on one of the following values:

0 = Not Zeroing
1 = Zeroing

8.4.1.5 *Autorange Status (Optional)* — An attribute which specifies whether the object is in the AUTORANGING sub-state. This attribute is an enumerated byte that can take on one of the following values:

0 = Not Autoranging
1 = Autoranging

8.4.1.6 *Initial and Default Values*

Table 8 Sensor-AI-MF Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Flow Totalizer	LVV	0	
Flow Hours	LVV	0	
Zero Offset Mode	LVV	Disable	
Zeroing Status	Not Zeroing	Not Zeroing	
Autorange Status	LVV	Not Autoranging	

8.4.2 *Sensor-AI-MF Object Services* — The services provided by the Sensor-AI-MF object instance are defined in SEMI E54.1. The Sensor-AI-MF object supports the additional services listed below.

All Gas Correction services are optional. Gas correction may be handled within the device as a pre-assigned gas calibration or may not be implemented at all. If these services are available, it is manufacturer-specific as to whether the device supports references to *gas standard number*, *gas standard symbol*, or both. It is strongly recommended that, if a device supports only one method of referencing gas types, it should be *gas standard number*.

A device may support any of these services, in whole or in part, as specified by the manufacturer. A manufacturer may specify a subset of the service parameter values which is supported. The following table lists the services supported by the Sensor-AI-MF object instance:

Table 9 Sensor-AI-MF Object Services

Service	*Service Identifier*	*Type*	*Description*
Perform Zero Offset	S1	R	Used to instruct the object to perform an automatic zeroing operation.
Query-Supported Gas Types	S2	R	Used to query the device to determine whether a specific gas calibration is supported.
Selected Programmed Gas Type	S3	R	Used to select the gas type and associated data to be used as the current programmed gas calibration.
Insert Gas Type	S4	R	Used to add a gas type to the list of available gas types.
Delete Gas Type	S5	R	Used to remove a gas type from the list of available gas types.
Get Gas Calibration Data Value	S6	R	Used to request the value of a specific gas calibration data value.
Set Gas Calibration Data Value	S7	R	Used to set the value of a specific gas calibration data value.
Autorange	S8	R	Used to enter the AUTORANGING state.
Reserved	S9–S64	—	Reserved for future expansion.
Manufacturer-Specified	> S64	—	Manufacturer-Specific services

8.4.2.1 *Perform Zero Offset (Optional)* — This service is used to instruct the Sensor-AI-MF object instance to perform a one-time automatic zeroing operation on the device or to reset the *offset* attribute value to zero. This service causes the automatic zeroing of the Sensor-AI-MF object instance *value* attribute by modifying the value of the *offset* attribute in order to yield a value of zero for the *value* attribute. Table 10 describes the parameters specified for this service.

Table 10 Perform Zero Service Parameter Definitions

Parameter	*Request/Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Command	M	—	Byte	Enumerated Byte: 0 = Set offset attribute to zero 1 = Calculate offset 2 = Cancel Zeroing 3–63 = Reserved 64–255 = Manufacturer-Specified

8.4.2.2 *Query-Supported Gas Types Service (Optional)* — This service is used to query the device to determine whether a specific gas type, range, and units is supported. Supported, in this context, implies that the device contains suitable gas calibration correction data or methods to correct the flow measurement for the specified gas type, range, and units. The query can be made by referencing either *gas standard number* or *gas standard symbol* (see Section 5 for a definition of “gas standard number” and “gas standard symbol”). The entire list of supported gas standard numbers or gas standard symbols (with ranges and units) can also be requested. The following table describes the parameters specified for this service:

Table 11 Query-Supported Gas Types Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Query Type	M	—	Byte	0 = specific gas type 1 = all currently supported gas calibrations 2 = currently programmed gas calibration
Gas Standard Number	C*	—	Unsigned Integer	0 = use standard gas symbol field n = gas standard number
Gas Standard Symbol	C*	—	Text String	null character = not specified text string = gas standard symbol
Full Scale Range	C*	—	Real	0 = not specified n = full scale range
Units	C*	—	UINT	Indication of the units associated with the full scale range.
Valid Flag	—	M	Byte	0 = Not Valid 1 = Valid
Size of List	—	M	Unsigned Integer	Number of gas calibrations in the list.
List of Gas Calibrations	—	M	Array of Structures	The list of gas calibrations.

* Parameter is Mandatory for Query Type = 0.

8.4.2.2.1 *Query Type* — This parameter is used to specify the type of service response. It is an enumerated byte that can take on the following values:

0 = specific gas type
1 = all currently supported gas calibrations
2 = currently programmed gas calibration
3–63 = Reserved
64–255 = Manufacturer-Specified

8.4.2.2.2 *Gas Standard Number* — This parameter is used to specify a gas standard number, for which device support is being queried. A value of “0” indicates that the following parameter “gas standard symbol” is used instead to reference the gas type.

8.4.2.2.3 *Gas Standard Symbol* — This parameter is used to specify a gas standard symbol, for which device support is being queried. If the gas standard number parameter has a value that is not zero, then this parameter will have the value of null character.

8.4.2.2.4 *Full Scale Range* — This parameter is used to specify the full scale range, for which device support is being queried. See Section 5 for a definition of “full scale range.” A value of “0” queries the device to return the entire list of full scale ranges for the specified gas type.

8.4.2.2.5 *Units* — This parameter is used to specify the units associated with the full scale range specified in the service request. Its values are defined in SEMI E54.1. The supported list includes:

SCCM
SLM
Percent
Volts
Millivolts
Counts

8.4.2.2.6 *Valid Flag* — The first parameter of a Query-Supported Gas Type service response is a byte that indicates whether the requested gas type, range, and units are supported. If an entire list was requested, and at least one gas calibration exists, this byte will have the value of “Valid.”

8.4.2.2.7 *Size of List* — This parameter is an unsigned integer that specifies the number of gas calibrations in the list that follows.

8.4.2.2.8 *List of Gas Calibrations* — This attribute is an array of structures that identifies the gas calibrations supported in the device. The format of the structure is *gas standard number*, *gas standard symbol* (zero if not supported), *full scale range*, and *units*.

8.4.2.3 *Select Programmed Gas Type Service (Optional)* — This service is used to select the gas type, range, and units of the programmed gas calibration to be used by the device (see Section 5 for a definition of "programmed gas calibration"). The following table describes the parameters specified for this service:

Table 12 Select Programmed Gas Type Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Gas Standard Number	M	—	UINT	0 = use gas standard symbol field n = gas standard number
Gas Standard Symbol	M	—	Text String	null character = not specified text string = gas standard symbol
Range Select Mode	M	—	Byte	0 = select highest full scale range 1 = use full scale range and units specified 2 = use full scale range and units greater than or equal to specified
Full Scale Range	C*	—	REAL	Full scale range of which the select references.
Units	C*	—	UINT	Indication of the units associated with the full scale range.

* Parameter is Mandatory for Range Select Mode = 1 and 2.

8.4.2.3.1 *Gas Standard Number* — This parameter is used to specify a gas standard number, for which device support is being queried. A value of "0" indicates that the following parameter "gas standard symbol" is used instead to reference the gas type.

8.4.2.3.2 *Gas Standard Symbol* — This parameter is used to specify a gas standard symbol, for which device support is being queried. If the gas standard number parameter has a value that is not zero, then this parameter will have the value of null character.

8.4.2.3.3 *Range Select Mode* — This parameter is used to specify the mode by which the programmed gas is selected. It is an enumerated byte that can take on the following values:

0 = Select highest full scale range
1 = Use full scale range and units specified
2 = Use full scale range and units greater than or equal to specified
3–63 = Reserved
64–255 = Manufacturer-Specified

8.4.2.3.4 *Full Scale Range* — This parameter is used to specify the full scale range to be selected as the current programmed gas calibration full scale range.

8.4.2.3.5 *Units* — This parameter specifies the units associated with the full scale range to be set as the current programmed gas calibration being used by the device. If the Full Scale Range parameter has the value "0," this parameter is not included in the request. Its values are defined in Section 8.4.2.2.

8.4.2.4 *Insert Gas Type Service (Optional)* — This service is used to add a gas calibration to the list of supported gas calibrations. This service will typically be invoked while calibrating the device, since it has not specified what, if any, gas calibration data or methods will be set as the new gas calibration. The Set Gas Calibration Data Value service will generally be required to set the gas calibration data or methods after invoking this service. The following table describes the parameters specified for this service:

Table 13 Insert Gas Type Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Gas Standard Number	M	—	UINT	0 = use gas standard symbol field n = gas standard number
Gas Standard Symbol	M	—	Text String	null character = not specified text string = gas standard symbol
Full Scale Range	M	—	REAL	n = full scale range
Units	M	—	UINT	Indication of the units associated with the full scale range.

8.4.2.4.1 *Gas Standard Number* — This parameter is used to specify a gas standard number, for which a gas calibration is to be added. A value of "0" indicates that the following parameter "gas standard symbol" is used instead to reference the gas type.

8.4.2.4.2 *Gas Standard Symbol* — This parameter is used to specify a gas standard symbol for which a gas calibration is to be added.

8.4.2.4.3 *Full Scale Range* — This parameter is used to specify the full scale range for which a gas calibration is to be added. See Section 5 for a definition of full scale range.

8.4.2.4.4 *Units* — This parameter is used to specify the units associated with the full scale range specified in the service request. Its values are defined in Section 8.4.2.2.

8.4.2.5 *Delete Gas Type Service (Optional)* — This service is used to remove a gas calibration from the list of supported gas calibrations. The gas calibration data or method used by the device, if the current programmed gas type is deleted, is manufacturer-specified. The following table describes the parameters specified for this service:

Table 14 Delete Gas Type Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Gas Standard Number	M	—	UINT	0 = use gas standard symbol field n = gas standard number
Gas Standard Symbol	M	—	Text String	null character = not specified text string = gas standard symbol
Full Scale Range	M	—	REAL	n = full scale range
Units	M	—	UINT	Indication of the units associated with the full scale range.

8.4.2.5.1 *Gas Standard Number* — This parameter is used to specify a gas standard number for which a gas calibration is to be deleted. A value of "0" indicates that the following parameter "gas standard symbol" is used instead to reference the gas type.

8.4.2.5.2 *Gas Standard Symbol* — This parameter is used to specify a gas standard symbol for which a gas calibration is to be deleted.

8.4.2.5.3 *Full Scale Range* — This parameter is used to specify the full scale range for which a gas calibration is to be deleted. See Section 5 for a definition of "full scale range."

8.4.2.5.4 *Units* — This parameter is used to specify the units associated with the full scale range specified in the service request. Its values are defined in Section 8.4.2.2.

8.4.2.6 *Get Gas Calibration Data Value Service (Optional)* — This service is used to retrieve the values associated with a gas calibration. The mechanism for referencing a data value involves specifying the gas type and full scale range (a default is provided to specify the programmed gas calibration currently in use by the device), followed by an index value which is used to specify the particular data value that is being requested. The following table describes the parameters specified for this service:

Table 15 Get Calibration Data Value Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Gas Standard Number	M	—	INT	-1 = current programmed gas calibration 0 = use gas standard symbol field n = gas standard number
Gas Standard Symbol	M	—	Text String	null character = not specified text string = gas standard symbol
Full Scale Range	M	—	REAL	0 = not specified n = full scale range
Units	M	—	UINT	Indication of the units associated with the full scale range.
Data Index	M	—	Byte	The identifier of the particular gas calibration datum within the list of data values.
Size of List	—	M	Byte	This parameter specifies the number of values returned in the list.
Zero	—	C	REAL	zero offset
Span	—	C	REAL	span multiplier
Calibration Date	—	C	Date	The date of calibration for a particular gas type and full scale range.
Calibration Gas Standard Number	—	C	UINT	The gas standard number representing the gas used to calibrate the device.
Calibration Temperature	—	C	REAL	The standard temperature of calibration conditions.
Calibration Pressure	—	C	REAL	The standard pressure of the calibration conditions.
Manufacturer-Specified Parameters	—	C	Manufacturer-Specific	

8.4.2.6.1 *Gas Standard Number* — This parameter is used to specify a gas standard number for which a gas calibration data value is being requested. Two special values are allowed: A value of "0" indicates that the following parameter "gas standard symbol" is used instead to reference the gas type. A value of "-1" indicates that the current programmed gas calibration is requested.

8.4.2.6.2 *Gas Standard Symbol* — This parameter is used to specify a gas standard symbol for which a gas calibration data value is being requested. If the *gas standard number* parameter has a value that is not "0," then this parameter is set to the null character.

8.4.2.6.3 *Full Scale Range* — This parameter is used to specify the full scale range for which a gas calibration data value is being requested. If the *gas standard number* parameter has a value that is "-1," then this parameter is set to zero.

8.4.2.6.4 *Units* — This parameter specifies the units associated with the *full scale range parameter*. Its values are defined in Section 8.4.2.2. If the *gas standard number* parameter has a value that is "-1," then this parameter is set to 0.

8.4.2.6.5 *Data Index* — This parameter is used to specify the index of the value being requested. It is an enumerated byte that can take on the values listed in the following table:

Table 16 Gas Calibration Data Value Matrix

Data Value Name	*Data Index*	*Access Network*	*Required*	*Form*
All	0	—	No	
Zero	1	RW	No	REAL
Span	2	RW	No	REAL
Calibration Date	3	R	No	Date
Calibration Gas Standard Number	4	R	No	UINT
Calibration Temperature	5	R	No	REAL
Calibration Pressure	6	R	No	REAL
Reserved	7–63	—	—	
Manufacturer-Specified	64–255	—	—	

Table 17 Gas Calibration Data Initial and Default Values

Data Value Name	*Data Index*	*Initial Value*	*Default Value*	*Comment*
Zero	1	LVV	0	
Span	2	LVV	1	
Calibration Date	3	LVV	0, 0, 0	
Calibration Gas Standard Number	4	LVV	Manufacturer-Specific	
Calibration Temperature	5	LVV	0.0	Defined by SEMI E12 as 0.0°C. Other industries may specify a different value.
Calibration Pressure	6	LVV	101.32	Defined by SEMI E12 as 101.32 kPa. Other industries may specify a different value.
Reserved	7–63	—	—	
Manufacturer-Specified	64–255	—	—	

8.4.2.6.5.1 *All* — This value for the data index parameter requests the list of all data values associated with a gas calibration. The returned parameter values are ordered by index as defined in Table 15. The size of the list returned is manufacturer-specified, since it includes the Manufacturer-Specific values.

8.4.2.6.5.2 *Size of List* — This parameter is used to specify the number of parameters returned in the response list.

8.4.2.6.5.3 *Zero* — This value is used in conjunction with the span value to correct the flow measurement. It is expressed in terms of the units parameter.

8.4.2.6.5.4 *Span* — This value is used in conjunction with the zero value to correct the flow measurement. It is a dimensionless value.

8.4.2.6.5.5 *Calibration Date* — This value identifies the date the device was last calibrated for the specified gas type and full scale range.

8.4.2.6.5.6 *Calibration Gas Standard Number* — This value identifies the gas type used when the device was calibrated for the referenced gas type and full scale range. It may be the same gas as gas type, a surrogate gas, nitrogen, or some other gas.

8.4.2.6.5.7 *Calibration Temperature* — This value identifies the Standard Temperature with respect to calibration conditions. The units for this value are degrees Centigrade.

8.4.2.6.5.8 *Calibration Pressure* — This value identifies the Standard Pressure with respect to calibration conditions. The units for this value are KiloPascal.

8.4.2.7 *Set Gas Calibration Data Value Service (Optional)* — This service is used to set the values associated with a gas calibration. The mechanism for referencing a data value involves specifying the gas type and full scale range (a default is provided to specify the programmed gas calibration currently in use by the device), followed by an index value which is used to specify the particular data value associated with the referenced gas calibration that is being set. The specific value to be set is the last parameter passed in the service request. The following table describes the parameters specified for this service:

Table 18 Set Calibration Data Value Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Gas Standard Number	M	—	INT	-1 = current programmed gas calibration 0 = use gas standard symbol field n = gas standard number
Gas Standard Symbol	M	—	Text String	null character = not specified text string = gas standard symbol
Full Scale Range	M	—	REAL	0 = not specified n = full scale range
Units	M	—	UINT	Indication of the units associated with the full scale range.
Data Index	M	—	Byte	The identifier of the particular gas calibration datum within the list of data values.
Size of List	M	—	Byte	This parameter specifies the number of values in the list that follows.
Zero	C	—	REAL	zero offset
Span	C	—	REAL	span multiplier
Calibration Date	C	—	Date	The date of calibration for a particular gas type and full scale range.
Calibration Gas Standard Number	C	—	UINT	The gas standard number representing the gas used to calibrate the device.
Calibration Temperature	C	—	REAL	The standard temperature of calibration conditions.
Calibration Pressure	C	—	REAL	The standard pressure of the calibration conditions.
Manufacturer-Specified Parameters	C	—	Manufacturer-Specific	

For a description of these parameters, see the preceding section.

8.4.2.8 *Autorange Service (Optional)* — This service is used to instruct the Sensor-AI-MF object instance to enter the AUTORANGING state from the NOT AUTORANGING state or to enter the NOT AUTORANGING state from the AUTORANGING state. The following table describes the parameters specified for this service:

Table 19 Autorange Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Command	M	—	Byte	Enumerated Byte: 0 = enter NOT AUTORANGING state 1 = enter AUTORANGING state 2–63 = Reserved 64–255 = Manufacturer-Specified

8.4.3 *Sensor-AI-MF Object Behavior* — The behavior exhibited by the Sensor-AI-MF object instance is inherited from the Sensor-AI object defined in SEMI E54.1. Additional specific behavior associated with the Sensor-AI-MF object is defined below.

8.4.3.1 *Sensor-AI-MF OPERATING Application Process* — A reading is retrieved from a physical flow sensor. This reading may be corrected with a manufacturer-specified algorithm. This corrected reading becomes the input to the offset and gain formula to generate the *value* attribute as referenced in SEMI E54.1.

For Gas Correction, the value retrieved is corrected with a manufacturer-specified algorithm using the correction values, parameters, coefficients, or methods for the programmed gas calibration.

8.4.3.2 *Sensor-AI-MF OPERATING Application Process–Flow Totalizer* — The value of the *flow totalizer* attribute is incremented at a rate of once every cubic centimeter of gas flow. Whenever the *flow totalizer* attribute reaches its maximum allowed value, it no longer is incremented and remains at the maximum value.

8.4.3.3 *Sensor-AI-MF OPERATING Application Process–Flow Hours* — The value of the *flow hours* attribute is incremented at a rate of once every hour. Whenever the *flow hours* attribute reaches its maximum allowed value, it no longer is incremented and remains at the maximum value.

8.4.3.4 *Sensor-AI-MF ZEROING Application Process* — The Zeroing application process is described as follows: Certain manufacturer-specified service requests may be sent to other objects. The value of *offset* is set such that *value* is nulled to zero. The Sensor-AI-MF object instance determines, using a manufacturer-specified method, when a Zeroing application process is completed.

If a Perform Zero Offset: Command = 2 (cancel) service request is received while in the ZEROING state, the original value of the *offset* attribute is restored, and the process is considered Failed. If a Perform Zero Offset: Command = 0 (set offset attribute to zero) service request is received while in the ZEROING state, the *offset* attribute is set to zero, and the process is considered Failed. If a Perform Zero Offset: Command = 1 (calculate offset) service request is received while in the ZEROING state, the process is simply restarted.

Upon completion, the appropriate Pass or Fail service response is reported to the requesting object instance, and an internal Operate service request to this object is generated.

The Sensor-AI-MF object instance supports the additional behavior sub-states (defined in Figure 3) within the OPERATING state. Table 20 defines the additional sub-states, and Table 21 defines the additional state transitions specified for this object.

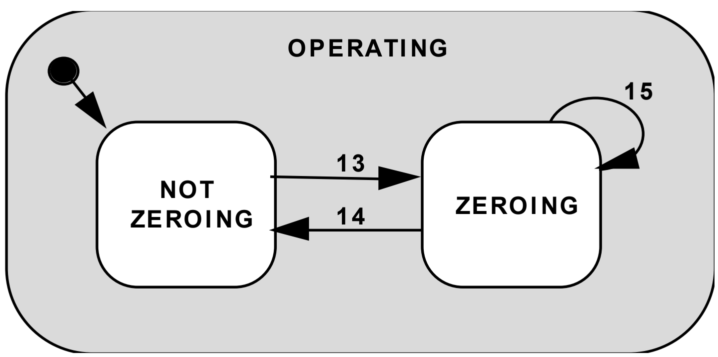

Figure 3
Sensor-AI-MF Object Behavior Additional Sub-States

Table 20 Sensor-AI-MF Object Behavior State Descriptions

State	*Description*
NOT ZEROING	The Sensor-AI-MF object instance is running the Sensor-AI-MF OPERATING application process.
ZEROING	The Sensor-AI-MF object instance is running the Sensor-AI-MF OPERATING application process. Additionally, the Sensor-AI-MF object instance is running the Sensor-AI-MF ZEROING application process.

Table 21 Sensor AI-MF Object Behavior State Transition Matrix

#	*Current State*	*Trigger*	*New State*	*Action*	*Comments*
4	NORMAL OPERATING	Get Attribute, Set Attribute, Restore Defaults request, Perform Zero Offset request (command ≠ 1)	NORMAL OPERATING	Get Attribute, Set Attribute, Restore Defaults appropriate response	Valid for all sub-states of NORMAL OPERATING.
13	NOT ZEROING	Perform Zero Offset request (command = 1)	ZEROING	Run the ZEROING application process. Set *zeroing status* to Zeroing.	
14	ZEROING	Operate request or Perform Zero Offset request (command ≠ 1)	NOT ZEROING	Resume the OPERATING application process. Set *zeroing status* to Not Zeroing. Report appropriate service response.	The mechanism for reporting is network-specific.
15	ZEROING	Perform Zero Offset request (command = 1)	ZEROING	Restart the ZEROING application process.	

8.4.3.5 *Sensor-AI-MF AUTORANGING Application Process* — The Sensor-AI-MF object instance supports the additional behavior sub-states (defined in Figure 4) within the OPERATING state. Table 22 defines the additional sub-states, and Table 23 defines the additional state transitions specified for this object.

The object instance is automatically selecting gas calibrations based on a manufacturer's specified method. This method may include a determination based on the value of the *value* attribute and/or on the value of the *setpoint value* attribute.

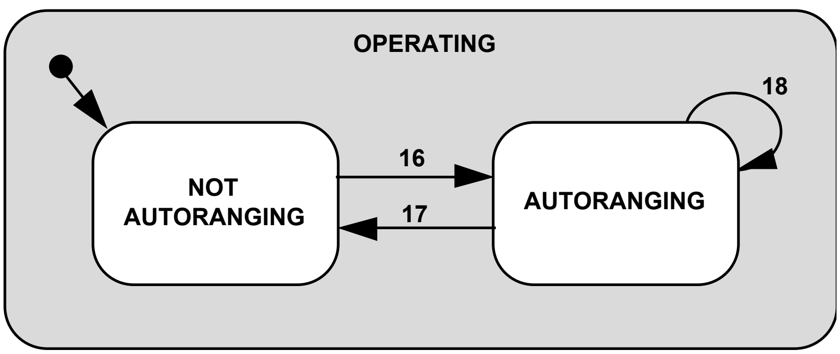

Figure 4
Sensor-AI-MF Object Behavior Additional Sub-States

Table 22 Sensor-AI-MF Object Behavior State Descriptions

State	*Description*
NOT AUTORANGING	The Sensor-AI-MF object instance is running the Sensor-AI-MF OPERATING application process.
AUTORANGING	The Sensor-AI-MF object instance is running the Sensor-AI-MF OPERATING application process. Additionally, the Sensor-AI-MF object instance is running the Sensor-AI-MF AUTORANGING application process (defined above).

Table 23 Sensor-AI-MF Object Behavior State Transition Matrix

#	*Current State*	*Trigger*	*New State*	*Action*	*Comments*
4	NORMAL OPERATING	Get Attribute, Set Attribute, Restore Defaults request, Autorange request (command = 0)	NORMAL OPERATING	Get Attribute, Set Attribute, Restore Defaults appropriate response	Valid for all sub-states of NORMAL OPERATING.
16	NOT AUTORANGING	Autorange request Command = 1	AUTORANGING	Run AUTORANGING application process. Set *Autoranging status* to Autoranging.	
17	AUTORANGING	Autorange request Command = 0	NOT AUTORANGING	Halt the Autoranging application process. Set *Autoranging status* to Not Autoranging.	
18	AUTORANGING	Autorange request Command = 1	AUTORANGING		No change.

8.5 *Sensor-AI-AT Object* — The Sensor-AI-AT object is an Ambient Temperature object instance which inherits attributes, services, and behavior from the Sensor-AI object as defined in SEMI E54.1. The Sensor-AI-AT object instance is the device component responsible for retrieving a reading from a physical temperature sensor and making the value available to the network.

8.5.1 *Sensor-AI-AT Object Attributes* — The inherited *value* attribute represents the ambient temperature measurement. There are no additional attributes defined for this object in this document.

8.5.2 *Sensor-AI-AT Object Services* — There are no additional services defined for this object in this document.

8.5.3 *Sensor-AI-AT Object Behavior* — The behavior exhibited by the Sensor-AI-AT object instance is defined in SEM E54.1. Additional specific behavior associated with the Sensor-AI-AT object is defined below.

8.5.3.1 *Sensor-AI-AT OPERATING Application Process* — A reading is retrieved from a physical temperature sensor. This reading may be corrected with a manufacturer-specified algorithm. This corrected reading becomes the input to the offset and gain formula to generate the *value* attribute as referenced in SEMI E54.1.

8.6 *Assembly-MFM Object* — The Assembly-MFM object inherits attributes, services, and behavior from the Assembly object. The Assembly object instance is the device component which provides a mechanism of grouping more than one attribute from one or more object instances into a single data structure for access over the network.

8.6.1 *Assembly-MFM Object Attributes*

Table 24 Assembly-MFM Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Data	A1	R	Yes	Structure as defined below.

8.6.1.1 *Data* — An attribute with the following list of attributes within its structure:

Table 25 Assembly-MFM Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	MFD3	A4	Sensor-AI-MF Value

8.7 *Sensor-AI-Aux Object* — The Sensor-AI-Aux object is an Auxiliary Input object instance which inherits attributes, services, and behavior from the Sensor-AI object as defined in SEMI E54.1. The Sensor-AI-Aux object instance is the device component responsible for retrieving a reading from a physical analog input and making the value available to the network.

8.7.1 *Sensor-AI-Aux Object Attributes* — The attributes provided by the Sensor-AI-Aux object instance are defined in SEMI E54.1. The *value* attribute represents the analog input measurement.

8.7.2 *Sensor-AI-Aux Object Services* — The services provided by the Sensor-AI object instance are defined in SEMI E54.1.

8.7.3 *Sensor-AI-Aux Object Behavior* — The behavior exhibited by the Sensor-AI-Aux object instance is defined in SEMI E54.1. Additional specific behavior associated with the Sensor-AI-Aux object is defined below.

8.7.3.1 *Sensor-AI-Aux OPERATING Application Process* — A reading is retrieved from a physical analog input. This reading may be corrected with a manufacturer-specified algorithm. This corrected reading becomes the input to the offset and gain formula to generate the *value* attribute as referenced in SEMI E54.1.

8.8 *Actuator-AO-MF Object* — The Actuator-AO-MF object instance inherits from the Actuator-AO object attributes, services, and behavior as defined in SEMI E54.1. The Actuator-AO-MF object instance is the component responsible for driving the physical mass flow control valve of the device. Override attributes are available to produce valve drives which either fully close or fully open the valve, irrespective of the value of the *setting* attribute.

8.8.1 *Actuator-AO-MF Object Attributes*

Table 26 Actuator-AO-MF Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Valve Type	A1	R	No	Enumerated Byte
Override	A2	RW	No	Enumerated Byte
Reserved	A3–A64	—	—	Reserved for future expansion.
Manufacturer-Specified	> A64	—	—	Manufacturer-Specific attributes.

8.8.1.1 *Valve Type (Optional)* — An attribute which specifies the type of valve present in the device. This attribute is an enumerated byte that can take on one of the following values:

0 = Solenoid

1 = Voice Coil

2 = Piezo Electric

3 = Thermal

4–63 = Reserved

64–255 = Manufacturer-Specified

8.8.1.2 *Override (Optional)* — An attribute which specifies an override to the controlled valve position derived from the Controller object instance. This attribute is an enumerated byte that can take on one of the following values:

0 = Normal — Normal control mode

1 = Flow Off — Valve Closed

2 = Purge — Valve Open

3 = Power Off — Valve to unpowered state

4–63 = Reserved

64–255 = Manufacturer-Specified

8.8.1.3 *Initial and Default Values*

Table 27 Actuator-AO-MF Object Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Valve Type	Default Value	Manufacturer-Specific	
Override	LVV	Normal	

8.8.2 *Actuator-AO-MF Object Services* — There are no additional services defined for this object in this document.

8.8.3 *Actuator-AO-MF Object Behavior* — The behavior exhibited by the Actuator-AO-MF object instance is defined in SEMI E54.1. The specific behavior associated with the Actuator-AO-MF object is defined below.

8.8.3.1 *Actuator-AO-MF OPERATING Application Process–Override* — The *override* attribute determines whether the position of the physical flow control valve will be overridden and, if so, to what position it will be driven. Otherwise, the physical flow control valve is driven by the converted signal derived from the Controller object instance.

8.9 *Controller Object* — The Controller object definition is provided in SEMI E54.1. This object instance is the device component which provides the closed-loop control of mass flow. There are no additional attributes, services, or behavior defined for this object in this document.

8.9.1 *Controller Object Attributes* — The following attribute table is provided to enhance the C Class Attribute table and provides a specific attribute "Form" definition.

Table 28 C Class Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Alarm Settling Time	CA21	RW	N	Real
Warning Settling Time	CA24	RW	N	Real

8.10 *Local Link Object* — The Local Link object is defined in SEMI E54.1. This object instance is the device component which provides a mechanism of linking two attributes within the device. There are no additional attributes, services, or behavior defined for this object in this document.

8.11 *SISO Object* — The SISO object provides a Single Input, Single Output function. At this level, only the input and output attributes are defined. An instance of this object makes no sense, because there is no transfer function defined, but rather, the attributes, services, and behavior of this object are inherited by the next level down (e.g., SISO-Setpoint Object).

8.11.1 *SISO Object Attributes*

Table 29 SISO Function Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Input	A1	RW	Yes	Data Type
Output	A2	R	Yes	Data Type
Data Type	A3	R	No	USINT
Reserved	A4–A32	—	—	For future revisions to this object.
Reserved	A33–A64			For next level object.
Manufacturer-Specified	> A64	—	—	For manufacturer specification.

8.11.1.1 *Input* — An attribute which specifies the input value, or independent variable, for the transfer function. The data type is specified by the *data type* attribute.

8.11.1.2 *Output* — An attribute whose value is the output, or dependent variable, of the transfer function. The data type is specified by the *data type* attribute.

8.11.1.3 *Data Type* — An attribute which specifies the data type of the *input* attribute and the *output* attribute. The format and values of this attribute are defined in SEMI E54.1.

8.11.1.4 *Initial and Default Values*

Table 30 SISO Object Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Input	LVV	0	
Output	LVV	manufacturer-specified	
Data Type	LVV	manufacturer-specified	

8.11.2 *SISO Object Behavior* — The only behavior defined at this level is that of a continuously operating transfer function: The Output attribute value is calculated as a function of the Input attribute value. The specific transfer function is defined by lower level objects which inherit from this object.

Output = F(Input)

where: F is the function specified

8.12 *SISO-Setpoint Object* — The SISO-Setpoint Object inherits from the SISO object. The definitions added by the SISO-Setpoint object include the behavior associated with the transfer function.

8.12.1 *SISO-Setpoint Object Attributes*

Table 31 SISO-Setpoint Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Ramp Type	A33	RW	No	USINT
Ramp Rate	A34	RW	No	Data Type
Ratio	A35	RW	No	REAL
Reserved	A36–A64	—	—	Reserved for future expansion.

8.12.1.1 *Ramp Type (Optional)* — An attribute which specifies a mechanism by which the *output* attribute is ramped to the current value of the *input* attribute.

0 = Disable

1 = Time in seconds

2 = Amount per second

3–63 = Reserved

64–255 = Manufacturer-specified

8.12.1.2 *Ramp Rate (Optional)* — An attribute specified to define the ramp rate at which the SISO-Setpoint object instance tracks towards the current *input* value. The ramp rate specifies how quickly the *output* is ramped from the previous *output* value to the current *input* value. This attribute is expressed in terms of seconds or amount of change per second.

8.12.1.3 *Ratio (Optional)* — An attribute which specifies the ratio multiplier to be applied to the *input* attribute value prior to the application of the ramp transfer function.

8.12.1.4 *Initial and Default Values*

Table 32 SISO-Setpoint Object Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Ramp Type	LVV	Disable	
Ramp Rate	LVV	0	
Ratio	LVV	1.0	

8.12.2 *SISO-Setpoint Object Behavior* — The general behavior exhibited by the SISO-Setpoint object instance is defined in SEMI E54.1. The specific behavior associated with this object is defined below.

8.12.2.1 *SISO-Setpoint OPERATING Application Process–Ramp* — The *ramp type* and *ramp rate* attributes determine the conditions under which the value of the *output* attribute is calculated and modified by this application process. The *ramp rate* attribute is defined to express the rate at which the *output* attribute is ramped to the value of the *input* attribute based on the value of the *ramp type* attribute. Table 33 describes the behavior of the SISO-Setpoint object instance based on the value of the *ramp type* attribute.

Table 33 SISO-Setpoint Object Behavior - Ramp

Ramp Type Value	*SISO-Setpoint Object Instance Behavior*
Disabled	Achieve a new output value in one step.
Time in Seconds	Achieve a new output value in the time interval specified by the *ramp rate* attribute.
Amount per Second	Achieve a new output value in the amount per second increments specified by the *ramp rate* attribute.

8.12.2.2 *SISO-Setpoint OPERATING Application Process–Ratio* — Prior to the application of the Ramp calculation, a multiplier is applied to the value of the *input* attribute. The value of the *ratio* attribute is multiplied to the value of the *input* attribute, and the result becomes the value which is used in the ramp calculation.

The combined formula for the SISO-Setpoint object is as follows:

Output = F(x)

where: F is the function as defined by ramp type above

and: x = (ratio)(input)

8.13 *Assembly-MFC Object* — The Assembly-MFC object inherits attributes, services, and behavior from the Assembly object. The Assembly object instance is the device component which provides a mechanism of grouping more than one attribute from one or more object instances into a single data structure for communication over the network.

8.13.1 *Assembly-MFC Object Attributes*

Table 34 Assembly-MFC Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Data	A1	R	Yes	Structure as defined below.

8.13.1.1 *Data* — An attribute with the following list of attributes within its structure:

Table 35 Assembly-MFC Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	MFD8	A1	Controller Status
3	MFD3	A4	Sensor-AI-MF Value
4	MFD8	A4	Controller Setpoint
5	MFD8	A6	Controller Control Variable

SEMI E54.4-0997
STANDARD FOR SENSOR/ACTUATOR NETWORK COMMUNICATIONS FOR DEVICENET

NOTE: This document was previously designated SEMI E59. Because this document is part of a suite of documents, its designation has been reassigned for ease of reference. Please note that the technical content of this document is unchanged from the 0697 version.

1 Purpose

This standard defines a communication specification based on the DeviceNet protocol to enable communications between intelligent devices on a sensor/actuator network (SAN) that operate according to SEMI- specified device models (common and device specific) in a semiconductor manufacturing tool.

1.1 *Background and Motivation* — DeviceNet provides for networking between simple industrial devices (e.g., sensors and actuators) and higher level devices such as controllers. DeviceNet provides:

- A solution to low-level device networking
- Access to intelligence present in low-level devices
- Master/Slave and Peer-to-Peer capabilities

DeviceNet is based on the Controller Area Network (CAN) technology. CAN defines a Media Access Control (MAC) methodology and physical signaling characteristics. DeviceNet wraps a communication model and protocol as well as a complete Physical Layer definition around CAN to provide a complete network definition.

This document enables communications between intelligent devices on a SEMI-compliant SAN by providing a presentation mapping of common and specific device network visible structure and behavior to a DeviceNet network.

2 Scope

2.1 This document specifies the protocol and services that compliant intelligent devices must support to interchange information over this semiconductor equipment sensor/actuator network.

2.2 This document specifies the utilization of the DeviceNet protocol to present externally visible device structure and behavior, specified in the Common Device Model (CDM) and appropriate Specific Device Models (SDM's), on a DeviceNet network.

2.3 This document is used in conjunction with a SEMI standard SAN Common Device Model specification and one or more SEMI standard-specific device model specifications (e.g., for a mass flow controller). Together, they describe the externally visible data structure and behavior of devices using the DeviceNet networking capability in a SEMI-compliant SAN system.

2.4 This standard, together with a sensor/actuator network interoperability guideline, the sensor/actuator network common device model, one or more sensor/actuator network specific device model documents, and the DeviceNet specifications, form a complete interoperability standard. The general sensor/actuator network document architecture is shown in the Sensor/Actuator Network Common Device Model document in Figure 1.

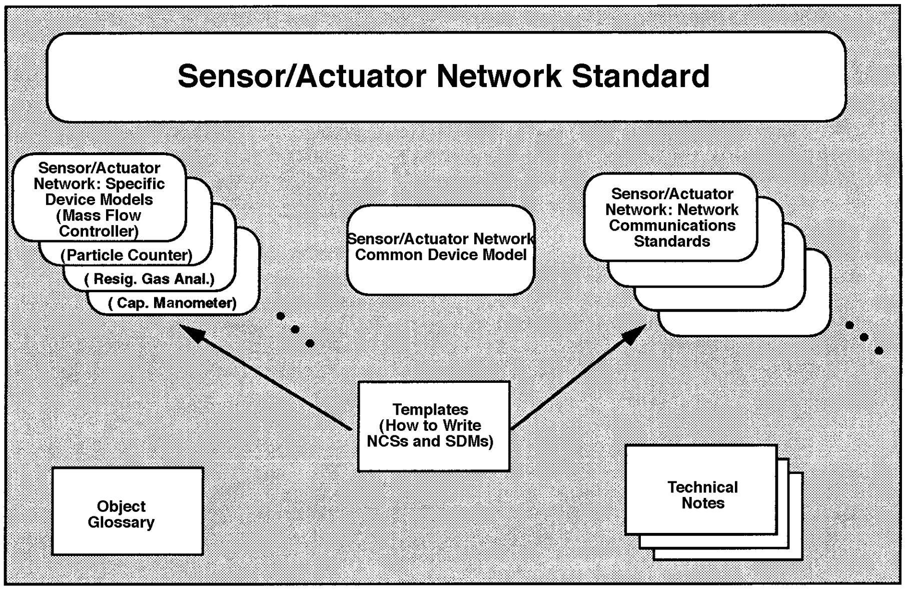

Figure 1
Sensor/Actuator Network Related Documents

2.5 *Document Structure* — The DeviceNet network communication standard complies with the SEMI SAN NCS template document structure; this structure is shown in Figure 2. The standard document is composed of two main parts. The first part (Sections 1 through 8) specifies the SAN enabling protocol as well as the presentation (i.e., mapping) of CDM object structure and behavior onto the network (referred to as the "CDM mapping"). The second part (Section 9) specifies the presentation (i.e., mapping) of SDM object structure and behavior onto the network for each SEMI-specified SDM (referred to as the "SDM mapping").

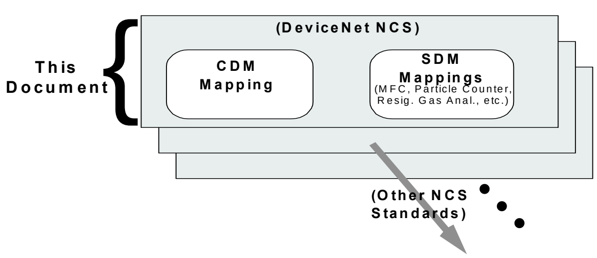

Figure 2
DeviceNet NCS Document Structure

2.6 *Adding SDM Mappings* — SDM mappings added to part two of this document are considered document additions and are balloted as such. An SDM mapping may only be balloted for addition to this document if the corresponding SEMI SDM has been standardized or is in the process of being balloted for standardization.

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on DeviceNet and is a companion document to the DeviceNet specification; thus, a complete specification of this standard necessarily includes the DeviceNet specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 This standard specifies enhancements that provide additional capabilities over and above those currently required by DeviceNet. In order to avoid document consistency problems, information in the DeviceNet specification that relates to this standard is not repeated in this document. This document is limited to describing enhancements or limitations to the DeviceNet specification that are imposed by this standard.

3.3 A complete specification of the conformance testing procedure shall include the DeviceNet protocol conformance testing specification. Conformance testing shall also include enhancements and limitations to the DeviceNet specification required by this standard.

4.2 *ISO Standards*[1]

ISO 7498 — Basic Reference Model for Open Systems Interconnection

ISO 11898 — Road Vehicles — Interchange of Digital Information — Controller Area Network (CAN) for High-Speed Communications

4.3 *Other Documents*

DeviceNet Specification — Volume I Release 1.3, Volume II Release 1.3 (includes DeviceNet Statement of Compliance)

Controller Area Network Specification — Version 2, R. Bosch GmbH, + Postfach 50 D-7000, Stuttgart 1, Germany, 1991

5 Terminology

Terminology that is common to all of the documents in this SAN standard may also be defined in the Sensor Actuator Network Standard. Terminology may be reproduced here which is defined in other SEMI documents.

5.1 *Acronyms*

5.1.1 *CAN* — Controller area network

5.1.2 *CDM* — Common device model

5.1.3 *DM* — Device manager (object)

5.1.4 *DN* — DeviceNet

5.1.5 *NCS* — Network communication standard

5.1.6 *OSI* — Open systems interconnect

5.1.7 *OSS* — Object services standard

5.1.8 *SAC* — Sensor, actuator, controller (object)

5.1.9 *SAN* — Sensor/actuator network

5.1.10 *SDM* — Specific device model

5.2 *Device Component Definitions* — As this standard defines the presentation or mapping of CDM data structure and behavior over a network, it makes use of many of the terms in the CDM document. Table 1 provides a mapping of fundamental terminology of the CDM document into this document and the DeviceNet specification. Note that Column 2 contains an equal sign "=" if the definition is used exactly as specified in the CDM specification.

Table 1 Mapping of CDM to NCS Terminology

CDM Term	*NCS Equivalent*	*DeviceNet Equivalent*
Device	=	=
Device Model	=	=
Object	=, Class	=, Class
Instance	=	=
Attribute	=	=
Behavior	=	=
Service	=	=
State Diagram	=	=
Byte	=	=
Nibble	=	=
Character String	=	=

5.3 *DeviceNet Specific Definitions*

5.3.1 *class* — a set of objects that all represent the same kind of system component. A class is a generalization of an object. All objects in a class are identical in form and behavior, but may contain different attribute values.

5.3.2 *controller area network (CAN)* — a protocol developed by the Bosch corporation for automotive in-vehicle networking. The CAN specification specifies OSI reference model layers 1 and 2, specifically the physical signaling and media access/data link protocols.

5.3.3 *device profile* — a DeviceNet specification for a device that contains an object model for the device type, the I/O data format for the device type, and the configuration data and the public interface(s) to that data.

5.3.4 *explicit message connections* — connections over a DeviceNet network that provide generic, multi-purpose communication paths between two devices. These connections often are referred to as just messaging connections. Explicit messages provide the typical request/response - oriented network communications.

5.3.5 *input/output connections* — connections over a DeviceNet network that provide dedicated, special-purpose communication paths between a producing application and one or more consuming applications. Application-specific I/O data moves through these ports.

1 International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211, Geneva 20, Switzerland

6 Communication Protocol High Level Structure

The DeviceNet protocol is loosely based on a three-layer architecture. These layers constitute a collapsed form of the OSI seven-layer architecture, mapping into the physical, data link, and application layers of the Reference Model; however, DeviceNet provides additional functionality (such as connection support) commonly attributed to other OSI layers. The high level protocol architecture is shown in Figure 3.

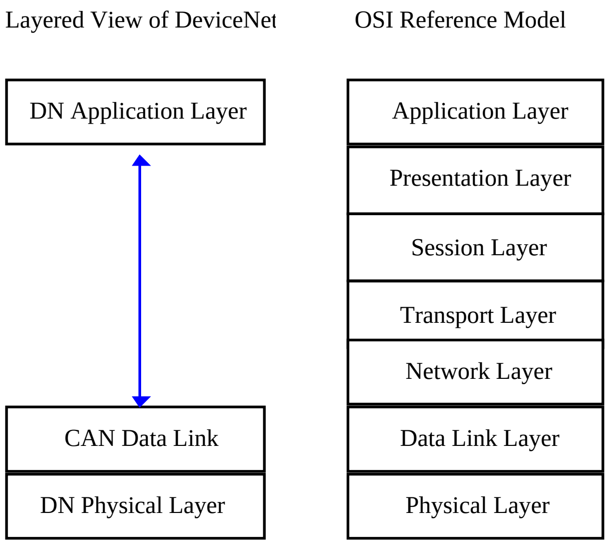

Figure 3
Layered View of DeviceNet

Note that Figure 3 represents a conceptual view of the device architecture. Conforming implementations must implement the services defined in this specification at each layer and must appear (from the network) to have implemented this architecture; however, an internal modular partitioning is not required. Implementations may sacrifice modularity in order to achieve high performance.

The DeviceNet physical layer is fully specified in Volume 1 of the DN Specification. Features of this layer include Trunkline - dropline configuration, simultaneous support for both network-powered and self-powered devices, and selectable data rates including at least 125k, 250k, and 500k baud. At the data link layer, the CAN specification defines a carrier sense multiple access mechanism for media access control that avoids collisions and sends frames reliably. The application layer is specified in Volumes 1 and 2 of the DN Specification and provides for the definition of DeviceNet applications as a collection of addressable objects. Two basic categories of objects exist: Communication Objects and Application Objects. Communication Objects manage and provide for the runtime exchange of messages across DeviceNet. Application Objects implement product-specific features and/or provide a logical interface to product-specific information of devices on a DeviceNet network.

In the remainder of this section, the protocol structure is described in more detail in terms of the OSI seven layer reference model, the object model environment, and network management specifications.

6.1 *Physical Layer* — The device shall comply with the DeviceNet physical layer specification (contained in Volume 1 of the DeviceNet specification). This includes physical signaling (levels and baud rates - detailed in the CAN specification), transceivers, node isolation, media topology, cable specifications, network connectors and taps, and power considerations (load limits, system tolerances, and power supply options).

6.1.1 *Physical Layer Enhancements* — This standard supports the following physical layer enhancement to the DeviceNet specifications:

> The transmission media, including both trunk cable and drop cable, shall be DeviceNet Thin Cable. Specifications on this cable and its utilization in DeviceNet systems (e.g., maximum trunk and drop lengths) are included in the DeviceNet specification.

6.2 *Data Link Layer* — The device shall comply with the DeviceNet Data Link Layer Specifications (i.e., Controller Area Network Specification: Version 2). This includes the media access control mechanism and the logical link control mechanism. Addressing is currently limited to 11 bits.

6.3 *Network Layer* — There is no distinct network layer.

6.4 *Transport Layer* — There is no distinct transport layer. Some of the functionality of this layer is implemented in the Application Layer. Specific functions include: segmentation/reassembly for full message delivery and the establishment of node-to-node connections.

6.5 *Session Layer* — There is no distinct session layer.

6.6 *Presentation Layer* — There is no distinct presentation layer. Data types and data presentation in DeviceNet messages are specified as part of the DeviceNet object definitions and object attribute and service communication protocol.

6.7 *Application Layer* — The device shall comply with the DeviceNet application layer specification for defining and addressing objects, including their attributes and services, and enabling specified network behavior. The device shall comply with the object model specifications provided in the DeviceNet specification. In addition, the device shall comply with the object specifications defined in Section 7 of this document.

6.7.1 *Object Models* — The DeviceNet protocol provides an object-oriented specification for creating, defining, and addressing objects explicitly, including their attributes and services (i.e., explicit messaging), and creating, defining, and communicating object attribute assemblies in an application-dependent format (i.e., input/output messaging). The device shall comply with the object model specifications provided in the DeviceNet documentation. In addition, the device shall comply with the object specifications defined in Section 7 of this document.

6.8 *Network Management* — The device shall comply with the DeviceNet network management specifications (e.g., physical layer bit rate, duplicate MAC ID detection, master-slave, and peer-to-peer network management). No (additional) network management functions are specified in this document.

7 Required Object Types

The DeviceNet specification identifies and describes objects (i.e., classes) that must exist in all DeviceNet-compliant devices. The Common Device Model specification additionally identifies two objects (namely the Device Manager (DM) and Sensor Actuator Controller (SAC) objects) that must exist in all SEMI-compliant SAN devices. The required object types for a SEMI-compliant SAN device, using the network communication specification described herein, necessarily comprise the union of the above to requirements.

A list of required and optional object types is given in Table 2. Note that the Sensor, Acutator, and Controller object types are not required and are indicated as optional in the CDM specification. These objects are aggregated together to form a SEMI- and DN-compliant device, as shown in Figure 4.

Table 2 Required Object Types

Object	*DN Class #**	*CDM Tag ***	*Required by DN **	*Required by CDM ***	*Required by NCS*
Identity	01	N.A.***	Yes	No	Yes
MR	02	N.A.	Yes	No	Yes
DN	03	N.A.	Yes	No	Yes
DM	64	DmI0	No	Yes	Yes
SAC	66	SACI0	No	Yes	Yes
Sensor	****	SenIn	No	No	No
Actuator	****	ActIn	No	No	No
Controller	****	CntIn	No	No	No
(Other)	****	N.A.	No	No	No

* See DeviceNet specification for further information; values are hexadecimal.

** See CDM specification for further information.

*** Not applicable.

**** Application-dependent.

An embodiment of a specific device type represented as an aggregation of the object types listed in Table 2, that is compliant with both the CDM specification and the DN specification, is a candidate for a SEMI SDM as well as a DN Device Profile. Conversely, all SEMI SDM's and DN Device profiles specified for operation over a SEMI-compliant DN network must be an aggregation of the object types listed in Table 2 and be compliant with both the CDM specification and the DN specification.

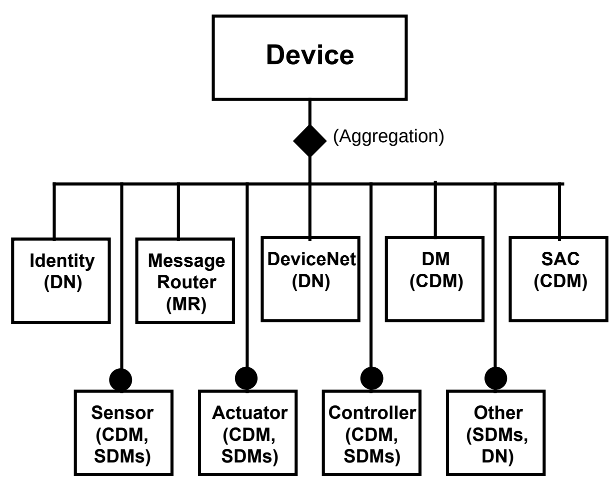

Figure 4
Aggregation of a Compliant Device

In the following sections, the presentation to the network of object addressing, object attributes, and object services for each of the object types listed in Table 2 and Figure 4 is described in detail.

7.1 *Identity Object* — This object provides identification of, and general information about, the device. The Identity Object must be present in all DeviceNet products. As specified by DeviceNet, each DeviceNet product shall support one (and only one) Identity object per physical connection to the DeviceNet communication link. Presentation of object identity, attributes, and services to the network for this object is described in the DeviceNet specification. Compliance with the DeviceNet specification shall constitute compliance with this NCS for the Identity Object.

7.2 *Message Router (MR) Object* — The MR Object provides a messaging connection point through which a service of any object class or instance residing in the physical device may be addressed. The MR object must be present in all DeviceNet products. As specified by DeviceNet, each DeviceNet product shall support one (and only one) Message Router object per physical connection to the DeviceNet communication link. Presentation of object identity, attributes, and services to the network for this object is described in the DeviceNet specification. Compliance with the DeviceNet specification shall constitute compliance with this NCS for the MR Object.

7.3 *DeviceNet (DN) Object* — The DN Object provides the configuration and status of a DeviceNet port. As specified by DeviceNet, each DeviceNet product shall support one (and only one) DN object per physical connection to the DeviceNet communication link. Presentation of object identity, attributes, and services to the network for this object is described in the DeviceNet specification. Compliance with the DeviceNet specification shall constitute compliance with this NCS for the DN Object.

7.4 *Device Manager (DM) Object* — The DM object is the device component responsible for managing and consolidating the device operation. Each device must support one (and only one) DM object. The DM object, as well as its common required and optional attributes, services, and behavior, is described in the CDM standard. The presentation of object attributes and services to the DN network shall be as indicated in Table 3.

Table 3 Network Presentation of DM Object Attributes and Services

Device Manager Object - - Object ID == 64			
Attributes			
ID *	**Name**		**CDM Tag**

10	Set_Attribute	Set_Attribute_Single	DmS5
4B	Execute	Execute ***	DmS6
4C	Perform_Diagnostics	Perform_Diagnostics ***	DmS7

* DN Attribute/Service Identifier. Values are hexadecimal.

** ID's are assigned beginning with 31 hexadecimal to avoid confusion with similiar variables defined for the DN Object Instance (see DN documentation).

*** These services will be detailed in later revisions of the DeviceNet specification. ID value assignments for Abort and Recover services may be changed to reflect the fact that these are deemed DeviceNet Common Services rather than Object Class Specific Services.

Note that the format of DM object attributes is detailed in the CDM document; the presentation of DM object attributes to the DN network is detailed in Table 3 and the DN specification; the format of DM object services is detailed in the CDM document and the DN specification; and the presentation of the DM object services is detailed in Table 3 and the DN specification.

7.4.1 *Device Manager (DM) Object: Alternate Format* — In Section 7.3, the presentation of the DM object structure and behavior is achieved through a distinct, addressable object. In applications where memory limitations are of primary concern, the DM object may be emulated as an extension of the Identity Object (see Section 7.1 and DeviceNet documentation). In this emulation, the presentation of DM object attributes and services shall be as indicated in Table 3 (above), except that the Object ID shall be the ID of the Identity Object (i.e., 01). Additionally, the behavior specified for the DM object (in the CDM standard) shall be incorporated into the Identity Object. Note that this emulation is an alternate format for DM object structure and behavior presentation; unless otherwise indicated (e.g., in the appropriate SDM specification or SDM mapping (see Section 9)), the DM object structure and behavior shall be presented as a distinct object (as detailed in the CDM and Table 3).

7.5 *Sensor, Actuator, Controller (SAC) Object* — The SAC object is the device component responsible for coordinating the interaction of the device with the sensory/actuation/control environment. Each device must support one (and only one) SAC object. The SAC object, as well as its common required and optional attributes, services, and behavior, is described in the CDM standard. The presentation of object attributes and services to the DN network shall be as indicated in Table 4.

Table 4 Network Presentation of SAC Object Attributes and Services

Sensor, Actuator, Controller Object - - Object ID == 66			
Attributes			
ID*	**Name**		**CDM Tag**
	None Defined		
Services			
ID*	**Name (SEMI)**	**Name (DN)**	**CDM Tag**
05	Reset	Reset	SacS1
4D ***	Abort	Abort***	SacS2
4E***	Recover	Recover***	SacS3

* DN Attribute/Service Identifier. Values are hexadecimal.
*** These services will be detailed in later revisions of the DeviceNet specification. ID value assignments for Abort and Recover services may be changed to reflect the fact that these are deemed DeviceNet Common Services rather than Object Class Specific Services.

Note that the format of SAC object attributes is detailed in the CDM document; the presentation of SAC object attributes to the DN network is detailed in Table 3 and the DN specification; the format of SAC object services is detailed in the CDM document and the DN specification; and the presentation of the SAC object services is detailed in Table 3 and the DN specification.

7.6 *Sensor Object, Acutator Object, Controller Object, and Other Object Types* — These object types are used collectively to model the type-specific structure and behavior of the device. The requirement and number of each of these object types in a device model is device type-specific. Further, the attributes, services, and behavior associated with each of these object classes and instances in a device is also device type-specific, but must be compliant with both SEMI and DN specifications. The specification of these object types for a specific device type can be found in the appropriate SDM. The method of presentation of object structure and behavior to the DN network for objects defined for, and associated with, a specific device type can be found in Section 9 of this document.

8 Protocol Compliance

A method of testing protocol compliance is required to verify implementation conformance to the standard. The test plan includes tests for duplicate address resolution, mandatory objects, etc.

The compliance test suite for this protocol necessarily includes the DeviceNet protocol compliance specification and test suite. Additional compliance specification required for compliance to this NCS is provided as a set of Protocol Specification Sheets.

Any enhancements to DeviceNet presented in this document must be accepted by the Open DeviceNet Vendors Association (ODVA) and incorporated into the DeviceNet Specification before they can be implemented as a DeviceNet product.

8.1 *Protocol Specification Sheets* — Compliance to this NCS necessarily requires adherence to a set of protocol specification sheets. These sheets are included as Appendix 1 of this document. Note that these sheets provide statements of compliance for general device data, physical conformance data, communications data, required object implementation (see also Section 7 or this document), and optional object implementation. Note also that these specification sheets must conform with DeviceNet specifications for “Statement of Compliance” forms. Finally note that additional specification sheets shall be completed as necessary to specify compliance with objects defined in SDM’s and SDM mappings (see Section 9).

9 Specific Device Model Mappings

This section provides for the mapping of network-visible specific device structure and behavior, specified in a SEMI standard SDM specification, to the DN network. Each subsection is devoted to a single SDM specification (e.g., 9.1: Mass Flow Controller). Additional SDM mappings are added as sub-sections to this NCS specfication according to SEMI guidelines and the guidelines of the SEMI SAN Interoperability standard.

APPENDIX 1
PROTOCOL SPECIFICATION SHEETS

NOTE A1-1: This appendix is not an official part of SEMI E54.4 and is not intended to modify or supercede the official standard. Determination of the suitability of the material is solely the responsibility of the user. This appendix contains a set of protocol specification sheets. Compliance to this NCS necessarily requires adherence to this set of protocol specification sheets (see Section 8.1).

The protocol specification set of sheets contains the following components:

- A General Device Data/Physical ConformanceData/ DeviceNet Communication Data statement of compliance. (Form F_1, 1 page.)
- DeviceNet required object implementation statements of compliance (for Identity, Message Router, and DeviceNet objects, see Section 7). (Forms F_2 through F_5, 4 pages.)
- NCS - DeviceNet required object implementation statements of compliance (for Device Manager and Sensor/Actuator/Controller objects, see Section 7). (Form F_6, 2 pages.)
- Open object- and vendor- specific implementation templates (for utilization by SDMs, vendors, etc.). (Forms F_6 through F_7, 2 pages.)

Note that these protocol specification sheets are aligned with DeviceNet specifications for “Statement of Compliance” documentation, available with the DeviceNet specification from ODVA. Detailed instructions on completing these forms are in this “Statement of Compliance” documentation. The set of protocol specification sheets begins on the following page.

DeviceNet **Statement of Compliance**

Complete this form using the definitions previously outlined.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer’s instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user’s attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E54.5-0997
STANDARD FOR SENSOR/ACTUATOR NETWORK COMMUNICATIONS FOR THE SMART DISTRIBUTED SYSTEM (SDS)

NOTE: This document was previously designated SEMI E60. Because this document is part of a suite of documents, its designation has been reassigned for ease of reference. Please note that the technical content of this document is unchanged from the 0697 version.

1 Purpose

This standard defines a communication protocol based on the Smart Distributed System (SDS) to enable communications between intelligent devices on a sensor/actuator network (SAN) to be used in semiconductor manufacturing equipment.

1.1 *Background and Motivation* — SDS provides interconnection of smart control devices such as sensors, actuators, and controllers in a fast-response time, low-cost network for industrial use. SDS enables multiple devices to share a single bus, thereby significantly reducing the point-to-point wiring between controllers, sensors, and actuators. The SDS system is based on CAN, the controller area network used in the automotive industry and defined by Bosch.

2 Scope

This document specifies a SAN communications standard based on the Smart Distributed System (SDS) specification that is in compliance with the SEMI SAN Common Device Model specification.

2.1 This document specifies the protocol and services that compliant intelligent devices must support to interchange information over this semiconductor equipment sensor/actuator network.

2.2 This document is used in conjunction with a SEMI standard SAN Common Device Model specification and one or more SEMI standard specific device model specifications (e.g., for a mass flow controller). Together, the model documents describe the data structure and behavior that are characteristic of the various devices on the network. This SAN communications standard identifies the protocol for the interaction with such a device over the network to make the data structures and behavior available to other devices.

2.3 This standard, together with a sensor/actuator network interoperability guideline, the sensor/actuator network common device model, one or more sensor/actuator network specific device model documents, and the SDS specifications, form a complete interoperability standard. The general sensor/actuator network document architecture is shown in the Sensor/Actuator Network Common Device Model document in Figure 1.

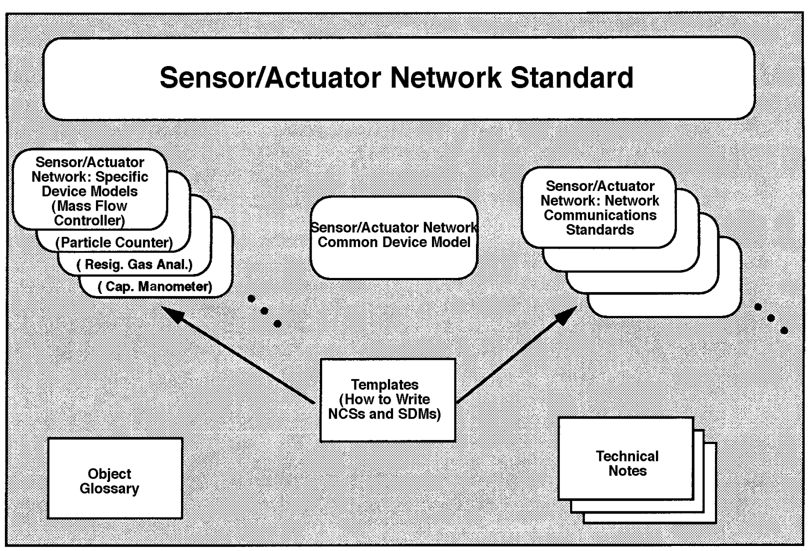

Figure 1
Sensor/Actuator Network Related Documents

The SDS Network communications standard document structure is shown in Figure 2. This standard specifies the mapping of the SAN common device model onto the SDS-specific network. In addition, the document will include mappings to specific device models (e.g., the mass flow controller). The latter mappings will be included in this document as the specific device models are defined.

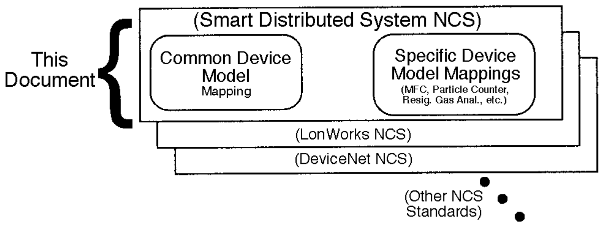

Figure 2
SDS Network Communications Standard Document Structure

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on SDS and is a companion document to the SDS specification; thus, a complete specification of this standard necessarily includes the SDS specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 This standard specifies enhancements that provide additional capabilities over and above those currently required by SDS. In order to avoid document consistency problems, information in the SDS specification that relates to this standard is not repeated in this document. This document is limited to describing enhancements or limitations to the SDS specification that are imposed by this standard.

3.3 A complete specification of the conformance testing procedure shall include the SDS protocol conformance testing specification. Conformance testing shall also include enhancements and limitations to the SDS specification required by this standard.

5 Terminology

Terminology that is common to all of the documents in this SAN series may also be defined in the *Sensor Actuator Network Interoperability Guideline.* Terminology may be reproduced here which is defined in other SEMI documents.

5.1 *Device Component Definitions* — This standard is based on the concepts developed in the Sensor Actuator Network Common Device Model (SEMI E54) document and makes use of the following terms defined in it:

a) device

b) device model

c) object

d) instance

e) attribute

f) behavior

g) service

---

1 International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211 Geneva 20, Switzerland

h) state diagram

i) byte

j) nibble

k) character string

5.2 *SDS-Specific Definitions* — In addition to the above terms, the following terms are defined for SDS networks.

5.2.1 *actions* — operations that a client may request an Embedded Object to perform. The action typically modifies the state of the device. Actions are more powerful than writing to an attribute, in that multiple input arguments may be provided as part of an action request. Also, results of the action are typically returned. Actions, like attributes, have identifiers that are specific to the type of the object. However, these identifiers are independent from attribute or event identifiers. The "request" services specified in SEMI E54 are implemented as SDS actions.

5.2.2 *controller area network (CAN)* — a protocol developed by the Bosch corporation for automotive in-vehicle networking. The CAN specification specifies OSI reference model layers 1 and 2, specifically the physical signaling and media access/data link protocols.

5.2.3 *embedded objects* — each SDS Logical Device contains at least one, and at most 32, Embedded Objects. An SDS Embedded Object is an abstraction representing an addressable entity "embedded" within a Logical Device having specific application-related interface characteristics. These characteristics include a defined set of attributes, actions, and events that are specific to the Embedded Object. Combinations of these Embedded Objects provide a mechanism for describing an arbitrary sensor/actuator network device. The behaviors required by SEMI E54 are specified as part of the definition of attributes, actions, and events.

5.2.4 *events* — Are used by objects to asynchronously report the occurrence of events within an Embedded Object. Event definitions specify the event reports that a specific Embedded Object type may emit. Events also have type-specific identifiers. Event definitions include: a text string defining the semantics of the event, an event identifier numerical value and textual name, and a syntax definition. The "notification" services specified in SEMI E54 are implemented as SDS events.

5.2.5 *logical device* — It is possible to have one or more independent Logical Devices within the Physical Component. This provides the illusion of multiple devices on the network that actually are implemented on the same physical hardware. Logical Devices are distinguished within the Physical Component using unique SDS bus addresses. The Logical Device defines a separately addressable entity within a Physical Component that has an independent interface definition.

5.2.6 *physical component* — An SDS Physical Component is an abstraction representing a single physical package of hardware and software that is connected to the network. This is equivalent to the CDM SEMI E54 definition for "device." The Physical Component contains one or more Logical Devices.

Table 1 provides a mapping of SEMI E54 definitions to SDS-specific definitions. Column 2 contains an equal sign "=" if the definition is used exactly as specified in SEMI E54. Otherwise, the appropriate SDS-specific term(s) are identified.

Table 1 Mapping of Terms Between SEMI E54 and SDS

SEMI E54 Term	*SDS Term*
Device	=
Device Model	Physical Component
Object	Embedded Object
Instance	=
Attribute	=
Behavior	Set of Attribute/Action/Event definitions
Service	Actions for Request Services and Events for Notification Services
State Diagram	=
Byte	=
Nibble	=
Character String	=

6 Communication Protocol High Level Structure

The SDS protocol is based on a three-layer architecture. These layers constitute a collapsed form of the OSI seven-layer architecture, mapping into the physical, datalink, and application layers of the Open Systems Interconnection Reference Model. The high level protocol architecture is shown in Figure 3.

Note that Figure 3 represents a conceptual view of the device architecture. Conforming implementations must implement the services defined in this specification at each layer and must appear (from the network) to have implemented this architecture; however, an internal modular partitioning is not required. Implementations may sacrifice modularity in order to achieve high performance.

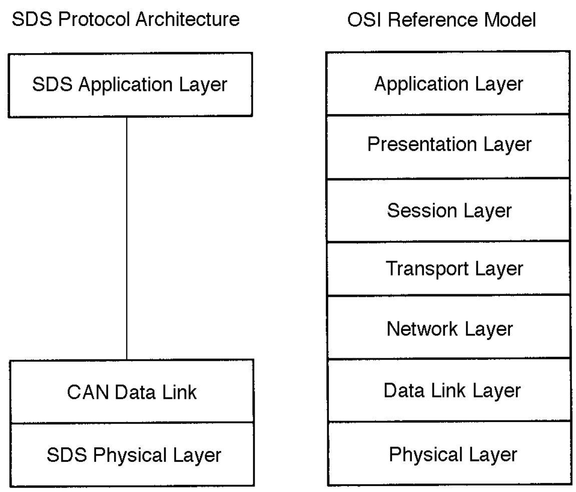

Figure 3
Protocol Architecture

SDS uses a three-layer protocol stack consisting of the physical, datalink, and application layers. The SDS physical layer uses two twisted pair to deliver power and data to smart devices at speeds ranging from 125 Kbps to 1 Mbps and distances up to 500 meters. At the data link layer, the CAN specification defines a carrier sense multiple access mechanism for media access control that avoids collisions and sends frames reliably. The application layer supports a concise set of services to set and get attributes of objects, to invoke operations on objects, and to report notifications from objects. These services are optimized for high performance in discrete control applications (e.g., 3 byte messages convey digital I/O state changes). In addition, a set of pre-defined and extensible component objects flexibly specifies all network-visible application level device capabilities.

6.1 *Physical Layer* — The device shall comply with the SDS physical layer specifications. These include physical signaling (levels and baud rates - detailed in the CAN specification), transceivers, node isolation, media topology, cable specifications, network connectors and taps, and power considerations (load limits, system tolerances, and power supply options).

6.2 *Data Link Layer* — The device shall comply with the SDS Data Link Layer Specifications (i.e., Controller Area Network Specification: Version 2). These include the media access control mechanism and the logical link control mechanism. Frame formats, interframe spacing, and error signaling shall comply with the CAN specifications. CAN frame identifiers shall be 11 bits in length.

6.3 *Network Layer* — There is no distinct network layer. A future extension of the SDS SEMI SAN protocol will support inter network messaging.

6.4 *Transport Layer* — There is no distinct transport layer. Specific functionality of this layer is implemented in the Application Layer. Functions include: segmentation and reassembly for large message delivery.

6.5 *Session Layer* — There is no distinct session layer.

6.6 *Presentation Layer* — There is no distinct presentation layer. Data types are specified as part of the SDS object definitions.

6.7 *Application Layer* — The device shall comply with the SDS application layer specification. This includes application object to application object communication mechanisms.

6.7.1 *Object Models* — The SDS protocol provides an object-oriented specification for defining and addressing objects, including their attributes, actions, and events. The device shall comply with the object model specifications provided in the SDS Component Model Specification. In addition, the device shall comply with the object specifications defined in Section 7 of this document.

6.8 *Network Management* — The device shall comply with the SDS system and network management specifications.

7 Required Object Types

The Common Device Model specification identifies the objects that must be supported in SEMI SAN-compliant devices. These objects are specified in Table 1 of SEMI E54 and include the following:

a) Device Manager (DM)

b) Sensor/Actuator/Controller (SAC)

c) Sensor (S_i)

d) Actuator (A_i)

e) Controller (C_i).

As specified in SEMI E54, a conforming device must support the DM, the SAC, and one or more of the remaining object types.

This section specifies the implementation of these required and optional objects in the SDS object model. SDS object types are defined for the DM and SAC objects. Sensor, actuator, or controller objects may be implemented using existing standard SDS object types, or new types may be specified, depending on the specific device model needs.

7.1 *Embedded Object Type Hierarchy* — SDS classifies Embedded Objects into specific object types (classes), and these types are organized into a class inheritance hierarchy. (For more information on classification and inheritance, see SEMI E39 -- Object Services Standard). Each SDS object type specifies the details of an object's attributes, actions, and events. The Embedded Object (an instance of a type) is a network-addressable entity within a logical device. The classification identifies common characteristics and enables reuse of object definitions. The top two levels of that hierarchy are shown in Figure 4 below.

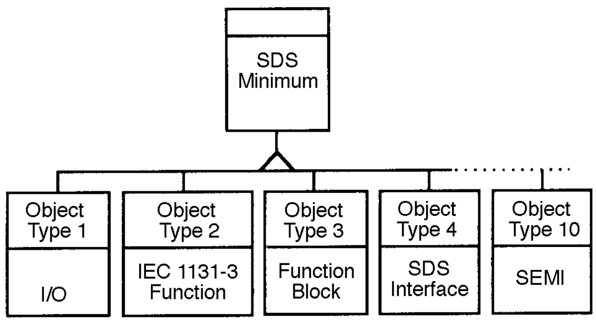

Figure 4
Top Levels of the SDS Embedded Object Type Hierarchy

The SDS object types are specified in detail in the SDS Component Modeling Specification. There are four primary Embedded Object types in the SDS type hierarchy. These include: I/O, IEC 1131-3 Function Object, Function Block, and SDS Interface. In addition, a new SEMI object type has been defined for use in developing classes necessary for SEMI SAN-compliant networks. Each of these object types is derived from a common type called SDS Minimum, which defines the minimum characteristics that are common to all SDS Embedded Objects.

All SDS object types inherit from the SDS Minimum object type, which provides the fundamental characteristics of an SDS device. The other top level SDS object types shown in Figure 4 are summarized below.

I/O Object (Type 1) — Defines the general characteristics of objects used for process I/O type functions. Subtypes of this type specify input and output objects with either analog or digital process variables. These may be used in SAN devices as the sensor or actuator objects.

IEC 1131-3 Function Object (Type 2) — Defines standard IEC 1131-3 Function Objects such as counters, timers, type conversion, bit-wise operations, character strings, etc.

Function Block Object (Type 3) — Collections of function objects that have a specific set of inputs and outputs (e.g., a predefined control algorithm). These may be used in the SAN devices as the controller objects.

SDS Interface Object (Type 4) — Models, network interfaces, gateways, etc.

SEMI Object (object Type 10) — Implement the additional object types necessary for SEMI SAN-compliant networks.

7.1.1 *SEMI Objects* — To implement SEMI-specific object types, the SDS object type hierarchy is augmented with type number 10 - SEMI object. This type, and the types derived from it, specify the new functionality necessary to implement this SEMI standard. Object type 10 is defined to include the common required attributes, services, and behaviors as described in the SAN Common Device Model standard SEMI E54. This definition is in terms of SDS Attributes, Actions, and Events.

In addition, there are derived types: types 10.1 implementing the SAC object and 10.2 implementing the Device Manager (DM) object (Figure 5). Object instances of these types are required in the Common Device Model document SEMI E54.

Each object type inheriting from the SEMI Object type 10 (e.g., 10.1 SAC object) automatically includes the features of the SEMI Object. Thus, both the SAC and the DM object have the reset, abort, and recover actions that are defined for the SEMI Object type 10. (See Section 7.2.) The Device Manager type augments the SEMI Object to provide the required characteristics over and above those specified in type 10 and SDS minimum.

As specific device models are defined, the SAC object type will be refined to be specific to that device. These object types are indicated in Figure 5 as object types SDM-1, SDM-2, etc. (examples include: Mass Flow Controller, Particle Counter, and Capacitance Manometer SAC objects). These object types have (at least) the set of attributes, actions, and events inherited from SDS Minimum, the SEMI Object type, and the SAC object type. Additionally, each SDM-n may have other, unique attributes, actions, and events which implement the desired behavior of a specific device SAC object.

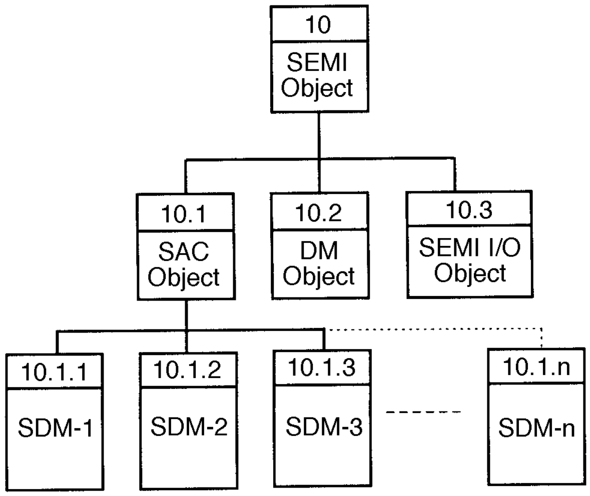

Figure 5
Second and Third Levels of the SEMI Object Type Hierarchy

The optional sensor and actuator objects described in the SEMI E54 specification may be instances of existing SDS object types (e.g., of type I/O object in Figure 4). In cases where a desired object type is not available under SDS object type 1, new I/O object types may be defined as sub-types of object type 10.3 SEMI I/O object.

7.1.2 *Example SEMI Device* — For clarification purposes, an example SEMI device is shown in Figure 6 (using Rumbaugh notation). It consists of three (or more) objects, including a DM, SAC, and binary input object. This is a complete and fully functional SEMI SAN-compliant digital input device.

In Figure 6, the Device is assigned an SDS address (e.g., 125), and each object is assigned an object instance number. The device address may be changed during installation. Each SDS message contains a device address and an object instance number.

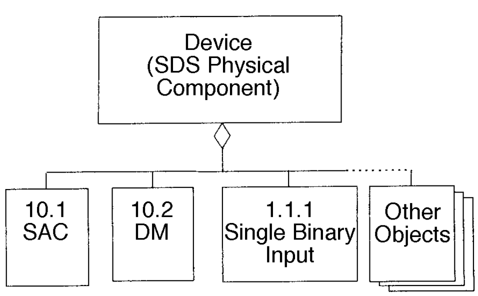

Figure 6
Example Device with Multiple Objects

7.2 *SEMI Object Type 10 Definition* — Table 2 formally specifies the SEMI Object (type 10). The three sections in this table specify SDS identifiers to code the required attributes, actions, or events. The first column is the SDS identifier number, the unique identifier used in SDS messaging. The second column is the SEMI E54-specified name associated with the ID#. The third column identifies the associated tag name (identifier) used in SEMI E54.

80	Reset	SacS1/DmS1
81	Abort	SacS2/DmS1
82	Recover	SacS3/DmS3
83–95	SEMI Reserved Action IDs	Reserve
Events		
ID	Name	SEMI E54 tag
	None defined.	
80–95	SEMI Reserved Event IDs	Reserve

There are no attributes that are currently identified in SEMI E54 that are common to all SEMI objects. As a result, there are no attributes defined in the table. However, 64 attribute IDs have been reserved for use in other sub-types derived from type 10 in this document and in future revisions of this document.

SEMI E54 defines three service requests (reset, abort, and recover) that are common to the Device Manager and the SAC objects. These service requests are implemented as specific SDS Actions. Each service is mapped to a designated SDS action in Table 2. The actions are identified as ID# 80, 81, and 82 respectively. Additional action identifiers are reserved for use in sub-types of this type and for future use.

Not explicitly shown as Actions are the SEMI E54 Get and Set Attribute services. The equivalent behavior is provided by the SDS Read and Write Attribute services that are implicit for every attribute.

The execution of a service request may cause a change in the object's state variable. When a device receives an SDS action message indicating a service request, the object transitions to the appropriate state, after which an SDS response message is transmitted to the service requester indicating the response to the request. For example, the SAC Object Instance Behavior State Transition Matrix in Table 4 of the SEMI E54 document defines the valid SAC state transitions.

Service Notifications (as defined in SEMI E54) are implemented with specific SDS event messages which are specified in the third part of the table. The SEMI object (type 10) has no events defined at this time. Additional event identifiers are reserved for use in sub-types of this type and for future use.

7.3 *Implementation of Sensor/Actuator/Controller Object Type (SAC)* — A single instance of a SAC object type is required in each SAN device. The actual object type used will typically be derived from the SAC object type rather than this exact type. The derived type will have added services and attributes that are device-specific (according to a Specific Device Model specification). The generic SAC type is, nevertheless, defined as a semantic type definition (sensor actuator controller object). The features of the SAC object include service requests (for Reset, Abort, Recover, etc.) that are mapped to SDS Action functions. Since these have been defined in the super type (object type 10), they are not re-defined here.

7.3.1 *SDS Object Model for Sensor/Actuator/Controller Object Type (SAC)* — The SDS object model for the SAC object type (Table 3) needs only to include the appropriate mapping for SAC-specific attributes and behavior (i.e., augmenting the SEMI Object Common Level - Table 8-1). The SAC Object Model contains no attributes, actions, or events beyond those specified in its super type (type 10).

An implementor of a specific device will normally derive a new SAC object type and add new attributes, actions, or events as necessary (i.e., 10.1.1 MFC SAC Object). Object type 10.1 is, in essence, a semantic grouping only—for a group of device-specific SAC object types implementing specific behavior.

The default object identifier that should be used for the SAC object in an SDS device is 1. The actual object identifier used may be reassigned by the implementor. The identifier may be determined on line via reading the object type attributes from all objects on the device.

Table 3 SAC Object Model (Object Type 10.1)

Type 10.1 Sensor/Actuator/Controller Object Model		
Attributes		
ID	Name	SEMI E54 tag
	None defined.	
Actions		
ID	Name	SEMI E54 tag
	None defined.	
Events		
ID	Name	SEMI E54 tag
	None defined.	

7.4 *Implementation of Device Manager Object Type (DM)* — A single instance of this type is required on each device.

7.4.1 *SDS Object Model for Device Manager Object Type (DM)* — The SDS object model for the DM object type includes the appropriate mapping for DM-specific attributes and behavior to SDS-specific identifiers (Table 4).

Table 4 DM Object Model (Object Type 10.2)

Type 10.2 Device Manager (DM) Object Model		
Attributes		
ID Name		SEMI E54 tag
81	Device Type	DmA1
82	Standard Revision Level	DmA2
83	Device Manufacturer Identifier	DmA3
84	Manufacturer Model Number	DmA4
85	Software or Firmware Revision Level	DmA5
86	Hardware Revision Level	DmA6
87	Serial Number (optional)	DmA7
88	Device Configuration (optional)	DmA8
89	Device Status	DmA9
90	Reporting Mode	DmA10
91	Exception Status Timer (optional)	DmA11
92	Exception Status	DmA12
93	Exception Detail Alarm (optional)	DmA13
94	Exception Detail Warning (optional)	DmA14
Actions		
ID	Name	SEMI E54 tag
83	Execute	DmS6
84	PerformDiagnostics	DmS7
Events		
ID	Name	SEMI E54 tag
81	Publish Attribute	DmS8

The DM Object Model maps exactly to the specification for the DM in SEMI E54. Refer to that document for detailed descriptions for the attributes, actions, and events defined in Table 4. The SEMI E54 tag column indicates the identifier used in SEMI E54.

The default object identifier that should be used for the DM object in an SDS device is 2. The actual object identifier used may be reassigned by the implementer.

7.5 *Implementation of Sensor Object Type (S_i)* — Zero or more instances of this object type are permitted on each device.

Sensor object types are already defined within the SDS object hierarchy (e.g., Object Type 1 - I/O Device). Implementation of a device which is compliant with this type results in compliance with this standard.

If the existing sensor object types defined in the SDS specifications do not meet the requirements of the application, new SEMI-specific types may be defined deriving from type 10.3. If new types are required that are generic (i.e., not specific to SEMI), they should be derived from type 1 - I/O Device.

7.6 *Implementation of Actuator Object Type (A_i)* — Zero or more instances of this object type are permitted on each device.

Actuator object types are already defined within the SDS object hierarchy (e.g., Object Type 1 - I/O Device). Implementation of a device which is compliant with this type results in compliance with this standard.

If the existing actuator object types defined in the SDS specifications do not meet the requirements of the application, new SEMI-specific object types may be defined deriving from type 10.3. If new types are required that are generic (i.e., not specific to SEMI), they should be derived from type 1 - I/O Device.

7.7 *Implementation of Controller Object Type (C_i)* — Zero or more instances of this object type are permitted on each device.

Specific controller object types are defined within the SDS object hierarchy (e.g., Object type 3 - Function Block Object). Implementation of a device which is compliant with these types results in compliance with this standard.

If the controller types defined in the SDS specifications do not meet the requirements of the application, new SEMI-specific object types may be defined deriving from type 10. If new types are required that are generic (i.e., not specific to SEMI), they should be derived from type 3 - Function Block Object.

8 Protocol Compliance

A method of testing protocol compliance is required to verify conformance to this standard. The device must satisfy the SDS protocol conformance requirements as documented in the SDS specifications. The SDS partners group provides a conformance verification test procedure service to its members. When this SEMI Sensor/Actuator Network standard is incorporated into the SDS Partners specification set, this service may be used to verify compliance with the SEMI guidelines.

8.1 *Compliance Statement* — Addendum A includes a compliance statement form that should be completed by device implementors for compliance verification.

9 Specific Device Model Mappings

9.1 *Device Model for Mass Flow Controller* — This model will be specified after the MFC-specific device model (SDM) standard is complete.

9.2 *Device Model for Capacitance Manometer* — This model will be specified after the capacitance manometer SDM standard is complete.

9.3 *Device Model for Particle Counter* — This model will be specified after the particle counter SDM standdard is complete.

9.4 *Device Model for Residual Gas Analyzer* — This model will be specified after the residual gas analyzer SDM is defined.

APPENDIX 1
STATEMENT OF COMPLIANCE

NOTE: This appendix was approved as an official part of SEMI E54.5 by full letter ballot procedure.

This form is used to specify conformance options with respect to the SDS and common device model SEMI E54 specifications.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E54.6-0997
STANDARD FOR SENSOR/ACTUATOR NETWORK COMMUNICATIONS FOR LONWORKS

NOTE: This document was previously designated SEMI E61. Because this document is part of a suite of documents, its designation has been reassigned for ease of reference. Please note that the technical content of this document is unchanged from the 0697 version.

1 Purpose

This standard defines a communication specification based on the LonWorks technology specification to enable communications between intelligent devices on a sensor/actuator network (SAN) that operate according to SEMI-specified device models (common and device specific) in a semiconductor manufacturing tool.

This document specifies a mapping of the SEMI common device model (CDM) onto LonWorks technology using the *LonMark Interoperability Guidelines* established for LonWorks devices. The LonMark Interoperability Association may incorporate into the Interoperability Guidelines any enhancements presented in this document.

1.1 *Background and Motivation* — The LonWorks communications system provides interconnection of smart control devices such as sensors, actuators, and controllers in a fast-response time, low-cost network for industrial use. LonWorks enables multiple devices to share a single network, thereby significantly reducing the point-to-point wiring between controllers, sensors, and actuators. The LonWorks network communications standard (NCS) is based on the seven-layer LonTalk Protocol, implemented by the Neuron Chip, a physical layer transceiver, and an optional host processor. The LonTalk Protocol was developed by Echelon and may be freely licensed for implementation on any hardware platform. The SEMI NCS for LonWorks is based on the LonMark interoperability guidelines, which provide a framework for interoperable use of the LonTalk Protocol at layers 1-6, as well as at the application layer. Where the LonMark interoperability guidelines do not provide the functionality required by the SEMI CDM, the guidelines are extended with SEMI-specific requirements.

2 Scope

This document specifies a SAN communications standard, based on the LonWorks specification, that enables communication with SAN devices configured according to the SEMI SAN Common Device Model and appropriate Specific Device Model (SDM) specifications.

2.1 This document specifies the use of LonWorks technology for services that compliant intelligent devices must support in order to exchange information over this semiconductor equipment sensor/actuator network.

2.2 This document specifies the utilization of LonWorks technology to present externally visible device structure and behavior, specified in the CDM and appropriate SDMs, on a LonWorks network.

2.3 This document is used in conjunction with a SEMI standard SAN Common Device Model specification and one or more SEMI standard Specific Device Model specifications (e.g., for a mass flow controller). Together, the model documents describe the externally visible data structures and behavior of devices using LonWorks technology in a SEMI-compliant SAN system.

2.4 This standard, together with a sensor/actuator network interoperability guideline, the sensor/actuator network common device model, one or more sensor/ actuator network specific device model documents, the LonTalk protocol specification, and the LonMark interoperability guidelines, specifies requirements for SEMI SAN implementations based on LonWorks technology. The general sensor/actuator network document architecture is shown in the Sensor/Actuator Network Common Device Model document in Figure 1.

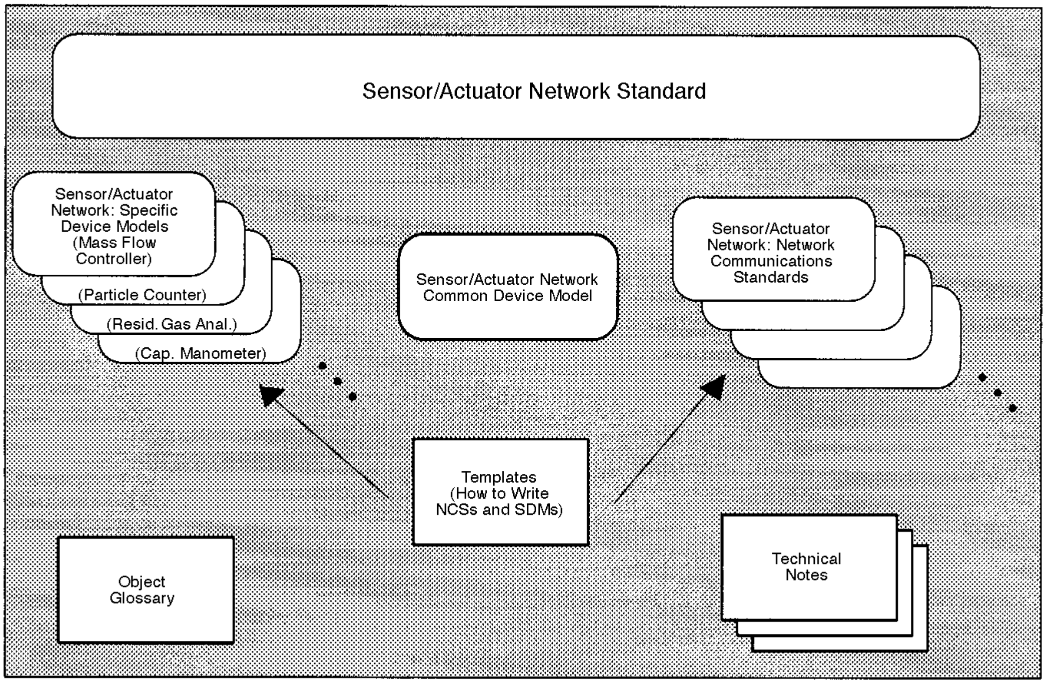

Figure 1
Sensor/Actuator Network Related Documents

2.5 *Document Structure* — The LonWorks network communications standard complies with the SEMI SAN NCS template document structure; this structure is shown in Figure 2. The standard document is composed of two main parts. The first part (Sections 1 through 8) specifies the SAN-enabling protocol as well as the presentation (i.e., mapping) of CDM object structure and behavior onto the network (referred to as the "CDM mapping"). The second part (Section 9) specifies the presentation (i.e., mapping) of SDM object structure and behavior onto the network for each SEMI-specified SDM (referred to as the "SDM mapping"). Device-type-specific items, such as connector deviations (see Section 6.1), may also be noted in Section 9.

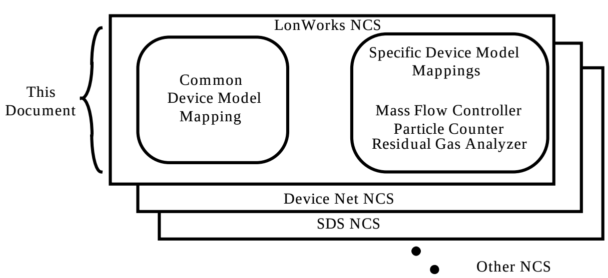

Figure 2
LonWorks Network Communications Standard Document Structure

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on LonWorks and is a companion document to the LonWorks protocol specification; thus, a complete specification of this standard necessarily includes the LonWorks specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 This standard specifies enhancements that provide additional capabilities over and above those currently required by the *LonMark Interoperability Guidelines*. In order to avoid document consistency problems, information in the LonWorks technology standard that relates to this standard is not repeated in this document. This document is limited to describing enhancements or limitations of LonWorks technology and the LonMark interoperability guidelines that are imposed by this standard.

3.3 A complete specification of the conformance testing procedure shall include the applicable LonMark interoperability conformance testing specification. Conformance testing shall include enhancements to the LonMark guidelines required by this standard.

5 Terminology

Terminology that is common to all of the documents in this SAN series may also be defined in the *Sensor Actuator Network Standard*. Terminology may be reproduced here which is defined in other SEMI documents.

5.1 *Acronyms*

5.1.1 *CDM* — Common device model

5.1.2 *DM* — DeviceManager

5.1.3 *DS* — Device status

5.1.4 *NCS* — Network communications standard

5.1.5 *NV* — Network variable

5.1.6 *OSI* — Open systems interconnect

5.1.7 *OSS* — Object services standard

5.1.8 *SAC* — Sensor, actuator, controller object

1 International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211, Geneva 20, Switzerland

5.1.9 *SAN* — Sensor/actuator network

5.1.10 *SCPT* — Standard configuration parameter type

5.1.11 *SDM* — Specific device model

5.1.12 *SNVT* — Standard network variable type

5.2 *Device Component Definitions* — As this standard defines the presentation or mapping of CDM data structure and behavior over a network, it makes use of many of the terms in the CDM document. Table 1 provides a mapping of fundamental terminology of the CDM document into this document and the LonWorks definitions. The symbol "=" indicates that the definition is used exactly as specified on the CDM specification.

In the following sections, additional clarification of some of these terms is provided in the context of the LonWorks protocol.

Table 1 Mapping of CDM to NCS Terminology

CDM Term	*NCS Equivalent*	*LonWorks Equivalent*
Device	=	Device or node
Device Model	=	Functional profile
Object	=	LonMark object type
Instance	=	LonMark object instance
Attribute	=	Network variable or configuration property
Behavior	=	=
Service	=	Network variable function or application message
State Diagram	=	=
Byte	=	=
Nibble	=	=
Character String	=	String of ASCII characters or string of international characters

5.2.1 *attribute* — Attributes are either input network variables, output network variables, or configuration properties. Input and output network variables may be read and/or written by the device itself, and all attributes may be polled over the network. Additionally, input network variables and configuration properties may be updated over the network, and the receipt of such an update causes an event to be propagated to the device's application layer. This corresponds to a RW (Read and Write) attribute of the object owning the network variable. Output network variables may not be updated over the network. This corresponds to a RO (Read Only) attribute of the object owning the network variable. When the device itself updates one of its output network variables, the value of that variable may be propagated over the network to destination address(es) determined at installation time. Finally, configuration properties are attributes typically stored in non-volatile memory and preserved across device resets and power cycles.

5.2.2 *behavior* — Generic object behavior is specified by the *LonMark Application Layer Interoperability Guidelines*. Additional object-specific behavior is specified by means of functional profiles.

5.2.3 *device* — A device (or node) consists of one network transceiver which implements the physical layer of the LonTalk Protocol, one Neuron Chip with associated firmware which implements the other layers of the LonTalk Protocol, and input/output hardware implementing the physical interface of the device to external sensor and/or actuator hardware. A LonWorks device may optionally contain a host processor and associated software or firmware which implements the application layer of the LonTalk Protocol.

5.2.4 *device model* — The device model comprises several elements which fully describe the external interface of the device for an interoperable network. The interface is made of the following pieces: a Device Manager (DM) object; a Sensor/Actuator/Controller (SAC) object; LonMark objects such as sensors, actuators, and controllers; individual network variables; and configuration properties.

5.2.5 *instance* — Real devices may have zero or more instances of each of the defined LonMark objects and functional profiles. Object instances are identified by means of an instance number within the device.

5.2.6 *object* — LonMark objects are defined as a set of one or more network variable inputs and/or outputs, implemented as Standard Network Variable Types, and a set of configuration properties, implemented as Standard Configuration Property Types. LonMark objects form the basis of interoperability at the application layer. The LonMark objects describe standard formats for how information is input to, and output from, a device, and shared with other devices on the network.

5.2.7 *service* — Request services are represented by LonTalk messages delivered to the device application. Notification services are represented by LonTalk messages originated by the device application.

5.2.8 *state diagram* — In a LonWorks device, state is represented by the collection of values of local and network variables of the application program. Transitions between states are the result of external events (such as the receipt of a network variable update, or other I/O event), or internal events (such as the expiration of a timer).

5.3 *LonWorks-Specific Definitions* — In addition to the standard data type definitions for bit, nibble, byte, and character, the LonTalk Protocol defines a set of standard data representations for use as attribute values.

5.3.1 *binding* — Network variables on the same or different devices may be associated together by means of a network management service known as binding. Binding is permitted only if all the network variables in the set are of the same data type. The values of network variables that are bound together are propagated over the network by the LonTalk protocol. Table 2 shows the permitted combinations for updating and polling of network variables.

Table 2 Updating and Polling of Network Variables

Network Variable Class	*Update from Network*	*Update from Device*	*Poll from Network*	*Poll from Device*
Input	Yes	Yes	Yes	Yes[2]
Output	No	Yes[1]	Yes	No
Config'n	Yes	No	Yes	Yes[2]

NOTES:

1. When the device updates one of its own output network variables, input network variables that are bound to this output network variable receive an update from the network.

2. When the device polls one of its own input or configuration network variables, output network variables that are bound to this input or configuration network variable receive a poll from the network.

5.3.2 *configuration properties* — These are attributes of a LonMark object that are used to configure the application-specific behavior of the object, such as sensor gain and offset, linearization table, and sample rate. These attributes are typically updated when the device is installed, configured, or calibrated, and are stored in non-volatile memory.

5.3.3 *functional profile* — A functional profile is a set of one or more LonMark objects, together with semantic definitions relating the behavior of the object(s) to the network variable values. The collection of functional profiles and LonMark objects in a device corresponds to the device-specific model for that device. Each type of functional profile is identified by a type number which is allocated when the profile is standardized.

5.3.4 *network variable* — This is a network-visible data attribute of a device, with a well-defined data type. Network variables are either input variables, output variables, or configuration variables. The value of a network variable may be updated either by the device itself, or over the network by some other device. This corresponds to a SetAttribute operation. The value of a network variable may be polled over the network by some other device, or retrieved by the device itself. This corresponds to a GetAttribute operation.

5.3.5 *object instance* — A device's external interface documentation specifies the type identifiers of the LonMark object instances contained within the device. Each instance is allocated an index number based on the order of the declaration of the instance in the device's external interface documentation. This documentation may be uploaded from the device, and completely specifies the functional profiles and LonMark objects contained within the device, as well as the network variables and configuration properties contained within each of the functional profiles.

5.3.6 *object type* — An object type is the definition of the attributes and behaviors of an abstract entity. Each type of LonMark object is identified by a type number which is allocated when the object type is standardized. A specific device type consists of instantiations of one or more of these object types. The term *LonMark object* is loosely used to refer to either a LonMark object type or to a specific instance of a LonMark object type. The attributes of a LonMark object are implemented as a collection of network variables of SNVT types and configuration properties of SCPT types.

5.3.7 *standard configuration parameter types* — These data types, also known as SCPTs, provide a data type definition and a semantic behavior for the configuration properties of LonMark objects. A list of all available SCPTs and details of their definitions is provided in the *SCPT Master List and Programmer's Guide*.

5.3.8 *standard network variable types* — These data types, also known as SNVTs, facilitate interoperability by providing a well-defined interface for communication between devices made by different manufacturers. A device may be installed in a network, and logically connected to other devices via network variables, as long as the data types match. A list of all available SNVTs and details of their definitions is provided in the *SNVT Master List and Programmer's Guide*.

6 Communication Protocol High Level Structure

The LonTalk Protocol is based on a seven-layer architecture. At each layer, there is a description of the services provided within that layer. The high level protocol architecture is shown in Figure 3.

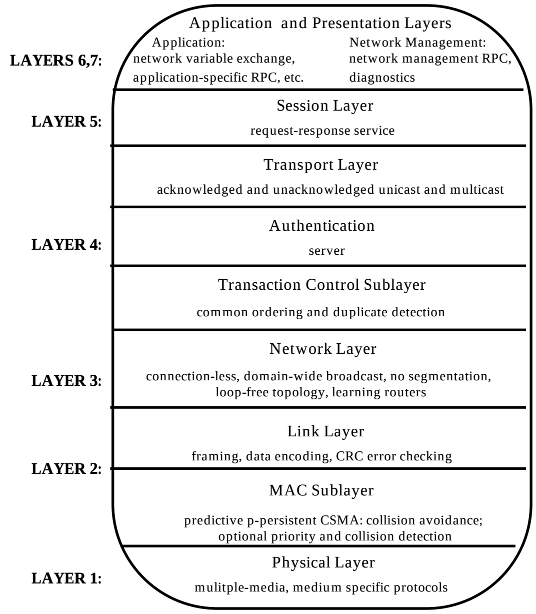

Figure 3
Layered View of the LonTalk Protocol

Note that Figure 3 represents a conceptual view of the device architecture. Implementations typically use the Neuron Chip and its associated firmware, which provide a conforming implementation of layers 2 through 6. The *LonMark Interoperability Guidelines* specify the protocol options to be used, most specifically at the physical layer (network transceivers) and at the application layer (object model).

6.1 *Physical Layer* — The device shall employ one of the LonMark-approved physical channels as specified in the *LonMark Layers 1–6 Interoperability Guidelines*. LonWorks-based SEMI SAN-compliant devices shall use, by default, a two-pin screw-terminal open pluggable connector (Weidmüller-Klippon SL2, Phoenix Combicon, or equivalent) for the network connection. The default connector specification may be overridden for specific device types if special requirements apply; any such overrides shall be noted in Section 9 of this document. This connection is polarity-insensitive. The requirements of semiconductor equipment may be met by one of the twisted pair channel specifications listed below.

6.1.1 *TP/XF-1250 Twisted Pair* — This twisted-pair channel operates at a bit rate of 1,250kbps and supports a bus topology using transformer-coupled transceivers.

6.1.2 *TP/FT-10 Twisted Pair* — This twisted-pair channel operates at a bit rate of 78kbps and supports both free topology and bus topology wiring, as well as optional link power.

The *LonMark Layers 1-6 Interoperability Guidelines* provide specific details of the characteristics of these transceivers. This document also provides specifications of wiring types and interconnection topologies to be used for guaranteed device interoperability. Note that the LonTalk Protocol supports heterogeneous networks. Devices with dissimilar transceivers may be interconnected and communicate via routers or repeaters. Similarly, routers and repeaters may be used to extend a physical channel beyond the device count, wire length, or other physical limitations imposed by the chosen transceiver.

Multiple physical layer protocols and data encoding methods are used in the LonTalk Protocol. Differential Manchester encoding is used on twisted pair physical layers.

6.2 *Link Layer* — The device shall comply with the LonTalk protocol link layer specification. This layer includes the media access control sublayer. For a number of reasons, including simplicity and compatibility with the multicast protocol, the LonTalk protocol supports a simple connectionless service. Its functions are limited to framing, frame encoding, and error detection, with no error recovery by retransmission.

6.2.1 *Media Access Control Sublayer* — In order to deal with a variety of media in the potential absence of collision detection, the MAC (Media Access Control) sublayer employs a collision avoidance algorithm called Predictive *p*-persistent CSMA (Carrier Sense, Multiple Access).

6.3 *Network Layer* — The device shall comply with the LonTalk protocol network layer specification. This layer handles packet delivery within a single domain, with no provisions for inter-domain communication. The network service is connection-less, unacknowledged, and supports neither segmentation nor re-assembly of messages. The routing algorithms employed by the network layer to learn the topology assume a tree-like network topology; routers with configured tables may operate on topologies with physical loops, as long as the communication paths are logically tree-like. In this configuration, a packet may never appear more than once at the router on the side on which the packet originated. The unicast routing algorithm uses learning for minimal overhead and no additional routing traffic. Use of configured routing tables is supported for both unicast and multicast addresses.

6.4 *Transport Layer* — The device shall comply with the LonTalk protocol transport layer specification. The heart of the protocol hierarchy is the Transport and Session layers. A common Transaction Control sublayer handles transaction ordering and duplicate detection for both layers. The transport layer is connectionless and provides reliable message delivery to both single and multiple destinations. Authentication of the message sender's identity is provided as an optional feature. The authentication server requires only the Transaction Control sublayer to accomplish its function. The transport and session layer messages may be authenticated using all of the LonTalk addressing modes other than broadcast. The transport layer supports end-to-end acknowledged service and an unacknowledged/ repeated service.

6.5 *Session Layer* — The device shall comply with the LonTalk protocol session layer specification. This layer implements a simple Request-Response mechanism for access to remote servers. This mechanism provides a platform upon which application-specific remote procedure calls can be built. The LonTalk network management protocol, for example, is dependent on the Request-Response mechanism in the Session layer, even though it accesses the protocol via the application layer interface.

6.6 *Presentation Layer* — The device shall comply with the LonTalk protocol presentation layer specification. The Presentation layer and the Application layer taken together form the foundation of interoperability for LonTalk devices. The application layer provides all the usual services for sending and receiving messages, but it also contains the concept of network variables. The presentation layer provides information in the Application Protocol Data Unit (APDU) header for how the APDU is to be interpreted for network variable updates. This application-independent interpretation of the data allows data to be shared among devices without prior arrangement. With agreement on which network variables are to be used for sensors, actuators, etc., intelligent components from different manufacturers may work together without prior knowledge of each other's characteristics.

6.7 *Application Layer* — At the application layer, interoperability between LonWorks-based devices is facilitated through the use of LonMark objects and Standard Network Variable Types (SNVTs). LonMark objects build upon network variables and provide a concise application layer interface that incorporates semantic meaning for specific device functions. LonMark objects not only define which SNVTs to use to convey data, but also provide semantic meaning about the information being communicated. To aid in the specification of specific device models with well-defined functional behavior, collections of objects with defined relations can be aggregated and referenced as functional profiles. The Application Layer also includes the LonTalk file transfer protocol, which provides segmentation and reassembly of arbitrary length files of data. This service may be used to get and set object attributes that exceed the network variable size limit of 31 bytes.

6.7.1 *Object Models* — The LonTalk Protocol provides an object-oriented specification for defining and addressing network variables and configuration properties, which are the representation of object attributes and events. The device shall comply with the object model specifications defined in Section 7 of this document.

6.7.2 *LonMark Object Structure* — The *LonMark Application Layer Interoperability Guidelines* define a number of object types. Each object type has a set of mandatory network variables, a set of optional network variables, a set of configuration properties (both mandatory and optional), and a manufacturer-defined section, which may be used for non-interoperable extensions to the object. This is illustrated in Figure 4. This notation is defined in the *LonMark Application Layer Interoperability Guidelines*.

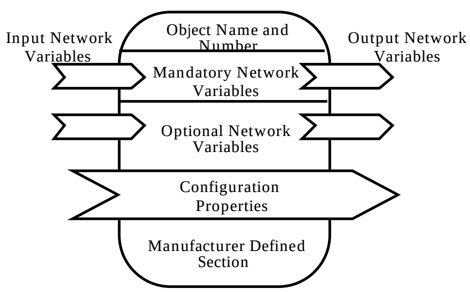

Figure 4
LonMark Object Structure[2]

The *LonMark Application Layer Interoperability Guidelines* provide for the definition of new Standard Network Variable Types, LonMark Object Types, and Functional Profiles. In the mapping of the SEMI CDM to the LonMark object structure in Section 7, extensions to the current SNVT list and Interoperability Guidelines are marked with an asterisk (*). Object type numbers are specified by the guidelines; a device may consist of one instance of a node object type, and one or more instances of LonMark object types, which are assigned sequential instance numbers starting from one.

6.8 *Network Management* — The LonTalk Protocol defines a complete network management and diagnostic protocol for LonWorks devices. This protocol is a layer above the Session layer (request/response service) and provides mechanisms for application downloading, device address assignment, distribution of destination addresses for implicit messaging, router configuration, and device-level diagnostics. The *LonMark Application Layer Interoperability Guidelines* define a device management layer for LonMark objects.

7 Required Object Types

The *LonMark Application Layer Interoperability Guidelines* describe sensor, actuator, and controller objects. A specific device may be implemented using these objects or functional profiles based on these objects. The Common Device Model specification additionally identifies two objects (namely the Device Manager (DM) and Sensor Actuator Controller (SAC) objects) that must exist in all SEMI-compliant SAN devices.

7.1 *Service Requests* — Common Device Model service requests are implemented as LonTalk foreign frame messages delivered to the application using the LonTalk request/response protocol. The transaction layer protocol ensures that response messages are correlated with the original request message. Tables 3 and 4 show the LonTalk APDU format for the Request/Indication message, and for the Response/Confirmation message respectively.

2 Diagram notation, the arrow-like symbol used in Figure 4 is defined in the LonMark Application Layer Interoperability Guidelines.

Table 3 SEMI SAN Request Message APDU Format

Field Name	*Size (bits)*	*Value*
Message Code	8	4D (hex). Indicates a SEMI SAN-compliant foreign frame message.
Object ID	16	Destination object's ID number. Based on the order of the declaration of the instance in the device's external interface documentation string.
Service Code	8	Defines the service being requested.
Request Parameters	optional	Service-specific request parameters.

Table 4 SEMI SAN Response Message APDU Format

Field Name	*Size (bits)*	*Value*
Message Code	8	Zero indicates successful execution of the requested service. Non-zero indicates failure. Values are request-specific.
Response Parameters	optional	Service-specific result parameters.

7.2 *Object Attributes* — The GetAttribute and SetAttribute service requests may also be implemented as network variable fetch, poll, and update requests addressed to the network variable corresponding to the specified attribute. This is appropriate when application-layer service responses are not required. A GetAttribute service request may be addressed directly to any network variable as a LonTalk request message, using the LonTalk protocol network management NV fetch mechanism. A GetAttribute service request may also be addressed to an output network variable as a LonTalk NV poll message, using the NV selection mechanism. A SetAttribute service request may be addressed to an input network variable as a LonTalk NV update message, using the NV selection mechanism. The confirmation of a SetAttribute (network variable update) is provided by the acknowledged service of the LonTalk protocol transport layer.

Each network variable in a LonMark object is identified by means of a self-documentation string stored in the device's memory. This string contains the object id of the object to which this variable belongs, and the sequence number of the network variable within its enclosing object. For the LonWorks NCS, this sequence number is identical to the numerical sequence number specified by the CDM tag.

Example: Suppose that the Device Manager object instance is declared as the second object instance in the device. It would, therefore, have object id 1. The Device Manager attribute Standard Revision Level has the tag DmA2. The self-documentation string for this network variable is, therefore, specified as "@1| 2."

The Publish notification service is implicit when an output network variable is updated. The device propagates the value of the output network variable (equivalent to a read-only attribute) to any input network variable(s) to which it may be bound.

The LonTalk protocol only supports propagation of output network variables. In CDM terminology, this means that only read-only attributes may be published. If a specific device model requires publication of a read/write attribute, an output network variable whose value mirrors the value of the input (read/write) network variable may be introduced to the object definition.

7.3 *Sensor/Actuator/Controller Object (*)* — The SEMI CDM SAC object coordinates the functionality of Sensor, Actuator, and Controller objects in the device. A new object type is defined, which forms part of the LonMark Functional Profile for SEMI SAN-compliant devices based on LonWorks. Table 5 summarizes the services implemented by the SAC object.

Table 5 SAC Object Services

Service Name	*CDM Tag*	*Service Code*
Reset	SacS1	1
Abort	SacS2	2
Recover	SacS3	3

7.4 *Device Manager Object (*)* — The SEMI CDM Device Manager Object combines attributes of device self-documentation with an exception reporting mechanism. A new object type is, therefore, defined with the following mandatory network variables and behaviors. This object type forms part of the LonMark Functional Profile for SEMI SAN-compliant devices based on LonWorks. Table 6 summarizes the network variables that implement the attributes of the Device Manager object.

Table 6 Device Manager Object Network Variables

Name	*Storage Class*	*CDM Tag*	*Standard NV DataType*
Device Type	const	DmA1	SNVT_str_asc or SNVT_str_int
Standard Rev. Level	const	DmA2	SNVT_str_asc or SNVT_str_int
Device Mfgr. Identifier	const	DmA3	SNVT_str_asc or SNVT_str_int
Mfr. Model Number	const	DmA4	SNVT_str_asc or SNVT_str_int
S/W or F/W Rev. Level	const	DmA5	SNVT_str_asc or SNVT_str_int
Hardware Rev. Level	const	DmA6	SNVT_str_asc or SNVT_str_int
Serial Number	const	DmA7	SNVT_str_asc or SNVT_str_int
Device Config'n	const	DmA8	SNVT_str_asc or SNVT_str_int
Device Status	output	DmA9	SNVT_dev_status
Reporting Mode	config	DmA10	SCPT_rept_mode
Exception Status Rept Interval	config	DmA11	SCPT_exc_sts_t
Exception Status	output	DmA12	SNVT_exc_status
Exception Detail Alarm	output	DmA13	SNVT_exc_detail
Exception Detail Warning	output	DmA14	SNVT_exc_detail

7.4.1 *Device Manager Object Requests* — Table 7 summarizes the services implemented by the Device Manager object.

Table7 Device Manager Object Request Services

Service Name	*CDM Tag*	*Service Code*	*Request Parameters*	*Result Parameters*
Reset	DmS1	1		
Abort	DmS2	2		
Recover	DmS3	3		
GetAttribute#	DmS4	4	Attribute ID##	Attribute Value
SetAttribute###	DmS5	5	Attribute ID##, Attribute Value	
Execute	DmS6	6		
Perform Diagnostics	DmS7	7	Test ID####	

\# The GetAttribute service may also be implemented as a network variable poll.
The attribute ID is the numerical sequence number specified by the CDM tag for the attribute. This is the same as the LonMark member ID of the network variable in its owning object.
The SetAttribute service may also be implemented as a network variable update.
The Test ID parameter will be the first parameter in the Perform Diagnostics Request Parameters field.

The Publish (DmS8) notification service for the Device Manager exception status is implemented when the device updates the output network variable of type SNVT_exc_status. This causes the value of this network variable to be propagated across the network to other network variable(s) to which it may be bound. The implementation of the Device Manager object updates this output network variable according to the conditions specified by the Reporting Mode and Exception Status Reporting Interval configuration properties of the object.

7.4.2 *Device Manager Object Constant Output Network Variables* — Table 6 lists the constant output network variables of the Device Manager object. The type of each of these network variables is either SNVT_str_asc, a Standard Network Variable Type that can represent from 0 to 30 ASCII characters, or SNVT_str_int, a Standard Network Variable Type that can represent from 0 to 14 international 16-bit characters.

7.4.3 *Device Manager Object Configuration Properties* — The DM object has two configuration properties to control exception reporting as shown in Table 6. These parameters are of Standard Configuration Parameter Types (SCPTs).

The type SCPT_rept_mode(*) contains two four-bit fields specifying the reporting method for alarms and warning conditions. For example, in Neuron C, the application programming language used on the Neuron Chip, the declaration of SCPT_rept_mode is as follows:

```
typedef enum {
   REP_REQUEST                  = 0,
   REP_REQ_LATCHED              = 1,
   REP_EVT_TRIGD_ON             = 2,
   REP_EVT_TRIGD_ONOFF          = 3,
   REP_TIME_TRIGD               = 4,
   REP_EVT_ON_TIME_TRIGD        = 5,
   REP_EVT_ONOFF_TIME_TRIGD     = 6,
} rept_mode_t;
typedef struct {
   rept_mode_t alarm_rept_mode :4;
   rept_mode_t warn_rept_mode  :4;
} SCPT_rept_mode;
```

The type SCPT_exc_sts_t(*) is a 16-bit value representing times from 0.00 to 655.35 seconds, with a resolution of 0.01 seconds. This parameter is optional. The default reporting mode is REP_REQUEST.

7.4.4 *Device Manager Object Output Network Variables* — The Device Manager object has four output network variables as shown in Table 6. The data type SNVT_dev_status is an enumeration, corresponding to the device status attribute defined in Table 6 of the CDM. The values of this type are defined in Table 8.

Table 8 Device Status Enumeration Values

Value	*Enumeration Tag*
0	DS_UNKNOWN
1	DS_INIT_SELFTEST
2	DS_IDLE
3	DS_SELFTEST_EXCPT
4	DS_EXECUTING
5	DS_ABORT_1
6	DS_ABORT_2

The value DS_ABORT_1 corresponds to the *Abort from Idle* or *Executing* state, and the value DS_ABORT_2 corresponds to the *Abort from Initialized/Self Testing or Self Test Exception* state of the DM object.

The type SNVT_exc_status(*) is a union of two structures, depending on whether expanded or basic exception reporting mode is used. For example, in Neuron C, the declaration of SNVT_exc_status is as follows:

```
typedef union {
 struct {
  int  excpt_method : 1; //set to 0
  int  dev_spec     : 7;
} basic_method;
 struct {
  int  excpt_method  : 1; //set to 1
  int  warn_mfr_spec : 1;
  int  warn_dev_spec : 1;
  int  warn_dev_comn : 1;
  int  resvd         : 1;
  int  alrm_mfr_spec : 1;
  int  alrm_dev_spec : 1;
  int  alrm_dev_comn : 1;
 } expanded_method;
} SNVT_exc_status;
```

The type SNVT_exc_detail(*) is a sequence of three structures containing arrays. The LonWorks Network Communication Standard limits the size of each of these arrays to 9 bytes, so that the type fits within the network variable size limit of 31 bytes. For example, in Neuron C, the declaration of SNVT_exc_detail is as follows:

```
typedef struct {
   u_char comn_exc_size;
   int    resvd1          : 1;
   int    real_time       : 1;
   int    communic        : 1;
   int    RAM             : 1;
   int    EEPROM          : 1;
   int    EPROM           : 1;
   int    microproc       : 1;
   int    diagnostic      : 1;
/*--------------------------*/
   int    resvd2          : 1;
   int    reset           : 1;
   int    notify_mfr      : 1;
   int    maintenance     : 1;
   int    power_inputV    : 1;
   int    power_outptV    : 1;
   int    power_resvd     : 1;
   int    power_overC     : 1;
   u_char comn_exc_dtl[7];
/*--------------------------*/
   u_char dev_exc_size;
   u_char dev_exc_dtl[9];
/*--------------------------*/
   u_char mfr_exc_size;
   u_char mfr_exc_dtl[9];
} SNVT_exc_detail;
```

7.5 *Sensor, Actuator, and Controller Objects* — These objects are necessarily specific to the Specific Device Models. The *LonMark Application Layer Interoperability Guidelines* provide a framework for defining LonMark objects, together with specifications of generic sensor and actuator objects. Specific Device Models may employ these objects, and/or may define their own objects and Standard Network Variable Types for device-specific requirements. As long as the LonMark object definition guidelines are followed, these device-specific objects may be proposed to the LonMark Interoperability Association for incorporation within the LonMark guidelines.

8 Protocol Compliance

A method of testing protocol compliance is required to verify implementation conformance to the standard. By virtue of the fact that the intermediate layers of the LonTalk protocol are implemented in commercially available silicon, compliance verification is needed only at the physical and application layers. The LonMark Interoperability Association provides a compliance verification service to its members. When the SEMI Sensor/Actuator Network standard is incorporated into the LonMark guidelines, this service may be used to verify compliance with the SEMI guidelines.

9 Specific Device Type Information

9.1 This section provides for the mapping of network-visible specific device structure and behavior, specified in a SEMI standard SDM specification, to the LonWorks network. Each subsection is devoted to a single SDM specification (e.g., Section 9.1: Mass Flow Controller). Additional SDM mappings are added as subsections to this NCS specification according to SEMI guidelines and the guidelines of the SEMI SAN Interoperability standard. Device-type-specific items, such as overrides to the standard connector, may also be noted in these subsections.

SEMI E54.7-0999
STANDARD FOR SENSOR/ACTUATOR NETWORK COMMUNICATION FOR SERIPLEX

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on July 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999.

1 Purpose

1.1 This standard defines a communication specification based on the Seriplex protocol to enable communications between intelligent devices on a sensor/actuator network (SAN) that operate according to SEMI specified device models (common and device specific) in a semiconductor manufacturing tool.

1.2 *Background and Motivation*

1.2.1 Seriplex is a component level network which provides a simple, inexpensive, fast, and deterministic means of exchanging data among control level industrial devices (e.g., sensors and actuators) and higher level devices such as controllers. Seriplex provides:

- A solution to low-level device networking
- Access to intelligence present in low-level devices
- Networking between higher level controllers
- Master/Slave and Peer-to-Peer capabilities

1.2.2 Seriplex specifies a communication model and protocol as well as a complete Physical Layer definition.

1.2.3 This document enables communications between intelligent devices on a SEMI compliant SAN by providing a presentation mapping of common and specific device network visible structure and behavior to a Seriplex network.

2 Scope

2.1 This document specifies the protocol and services that compliant intelligent devices must support to exchange information over this semiconductor equipment sensor/actuator network.

2.2 This document specifies the utilization of the Seriplex protocol to present externally visible device structure and behavior, specified in the Common Device Model (CDM) and appropriate Specific Device Models (SDMs), on a Seriplex network.

2.3 This document is used in conjunction with a SEMI standard SAN Common Device Model specification, one or more SEMI standard Specific Device Model (SDM) specifications (e.g. for a mass flow controller) and the Seriplex Standard Specification. Together, they describe the Seriplex protocol, the externally visible data structures and behaviors of devices utilizing the Seriplex networking capability in a SEMI compliant SAN system.

2.4 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicablity of regulatory limitations prior to use.

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on Seriplex and is a companion document to the Seriplex standard specification; thus a complete specification of this standard necessarily includes the Seriplex standard specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 This standard specifies enhancements that provide additional capabilities over and above those currently required by Seriplex. In order to avoid document consistency problems, information in the Seriplex standard specification that relates to this standard is not repeated in this document. This document is limited to describing enhancements or limitations to the Seriplex standard specification that are imposed by this standard.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E54.1 — Standard for Sensor/Actuator Network Common Device Model

SEMI E54.3 — Specification for Sensor/Actuator Network Specific Device Model for Mass Flow Device

4.2 *Other Documents*

Bulletin No. 8310PD9603 — Seriplex Standard Specification: August 1997, Technology Organization, Inc. Raleigh, NC, USA. [1]

ISO 7498 — Basic Reference Model for Open Systems Interconnection[2]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 Terminology that is common to all of the documents in this SAN standard may also be defined in the Sensor/Actuator Network Standard. Terminology may be reproduced here which is defined in other SEMI documents.

5.2 *Abbreviations and Acronyms*

CDM — Common Device Model

DM — Device Manager (object)

NCS — Network Communication Standard

OSI — Open Systems Interconnect

OSS — Object Services Standard

SAC — Sensor, Actuator, Controller (Object)

SAN — Sensor/Actuator Network

SDM — Specific Device Model

STO — Seriplex Technology Organization

VDC — Volts, Direct Current

5.3 *Device Component Definitions*

5.3.1 As this standard defines the presentation or mapping of CDM data structure and behavior over a network, it makes use of many of the terms in the SEMI E54.1 CDM document. Table 1 provides a mapping of fundamental terminology of the CDM document into this document and the Seriplex standard specification. Note that Column 2 contains an equal sign '=' if the definition is used exactly as specified in the CDM specification.

Table 1 Mapping of CDM to NCS Terminology

CDM Term	*NCS Equivalent*	*Seriplex Equivalent*
Device	=	=
Device Model	=	=
Object	=, Class	=, Class
Instance	=	=
Attribute	=	=
Behavior	=	=
Service	=	=
State Diagram	=	=
Byte	=	=
Nibble	=	=
Character String	=	=

5.4 *Seriplex Specific Definitions*

class — a set of objects that all represent the same kind of system component. A class is a general-ization of an object. All objects in a class are identical in form and behavior, but may contain different attri-bute values.

master/slave mode — communication over a Seriplex network that provides exclusive control of data by a "master" or "host" device. All bus input data is reported exclusively to the host, and the host has exclusive control over the states of all bus output signals, with all bus I/O devices acting as 'slaves". Master/Slave mode provides the typical request/ response oriented network communications.

peer-to-peer mode — communication over a Seriplex network that provides sharing of bus input and output data directly among devices. This mode allows dedicated or broadcast data to be shared between a producing application and one or more consuming applications. Application specific I/O data moves though these devices.

seriplex — an open protocol maintained by the Seriplex Technology Organization (STO) as a standard means of interconnection for simple field devices. The Seriplex standard specification specifies OSI reference model layers 1, 2, 4 and 7 specifically the physical signaling, the media access/data link protocols, the transport capability of end-to-end transmission of data, and the application layer.

6 Communication Protocol High Level Structure

6.1 The Seriplex protocol is loosely based on a four-layer architecture. These layers constitute a collapsed form of the OSI seven layer architecture, mapping into the physical, data link, transport and application layers

1 Seriplex Technology Organization, P.O. Box 27446, Raleigh, NC 27611, www.seriplex.org
2 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland

of the Reference Model. The high level protocol architecture is shown in Figure 1.

6.1.1 Note that Figure 1 represents a conceptual view of the device architecture. Conforming implementations must implement the services defined in this specification at each layer and must appear (from the network) to have implemented this architecture, however an internal modular partitioning is not required. Implementations may sacrifice modularity in order to achieve high performance.

6.1.2 The Seriplex physical layer is fully specified in the Seriplex Standard Specification. There are guideline specified for the topology of the bus cable, length of bus cable and number of bus nodes within the system. Typical configurations include: Daisy Chain, Trunk/Dropline, Tree, Loop, Star and Combinations of the above. Reference guidelines are specified for the cable length and node limits determined by a system's Clock rate and total data line capacity within a system. Bus Power Supply provides power for the Seriplex bus itself – that is, for the Seriplex bus communication circuitry within each bus device. The bus power supply normally provides a 24 VDC source for the bus. In general, the bus supply does not provide power to monitoring and control devices.

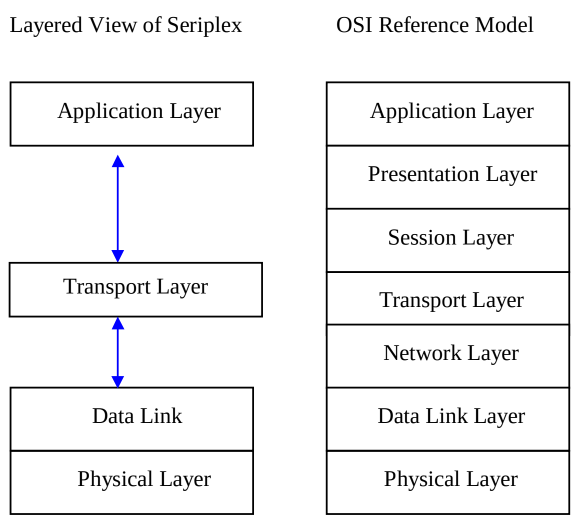

Figure 1
Layered View of Seriplex

6.1.3 At the data link layer, the Seriplex standard messaging specification defines a carrier sense multiple access mechanism for media access control that supports non-destructive collision resolution and sends frames reliably.

6.1.4 The application layer is specified in the Seriplex standard specification and provides for the definition of Seriplex applications as a collection of addressable objects. A subset of these objects may be addressed over the network (as defined by the implementation).

6.1.5 In the remainder of this section the protocol structure is described in more detail in terms of the OSI seven layer reference model, the object model environment and network management specifications.

6.2 *Physical Layer* — The device shall comply with the Seriplex physical layer specification (contained in Seriplex standard specification). This includes physical signaling (levels and data rates), transceivers, node isolation, media topology, cable specifications, network connectors and taps, and power considerations (load limits, system tolerances, and power supply options).

6.3 *Data Link Layer* — The device shall comply with the Seriplex standard specification for the Data Link Layer. This includes the media access control mechanism and the logical link control mechanism. Addressing is currently limited to 8 bits of source address and 8 bits of destination address. Bitwise arbitration is used to gain access to the network in cases where multiple nodes contend for the same message bandwidth.

6.4 *Network Layer* — There is no distinct network layer.

6.5 *Transport (Messaging) Layer* — The device shall comply with the Seriplex standard specification for the Messaging Layer. The messaging layer provides transparent transfer of data between objects in application-entities. Some of the functionality, of this layer is implemented in the Application Layer. Specific functions include: segmentation/re-assembly (fragmentation) for full message delivery.

6.6 *Session Layer* — There is no distinct session layer.

6.7 *Presentation Layer* — There is no distinct presentation layer. Object addressing and data presentation in Seriplex messages are specified as part of the Seriplex object definitions and object attribute and service communication protocol.

6.8 *Application Layer* — The device shall comply with the Seriplex application layer specification for defining and addressing objects, including their attributes and services, and enabling specified network behavior. The device shall comply with the object messaging and object model specifications included in the Seriplex standard specification. In addition the device shall comply with the object specifications defined in Section 7 of this document.

6.8.1 *Object Models* — The Seriplex protocol has been enhanced to provide an object-oriented specification for creating, defining and addressing objects explicitly, including their attributes and services, and creating, defining and communicating object attributes in an application dependent format. The device shall comply with the object messaging and object model specifications included in the Seriplex standard specification documentation. In addition the device shall comply with the object specifications defined in Section 7 of this document.

6.8.2 *Alternate Method for the Communication Transmission of Attributes* — In order to take advantage of the Seriplex network's speed and deterministic characteristics, the Seriplex Standard Specification details a mechanism of transmitting data over the network by assigning, in advance, a sequence of serial frames to be used collectively to deliver specific sensor and/or actuator attribute data. This mechanism can be utilized as an alternative to the object messaging specification of the Seriplex Standard Specification to implement the behavior associated with the GetAttribute and SetAttribute services detailed in Section 7. This mechanism may be used to provide an efficient and optimum implementation of data transmission over the network.

6.9 *Network Management* — The device shall comply with the Seriplex network management specifications detailed in the Seriplex Standard Specification (e.g., physical layer bit rate, master/slave and peer-to-peer network management, etc.). No (additional) network management functions are specified in this document.

7 Required Object Types

7.1 At this time, the Seriplex Standard Specification does not require any specific objects to exist in a Seriplex device in order to be a compliant Seriplex device. The Seriplex Standard Specification will be extended to identify and describe objects (i.e. classes) that must exist in devices that are to be interoperable and interchangeable on a Seriplex SEMI compliant SAN network.

7.1.1 The Common Device Model specification identifies two objects (namely the Device Manager (DM) and Sensor Actuator Controller (SAC) objects) that must exist in all SEMI compliant SAN devices. The required object types for a SEMI compliant SAN device utilizing the network communication specification described herein, necessarily comprises the union of the above two requirements.

7.1.2 A list of required and optional object types is given in Table 2. Additional objects that are specified in a particular SDM are given identifiers in that SDM specification; Seriplex specific presentation information for these identifiers is given in Section 9 of this document.

7.1.3 An embodiment of a specific device type, represented as an aggregation of the object types listed in Table 2, that is compliant with both the CDM specification and the Seriplex specification, is a candidate for a SEMI SDM as well as a Seriplex device definition. Conversely, all SEMI SDM's and Seriplex device definitions specified for operation over a SEMI compliant Seriplex network must be an aggregation of the object types listed in Table 2, and be compliant with both the CDM specification and the Seriplex standard specification.

7.1.4 In the following sections the presentation to the network of object addressing, object attributes, and object services for each of the object types listed in Table 2 is described in detail. Refer to the CDM standard to determine if the object instance attribute and service is specified as required or optional. Unless otherwise noted, all attributes and services described are instance level attributes (as opposed to class level attributes). A class level attribute and service is accessed as instance number zero.

7.1.5 Note that the formats of object attributes and services are detailed in the CDM document; the presentation of object attributes and services to the Seriplex network is detailed in the tables contained in the following sub-sections and in the Seriplex standard specification.

7.2 *Device Manager (DM) Object* — The DM object is the device component responsible for managing and consolidating the device operation. Each device must support one (and only one) DM object. The DM object as well as its common required and optional attributes, services and behavior are described in the CDM standard. The presentation of object instance attributes and services to the Seriplex network shall be as indicated in Table 3.

7.2.1 Note that the formats of DM object attributes are detailed in the CDM document; the presentation of DM object attributes to the Seriplex network is detailed in Table 3 and the Seriplex standard specification; the format of DM object services is detailed in the CDM document and the Seriplex standard specification; and the presentation of the DM object services is detailed in Table 3 and the Seriplex standard specification.

Table 2 Required and Optional Object Types

Object Name	*Seriplex Class ID/Instance ID (See Note 1)*	*CDM Tag (See Note 2)*	*Required by Seriplex (See Note 1)*	*Required by CDM (See Note 2)*	*Required by NCS*
Device Manager	1/1	DmI0	No	Yes	Yes
Sensor/ Actuator/ Controller	2/1	SacI0	No	Yes	Yes
Assembly	3/1 through i	Asm	No	No	No
Local Link	4/1 through j	Lnk	No	No	No
Sensor – AI	33/1 through k	Sai	No	No	No
Sensor – EI	34/1 through l	Sei	No	No	No
Sensor – BI	35/1 through m	Sbi	No	No	No
Actuator – AO	36/1 through n	Aao	No	No	No
Actuator – EO	37/1 through o	Aeo	No	No	No
Actuator – BO	38/1 through p	Abo	No	No	No
Controller	39/1 through q	Ca	No	No	No
Application Objects	129 through x/ 1 through r	(See Note 3)	No	No	No

NOTE 1: See Seriplex specification for further information; values are decimal; ‘i’, ‘j’, ‘k’, ‘l’, ‘m’, ‘n’, ‘o’, ‘p’, ‘q’ and ‘r’ represent arbitrary numbers (greater than or equal to 1) indicating that more than one instance may be supported. ‘x’ is a number greater than or equal to 129 indicating that one or more application object classes may be supported.

NOTE 2: See CDM specification for further information.

NOTE 3: Application Dependent objects as specified in SDM.

7.3 *Sensor, Actuator, Controller (SAC) Object* — The SAC object is the device component responsible for coordinating the interaction of the device with the sensory/actuation/control environment. Each device must support one (and only one) SAC object. The SAC object as well as its common required and optional attributes, services and behavior are described in the CDM standard. The presentation of object instance attributes and services to the Seriplex network shall be as indicated in Table 4.

Table 4 SAC Object Instance Attributes and Services

Sensor, Actuator, Controller Object (SAC) Class ID = 02, Instance ID = 01		
Attributes		
ID	*Attribute Name*	*CDM Tag*
01	Last Calibration Date	SacA1
02	Next Calibration Date	SacA2
03	Expiration Timer	SacA3
04	Expiration Warning Enable	SacA4
05	Run Hours	SacA5
Services		
ID	*Service Name*	*CDM Tag*
01	Reset	SacS1

25	Operate	SacA6
27	Restore Default	SacA7
29	Publish Attribute	SacA8

7.3.1 Note that the format of SAC object attributes is detailed in the CDM document; the presentation of SAC object attributes to the Seriplex network is detailed in Table 3 and the Seriplex standard specification; the format of SAC object services is detailed in the CDM document and the Seriplex standard specification; and the presentation of the SAC object services is detailed in Table 3 and the Seriplex standard specification.

7.4 *Assembly Object (Asm)* — The Assembly (Asm) object instances may be used to provide for grouping more than one attribute from one or more object instances is a device into a single data structure for communication over the Seriplex network. The presentation of object instance attributes and services shall be as indicated in Table 5.

Table 5 Assembly Object Instance Attributes and Services

8 Protocol Compliance

8.1 A method of testing protocol compliance is required to verify implementation conformance to the standard. The Seriplex Technology Organization (STO)[3] has established a mechanism for self certification of devices on a Seriplex network. This certification includes procedures and reporting mechanisms to demonstrate conformance testing and interoperability testing of devices.

9 Specific Device Model Mappings

9.1 This section provides for the mapping of network visible specific device structure and behavior, specified in a SEMI standard SDM specification, to the Seriplex network. Each subsection is devoted to a single SDM specification. Additional SDM mappings are added as sub-sections to this NCS specification according to SEMI guidelines and the guidelines of the SEMI SAN Interoperability standard.

9.2 *Specific Device Model For Mass Flow Device*

9.2.1 This section details the network mapping required to support the Specific Device Model For Mass Flow Devices. Table 14 summarizes the Mass Flow Device Object types. Subsequent tables 15 to 24 details the attributes and services associated with each Mass Flow Device object type.

Table 14 Mass Flow Device Object Types

SDM Object Identifier	*Object Name*	*Seriplex Class ID*
MFD1 (DM)	Device Manager	1
MFD2 (SAC)	Sensor Actuator Controller	2
MFD3	Sensor-AI-MF	129
MFD4	Sensor-AI-AT	130
MFD5	Assembly-MFM	131
MFD6	Sensor-AI-Aux	132
MFD7	Actuator-AO-MF	133
MFD8	Controller	39

SEMI E54.8-0999
STANDARD FOR SENSOR/ACTUATOR NETWORK COMMUNICATIONS FOR PROFIBUS-DP

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available at www.semi.org August 1999; to be published September 1999.

1 Purpose

1.1 This specification is part of the SEMI Sensor/Actuator Network (SAN) suite of standards and defines a specific communications protocol based on the PROFIBUS-DP standard. This Network Communication Standard (NCS) taken together with the SEMI Sensor/Actuator Network standard suite and the PROFIBUS standard completely and unambiguously defines an open standard providing an industry specific solution to off-the-shelf interoperability of networked devices in semiconductor manufacturing equipment.

1.2 PROFIBUS is a vendor independent, open fieldbus standard for a wide range of applications in manufacturing, process and building automation. Vendor independence and openness are guaranteed by the European standard for PROFIBUS, EN 50 170. PROFIBUS-DP is one version of PROFIBUS which is optimized for high speed and inexpensive connectivity between automation control systems and distributed I/O at the device level.

2 Scope

2.1 This document specifies a SAN communications standard based on the PROFIBUS-DP specification that is in compliance with SEMI E54.1. As such, it specifies the protocol, services, and behavior that compliant intelligent devices must support in order to interchange information over this SAN in a method compatible with SEMI E39.

2.2 In conjunction with a SEMI standard SAN Common Device Model (CDM) specification and one or more SEMI standard Specific Device Model (SDM) specifications (e.g., for a mass flow controller), this Network Communication Standard (NCS) with the related PROFIBUS-DP standard describe the data structures, interactions, and behavior that are characteristic of the various devices on the network. This composite model forms a complete interoperability standard for communications among intelligent sensors, actuators, and controllers in semiconductor manufacturing equipment.

2.3 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicablity of regulatory limitations prior to use.

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on PROFIBUS-DP and is a companion document to the PROFIBUS-DP specification, including, by reference, the PROFIBUS-DPV1 standard; thus, a complete specification of this standard necessarily includes the PROFIBUS-DP specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 The specifications within are strictly enhancements that provide additional capabilities over and above those currently required by PROFIBUS-DP. Included throughout this document, primarily in Section 6, is information paraphrased from the PROFIBUS-DP specifications such as: protocol structure, capabilities, options, and limitations. This information is provided here for reference only and is not intended to provide specification definitions. In all such areas, refer to the PROFIBUS-DP specification documents for information. This document is limited to describing enhancements or limitations to the PROFIBUS-DP specification that are imposed by this standard.

3.3 A complete specification of the conformance testing procedure shall include the PROFIBUS-DP protocol conformance testing specification. Conformance testing shall also include enhancements and limitations to the PROFIBUS-DP specification required by this standard.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E54.1 — Standard for Sensor/Actuator Network Common Device Model

SEMI E54.3 — Specification for Sensor/Actuator Network Specific Device Model for Mass Flow Device

4.2 *ISO Standard*[1]

ISO 7498 OSI — Basic Reference Model for Open Systems Interconnection

4.3 *Other Standard*

EN 50 170 Volume 2 — DIN 19245 Part 1 to 4 — PROFIBUS Standard[23]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Acronyms*

CDM — Common Device Model

CSRD — Cyclic Send and Request Data

DDLM — Direct Data Link Mapper

DP — Decentralized Periphery

DPM1 — DP-Master Class 1

DPM2 — DP-Master Class 2

DPV1 — DP Extensions Version 1

DSAP — Destination SAP

FDL — Fieldbus Data Link

FMA1/2 — Fieldbus Management for Layers 1 and 2

NCS — Network Communication Standard

OSI — Basic Reference Model for Open Systems Interconnection (ISO 7498)

PDU — Protocol Data Unit

PHY — Physical Layer

SAN — Sensor/Actuator Network

SAP — Service Access Point

SDA — Send Data with Acknowledge

SDM — Specific Device Model

SDN — Send Data with No acknowledge

SRD — Send and Request Data with reply

SSAP — Source SAP

UI — User Interface

5.2 *Terminology Defined in Sensor/Actuator Network Common Device Model (SEMI E54.1)*

attribute

behavior

byte

common device model

device

Device Manager (DM) Object

device model

instance

network communication standard

object

Sensor, Actuator and Controller (SAC) Object

service

specific device model

state diagram

5.3 *Terminology Defined in PROFIBUS*

Device Data Base — an electronic file that provides a clear and comprehensive description of the characteristics of a device type in a precisely defined format. Also called a GSD File.

Device Profile — a Device Data Base Sheet, which specifies the characteristic features of a device, and a GSD File.

Direct Data Link Mapper — a protocol layer that provides an interface to the User Interface Layer by translating service requests and responses between the User Interface Layer and the Fieldbus Data Link.

DP-Master Class 1 (DPM1) — a device that polls its assigned DP-Slave devices and handles user data exchange.

DP-Master Class 2 (DPM2) — a device that interacts as a configuration or diagnostic tool; usually a programming device.

DP-Slave — a device that is configured, managed, and polled by Master devices; a DP-Slave initiates no unsolicited communications.

Fieldbus Data Link — the PROFIBUS-DP model for the OSI Layer 2 definition.

GSD File — see Device Data Base

Service Access Point — an addressable location in a device for the directing of service requests.

---

1 International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211, Geneva 20, Switzerland

2 Deutches Institut für Normung e.V., Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-10787 Berlin, Germany, PROFIBUS Trade Organization, 5010 East Shea Blvd., Scottsdale, AZ 85254, USA

3 The original Profibus standard was the DIN standard listed, in March 1996, the DIN standard became the EN standard listed.

Send Data with No acknowledge — a service request that sends data with no reply.

Send and Request Data with reply — a service request that sends data followed by a reply by the receiving device.

Slave Diagnostics — a method of retrieving a specifically formatted Data Structure that represents the diagnostic status of a DP-Slave.

5.4 *Terminology Defined in This Document*

DP Service Protocol — a messaging specification for the request of, and response to, services for the PROFIBUS-DP NCS using the PROFIBUS-DP standard.

DPV1 Service Protocol — a messaging specification for the request of, and response to, services for the PROFIBUS-DP NCS using the PROFIBUS-DPV1 standard.

6 Communication Protocol High Level Structure

6.1 In a typical remote I/O configuration, single master architectures are used to optimize response times. In lower speed applications, multi-master architectures are also possible. PROFIBUS-DP uses the polling principle for communication (Master-Slave method).

6.1.1 Message transfer is organized in cycles. A message cycle mainly consists of a request-frame followed by a corresponding acknowledge/response-frame of the addressed station. An exception to this is the global-control function for synchronization and coordination of several remote I/O stations.

6.1.2 A brief description of the PROFIBUS-DP protocol as it relates to the ISO 7498 OSI model follows in the sections below. For protocol efficiency, PROFIBUS-DP does not define layers 3 to 7. However, since the OSI model specifies Layer 7 as the interface between the Application Process and the communication stack, it is appropriate to discuss several aspects of the PROFIBUS-DP standard at this level. These include: the Direct Data Link Mapper, the User Interface, the Service Access Point, the Device Profile, and the Device Data Base.

NOTE 2: The information contained in this section is for reference only. It in no way represents specifications for PROFIBUS-DP. See related documentation for these specifications.

6.2 *Physical Layer — Layer 1*

6.2.1 There are currently two options specified for the Physical Layer (PHY): RS-485 and Optical. See the PROFIBUS-DP standard for more information about these options.

6.3 *Data Link Layer — Layer 2*

6.3.1 *Data Transfer*

6.3.1.1 The Data Link Layer or Fieldbus Data Link (FDL) provides the functions for sending and receiving data over the network. Protocol Data Units (PDU) are packaged, delivered, and checked. Acknowledgements, responses, retries, and timeouts are used to guard against Line Protocol Errors (e.g., frame, overrun, and parity) and Transmission Protocol Errors (e.g., start and end delimiters, frame check, frame length, and response times).

6.3.1.2 A PDU is restricted to 246 bytes. Preferably, the PDU size should not exceed 32 bytes for optimum performance. In addition to the PDU, a transmission frame of variable length will contain 8 bytes of overhead; one of fixed length (8 bytes) will contain 6 bytes of overhead. Various acknowledgement and response frames are also defined.

6.3.1.3 To better understand the FDL, a summary of FDL data transfer services is given by the following list:

- Send Data with Acknowledge (SDA),
- Send Data with No Acknowledge (SDN),
- Send and Request Data with Reply (SRD), and
- Cyclic Send and Request Data with Reply (CSRD).

6.3.2 *Bus Management*

6.3.2.1 The Fieldbus Management for Layers 1 and 2 is provided by the FMA1/2 component. The FMA1/2 acts as a mediator between the local FMA1/2 user and layers 1 and 2. Requests from the FMA1/2 user, modified as required, are transferred to the FDL and PHY control, and acknowledged with a confirmation to the local FMA1/2 user. The FMA1/2 immediately receives indications from the FDL and PHY if status changes have occurred within the layers, which then leads to an FMA1/2 user indication.

6.4 *Application Layer — Layer 7*

6.4.1 As stated above, PROFIBUS-DP does not define Layer 7. The following components may be considered part of, or above, Layer 7.

6.4.2 *Direct Data Link Mapper (DDLM)*

6.4.2.1 The DDLM performs the interpretation of service requests from, and responses to, the User Interface (UI). The DDLM offers a well defined, easy interface between the UI and the FDL. Table 1 is included to demonstrate the basic structure of the

PROFIBUS-DP DDLM. For speed and efficiency, the PROFIBUS-DP protocol defines the Service Access Point (SAP). These are included in the transmission protocol to direct messages within the device for fast dedicated processing. Defined are Destination SAP (DSAP) and Source SAP (SSAP).

6.4.3 *User Interface (UI)*

6.4.3.1 The UI provides the user with access to functionality of the PROFIBUS-DP protocol. There is one UI definition for DPM1 devices and one for DPM2 devices. To better understand the UI, a summary of application functions follows:

6.4.3.2 *DPM1 and DPM2 UI — Master-Slave Application Functions*

- Read Diagnostic Information of DP-Slaves
- Cyclic User Data Exchange
- Parameterization and Configuration Checking
- Submit Control Commands

6.4.3.3 *DPM2 UI — Master-Slave Application Functions*

- Read Configuration of a DP-Slave
- Read Input/Output Values
- Address Assignment to DP-Slaves

Table 1 DDLM Primitive Functions

DDLM Function	*Description*	*SSAP*	*DSAP*	*FDL SRV*
Master-Slave				
DDLM_Data_Exchange	Exchanges I/O Data	NIL	NIL	SRD
DDLM_Check_Cfg	Sends Configuration to DP-Slave for verification.	62	62	SRD
DDLM_Set_Prm	Sends Parametric Data to DP-Slave.	62	61	SRD
DDLM_Slave_Diag	Retrieves the Diagnostic Data Structure from a DP-Slave.	62	60	SRD
DDLM_Get_Cfg	Retrieves the Configuration Data Structure from a DP-Slave.	62	59	SRD
DDLM_Global_Control	Controls the Operational and Synchronization Modes of DP-Slaves.	62	58	SDN
DPM2-Slave				
DDLM_RD_Outp	Retrieves the Status of the Outputs of the DP-Slave.	62	57	SRD
DDLM_RD_Inp	Retrieves the Values of the Inputs of the DP-Slave.	62	56	SRD
DDLM_Set_Slave_Add	Sets the Node Address of a DP-Slave.	62	55	SRD
Master-Master				
DDLM_xxx	Various Services for Master-Master Communications	54	54	SRD
DDLM_Act_Para_Brct	Accept and Activate the most recent Download of Parameters.	54	54	SDN
Master-Slave — Extended Communications				
DDLM_Read	Acyclic Read of DP-Slave Data	62	51	SRD
DDLM_Write	Acyclic Write of DP-Slave Data	62	51	SRD
DPM2-Slave — Connection Configuration				
DDLM_xxx	Various Services for Control and Management of the MSAC_C2 Connection	50	40–48	

6.4.3.4 *DPM2 UI — Master-Master Application Functions*

- Read DP-Master Class 1 Diagnostic Information of the Associated DP-Slaves
- Upload and Download of Parameters
- Activate Bus Parameters
- Activate and Deactivate DP-Slaves
- Select Operating Mode of a DP-Master Class 1

6.4.4 *Service Access Point (SAP)*

6.4.4.1 The Service Access Point provides standard access addressing for messages. The FDL message frame includes fields for Source and Destination SAP. By directing a message to a particular Destination SAP, its context is immediately known. This provides a fast and interoperable environment for device messaging.

6.4.5 *Device Profile/Device Data Base*

6.4.5.1 PROFIBUS devices have different performance characteristics. Features differ in regard to available functionality (i.e., number of I/O signals and diagnostic messages) or possible bus parameters such as baud rate and time monitoring. These parameters vary individually for each device type and vendor. These parameters are usually documented in the technical manual. To achieve simple plug-and-play configuration of PROFIBUS, the characteristic features are specified in an electronic data sheet called a Device Data Base file or GSD file.

6.4.5.2 The GSD Files provide a clear and comprehensive description of the characteristics of a device type in a precisely defined format. These are prepared individually by the vendor for each type of device and made available to the user in the form of a Device Data Base Sheet and a GSD File. The device data base file is divided into three parts: General Specifications, Master Related Specifications, and Slave Related Specifications.

6.4.5.3 These GSD Files are maintained and managed by the PROFIBUS Trade Organization.

6.5 *Network Management*

6.5.1 The PROFIBUS-DP system is managed through several phases of operation. A Master device must have knowledge of the Device Profile for each of the Slave devices it will connect. The Device Data Base Files serve this purpose. Upon initialization, a Master will control a DP-Slave through three operational modes: Parameterization, Configuration, and I/O Data Exchange. In any operational mode, a Master may interrogate a DP-Slave for its Diagnostic information.

6.5.2 In the sections that follow, these operation modes are mapped to related SAN CDM behavior states.

7 Required Object Types

7.1 This section describes a general mapping of the SEMI SAN Object Model to the PROFIBUS-DP environment. Component definitions are clarified and the mapping of Attributes, Services, and Behaviors are specified.

7.2 *Object Model*

7.2.1 The Object Model defined in the CDM is represented in the PROFIBUS NCS. Specifically, the DM and SAC objects are mapped.

7.2.2 The Application Objects associated with the SDM standards are mapped in PROFIBUS-DP Device Data Base documents as defined above in the Device Profile/Device Data Base section. Section 9 specifies the mapping of SDM Objects in PROFIBUS-DP.

7.3 *Component Mapping Summary*

7.3.1 Table 2 provides a summary of the components of the CDM object model as they relate to the components of PROFIBUS-DP.

Table 2 Component Mapping Summary

SEMI SAN			*PROFIBUS-DP*	
Definition	*Object*	*Component*	*Device*	*Component*
Attributes	DM	Identification and related device attributes	Remote	Device Data Base
	DM	Status and Exception	Slave	Diagnostics
	Active Element	Input/Output	Master/Slave	I/O Data Exchange
	DM & Active Element	Configuration	Slave	Configuration

SEMI SAN			PROFIBUS-DP	
Definition	*Object*	*Component*	*Device*	*Component*
Services	All	Get_Attribute and Set_Attribute	Master/Slave	Service Request
	DM & SAC	Reset	Slave	Service Request Master_Unlock
	DM & SAC	Operate and Recover	Slave	Service Request Send Parameter Data Check Configuration
	DM & SAC	Abort	Slave	Service Request Clear_Data
Behavior States	DM & SAC	Initialized/Self Testing	Slave	Wait_Prm
	DM & SAC	Idle	Slave	Wait_Cfg
	DM & SAC	Executing	Slave	Data_Exch
	DM & SAC	Self Test Exception and Critical Fault	Slave	Diag.Station_Not_Ready
	DM & SAC	Abort	Slave	Device Clear

7.4 *Objects*

7.4.1 The required objects of the CDM are identified here. Additional objects that are contained in the SDM are given identifiers in the Device Profile. Section 9 specifies additional mapping information.

7.4.2 Table 3 lists the Object Identifiers specified for use in protocol messages.

Table 3 Object Identifiers

Object ID	*Object*
0	Invalid
1	DM Object
2	SAC Object
3–n	Application Objects as specified in Section 9.

7.5 *Attributes*

7.5.1 All attributes are accessible via Get_Attribute and Set_Attribute services defined in the sections below. Additionally, attributes are accessible via different PROFIBUS-DP defined methods which are mapped in this document based on attribute type.

7.5.1.1 The attributes of the DM object are divided into three types: Identification, Status, and Configuration. Identification attributes are communicated with the Device Data Base. Status attributes are communicated using the DP-Slave Diagnostic method. Configuration attributes are communicated using the Configuration method.

7.5.1.2 The attributes of Application objects are divided into two types: Input/Output and Configuration. Input/Output attributes are communicated using the I/O Data Exchange method. Configuration attributes are communicated using the Configuration method.

7.5.1.3 See Table 5 for a list of DM attributes and their related alternative access methods.

7.5.2 *PROFIBUS-DP Device Data Base*

7.5.2.1 The specification of the Device Data Base (or GSD file) for a given SDM is beyond the scope of this document. The PROFIBUS Trade Organization is responsible for the management of these files.

7.5.2.2 Table 5 lists which attributes of the CDM are mapped to the GSD file.

7.5.2.3 *PROFIBUS-DP Slave Diagnostics*

7.5.2.3.1 The two attributes of the DM object listed in Table 5 that are identified with an alternative access method of slave diagnostics are mapped into the PROFIBUS-DP Slave Diagnostics as specified in this section. See the PROFIBUS-DP standard for a description of the DP Slave Diagnostics.

7.5.2.3.2 These two attributes, each a single byte in length, are mapped into the Slave Diagnostic data structure. Additional diagnostic data may be included as specified by PROFIBUS-DP.

7.5.2.3.3 In response to a DDLM_Slave_Diag request, the device responds with its Diag_Data. Specifically, Table 4 shows the mapping that applies to the Device Related Diagnostic Block.

Table 4 Device Related Diagnostic Block Format

Byte	*Definition*	*Value*
0	Length	3
1	Octet 1	Device Status
2	Octet 2	Exception Status

7.5.3 *PROFIBUS-DP I/O Data Exchange*

7.5.3.1 Input/Output attributes of the Application objects are communicated using the I/O Data Exchange method of PROFIBUS-DP. This method is described in the PROFIBUS-DP standard. A list of which attributes are accessible with this method is included in the PROFIBUS Device Profile for a given device type.

7.5.4 *PROFIBUS-DP Configuration*

7.5.4.1 Configuration attributes of the DM object and Application objects are communicated using the Configuration method of PROFIBUS-DP. This method is described in the PROFIBUS-DP standard. A list of which Application object attributes are accessible with this method is included in the PROFIBUS Device Profile for a given device type.

7.5.4.2 *Attribute Identifiers*

7.5.4.2.1 Every object specified in the CDM and SDMs uses tags to identify its attributes. These tags are formatted with letters (identifying the object) followed by an upper case “A”, followed by a numerical identifier. The Attribute ID used in the PROFIBUS-DP NCS is simply the numerical portion of these tags.

7.5.4.2.2 The PROFIBUS attribute ID is used to identify attributes for access via PROFIBUS-DP message requests, which are explained in later sections.

7.5.4.2.3 Table 5 shows the attributes defined in the SEMI CDM with the respectively mapped ID numbers. Also shown is the alternative PROFIBUS-DP access method.

7.6 *Services*

7.6.1 PROFIBUS-DP specifies standard mechanisms for the communication of data over the network. These mechanisms are used to communicate attributes specified in the device model of a DP-Slave device. The attributes of the DM that are accessible with this method are identified in Table 5.

7.6.2 Additionally, PROFIBUS-DP specifies standard methods for the control of devices over the network. These mechanisms are used to control the basic operational states associated with a DP-Slave device. These standard mechanisms and methods are identified in this document but specified in the PROFIBUS-DP standard.

Table 5 DM Object Attribute Identifiers

SEMI CDM Attribute ID	*PROFIBUS Attribute ID*	*Attribute*	*Alternative Access Method*
DmA1	1	Device Type	Device Data Base
DmA2	2	Standard Revision Level	Device Data Base
DmA3	3	Device Manufacturer Identifier	Device Data Base
DmA4	4	Manufacturer Model Number	Device Data Base
DmA5	5	Software or Firmware Revision Level	Device Data Base
DmA6	6	Hardware Revision Level	Device Data Base
DmA7	7	Serial Number	Device Data Base
DmA8	8	Device Configuration	Device Data Base
DmA9	9	Device Status	Slave Diagnostics
DmA12	12	Exception Status	Slave Diagnostics
DmA13	13	Exception Detail Alarm	N/A
DmA14	14	Exception Detail Warning	N/A
DmA15	15	Visual Indicator	N/A
DmA16	16	Alarm Enable	Configuration
DmA17	17	Warning Enable	Configuration

7.6.3 *Service Requests*

7.6.3.1 There are two methods defined in this standard that allow service requests to be delivered to DP-Slave devices.

7.6.3.2 The PROFIBUS-DPV1 method can be used by devices with Extended Data Communications capabilities as defined by the PROFIBUS-DPV1 specification. The specification for communication of these service requests is defined in the following sections.

7.6.3.3 The PROFIBUS-DP method is used by devices without Extended Data Communications capabilities. Support of the PROFIBUS-DP method requires specific definitions for I/O Data Exchange data. These definitions are described in the following sections.

7.6.3.4 *DPV1 Service Request*

7.6.3.4.1 For systems utilizing the Extended Data Communication capabilities, additional services may be requested over the network using the Extended Data Communications together with the DPV1 Service Request Protocol specified in this section.

7.6.3.4.2 The Extended Data Communication definition describes a method of establishing connections between a DPM1 and DP-Slaves via the Supplemental Service Access Point — SAP 51.

7.6.3.4.3 *DPV1 Service Request Protocol*

7.6.3.4.3.1 All service request messages, except Get-Attribute and Set_Attribute, are sent to a DP-Slave using the DDLM_Write function of PROFIBUS-DPV1. The responses to these message requests are specified by PROFIBUS-DPV1.

7.6.3.4.3.2 The DPV1 Service Request message is formatted (as defined by PROFIBUS-DPV1) with the following Protocol Fields defined:

Slot = Object ID
Index = 0

7.6.3.4.3.3 Table 6 shows the Data Fields defined by this standard for the Extended Data Communications.

Table 6 Data Field of DPV1 Service Request Protocol

Byte	*Description*
0	Service Request ID
1–n	Service Parameters

NOTE 1: Service ID 4 (Get_Attribute) and Service ID 5 (Set_Attribute) are invalid for this protocol. The following two sections specify the protocol for these service requests.

7.6.3.4.4 *DPV1 Set_Attribute Protocol*

7.6.3.4.4.1 The DPV1 Service Request message for the Set-Attribute is sent to a DP-Slave device using the DDLM_Write function of PROFIBUS-DPV1. It is formatted with the following protocol fields defined:

Slot = Object ID
Index = Attribute ID
Data Field = Attribute Value

7.6.3.4.4.2 The Slot and Index limit is 255 and data is limited to 244 bytes. Therefore, the Device Models of the PROFIBUS-DP devices defined here are limited to 255 Objects, each with no more than 255 attributes, each no larger than 244 bytes.

7.6.3.4.5 *DPV1 Get_Attribute Protocol*

7.6.3.4.5.1 The DPV1 Service Request message for the Get-Attribute is sent to a DP-Slave device using the DDLM_Read function of PROFIBUS-DPV1. It is formatted with the following protocol fields defined:

Slot = Object ID
Index = Attribute ID

7.6.3.4.5.2 The Slot and Index limits are as defined above for Set_Attribute. The response to this request is the attribute value.

7.6.3.5 *DP Service Request*

7.6.3.5.1 Beyond that which is specified by PROFIBUS-DP, additional services may be requested over the network using the I/O Data Exchange method definition together with the DP Service Protocol specified in this section. Additionally, specified in this standard is a DP Service Response Protocol.

7.6.3.5.2 A DP-Slave device must identify support for the DP Service protocol in its GSD File. Support is enabled during the configuration of the DP-Slave device. In this mode of I/O Data Exchange, each data packet delivered to the DP-Slave device is formatted per the DP Service Request protocol and each data packet received from the DP-Slave device is formatted per the DP Service Response protocol.

7.6.3.5.3 The I/O Data Exchange data length must be specified for the longest message (MAX). That is, the DP-Slave device output data length must be set to accommodate the longest request message; and the input data must be set for the longest response message.

7.6.3.5.4 The SDM may specify services in addition to what is specified in the CDM. However, for reference, support of the services of the CDM requires a maximum request message length of three bytes plus the maximum data value length associated with the Set_Attribute.

7.6.3.5.5 In the same context, support of the services of the CDM requires a maximum response message length of one byte plus the maximum data value length associated with the Get_Attribute.

7.6.3.5.6 *DP Service Request Protocol* — The output data communicated to a DP-Slave device configured for DP Services is formatted as specified in Table 7.

Table 7 Data I/O Data Field for DP Service Request Protocol

Byte	*Description*
0	Object ID
1	Service ID
2 through n	Service Parameters
(n+1) through Max	Zero

7.6.3.6 *DP Service Response*

7.6.3.6.1 The response to a service request may or may not contain data based upon the type of request. However, all service responses contain a Response Code.

7.6.3.6.2 A Response Code of Zero indicates a successful service completion. A non-zero Response Code indicates an error. An error is identified via the DP-Slave diagnostics.

7.6.3.6.3 *DP Service Response Protocol* — The input data communicated from a DP-Slave device configured for DP Services is formatted as specified in Table 8.

Table 8 Data I/O Data Field for DP Service Response Protocol

Byte	*Description*
0	Response Code
1 through n	Data
(n+1) through Max	Zero

7.6.3.7 *Service Identifiers* — The required services of the CDM are identified here. Additional services that are contained in the SDM are given identifiers in the Device Profile. Table 9 specifies the required services and ID numbers.

Table 9 Service Identifiers

Service ID	*Service*
0	Invalid
1	Reset
2	Abort
3	Recover
4	Get Attribute
5	Set Attribute
6	Execute
7	Perform Diagnostics

7.6.4 *Specified Services*

7.6.4.1 The following sections define the details associated with each of the services required by the CDM.

7.6.4.2 *Reset*

7.6.4.2.1 The Reset Request specifies no parameters.

7.6.4.2.2 In addition to an explicit Reset Service Request, PROFIBUS-DP specifies others methods whereby a DP-Slave device can be reset. The following sections describe methods by which a DP-Slave will execute a reset.

7.6.4.2.3 *Startup* — During the startup phase, a DP-Master locks the DP-Slave for protection. A DP-Master can also unlock a DP-Slave which causes a Reset to the DP-Slave.

7.6.4.2.4 *Incorrect Configuration* — If a DP-Master delivers an incorrect set of data for parameterization or for configuration to a DP-Slave, it will automatically reset that DP-Slave.

7.6.4.2.5 *Watchdog* — A DP-Slave will automatically reset upon the expiration of its watchdog timer. During the startup phase, a DP-Master sends a Watchdog Time to the DP-Slave. This time must be longer than the Buscycle time for the DP-Slave to operate properly. A DP-Master can also send a Watchdog Time to a DP-Slave during normal operation. Therefore, a DP-Master could affect a reset by intentionally sending a Watchdog Time that is shorter than the Buscycle time.

7.6.4.3 *Abort* — The Abort Service Request specifies no parameters.

7.6.4.4 *Recover* — The Recover Service Request specifies no parameters.

7.6.4.5 *Get Attribute* — As defined above, in the section on attributes there are several methods used to retrieve the value of an attribute: Device Data Base, DP-Slave Diagnostic, I/O Data Exchange, and explicit use of the Get Attribute Service request.

7.6.4.6 *Set Attribute* — As defined above, there are several methods used to set the value of an attribute: Configuration, I/O Data Exchange, and explicit use of the Set Attribute Service request.

7.6.4.7 *Execute* — The Execute Service Request specifies no parameters.

7.6.4.8 *Perform Diagnostics* — The Perform Diagnostic Request specifies one parameter: Test ID. The Test ID parameter is one byte in length, as specified in the CDM.

7.7 *Behavior*

7.7.1 The behavior of PROFIBUS-DP devices is broken down by device type. A DP-Master device controls the operational modes of its assigned DP-Slave devices and polls them using a cyclic communication scheme. This cyclic communication is used to set outputs, read inputs and check the status of DP-Slaves. DP-Slave devices implement the CDM and one or more SDM standards in addition to the DP-Slave standards for behavior.

7.7.2 *DP-Master*

7.7.2.1 A DPM1 device can be controlled either locally or via the network by the configuration Device. A DPM1 device has three main states as described in Table 10:

Table 10 DPM1 Behavior States

State	*Description*
Stop	No data transmission between the DPM1 and DP-Slaves occurs.
Clear	The DPM1 reads input information from the DP-Slaves and holds the outputs in fail-safe status.
Operate	The DPM1 is in the data transfer phase. In a cyclic communication scheme, inputs of the DP-Slaves are read and output information is written to the DP-Slaves.

7.7.3 *DP-Slave*

7.7.3.1 The DM object shares a unique relationship with the DP-Slave device. State Transitions associated with the DP-Slave device cause analogous transitions in the DM Object. However, Transitions associated with the DM object may, or may not, cause transitions in the DP-Slave device.

7.7.3.2 There are essentially four states associated with a DP-Slave device. These states are mapped to the states of the CDM DM Model. Any change of state in one context (i.e., DM object or DP-Slave) causes the corresponding change of state in the other context. This mechanism is achieved via implicit service requests automatically generated within the device to affect the correlated change of state.

7.7.3.3 Table 11 defines the correlation of DP-Slave states to DM object states. Table 12 shows the reverse correlation of DM object states to DP-Slave states.

Table 11 DP-Slave Behavior States Effect on DM Object

DP-Slave State	*Resulting DM State*
Wait_Prm	Initialized/Self Testing
Wait_Cfg	Idle
Data_Exch	Executing
Device_Clear	Abort

Table 12 DM Object Behavior States Effect on DP-Slave

DM State	*Resulting DP-Slave State*
Initialized/Self Testing	Wait_Prm
Idle	Diag.Station_Not_Ready
Executing	Data_Exch
Self Test Exception	Diag.Station_Not_Ready
Critical Fault	Diag.Station_Not_Ready
Abort	Device_Clear

8 Protocol Compliance

8.1 PROFIBBUS International has established a qualified certification system, with test laboratories in Europe and USA, which includes conformance testing and interoperability testing. Certified products are listed with their certificate number in the PROFIBUS Electronic Product Guide.

8.2 GSD files of all PROFIBUS-DP devices that are tested for their conformity to the PROFIBUS standard are available in the GSD library on the World Wide Web Server of the PROFIBUS User Organization at http://www.PROFIBUS.com.

9 Specific Device Model Mappings

9.1 Every type of device must have an identifier number. Vendors must apply for an identifier number from the PROFIBUS User Organization for every Device Type. In order to receive a valid identifier number, a Device Profile must be submitted in the form of a GSD File and Device Data Base Sheet.

9.1.1 The Device Profile must specify the identifiers for Objects, Attributes and Services for CDM and SDM components, including data formats and bit mappings for specified parameters, as represented in this document.

9.1.2 The following sections specify mappings for Sensor Actuator Network Specific Device Models.

9.2 *Mass Flow Device*

9.2.1 Reference SEMI E54.3 for a complete specification of the SDM for Mass Flow Devices. Accordingly, the following mapping rules apply to the identification tags for the Objects, Attributes and Services of this model.

9.2.2 *Objects*

9.2.2.1 Consistent with SEMI E54.3 and Section 7.4 above, the DM and SAC objects are identified as Object 1 and Object 2, respectively.

9.2.2.2 Notice that references for the Local Link Objects are not included; the existence of these objects are implied by behavior and not explicitly included. Therefore, these objects are not accessible from the network and the Sensor-AI-Aux Object is not supported. Also, Assembly Objects are defined in the Device Profile as required.

9.2.2.3 Table 13 shows the mapping of the SDM Object Instances specified in SEMI E54.3 Instance numbers are listed under the heading Instance in the table and the PROFIBUS Object ID is listed under ID in the table.

Table 13 MFD Object Identifiers

SDM Object Name	*SDM Object ID*	*Instance*	*ID*
Sensor-AI-MF	MFD3	1	3
Actuator-AO-MF	MFD7	1	4
Controller	MFD8	1	5
SISO-Setpoint	MFD11	1	6
Sensor-AI-AT	MFD4	1	7

NOTE 1: Additional objects may be defined by the manufacturer in the Device Profile for a given device.

9.2.3 *Attributes*

9.2.3.1 The mapping of Attribute Tags and Identifiers is defined in Section 7.5.4.2 for the CDM. The same method applies here for the SDM.

9.2.4 *Services*

9.2.4.1 The mapping of Service Tags and Identifiers is defined in Section 7.6.3.7 for the CDM. The same method applies here for the SDM.

SEMI E54.9-1000
SPECIFICATION FOR SENSOR/ACTUATOR NETWORK COMMUNICATION FOR MODBUS/TCP OVER TCP/IP

This specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on July 14, 2000. Initially available at www.semi.org September 2000; to be published October 2000. Originally published February 2000.

1 Purpose

1.1 This standard defines a communication specification based on the Modbus/TCP protocol over a Transmission Control Protocol/Internet Protocol (TCP/IP) network to enable communications between intelligent devices on a sensor/actuator network (SAN) that operate according to SEMI specified device models (common and device specific) in a semiconductor manufacturing tool.

1.2 *Background and Motivation*

1.2.1 Modbus/TCP over TCP/IP is a component level network which provides a simple, inexpensive, and fast means of exchanging data among control level industrial devices (e.g., sensors and actuators) and higher level devices such as controllers. Modbus/TCP over TCP/IP provides:

- A solution to low-level device networking,
- Access to intelligence present in low-level devices,
- Networking between higher level controllers, and
- Master/Slave and Peer-to-Peer communication capabilities.

1.2.2 Modbus/TCP specifies a communication model and protocol. The Physical, Data Link, and Network Layer definitions are defined by the network in which the Modbus/TCP protocol is embedded such as TCP/IP Ethernet.

1.2.3 This document enables communications between intelligent devices on a SEMI compliant SAN by providing a presentation mapping of common and specific device network visible structure and behavior to Modbus/TCP over a TCP/IP network.

2 Scope

2.1 This document specifies the protocol and services that compliant intelligent devices must support to exchange information over this semiconductor equipment sensor/actuator network.

2.2 This document specifies the utilization of the Modbus/TCP protocol to present externally visible device structure and behavior, specified in the Common Device Model (CDM) and appropriate Specific Device Models (SDMs), for the Modbus/TCP protocol over a TCP/IP network.

2.3 This document is used in conjunction with a SEMI standard SAN Common Device Model specification, one or more SEMI standard Specific Device Model (SDM) specifications (e.g., for a mass flow device), the Modicon Modbus Protocol Reference Guide and the Open Modbus/TCP Specification. Together, they describe the Modbus/TCP protocol, the externally visible data structures and behaviors of devices utilizing the Modbus/TCP networking capability in a SEMI compliant SAN system.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on Modbus/TCP over a TCP/IP network and is a companion document to the Open Modbus/TCP Specification; thus a complete specification of this standard necessarily includes the Modbus/TCP and Modbus protocol specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 This standard specifies enhancements that provide additional capabilities over and above those currently required by Modbus/TCP. In order to avoid document consistency problems, information in the Modbus/TCP standard specifications that relate to this standard is not repeated in this document. This document is limited to describing enhancements or limitations to the Modbus/TCP standard specifications that are imposed by this standard.

5.2.5 *OSI* — Open Systems Interconnect

5.2.6 *OSS* — Object Services Standard

5.2.7 *SAC* — Sensor, Actuator, Controller (Object)

5.2.8 *SAN* — Sensor/Actuator Network

5.2.9 *SDM* — Specific Device Model

5.2.10 *TCP* — Transmission Control Protocol

5.3 *Device Component Definitions*

5.3.1 As this standard defines the presentation or mapping of CDM data structure and behavior over a network, it makes use of many of the terms in SEMI E54.1. Table 1 provides a mapping of fundamental terminology of the CDM document into this document and the Modbus/TCP standard specifications.

NOTE 2: Column 2 contains an equal sign "=" if the definition is used exactly as specified in the CDM specification.

Table 1 Mapping of CDM to NCS Terminology

CDM Term	*NCS Equivalent*	*Modbus/TCP Equivalent*
Device	=	=
Device Model	=	=
Object	=, Class, Instance	=, Class, Instance
Instance	=	=
Attribute	=	=
Behavior	=	=
Service	=	=
State Diagram	=	=
Byte	=	=
Nibble	=	=
Character String	=	=

5.4 *Modbus/TCP Specific Definitions*

5.4.1 *class* — a set of objects that represent the same kind of system component. A class is a generalization of an object. All objects in a class are identical in form and behavior, but may contain different attribute values as well as additional attributes and services. Refer to SEMI E39 for further definition.

5.4.2 *master/slave* — communication over a Modbus network, which is referred to as "client/server", that provides exclusive control of data by a "master" or "host" device acting as a "client". All network input data is reported exclusively to the host when requested by the host, and the host has exclusive control over the states of all network output signals of all nodes acting as it's "slaves" or "servers". Master/Slave communication provides the typical request/response oriented network communications.

5.4.3 *modbus/TCP* — an open protocol established at The University of Michigan's Electronics Manufacturing Laboratory as a standard means of interconnection for simple field devices. The Modbus/TCP over TCP/IP standard specifies OSI reference model layers 1, 2, 3, 4 and 7 specifically the physical signaling, the media access/data link protocols, internetworking capability, the transport capability of end-to-end transmission of data, and the application layer.

1 IEEE, 3 Park Avenue, 17th Floor, New York, NY 10016 U.S.A. tel: 212 419 7900 fax: 212 752 4929. http://www.ieee.org/
2 http://src.doc.ic.ac.uk/computing/internet/rfc/rfc791.txt
3 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland
4 http://www.modicon.com/openmbus/standards/standards.htm

5.4.4 *peer-to-peer* — on Modbus/TCP over TCP/IP networks, messages formatted according to the Modbus/TCP protocol are embedded into the TCP packet structure that is used on the TCP/IP network. The Modbus protocol over TCP/IP supports the asynchronous or unsolicited bi-directional transmission of data between nodes. This type of communication is referred to as peer-to-peer.

6 Communication Protocol High Level Structure

6.1 The Modbus/TCP protocol over TCP/IP is loosely based on a five-layer architecture. These layers constitute a collapsed form of the OSI seven layer architecture, mapping into the physical, data link, network, transport, and application layers of the Reference Model. This section has been formatted to be aligned with the Basic Reference Model for OSI. The high-level protocol architecture is shown in Figure 1.

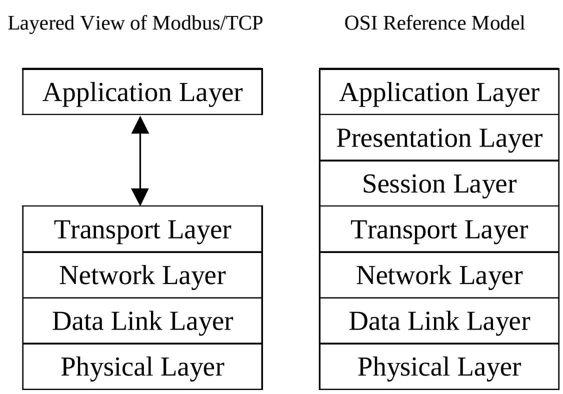

Figure 1
Layered View of Modbus/TCP Over TCP/IP

NOTE 3: Figure 1 represents a conceptual view of the communication device architecture. Conforming implementations must implement the services defined in this specification at each layer and must appear (from the network) to have implemented this architecture, however, an internal modular partitioning is not required. Implementations may sacrifice modularity in order to achieve high performance.

6.1.1 The application layer is specified in the Modicon Modbus Protocol Reference Guide and provides for the definition of Modbus applications as a collection of addressable objects. A subset of these objects may be addressed over the network (as defined by the implementation).

6.1.2 In the remainder of this section the protocol structure is described in more detail in terms of the OSI seven layer reference model, the object model environment and network management specifications.

6.2 *Physical Layer* — The device shall comply with a physical layer specification identified in the Modbus/TCP specification. The recommended and default Modbus/TCP physical layer is IEEE 802.3. If an accepted physical layer specification other than IEEE 802.3 is being used, this must be clearly specified in product literature. Physical layer specification includes physical signaling (levels and data rates), transceivers, node isolation, media topology, cable specifications, network connectors and taps, and power considerations (load limits, system tolerances, and power supply options).

6.3 *Data Link Layer* — The device shall comply with a data link layer specification of the Modbus/TCP specification. The recommended and default Modbus/TCP data link layer is IEEE 802.3. If an accepted data link layer specification other than IEEE 802.3 is being used, this must be clearly specified in product literature. Data link layer specification includes the media access control mechanism and the logical link control mechanism.

6.4 *Network Layer* — The device shall comply with a network layer specification of the Modbus/TCP specification. This specification is the IP or Internet Protocol as defined in the Modbus/TCP standard specification. The network layer specification includes network routing and internetworking.

6.5 *Transport (Messaging) Layer* — The device shall comply with the Modbus/TCP standard specification for the Transport Layer. This specification is the Transmission Control Protocol as defined in the Modbus/TCP standard specification. The transport layer provides transparent transfer of data between objects in application-entities. Some of the functionality of this layer is implemented in the Application Layer. Specific functions include: object data segmentation/re-assembly (fragmentation) for full message delivery.

6.6 *Session Layer* — There is no distinct session layer.

6.7 *Presentation Layer* — There is no distinct presentation layer. Object addressing and data presentation in Modbus messages are specified as part of the Modbus object definitions and object attribute and service communication protocol. Data byte transmission ordering is defined in IP RFC 791, Appendix B.

6.8 *Application Layer* — The device shall comply with the Modbus/TCP application layer specification for defining and addressing objects, including their attributes and services, and enabling specified network behavior. The device shall comply with the object messaging and object model specifications included in the Modbus/TCP standard specifications. In addition, the device shall comply with the object specifications defined in Section 7 of this document.

6.8.1 *Object Models* — The Modbus/TCP protocol has been enhanced to provide an object-oriented specification for creating, defining, and addressing objects explicitly, including their attributes and services, and creating, defining, and communicating object attributes in an application dependent format. The device shall comply with the object messaging and object model specifications included in the Modbus/TCP standard specification documentation. In addition, the device shall comply with the object specifications defined in Section 7 of this document.

6.9 *Network Management* — The device shall comply with the Modbus/TCP and TCP/IP network management specifications detailed in the Modbus/TCP Standard Specifications (e.g., physical layer bit rate, master/slave and peer-to-peer network management, etc.). No (additional) network management functions are speci fied in this document.

7 Required and Optional Object Types

7.1 At this time, the Modbus/TCP standard specifications do not require any specific objects to exist in a Modbus/TCP device in order to be a compliant Modbus/TCP device. The Modbus/TCP standard specifications will be extended to identify and describe objects (i.e., classes) that must exist in devices that are to be interoperable and interchangeable on a Modbus/TCP SEMI compliant SAN network.

7.1.1 The Common Device Model (CDM) specification identifies two objects (namely the Device Manager (DM) and Sensor Actuator Controller (SAC) objects) that must exist in all SEMI compliant SAN devices.

7.1.2 The required object types for a SEMI compliant SAN device utilizing the network communication specification described herein, necessarily comprises, at minimum, the union of the Modbus/TCP object type requirements and the CDM specification requirements.

7.1.3 A list of required and optional object types is given in Table 2. Additional objects that are specified in a particular SDM are given identifiers in that SDM specification. Modbus specific presentation information for these identifiers is given in Section 9 of this document.

Table 2 Required and Optional Object Types

Object Name	*Modbus Class ID/Instance ID (See Note 1)*	*CDM Tag (See Note 2)*	*Required by Modbus (See Note 1)*	*Required by CDM (See Note 2)*	*Required by NCS*
Device Manager	1/1	DmI0	No	Yes	Yes
Sensor/Actuator/ Controller	2/1	SacI0	No	Yes	Yes
Assembly	3/1 through i	Asm	No	No	No
Local Link	4/1 through j	Lnk	No	No	No
Sensor – AI	33/1 through k	Sai	No	No	No
Sensor – EI	34/1 through l	Sei	No	No	No
Sensor – BI	35/1 through m	Sbi	No	No	No
Actuator – AO	36/1 through n	Aao	No	No	No
Actuator – EO	37/1 through o	Aeo	No	No	No
Actuator – BO	38/1 through p	Abo	No	No	No
Controller	39/1 through q	Ca	No	No	No
Application Objects	129 through x/ 1 through r	(See Note 3)	No	No	No

NOTE 1: See Modbus specification for further information; values are decimal: “i”, “j”, “k”, “l”, “m”, “n”, “o”, “p”, “q” and “r” represent arbitrary numbers (greater than or equal to 1) indicating that more than one instance may be supported. “x” is a number greater than or equal to 129 indicating that one or more application object classes may be supported.

NOTE 2: See CDM specification for further information.

NOTE 3: Application Dependent objects as specified in SDM.

7.1.4 An embodiment of a specific device type represented as an aggregation of the object types listed in Table 2 that is compliant with both the CDM specification and the Modbus/TCP specification, is a candidate for a SEMI SDM as well as a Modbus/TCP device definition. Conversely, all SEMI SDM's and Modbus/TCP device definitions specified for operation over a SEMI compliant Modbus/TCP network must be an aggregation of the object types listed in Table 2, and be compliant with both the CDM specification and the Modbus/TCP standard specifications.

7.1.5 In the following sections the presentation to the network of object addressing, object attributes, and object services for each of the object types listed in Table 2 is described in detail. Refer to the CDM standard to determine if the object instance attribute and service is specified as required or optional. Unless otherwise noted, all attributes and services described are instance level attributes (as opposed to class level attributes). A class level attribute and service is accessed as instance number zero.

NOTE 4: The formats of object attributes and services are detailed in the CDM document; the presentation of object attributes and services to the Modbus/TCP over a TCP/IP network is detailed in the tables contained in the following sub-sections and in the Modbus/TCP standard specifications.

7.2 *Device Manager (DM) Object* — The DM object instance is the device component responsible for managing and consolidating the device operation. Each device must support one (and only one) DM object. The DM object as well as its common required and optional attributes, services and behavior are described in the CDM standard. The presentation of object instance attributes and services to the Modbus/TCP network shall be as indicated in Table 3. Note that all service ID values identified refer to the ID of the request or notification component of that service. Corresponding reply components to request/reply services shall have a service ID value equal to the request component ID plus one.

Table 3 DM Object Instance Attributes and Services

Device Manager Object (DM) Class ID = 01, Instance ID = 01		
Attributes		
ID	*Attribute Name*	*CDM Tag*
01	Device Type	DmA1
02	Standard Revision Level	DmA2

15	Publish Attribute	DmS8
17	Lock	DmS9
19	Unlock	DmS10
21	Get Exception Queue	DmS11
23	Clear Exception Queue	DmS12

7.3 *Sensor, Actuator, Controller (SAC) Object* — The SAC object instance is the device component responsible for coordinating the interaction of the device with the sensory/actuation/control environment. Each device must support one (and only one) SAC object instance. The SAC object instance as well as its common required and optional attributes, services, and behavior are described in the CDM standard. The presentation of object instance attributes and services to the Modbus/TCP network shall be as indicated in Table 4.

Table 4 SAC Object Instance Attributes and Services

Sensor, Actuator, Controller Object (SAC) *Class ID = 02, Instance ID = 01*		
Attributes		
ID	*Attribute Name*	*CDM Tag*
01	Last Calibration Date	SacA1
02	Next Calibration Date	SacA2
03	Expiration Timer	SacA3
04	Expiration Warning Enable	SacA4
05	Run Hours	SacA5
Services		
ID	*Service Name*	*CDM Tag*

09	Set Attribute	SacA5
25	Operate	SacA6
27	Restore Default	SacA7
29	Publish Attribute	SacA8

7.4 *Assembly Object (Asm)* — The Assembly (Asm) object instances may be used to provide for grouping more than one attribute from one or more object instances in a device into a single data structure for communication over the Modbus/TCP network. The presentation of object instance attributes and services shall be as indicated in Table 5.

Table 5 Assembly Object Instance Attributes and Services

ASSEMBLY Object (Asm) *Class ID == 03, Instance ID = 01 through i*

8 Protocol Compliance

8.1 A method of testing protocol compliance is required to verify implementation conformance to the standard. An independent compliance testing laboratory has been established at The University of Michigan's Electronics Manufacturing Laboratory for the testing of Modbus/TCP over TCP/IP solutions. This laboratory utilizes an established, documented and freely available mechanism for compliance certification of devices on a Modbus/TCP over a TCP/IP network. This certification includes procedures and reporting mechanisms to demonstrate conformance and interoperability of Modbus/TCP devices. Information on the conformance testing laboratory can be found on the World Wide Web.[5] Additional information on certification procedures can also be found on the World Wide Web.[6]

9 Specific Device Model Mappings

9.1 This section provides for the mapping of network visible specific device structure and behavior, specified in a SEMI SDM specification, to the Modbus/TCP network. Each subsection is devoted to a single Specific Device Model (SDM) specification. Additional SDM mappings are added as sub-sections to this NCS specification according to SEMI guidelines and the guidelines SEMI E54. Unless otherwise noted, all attributes and services described are instance level attributes (as opposed to class level attributes).

NOTE 5: The formats of object instance attributes and services are detailed in the associated SDM specification; the presentation of object attributes and services to the Modbus/TCP over a TCP/IP network is detailed in the tables contained in the following sub-sections and in the Modbus/TCP standard specifications.

NOTE 6: Relationships between object classes, including inheritance is defined in the associated SDM specification and the CDM specification.

9.1.1 The instance identifier of 1 through r, assigned to an object type, refers to the possibility of multiple instantiations of the object type. Refer to Table 2 of this document and the CDM document for a further explanation of object instance identifier assignments.

9.2 *Specific Device Model for Mass Flow Device* — These sections detail the network mapping required to support the Specific Device Model for Mass Flow Devices. Table 14 summarizes the Mass Flow Device Object types. Subsequent Tables 15 to 24 detail the instance attributes and services associated with each Mass Flow Device object type.

Table 14 Mass Flow Device Object Types

SDM Object Identifier	*Object Name*	*Modbus Class ID*
MFD1 (DM)	Device Manager	1
MFD2 (SAC)	Sensor Actuator Controller	2
MFD3	Sensor-AI-MF	129
MFD4	Sensor-AI-AT	130
MFD5	Assembly-MFM	131
MFD6	Sensor-AI-Aux	132
MFD7	Actuator-AO-MF	133

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E54.10-0600
SPECIFICATION FOR SENSOR/ACTUATOR NETWORK SPECIFIC DEVICE MODEL FOR AN IN-SITU PARTICLE MONITOR DEVICE

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org May 2000; to be published June 2000.

1 Purpose

1.1 This specification is part of a suite of standards that specify the implementation of SEMI standards for the Sensor/Actuator Network. The specific purpose of this specification is to describe a network independent application model comprised of device objects that are common to all In-Situ Particle Monitor Devices on a semiconductor equipment Sensor/Actuator communications network.

2 Scope

2.1 An In-Situ Particle Monitor (ISPM) is a device that measures and counts particles. These devices classify by size and count, particles in the environment (gaseous, liquid, or vacuum) utilizing a technique such as detecting light from a sample region of the environment's space. These counts are accumulated in bins and then reported. The number of bins varies by vendor and model.

2.2 This specification specifically addresses the minimum attributes, services, and behavior an In-Situ Particle Monitor (ISPM) device must support to be interoperable on the Sensor/Actuator Network.

2.3 This specification is intended to ensure a high-degree of device interoperability on the Sensor/Actuator Network, while still allowing flexibility for product differentiation and technology evolution.

2.4 The model specified in this specification is used in conjunction with SEMI E54.1 (Standard for Sensor/Actuator Network Common Device Model (CDM)) to completely describe the ISPM as it appears from the network interface.

2.5 This specification, together with SEMI E54, SEMI E54.1, and one of the Sensor/Actuator Network Communication Specifications, form a complete interoperability specification for the ISPM.

2.6 To comply with this specification, a device must implement and support, at a minimum, the required attributes, services, and behavior identified in these documents. Support for optional attributes, services, and behavior is not required to be compliant to this specification. Optional attributes, services, and behavior are specified in these documents to promote further device interoperability as features evolve and are adopted by more manufacturers. If optional attributes, services, and behavior are implemented for this device they must be implemented as identified in this document.

2.7 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification is a companion to a suite of specifications that together make up the Sensor/Actuator Network Communication standard. Therefore, using portions of this specification that relate to network communications necessarily requires an understanding of the associated network specification.

3.2 As this document is a specification for the In-Situ Particle Monitor Device Model, it does not contain any definition of objects, attributes, services, or behavioral descriptions that are already defined in SEMI E54.1. Additional attributes, attribute assignments, services, and/or service parameters that are ISPM Device specific and/or implementation specific are contained in this specification.

3.3 While this specification is sufficient to completely describe the ISPM as it appears from the network, it does not fully describe behavior of the ISPM which is not visible from the network. This allows flexibility in implementation techniques and product differentiation between manufacturers. Manufacturer specific objects may be defined by the manufacturer but are, by definition, outside the scope of this standard.

3.4 This specification is compatible, but not compliant with SEMI E39. This means that although this specification does not require compliance with SEMI E39, it is extensible such that implementations may be developed that are fully compliant with both standards. Note that the concepts and terminology of this specification are compatible with those of SEMI E39. However, SEMI E39 has specific requirements that are intended for higher level applications and thus are not applied to the In-Situ Particle Monitor Device Model.

3.5 Operation over the entire range specified for an attribute within a specific object is not a requisite for compliance with this specification.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E54 — Sensor/Actuator Network Standard

SEMI E54.1 — Standard for Sensor/Actuator Network Common Device Model

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *LCS* — an ISPM sensor named the Laser Current Sensor.

5.1.2 *MNS* — an ISPM sensor named the Median Noise Sensor.

5.1.3 *SLS* — an ISPM sensor named the Stray Light Sensor.

5.2 *Terminology Defined in This Document*

5.2.1 *In-Situ Particle Monitor (ISPM)* — a self-contained device, consisting of a laser that generates light, a light detector, counters, diagnostics and control and signal-processing electronics, commonly used in the semiconductor industry to measure and count particles in a specific area.

5.3 This document inherits the terminology defined by SEMI E54.1 [3].

5.3.1 *Attribute*

5.3.2 *Behavior*

5.3.3 *Boolean*

5.3.4 *Byte*

5.3.5 *Character*

5.3.6 *Common Device Model (CDM)*

5.3.7 *Data Type*

5.3.8 *Data Units*

5.3.9 *Device*

5.3.10 *Device Manager (DM) Object*

5.3.11 *Device Model*

5.3.12 *Double Integer (DINT)*

5.3.13 *Enumerated Byte*

5.3.14 *Full Scale Range*

5.3.15 *Instance*

5.3.16 *Last Valid Value (LVV)*

5.3.17 *Long Integer (LINT)*

5.3.18 *Long Real (LREAL)*

5.3.19 *Manufacturer*

5.3.20 *Nibble*

5.3.21 *Null Character*

5.3.22 *Object*

5.3.23 *Real (REAL)*

5.3.24 *S, A, and C Objects*

5.3.25 *Sensor Actuator Controller (SAC) Object*

5.3.26 *Service*

5.3.27 *Short Integer (SINT)*

5.3.28 *Signed Integer (INT)*

5.3.29 *State Diagram*

5.3.30 *Test String*

5.3.31 *Unsigned Double Integer (UDINT)*

5.3.32 *Unsigned Double Long Integer (UDLINT)*

5.3.33 *Unsigned Integer (UINT)*

5.3.34 *Unsigned Long Integer (ULINT)*

5.3.35 *Unsigned Short Integer (USINT)*

6 Requirements and Specifications

6.1 In order to implement this standard in an In-Situ Particle Monitor Device, it is necessary to also implement SEMI E54.1 and one of the Sensor/Actuator Network Communication Standards [2]. See Section 1.1 for more information on a complete interoperability standard.

6.2 This specification also requires the implementation of a Date_And_Time data structure used to represent the current device Date and Time. Table 1 defines the format of the Date_And_Time data type.

Table 1 Date_And_Time Format

Data Item	*Description*	*Range*
1	Number of milli-seconds since midnight	Unsigned Double Integer (UDINT)
2	Number of days since	Unsigned Integer

Data Item	Description	Range
	1/1/72	(UINT)

7 Conventions

7.1 This document embraces the conventions and notations stated in Section 6 of SEMI E54.1 [3].

8 Device High Level Structure

8.1 *General Description*

8.1.1 The high-level object view of an In-Situ Particle Monitor (ISPM) Device is shown in Figure 1.

8.1.2 Note that the "ISPM" device object is depicted in Figure 1 only for the purposes of illustrating a high level view of the device and its component objects. In the context of this document, this object is not addressable, does not have addressable attributes, does not have accessible services, and does not exhibit any defined behavior.

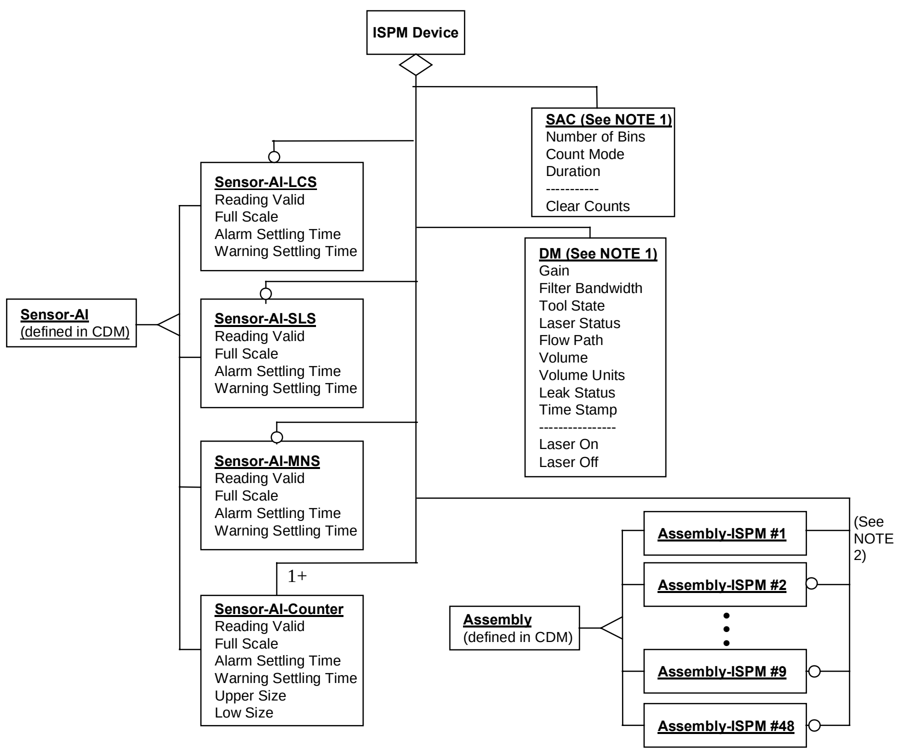
8.1.3 In the remainder of this section, this document defines in detail all of the component objects unique to the ISPM device. References, rather than definitions, are included for the DM, the SAC, and other objects defined in SEMI E54.1 [3].

8.1.4 Many of the objects defined in this document inherit properties from other objects. The properties inherited include attribute, services, and behavior definitions. These other objects are specified here or in SEMI E54.1 [3].

8.1.5 This document provides for future extensions as well as manufacturer specific enhancements by reserving object attribute identifiers and object service identifiers. Specifically, all object definitions in this document specify or reserve the first 64 attribute identifiers (A1 through A64) and the first 64 service identifiers (S1 through S64) allowing manufacturers to specify identifiers beyond these ranges. Additionally, byte enumerated attributes are specified or reserved from 0 to 63 allowing manufacturers to specify an enumeration beyond this range (64 to 255).

8.1.6 *In-Situ Particle Monitor (ISPM) Device Description*

8.1.6.1 An In-Situ particle Monitor device profile is composed of the component objects and object relationships shown in Figure 1.



NOTE 1: The DM and SAC are taken from the CDM. Additional attributes and services are added to support the ISPM device.

NOTE 2: Assembly-ISPM #1 and Assembly-ISPM #6 objects are required. Other Assembly-ISPM objects are optional.

Figure 1
In-Situ Particle Monitor Device High Level Structure

8.1.7 *General Requirements*

8.1.7.1 *Device Objects* — All objects are defined in terms of their object name and Class/Object identifier. Identifiers for all objects described in this document are summarized in Table 2.

Table 2 In-Situ Particle Monitor Device Objects

Referenced Document Section	*Object Name*	*Class/Object Identifier*	*Minimum #*	*Maximum #*
8.2	Device Manager (DM)	ISPMD1	1	1
8.3	Sensor Actuator Controller (SAC)	ISPMD2	1	1
8.5	Sensor-AI-LCS	ISPMD3	0	1
8.6	Sensor-AI-SLS	ISPMD4	0	1
8.7	Sensor-AI-MNS	ISPMD5	0	1
8.8	Sensor-AI-Counter	ISPMD16	1	1024
8.9	Assembly-ISPM#1	ISPMD17	1	1
8.9	Assembly-ISPM#2	ISPMD18	0	1
8.9	Assembly-ISPM#3	ISPMD19	0	1
8.9	Assembly-ISPM#4	ISPMD20	0	1
8.9	Assembly-ISPM#5	ISPMD21	0	1
8.9	Assembly-ISPM#6	ISPMD22	1	1
8.9	Assembly-ISPM#7	ISPMD23	0	1
8.9	Assembly-ISPM#8	ISPMD24	0	1
8.9	Assembly-ISPM#9	ISPMD25	0	1
8.9	Assembly-ISPM#48	ISPMD64	0	1
—	Reserved	ISPM26–ISPM63	—	—
—	Manufacturer Specified	> ISPM64	—	—

8.1.7.2 *Object Services* — Not all object services listed in this document can necessarily be requested over the network. They are included in this document because their behavior may generate network activity.

8.1.7.3 *Object Behavior* — For all service requests received over the network that are not supported by the object, or contain a parameter value which is beyond the supported range, or which is otherwise invalid, a network specific service error response is generated.

8.2 *Device Manager Object (DM)* — The Device Manager object is the device component responsible for managing and consolidating the device operation as specified in SEMI E54.1 [3]. The following sections specify the components of the DM object that are not specified in SEMI E54.1 or require further definition than specified in SEMI E54.1.

8.2.1 *Device Manager Object Attributes* — Required and optional DM object attributes are listed in Table 3.

Table 3 DM Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Device Type	A1	R	Yes	refer to CDM [1]
Exception Detail Alarm	A13	R	No	refer to CDM [1]
Exception Detail Warning	A14	R	No	refer to CDM [1]
Gain	A33	RW *	No	REAL
Filter Bandwidth	A34	RW *	No	REAL
Tool State	A35	R	No	USINT, enumerated
Laser Status	A36	R	Yes	USINT, enumerated
Flow Path	A37	RW	No	USINT
Volume	A38	R	No	REAL
Volume Units	A39	R	No	Byte, enumerated

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Leak Status	A40	R	No	Byte, enumerated
Time Stamp	A41	RW	No	Date_And_Time
Reserved	A42–A64	—	—	Reserved for SDM future expansion
Manufacturer Specified	> A64	—	—	Manufacturer Specific attributes

NOTE 1: "*" Indicates that the specific attribute is nonvolatile. Nonvolatile requires that the current attribute value be maintained through a component power cycle.

8.2.1.1 *Device Type* — An attribute that uniquely identifies the type of the device on the network. The device type attribute is assigned as follows:

In-Situ Particle Monitor Device = "ISPM"

8.2.1.2 *Exception Detail Alarm (Optional)* — An attribute which identifies the detailed alarm status of the device. Table 4 defines the bit assignments associated with the alarm exception detail.

Table 4 Exception Detail Alarm Bit Assignments

Bit	*Device Specific Alarm[0]*
0	Reserved
1	Interlock
2	Sensor Not Detected
3	Leak Detected
4	Reserved
5	Sensor Type Changed
6	Reserved
7	Reserved

Bit	*Device Specific Alarm[1]*
0	High Laser Current
1	High Stray Light
2	High Median Noise
3	High Calibration
4	High Fill Rate
5	High Flow Rate
6	Reserved
7	Reserved

Bit	*Device Specific Alarm[2]*
0	Low Laser Current
1	Low Stray Light
2	Low Median Noise
3	Low Calibration
4	Low Fill Rate
5	Low Flow Rate
6	Reserved
7	Reserved

8.2.1.3 *Exception Detail Warning (Optional)* — An attribute which identifies the detailed warning status of the device. Table 5 defines the bit assignments associated with the warning exception detail.

Table 5 Exception Detail Warning Bit Assignments

Bit	*Device Specific Warning[0]*
0	Reserved
1	0
2	0
3	0
4	Reserved
5	0
6	Reserved

6	Reserved
7	Reserved

8.2.1.4 *Manufacturer Exception Detail Size (Optional)* — An attribute that specifies the number of exception detail bytes included in the alarm or warning details.

8.2.1.5 *Gain (Optional)* — An attribute that specifies the Gain value of the amplifier for the photodiode signal. The factory configured out-of-box value is determined by the manufacturer based on the sensor type.

8.2.1.6 *Filter Bandwidth (Optional)* — An attribute that determines the bandwidth in kilohertz of the amplifier for the photodiode signal. The factory configured out-of-box value is determined by the manufacturer based on the sensor type.

8.2.1.7 *Tool State (Optional)* — An attribute that identifies the current state of the tool that is utilizing the counter. In many cases, the ISPM device can detect and report the Tool State; this variable is utilized for this type of reporting. This attribute is enumerated and is specified by the manufacturer.

8.2.1.8 *Laser Status* — An attribute that records the current status of the laser. This attribute is enumerated. The possible enumeration and the requirement for support are as follows:

0 = LASER OFF (required)
1 = LASER TURNING ON (optional)
2 = LASER ON BUT NOT STABLE (optional)
3 = LASER ON AND STABLE (required)
4 = LASER INTERLOCKED (optional)
5 = SENSOR MISSING (required)
6–63 = Reserved
64–255 = Manufacturer Specified (optional)

8.2.1.9 *Flow Path (Optional)* — An attribute that identifies the current flow path (from multiple sources) being utilized. The source may be modified by a Host at anytime. Changing the "Flow path" attribute connects the ISPM device to a different source. When changing sources, data is not valid for a time interval whose length is a function of the distance to the source.

8.2.1.10 *Volume (Optional)* — An attribute that maintains the sample volume. This attribute is used primarily by liquid particle counters utilizing a sampling technique in a small container to extrapolate the particle count in the volume of interest. The value of this attribute is the size of the small container.

8.2.1.11 *Volume Units (Optional)* — An attribute that specifies the unit for the "Volume" attribute. This attribute is enumerated and can take on one of the following values: milliliters or gallons. (See Appendix 1 of SEMI E54.1 for assigned values.)

8.2.1.12 *Leak Status (Optional)* — An attribute that indicates which one of the potential leak locations is actually leaking. This attribute is enumerated and is specified by the manufacturer. The enumerated value corresponds to a specific leak location.

8.2.1.13 *Time Stamp (Optional)* — An attribute that records the time when the last counting event completed.

8.2.1.14 *Duration (Optional)* — An attribute that defines the interval of time during which the particle counts are collected and put into the bin assemblies.

8.2.1.15 *Initial and Default Values*

Table 6 DM Object Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Device Type	ISPM	ISPM	ISPM = In-Situ Particle Monitor Device
Exception Detail Alarm	0	0	
Exception Detail Warning	0	0	
Laser Status	0	0	Laser Off

8.2.2 *Device Manager Object Services* — The services provided by the Device Manager object are defined in SEMI E54.1 [1]. The Device Manager object supports the additional services listed below.

Table 7 Device Manager Object Services

Service	*Service Identifier*	*Type*	*Description*
Laser On	S1	R	Used to prompt the device to take the laser from the LASER OFF state to LASER ON AND STABLE state as defined by the Laser Status attribute.
Laser Off	S2	R	Used to prompt the device to take the laser immediately to the LASER OFF state as defined by the Laser Status attribute.
Reserved	S3–S64	—	Reserved for future expansion
Manufacturer Specified	> S64	—	Manufacturer Specific services

8.2.2.1 *Laser On (Optional)* — This service is used to prompt the device to take the laser from the LASER OFF state through supported laser states 1 and/or 2, to state 3, as defined by the Laser Status attribute. If the laser turns on successfully, a "success" response code is returned. If the sensor is missing or interlocked off, a "object state conflict" error response is returned and the laser remains in the appropriate state.

8.2.2.2 *Laser Off (Optional)* — This service is used to prompt the device to take the laser to the LASER OFF state immediately. If the laser turns off successfully, a "success" response is returned. If the sensor is in an interlocked state, a "object state conflict" error response is returned and the laser remains in the interlocked off state.

8.2.3 *Device Manager Object Behavior* — The behavior exhibited by the Device Manager object is defined in SEMI E54.1 [1]. Additional behavior is detailed below.

8.2.3.1 *Device Manager EXECUTING State Behavior* — Required sub-states within the EXECUTING state, descriptions of these substates, and a transition matrix associated with these sub-states are given in Figure 2, Table 8, and Table 9 respectively.

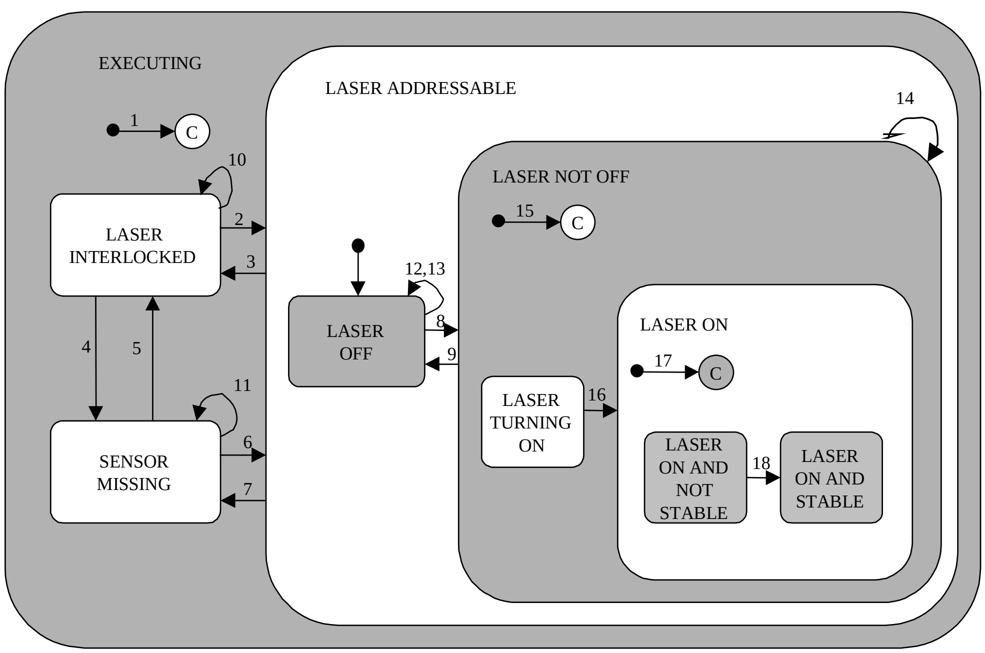

Figure 2
Device Manager Object Behavior Within the EXECUTING State

Table 8 Device Manager Behavior EXECUTING Sub-State Description

State	*Description*
EXECUTING	Laser is in one of the following enumerated states as indicated in the Laser Status Device Manager attribute: LASER INTERLOCKED (optional), LASER MISSING (optional), or LASER OFF. Device will respond to Laser On and Laser Off services as appropriate to move between sub-states within the EXECUTING and LASER ADDRESSABLE states.
LASER ADDRESSABLE	Laser is in one of the following enumerated states as indicated in the Laser Status Device Manager attribute: LASER OFF, LASER ON AND STABLE, LASER TURNING ON (optional), or LASER ON BUT NOT STABLE (optional). Device will respond to Laser On and Laser Off services as appropriate to move between sub-states within the LASER ADDRESSABLE state.
LASER OFF	This is the entry sub-state to LASER ADDRESSABLE; Laser is Off; Laser Status Device Manager attribute is in the enumerated state: LASER OFF. Device is not performing the “counting” process. (See NOTE 1.)
LASER ON AND STABLE	Sub-state of LASER ADDRESSABLE; device is “counting” (See NOTE 1); Laser Status Device Manager attribute is the enumerated state: LASER ON AND STABLE. Laser is performing the “counting” process.
LASER INTERLOCKED	Laser is Interlocked off; Laser Status Device Manager attribute is in the enumerated state: LASER INTERLOCKED. Device is not performing the “counting” process. (See NOTE 1.) Sensor may or may not be missing. Device cannot move to the LASER ADDRESSABLE or SENSOR MISSING states until the interlock is removed.
SENSOR MISSING	Laser sensor is missing; Laser Status Device Manager attribute is in the enumerated state: SENSOR MISSING. Device is not performing the “counting” process. (See NOTE 1.) Device cannot move to the LASER ADDRESSABLE state until the sensor is replaced.
LASER NOT OFF	Laser is in one of the enumerated states as indicated in the Laser Status Device Manager attribute: LASER TURNING ON (optional), LASER ON AND NOT STABLE (optional), or LASER ON AND STABLE. Device will respond to Laser Off service as appropriate to move between sub-states within the LASER ADDRESSABLE state.
LASER TURNING ON	An optional sub-state of LASER NOT OFF. This is a conditional entry sub-state to LASER NOT OFF. Device is preparing to turn on. Device is not performing the “counting” process. (See NOTE 1.)
LASER ON	Laser is in one of the enumerated states as indicated in the Laser Status Device Manager attribute: LASER ON AND NOT STABLE (optional) or LASER ON AND STABLE. Device will respond to Laser Off service as appropriate to move between sub-states within the LASER ADDRESSABLE state.
LASER ON AND NOT STABLE	Sub-state of LASER ON; device is not “counting” (See NOTE 1); Laser Status Device Manager attribute is the enumerated state: LASER ON AND NOT STABLE. Laser is not performing the “counting” process.

NOTE 1: The “counting” process is defined in Section 8.8.3.1.

Table 9 Device Manager Behavior EXECUTING Sub-State Transition Matrix (See NOTE 1.)

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	Entry into EXECUTING	Device detects interlock condition, and availability and state of laser.	Conditional: LASER ADDRESSABLE/ LASER OFF or LASER INTERLOCKED or SENSOR MISSING	If the sensor is in an interlocked or missing condition then state is LASER INTERLOCKED. If laser interlock and or laser missing is not supported then state is LASER OFF. Set Laser Status attribute to appropriate value.	Entry state depends on availability of laser and physical laser interlock setting on device.
2	LASER INTERLOCKED	Device detects removal of interlock condition	LASER MISSING	Set Laser Status attribute to	Device moves to LASER OFF state.

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
		and determines that sensor is not missing.		appropriate value.	
3	LASER ADDRESSABLE	Device detects that it has been set to a laser interlock condition.	LASER INTERLOCKED	Set Laser Status attribute to appropriate value.	Valid for all sub-states of LASER ADDRESSABLE.
4	LASER INTERLOCKED	Device detects removal of interlock condition and determines that sensor is missing.	SENSOR MISSING	Set Laser Status attribute to appropriate value.	
5	SENSOR MISSING	Device detects that it has been set to a laser interlock condition.	LASER INTERLOCKED	Set Laser Status attribute to appropriate value.	
6	SENSOR MISSING	Device detects replacement of sensor.	LASER ADDRESSABLE/ LASER OFF	Set Laser Status attribute to appropriate value.	Device moves to LASER OFF.
7	LASER ADDRESSABLE/ LASER OFF	Device detects that sensor is missing.	SENSOR MISSING	Set Laser Status attribute to appropriate value.	
8	LASER OFF	Laser On request	LASER ON AND STABLE	Take the object from the LASER OFF state through optional laser states LASER TURNING ON and LASER ON BUT NOT STABLE to the required LASER ON AND STABLE state, turning on the laser and stabilizing it respectively. Set the Laser Status attribute to the appropriate values throughout the transition. Issue Laser On response and begin the “counting” process. (See NOTE 2.)	LASER TURNING ON and “LASER ON BUT NOT STABLE” are optional intermediate states between LASER OFF and LASER ON AND STABLE. Laser must not be missing or in an interlocked off state. Service response is not issued until transition to LASER ON AND STABLE is completed.
9	LASER ON AND STABLE	Laser Off request	LASER OFF	Stop the “counting” process. (See NOTE 2.) Turn the laser off. Issue Laser Off response.	
10	LASER INTERLOCKED	Laser Off request or Laser On request	LASER INTERLOCKED	Error response	Object cannot move from this state until interlock is turned off.
11	SENSOR MISSING	Laser Off request or Laser On request	SENSOR MISSING	Error response	Object cannot move to LASER ADDRESSABLE state until sensor is replaced.
12	LASER OFF	Laser Off request	LASER OFF	Error response	Laser is already off.
13	LASER OFF	Laser On request	LASER OFF	Device attempts to take the laser from the “Laser Off” state through optional laser	Behavior associated with determining that laser will not turn on properly or

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
				state "Laser Turning On" and to required state "Laser On But Not Stable". Set the Laser Status attribute to the appropriate values throughout the transition attempt. Laser either won't turn on properly or won't stabilize. Turn laser back off and generate Error response.	won't stabilize is manufacturer specific.
14	LASER ON		LASER ON AND STABLE	Error response	Laser is attempting to turn on.
15	Entry into LASER NOT OFF	Laser On request	Conditional: LASER NOT OFF/LASER TURNING ON or LASER ON/LASER ON AND NOT STABLE or LASER ON AND STABLE	Set Laser Status attribute to appropriate value.	Entry state depends on device support for optional states LASER TURNING ON and LASER ON / LASER ON AND NOT STABLE or LASER ON AND STABLE
16	LASER TURNING ON	Device detects that the laser is on.	LASER ON/LASER ON AND NOT STABLE or LASER ON AND STABLE	Set Laser Status attribute to appropriate value.	Behavior associated with determining that laser is in the process of turning on and is manufacturer specific.
17	Entry into LASER ON	Laser On request	Conditional: LASER ON/LASER ON AND NOT STABLE or LASER ON AND STABLE	Set Laser Status attribute to appropriate value.	Entry state depends on device support for optional states LASER ON AND NOT STABLE or LASER ON AND STABLE.
18	LASER ON AND NOT STABLE	Device determines that the laser is stable.	LASER ON AND STABLE	Set Laser Status attribute to appropriate value.	Laser is on. Behavior associated with determining that laser will turn on properly or won't stabilize is manufacturer specific.

NOTE 1: Note that this matrix augments the Device Manager Behavior State Transition Matrix as defined in SEMI E54.1 [3]. All transitions are in addition to those specified in SEMI E54.1.

NOTE 2: The "counting" process is defined in Section 8.8.3.1.

8.3 *Sensor Actuator Controller Object (SAC)* — The Sensor Actuator Controller object is the device component responsible for coordinating the interaction of the ISPM device with the sensory/actuation/control environment as specified in SEMI E54.1 [3]. The following sections specify the components of the SAC object that are not specified in the Common Device model or require further definition than specified in the CDM.

8.3.1 *Sensor Actuator Controller Object Attributes* — The attributes provided by the Sensor Actuator Controller object are defined in SEMI E54.1 [3]. Table 10 contains the additional attributes required for the Sensor Actuator Controller object.

Table 10 SAC Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Number of Bins	SacA65	R*	Yes	UINT
Count Mode	SacA66	RW*	Yes	Enumerated, USINT
Duration	SacA67	R	No	REAL

NOTE 1: "*" Indicates that the specific attribute is nonvolatile. Nonvolatile requires that the current attribute value be maintained through a component power cycle.

8.3.1.1 *Number of Bins* — An attribute that specifies the number of counters in the device. This value represents the number of Sensor-AI-Counter objects in the device.

8.3.1.2 *Count Mode* — An attribute that specifies whether all count object values are cleared (to zero) when read. This attribute is an enumerated USINT that can take on one of the following values:

0 = The particle counter count is not affected by reading the count.
1 = The particle counter count is cleared to zero when the count ("value" attribute of the Counter object) is read or reported through a service request to or from an Assembly-ISPM object that contains that count.
2 = The particle counter count is cleared to zero when the count ("value" attribute of the Counter object) is read or reported (regardless of the connection) through a service request to or from either an Assembly-ISPM object that contains that count ("value" attribute), or the Counter object that contains the count.
3–63 = Reserved
64–255 = Manufacturer Specified

8.3.1.3 *Duration (Optional)* — An attribute that defines the interval of time during which the particle counts (value of *Value* object attribute) are collected and put into the bin assemblies.

8.3.1.4 *Initial and Default Values*

Table 11 SAC Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Number of Bins	Manufacturer Specified	Manufacturer Specified	
Count Mode	LVV	0	Do not clear particle counter value.
Duration	Manufacturer Specified	Manufacturer Specified	

8.3.2 *Sensor Actuator Controller Object Services* — The services provided by the Sensor Actuator Controller object are defined in SEMI E54.1 [1]. Table 12 contains the additional services required for the Sensor Actuator Controller object.

Table 12 SAC Object Services

Service	*Service Identifier*	*Type*	*Description*
Clear Counts	S33	R	Used to clear the "Value" attribute of all Sensor-AI-Counter sensor objects.
Reserved	S34–S64	—	Reserved for future expansion
Manufacturer Specified	> S64	—	Manufacturer Specific services

8.3.2.1 *Clear Counts (Optional)* — This service is used to instruct all of the Sensor-AI-Counter object to perform a one-time clear of their respective Sensor-AI-Counter "*Value*" attributes by setting the value to zero. There are no parameters required for this service.

8.3.3 *Sensor Actuator Controller Object Behavior*

8.3.3.1 The behavior exhibited by the Sensor Actuator Controller object is defined in SEMI E54.1 [3]. Additional behavior is detailed below.

8.3.3.2 The "*Value*" attribute is cleared (to zero) in each ISPM counter sensor object, after being read, if the "*Count Mode*" attribute has a value of 1. It may also be cleared by a "Clear Counts" service of the SAC object or the "Reset" service issued to the S-Analog Sensor class.

8.4 *Sensor-AI Object* — The Sensor-AI object is the device component responsible for coordinating the behavior common to all analog input sensor elements in the ISPM device as specified in SEMI E54.1 [3].

8.4.1 *Sensor-AI Object Attributes* — The attributes provided by the Sensor-AI object are defined in SEMI E54.1 [1]. There are no additional attributes required for the Sensor-AI object.

8.4.2 *Sensor-AI Object Services* — The services provided by the Sensor-AI object are defined in SEMI E54.1 [3]. There are no additional services required for the Sensor-AI object.

8.4.3 *Sensor-AI Object Behavior* — The behavior exhibited by the Sensor-AI object is defined in SEMI E54.1 [3]. There is no additional behavior required for the Sensor-AI object.

8.5 *Sensor-AI-LCS Object* — The Sensor-AI-LCS (Laser Current Sensor) object inherits the attributes, services, and behavior of the Sensor-AI as defined in SEMI E54.1 [3]. The Sensor-AI-LCS is the device component responsible for retrieving a reading from a physical laser current sensor, optionally correcting the reading with a manufacturer specified algorithm, or algorithms, then making the value available through the "*Value*" attribute.

8.5.1 *Sensor-AI-LCS Object Attributes* — The attributes provided by the Sensor-AI object are defined in SEMI E54.1 [3]. The Sensor-AI object attribute content and its attribute extensions to support the Sensor-AI-LCS object are listed in Table 13.

Table 13 Sensor-AI and Sensor-AI-LCS Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Value	SaiA16	R	Yes	UINT
Gain	SaiA65	R	Yes	REAL
Data Type	SaiA66	R	Yes	USINT
Data Units	SaiA67	R	Yes	Enumerated, UINT milliAmps only value supported
Reading Valid	LcsA1	R	Yes	Enumerated, Byte
Full Scale	LcsA2	R	Yes	UINT
Alarm Settling Time	LcsA3	R	Yes	UINT
Warning Settling Time	LcsA4	R	Yes	UINT
Reserved	LcsA5–LcsA64	—	—	Reserved for future expansion.
Manufacturer Specified	> LcsA64	—	—	Manufacturer Specific attributes

8.5.1.1 *Value* — The attribute that maintains the laser current sensor value. This value is always read as milliAmps.

8.5.1.2 *Gain* — The attribute that specifies the gain of the laser current measuring circuit.

8.5.1.3 *Data Type* — The attribute which defines the format of the data associated with the "value" attribute.

8.5.1.4 *Data Units* — The attribute which specifies the units for the "*Value*" attribute. This attribute is an enumerated UINT that can take only one value:

MilliAmps (as assigned in Appendix 1 of SEMI E54.1).

8.5.1.5 *Reading Valid* — An attribute which specifies whether the "*Value*" attribute contains a valid value. This attribute is an enumerated byte that can take on one of the following values:

0 = Invalid, or
1 = Valid.

8.5.1.6 *Full Scale* — An attribute which specifies the maximum value allowed for the "*Value*" attribute.

8.5.1.7 *Alarm Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before an alarm is generated.

8.5.1.8 *Warning Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before a warning is generated.

8.5.1.9 *Initial and Default Values*

Table 14 Sensor-AI and Sensor-AI-LCS Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Value	0	0	
Gain	LVV	1.0	
Data Type	LVV	UINT	
Data Units	LVV	MilliAmps	See Appendix 1 of SEMI E54.1.
Reading Valid	0	0	Invalid
Full Scale	LVV	0XFFFF	
Alarm Settling Time	LVV	1000	Milliseconds
Warning Settling Time	LVV	1000	Milliseconds

8.5.2 *Sensor-AI-LCS Object Services* — The services provided by the Sensor-AI-LCS are inherited from the Sensor-AI object defined in SEMI E54.1 [3]. There are no additional services required for the Sensor AI-LCS object.

8.5.3 *Sensor-AI-LCS Object Behavior* — The behavior exhibited by the Sensor-AI-LCS object is inherited from the Sensor-AI object defined in SEMI E54.1 [3]. Additional specific behavior associated with the Sensor-AI-LCS object is defined below.

8.5.3.1 *Sensor-AI-LCS OPERATING Application Process* — A reading is retrieved from a physical laser current sensor. This reading may be corrected with a manufacturer-specified algorithm. This corrected reading becomes the input to the gain formula to generate the *value* attribute as referenced in SEMI E54.1 [3]. This process is executed only when the Device Manager Object is in the EXECUTING state as defined in the Common Device Model. When not in the EXECUTING state, the value of the "*Reading Valid*" attribute shall be set to "Invalid". When in one of the sub-states of the EXECUTING state, the validity of the "*Value*" attribute shall be manufacturer specific.

8.6 *Sensor-AI-SLS Object* — The Sensor-AI-SLS (Stray Light Sensor) object inherits the attributes, services, and behavior of the Sensor-AI as defined in SEMI E54.1 [3]. The Sensor-AI-SLS is the device component responsible for retrieving a reading from a physical stray light sensor, optionally correcting the reading with a manufacturer specified algorithm, or algorithms, then making the value available through the "*Value*" attribute.

8.6.1 *Sensor-AI-SLS Object Attributes* — The attributes provided by the Sensor-AI object are defined in SEMI E54.1 [3]. The Sensor-AI object attribute content and its attribute extensions to support the Sensor-AI-SLS object is listed in Table 15.

Table 15 Sensor-AI and Sensor-AI-SLS Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Value	SaiA16	R	Yes	UINT
Gain	SaiA65	R	Yes	REAL
Data Type	SaiA66	R	Yes	USINT
Data Units	SaiA67	R	Yes	Enumerated, UINT milliVolts only value supported
Reading Valid	SlsA1	R	Yes	Enumerated, Byte

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Full Scale	SlsA2	R	Yes	UINT
Alarm Settling Time	SlsA3	R	Yes	UINT
Warning Settling Time	SlsA4	R	Yes	UINT
Reserved	SlsA5–SlsA64	—	—	Reserved for future expansion.
Manufacturer Specified	> SlsA64	—	—	Manufacturer Specific attributes

8.6.1.1 *Value* — The attribute that maintains the stray light sensor value. This value is always read as milliVolts.

8.6.1.2 *Gain* — The attribute that specifies the gain between the photodiode (or some other light detection source) and the stray light reading.

8.6.1.3 *Data Type* — The attribute which defines the format of the data associated with the "value" attribute.

8.6.1.4 *Data Units* — The attribute which specifies the units for the "*Value*" attribute. This attribute is an enumerated UINT and can take only one value:

MilliVolts (as assigned in Appendix 1 of SEMI E54.1).

8.6.1.5 *Reading Valid* — An attribute which specifies whether the "*Value*" attribute contains a valid value. This attribute is an enumerated byte that can take on one of the following values:

0 = Invalid, or
1 = Valid.

8.6.1.6 *Full Scale* — An attribute which specifies the maximum value allowed for the "*Value*" attribute.

8.6.1.7 *Alarm Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before an alarm is generated.

8.6.1.8 *Warning Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before a warning is generated.

8.6.1.9 *Initial and Default Values*

Table 16 Sensor-AI and Sensor-AI-SLS Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Value	0	0	
Gain	LVV	1.0	
Data Type	LVV	UINT	
Data Units	LVV	MilliVolts	See Appendix 1 of SEMI E54.1.
Reading Valid	0	0	Invalid
Full Scale	LVV	0XFFFF	
Alarm Settling Time	LVV	1000	Milliseconds
Warning Settling Time	LVV	1000	Milliseconds

8.6.2 *Sensor-AI-SLS Object Services* — The services provided by the Sensor-AI-SLS object are inherited from the Sensor-AI object defined in SEMI E54.1 [3]. There are no additional services required for the Sensor AI-SLS object.

8.6.3 *Sensor-AI-SLS Object Behavior* — The behavior exhibited by the Sensor-AI-SLS object is inherited from the Sensor-AI object defined in SEMI E54.1 [3]. Additional specific behavior associated with the Sensor-AI-SLS object is defined below.

8.6.3.1 *Sensor-AI-SLS OPERATING Application Process* — A reading is retrieved from a physical stray light sensor. This reading may be corrected with a manufacturer-specified algorithm. This corrected reading becomes the input to the gain formula to generate the *value* attribute as referenced in SEMI E54.1 [3]. This process is executed only when the Device Manager Object is in the EXECUTING state as defined in the Common Device Model. When not in the EXECUTING state, the value of the "*Reading Valid*" attribute shall be set to "Invalid". When in one of the sub-states of the EXECUTING state, the validity of the "*Value*" attribute shall be manufacturer specific.

8.7 *Sensor-AI-MNS Object* — The Sensor-AI-MNS (Median Noise Sensor) object inherits the attributes, services, and behavior of the Sensor-AI as defined in SEMI E54.1 [3]. The Sensor-AI-MNS is the device component responsible for retrieving a reading from a physical median noise sensor, optionally correcting the reading with a manufacturer specified algorithm, or algorithms, then making the value available through the "*Value*" attribute.

8.7.1 *Sensor-AI-MNS Object Attributes* — The attributes provided by the Sensor-AI object are defined in SEMI E54.1 [3]. The Sensor-AI object attribute content and its attribute extensions to support the Sensor-AI-MNS object is listed in Table 17.

Table 17 Sensor-AI and Sensor-AI-MNS Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Value	SaiA16	R	Yes	UINT
Gain	SaiA65	R	Yes	REAL
Data Type	SaiA66	R	Yes	USINT
Data Units	SaiA67	R	Yes	Enumerated, UINT milliVolts only value supported
Reading Valid	MnsA1	R	Yes	Enumerated, Byte
Full Scale	MnsA2	R	Yes	UINT
Alarm Settling Time	MnsA3	R	Yes	UINT
Warning Settling Time	MnsA4	R	Yes	UINT
Reserved	MnsA5–MnsA64	—	—	Reserved for future expansion.
Manufacturer Specified	> MnsA64	—	—	Manufacturer Specific attributes

8.7.1.1 *Value* — The attribute that maintains the median noise sensor value. This is the noise level at the output of the sensor amplifier. The value is calculated by taking the median value of the last manufacturer specific number of rolling samples of the sensor amplifier output. This value is always read as milliVolts.

8.7.1.2 *Gain* — The attribute that specifies the gain of the median noise measuring circuit.

8.7.1.3 *Data Type* — The attribute which defines the format of the data associated with the "value" attribute.

8.7.1.4 *Data Units* — The attribute which specifies the units for the "*Value*" attribute. This attribute is an enumerated UINT and can take only one value:

MilliVolts (as assigned in Appendix 1 of SEMI E54.1).

8.7.1.5 *Reading Valid* — An attribute which specifies whether the "*Value*" attribute contains a valid value. This attribute is an enumerated byte that can take on one of the following values:

0 = Invalid, or
1 = Valid.

8.7.1.6 *Full Scale* — An attribute which specifies the maximum value allowed for the "*Value*" attribute.

8.7.1.7 *Alarm Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before an alarm is generated.

8.7.1.8 *Warning Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before a warning is generated.

8.7.1.9 *Initial and Default Values*

Table 18 Sensor-AI and Sensor-AI-MNS Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Value	0	0	
Gain	LVV	1.0	
Data Type	LVV	UINT	
Data Units	LVV	MilliVolts	See Appendix 1 of SEMI E54.1.
Reading Valid	0	0	Invalid
Full Scale	LVV	0XFFFF	
Alarm Settling Time	LVV	1000	Milliseconds
Warning Settling Time	LVV	1000	Milliseconds

8.7.2 *Sensor-AI-MNS Object Services* — The services provided by the Sensor-AI-MNS object are inherited from the Sensor-AI object defined in SEMI E54.1 [3]. There are no additional services required for the Sensor AI-MNS object.

8.7.3 *Sensor-AI-MNS Object Behavior* — The behavior exhibited by the Sensor-AI-MNS object is inherited from the Sensor-AI object defined in SEMI E54.1 [3]. Additional specific behavior associated with the Sensor-AI-MNS object is defined below.

8.7.3.1 *Sensor-AI-MNS OPERATING Application Process* — A reading is retrieved from the physical median noise sensor. This reading is maintained in a rolling count of manufacturer specified samples and then the median value of the manufacturer specified samples is calculated. This median reading becomes the input to the gain formula to generate the *value* attribute as referenced in SEMI E54.1 [3]. This process is executed only when the Device Manager Object is in the EXECUTING state as defined in SEMI E54.1. When not in the EXECUTING state, the value of the "*Reading Valid*" attribute shall be set to "Invalid". When in one of the sub-states of the EXECUTING state, the validity of the "*Value*" attribute shall be manufacturer specific.

8.8 *Sensor-AI-Counter Object* — The Sensor-AI-Counter object inherits the attributes, services, and behavior of the Sensor-AI as defined in SEMI E54.1 [3]. The Sensor-AI-Counter is the device component responsible for maintaining a count of the number of particles deposited in each bin and then making the value available through the "*Value*" attribute.

8.8.1 *Sensor-AI-Counter Object Attributes* — The attributes provided by the Sensor-AI object are defined in SEMI E54.1 [3]. The Sensor-AI object attribute content and its attribute extensions to support the Sensor-AI-Counter object is listed in Table 19.

Table 19 Sensor-AI and Sensor-AI-Counter Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Value	SaiA16	R	Yes	UDINT
Data Type	SaiA66	R	Yes	USINT
Data Units	SaiA67	R	Yes	Enumerated, UINT
Reading Valid	CounterA1	R	Yes	Enumerated, Byte
Full Scale	CounterA2	R	Yes	UDINT
Alarm Settling Time	CounterA3	R	Yes	UINT
Warning Settling Time	CounterA4	R	Yes	UINT
Upper Size	CounterA5	RW (See NOTE 1.)	Yes	REAL
Lower Size	CounterA6	RW (See NOTE 1.)	Yes	REAL
Reserved	CounterA7–CounterA64	—	—	Reserved for future expansion.
Manufacturer Specified	> CounterA64	—	—	Manufacturer Specific attributes

NOTE 1: Consult the manufacturer's specification for specific "Write" capabilities of this attribute.

8.8.1.1 *Value* — The attribute that maintains the particle count in the bin.

8.8.1.2 *Data Type* — The attribute that defines the format of the data associated with the "*Value*" attribute.

8.8.1.3 *Data Units* — The attribute which specifies the units for the "*Value*" attribute. This attribute is an enumerated UINT that can take on one of the following values: raw counts, count per second, counts per milliliter, and counts per gallon. (See Appendix 1 of SEMI E54.1.)

8.8.1.4 *Reading Valid* — An attribute which specifies whether the "*Value*" attribute contains a valid value. This attribute is an enumerated byte that can take on one of the following values:

0 = Invalid, or
1 = Valid.

8.8.1.5 *Full Scale* — An attribute which specifies the maximum value allowed for the "*Value*" attribute.

8.8.1.6 *Alarm Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before an alarm is generated.

8.8.1.7 *Warning Settling Time* — An attribute which specifies the maximum time in milliseconds that the "*Value*" attribute may take to stabilize before a warning is generated.

8.8.1.8 *Upper Size* — An attribute which specifies the upper bound of the particle size, in microns, included in the bin counts.

8.8.1.9 *Lower Size* — An attribute which specifies the lower bound of particle size, in microns, included in the bin counts.

8.8.1.10 *Initial and Default Values*

Table 20 Sensor-AI and Sensor-AI-Counter Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Value	0	0	
Data Type	LVV	UDINT	
Data Units	LVV	0	Raw counts
Reading Valid	0	0	Invalid
Full Scale	LVV	0XFFFFFFFF	
Alarm Settling Time	LVV	1000	Milliseconds
Warning Settling Time	LVV	1000	Milliseconds
Upper Size	LVV	Manufacturer Specified	Manufacturer Specific
Lower Size	LVV	Manufacturer Specified	Manufacturer Specific

8.8.2 *Sensor-AI-Counter Object Services* — The services provided by the Sensor-AI-Counter object are defined in SEMI E54.1 [1]. There are no additional services required for the Sensor AI-Counter object.

8.8.3 *Sensor-AI-Counter Object Behavior* — The behavior exhibited by the Sensor-AI-Counter object is inherited from the Sensor-AI object defined in SEMI E54.1. Additional specific behavior associated with the Sensor-AI-Counter object is defined below.

8.8.3.1 *Sensor-AI-Counter OPERATING Application Process*

8.8.3.1.1 A reading is retrieved from the physical median noise sensor. This reading is filtered through an analysis of a manufacturer specified number of samples. The *value* attribute is set to this processed reading. This process is called "counting" and is executed only when the Device Manager Object is in the EXECUTING state as defined in the Common Device Model.

8.8.3.1.2 Whenever an Interlock alarm, Sensor Not Detected alarm, Leak Detected alarm, and Sensor Type Change alarm is active the ISPM device shall stop "counting" until the alarm clears (see Section 8.2).

8.8.3.1.3 The ISPM is a device that measures and counts particles. As part of counting, particles are classified by size and count and accumulated in bins over time intervals then reported. The number of bins varies by vendor and device model.

8.8.3.1.4 The *value* attributes for all Sensor-AI-Counter objects, shall be held at zero unless the device laser is on and stable (i.e., Laser Status attribute of Device Manager Object has a value indicating "LASER ON AND STABLE"). The *value* attribute of any Sensor-AI-Counter object may be cleared (to zero) in a counter sensor after being read; the conditions under which this clearing behavior occurs may be further specified in the associated Network Communication Standard or by the manufacturer. The *value* shall also be cleared (to zero) by a valid "Clear Counts" service from the SAC object or the "Reset" service issued to the Sensor AI Class Object.

8.8.3.1.5 When attempting to set the "Upper Size" attribute to a value above the capability of the sensor, or to a value equal to or below the current "Lower Size" attribute value, an error response shall be generated indicating an invalid operation has been attempted. Similarly, an attempt to set the "Lower Size" attribute to a value below the capability of the sensor, or to a value equal to or above the current "Upper Size" attribute value, an error response shall be generated indicating an invalid operation has been attempted.

8.9 *Assembly-ISPM Objects* — Assembly-ISPM objects inherit attributes, services, and behavior from the Assembly object. The Assembly object is the device component which provides a mechanism of grouping more than one attribute from one or more objects into a single data structure for communication over the network.

8.9.1 Table 21 identifies the Assembly-ISPM objects defined for the ISPM device.

Table 21 Assembly List

Object	*Access Network*	*Required*	*Form*
Assembly-ISPM#1	R	Yes	Status and Counters (Counters ≤ 1024); Default Assembly
Assembly-ISPM#2	R	No	Status, Count and Counters (Counters ≤ 1024)
Assembly-ISPM#3	R	No	Status Diagnostics, and Counters (Counters ≤ 1024)
Assembly-ISPM#4	R	No	Status, Tool State, Time Stamp, Duration, and Counters (Counters ≤ 1024)
Assembly-ISPM#5	R	No	Status, Tool State, Time Stamp, Duration, Diagnostics, and Counters (Counters ≤ 1024)
Assembly-ISPM#6	R	Yes	Status
Assembly-ISPM#7	R	No	Exception Detail Alarm
Assembly-ISPM#8	R	No	Exception Detail Warning
Assembly-ISPM#9	R	No	Exception Detail Alarm and Exception Detail Warning
Assembly-ISPM#40	RW	No	Device Configuration

8.9.2 *Assembly-ISPM Objects Attributes* — Table 22 provides a list of attributes common to all Assembly-ISPM object types.

Table 22 Assembly-ISPM Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Data (See NOTE 1.)	A1	RW	Yes	Structure as defined below

NOTE 1: Inherited from the Assembly object as shown in Figure 1.

8.9.2.1 *Data Attribute Format for Assembly-ISPM Objects* — The Data attribute of all Assembly-ISPM objects is a structured attribute containing an ordered list of attributes within its structure. In the following tables (23 through 31), the structure of the Data attribute for each of the Assembly-ISPM object types is defined.

Table 23 Assembly-ISPM #1 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #1 Value
3	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #2 Value
.	ISPMD16	SaiA16	Sensor-AI-Counter #3 to Sensor-AI-Counter-ISPM #N-1 Value
N≤1024 (See NOTE 1.)	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #N Value

NOTE 1: "N" is the value of the Sensor-AI-Counter object attribute "Number of Bins". Note also that the number of bins reported in an assembly is fixed throughout the life of the device, and is specified by the manufacturer.

Table 24 Assembly-ISPM #2 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	ISPMD2	SacA65	SAC Number of Bins
3	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #1 Value
4	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #2 Value
.	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #3 to Sensor-AI-Counter-ISPM #N-1 Value
N≤1024 (See NOTE 1.)	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #N Value

NOTE 1: "N" is the value of the Sensor-AI-Counter object attribute "Number of Bins". Note also that the number of bins reported in an assembly is fixed throughout the life of the device, and is specified by the manufacturer.

Table 25 Assembly-ISPM #3 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	ISPMD3	SaiA16	Sensor-AI-LCS Value (Laser Current Diagnostic)
3	ISPMD4	SaiA16	Sensor-AI-SLS Value (Stray Light Diagnostic)
4	ISPMD5	SaiA16	Sensor-AI-MNS Value (Median Noise Diagnostic)
5	–	–	Reserved (2 bytes)
6	ISPMD2	SacA65	SAC Number of Bins
7	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #1 Value
8	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #2 Value
.	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #3 to Sensor-AI-Counter-ISPM #N-1 Value

Data Index	Source Object ID	Source Attribute ID	Description
N ≤ 1024 (See NOTE 1.)	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #N Value

NOTE 1: “N” is the value of the Sensor-AI-Counter object attribute “Number of Bins”. Note also that the number of bins reported in an assembly is fixed throughout the life of the device, and is specified by the manufacturer.

Table 26 Assembly-ISPM #4 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	DM1	A35	Device Manager Tool State
3	DM1	A41	Device Manager Time Stamp
4	ISPMD2	SacA67	SAC Duration
6	ISPMD2	SacA65	Sensor-AI-Counter Number of Bins
7	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #1 Value
8	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #2 Value
.	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #3 to Sensor-AI-Counter-ISPM #N-1 Value
N ≤ 1024 (See NOTE 1.)	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #N Value

NOTE 1: “N” is the value of the Sensor-AI-Counter object attribute “Number of Bins”. Note also that the number of bins reported in an assembly is fixed throughout the life of the device, and is specified by the manufacturer.

Table 27 Assembly-ISPM #5 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	DM1	A12	Device Manager Exception Status
2	DM1	A35	Device Manager Tool State
3	DM1	A41	Device Manager Time Stamp
4	ISPMD2	SacA67	SAC Duration
5	ISPMD3	SaiA16	Sensor-AI-LCS Value (Laser Current Diagnostic)
6	ISPMD4	SaiA16	Sensor-AI-SLS Value (Stray Light Diagnostic)
7	ISPMD5	SaiA16	Sensor-AI-MNS Value (Median Noise Diagnostic)
8	–	–	Reserved (2 bytes)
9	ISPMD2	SacA65	SAC Number of Bins
10	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #1 Value
11	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #2 Value

Data Index	Source Object ID	Source Attribute ID	Description
.	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #3 to Sensor-AI-Counter-ISPM #N-1 Value
N ≤ 1024*	ISPMD16	SaiA16	Sensor-AI-Counter-ISPM #N Value

NOTE 1: "N" is the value of the Sensor-AI-Counter object attribute "Number of Bins". Note also that the number of bins reported in an assembly is fixed throughout the life of the device, and is specified by the manufacturer.

Table 32 Assembly-ISPM #40 Object Data List

Data Index	Source Object ID	Source Attribute ID	Description
1	DM1	A33	Device Manager Gain
2	DM1	A13	Device Manager Filter Bandwidth
3	ISPMD2	SacA65	SAC Number of Bins
4	ISPMD3	SaiA73	Sensor-AI-LCS Alarm Trip Point High (See NOTE 1.)
5	ISPMD3	SaiA76	Sensor-AI-LCS

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
			Warning Trip Point High (See NOTE 1.)
6	ISPMD3	SaiA74	Sensor-AI-LCS Alarm Trip Point Low (See NOTE 1.)
7	ISPMD3	SaiA77	Sensor-AI-LCS Warning Trip Point Low (See NOTE 1.)
8	ISPMD4	SaiA73	Sensor-AI-SLS Alarm Trip Point High (See NOTE 1.)
9	ISPMD4	SaiA76	Sensor-AI-SLS Warning Trip Point High (See NOTE 1.)
10	ISPMD4	SaiA74	Sensor-AI-SLS Alarm Trip Point Low (See NOTE 1.)
11	ISPMD4	SaiA77	Sensor-AI-SLS Warning Trip Point Low (See NOTE 1.)
12	ISPMD5	SaiA73	Sensor-AI-MNS Alarm Trip Point High (See NOTE 1.)
13	ISPMD5	SaiA76	Sensor-AI-MNS Warning Trip Point High (See NOTE 1.)
14	ISPMD5	SaiA74	Sensor-AI-MNS Alarm Trip Point Low (See NOTE 1.)
15	ISPMD5	SaiA77	Sensor-AI-MNS Warning Trip Point Low (See NOTE 1.)

NOTE 1: Objects to which these attributes are linked are optional. If the associated object is not supported in the ISPM device, the data field for the associated attribute in this assembly is set to zero and should be interpreted as having no meaning.

SEMI E54.11-0301
SPECIFIC DEVICE MODEL FOR ENDPOINT DEVICES

This specific device model was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org January 2001; to be published March 2001.

1 Purpose

1.1 This specification is part of a suite of standards that specify the implementation of SEMI standards for the Sensor/Actuator Network. The specific purpose of this specification is to describe a network independent application model comprised of device objects that are common to all Endpoint Devices on a semiconductor equipment Sensor/Actuator communication network.

2 Scope

2.1 An Endpoint device (EPD) is a device that measures and monitors process characteristics to determine when a specific threshold or event has been obtained usually to signal the completion of a process or process step. These endpoint devices are, but not limited to, devices that may classify a process endpoint by determining the size and count of particles in the process environment, detecting and determining optical light from a sample region of the environment's space, or determining motor current of an equipment component.

2.2 This specification specifically addresses the minimum attributes, services and behavior an Endpoint (EPD) device must support to be interoperable on the Sensor/Actuator Network.

2.3 This specification is intended to ensure a high-degree of device interoperability on the Sensor/Actuator Network, while still allowing flexibility for product differentiation and technology evolution.

2.4 The model specified in this specification is used in conjunction with the Sensor/Actuator Network Common Device Model (CDM) to completely describe the Endpoint device (EPD) as it appears from the network interface.

2.5 This specification, together with the Sensor/Actuator Network Standard, the Sensor/Actuator Network Common Device Model, and a Sensor/Actuator Network Communication Specification, form a complete interoperability specification for the EPD.

2.6 To comply with this specification, a device must implement and support, at a minimum, the required attributes, services, and behavior identified in these documents. Support for optional attributes, services and behavior is not required to be compliant to this specification. Optional attributes, services, and behavior are specified in these documents to promote further device interoperability as features evolve and are adopted by more manufacturers. If optional attributes, services, and behavior are implemented for this device they must be implemented as identified in this document.

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use

3 Limitations

3.1 This specification is a companion to a suite of specifications that together make up the Sensor/Actuator Network Communication standard. Therefore, using portions of this specification that relate to network communications necessarily requires an understanding of the associated network specification.

3.2 As this document is a specification for the Endpoint Device Model, it does not contain any definition of objects, attributes, services, or behavioral descriptions that are already defined in the Sensor/Actuator Network Common Device Model (CDM). Additional attributes, attribute assignments, services and/or service parameters that are Endpoint Device specific and/or implementation specific are contained in this specification.

3.3 While this specification is sufficient to completely describe the EPD as it appears from the network, it does not fully describe behavior of a specific endpoint device type which is not visible from the network. This allows flexibility in implementation techniques and product differentiation between manufacturers. Manufacturer specific objects may be defined by the manufacturer but are, by definition, outside the scope of this standard.

3.4 This specification is compatible, but not compliant with SEMI E39. This means that although this specification does not require compliance with SEMI E39, it is extensible such that implementations may be developed that are fully compliant with both standards. Note that the concepts and terminology of this specification are compatible with those of SEMI E39.

However, SEMI E39 has specific requirements that are intended for higher level applications and thus are not applied to the Endpoint Device Model.

3.5 Operation over the entire range specified for an attribute within a specific object is not a requisite for compliance with this specification.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E54 — Sensor/Actuator Network Standard

SEMI E54.1— Standard for Sensor/Actuator Network Common Device Model

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *EP* — an EPD sensor named Endpoint.

5.2 *Definitions*

5.2.1 *Endpoint Device (EPD)* — a self-contained device, consisting of device specific signal-processing electronics, which is capable of monitoring and measuring the occurrence of a process endpoint.

5.2.2 *Endpoint Detection Event* — consists of the device operation of monitoring, measuring, analyzing, waiting, and reporting endpoint.

5.3 This document inherits the terminology defined by SEMI E54.1

5.3.1 *Attribute*

5.3.2 *Behavior*

5.3.3 *Boolean (BOOL)*

5.3.4 *Byte*

5.3.5 *Character*

5.3.6 *Common Device Model (CDM)*

5.3.7 *Data Type*

5.3.8 *Data Units*

5.3.9 *Device*

5.3.10 *Device Manager (DM) Object*

5.3.11 *Device Model*

5.3.12 *Double Integer (DINT)*

5.3.13 *Enumerated Byte*

5.3.14 *Full Scale Range*

5.3.15 *Instance*

5.3.16 *Last Valid Value (LVV)*

5.3.17 *Long Integer (LINT)*

5.3.18 *Long Real (LREAL)*

5.3.19 *Manufacturer*

5.3.20 *Nibble*

5.3.21 *Null Character*

5.3.22 *Object*

5.3.23 *Real (REAL)*

5.3.24 *S, A, and C Objects*

5.3.25 *Sensor Actuator Controller (SAC) Object*

5.3.26 *Service*

5.3.27 *Signed Integer (INT)*

5.3.28 *Short Integer (SINT)*

5.3.29 *State Diagram*

5.3.30 *Test String*

5.3.31 *Unsigned Double Integer (UDINT)*

5.3.32 *Unsigned Double Long Integer (UDLINT)*

5.3.33 *Unsigned Integer (UINT)*

5.3.34 *Unsigned Long Integer (ULINT)*

5.3.35 *Unsigned Short Integer (USINT)*

6 Requirements and Specifications

6.1 In order to implement this standard in an Endpoint Device, it is necessary to also implement SEMI E54.1 and one of the Sensor/Actuator Network Communication Standards (SEMI E54.4–E54.9). See Section 3 for more information on a complete interoperability standard.

6.2 This specification also requires the implementation of a Date_And_Time data structure used to represent the current device Date and Time. Table 1 defines the format of the Date_And_Time data type.

Table 1 Date_And_Time Format

Data Item	*Description*	*Range*
1	Number of milliseconds since midnight	Unsigned Double Integer (UDINT)
2	Number of days since 1/1/72	Unsigned Integer (UINT)

7 Conventions

7.1 This document embraces the conventions and notations stated in section 6 of SEMI E54.1.

8 Device High Level Structure

8.1 *General Description*

8.1.1 The high-level object view of an Endpoint Device (EPD) profile is shown in Figure 1.

8.1.2 Note that the profile for an "EPD Device" object is depicted in Figure 1 only for the purposes of illustrating a high level view of the device and its component objects. In the context of this document, this object is not addressable, does not have addressable attributes, does not have accessible services and, does not exhibit any defined behavior.

8.1.3 In the remainder of this section, this document defines in detail the component objects unique to the EPD device. References, rather than definitions, are included for the DM, the SAC and other objects defined in SEMI E54.1.

8.1.4 Many of the objects defined in this document inherit properties from other objects. The properties inherited include attribute, service and behavior definitions. These other objects are specified here or in SEMI E54.1.

8.1.5 This document provides for future extensions as well as manufacturer specific enhancements by reserving object attribute identifiers and object service identifiers. Specifically all object definitions in this document specify or reserve the first 64 attribute identifiers (A1 through A64) and the first 64 service identifiers (S1 through S64) allowing manufacturers to specify identifiers beyond these ranges. Additionally, byte enumerated attributes are specified or reserved from 0 to 63 allowing manufacturers to specify an enumeration beyond this range (64 to 255).

8.1.6 *Endpoint Device (EPD) Description* — An Endpoint device profile is composed of the component objects and object relationships shown in Figure 1.

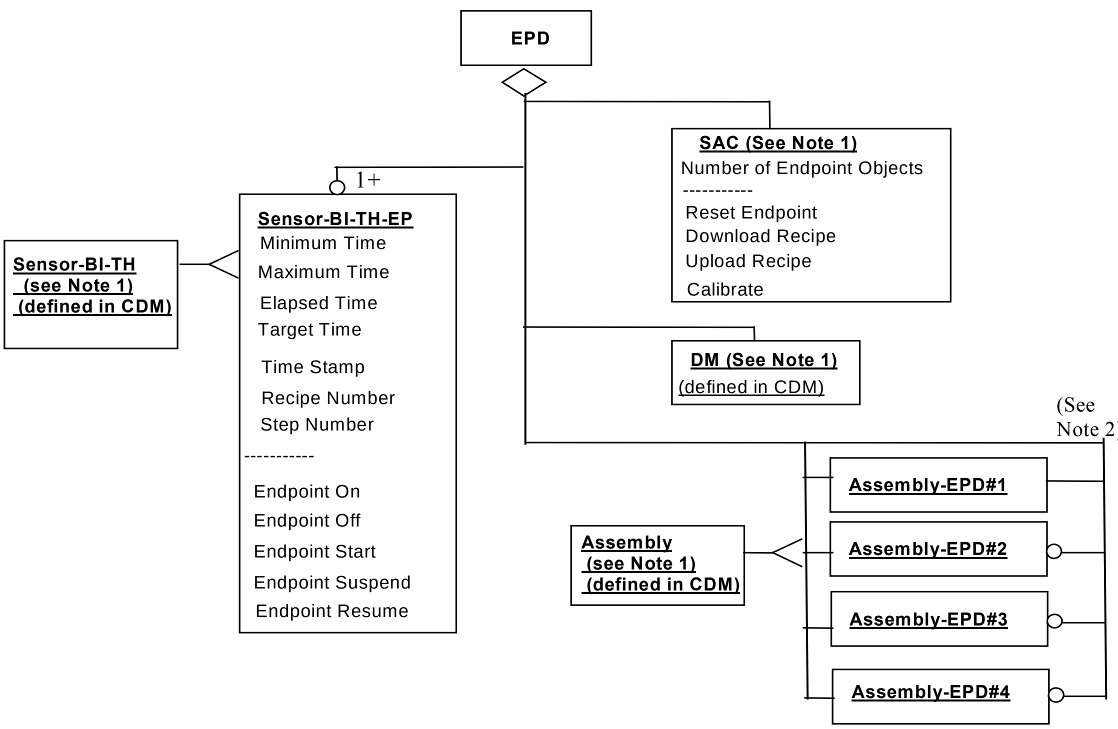

Figure 1
Endpoint Device High Level Structure

NOTE 1: The Sensor-BI-TH, DM, SAC, and Assembly are defined in the CDM. Additional attributes and services are added to support the EPD.

NOTE 2: Assembly-EPD #1 object is required. Other Assembly-EPD objects are optional.

8.1.7 *General Requirements*

8.1.7.1 *Device Objects* — All objects are defined in terms of their object name and Class/Object identifier. Identifiers for all objects described in this document are summarized in Table 2.

Table 2 Endpoint Device Objects

Referenced Document Section	*Object Name*	*Class/Object Identifier*	*Minimum #*	*Maximum #*
8.2	Device Manager (DM)	EPD1	1	1
8.3	Sensor Actuator Controller (SAC)	EPD2	1	1
8.5	Sensor-BI-TH-EP	EPD3	1	1024
8.6	Assembly-EPD#1	EPD4	1	1
8.6	Assembly-EPD#2	EPD5	0	1
8.6	Assembly-EPD#3	EPD6	0	1
8.6	Assembly-EPD#4	EPD7	0	1
—	Reserved	EPD7 – EPD63	-	—
—	Manufacturer Specified	> EPD64	-	—

8.1.7.2 *Object Services* — Not all object services listed in this document can necessarily be requested over the network. They are included in this document because their behavior may generate network activity.

8.1.7.3 *Object Behavior* — A network specific service error response is generated for all service requests received over the network that are not supported by the object, or contain a parameter value which is beyond the supported range, or which is otherwise invalid.

8.2 *Device Manager Object (DM)* — The Device Manager object is the device component responsible for managing and consolidating the device operation as specified in SEMI E54.1. The following sections specify the components of the DM object that are not specified in the Common Device Model or require further definition than specified in SEMI E54.1.

8.2.1 *Device Manager Object Attributes* — Required and optional DM object attributes are listed in Table 3.

Table 3 DM Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Device Type	A1	R	Yes	Refer to SEMI E54.1.
Exception Detail Alarm	A13	R	No	Refer to SEMI E54.1.
Exception Detail Warning	A14	R	No	Refer to SEMI E54.1.
Reserved	A33-A64	—	—	Reserved for SDM future expansion
Manufacturer Specified	> A64	—	—	Manufacturer Specific attributes

8.2.1.1 *Device Type* — An attribute that uniquely identifies the type of the device on the network. The device type attribute is assigned as follows:

Endpoint Device = “EPD”

NOTE 2: If the “Endpoint Device” functionality is implemented by another Sensor/Actuator Network Specific Device Model, the ‘*Device Type*’ attribute value may be specified by the manufacturer to identify the other Specific Device Model.

8.2.1.2 *Exception Detail Alarm (Optional)* — An attribute that identifies the detailed alarm status of the device. Table 4 defines the bit assignments associated with the alarm exception detail.

Table 4 Exception Detail Alarm Bit Assignments

Bit	*Device Specific Alarm[0]*
0	Unexpected Conditions Detected
1	Reserved
2	Sensor Not Detected
3	Reserved
4	Reserved
5	Reserved
6	Reserved
7	Endpoint Failure

8.2.1.3 *Exception Detail Warning (Optional)* — An attribute that identifies the detailed warning status of the device. Table 5 defines the bit assignments associated with the warning exception detail.

Table 5 Exception Detail Warning Bit Assignments

Bit	*Device Specific Warning[0]*
0	Unexpected Conditions Detected
1	Reserved
2	0
3	Reserved
4	Reserved
5	Reserved
6	Reserved
7	Endpoint Warning

8.2.1.4 *Manufacturer Exception Detail Size (Optional)* — An attribute that specifies the number of exception detail bytes included in the alarm or warning details.

8.2.1.5 *Initial and Default Values*

Table 6 DM Object Attribute Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Device Type	EPD	EPD	EPD = Endpoint Device
Exception Detail Alarm	0	0	
Exception Detail Warning	0	0	

8.2.2 *Device Manager Object Services* — The services provided by the Device Manager object are defined in SEMI E54.1. There are no additional services required for the Device Manager object.

8.2.3 *Device Manager Object Behavior* — The behavior exhibited by the Device Manager object is defined in SEMI E54.1. There is no additional behavior specified for the Device Manager object.

8.3 *Sensor Actuator Controller Object (SAC)* — The Sensor Actuator Controller object is the device component responsible for coordinating the interaction of the EPD device with the sensory/actuation/control environment as specified in SEMI E54.1. The following sections specify the components of the SAC object that are not specified in the Common Device Model or require further definition than specified in the Common Device Model.

8.3.1 *Sensor Actuator Controller Object Attributes* — The attributes provided by the Sensor Actuator Controller object are defined in SEMI E54.1. Table 7 contains the additional attributes required for the Sensor Actuator Controller object.

Table 7 SAC Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Number of Endpoint Objects	SacA65	R	No	UINT

8.3.1.1 *Number of Endpoint Objects* — An attribute that specifies the number of endpoint objects in the device. This value represents the number of Sensor-BI-TH-EP objects in the device. If this attribute is not supported then the default value of 1 Endpoint object is supported.

8.3.1.2 *Initial and Default Values*

Table 8 SAC Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Number of Endpoint Objects	Manufacturer Specified	Manufacturer Specified	There must be at least one Endpoint object.

8.3.2 *Sensor Actuator Controller Object Services* — The services provided by the Sensor Actuator Controller object are defined in SEMI E54.1. Table 9 contains the additional services required for the Sensor Actuator Controller object.

Table 9 SAC Object Services

Service	*Service Identifier*	*Type*	*Description*
Reset Endpoint	S33	R	Used to 'Reset' all of the Sensor-BI-TH-EP sensor objects.
Download Recipe	S34	R	Used to download the Sensor-BI-TH-EP sensor objects with manufacturer specific recipe data.
Upload Recipe	S35	R	Used to upload, from the device, manufacturer specific recipe data.
Calibrate	S36	R	Used to execute a device manufacture specific calibration procedure.
Reserved	S37–S64	—	Reserved for future expansion
Manufacturer Specified	> S64	—	Manufacturer Specific services

8.3.2.1 *Reset Endpoint (Optional)* — This service is used to instruct all of the Sensor-BI-TH-EP objects to perform a 'Reset' of their endpoint monitoring and measuring events. A one-time reset of their respective Sensor-BI-TH-EP attributes is performed. There are no parameters required for this service.

8.3.2.2 *Download Recipe (Optional)* — This service is used to set the recipe parameters associated with the endpoint sensor or a specific Sensor-BI-TH-EP object. The format and type of data comprising recipe data and the mechanism implemented to interrupt recipe data and distribute its contents to the appropriate Sensor-BI-TH-EP object is manufacturer specific. The parameter 'Recipe Data' may be a formatted data structure or a list of individual data items. The following table describes the parameters specified for this service.

Table 10 Download Recipe Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Recipe Data #1	M	U	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Recipe Data #2	M	U	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Recipe Data #3 through Recipe Data #N-1	M	U	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Recipe Data #N	M	U	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.

8.3.2.3 *Upload Recipe (Optional)* — This service is used to read the recipe parameters associated with the endpoint sensor or a specific Sensor-BI-TH-EP object. The format and type of data comprising recipe data and the mechanism implemented to assemble recipe data to be read is manufacturer specific. The parameter 'Recipe Data' may be a formatted data structure or a list of individual data items. The following table describes the parameters specified for this service.

Table 11 Upload Recipe Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Recipe Data #1	M	M	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Recipe Data #2	M	M	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Recipe Data #3 through Recipe Data #N-1	M	M	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Recipe Data #N	M	M	Manufacturer Specific	The recipe parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.

8.3.2.4 *Calibrate (Optional)* — This service is used to set the calibration parameters associated with the endpoint sensor or a specific Sensor-BI-TH-EP object. The format and type of data comprising calibration data and the mechanism implemented to interrupt calibration data and execute a calibration algorithm is manufacturer specific. The parameter 'Calibration Data' may be a formatted data structure or a list of individual data items. The following table describes the parameters specified for this service.

Table 12 Calibration Service Parameter Definitions

Parameter	*Request/ Indication*	*Response/ Confirmation*	*Data Type*	*Description*
Calibration Data #1	C	C	Manufacturer Specific	The calibration parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Calibration Data #2	C	C	Manufacturer Specific	The calibration parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Calibration Data #3 through Calibration Data #N-1	C	C	Manufacturer Specific	The Calibration parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.
Calibration Data #N	C	C	Manufacturer Specific	The calibration parameter format is manufacturer specific. The implementation behavior required to support this service is also manufacturer specific.

8.3.3 *Sensor Actuator Controller Object Behavior*

8.3.3.1 The behavior exhibited by the Sensor Actuator Controller object is defined in SEMI E54.1. Additional behavior is detailed below.

8.3.3.2 The *"Reset Endpoint"* service will issue an "Endpoint Restart" object service to each Sensor-BI-TH-EP sensor object.

8.4 *Sensor-BI-TH Object* — The Sensor-BI object is the device component responsible for coordinating the behavior common to all Boolean input threshold sensor elements in the EPD device as specified in SEMI E54.1.

8.4.1 *Sensor-BI-TH Object Attributes* — The attributes provided by the Sensor-BI-TH object are defined in SEMI E54.1. There are no additional attributes required for the Sensor-BI-TH object.

8.4.2 *Sensor-BI-TH Object Services* — The services provided by the Sensor-BI-TH object are defined in SEMI E54.1. There are no additional services required for the Sensor-BI-TH object.

8.4.3 *Sensor-BI-TH Object Behavior* — The behavior exhibited by the Sensor-BI-TH object is defined in SEMI E54.1. There is no additional behavior required for the Sensor-BI-TH object.

8.5 *Sensor-BI-TH-EP Object* — The Sensor-BI-TH-EP (Endpoint) object inherits the attributes, services, and behavior of the Sensor-BI-TH as defined in SEMI E54.1. The Sensor-BI-TH-EP is the device component responsible for retrieving a reading, or readings, from the device specific signal-processing sensors, optionally processing the readings with a manufacturer specified algorithm, or algorithms, and then making the endpoint result available through the "*Value*" attribute.

8.5.1 *Sensor-BI-TH-EP Object Attributes* — The attributes provided by the Sensor-BI-TH object are defined in SEMI E54.1. The Sensor-BI-TH object attribute content and its attribute extensions to support the Sensor-BI-TH-EP object are listed in the table below.

Table 13 Sensor-BI, Sensor-BI-TH, and Sensor-BI-TH-EP Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Value	SbithepA16	R	Yes	BOOL
Reading Valid	SbithA64	R	Yes	BOOL
State	SbithA65	R	No	Enumerated, Byte
Status	SbithA66	R	No	Enumerated, Byte
Minimum Time	EpA1	RW*	No	UDINT
Maximum Time	EpA2	RW*	No	UDINT
Target Time	EpA3	RW*	No	UDINT
Elapsed Time	EpA4	R	No	UDINT
Time Stamp	EpA5	R	No	Date_And_Time
Recipe Identifier	EpA6	RW*	No	Text String
Step Identifier	EpA7	RW*	No	Text String
Reserved	EpA8 –EpA64	—	—	Reserved for future expansion
Manufacturer Specified	> EpA64	—	—	Manufacturer Specific attributes

NOTE 1: "*" Indicates that the specific attribute is nonvolatile. Nonvolatile requires that the current attribute value be maintained through a component power cycle.

8.5.1.1 *Value* — The attribute that maintains the current endpoint event result. The value of the *'Value'* attribute is read as a Boolean (True or False) endpoint detection event result.

8.5.1.2 *Reading Valid* — An attribute which specifies whether the "*Value*" attribute contains a valid value. This attribute is Boolean that can take on one of the following values:

0 = INVALID
1 = VALID

NOTE 3: The 'Reading Valid' attribute is identified as an optional attribute of the SBITH object class but is identified as a required attribute for the SBITHEP object class.

8.5.1.3 *State* — An attribute that records the current state of the endpoint object. This attribute is an enumerated byte. The possible enumeration and the requirement for support are as follows:

0 = ENDPOINT OFF (required)
1 = ENDPOINT IN PROCESS (required)
2 = ENDPOINT IDLE (optional)
3 = ENDPOINT SUSPENDED (optional)
4 = ENDPOINT FAILURE (optional)

5-63 = Reserved
64-255 = Manufacturer Specified (optional)

8.5.1.4 *Status* — An attribute which specifies whether endpoint detection event reporting is active based upon the services 'Endpoint On', 'Endpoint Start', and 'Endpoint Off or On'. This attribute is an enumerated byte that can take on one of the following values:

0 = Endpoint Off
1 = Endpoint On

8.5.1.5 *Minimum Time* — An attribute that specifies the minimum time in milliseconds for an endpoint detection event. No attempt to report an endpoint detection event will take place until the minimum time specified has expired.

8.5.1.6 *Maximum Time* — An attribute that specifies the maximum time in milliseconds for an Endpoint detection event before an alarm is reported.

8.5.1.7 *Target Time* — An attribute that specifies the expected time in milliseconds for an Endpoint detection event.

8.5.1.8 *Elapsed Time* — An attribute that specifies in milliseconds the amount of time that has elapsed since the beginning of the current endpoint detection event. This attribute will behave as a count up timer that is frozen when the endpoint event is detected.

8.5.1.9 *Time Stamp* — An attribute that specifies the time when the endpoint detection event completed.

8.5.1.10 *Recipe Identifier* — An attribute that specifies a manufacturer specific endpoint algorithm or algorithms to be utilized to determine the current endpoint detection event. The interpretation of this attribute is manufacturer specific.

8.5.1.11 *Step Identifier* — An attribute that specifies a process recipe step that is associated with the current endpoint detection recipe and/or event. The interpretation of this attribute is manufacturer specific.

8.5.1.12 *Initial and Default Values*

Table 14 Sensor-BI and Sensor-BI-EP Object Attributes Initial and Default Values

Attribute	*Initial Value*	*Default Value*	*Comment*
Value	FALSE	FALSE	
Reading Valid	0	0	Invalid Reading
State	LVV	0	ENDPOINT OFF
Status	0	Endpoint Off	
Minimum Time	LVV	0	Milliseconds
Maximum Time	LVV	0	Milliseconds
Target Time	LVV	0	Milliseconds
Elapsed Time	LVV	0	Milliseconds
Time Stamp	LVV	Manufacture Specified	Date_And_Time
Recipe Identifier	LVV	Manufacture Specified	
Step Identifier	LVV	Manufacturer Specified	

8.5.2 *Sensor-BI-EP Object Services* — The services provided by the Sensor-BI-EP are inherited from the Sensor-BI object defined in SEMI E54.1. The Sensor-BI-EP object supports the additional services listed in Table 15 below.

Table 15 Sensor-BI-EP Object Services

Service	*Service Identifier*	*Type*	*Description*
Endpoint On	S1	R	Used to prompt the endpoint object to go from the ENDPOINT OFF state to ENDPOINT ON/ENDPOINT IDLE state as defined by the State and Status attribute.
Endpoint Off	S2	R	Used to prompt the endpoint object to go immediately to the ENDPOINT OFF state as defined by the State and Status attribute. All endpoint detection processes are aborted and all active timers are stopped.
Endpoint Start	S3	R	Used to prompt the endpoint object to go from the ENDPOINT OFF or ENDPOINT IDLE (optional) state to the ENDPOINT IN PROCESS state and begin the endpoint detection event process.
Endpoint Suspend	S4	R	Used to prompt the endpoint object to go to the ENDPOINT SUSPENDED state from the ENDPOINT IN PROCESS state. All endpoint detection event processes and active timers are suspended.
Endpoint Resume	S5	R	Used to prompt the endpoint object to go from the ENDPOINT SUSPENDED state to the ENDPOINT IN PROCESS state. All endpoint detection event processes and active timers resume from where they were suspended.
Reserved	S6–S64	—	Reserved for future expansion
Manufacturer Specified	> S64	—	Manufacturer Specific services

8.5.2.1 *Endpoint On (Required)* — This service is used to prompt the endpoint object to go from the ENDPOINT OFF state to the ENDPOINT ON / ENDPOINT IDLE state as defined by the State attribute. If the device does not support the ENDPOINT IDLE state then the endpoint object goes immediately to the ENDPOINT ON / ENDPOINT IN PROCESS state. If the State attribute is already set to ENDPOINT IDLE or ENDPOINT IN PROCESS, the endpoint object is set to the appropriate state. If the device turns on successfully, a “success” response is returned. If the device fails to turn on properly, a “fail” response is returned and the endpoint object remains in the appropriate state.

8.5.2.2 *Endpoint Off (Required)* — This service is used to prompt the endpoint object to go immediately to the ENDPOINT OFF state from the ENDPOINT ON state as defined by the State attribute. All endpoint detection event processes are aborted and all active timers are stopped. If the state attribute is already set to ENDPOINT OFF, the endpoint object remains in the appropriate state. If the device turns off successfully, a “success” response is returned. If the device fails to turn off properly, a “fail” response is returned and the endpoint object remains in the current state.

8.5.2.3 *Endpoint Start (Optional)* — This service is used to prompt the endpoint object to go from the ENDPOINT OFF or ENDPOINT IDLE state to the ENDPOINT IN PROCESS state and begin the endpoint detection event process with the initial endpoint attribute parameter values. If the State attribute is not currently in the ENDPOINT OFF or ENDPOINT IDLE state, an “object state conflict” error response is returned and the endpoint event remains in the appropriate state.

8.5.2.4 *Endpoint Suspend (Optional)* — This service is used to prompt the endpoint object to go from the ENDPOINT IN PROCESS state to the ENDPOINT SUSPENDED state and suspend the endpoint detection event process. All active timers are suspended and held at their current values. If the State attribute is not currently in the ENDPOINT IN PROCESS state, an “object state conflict” error response is returned and the endpoint object remains in the appropriate state. The Endpoint Suspend service is conditional on the Endpoint Resume service being supported.

8.5.2.5 *Endpoint Resume (Optional)* — This service is used to prompt the endpoint object to go from the ENDPOINT SUSPENDED state to the ENDPOINT IN PROCESS state and resume the endpoint detection event process. The process resumes using the endpoint attribute parameter values and timer readings that were saved when the endpoint was suspended by the Endpoint Suspend service request. If the Endpoint Resume service is issued while the State attribute is not in the ENDPOINT SUSPENDED state, an “object state conflict” error response is returned and the endpoint event remains in its existing state. The Endpoint Resume service is conditional on the Endpoint Suspend service being supported.

8.5.3 *Sensor-BI-TH-EP Object Behavior* — The behavior exhibited by the Sensor-BI-TH-EP object is inherited from the Sensor-BI-TH object defined in SEMI E54.1. Additional specific behavior associated with the Sensor-BI-TH-EP object is defined below.

8.5.3.1 *Sensor-BI-EP OPERATING Application Process* — When in the ENDPOINT ON / ENDPOINT IN PROCESS state, the '*Value'* attribute is set to FALSE and the '*Reading Value'* attribute is set to VALID. *A* reading, or readings, may be retrieved from the device physical signal processing electronics. This reading may be filtered, analyzed, and corrected with a manufacturer-specified algorithm. This corrected reading becomes the input to the endpoint formula to generate the 'V*alue'* attribute as referenced in SEMI E54.1. This process is called "endpoint detection" and is executed only when the Sensor-BI-TH-EP object is in the OPERATING state as defined in SEMI E54.1. When an Endpoint event is detected, the '*Value'* attribute is set to TRUE and the '*Reading Valid'* attribute is VALID. When not in the OPERATING state, the value of the '*Reading Valid*' attribute shall be set to INVALID. When in one of the sub-states of the OPERATING state, the validity of the '*Value*' attribute shall be manufacturer specific. Required sub-states within the OPERATING state, descriptions of these sub-states, and a transition matrix associated with these sub-states are given in Figure 2, Table 16 and Table 17 respectively.

8.5.3.1.1 Whenever a 'Sensor Not Detected' alarm, 'Endpoint Failure' alarm or 'Unexpected Conditions Detected' alarm is active, the EPD device shall turn off the endpoint detection event process and hold the device in the ENDPOINT OFF state until the alarm clears (see Section 8.2).

8.5.3.1.2 A device can concurrently monitor and report many endpoint detection events. The number of endpoint detection events varies by vendor and device model.

8.5.3.1.3 The 'Value' attributes for all Sensor-BI-TH-EP objects shall be held at 'FALSE' until a valid endpoint detection event is determined. An endpoint detection event is initiated when the endpoint service request 'Endpoint Start' or Endpoint On (if the state ENDPOINT ON / ENDPOINT IDLE is not supported) is received and the endpoint object can successfully transition to the ENDPOINT ON / ENDPOINT IN PROCESS state.

8.5.3.1.4 When attempting to set the "Minimum Time", "Maximum Time", and "Target Time" attribute to a value above the capability of the endpoint detection event an error response shall be generated indicating an invalid operation has been attempted.

8.5.3.1.5 When attempting to set the "Recipe Identifier" or "Step Identifier" attribute to an identifier outside the range of the endpoint detection event an error response shall be generated indicating an invalid operation has been attempted.

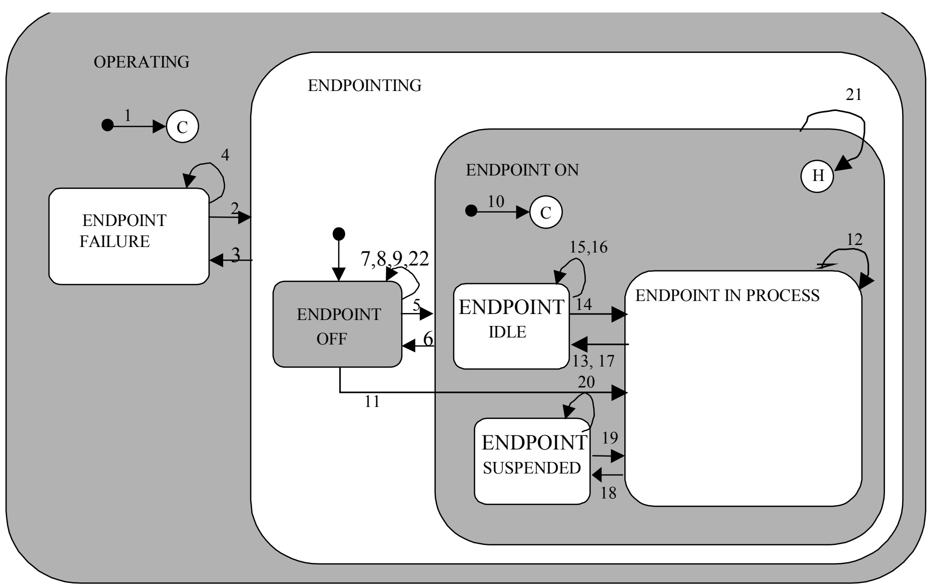

Figure 2
Sensor-BI-TH-EP Object Behavior Within the Operating State

Table 16 Sensor-BI-TH-EP Behavior OPERATING Sub-state Description

State	*Description*
OPERATING	Endpoint is in one of the following enumerated states as indicated in the Sensor-BI-TH-EP State attribute: ENDPOINT FAILURE (optional), ENDPOINT OFF, ENDPOINT IDLE (optional), ENDPOINT IN PROCESS, or ENDPOINT SUSPENDED (optional). Endpoint will respond to Endpoint On and Endpoint Off services as appropriate to move between sub-states within the ENDPOINTING and ENDPOINT ON states.
ENDPOINTING	Endpoint is in one of the following enumerated states as indicated in the Sensor-BI-TH-EP State attribute: ENDPOINT OFF, ENDPOINT IDLE, ENDPOINT SUSPENDED, and ENDPOINT IN PROCESS. Endpoint will respond to Endpoint On, Endpoint Off, Endpoint Start, Endpoint Suspend, and Endpoint Resume services as appropriate to move between sub-states within the ENDPOINTING state.
ENDPOINT OFF	This is a sub-state to ENDPOINTING; Endpoint Off is the status of the Sensor-BI-TH-EP Status attribute and ENDPOINT OFF is the enumerated state of the Sensor-BI-TH-EP State attribute. Endpoint object is **NOT** performing the “endpoint” detection event process. The endpoint object may be downloaded with new recipe parameters when in this state.
ENDPOINT ON	This is a sub-state of ENDPOINTING; Endpoint On is the status of the Sensor-BI-TH-EP Status attribute and ENDPOINT IDLE, ENDPOINT SUSPENDED or ENDPOINT IN PROCESS is the enumerated state of the Sensor-BI-TH-EP State attribute. Endpoint object may not be performing the “endpoint” detection event process.
ENDPOINT IDLE	This is a sub-state to ENDPOINT ON. Endpoint On is the status of the SENSOR-BI-TH-EP Status attribute and ENDPOINT IDLE is the enumerated state of the Sensor-BI-TH-EP State attribute. Endpoint object is not performing the “endpoint” detection event process. The endpoint object may be downloaded with new recipe parameters.
ENDPOINT IN PROCESS	This is a sub-state to ENDPOINT ON. Endpoint On is the status of the Sensor-BI-TH-EP Status attribute and ENDPOINT IN PROCESS is the enumerated state of the Sensor-BI-TH-EP State attribute. Endpoint object is performing the “endpoint” detection event process. The endpoint object may not be downloaded with new recipe parameters when in this state.
ENDPOINT SUSPENDED	This is a sub-state to ENDPOINT ON; Endpoint On is the status of the Sensor-BI-TH-EP Status attribute and ENDPOINT SUSPENDED is the enumerated state of the Sensor-BI-TH-EP State attribute. Endpoint object is **NOT** performing the “endpoint” detection event process. The endpoint object may not be downloaded with new recipe parameters when in this state.
ENDPOINT FAILURE	Endpoint electronics failure; Sensor-BI-TH-EP State attribute is in the enumerated state: ENDPOINT FAILURE. Endpoint is not performing the “endpoint” detection event process. Endpoint cannot move to the ENDPOINTING state until the electronics are repaired or replaced. A Perform Diagnostics or Reset service request to the Device Manager object may be sent to validate that the failure has been cleared. The endpoint object may not be downloaded with new recipe parameters when in this state.

Table 17 Sensor-BI-TH-EP Behavior EXECUTING Sub-state Transition Matrix*

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	Entry into OPERATING	Power Up	Conditional: ENDPOINTING or ENDPOINT FAILURE (optional)	If the endpoint electronics are in a failure condition than State is ENDPOINT FAILURE (optional) or ENDPOINTING. If endpoint failure checking is not supported the state is ENDPOINTING / ENDPOINT OFF. Set Status attribute to appropriate value.	Entry state depends on availability of endpoint electronics checking.

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
2	ENDPOINT FAILURE	Perform Diagnostics or Reset service request received and device determines that the failure no longer exists or the Endpoint device detects replacement of electronics that caused the failure	ENDPOINTING / ENDPOINT OFF	Set Status attribute to appropriate value.	Endpoint moves to ENDPOINT OFF state.
3	ENDPOINTING	Endpoint device detects an endpoint electronics failure	Conditional: ENDPOINT FAILURE or ENDPOINTING / EDNDPOINT OFF	Set State attribute to appropriate value.	The setting of the Status attribute is manufacturer specific.
4	ENDPOINT FAILURE	Endpoint Off, Endpoint On, Endpoint Start, Endpoint Resume, Endpoint Suspend, Download Recipe, Upload Recipe, and Calibrate request	ENDPOINT FAILURE	Error response	Object cannot move to ENDPOINTING / ENDPOINT OFF state until the electronics are repaired.
5	ENDPOINT OFF	Endpoint On request	Conditional: ENDPOINT ON / ENDPOINT IDLE or ENDPOINT ON / ENDPOINT IN PROCESS	If ENDPOINT IDLE supported: Take the object from the ENDPOINT OFF state to the ENDPOINT IDLE state and wait for an Endpoint Start request. Recipe parameter downloads are allowed. If ENDPOINT IDLE is not supported: Take the object from the ENDPOINT OFF state immediately to the ENDPOINT IN PROCESS state and begin the endpoint detection event process. Set the Status attribute to the appropriate values throughout the transition. Issue an Endpoint On response.	ENDPOINT IDLE is an optional intermediate state between ENDPOINT OFF and ENDPOINT IN PROCESS. Endpoint electronics must not be in failure. Service response is not issued until transition to ENDPOINT IDLE or ENDPOINT IN PROCESS is completed.
6	ENDPOINT ON	Endpoint Off request	ENDPOINT OFF	Stop the “endpoint” detection event process. Issue an Endpoint Off response.	This results in the same state transition as when a valid Abort service request is issued to the device.
7	ENDPOINT OFF	Endpoint Off request	ENDPOINT OFF	Error response	Endpoint is already off.

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
8	ENDPOINT OFF	Endpoint Suspend, or Endpoint Resume request	ENDPOINT OFF	Error response	Endpoint event process remains off.
9	ENDPOINT OFF	Endpoint On or Endpoint Start request. Endpoint is unable to turn on properly.	ENDPOINT OFF	Endpoint attempts to take the object from the ENDPOINT OFF state to an ENDPOINT ON state. Endpoint won't turn on properly. Turn "endpoint" detection event process back off and generate an Error response.	Behavior associated with determining that the endpoint will not turn on properly is manufacturer specific.
10	Entry into ENDPOINT ON	None	Entry state for ENDPOINT ON state. Conditional: ENDPOINT ON / ENDPOINT IDLE or ENDPOINT ON / ENDPOINT IN PROCESS	ENDPOINT IDLE state entered if supported; otherwise ENDPOINT IN PROCESS state entered	Entry depends on endpoint electronics functioning properly.
11	ENDPOINT OFF	Endpoint Start request	ENDPOINT ON / ENDPOINT IN PROCESS	Go immediately to the ENDPOINT ON / ENDPOINT IN PROCESS state and begin the endpoint detection event process. Issue an Endpoint Start response	Behavior associated with determining that the endpoint will not turn on properly is manufacturer specific.
12	ENDPOINT IN PROCESS	Endpoint On, Endpoint Start, Endpoint Resume, Download Recipe, Upload Recipe	ENDPOINT IN PROCESS	Error response	Endpoint is already in process.
13	ENDPOINT IN PROCESS	Endpoint detection completed and idle state supported	ENDPOINT IDLE	Endpoint event detected. Endpoint event reported.	
14	ENDPOINT IDLE	Endpoint Start Request	ENDPOINT IN PROCESS	Endpoint event detection process is started. Issue an Endpoint Started success response.	
15	ENDPOINT IDLE	Download Recipe, and Upload Recipe Request	ENDPOINT IDLE	Valid recipes are Downloaded or Uploaded and a services response is generated.	
16	ENDPOINT IDLE	Endpoint Suspend and Endpoint Resume request	ENDPOINT IDLE	Error response	Endpoint is not in process so it can not be suspended.

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
17	ENDPOINT IN PROCESS	Endpoint detection failed	Conditional: ENDPOINTING ON / ENDPOINT IDLE or ENDPOINTING / ENDPOINT OFF	Endpoint event not detected within the allotted endpoint active timers. Endpoint event failure reported.	
18	ENDPOINT IN PROCESS	Endpoint Suspend request and service supported	ENDPOINT SUSPENDED	Take the object from the ENDPOINT IN PROCESS state to ENDPOINT SUSPENDED state, turning off the endpoint event process. All active endpoint timers are held at their current values. Set the Status attribute to the appropriate value. Issue an Endpoint Suspended response and stop the “endpoint” detection process.	Endpoint event process is temporally suspended. All timers are suspended.
19	ENDPOINT SUSPENDED	Endpoint Resume request	ENDPOINT IN PROCESS	Take the object from ENDPOINT SUSPENDED state to ENDPOINT IN PROCESS. Begin the “endpoint” detection event process form the point it was suspended. All active endpoint timers are reinstated to their last held values. Issue an Endpoint Resume response.	Endpoint event process is resumed from the point it was suspended.
20	ENDPOINT SUSPENDED	Endpoint On, Endpoint Start, Endpoint Suspend , Download Recipe, Upload Recipe request	ENDPOINT SUSPENDED	Error response	Endpoint event process remains suspended.
21	ENDPOINT ON	Endpoint On, Endpoint Start, Endpoint Resume, Download Recipe, and Upload Recipe request	ENDPOINT ON	Error response	Endpoint detection event process remains on and continues endpoint process from its current attribute settings.
22	ENDPOINT OFF	Download Recipe or Upload Recipe request	ENDPOINT OFF	Valid recipes are Downloaded or Uploaded and a services response is generated.	

8.6 *Assembly-EP Objects* — Assembly-EP objects inherit attributes, services, and behavior from the Assembly object. The Assembly object is the device component that provides a mechanism of grouping more than one attribute from one or more objects into a single data structure for communication over the network.

Table 18 identifies the Assembly-EP objects defined for the EPD device.

Table 18 Assembly List

Object	*Access Network*	*Required*	*Form*
Assembly-EPD#1	R	Yes	Status; Default Assembly
Assembly-EPD#2	R	No	Value, Reading Valid
Assembly-EPD#3	R	No	Status, Number of Endpoint Objects and Value (Values ≤ 1024)
Assembly-EPD#4	R	No	Status, Exception Detail Alarm and Exception Detail Warning

8.6.1 *Assembly-EP Objects Attributes* — Table 19 provides a list of attributes common to all Assembly-EP object types.

Table 19 Assembly-EP Object Attributes

Attribute Name	*Attribute Identifier*	*Access Network*	*Required*	*Form*
Data (See NOTE 1.)	A1	RW	Yes	Structure as defined below.

NOTE 1: Inherited from the Assembly object as shown in Figure 1.

8.6.1.1 *Data Attribute Format for Assembly-EP Objects* — The Data attribute of all Assembly-EP objects is a structured attribute containing an ordered list of attributes within its structure. In the following tables (20 through 23), the structure of the Data attribute for each of the Assembly-EP object types is defined.

Table 20 Assembly-EPD #1 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	EPD1	A12	Device Manager Exception Status

Table 21 Assembly-EPD #2 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	EPD3	SbithepA16	Sensor-BI-TH-EP #1 Value Reading Valid

Table 22 Assembly-EPD #3 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	EPD1	A12	Device Manager Exception Status
2	EPD2	SacA65	SAC Number of Endpoint Objects
3	EPD3	SbithepA16	Sensor-BI-TH-EP #1 Value
4	EPD3	SbithepA16	Sensor-BI-TH-EP #2 Value
.	EPD3	SbithepA16	Sensor-BI-YH-EP #3 to Sensor-BI-TH-EP #N-1 Value
N ≤ 1024 (See NOTE 1.)	EPD3	SbithepA16	Sensor-BI-TH-EP #N Value

NOTE 1: 'N' is the value of the Sensor-BI-EP object attribute "Number of Endpointing Objects". Note also that the number of endpoints reported in an assembly is fixed throughout the life of the device, and is specified by the manufacturer.

Table 23 Assembly-EPD #4 Object Data List

Data Index	*Source Object ID*	*Source Attribute ID*	*Description*
1	EPD1	A12	Device Manager Exception Status
2	EPD1	A13	Device Manager Exception Detail Alarm
3	EPD1	A14	Device Manager Exception Detail Warning

SEMI E54.12-0701^E
SPECIFICATION FOR SENSOR/ACTUATOR NETWORK COMMUNICATIONS FOR CC-LINK

This specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Global Information and Control Committee. Current edition approved by the North American Information and Control Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001.

E This standard was editorially modified in September 2001 to correct a typographical error and the omission of a required disclaimer. Section 2.3 was added and changes were made to Section 7.6.2.6.

1 Purpose

1.1 This specification is part of the SEMI Sensor/Actuator Network (SAN) suite of standards and defines a specific communications protocol based on the CC-Link standard. This Network Communication Standard (NCS) taken together with the SEMI Sensor/Actuator Network standard suite and the CC-Link standard completely and unambiguously defines an open standard providing an industry specific solution to off-the-shelf interoperability of networked devices in semiconductor manufacturing equipment.

1.2 CC-Link is a vendor independent, open device level network standard. Vendor independence and openness are guaranteed by the CC-Link Partner Association.

2 Scope

2.1 This document specifies a SAN communications standard based on the CC-Link specification that is in compliance with SEMI E54.1. As such, it specifies the protocol, services and behavior that compliant intelligent devices must support in order to interchange information over this SAN in a method compatible with SEMI E39.

2.2 In conjunction with a SEMI standard SAN Common Device Model (CDM) specification and one or more SEMI standard Specific Device Model (SDM) specifications (e.g., for a mass flow controller), this Network Communication Standard (NCS) with the related CC-Link standard describe the data structures, interactions and behavior that are characteristic of the various devices on the network. This composite model forms a complete interoperability standard for communications among intelligent sensors, actuators and controllers in semiconductor manufacturing equipment.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This document specifies a semiconductor equipment SAN based solely on CC-Link; thus, a complete specification of this standard necessarily includes the CC-Link specifications. There are other semiconductor equipment SAN communications options. The specifications for these options are not included here.

3.2 The specifications within are strictly enhancements that provide additional capabilities over and above those currently required by CC-Link. Included throughout this document, primarily in Section 6, is information paraphrased from the CC-Link specifications — such as: protocol structure, capabilities, options and limitations. This information is provided here for reference only and is not intended to provide specification definitions. In all such areas, refer to the CC-Link specification documents for information. This document is limited to describing enhancements or limitations to the CC-Link specification that are imposed by this standard.

3.3 A complete specification of the conformance testing procedure shall include the CC-Link protocol conformance testing specification. Conformance testing shall also include enhancements and limitations to the CC-Link specification required by this standard.

4 Referenced Standards

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

7498 OSI — Basic Reference Model for Open Systems Interconnection

4.3 *CC-Link Partner Association*[2]

CC-Link Specification, Version 1.11 (or later)

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CDM* — Common Device Model

5.1.2 *NCS* — Network Communication Standard

5.1.3 *OSI* — Basic Reference Model for Open Systems Interconnection (ISO 7498)

5.1.4 *SAN* — Sensor/Actuator Network

5.1.5 *SDM* — Specific Device Model

5.2 *Definitions from Sensor/Actuator Network Common Device Model (SEMI E54.1)*

5.2.1 *Attribute*

5.2.2 *Behavior*

5.2.3 *Byte*

5.2.4 *Common Device Model*

5.2.5 *Device*

5.2.6 *Device Manager (DM) Object*

5.2.7 *Device Model*

5.2.8 *Instance*

5.2.9 *Network Communication Standard*

5.2.10 *Object*

5.2.11 *Sensor, Actuator and Controller (SAC) Object*

5.2.12 *Service*

5.2.13 *Specific Device Model*

5.2.14 *State Diagram*

5.3 *Definitions*

5.3.1 *broadcast polling method* — polling to each station and the data communication are executed by the same packet, and the data is transmitted to all of the stations in this method.

5.3.2 *cyclic transmission* — function to transmit the data from master station to all stations periodically, then for each station to transmit the response data to master station.

5.3.3 *intelligent device station* — station which can send cyclic transmission and transient transmission to master station.

5.3.4 *local station* — station which can send cyclic transmission and transient transmission to master station and other local stations.

5.3.5 *master station* — station that controls all stations on CC-Link. One (and only one) master station per system is required.

5.3.6 *profiles* — Application Object Model specifications.

5.3.7 *remote device station* — station that handles bit data and word data.

5.3.8 *remote I/O station* — station that handles only bit data.

5.3.9 *remote station* — generic name of remote I/O station and remote device station.

5.3.10 *slave station* — generic name of station other than master station.

5.3.11 *station* — equipment which can be connected with CC-Link and is assigned a station number of 0–64.

5.3.12 *transient transmission* — function to transmit the non-periodic data generated in master station, local station, and intelligent device station.

6 Communication Protocol High Level Structure

6.1 Message transfer is organized in cycles. A message cycle mainly consists of a request-frame followed by a corresponding acknowledge/response-frame of the addressed station.

6.2 A brief description of the CC-Link protocol as it relates to the ISO 7498 OSI model follows in the sections below. For protocol efficiency, CC-Link does not define layers 3 to 6.

NOTE 2: The information contained in this section is for reference only. It in no way represents specifications for CC-Link. See related documentation for these specifications.

6.3 *Physical Layer - Layer 1* — the Physical Layer conforms to the EIA RS-485 standard. See the CC-Link standard for more information.

6.4 *Data Link Layer - Layer 2* — the Data Link Layer conforms to the HDLC standard. See the CC-Link standard for more information.

6.5 *Application Layer - Layer 7* — the Application Layer defines services and protocols for Network

1 ISO - International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211, Geneva 20, Switzerland

2 CC-Link Partner Association - <www.cc-link.org>

Management, Cyclic Transmission and Non-Cyclic Transmission (or Transient Transmission). Also, Application Object Models are specified as "Profiles". See the CC-Link standard for more information.

6.6 Version 1.11 of the CC-Link Standard introduces two methods for request/response messaging.

6.7 Devices that support the CC-Link Transient Transmission capability, use this method, together with a messaging protocol to transmit Service Requests and Responses.

6.8 Devices that do not support the Transient Transmission capability, use the Cyclic Transmission method. A protocol is defined for changing the context of the cyclic data from I/O to a messaging protocol for Service Requests and Responses.

6.9 See the CC-Link standard for more information.

7 Required Object Types

7.1 This section describes a general mapping of the SEMI SAN Object Model to the CC-Link environment. Component definitions are clarified and the mapping of Attributes, Services and Behaviors are specified.

7.2 *Object Model* — The Object Model defined in the CDM is represented in the CC-Link NCS. Specifically, the DM and SAC objects are mapped.

7.2.1 Section 9 specifies the mapping of SDM Objects in CC-Link.

7.3 *Objects* — The required objects of the CDM are identified here. Additional objects that are contained in the SDM are given identifiers in the Device Profile. Section 9 specifies additional mapping information.

7.3.1 Table 1 lists the Object Identifiers specified for use in protocol messages.

Table 1 Object Identifiers

Object ID	*Object*
0	Invalid
1	DM Object
2	SAC Object
3–n	Application Objects as specified in Section 9

7.4 *Attributes* — All attributes are accessible via Get_Attribute and Set_Attribute services defined in the sections below.

7.4.1 *Attribute Identifiers* — Every object specified in the CDM and SDMs uses tags to identify its attributes. These tags are formatted with letters (identifying the object) followed by an upper case "A", followed by a numerical identifier. The Attribute ID used in the CC-Link NCS is simply the numerical portion of these tags.

7.5 See Table 2 for a list of DM attributes.

Table 2 DM Object Attribute Identifiers

SEMI CDM Attribute ID	*CC-Link Attribute ID*	*Attribute*
DmA1	1	Device Type
DmA2	2	Standard Revision Level
DmA3	3	Device Manufacturer Identifier
DmA4	4	Manufacturer Model Number
DmA5	5	Software or Firmware Revision Level
DmA6	6	Hardware Revision Level
DmA7	7	Serial Number
DmA8	8	Device Configuration
DmA9	9	Device Status
DmA12	12	Exception Status
DmA13	13	Exception Detail Alarm
DmA14	14	Exception Detail Warning
DmA15	15	Visual Indicator
DmA16	16	Alarm Enable
DmA17	17	Warning Enable

7.6 *Services*

7.6.1 *Service Identifiers* — The required services of the CDM are identified here. Additional services that are contained in the SDM are given identifiers in the Device Profile. Table 3 specifies the required services and ID numbers.

Table 3 Service Identifiers

Service ID	*Service*
0	Invalid
1	Reset
2	Abort
3	Recover
4	Get Attribute
5	Set Attribute
6	Execute
7	Perform Diagnostics

7.6.2 *Specified Services* — The following sections define the details associated with each of the services required by the CDM.

7.6.2.1 *Reset* — The Reset Request specifies no parameters. In addition to an explicit Reset Service Request, CC-Link specifies others methods whereby a Slave device can be reset.

7.6.2.2 *Abort* — The Abort Service Request specifies no parameters.

7.6.2.3 *Recover* — The Recover Service Request specifies no parameters.

7.6.2.4 *Get Attribute* — The Get Attribute Request specifies two parameters: the Object ID and the Attribute ID. Each are currently defined in the range 1–255. Both are expandable to 65,535.

7.6.2.5 *Set Attribute* — The Set Attribute Request specifies three parameters: the Object ID, the Attribute ID and the Attribute Value to set. The Object ID and the Attribute ID are defined the same as for the Set Attribute Service. The length of the Attribute Value is based on the specification of the attribute.

7.6.2.6 *Execute* — The Execute Service Request specifies no parameters.

7.6.2.7 *Perform Diagnostics* — The Perform Diagnostic Request specifies one parameter: Test ID. The Test ID parameter is one byte in length.

8 Protocol Compliance

8.1 The CC-Link Partner Association has established a qualified certification system, with test laboratories in Japan that include conformance testing and interoperability testing.

9 Specific Device Model Mappings

9.1 The following sections specify mappings for Sensor Actuator Network Specific Device Models.

9.2 *Mass Flow Device* — Reference SEMI E54.3 for a complete specification of the SDM for Mass Flow Devices. Accordingly, the following mapping rules apply to the identification tags for the Objects, Attributes and Services of this model.

9.2.1 *Objects* — Consistent with SEMI E54.3 and Section 7.3 above, the DM and SAC objects are identified as Object 1 and Object 2, respectively.

9.2.1.1 Table 4 shows the mapping of the SDM Object Instances specified in SEMI E54.3 (Instance numbers are listed under heading Inst. in the table) and the CC-Link Object ID (listed under ID in the table).

Table 4 MFD Object Identifiers

SDM Object Name	*SDM Object ID*	*Inst.*	*ID*
Sensor-AI-MF	MFD3	1	3
Actuator-AO-MF	MFD7	1	4
Controller	MFD8	1	5
SISO-Setpoint	MFD11	1	6
Sensor-AI-AT	MFD4	1	7

9.2.1.2 Additional objects may be defined by the manufacturer in the Device Profile for a given device.

9.2.2 *Attributes* — The mapping of Attribute Tags and Identifiers is defined in Section 7.4.1 for the CDM. The same method applies here for the SDM.

9.2.3 *Services* — The mapping of Service Tags and Identifiers is defined in Section 7.6.1 for the CDM. The same method applies here for the SDM.

9.3 *In-Situ Particle Monitor* — Reference SEMI E54.10 for a complete specification of the SDM for In-Situ Particle Monitor Devices. Accordingly, the following mapping rules apply to the identification tags for the Objects, Attributes and Services of this model.

9.3.1 *Objects* — Consistent with SEMI E54.10 and Section 7.3 above, the DM and SAC objects are identified as Object 1 and Object 2, respectively.

9.3.1.1 Table 5 shows the mapping of the SDM Object Instances specified in SEMI E54.3 (Instance numbers are listed under heading Inst. in the table) and the CC-Link Object ID (listed under ID in the table).

Table 5 ISPM Object Identifiers

SDM Object Name	*SDM Object ID*	*Inst.*	*ID*
Sensor-AI-LCS	ISPMD3	1	3
Sensor-AI-SLS	ISPMD4	1	4
Sensor-AI-MNS	ISPMD5	1	5
Assembly-ISPM#1	ISPMD17	1	6
Assembly-ISPM#2	ISPMD18	1	7
Assembly-ISPM#3	ISPMD19	1	8
Assembly-ISPM#4	ISPMD20	1	9
Assembly-ISPM#5	ISPMD21	1	10
Assembly-ISPM#6	ISPMD22	1	11
Assembly-ISPM#7	ISPMD23	1	12
Assembly-ISPM#8	ISPMD24	1	13
Assembly-ISPM#9	ISPMD25	1	14
Assembly-ISPM#40	ISPMD64	1	15
Sensor-AI-Counter	ISPMD16	1	16
Sensor-AI-Counter	ISPMD16	n	15 + n
Sensor-AI-Counter	ISPMD16	1024	1039

9.3.1.2 Additional objects may be defined by the manufacturer in the Device Profile for a given device.

9.3.2 *Attributes* — The mapping of Attribute Tags and Identifiers is defined in Section 7.4.1 for the CDM. The same method applies here for the SDM.

9.3.3 *Services* — The mapping of Service Tags and Identifiers is defined in Section 7.6.1 for the CDM. The same method applies here for the SDM.

SEMI E58-0301
AUTOMATED RELIABILITY, AVAILABILITY, AND MAINTAINABILITY STANDARD (ARAMS): CONCEPTS, BEHAVIOR, AND SERVICES

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on October 19, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published June 1997.

CONTENTS

SEMI E58-0301
AUTOMATED RELIABILITY, AVAILABILITY, AND MAINTAINABILITY STANDARD (ARAMS): CONCEPTS, BEHAVIOR, AND SERVICES

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on October 19, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published June 1997.

1 Purpose

1.1 This document provides standards for implementing and collecting SEMI E10 state changes at the equipment level per SEMI E10.

1.1.1 SEMI E10 defines various terms and equipment states but was not written specifically for application by automated equipment. This document is intended to provide a consistent interpretation of these equipment states through formal state model methodology.

1.1.2 ARAMS defines concepts, behavior, and message services to support the integration of automated systems within a semiconductor factory.

1.2 *Background and Motivations* — To implement the integration of SEMI E10 states on automated equipment, integration of definitions and requirements must be detailed and precise to ensure interpretations are consistent across equipment suppliers. This provides an opportunity to automatically retain information at the equipment itself.

1.2.1 Both equipment supplier and equipment user benefit from the automation of SEMI E10 data collection at the equipment through application of a consistent state model.

1.2.2 SEMI E10 defines specific states but does not address transitions between states. The ARAMS standard specifies the triggers for state transitions made by automated equipment. Extensions to SEMI E10 described in this document apply to decisions made by automated equipment only.

2 Scope

2.1 This standard is applicable to the following relationships: traditional host/equipment, operator/equipment, and cluster tool controller/attached module. The scope of this document is to define standards which facilitate equipment-level capture and communication of SEMI E10 related data. Specifically, this document provides the following:

- An equipment state model that defines the rules for equipment state changes,
- A set of standard equipment codes for representing substates of the six basic equipment states defined in SEMI E10,
- Definition of equipment-generated data,
- Concepts and messages required to exchange information, and
- Requirements for fundamental compliance to ARAMS
- Additional optional specifications.

2.2 This standard is intended as a supplement to SEMI E10 to be used for equipment support of SEMI E10. Formal definitions of all terms common to both documents are provided solely by SEMI E10.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E38 — Cluster Tool Module Communications (CTMC)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E41 — Exception Management (EM) Standard

SEMI E42 — Recipe Management Standard: Concepts, Behavior, and Message Services

SEMI E53 — Event Reporting

3.2 *Other Document*

Harel, D., "Statecharts: A Visual Formalism for Complex Systems," *Science of Computer Programming 8* (1987) 231–274

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *Acronyms* — The following acronyms are used in this document.

4.1.1 *ARAMS* — Automated Reliability, Availability, and Maintainability Standard, as defined by this document.

4.1.2 *CTMC* — Cluster Tool Module Communications [SEMI E38].

4.1.3 *EMS* — Exception Management Standard [SEMI E41].

4.1.4 *ERS* — Event Reporting Standard [SEMI E53].

4.1.5 *GEM* — Generic Equipment Model [SEMI E30].

4.1.6 *OSS* — Object Services Standard [SEMI E39].

4.1.7 *RAM* — Reliability, Availability, and Maintainability.

4.2 *General Terms* — The following definitions for general terms are used in this document. References are given in brackets.

4.2.1 *alarm* — Related to any abnormal situation on the equipment that may endanger people, equipment, or material being processed [SEMI E30, SEMI E41].

4.2.2 *collection event* — An event (or grouping of related events) on the equipment that is considered to be significant to the host [SEMI E30].

NOTE 2: A state transition in a formal state model always represents a collection event unless explicitly stated otherwise.

4.2.3 *equipment production criteria* — The set of conditions and operating specifications that must be satisfied for the equipment to consider itself as performing its intended function. This includes basic requirements for information, material to process, and the absence of any detectable exception conditions (e.g., no alarms). It also includes criteria specific to the equipment model, such as a required level for vacuum pressure and availability of consumables and support tools required for its process.

4.2.4 *event* — A detectable occurrence significant to the equipment.

NOTE 3: Within the context of ARAMS, an event may be detected by either the equipment or the user.

4.2.5 *event report* — A message the equipment sends to the host on the occurrence of a collection event.

4.2.6 *exception* — An alarm or error that is reported to the user and that may or may not be recoverable.

4.2.7 *fault* — An exception.

4.2.8 *host* — The intelligent system that communicates with the equipment, acts as a supervisory agent, and represents the factory and the user to the equipment.

4.2.9 *intended function* — A manufacturing function that the equipment was built to perform. This includes transport functions for transport equipment and measurement functions for metrology equipment as well as process functions such as physical vapor deposition and wire bonding. Complex equipment may have more than one intended function.

4.2.10 *interrupt (interruption)* — A failure [SEMI E10].

4.2.11 *operator* — Any person who communicates locally with the equipment through the equipment's control panel.

4.2.12 *state* — A static set of conditions and associated behavior. While all of its conditions are met, the state is current (active). Behavior within a given state includes the response to various stimuli.

NOTE 4: Within the scope of this document, the term "state" generally refers to one of the six equipment states defined by SEMI E10 and used in the ARAMS State Model: productive, standby, engineering, scheduled downtime, unscheduled downtime, and non-scheduled time.

4.2.13 *state model* — A collection of states and state transitions that combine to describe the behavior of a system. This model includes a definition of the conditions that delineate a state, the activities possible within a state, the events that trigger transitions to other states, and the process of transitioning between states.

4.2.14 *state transition* — A change from one state to another state.

4.2.15 *standby condition* — Any condition during manufacturing time when the equipment's production criteria are not satisfied, and it is fault free and otherwise able to perform its intended function.

4.2.16 *substate* — A refinement of a state.

NOTE 5: States may be subdivided into substates to facilitate more concise definition of behavior. Thus, a hierarchy is defined whereby any state may be a substate of some parent state and in turn be the parent of its own substates [SEMI E30, Appendix].

4.2.17 *superstate* — The parent state of two or more states.

4.2.18 *symptom* — A user-detected event (e.g., smoke observed).

4.2.19 *timestamp* — The notation of the date and time of the occurrence of an event [SEMI E42].

4.2.20 *timestamp format* — A text string of the form "YYYYMMDDhhmmsscc", where:

YYYY = year (e.g., 1995)

MM = month (01–12)

DD = day (01–31)

hh = hour (00–23)

mm = minute (00–59)

ss = second (00–59)

cc = centisecond (00–99)

4.2.21 *trigger* — An event that causes a change in the state of the equipment. Examples are changes in sensor readings, alarms, messages received from the host, and operator commands.

4.2.22 *user* — Any entity interacting with the equipment, either locally as an operator or remotely via the host. From the equipment's viewpoint, both the operator and the host represent the user.

4.3 *data types* — The following terms are used to represent valid types of data.

4.3.1 *form* — Type of data: positive integer, unsigned integer, integer, floating point (float) enumerated, Boolean, text, formatted text, structure, list, ordered list.

4.3.2 *positive integer* — May take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

4.3.3 *unsigned integer* — May take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

4.3.4 *integer* — May take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

4.3.5 *floating point (float)* — May take on any single (real) numeric value, positive or negative. Messaging protocol may impose a limit on the range of possible values.

4.3.6 *enumerated* — May take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

4.3.7 *boolean* — May take on one of two possible values, equating to TRUE and FALSE.

4.3.8 *text* — A character string. Messaging protocol may impose restrictions, such as length or ASCII representation.

4.3.9 *formatted text* — A character string with an imposed format. This could be by position, by use of special characters, or both.

4.3.10 *structure* — A specific set of items, of possibly mixed data types, in a specified arrangement.

4.3.11 *list* — A set of one or more items that are all of the same form (one of the above forms).

4.3.12 *ordered list* — A set of items in specific sequence.

5 Basic Requirements

5.1 An ARAMS-compliant implementation requires provision of certain capabilities defined by other standards: accessibility to status information, event reporting, alarm management, and provision of an internal time-and-date clock. These requirements may be satisfied through compliance to one of the following sets of requirements:

- The Generic Equipment Model (GEM):
  - Clock Services
  - Event Notification
  - Status Data Collection
  - Equipment Constants
  - Alarm Management
- The following set of standards:
  - Object Services Standard
  - Clock Services, Cluster Tool Module Communications
  - Event Reporting Standard
  - Exception Management Standard

5.2 The developer is expected to be familiar with the appropriate documents before attempting to implement ARAMS (see Section 16.1).

6 Conventions

This document follows the conventions for state model methodology and service definitions used by the SEMI standards referenced in Section 3.

6.1 *State Model Methodology* — This document uses the state model methodology in SEMI E30 to describe the behavior of equipment. A state model has three elements: definitions of each state and substate, a diagram of the states and the transitions between states, and a state transition table. The diagram of the state model uses the Harel State Chart notation. An overview of this notation is presented in an appendix of SEMI

E30. The formal definition of this notation is presented in *Science of Computer Programming 8*, "Statecharts: A Visual Formalism for Complex Systems", by D. Harel, 1987.

6.1.1 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A **transition table** contains columns for Transition #, Current State, Trigger, New State, Action(s), and Comment. The "trigger" (column 3) for the transition occurs while in the "current" state. The "actions" (column 5) includes a combination of 1) actions taken upon exit of the current state, 2) actions taken upon entry of the new state, and 3) actions taken which are most closely associated with the transition. No differentiation is made between these cases.

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
Transition #					

6.2 *Object Attribute Representation* — The object information models for standardized objects will be supported by an **attribute definition table** with the following column headings:

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
The formal text name of the attribute.	Description of the information contained.	RO or RW	Y or N	(see below)

6.2.1 The Access column uses RO (Read Only) or RW (Read and Write) to indicate the access that users of the service have to the attribute.

6.2.2 A 'Y' or 'N' in the Required (Reqd) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

6.2.3 The Form column is used to indicate the format of the attribute (see Section 4 for definitions).

6.3 *Service Message Representation*

6.3.1 *Service Resource Definition* — A **service definition table** defines the specific set of messages for a given service resource, as shown in the following table:

Message Service Name	*Type*	*Description*
Message name	N or R	The intent of the service

6.3.1.1 Type can be either N = Notification or R = Request.

6.3.1.2 Notification type messages are initiated by the service provider and the provider does not expect to get a response from the service user (consumer/subscriber).

6.3.1.3 Request messages are initiated by a service user. Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

6.3.2 *Service Parameter Dictionary* — A **service parameter dictionary table** defines the parameters for one or more services, as shown in the following table:

Parameter	*Description*	*Form*
Parameter X	A parameter called X is B in A.	Data type.

6.3.2.1 A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and contents of the corresponding parameter.

6.3.2.2 The Form column is used to indicate the type of data contained in a parameter (see Section 4 for definitions).

6.3.2.3 The Description column in the Service Parameter Dictionary table describes the meaning of the parameter, the allowed values, and any interrelationships with other parameters.

6.3.2.4 To prevent the definition of numerous parameters named "XxxList", this document adopts the convention of referring to the list as "(List of) Xxx". In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type.

6.3.2.5 Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element unless zero elements are specifically allowed.

6.3.3 *Service Message Definition* — A **service message definition table** defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Parameter X	(see below)	(see below)	A description of the parameter.

6.3.3.1 The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication". The receiver may then send a "Response", which the original sender terms the "Confirmation".

6.3.3.2 The following codes appear in the Req/Ind and Rsp/Conf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M" - *Mandatory parameter* — Must be given a valid value.

"C" - *Conditional parameter* — May be defined in some circumstances and undefined in others. Whether a value is given may be a completely optional or may depend on the value of other parameters.

"U" - *User-defined parameter*

"-" — The parameter is not used.

"=" — (For response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

7 Overview

7.1 This section provides an overview of how ARAMS will be applied and the capabilities that ARAMS defines.

7.2 Systems that are used to track equipment performance should be based on SEMI E10's definitions of the six basic equipment states. The tracking systems typically rely on factory personnel to manually enter SEMI E10 state changes. Individual factories may have further company-specific and/or facilities-specific refinements of the states. For example, the basic equipment state may be "unscheduled downtime" with a refinement of "waiting for parts". In addition to entering a state change, the operator (who may be the production operator, a process engineer, an equipment engineer, or a supplier field service engineer) may select from a pre-defined set of behaviors (symptoms) that prompted the change of state, such as "smoke observed".

7.3 Specifications provided by ARAMS are intended to support the integration of equipment systems with factory tracking systems. For this purpose, equipment needs to be cognizant of the ARAMS states and substates, must know its current state, and must follow common rules for determining if equipment-initiated transitions can be made. In addition, the user needs to be able to interact with the tracking system at either the host system's console or the equipment's operator console. This requires that the operator be able to enter certain information at the equipment's console: a new state or substate request, and specific observed behavior that prompted the request. The host system is then notified that a change in state has occurred.

7.4 Integrated systems are able to provide more accurate data for those state changes than the equipment alone is able to detect. While the user is still required to initiate state changes for other conditions, this can be accomplished either directly at the equipment's console or remotely at the host tracking system terminal.

7.5 Exchange of information is accomplished through standardization of the meaning and form of data and the specification of the message services for the exchange. ARAMS provides generic definitions for the common substates described in SEMI E10. ARAMS also defines two tables and the message services required for the equipment and host to exchange tables. The first table contains a set of ARAMS substate definitions (an ARAMS code identifying the substate) and a corresponding description. The second table defines a set of symptoms with a numeric symptom identifier and a corresponding description.

7.6 While the above discussion assumes that the equipment is interacting with host systems, the ARAMS state model only requires interactions with a "user", which might be either a local operator or a host system.

8 State Models

8.1 This section defines the formal state model for ARAMS, called the ARAMS State Model, which is required for ARAMS compliance. To clarify the relationships between this state model and the equipment's operations, it introduces a second state model, called the General Equipment Operations Model, which is used for purposes of illustration. The General Equipment Operations Model is assumed to exist in some form but is not required for ARAMS compliance.

8.1.1 This document follows the convention of using upper-case to denote the formal names of states. Informal references may use lower case. For example, the ARAMS states SCHEDULED DOWNTIME and UNSCHEDULED DOWNTIME may be referred to as downtime states.

8.1.2 Detailed requirements for equipment behavior are provided in Section 16.

NOTE 6: Although the equipment is unable to detect a condition of no power, it is able to detect when the INITIALIZING state has been entered and is able to differentiate between a hard reset (Transition 6) and a soft re-boot (Transition 5).

8.2 *SEMI E10 Equipment States* — Figure 1 contains a diagram of SEMI E10 equipment states using the Harel notation. SEMI E10 divides total time into six basic states: PRODUCTIVE, ENGINEERING, STANDBY, SCHEDULED DOWNTIME, UNSCHEDULED DOWNTIME, and NON-SCHEDULED TIME. These six states are shown in Figure 1 with solid lines.

8.2.1 OPERATIONS TIME, UPTIME, DOWNTIME, and MANUFACTURING TIME are derived by grouping states defined in SEMI E10 and are useful for classification purposes, but formally they are not considered as SEMI E10 equipment states. Time in these groupings can be derived by summing the time in their corresponding states, based on Figure 1.

NOTE 7: Figure 1 uses shadings to show derived states. It is not intended as a formal state model.

8.2.2 MANUFACTURING TIME includes time spent in PRODUCTIVE and STANDBY. UPTIME includes the time spent in MANUFACTURING TIME and ENGINEERING. DOWNTIME includes the time spent in SCHEDULED DOWNTIME and UNSCHEDULED DOWNTIME.

8.2.3 In SEMI E10, precise rules governing state transitions are not required. The ARAMS model, in contrast, is intended to be used by automated equipment capable of detecting internal conditions. Conditions for each valid state transition are defined, both those initiated by equipment and those determined by interactions between the user and the equipment.

8.3 *ARAMS State Model Definition* — This section contains the formal definition of the ARAMS State Model, consisting of three parts:

- A diagram of the ARAMS State Model (Figure 2), using Harel notation,
- a description of each state and the behavior of the equipment within that state, and
- a table of transitions (Table 1) showing the previous state before the transition, the trigger for the transition, the new state after the transition, a description of any actions to be taken upon entry, and comments concerning the new state.

8.3.1 *ARAMS State Model Diagram* — Figure 2 contains the diagram of the ARAMS State Model.

8.3.2 *Descriptions of ARAMS States* — This section provides brief descriptions of the basic states for model completeness.

NOTE 8: These are informal descriptions included for the completeness of the ARAMS State Model. They do not replace the formal definitions in SEMI E10.

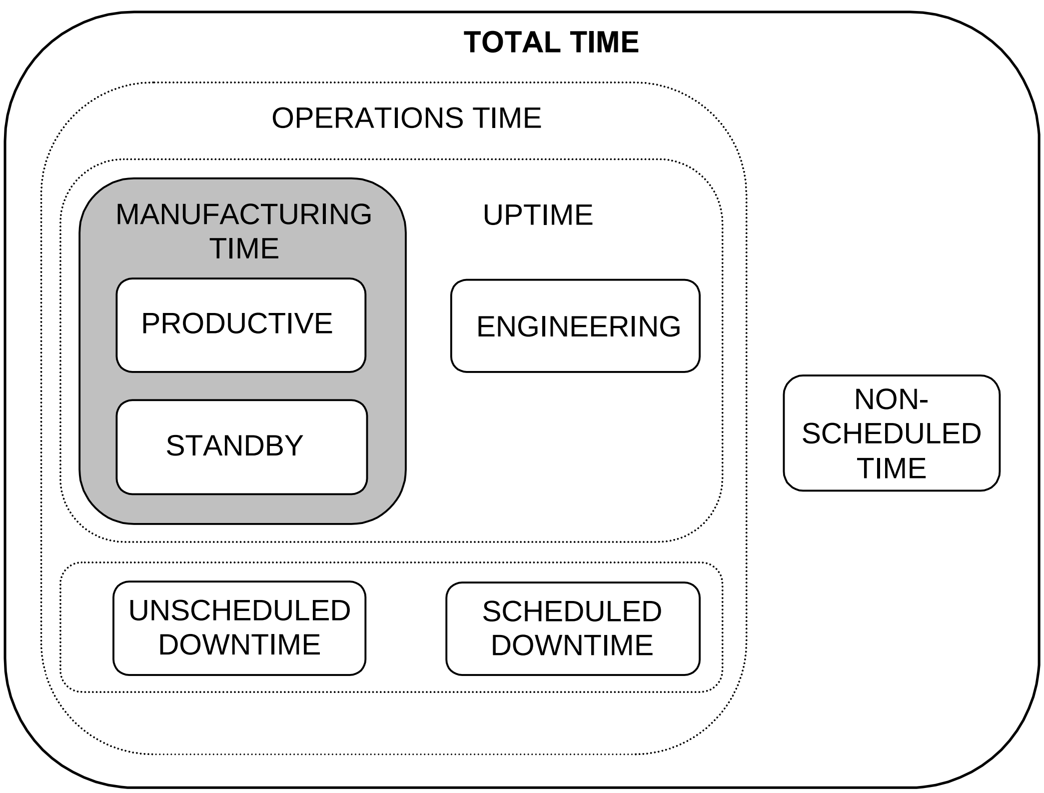

Figure 1
SEMI E10 Equipment States in Harel Notation

8.3.2.1 *TOTAL TIME* — The TOTAL TIME state includes 100% of real time; the sum of the time in the six basic SEMI E10 states, including time when the equipment is powered down. PRODUCTIVE, STANDBY, and ENGINEERING are called *uptime*, and SCHEDULED DOWNTIME and UNSCHEDULED DOWNTIME are called *downtime*.

8.3.2.2 *MANUFACTURING* — The ARAMS State Model includes MANUFACTURING as a user-selectable superstate of PRODUCTIVE and STANDBY. When the user selects MANUFACTURING, the equipment automatically transitions to either PRODUCTIVE or STANDBY, depending upon its internal status at the time.

8.3.2.2.1 Equipment is fault-free during MANUFACTURING.

NOTE 9: MANUFACTURING is not a SEMI E10 equipment state.

8.3.2.3 *PRODUCTIVE* — The PRODUCTIVE state covers the time spent by the equipment in performing its intended function. This also includes time spent loading and unloading product. PRODUCTIVE is an uptime manufacturing state.

8.3.2.3.1 The equipment is in PRODUCTIVE when, and only when, it is in MANUFACTURING, its equipment production criteria are satisfied, and it is busy performing its intended function.

NOTE 10: Although by definition, the equipment is only considered to be "performing its intended function" in the PRODUCTIVE state, equipment processing cycles may occur in any of the basic SEMI E10 states except STANDBY.

8.3.2.4 *STANDBY* — The STANDBY state is an uptime manufacturing state that covers the time the equipment is waiting to enter the PRODUCTIVE state.

8.3.2.4.1 The equipment enters this state automatically from the PRODUCTIVE state whenever it is in the MANUFACTURING superstate and the requirements for PRODUCTIVE do not apply. This includes periods during which it detects a normal standby condition, such as no work, no operator, etc. During STANDBY, the equipment monitors conditions for PRODUCTIVE. When all requirements for PRODUCTIVE are satisfied, then it transitions automatically to PRODUCTIVE.

8.3.2.5 *ENGINEERING* — The ENGINEERING state is an uptime state that is selected by the user for process and equipment engineering purposes, such as process development or characterization.

8.3.2.5.1 Because the equipment may be pushed deliberately outside of its normal operating conditions, faults that may occur in the ENGINEERING state do not trigger equipment-initiated transitions to UNSCHEDULED DOWNTIME. The equipment may also be powered off while in ENGINEERING.

8.3.2.6 *UNSCHEDULED DOWNTIME* — The UNSCHEDULED DOWNTIME state is used for unplanned downtime activities, such as maintenance, setups, conversions, change of consumables, factory-related problems, etc.

8.3.2.6.1 Any transition from PRODUCTIVE to UNSCHEDULED DOWNTIME, whether equipment or user initiated, counts as a SEMI E10 failure. In some cases, where the equipment has detected an alarm condition and has transitioned to UNSCHEDULED DOWNTIME, the equipment is able to recover and return to PRODUCTIVE.

8.3.2.7 *SCHEDULED DOWNTIME* — The SCHEDULED DOWNTIME state is used for planned downtime activities, such as preventive maintenance, setups, conversions, change of consumables, factory-related events, etc.

8.3.2.8 *NON-SCHEDULED TIME* — The NON-SCHEDULED TIME state is used to account for time outside of the normal factory production schedule. This includes time when the factory itself is not operating and time when the equipment is being used for purposes other than production, engineering, or maintenance. Examples of such time include unworked shifts, holidays, plant shutdowns, installation, and off-line (outside of normal factory operations) training of personnel.

8.3.3 *ARAMS Substates* — Each of the six basic ARAMS states have refinements defined in SEMI E10. These refinements are captured by the ARAMS Substate Codes in Section 9. The host requests an ARAMS state change by specifying an ARAMS Substate Code directly, while the operator selects a state and substate combination, through the human interface, that results in an ARAMS Substate Code. The equipment then determines the appropriate ARAMS state/substate based on this code.

8.3.4 *State Transitions* — The user may ask the equipment to go to any ARAMS state at any time by specifying a new ARAMS Substate Code (see Section 9) or by specifying a code of "0000" to request a change to the MANUFACTURING superstate.

NOTE 11: A user-initiated ARAMS state change is not intended to initiate a change in the equipment's operation. For example, if the operator puts the equipment in UNSCHEDULED DOWNTIME while the equipment is completing a process cycle of material, the equipment shall complete its normal cycle. If the operator intends to abort the process, then the process must be specifically aborted.

8.3.4.1 Table 1 defines the triggers for each transition shown in Figure 2.

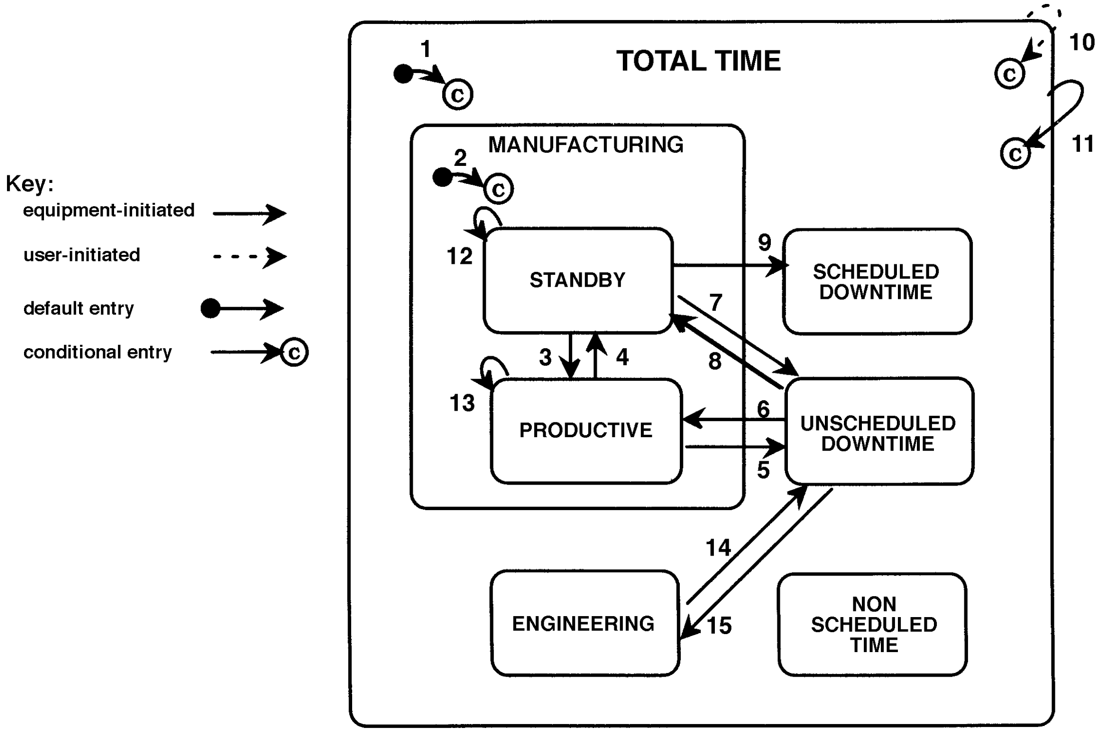

Figure 2
ARAMS State Model

Table 1 Transitions for ARAMS State Model

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
1	(Either undeterminable or any state except PRODUCTIVE or STANDBY)	Powerup/reset	Depends upon the state in which Transition 11 occurred (see Section 8.5.2).	None	Entry state is dependent upon previous state (see NOTE 1) where this can be determined. May not generate an event report.
2	(any state)	User selects a manufacturing state.	PRODUCTIVE or STANDBY, depending upon the status of the equipment.	Determine the new ARAMS state/substate.	Equipment determines if production criteria are satisfied. If not, it transitions to STANDBY. No event report is generated.
3	STANDBY	Equipment detects that all its production criteria are satisfied.	PRODUCTIVE	Set ARAMSState to value in PrdState (Section 11.2).	May begin or resume processing.
4	PRODUCTIVE	Equipment detects a standby condition.	STANDBY	Monitor all production criteria.	Equipment may detect a standby condition at any time.
5	PRODUCTIVE	Equipment detects an exception.	UNSCHEDULED DOWNTIME	Increment InterruptionPrd (Section 11.5).	Alarm or exception report generated by same trigger.

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
6	UNSCHEDULED DOWNTIME	All fault conditions have been cleared.	PRODUCTIVE	Resume processing	Transition 6 can only follow Transition 5. Automatic recovery without operator direction may be disabled by the user. (See NOTE 2.) May resume processing. Process should be recoverable without degradation.
7	STANDBY	Equipment detects fault condition.	UNSCHEDULED DOWNTIME	None	Alarm or exception report generated by same trigger.
8	UNSCHEDULED DOWNTIME	All fault conditions have been cleared.	STANDBY	Monitor all production criteria.	Transition 8 can only follow Transition 7 and may be disabled by the user. (See NOTE 3.)
9	STANDBY	A monitored parameter has reached a pre-defined limit.	SCHEDULED DOWNTIME	None	Preventive maintenance may require reset of the monitored parameter.
10	(Any ARAMS state/substate)	User selects a new ARAMS Substate Code.	(Based on state/substate selected by user)	Depends upon state/substate selected.	The user may select a new ARAMS state or substate at any time.
11	(Any of the six basic states)	Powerdown	UNSCHEDULED DOWNTIME, SCHEDULED DOWNTIME, or NON-SCHEDULED TIME.	None	On powerup, the equipment assumes this transition has occurred. This state transition does not represent a collection event.
12	STANDBY	Equipment detects a change in standby conditions.	STANDBY	None	Transitions 12 and 13 are optional and may be disabled by the user. (See NOTE 4.)
13	PRODUCTIVE	Equipment detects a change in productive conditions.	PRODUCTIVE	None	Transitions 12 and 13 are optional and may be disabled by the user. (See NOTE 4.)
14	ENGINEERING	Equipment detects a fault condition.	UNSCHEDULED DOWNTIME	None	Transitions 14 and 15 may be disabled by the user. (See NOTE 5.)
15	UNSCHEDULED DOWNTIME	All fault conditions have been cleared.	ENGINEERING	None	Transition 14 shall only follow Transition 15. (See NOTE 6.)

NOTE 1: See the variable ARAMSState in Section 11.2.4.

NOTE 2: See PrdRecovery variable in Section 11.4.5.

NOTE 3: See SbyRecovery variable in Section 11.4.6.

NOTE 4: See SubstateSelect variable in Section 11.4.7.

NOTE 5: See EngInterrupt variable in Section 11.4.1.

NOTE 6: EngRecovery variable in Section 11.4.2 required for automatic recovery.

8.4 *General Equipment Operations Model* — The equipment has various state models that it maintains in addition to the ARAMS State Model. The state model presented in this section (Figure 3) is provided as a high-level example of one such model to clarify the relationship between ARAMS and the equipment's operations. For purposes of ARAMS, it is referred to as the General Equipment Operations Model.

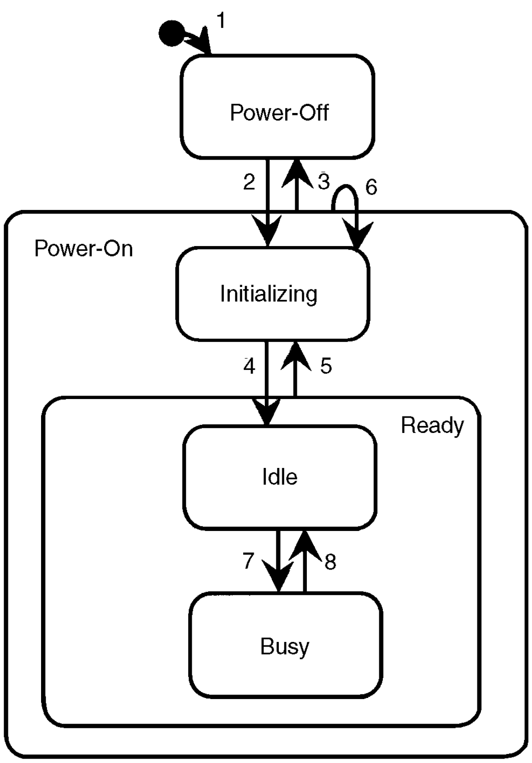

Figure 3
Example of General Equipment Operations Model

8.4.1 ARAMS assumes that a similar model, either formal or implicit, exists, although it may differ in detail depending upon the equipment type and the application. Formal implementation of the General Equipment Operations Model is not required for ARAMS compliance.

8.4.1.1 The states of the General Equipment Operations Model are not SEMI E10 states or substates.

NOTE 12: To minimize confusion between references to states and events, the events of losing power and recovering power are termed *powerdown* and *powerup* respectively.

8.4.2 *State Definitions* — The General Equipment Operations Model uses the following states:

8.4.2.1 *POWER-OFF* — The equipment has no power and is unable to function. While this state is only valid from a view external to the equipment, it is required to cover all periods of time to match the ARAMS model.

8.4.2.2 *POWER-ON* — The POWER-ON state includes all the functions of the equipment. It has two substates, INITIALIZING and READY.

8.4.2.3 *INITIALIZING* — When equipment is first powered on or recovers from a reset, it must initialize its hardware and software subsystems and components, including its different internal state models. This process takes time, which is represented by the INITIALIZING state.

8.4.2.4 *READY* — When all initializations are complete, the equipment enters the READY state and is able to interact with the user. The READY state has two substates, IDLE and BUSY.

8.4.2.5 *IDLE* — In the IDLE state, the equipment is inactive and able to accept a command for automatic processing or manual operations.

NOTE 13: IDLE is not the same as the SEMI E10 STANDBY state. (See Section 8.5.3.)

8.4.2.6 *BUSY* — In the BUSY state, the equipment is active. BUSY includes all operations of the equipment.

NOTE 14: BUSY is not the same as the SEMI E10 PRODUCTION state. (See Section 8.5.3.)

8.4.3 *General Equipment Operations Model Table of Transitions* — Table 2 defines the triggers for each transition shown in Figure 3. The second column, labeled Table 1, shows the corresponding transition in the ARAMS state model.

Table 2 Table of Transitions for General Equipment Operations Model

#	*Table 1*	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
1	None	(undefined)	Equipment is installed.	POWER-OFF	None	New equipment
2	None	POWER-OFF	Power is turned on (powerup).	INITIALIZING	Begin system initialization.	Initialization of hardware and software.
3	11	POWER-ON	Power is turned off (powerdown).	POWER-OFF	None	Equipment does not function.

#	*Table 1*	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
4	1	INITIALIZING	System initialization is complete.	IDLE	Begin normal internal activities. Wait for input.	Normal. Equipment is able to interact with the user.
5	11	READY(any substate)	Internal error, or soft re-boot by request.	INITIALIZING	Re-initialize system.	This is treated in the same way as Transition 2.
6	1	(any substate of) POWER-ON	System reset.	INITIALIZING	Re-initialize system.	A reset is done through hardware.
7	Conditional	IDLE	Equipment receives instructions to perform an automated or manual function.	BUSY (See NOTE 1.)	Perform the requested function.	Equipment may be capable of performing multiple functions while in BUSY.
8	Continued Conditional	BUSY (See NOTE 1.)	The equipment has completed all requested functions.	IDLE	Wait for new instructions.	Equipment may be capable of performing non-hardware-related functions in IDLE.

NOTE 1: The PROCESSING ACTIVE state of the Processing State Model example in SEMI E30 would be a substate of BUSY. Other substates may exist for maintenance and diagnostics.

8.5 *State Model Relationships* — Figure 4 shows the ARAMS State Model and the General Equipment Operations Model as both simultaneously active. Certain relationships exist between the two models.

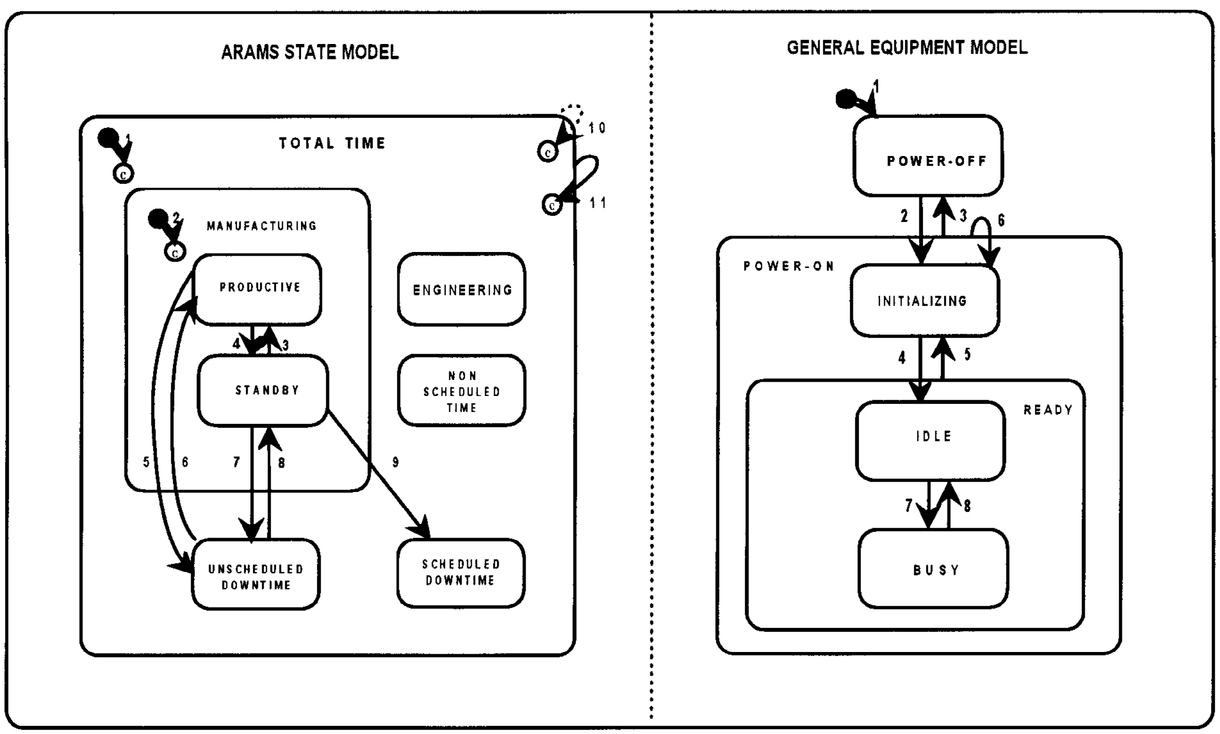

Figure 4
ARAMS State Model and General Equipment Operations Model

8.5.1 Both models cover all time, twenty-four hours each day. The ARAMS State Model describes how the equipment is used in the factory. The General Equipment Operations Model describes the equipment's activities, including the time when it has no power and is completely inactive.

8.5.1.1 The General Equipment Operations Model is provided to clarify two specific areas of relationship:

- The transitions related to powerup (#2), powerdown (#3), soft re-boot (#5), and reset (#6).
- The IDLE and BUSY activity states.

8.5.1.2 The term "reset" is used in this document to collectively represent both the soft re-boot and the hardware reset where no powerdown occurs.

8.5.1.3 Requirements related to powerup, powerdown, re-boot, and reset are specified in Section 16.

NOTE 15: Although the equipment is unable to detect a condition of no power, it is able to detect when the INITIALIZING state has been entered and is able to differentiate between a hard reset (Transition 6) and a soft re-boot (Transition 5).

8.5.2 *IDLE and BUSY* — By definition, the equipment is not in the IDLE state and in the PRODUCTIVE state at the same time, and it is not intended to be in the BUSY state while in STANDBY. The PRODUCTIVE and STANDBY states correspond to implicit substates of the BUSY and IDLE states only for the time the equipment is within the MANUFACTURING superstate — that is, it is scheduled for manufacturing (non-engineering factory operations) and is in a condition to perform its intended function.

8.5.2.1 Occasional exceptions may occur due to improper timing of a user request to change to a manufacturing state before the equipment completes a non-processing activity started in another state. For example, the equipment may be performing an automatic calibration during routine maintenance in a downtime state. In this case, the equipment determines that its production criteria are not satisfied and shall transition to STANDBY, as it is busy performing a function other than its intended function.

8.5.3 *Non-Manufacturing States* — The equipment may be in any of the POWER-OFF, INITIALIZING, IDLE, or BUSY states in the General Equipment Operations Model while in any of the non-manufacturing states: ENGINEERING, UNSCHEDULED DOWNTIME, SCHEDULED DOWNTIME, or NON-SCHEDULED TIME. For example, it may be powered off while being installed (NON-SCHEDULED TIME) or repaired (SCHEDULED or UNSCHEDULED DOWNTIME). It may be required to perform its normal processing cycle (its intended function) in ENGINEERING, NON-SCHEDULED TIME or in a downtime state.

9 ARAMS Substate Codes

9.1 This section defines the format for ARAMS Substate Codes and a set of reserved values for generic substates based on the descriptions in SEMI E10. The format is defined specifically to allow further resolution of the six basic SEMI E10 equipment states by both the factory and equipment supplier.

9.1.1 An ARAMS Substate Code consists of four ordered alphanumeric text characters, where the first two characters are reserved digits. The first character indicates the primary ARAMS state as follows:

1. PRODUCTIVE
2. STANDBY
3. ENGINEERING
4. SCHEDULED DOWNTIME
5. UNSCHEDULED DOWNTIME
6. NON-SCHEDULED TIME

9.1.2 The second character of the code, if non-zero, indicates a substate of the primary state. A zero in the second position indicates no substate has been selected. This may also be referred to as a substate of "default".

9.1.3 Codes of the form "n000" indicate no substates of a basic state have been selected. This is the "default code" for that basic state. For example, a code of "1000" indicates the PRODUCTIVE state with no substates.

9.1.4 Descriptive formatted text is defined to correspond to each ARAMS code. The first three characters of this text represent the basic state. If the next character is a forward slash "/", then subsequent text represents a substate of the basic state.

9.2 *Reserved Codes* — States and substates referenced by the reserved text in this section are based on SEMI E10 specifications. For further definition of terminology, see SEMI E10.

9.2.1 The following ARAMS Substate Codes, and the corresponding descriptive text strings for the English language (delimited by quotes), are reserved. Descriptive text with a substate of "Reserved" indicates the corresponding code is reserved for future expansion by this standard.

9.2.2 In the future, text strings in other languages may also be reserved. Equipment supporting other languages shall provide a method for the user to define alternative text strings. This provides the consistency, across different equipment, that is important to the user.

PRODUCTIVE

1000 “PRD” (default productive code)

1100 “PRD/Regular production”

1200 “PRD/Work for third parties”

1300 “PRD/Rework”

1400 “PRD/Engineering runs”

1500 “PRD/Reserved*”

1600 “PRD/Reserved”

1700 “PRD/Reserved”

1800 “PRD/Reserved”

1900 “PRD/Reserved”

STANDBY

2000 “SBY” (default standby code)

2100 “SBY/No operator”

2200 “SBY/No product”

2300 “SBY/No support tool”*

2400 “SBY/Associated cluster module down”

2500 “SBY/No host”

2600 “SBY/Reserved”

2700 “SBY/Reserved”

2800 “SBY/Reserved”

2900 “SBY/Reserved”

* NOTE: A support tool is a mechanical device used by, but not part of, the equipment. This includes cassettes, probe cards, etc.

ENGINEERING

3000 “ENG” (default engineering code)

3100 “ENG/Process experiments”

3200 “ENG/Equipment experiments”

3300 “ENG/Reserved”

3400 “ENG/Reserved”

3500 “ENG/Reserved”

3600 “ENG/Reserved”

3700 “ENG/Reserved”

3800 “ENG/Reserved”

3900 “ENG/Reserved”

SCHEDULED DOWNTIME

4000 “SDT” (default scheduled downtime code)

4100 “SDT/User maintenance delay”

4200 “SDT/Supplier maintenance delay”

4300 “SDT/Preventive maintenance”

4400 “SDT/Change of consumables”

4500 “SDT/Setup”

4600 “SDT/Production test”

4700 “SDT/Facilities-related”

4800 “SDT/Reserved”

4900 “SDT/Reserved”

UNSCHEDULED DOWNTIME

5000 “UDT” (default unscheduled downtime code)

5100 “UDT/User maintenance delay”

5200 “UDT/Supplier maintenance delay”

5300 “UDT/Repair”

5400 “UDT/Out-of-spec input material”

5500 “UDT/Change of consumables”

5600 “UDT/Facilities-related”

5700 “UDT/Reserved”

5800 “UDT/Reserved”

5900 “UDT/Reserved”

NON-SCHEDULED TIME

6000 “NST” (default non-scheduled downtime code)

6100 “NST/Unworked shifts”

6200 “NST/Equipment installation”

6300 “NST/Equipment modifications” (modify, rebuild, upgrade)

6400 “NST/Off-line training”

6500 “NST/Shutdown/startup”

6600 “NST/Reserved”

6700 “NST/Reserved”

6800 “NST/Reserved”

6900 “NST/Reserved”

9.3 *Additional Codes* — Additional codes may be defined by both the user and supplier, subject to the following constraints:

- The new code defines a refinement of a primary ARAMS state, as defined in Section 9, through use of the characters in the third and fourth positions.
- Alphabetic characters are permitted in the third and fourth positions. For purposes of sorting, these characters are assumed to be case-sensitive. All characters other than alphanumeric are prohibited.
- The third character is used to differentiate between codes defined by the user (factory) and those defined by the equipment supplier. If the third character is a digit, then the code is user defined. Otherwise, the code is supplier-defined. The user is free to assign values between "01" and "9z" as the third and fourth characters, while the supplier may assign values between "A0" and "zz".

* NOTE: Additional reserved codes may be added to Section 9.2 in the future.

9.3.1 Code definitions are exchanged as ARAMS Substate Tables, described in Section 10.3.

9.4 *Valid ARAMS Substate Code* — A valid ARAMS Substate Code is defined as any code with four alphanumeric characters where the first character is a digit between 1 and 6 and the second character is a digit between 0 and 9.

9.5 *Manufacturing Code* — A user request for the equipment to go to manufacturing specifies a special code of "0000". The code "0000" is not itself an ARAMS Substate Code and shall not be used as a code representing the current ARAMS state/substate in the variable ARAMSState.

10 ARAMS Tables

10.1 The information in this section is not required unless the equipment supports one or both of the two **ARAMS Tables** defined in Sections 10.3 and 10.4 respectively.

10.1.1 ARAMS defines two sets of data that are to be exchanged between equipment and host. These sets of data are transferred as "tables". A table is a vehicle for exchanging information and is independent of actual storage mechanisms.

10.1.2 This section introduces the concept and definitions of a generic table and defines the two specific types of tables required by ARAMS, the ARAMS Substate Table, and the ARAMS Symptom Table.

10.2 *Definition of Tables* — A table represents a general way of exchanging sets of data arranged in a tabular format. A table consists of one or more ordered sets of data, called rows, where the format and interpretation of each element of data within a row depends upon its relative position within the row, called column. Tables are transferred by providing:

- An ordered list of predefined text strings, called column headers, that identify the data element at the corresponding column position within each row,
- one or more rows of data, where each row is an ordered set of individual data elements, presented in the order specified by the column headers, and
- a set of information (attributes) about the table as a whole.

10.2.1 *Table Types and Identifiers* — Each instance of a table has a formally defined table type and a table identifier. This allows definition of general-purpose services for exchanging tables. It also allows multiple instances of a specific type of table to be referenced. OSS-compliant applications consider a table as a type of object, and a table type as a specialization of a table.

10.2.1.1 The table type definition includes specification of a reserved text string that begins with the string "Table". Table services (Section 15) and OSS services (SEMI E39) use the reserved text string as the ObjType attribute of the table object. The general table definition does not specify requirements for assigning identifiers to individual tables.

10.2.1.2 The table identifier is a text string that conforms to the requirements for an object identifier (ObjID) as specified in SEMI E39, which prohibits specific characters in ASCII. The identifier is used to identify a specific instance of a given table type and shall be unique for all tables of a given type.

10.2.1.3 A column in a table refers to all data elements at a given position across all rows of the table. Column headers are pre-defined text strings that identify the individual elements used and their relative order within each row.

10.2.2 *Table Row Definition* — A formal table type requires definition of the individual data elements within a row of the table and the specification of the column header. This information is provided in Table 3.

Table 3 Definition for Table Row Format

Column Header	*Data Element Definition*	*Form*
Text string for column position.	Definition of data element at the corresponding column position.	Valid form for data element.

10.2.2.1 The order of elements within a row shall be invariant for a given table instance and shall strictly conform to the order in which column headers are presented. The length of any given row (the number of elements within the row) may not exceed the number of defined positions (columns). Partial rows that omit elements at the end of the row are permitted by the general definition, so long as they retain the meaning of the column positions included. That is, if a complete row consists of n columns, then an individual row may consist of the first m elements, for $m \leq n$.

10.2.2.2 The first element (first column position) of a row must contain a value that is unique for all rows within a specific table instance. This value may be used as a key to identify a specific row within the table and therefore shall be a single item (e.g., not a list or structure) and may not be a floating point number. Other elements within the row may be simple lists or simple structures that do not themselves contain embedded (nested) lists or structures.

10.2.3 *Table Attributes* — It is also important to be able to exchange information about the table itself. In addition to the definition of data elements and columns, tables also have predefined attributes. The general table definition specifies three attributes: the number of columns, the number of rows, and the size of the table exclusive of formatting used for storing or transferring the table. (See Section 13.2.)

10.2.4 *Additional Requirements* — Specific table types may have additional requirements and restrictions.

10.2.4.1 ARAMS tables, defined in Sections 10.3 and 10.4, have additional requirements as follows:

- Tables shall be stored in non-volatile memory and shall be capable of subsequent modifications.
- Elements within a row shall follow the order specified in the table definitions.
- All rows shall consist of the full number of columns specified. Partial rows are prohibited.

10.2.4.2 A table is considered structurally valid if it conforms to the requirements in this section and to the row format defined for its specific type. A structurally valid table may or may not have correct content — that is, the values within any given row may or may not meet other requirements or expectations.

10.2.4.3 ARAMS tables are provided only for use by the operator and the associated data sent to the host. Equipment shall not reject a user-defined table that is structurally valid for its table type because of its contents. Equipment shall not use the contents of tables to validate ARAMS Substate Codes or symptom information provided by the host.

10.2.4.4 Certain errors in the contents may cause the tables to not work properly in some way. For example, if a row identifier is used more than once, then the equipment may fail to find any but the first occurrence. However, the user shall accept responsibilities for any errors in the contents of ARAMS tables.

10.3 *ARAMS Substate Table* — The ARAMS Substate Table provides extensions to the generic substate definitions contained in Section 9.

10.3.1 Each row in an ARAMS Substate Table consists of a four-character ARAMS Substate Code as the first element of the row, and a corresponding text string containing a brief description of the state as the second element. Table 4 defines the ARAMS Substate Table row format.

Table 4 ARAMS Substate Table Row Definition

Column Header	*Data Element Definition*	*Form*
"Code"	ARAMS Substate Code.	Four-character text string.
"Text"	Brief description of ARAMS Substate Code.	Formatted text, Sections 9.1, 9.2.

10.3.2 The descriptive text is displayed as a prompt or selection item for the operator when selecting a new ARAMS state. The description selected is placed in the variable ARAMSText and the corresponding ARAMS Substate Code is placed in the variable ARAMSState as the new ARAMS state (see Section 11.2).

10.3.3 Extensions to ARAMS codes may be defined by either the user or supplier according to the rules in Section 9.3. The ARAMS Substate Table provides a formal method for each to obtain the codes and text defined by the other. The table's identifier provides a method for differentiating between the three sets of information (generic definitions, user-defined definitions, and supplier-defined definitions) when necessary to remove ambiguity in communications. The user at all times shall be able to select an ARAMS state or substate based on the combination of the three sources of definitions.

10.3.4 An ARAMS Substate Table has a table type of "TableARAMSCode". The row format is defined in Table 4.

10.4 *ARAMS Symptom Table* — The user may define an optional table of common human-observable symptoms called the ARAMS Symptom Table, with a table type of "TableARAMSSymptom". The row of this table is defined in Table 5 below.

Table 5 ARAMS Symptom Table Row Definition

Column Header	*Data Element Definition*	*Form*
"ID"	Identifier of ARAMS symptom.	Unsigned integer.
"Indicator"	First one to four characters of ARAMS code to which symptom may be applied.	Formatted text. 1 to 4 characters. (See Sections 9.2–9.3.)
"Text"	Brief description of ARAMS symptom.	Text. Maximum length is 80 characters.

10.4.1 Each table row consists of three items: a symptom identifier, an ARAMS substate indicator, and a text string describing the symptom.

10.4.2 The symptom identifier and text are analogous to the equipment's alarm or exception identifier and corresponding text description. The identifier and text should each be unique. A symptom identifier with a value of zero is reserved to indicate "no symptom".

10.4.3 The substate indicator consists of the first one to four characters of an ARAMS Substate Code and indicates the ARAMS state or state/substate where the symptom is to be applied. For example, a symptom that is to be applied whenever the user requests a change to the UNSCHEDULED DOWNTIME state, including any of its substates, is assigned an indicator of "5". A symptom that is to be applied in any case of "UDT/change of consumable" would use an indicator of "55" as the first two digits of the corresponding ARAMS code.

10.4.4 Whenever the operator requests a change in the ARAMS state or substate, the operator shall be presented with the text descriptions from the appropriate Symptom Table. The text description of the selection is placed in the status variable SymptomText, and the corresponding identifier is placed in SymptomID.

11 ARAMS Data

11.1 This section defines the data requirements for ARAMS. This includes requirements for retaining data across a powerdown or reset. Data retention requirements are classified for each item of ARAMS data in one of the following ways:

Class 1 — A "soft" value that is reset to a default value as part of system initialization (e.g., DowntimeAlarm)

Class 2 — A "hard" value that never changes (e.g., "EqpSerialNum")

Class 3 — A "firm" value that changes infrequently and is to be retained in non-volatile memory (e.g., "EqpName")

Class 4 — A "dynamic" value that is retained in non-volatile memory and changes whenever an ARAMS state transition occurs.

Class 5 — A "very dynamic" value that may change rapidly and is important to retain but does not require absolute accuracy (e.g., CycleCtr for high throughput equipment). Current values shall be saved in non-volatile memory periodically at least once per minute.

11.1.1 Except where otherwise specified, data is assumed to be Class 1.

11.1.2 Variables within each section are presented in alphabetical order.

11.2 *Status Information* — Status data is information that is maintained by equipment and in general cannot be changed by the host. This section defines specific elements of status data that the user is able to read upon request and that may be included in event report messages to the host.

11.2.1 A mechanism shall be provided for the user to read these values.

11.2.2 All date/time values are text strings with a timestamp format (see Section 4).

NOTE 16: The timestamp format is not a requirement for clock precision.

NOTE 17: Subsequent references to subsections of 11.2 below are using the original numbers.

11.2.3 *ARAMSInfo* — Additional information set or cleared by the equipment at the time an ARAMS state transition occurs. Optional. Form: text. 0–80 characters.

11.2.4 *ARAMSState* — The ARAMS Substate Code corresponding to the ARAMS state/substate that became active following the most recent ARAMS state transition. When an ARAMS state transition occurs, ARAMSState is the specific code representing the new ARAMS state/substate. It shall be retained as Class 4 data. The value of "0000" is prohibited. Form: formatted alphanumeric text. 4 characters.

11.2.5 *ARAMSText* — The descriptive text corresponding to the code in ARAMSState. Form: text. 5–80 characters.

11.2.6 *Clock* — Contains the current value of the date and time at the equipment. When included in an event report, Clock represents the timestamp for the occurrence of the event. Clock may represent the current value of a real-time date/time clock available upon demand. Form: formatted text.

11.2.7 *CycleCtr* — The number of cycles (equipment cycles) during the lifetime of the equipment (not resettable). It shall be retained as Class 5 data. Form: unsigned integer.

NOTE 18: See SEMI E10 for a formal definition of cycle.

11.2.8 *DowntimeAlarm* — Identifier of the most recent alarm or exception triggering an equipment-initiated transition to SCHEDULED DOWNTIME or UNSCHEDULED DOWNTIME from the PRODUCTIVE or STANDBY states. This value is reset to zero for all other ARAMS state transitions to indicate "no associated alarm/exception". Form: unsigned integer.

11.2.9 *DowntimeAlarmText* — Text associated with DowntimeAlarm. This value is cleared (set to a zero-length string) for all ARAMS state transitions except the transition to SCHEDULED DOWNTIME or UNSCHEDULED DOWNTIME from the PRODUCTIVE or STANDBY states. Form: text. 0–80 characters.

11.2.10 *DowntimeData* — Text associated with transitions to, or within, the SCHEDULED or UNSCHEDULED DOWNTIME states. For transitions following powerup/reset (see Section 8.5.2), the value in DowntimeData shall be set to "Power Loss". This value is reset to a zero length (empty) string for other ARAMS state transitions. When associated with equipment initiated transitions, this may be used to carry fault information (e.g., the component serial number of a repaired component, as defined by the equipment supplied). When associated with operator-initiated transitions, it may consist of comments entered at the equipment's control panel. Form: text. 0–256 characters.

11.2.11 *LastPowerdown* — Contains a date/time timestamp that estimates the time when the last loss of power or reset occurred (Transition 11), based on the value in PowerdownTime on powerup. It shall be retained as Class 3 data. Form: formatted text.

11.2.12 *PowerdownTime* — Contains a date/time timestamp used as an estimate for the timestamp for loss of power or reset and used for reports associated with ARAMS state Transition 11. It shall be retained as Class 5 data. Form: formatted text.

11.2.13 *PrdState* — The ARAMS code corresponding to the last user-specified ARAMS Substate Code for PRODUCTIVE. Used as the default substate for PRODUCTIVE. Initialized to "1000" at Transition 1. Form: formatted alphanumeric text. 4 characters.

11.2.14 *PrevARAMSState* — The ARAMS code corresponding to the ARAMS state/substate that was active immediately preceding the most recent ARAMS state transition. This value is useful for resynchronization after a period of inability to communicate. It shall be retained as Class 4 data. Form: formatted alphanumeric text. 4 characters.

11.2.15 *SymptomID* — A numeric identifier of a symptom selected by the user when requesting the equipment to change states. A value of zero is equivalent to a selection of "no symptom". Form: unsigned integer.

11.2.16 *SymptomText* — The descriptive text for the symptom selected by the user when requesting the equipment to change states. A zero-length string corresponds to a selection of "no symptom". Form: text. 0–80 characters.

11.3 *Constant Data* — Equipment shall provide and maintain the following values as class 2 data. These values are set by the equipment manufacturer and shall not be changeable by the user. These data elements are required for equipment with formally defined components that are also ARAMS compliant, such as clustertools. This data is used for event reports, to identify the original source of the event.

11.3.1 *EqpModel* — A text string containing the equipment model. Form: 1–80 characters.

11.3.2 *EqpSerialNum* — A text string containing the product serial number assigned by the supplier. Form: 1–80 characters.

11.4 *User-Configurable Data* — The data elements in this section shall be settable by both the operator and the host. They shall be retained as Class 3 data.

11.4.1 *EngInterrupt (optional)* — A Boolean value that enables (TRUE) or disables (FALSE) equipment-initiated transitions from ENGINEERING to UNSCHEDULED DOWNTIME (Transition 14 in Figure 2) when a fault condition is detected. This variable is required if EngRecovery is supported. Form: Boolean.

11.4.2 *EngRecovery (optional)* — A Boolean value that enables (TRUE) or disables (FALSE) automatic recovery returning to ENGINEERING from UNSCHEDULED DOWNTIME (Transition 15 in Figure 2) following an equipment-detected fault that has spontaneously cleared. Form: Boolean.

11.4.3 *EqpName (required)* — A text string representing the user-assigned logical name of the equipment. Form: 1–80 characters.

NOTE 19: For OSS-compliant equipment, this corresponds to the ObjID attribute of the object "Agent", "PM", "CM", or "TM" in other standards.

11.4.4 *PowerupState (optional)* — A text character indicating the powerup (default entry) state when a powerdown occurs during manufacturing time. May be either "2" for STANDBY or "5" for UNSCHEDULED DOWNTIME.

11.4.5 *PrdRecovery (optional)* — A boolean value that enables (TRUE) or disables (FALSE) the equipment-initiated return to PRODUCTIVE (Transition 6 in Figure 2) following an equipment-detected fault that has cleared without operator intervention. Form: boolean.

11.4.6 *SbyRecovery (optional)* — A boolean value that enables (TRUE) or disables (FALSE) the equipment-initiated return to STANDBY (Transition 8 in Figure 2) following an equipment-detected fault that has cleared. Form: boolean.

11.4.7 *SubstateSelect (optional)* — A Boolean value that enables (TRUE) or disables (FALSE) equipment-initiated selection of substates of STANDBY and PRODUCTIVE (including Transitions 12 and 13). Form: Boolean.

11.5 *Accumulators* — This section defines a set of optional accumulators that either count time in one of the six basic SEMI E10 states or count interruptions occurring in the PRODUCTIVE state. It shall be possible for both the operator and host to (1) adjust the values in the individual accumulators, and (2) reset all seven values to zero simultaneously. Operator and host assume responsibility for the edited values and their accuracy. Equipment shall not impose restrictions on the modified values.

11.5.1 In addition, two timestamps are required for support of the accumulators. These timestamps shall not be changed by the user.

11.5.1.1 Where accumulators are supported, the variables defined in this section shall be supported as a set as Class 4 data.

11.5.1.2 The time accumulators are reported in minutes with an accuracy of ± one minute. Internal representations of the accumulators in smaller units may be required for short processes.

11.5.2 *ARAMSAccumReset* — The timestamp of when the following seven accumulators were last reset to zero. Form: formatted numeric text.

11.5.3 *ARAMSTimestamp* — The timestamp of the most recent ARAMS state change to the state identified in ARAMSState. This value is updated whenever a transition to a new ARAMS state occurs and is used in conjunction with PowerdownTime to update the accumulators following a powerup or reset. Form: formatted numeric text.

11.5.4 *EngTime* — Time in ENGINEERING.

11.5.5 *InterruptionPrd* — The number of transitions to UNSCHEDULED DOWNTIME from PRODUCTIVE.

NOTE 20: This includes the equipment-initiated Transition 5, a user-initiated transition covered by Transition 10, and the powerdown Transition 11, when occurring from PRODUCTIVE.

11.5.6 *InterruptionTotal* — The total number of transitions to UNSCHEDULED DOWNTIME from any state. This includes equipment-initiated transitions and user-initiated transitions.

11.5.7 *NSTime* — Time in NON-SCHEDULED TIME.

11.5.8 *PrdTime* — Time in PRODUCTIVE.

11.5.9 *SbyTime* — Time in STANDBY.

11.5.10 *SDTime* — Time in SCHEDULED DOWNTIME.

11.5.11 *UDTime* — Time in UNSCHEDULED DOWNTIME.

12 Events and Pre-Defined Event Reports

12.1 Each transition in the ARAMS State Model, with the exception of Transitions 2 and 11, represents a unique collection event that shall be reportable to the host. A generic collection event ARAMS State Change shall be provided that corresponds to any ARAMS state change. This allows greater efficiency for common data to be placed in a single report.

12.2 The equipment shall support one of the two following requirements:

- The capability of allowing the host to define reports associated with each ARAMS state change event, or
- A set of pre-defined (default) event reports for the ARAMS State Change Event, equipment-initiated transitions to UNSCHEDULED DOWNTIME (Transitions 5 and 7, and Transition 1 as appropriate), and user-initiated transitions to UNSCHEDULED DOWNTIME.

12.3 The pre-defined reports, defined below, are labeled “A”, “B”, and “C”, for ease of reference only. Report “A” represents the information required for every ARAMS State Change Event. Implementations of these reports shall provide, at a minimum, the updated values of the indicated variables.

Report “A”

ARAMS State Change Event

EqpModel

EqpSerialNum

EqpName

Clock

ARAMSState

PrevARAMSState

Report “B”

Equipment-Initiated Transitions to UNSCHEDULED DOWNTIME Event

DowntimeAlarm

DowntimeAlarmText

DowntimeData

Report “C”

User-Initiated Transition

SymptomID

SymptomText

DowntimeData

13 Object Services Compliance

This section provides information required for equipment that is OSS-compliant. OSS compliance is not required for ARAMS compliance.

13.1 *Equipment Object* — ARAMS-compliant equipment (equipment subsystems) that are compliant to OSS (SEMI E39) and that provide an object representing the equipment (equipment subsystems) shall include as attributes of that object the attributes listed in Table 6.

13.1.1 The data element Clock may be represented by a Clock object. In this case, Clock is not an attribute of the Equipment object but is a component of the Equipment object and is accessible through OSS services.

13.1.2 Table 6 defines the variables specified in earlier sections as object attributes conformant with the requirements of OSS. The column labeled “Access” indicates whether the attribute is read-only (RO) or read-write (RW), and the column labeled “Reqd” indicates if the attribute is required for ARAMS compliance.

Table 6 ARAMS Object Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ARAMSAccumReset	Timestamp for when time-in-state accumulators were last reset to zero. Required if accumulators are supported.	RO	N	Formatted numeric text: timestamp format.
ARAMSInfo	Additional information set by the equipment at the time of an ARAMS state transition.	RO	N	Text. 0–80 characters.
ARAMSState	Code corresponding to currently selected ARAMS state/substate.	RO	Y	Formatted alphanumeric text. 4 characters.
ARAMSText	Descriptive text corresponding to code in ARAMSState.	RO	Y	Text. 5–80 characters.

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ARAMSTimestamp	Timestamp of last ARAMS state change.	RO	N	Formatted numeric text: timestamp format.
Clock (See NOTE 1.)	Current time and date.	RW	Y	Formatted numeric text: timestamp format.
CycleCtr	Non-resettable counter of equipment run cycles.	RO	Y	Unsigned integer.
DowntimeAlarm	Identifier of last alarm or exception triggering an equipment-initiated transition to a downtime state and/or substate.	RO	Y	Text. Conforms to ObjID.
DowntimeAlarmText	Text associated with DowntimeAlarm.	RO	Y	Text. 0–80 characters.
DowntimeData	Equipment-defined text associated with transitions to downtime state and/or substate.	RO	Y	Text. 0–256 characters.
EngInterrupt	Enables (TRUE) or disables (FALSE) an equipment-initiated transition from ENGINEERING to UNSCHEDULED DOWNTIME. Required in EngRecovery is supported.	RW	N	Boolean.
EngRecovery	Enables (TRUE) or disables (FALSE) automatic recovery from UNSCHEDULED DOWNTIME to ENGINEERING.	RW	N	Boolean.
EngTime	Accumulated minutes in the ENGINEERING state/substate. Required if accumulators are supported.	RW	N	Unsigned integer.
EqpModel	The equipment model.	RO	Y	Text. 1–80 characters.
EqpSerialNum	Equipment serial number.	RO	Y	Text. 1–80 characters.
InterruptionPrd	Counts number of transitions from PRODUCTIVE to UNSCHEDULED DOWNTIME. Required if accumulators are supported.	RW	N	Unsigned integer.
InterruptionTotal	Counts total number of transitions to UNSCHEDULED DOWNTIME. Required if accumulators are supported.	RW	N	Unsigned integer.
LastPowerdown	Estimate of last powerdown time.	RO	Y	Formatted numeric text: timestamp format.
NSTime	Accumulated minutes in NON-SCHEDULED TIME state/substate. Required if accumulators are supported.	RW	N	Unsigned integer.
PowerdownTime	Estimate of powerdown time.	RO	Y	Formatted numeric text: timestamp format.
PowerupState	Indicates the powerdown state when powerdown occurs during manufacturing time.	RW	N	Text digit: “2” = standby, “5” =unscheduled downtime.
PrdRecovery	Enables (TRUE) or disables (FALSE) the equipment-initiated return to PRODUCTIVE from UNSCHEDULED DOWNTIME. Required for support of automatic equipment-initiated recovery.	RW	N	Boolean.
PrdState	The last ARAMS code specified by the user for PRODUCTIVE.	RO	Y	Formatted alphanumeric text. 4 characters.
PrdTime	Accumulated minutes in PRODUCTIVE state/substate. Required if accumulators are supported.	RW	N	Unsigned integer.
PrevARAMSState	ARAMS Substate Code corresponding to state prior to last state transition.	RO	Y	Formatted alphanumeric text. 4 characters.
SDTime	Accumulated minutes in SCHEDULED DOWNTIME state/substate. Required if accumulators are supported.	RW	N	Unsigned integer.
SbyRecovery	Enables or disables the equipment-initiated return to STANDBY from UNSCHEDULED DOWNTIME. Required for support of automatic equipment-initiated recovery.	RW	N	Boolean.
SbyTime	Accumulated minutes in STANDBY state/substate. Required if accumulators are supported.	RW	N	Unsigned integer.

Attribute Name	Definition	Access	Reqd	Form
SubstateSelect	Enables (TRUE) or disables (FALSE) equipment-initiated selection of substates in PRODUCTIVE and STANDBY.	RW	N	Boolean.
SymptomID	The identifier of a symptom selected by the user when requesting a state change.	RO	Y	Text. Conforms to ObjID.
SymptomText	The descriptive text of the symptom selected by the user when requesting a state change.	RO	Y	Text. 0–80 characters.
UDTime	Accumulated minutes in UNSCHEDULED DOWNTIME state/substate. Required if accumulators are supported.	RW	N	Unsigned integer.

NOTE 1: The Clock attribute may be replaced by a Clock object having a DateTime attribute, as defined in SEMI E38.

13.2 *Table Objects* — Table 7 defines the attributes of a generic table. This is an abstract type of object that is not itself directly implemented. Specific table types, which require definitions of their row formats (Section 10.2), are subtypes of the generic table supertype and inherit all of the attributes of the supertype (see SEMI E39, Appendix).

Table 7 Table Object Attribute Definition

Attribute Name	Definition	Access	Reqd	Form
ObjType	The object type.	RO	Y	Text = “Table”.
ObjID	The object’s identifier.	RO	Y	Text. 1–80 characters.
NumCols	Number of columns.	RO	Y	Unsigned integer.
NumRows	Number of rows.	RO	Y	Unsigned integer.
DataLength	Total number of bytes required to store the table elements, exclusive of any formatting required for storage or transfer.	RO	Y	Unsigned integer.

13.3 Different applications may define additional table attributes for specific table types. The subtypes defined by ARAMS (Sections 10.3 and 10.4) are “TableARAMSCode” and “TableARAMSSymptom” and have no additional attributes.

14 Human Interface Requirements

This section provides a central location for requirements affecting the human interface. It specifies the functions that shall be available to the operator through the equipment’s console (human interface), where the equipment provides such an interface. Applications that do not otherwise provide such an interface (e.g., cluster modules) are exempted from these requirements.

14.1 *Data Access* — All supported data elements defined in Section 11 shall be accessible to the operator. Specifically, the operator shall be able to view all ARAMS data provided by the equipment and shall be able to modify the values of all data defined in Section 11.4.

14.1.1 Where the accumulators defined in Section 11.5 are supported, the operator shall be able to change their individual values, with the exception of ARAMSAccumReset, and to reset the entire set together.

14.2 *Selection of an ARAMS State/Substate* — The operator shall be able to select any of the standard ARAMS states and substates defined in Section 9.2, exclusive of those definitions with a “Reserved” substate that are reserved for future standards. The operator shall also be able to select MANUFACTURING.

14.2.1 Where ARAMS Substate Tables are provided with user-defined or supplier-defined extensions, these extensions shall also be available to the operator for selecting a change in the current ARAMS state and /or substate.

14.2.2 When selecting a SCHEDULED DOWNTIME or UNSCHEDULED DOWNTIME state/substate, the operator shall be able to enter a comment to be stored in DowntimeData (Section 11.2.10).

14.3 *User-Defined ARAMS Symptom Tables* — Where ARAMS Symptom Tables are supported, the descriptive text for symptoms provided within existing ARAMS Symptom Tables shall be presented to the operator for selection, according to the specifications in Section 10.4, at the time the operator selects an ARAMS State (Section 14.3). The operator is not required to select a symptom. If the operator selects a symptom, the symptom identifier is stored in the variable SymptomID and the descriptive text is stored in SymptomText.

14.4 *Table Access* — Where the equipment supports one or both types of tables specified by ARAMS (Sections 10.3 and 10.4), the operator shall have full access to entries within those tables that are user-defined. The operator shall be able to enter (define), modify, and delete user-defined entries within ARAMS table. The operator shall not be able to change or delete the generic ARAMS Substate Codes defined in Section 9 or supplier extensions to those generic codes.

14.4.1 The operator shall be able to read the contents of all existing ARAMS tables.

14.5 *Color Codes* — The use of color associated with the display of ARAMS state information is optional. To ensure consistency for the user, the following color schemes shall be applied for all cases where color is associated with an ARAMS state.

Uptime states

PRODUCTIVE: green

STANDBY: yellow

ENGINEERING: blue

Downtime states

SCHEDULED DOWNTIME: light red

UNSCHEDULED DOWNTIME: red

Other

NON-SCHEDULED TIME: grey

14.5.1 This scheme provides a visual grouping.

NOTE 21: The colors used for the two downtime states should be both clearly related and readily distinguishable, such as pink and bright red.

15 Services

15.1 This section formally defines the message services specifically required to support ARAMS functionality.

15.1.1 Formal definition has three parts:

- A list of the services defined (Table 8),
- a common parameter dictionary defining all of the parameters of these services (Table 9), and
- a dictionary of the individual services that defines the parameters used by each service.

15.1.2 Services that are used by ARAMS, but are not specific to ARAMS, are defined by other standards and are referenced in Section 3.

15.1.3 Both the equipment and the host provide the services TableSend and TableRequest, and both may use the services provided by the other. The service ARAMSStateChange is provided by equipment only.

15.1.4 Table 8 lists the ARAMS services. There are two types of services:

- An initial message and response between the service user and the service provider.
- A notification message from the service provider to the service user that does not require a response.

15.1.5 The column in Table 8 that is called “Type” is used to indicate whether the service consists of a request/response message pair (R) or a single notification message (N).

Table 8 ARAMS Services

Message Service Name	*Type*	*Description*
TableSend	R	Used by the service user to send or delete a table.
TableRequest	R	A request to receive a table.
ResetAccumulators	R	A request to reset the set of accumulators.
ARAMSStateChange	R	Request to go to a specified ARAMS state/substate.

15.1.6 Figure 5 shows the message flow for each of the above ARAMS services.

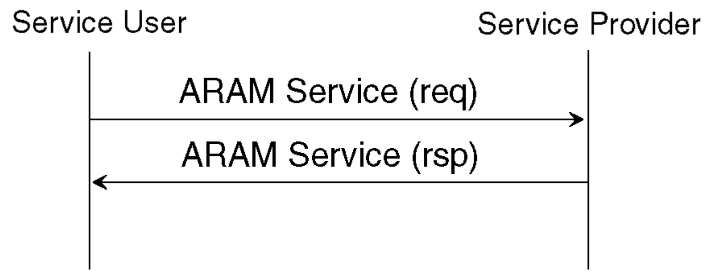

Figure 5
ARAM Service Message Flow

15.2 *Services Parameter Dictionary* — Table 9 defines all of the parameters, including the elements of complex parameters, used in ARAMS message services. Parameters are listed in alphabetical order.

15.2.1 The "Form" column in Table 9 indicates the data type for the parameter. A list of the standard data types for "Form" is included in Section 4.3.

Table 9 ARAMS Services Parameter Dictionary

Parameter	*Definition*	*Form*
ARAMSCode	ARAMS state/substate code.	Alphanumeric text with fixed length of four characters.
AttrData	The value of an attribute.	Varies with attribute.
AttrName	The attribute's name.	Text. Varies with object type.
ColHdr	Column header.	Text. 1–20 characters.
ErrorCode	Contains the code for the specific error found.	Enumerated.
ErrorText	Text in support of the error code to provide additional information.	Text.
ObjSpec	The object specifier, used to specify the owner of the target object.	Formatted text.
RequestStatus	The result of the request to change to a new ARAMS state/substate.	Enumerated: 0 = Acknowledge, action has been effected. 2 = Cannot perform now. 3 = Invalid parameter 4 = Acknowledge, action will be performed with completion signaled later by an event. 6 = Object unknown.
Status	Error information.	Structure consisting of ErrorCode and ErrorText.
SymptomID	The numeric symptom identifier.	Unsigned integer.
SymptomText	Descriptive text for symptom.	Text. 0–80 characters.
TableAck	Indicates the success (=T) or failure (=F) of the operation.	Boolean.
TableAttr	A table attribute other than object (table) type or object (table) identifier. (See NOTE 1.)	Structure consisting of AttrName and AttrData.
TableCmd	Instructions concerning the table transfer.	Enumerated: Entire table Add new rows Append new columns Replace existing rows Replace existing columns
TableElem	One of the basic elements of a table.	Varies with table type and (column) position within the row.

Parameter	Definition	Form
TableID	Table identifier.	Text. 1–80 characters.
TableRow	A row of the table in terms of its elements TableElem.	Structure, consisting of different table elements, following the order of the column headers.
TableStatus	Information concerning the success or failure of the operation.	Structure consisting of TableAck and (List of) Status.
TableType	Type of table.	Text = "TableARAMSCode" or "TableARAMSSymptom".

NOTE 1: ARAMS tables use only the general table attributes: number of rows, number of columns, and table length.

15.3 *TableSend* — The TableSend service is used to transfer or delete a table.

15.3.1 Table 10 defines the parameters for the TableSend service. A table that is not structurally valid shall be rejected and discarded.

Table 10 TableSend Service

Parameter	Req/Ind	Rsp/Conf	Description
ObjSpec	C	-	The object specifier, used to specify the owner of the target object. When omitted, the receiver of the message is intended.
TableType	M	M	Signifies the type of table to be sent.
TableID	C	C(=)	Table identifier. Required for table type TableARAMSSymptom.
TableCmd	M	-	Instructions about the table being transferred.
TableAttr (list of)	M	-	The table's attributes.
ColHdr (list of)	M	-	Table column headers.
TableRow (list of)	C	-	Table contents, organized by rows. Rows may or may not be ordered, depending on the definition for a specific table type. Must be omitted when deleting a table.
TableStatus	-	M	Information concerning the success or failure of the request.

15.4 *TableRequest* — The TableRequest service is used to request the service provider to send a table. A table that is not structurally valid shall be discarded.

15.4.1 Table 11 defines the parameters for the TableRequest service.

Table 11 TableRequest Service

Parameter	Req/Ind	Rsp/Conf	Description
ObjSpec	C	-	The object specifier, used to specify the owner of the target object. When omitted, the receiver of the message is intended.
TableType	M	M	Signifies the type of table to be sent.
TableID	C	C(=)	Table identifier. Required for table type TableARAMSSymptom.
TableCmd	M	-	Instructions about the table being transferred.
TableElem (list of)	C	-	Row identifiers of requested rows. If omitted, entire table is requested.
TableAttr (list of)	-	M	Table attributes.
ColHdr (list of)	-	M	Table column headers. Omitted only if table for specified type and identifier does not exist.
TableRow (list of)	-	M	Table rows. Omitted only if table for specified type and identifier does not exist.
TableStatus	-	M	Information concerning the success or failure of the request.

15.5 *ARAMSStateChange* — The ARAMSStateChange service is sent to the service provider to request a change to a new ARAMS state/substate.

15.5.1 Table 12 defines the parameters for the ARAMSStateChange service.

Table 12 ARAMSStateChange Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier, used to specify the owner of the target object. When omitted, the receiver of the message is intended.
ARAMSCode	M	-	New ARAMS state/substate requested.
SymptomID	C	-	ARAMS Symptom ID. Optional.
SymptomText	C	-	Symptom description. Optional.
RequestStatus	-	M	Information concerning the success or failure of the request.

15.6 *ResetAccumulators* — The ResetAccumulators service is sent to the service provider to request that the set of accumulators defined in Section 11.5 be reset.

15.6.1 Table 13 defines the parameters for the ResetAccumulators service.

Table 13 ResetAccumulators Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier, used to specify the owner of the target object. When omitted, the receiver of the message is intended.
RequestStatus	-	M	Information concerning the success or failure of the request.

16 ARAMS Behavioral Requirements

This section specifies the behavior required for ARAMS compliance.

16.1 *ARAMS State Transitions* — ARAMS compliance requires that the equipment be capable of Transitions 1 through 11 in Table 1, with the exception of Transition 9. Transitions 12 and higher are optional.

16.1.1 Transition 9 is required only of equipment that puts itself in a preventive maintenance mode based on one or more internally monitored parameters, such as a cycle counter. Transition 9 specifies that such a transition takes place from STANDBY to SCHEDULED DOWNTIME only. For equipment without this feature, Transition 9 never occurs.

16.1.2 The equipment is required to provide the capability to report to the host each time a state transition occurs and to include data related to that transition in these reports. Transition data included in these reports allows the factory to calculate the amounts of time spent in the different states.

16.1.3 At all transitions except Transition 10, when a manufacturing state is specified, and Transition 11, the current value of ARAMSState is stored in PrevARAMSState and the ARAMS Substate Code specified is then stored in ARAMSState. A user selection of a specific manufacturing state is discussed in Section 16.5 below.

16.1.4 For all equipment-initiated transitions, except as specified in Sections 16.5 and 16.6, the equipment shall use an ARAMS Substate Code representing the default for that state and shall not select a substate.

16.1.5 DowntimeAlarm and DowntimeAlarmText are set only for equipment-initiated transitions to SCHEDULED DOWNTIME and UNSCHEDULED DOWNTIME. For all other transitions, these variables are cleared.

16.1.6 If the equipment supports ARAMS accumulators (Section 11.5), then the time spent in the previous state is calculated and the appropriate accumulator is updated at this time.

16.2 *Powerup Entry* — The ARAMS State Model becomes active during or after initialization following a powerup or reset when Transition 1 occurs. The state entered at Transition 1 (the default entry state) depends upon the ARAMS state that was last active before the powerdown or reset occurred. This is determined by the ARAMS Substate Code stored in ARAMSState (Section 11.2.4). If this value is not a valid ARAMS Substate Code as defined in Section 9.4, then the default entry state is NON-SCHEDULED TIME.

16.2.1 At Transition 1, if the value in Powerdown-Time does not represent a valid date and time, it shall be set to a string of all zeroes. The value stored in PowerdownTime is then stored in LastPowerdown to preserve the estimate of the timestamp of the last powerdown or reset. PowerdownTime is next set to the current date and time, and periodic updating of Class 5 variables is enabled.

16.2.2 Normal communications to both operator and host are unavailable from powerdown to a point within or following system initialization. It is recommended that initializations affecting communications with the host precede initialization of the ARAMS State Model, to allow an event report to be sent to the host on Transition 1. It is highly desirable to the host to receive an event report for Transition 1. However, it is not required for ARAMS compliance.

16.2.3 Transition 11 never generates an event report.

16.3 *Powerup and Powerdown States* — The ARAMS state entered at Transition 1 is the default or powerup entry state for the ARAMS State Model. The powerdown state is the state that was active at Transition 11 and is determined by the value stored in ARAMSState at the time of Transition 1.

16.3.1 If the value in ARAMSState indicates any non-manufacturing state (ENGINEERING, SCHEDULED DOWNTIME, UNSCHEDULED DOWNTIME, or NON-SCHEDULED TIME), it is regarded by the factory as continuing in that state both during the time it is powered off and at Transition 1. The powerup entry state is the same as the powerdown state.

16.3.1.1 If the equipment is in PRODUCTIVE or STANDBY and is powered off, it is regarded by the factory as in UNSCHEDULED DOWNTIME from the time of the powerdown, through any subsequent powerup, and until it is specifically put into a different state by the user. The ARAMS powerup entry state either is UNSCHEDULED DOWNTIME or is determined by an optional variable PowerupState (Section 11.4.2) to be either UNSCHEDULED DOWNTIME or STANDBY.

16.3.1.2 If the ARAMS state prior to powerdown cannot be determined (e.g., if it has never been set or is invalid), the state entered after powerup is NON-SCHEDULED TIME.

16.3.1.3 Time-in-state calculations for the powerdown state assume that any transition to a new state occurs at the time of powerdown, re-boot, or reset.

16.3.2 *PowerupState* — PowerupState, where supported, shall be configurable by the user to specify either UNSCHEDULED DOWNTIME or STANDBY as the powerup entry state after a powerdown has occurred from PRODUCTIVE or STANDBY. The impact of loss of power has different effects on different types of equipment. An entry state of STANDBY allows those types of equipment that do not have safety or setup concerns to be powered off and on and returned to manufacturing. PowerupState contains a text character of either "2" (STANDBY) or "5" (UNSCHEDULED DOWNTIME) and has an initial default value of "5". If the value in PowerupState is neither "2" nor "5", then it shall be set to "5".

16.4 *User-Initiated State Change Requests* — The user may request an ARAMS state change at any time. The host requests a state change through the ARAMS message ARAMSStateChange (Section 15.5), specifying an ARAMS Substate Code or the special manufacturing code "0000". The operator uses the human interface to request a state change, and this shall result in the specification of a valid ARAMS Substate Code (Section 9.4) or of the manufacturing code.

16.4.1 The equipment shall deny the request if the specified code is not valid or if the user specifies a code for manufacturing when any exception condition exists that would prevent the equipment from performing its intended function.* Otherwise, Transition 10 occurs, regardless of whether the new ARAMS Substate Code is the same or different from the value in ARAMSState representing the current state.

* NOTE: See SEMI E10 definitions.

16.4.2 If the user specifies a manufacturing state, and the equipment accepts the state change request, then Transition 10 occurs and is immediately followed by Transition 2. Transition 2 always occurs in conjunction with Transition 10 and does not generate a report separately from Transition 10. It is regarded as an extension of Transition 10 where the equipment determines the specific state/substate based on its internal status at the time.

16.4.3 At Transition 2, the equipment determines the new state as either PRODUCTIVE or STANDBY, based on its internal condition at the time. It is prohibited from transitioning to PRODUCTIVE unless its productive criteria have been met and it is busy performing its intended function. The current value of ARAMSState is moved to PrevARAMSState, and the ARAMS Substate Code for the new state is placed in ARAMSState. The event report associated with Transition 10 shall be generated after the equipment has determined the new state at Transition 2 and updated the appropriate variables.

16.4.4 The user may optionally specify a symptom identifier and text, which are saved in the variables SymptomID and SymptomText (Section 11.2). If not provided, SymptomID is set to zero and SymptomText is set to a zero-length text string. The equipment does not otherwise set these values.

16.4.5 The user also may optionally enter comments that are stored in DowntimeData when selecting a transition to UNSCHEDULED DOWNTIME from a manufacturing state. Otherwise, DowntimeData is set to a zero-length text string.

16.5 *Production and Standby Substates* — Transitions 2, 3, and 4 are made automatically by the equipment. User requests to change to PRODUCTIVE or STANDBY are accepted as methods of setting the current substate of PRODUCTIVE or STANDBY. However, within the MANUFACTURING superstate, the equipment is responsible for determining when its production criteria are satisfied.

16.5.1 Unless the equipment has information as specified in this section concerning the appropriate substate of PRODUCTIVE or STANDBY, then the equipment shall select the appropriate default ARAMS Substate Code ("1000" or "2000", defined in Section 9.2).

16.5.2 To provide substate refinements important to the user, the equipment shall remember the last ARAMS Substate Code specified by the user for the PRODUCTIVE state at Transition 10 and use this as a default PRODUCTIVE substate value PrdState (Section 11.2) until a new value is specified. This value shall be used for the new (current) ARAMS state/substate information in the variable ARAMSState whenever the equipment transitions to PRODUCTIVE.

16.5.3 The equipment normally uses the default code for all transitions to STANDBY ("2000"). However, when the user specifies an ARAMS Substate Code for STANDBY with a substate, this value is to be used at the next following transition to STANDBY at Transition 2 (if the equipment then transitions to STANDBY) or at the subsequent occurrence of Transition 4 (if the equipment transitioned to PRODUCTIVE at Transition 2).

16.5.4 This value is discarded (or reset to "2000") after a single use or upon any other transition that intervenes between the Transition 10 where it is specified and the time it is applied. This includes intervening occurrences of a new Transition 10 as well as of Transitions 11, 1, and others.

16.5.5 It is not important that the equipment provide the user access to this value except when it is stored in ARAMSState.

16.6 *Equipment-Selected Substates* — Equipment may provide an optional capability to select substates of PRODUCTIVE and STANDBY. In this case, the equipment shall provide a user-configurable variable SubstateSelect that enables and disables this capability (Section 11.4.7).

16.6.1 Substate selection by the equipment is subject to the requirements specified in Section 16.5. If the user has selected a substate of PRODUCTIVE or STANDBY, the equipment is restricted to that substate or extensions of that substate. Note that a user-selected substate of STANDBY is applied at most once.

16.6.2 The capability of selecting substates includes the ability to select a new substate of the current state. Transistions 12 and 13 shall be used for this purpose.

16.6.3 When transitioning to STANDBY, normally at the completion of a process cycle, multiple standby conditions may exist. For example, the equipment may need both material and instructions from the host. In general, a substate code of 2200 (SBY/No product) shall take precedence over 2100 (SBY/No operator) and 2500 (SBY/No host).

16.6.4 If the standby condition represented by the currently selected substate clears, then the equipment shall either select a new substate of STANDBY (Transition 12) or transition from STANDBY (Transition 3).

16.6.5 Additional rules for determining substates may be specific to a type of equipment and may be specified by standards defining the capabilities for that type of equipment.

16.6.6 The equipment supplier shall document the prioritization of standby conditions used by the equipment and of the basis for selecting substates of PRODUCTIVE.

16.7 *Equipment-Detected Exceptions* — The equipment may detect exceptions in any ARAMS state. However, only those exceptions that occur during an uptime state are of interest to the host.

16.7.1 Transitions 5 and 7 indicate the equipment detects a fault condition and transitions to UNSCHEDULED DOWNTIME from STANDBY and PRODUCTIVE respectively. Transitions 6 and 8 are provided to allow the equipment to return to its prior state and are discussed in the following section.

16.7.2 When the equipment detects an exception condition during PRODUCTIVE or STANDBY, so that it is unable to perform its intended function, it shall immediately transition to UNSCHEDULED DOWN-TIME. The identifier of the associated alarm is stored in DowntimeAlarm, and any description text associated with that alarm is stored in DowntimeAlarmText. The equipment supplier may provide additional descriptive text that would be useful in diagnostics or analysis in DowntimeData. In the case of the failure of a component, attributes of that component (e.g., serial number, installation date, lifetime cycles) is desirable.

16.7.3 If the equipment detects an exception condition in non-uptime states, it shall not initiate a state change. Exceptions occur for many reasons in non-manufacturing states. For example, the equipment may be improperly or incompletely installed, or it may be deliberately pushed past its limits.

16.7.4 *Fault Detection in ENGINEERING* — The equipment may also provide optional capability of transitioning to UNSCHEDULED DOWNTIME from ENGINEERING (Transition 12) when it detects an exception. Alarm-related variables in this case are handled in the same way as described above.

16.7.5 The user shall be able to enable and disable this capability with the user-configurable variable EngInterrupt (Section 11.4.1).

16.8 *Equipment-Initiated Recovery* — Equipment-initiated transitions 6, 8, and 13 from UNSCHEDULED DOWNTIME are provided to allow equipment to recover from an equipment-detected fault when the operator intervenes, corrects the fault, and indicates the process can be recovered. For Transition 6 to occur, the equipment shall be able to resume processing without degradation of the process or the material. The equipment is responsible for ensuring the safety of persons, material, and for the equipment itself.

16.8.1 Transition 13 is required if Transition 12 is supported and is prohibited otherwise.

16.8.2 *Automatic Recovery* — Equipment may also provide optional capabilities to recover automatically from transient faults that clear spontaneously. Automatic recovery at Transitions 6, 8, and 13 shall be separately enabled and disabled using the user-configurable variables PrdRecovery (Transition 6), SbyRecovery (Transition 8), and EngRecovery (Transition 13). Equipment is otherwise prohibited from using Transitions 6, 8, or 13 to recover without explicit operator approval.

16.8.2.1 Automatic recovery to manufacturing and automatic recovery to ENGINEERING are regarded as two separate capabilities.

16.8.2.2 If EngInterrupt (Section 11.4.1) is not supported or is disabled, then Transition 13 is prohibited.

17 Requirements for Compliance

This section summarizes the requirements for compliance to ARAMS that are defined in this document.

17.1 *Fundamental Requirements* — Compliance to ARAMS requires certain capabilities that are defined by other standards.

17.1.1 *Event Notification* — A standard method for notifying the host that an event of interest has occurred and for providing specific information related to the event.

17.1.2 *Clock Services* — Provision of a real-time date/time clock with methods for setting and reading the clock from the host.

17.1.3 *Read-Only Data Access* — A standard method for the host to obtain the current values of selected status variables and constants specified in Sections 11.2 and 11.3.

17.1.4 *User-Configurable Data Access* — A standard method for the host to change the values of selected variables defined in Sections 11.4 and 11.5.

17.1.5 *Alarm/Exception Management* — A standard method for notifying the host of abnormal events and/or conditions.

17.1.5.1 In addition to the requirements defined in other standards, the following, defined by ARAMS, are required for compliance to ARAMS:

17.1.6 *ARAMS State Model* — Conformance to the behavior of the ARAMS state model defined in Section 8.3.

17.1.7 *ARAMS State Transition Notification* — Using standard event report mechanisms (above), the host shall be notified of all state transitions as described in Sections 12 and 16.1.

17.1.8 *ARAMS Substate Codes* — Support for ARAMS Substate Code formats, used for equipment variables and service parameters defined in Section 9.

17.1.9 *ARAMS Status Data* — Support for all status variables defined in Section 11.2.

17.1.10 *ARAMS Constant Data* — Support for all data constants and for the user-configurable variable EqpName defined in Sections 11.3 and 11.4.

17.1.11 *ARAMS Event Report Data* — Support for the requirements of Section 12 requires either the provision of pre-defined event reports or provision of the Dynamic Event Report Configuration capability that allows the host to dynamically modify the equipment event reporting setup and define the content of reports for each event.

17.1.12 *Host State Change Request* — Support for the ARAMSStateChange service, defined in Sections 15.1, 15.2, and 15.5.

17.1.13 *Estimation of Powerdown Time* — Provision of a method for maintaining PowerdownTime as an estimate of the time of powerdown to an accuracy within ± one minute.

17.1.14 *ARAMS Behavioral Requirements* — Conformance to all requirements in Section 16 except those identified as optional or requiring optional variables.

17.1.14.1 Table 14 lists the requirements for fundamental compliance to ARAMS and the section references to ARAMS or (where applicable) the standards where these capabilities are defined. These requirements shall all be satisfied for equipment to be termed ARAMS-compliant.

Table 14 Fundamental ARAMS Requirements

Requirement	*Reference*
Event Notification	GEM 4.2.1.1 or ERS
Clock Services	GEM 4.10 or CTMC 8.7
Read-Only Data Access	GEM 4.2.2 or OSS 12.1
User-Configurable Data Access	GEM 4.5 or OSS 12.1
Alarm/Exception Management	GEM 4.3 or EMS
ARAMS State Model	ARAMS 8.3
ARAMS State TransitionNotification	ARAMS 12, 16.1
ARAMS Substate Codes	ARAMS 9
ARAMS Status Data	ARAMS 11.2
ARAMS Constant Data	ARAMS 11.3, 11.4
ARAMS Event Report Data	ARAMS 12, GEM 4.2.1.1, GEM 4.2.1.2.
Host State Change Request	ARAMS 15.1, 15.2, 15.5
Estimation of Powerdown Time	ARAMS 16.2
ARAMS Behavioral Requirements	ARAMS 16 (all except 16.3.2, 16.7.4, 16.8.2)

17.2 *Additional Capabilities* — The following capabilities are not required for fundamental compliance to ARAMS. They are recommended for equipment that provide a local operator interface and are not expected from equipment such as individual process modules of a cluster tool.

17.2.1 *User-Configurable Powerup State* — Provision of the user-programmable variable PowerupState, which allows the user to select either STANDBY or UNSCHEDULED DOWNTIME as the powerup state following powerdowns that occurred during STANDBY. (See Section 16.3.2.)

17.2.2 *User-Configurable Fault Recovery to Manufacturing* — Provision of user-programmable variables, PrdRecovery and SbyRecovery, that allows the user to enable or disable automatic equipment-initiated recovery from faults that clear without user intervention. (See Section 16.7.4.)

17.2.3 *Accumulator Data* — Support for the variables defined in Section 11.5, together with access to this data by the operator (Section 14.1) and the host, with support for the ResetAccumulators service. (See Sections 11.5 and 15.6.)

17.2.4 *User-Generated ARAMS Substate Table(s)* — The ability to accept one or more sets of user-generated ARAMS Substate Codes, as defined in ARAMS Substate Tables, that may be selected by the user in a request to change to a new state or substate. This includes support of the TableSend and TableRequest services and methods for operator access. (See Sections 10.3, 14.2, and 15.3.)

17.2.5 *Equipment-Generated ARAMS Substate Table(s)* — Provision of a set of equipment-defined ARAMS Substate Codes that can be selected by the user in a request to change to a new ARAMS state or substate. This includes support of the TableRequest service. (See Sections 10.3 and 15.4.)

17.2.6 *User-Generated Symptom Table(s)* — The ability to accept one or more user-defined ARAMS Symptom Table, allows the operator to select a symptom when requesting a transition to a new ARAMS state, and the associated data. This includes support for the TableRequest service and methods for operator access. (See Sections 10.4, 14.3, and 15.3.)

17.2.7 *Human Interface Requirements* — Operator access to ARAMS tables as defined in Sections 14.2 through 14.4. Where color is used, conformance to color code in Section 14.5.

17.2.8 *Equipment-Selected Substates* — Support for the user-configurable variable SubstateSelect (Section 11.4.5) allowing the user to enable and disable the capability to select substates of PRODUCTIVE and STANDBY. Documentation of the prioritization of substate selection. (See Section 16.6).

17.2.9 *User-Configurable Fault Detection in ENGINEERING* — Support for Transitions 12 and 13 (Section 16.7.4) and the user-configurable variable EngInterrupt (Section 11.4.1) allowing the user to enable and disable Transitions 12 and 13.

17.2.10 *User-Configurable Fault Recovery to ENGINEERING* — Support for automatic recovery (Transition 13, Sections 16.8.1 and 16.8.2) and the user-configurable variable EngRecovery (Section 11.4.2) allowing the user to enable and disable automatic recovery in Transition 13.

17.2.10.1 Table 15 provides the section references for additional ARAMS capabilities.

Table 15 Section References for Additional ARAMS Capabilities

Capability	*Section Reference*
User-Configurable Powerup State	ARAMS 11.4.4, 16.3.2
User-Configurable Fault Recovery	ARAMS 11.4.2, 11.4.5, 11.4.6, 16.8.2
Accumulator Data	ARAMS 11.5, 15.5
User-Generated ARAMS Substate Table(s)	ARAMS 10.1, 10.2, 10.3, 14.3, 15.3
Equipment-Generated ARAMS Substate Table(s)	ARAMS 10.1, 10.2, 10.3, 15.4
User-Generated ARAMS Symptom Table(s)	ARAMS 10.1, 10.2, 10.4, 14.3, 14.4, 15.3
Human Interface Requirements	ARAMS 14.2, 14.3, 14.4, 14.5
Equipment-Selected Substates	ARAMS 11.4.7, 16.6
User-Configurable Fault Detection in ENGINEERING	ARAMS 11.4.1, 16.7, 16.7.4
User-Configurable Fault Recovery to ENGINEERING	ARAMS 11.4.2, 16.8
Human Interface Requirements	ARAMS 14, 14.1, 14.2.

17.2.11 *Human Interface Requirements* — Operator access to ARAMS data and state change, defined in Sections 14, 14.1, and 14.2.

17.3 *Requirements for Compliance* — Table 16 provides a checklist for ARAMS compliance.

NOTE 1: Do not mark YES unless all fundamental ARAMS requirements are implemented.

NOTE 2: Additional capabilities may not be marked ARAMS-compliant unless all fundamental ARAMS requirements are implemented.

18 ARAMS States for Multi-Module Equipment

18.1 The preceding sections define how ARAMS is to be supported by simple equipment. Simple equipment includes equipment with at most one process chamber, and a single process capability, where individual modules are not treated separately from the equipment.

NOTE 22: Process capability, in this context, refers to the factory's manufacturing process. Equipment with more than one process capability may be used in different ways at different steps, typically through different process recipes. Such equipment may be "available" for one process but not for another. This type of complexity is neither addressed nor affected by SEMI E10 or by ARAMS.

18.2 This section addresses the application of ARAMS to complex equipment, including modular equipment where individual modules may be in different ARAMS states/substates. Complex equipment includes cluster tools and any other type of equipment that is organized into separate subsystems that can be addressed individually. In this case, it is advantageous for each module or subsystem to be given its own ARAMS state model. In addition, the overall equipment system itself has an ARAMS state model. This situation is illustrated in Figure 6.

18.3 The complexities of possible interactions between ARAMS states of the individual modules and the ARAMS state of the cluster tool as a whole are beyond the scope of this document. The following approach is recommended:

- Each module complies to fundamental requirements for the ARAMS state model, data variables, and message services.
- The integrated cluster tool complies to requirements for the ARAMS state model, data variables, and message services.
- The set of all the ARAMS models above are simultaneously active, as represented in Figure 6.
- The relationships between the ARAMS state for the cluster tool and the ARAMS states for the individual modules are user-configurable wherever possible. (Certain relationships between the cluster and critical modules, such as central wafer handler or central load lock, may not be configurable: e.g., if the critical module is down, the cluster is down.)

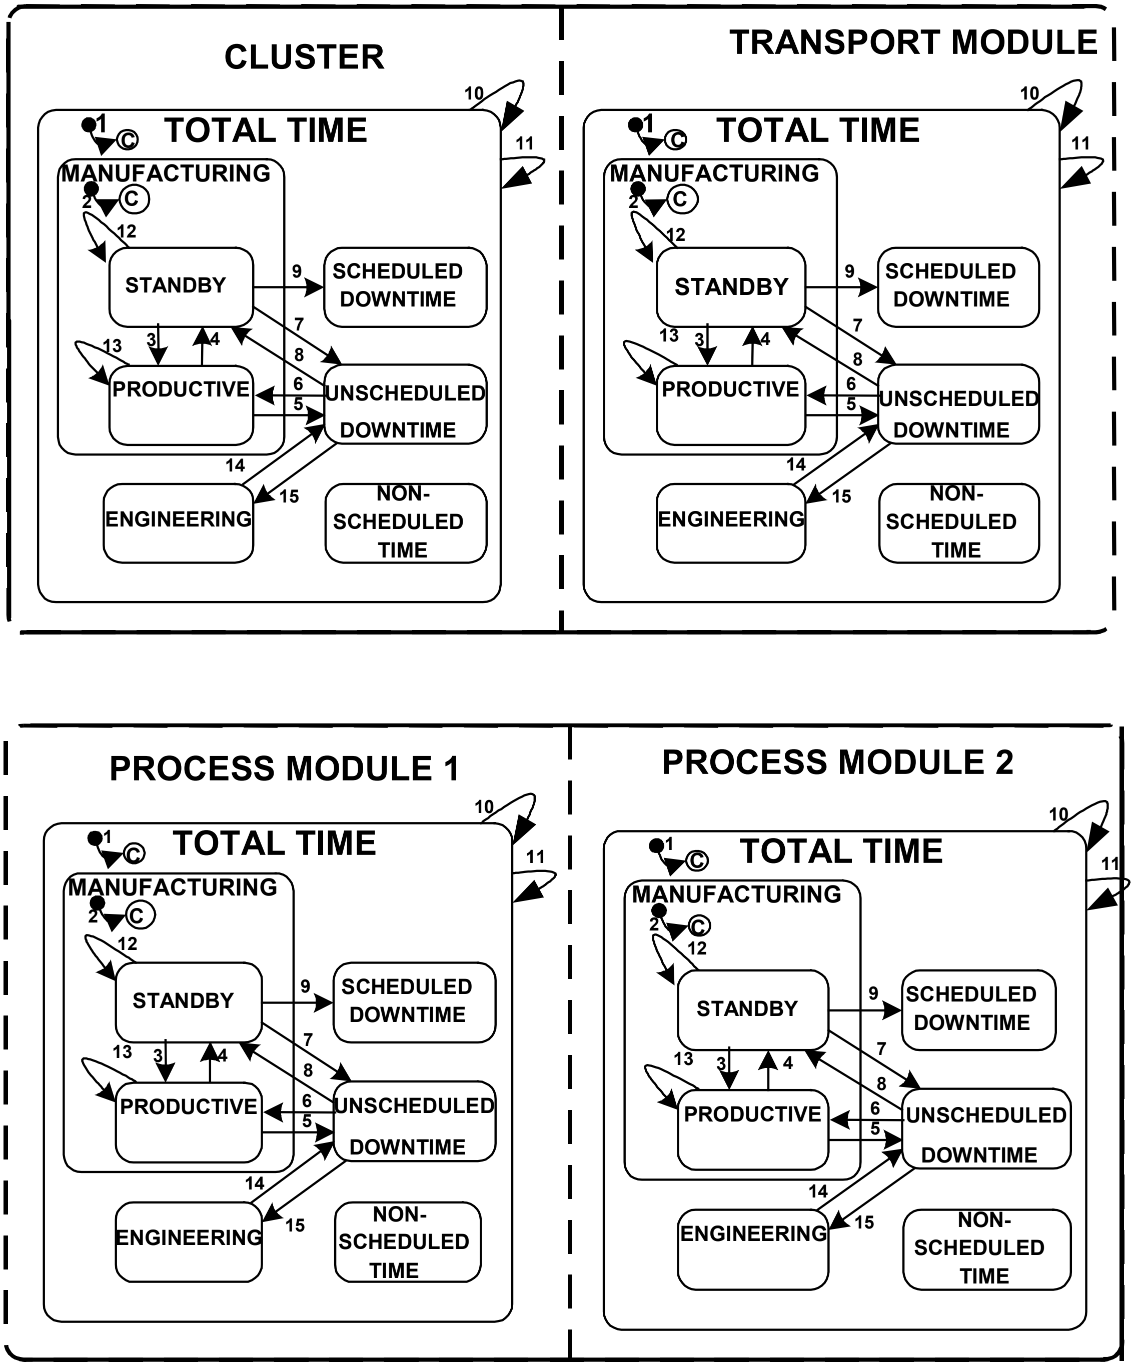

Figure 6
ARAMS Model for Cluster

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E58 and is not intended to modify or supersede the official standard. Rather, these notes are auxiliary information provided as background or examples of possible application and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

This section describes different applications of ARAMS, including an example of a method for estimating the time of powerdown as well as various scenarios.

R1-1 Estimating Powerdown Time

R1-1.1 This section describes a method for estimating the time at which a loss of power, reset, or re-boot occurs. Estimation of this time, allows the accumulation of time-in-state for the previous ARAMS state to be maintained.

R1-1.1.1 The equipment maintains a date/time value, PowerdownTime, that is used to estimate the time when a loss of power occurred (see Section 11.2.12). In this example, the equipment provides an additional user-configurable variable, UpdatePeriod, that defines the number of seconds in an update period. UpdatePeriod is used to set an interval timer. PowerdownTime is updated with the current date and time at the end of each timed interval.

R1-1.1.2 Whenever the equipment enters the initialization state, whether through powerup, reset, or re-boot, it uses the value found in PowerdownTime as the estimate of when the powerdown occurred. If a state change occurs as the result of a powerdown, then the time that has elapsed since the point of powerdown is used to update the appropriate time-in-state accumulator for the previous ARAMS state.

R1-1.1.3 For an example of the sequence of events and actions following a powerup, see Section R1-2.

R1-1.1.4 Figure R1-1 provides a simple logic flowchart as an illustration of the update process.

R1-1.2 *UpdatePeriod* — The length of the time interval, in seconds, for updating PowerdownTime. Form: positive integer.

R1-2 Powerup Scenario

R1-2.1 This scenario is analogous to a timing diagram. It illustrates the actions that occur at different times in sequence, showing the effect of a powerdown that occurs while the equipment was in the PRODUCTIVE state. In this example, accumulators defined in Section 11.5 are supported. UpdatePeriod is defined in the prior section and is set to a value of 30 seconds.

R1-2.2 In this example, the equipment received instructions for processing prior to the start of the timing and waited briefly for the material to arrive. Timing shown in this example begins when it receives the expected material and transitions from STANDBY to PRODUCTIVE at time = t_0. After a sequence of its normal periodic updates ($t_i = t_{i-1}$ + UpdatePeriod) of the estimated time of powerdown, it loses power while still in the PRODUCTIVE state. Following powerup, it determines the new ARAMS state, sets the required variables, and reports the state change to the host.

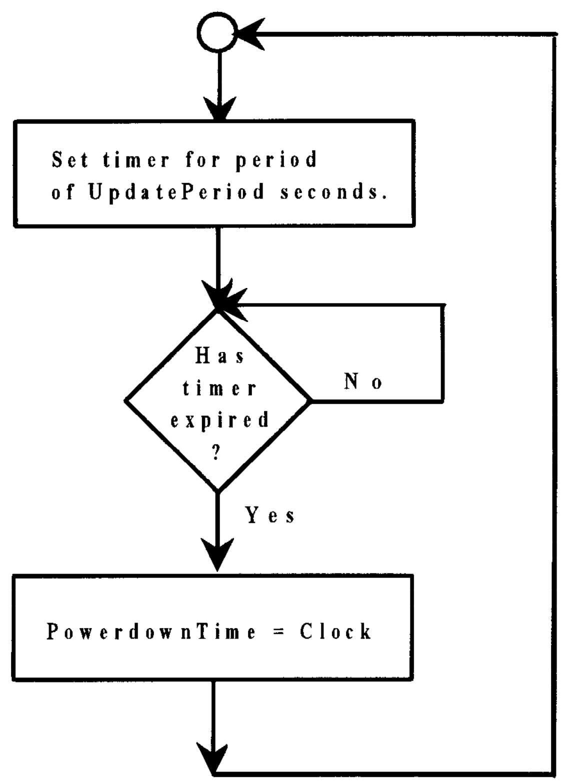

Figure R1-1
Periodic Update Logic

R1-2.3 The notation "=" indicates the value of a variable, while ":=" is used to indicate the act of setting a variable to a specific value. The notation "←" is used to indicate a message sent from equipment to host, and the notation "→" is used to indicate a message sent from the host to equipment.

Table R1-1 Powerup Scenario

Time	*Action*	*Comment*
	ARAMSState = “2000” ARAMSTimestamp = t_{-1} PrdState = “1100”	Initial conditions prior to t = t_0: Equipment is in STANDBY PRODUCTION substate is “regular”
t_0	ARAMSTimestamp:= Clock PrevARAMSState:= ARAMSState ARAMSState:= PrdState	Requirements for PRODUCTIVE are satisfied. Equipment transitions automatically.
$t_1 = t_0 + 30$	PowerdownTime:= Clock	Periodic update of estimated powerdown time.
$t_2 = t_1 + 30$	PowerdownTime:= Clock	Periodic update of estimated powerdown time.
$t_3 = t_2 + 30$	PowerdownTime:= Clock	Periodic update of estimated powerdown time.
$t_4 = t_3 + 30$	PowerdownTime:= Clock	Periodic update of estimated powerdown time.
$t_5 = t_4 + 30$	PowerdownTime:= Clock	Periodic update of estimated powerdown time.
$t_6 = t_5 + 30$	PowerdownTime:= Clock	Periodic update of estimated powerdown time.
t_7		Powerdown
t_8	LastPowerdown:= PowerdownTime PowerdownTime:= Clock Elapsed time before powerdown = LastPowerdown – ARAMSTimestamp ($t_6 - t_0$) ARAMSTimestamp:= LastPowerdown (t_6) PrevARAMSState:= ARAMSState (“1100”) ARAMSState:= “5000” (“UDT”) PrdTime:= PrdTime + elapsed time ($t_6 - t_0$)	Powerup: Transition 1 Equipment system initialization ARAMS housekeeping Transition complete.
t_9	← ARAMS State Change Event Report “A” ← ARAMS Transition Event Report “B”	Equipment sends event notification to host.

R1-3 Equipment-Initiated Transition

R1-3.1 This scenario illustrates the events and activities that occur as the result of an equipment-initiated transition from PRODUCTIVE to UNSCHEDULED DOWNTIME, for equipment supporting the accumulators in Section 11.4.

Table R1-2 Equipment-Initiated Transition

Comment	*Host*	*Equipment*	*Comment*
		ARAMSState = “1100” (“PRD/Regular Production”)	Initial conditions.
			Equipment detects mechanical fault in wafer handler.
			Equipment suspends processing, transitions to UNSCHEDULED DOWNTIME, and notifies user.
		Elapsed time: = Clock – ARAMS ARAMSTimestamp:= Clock PrevARAMSState:= ARAMSState (“1100”) ARAMSState:= “5000” (“UDT”) DowntimeAlarm:= alarm/exception identifier DowntimeAlarmText := alarm/exception description DowntimeData:= additional information Prdtime:= Prdtime + elapsed time	

		← ARAMS State Change Event (Report "A")	
		← ARAMS Transition Event (Report "B")	

R1-4 Operator-Initiated Transition

R1-4.1 This scenario illustrates the events and activities that occur as the result of an operator-initiated transition from PRODUCTIVE to UNSCHEDULED DOWNTIME.

Table R1-3 Operator-Initiated Transition

Comment	*Host*	*Equipment*	*Comment*
		ARAMSState = "1100" ("PRD/Regular Production")	Initial conditions.
			Operator aborts process. Equipment halts processing.
		PrevARAMSState:=ARAMSState ("1100") ARAMSState:= "5000" ARAMSTimestamp:= Clock SymptomID:= corresponding symptom identifier. SymptomText:= corresponding symptom description.	Operator selects new ARAMS state of UNSCHEDULED DOWNTIME ("5000"). Operator selects description of a symptom.
		Elapsed time:= Clock – ARAMSTimestamp ARAMSTimestamp:= Clock ARAMSState:= "5000" ("UDT") DowntimeAlarm:= alarm/exception identifier DowntimeAlarmText:= alarm/exception description DowntimeData:= additional information PrdTime:= PrdTime + elapsed time	
		← ARAMS State Change Event (Report "A")	
		← ARAMS Transition Event (Report "C")	

R1-5 Host-Initiated Transition

R1-5.1 This scenario illustrates the events and activities that occur as the result of a host-initiated transition from its current substate of STANDBY to a different substate of STANDBY.

Table R1-4 Host-Initiated Transition

Comment	*Host*	*Equipment*	*Comment*
		ARAMSState = "2800" ("SBY/No host")	Initial conditions.
Host sends new ARAMS substate code.	ARAMSStateChange.req → (ARAMSCode = "2400")		
		Elapsed time:= Clock Ð ARAMSTimestamp PrevARAMSState:= ARAMSState ("2800") ARAMSState:= "2400" ("SBY")	NOTE – ARAMSTimestamp is unchanged.
		← ARAMSStateChange.rsp	Equipment acknowledges the new state change.
		← ARAMS State Change Event (Report "A") ← ARAMS Transition Event (Report "C")	Equipment notifies host of ARAMS state change.

RELATED INFORMATION 2

NOTE: This related information is not an official part of SEMI E58 and is not intended to modify or supersede the official standard. Rather, these notes are auxiliary information provided as background or examples of possible application and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

This section discusses issues that may arise through implementations of ARAMS.

R2-1 User-Initiated Transitions to UNSCHEDULED DOWNTIME

R2-1.1 Although substates of UNSCHEDULED DOWNTIME include (unplanned) change of consumables, out-of-spec input material, and facilities-related downtime, transitions to UNSCHEDULED DOWNTIME are generally regarded as resulting from an equipment fault. Operators have sometimes been known to log the equipment into UNSCHEDULED DOWNTIME as a way of freeing time, even though the equipment is operating completely within specifications.

R2-1.2 The equipment may use the status (read-only) ARAMSInfo to record information, such as Operator ID, that could be used in its defense.

R2-1.3 Additionally, equipment is encouraged to maintain an internal log of events. While the host may or may not request ARAMSInfo in an event report, the equipment's log could be used to record the information and would be accessible to field service personnel for analysis. Recording information such as the date, day of week, time of day, identifier of the operator (where known) could be an effective protection against abuse.

SEMI E58.1-0697
SECS-II PROTOCOL FOR AUTOMATED RELIABILITY, AVAILABILITY, AND MAINTAINABILITY STANDARD (ARAMS): CONCEPTS, BEHAVIOR, AND SERVICES

1 Purpose

This document maps the services and data of the Automated Reliability, Availability, and Maintainability Standard (ARAMS) to SECS-II streams and functions and data definitions.

2 Scope

This document applies to all implementations of ARAMS that use the SECS-II message protocol (SEMI E5).

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E58 — Automated Reliability, Availability and Maintainability Standard (ARAMS): Concepts, Behavior, and Services

4 Services Mapping

Table 1 shows the specific SECS-II streams and functions that shall be used for SECS-II implementations of the services defined in ARAMS.

The ARAMSStateChange service may be mapped either to S2,F41/F42 or to S2,F49/F50 or both. The equipment supplier is required to document the mapping used.

Table 1 Services Mapping Table

Message Name	*Stream, Function*	*SECS-II Message Name*
ARAMSStateChange	S2,F41/F42 S2,F49/F50	Host Command Send/Acknowledge Enhanced Remote Command/Acknowledge
ResetAccumulators	S2,F41/F42 S2,F49/F50	Host Command Send/Acknowledge Enhanced Remote Command/Acknowledge
TableSend	S13,F13/F14	Table Data Send/Acknowledge
TableRequest	S13,F15/F16	Table Data Request/Table Data

5 Service Parameter Mappin g

Table 2 shows the mapping between service parameters defined by ARAMS and the data items defined by SEMI E5. An additional mapping for the ARAMSStateChange and ResetAccumulators services is shown in Table 4 below.

Table 2 Service Parameter Mapping Table

Parameter Name	*SECS-II Data Item*
AttrData	ATTRDATA
AttrName	ATTRID
ColHdr	COLHDR
ErrorCode	ERRCODE
ErrorText	ERRTEXT
ObjSpec	OBJSPEC
RequestStatus	HCACK
TableAck	TBLACK
TableCmd	TBLCMD
TableElem	TBLELT
TableID	TBLID
TableType	TBLTYP

Table 3 shows the data items in SECS-II messages that do not have a corresponding service parameter.

Table 3 Additional Data Item Requirement Table

Function	*SECS-II Data Item*
Used to satisfy SECS-II conventions for linking a multi block inquiry with subsequent multilock message.	DATAID
Used by S2F41 and S2F49 to indicate the ARAMSStateChange Service.	RCMD="ARAMSStateChange"
Used by S2F41 and S2F49 to indicate the ResetAccumulators Service.	RCMD="ResetAccumulators"

NOTE: The text strings specified in Table 3 for RCMD shall be recognized by the equipment, whether the equipment is or is not case-sensitive.

Table 4 provides the parameter mapping for the ARAMSStateChange and the S2,F41 and S2,F49 messages.

Table 4 Service Parameter Mapping (S2F41 and S2F49)

Parameter Name	*CPNAME*	*CPVAL/CEPVAL (Form)*
ARAMSCode	"ARAMSCode"	Text, 4 characters
ObjSpec	"ObjSpec"	Text. Conforms to data item OBJSPEC. NOTE: in S2,F49, ObjSpec maps directly to the data item OBJSPEC.
SymptomID	"SympID"	Unsigned integer
SymptomText	"SympText"	Text, 0–80 characters

NOTE: The text strings specified in Table 4 for CPNAME shall be recognized by the equipment, whether the equipment is or is not case-sensitive.

SEMI E81-0600
PROVISIONAL SPECIFICATION FOR CIM FRAMEWORK DOMAIN ARCHITECTURE

This provisional specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org April 1999; to be published June 2000. Originally published June 1999.

1 Purpose

1.1 This document is an overview of the structure and contents of a suite of documents representing an application framework for the Computer Integrated Manufacturing (CIM) systems as used in semiconductor factories. A framework is a software infrastructure that creates a common environment for integrating applications and sharing information in a given domain. The purpose of this framework is to establish an industry standard architecture for complex manufacturing systems, leading to an open, multisupplier CIM system environment. The framework described in this specification is called the CIM Framework.

2 Scope

2.1 The intent of this document is to describe the Manufacturing Execution Systems (MES) domain that is the subject of the CIM Framework and to provide a reference for concepts that are common to the set of documents that specify the CIM Framework. The *Provisional Specification for CIM Framework Domain Architecture* defines the structure, relationships and interworkings of the components that together comprise the CIM Framework. This architecture defines the partitioning of the CIM Framework components and the responsibilities of each of those components. It also specifies the common abstractions for manufacturing jobs, material, and factory resources that are used consistently throughout the CIM Framework as unifying themes.

2.2 The CIM Framework Domain Architecture does not address the dependencies on computing technologies needed to implement these components. These aspects apply more to the realization of the components as software artifacts than to their functionality in terms of semiconductor manufacturing concepts. The technical aspects of the CIM Framework architecture are captured in a separate document, SEMI E96, Guide for CIM Framework Technical Architecture.

2.3 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The CIM Framework Specification must continue to evolve to meet the needs of a competitive and vital industry. The content of this framework represents a significant amount of real development experience from a number of commercial software suppliers and their customers. These specifications reflect the product architectures of those companies, as well as the requirements of their customers.

3.2 As a SEMI Provisional Standard, the Specification for CIM Framework Domain Architecture has specific deficiencies that must be addressed before it may be upgraded to full SEMI Standard status. These deficiencies are:

- Ensuring consistency with the details of subsequent related specifications that are based on this domain architecture.
- Evolving from coarse-grained component partitions to fine-grained components that provide substitutability of smaller components.
- Expanding interfaces to include build-time configuration functions.
- Providing fully validated models using the standard Unified Modeling Language (UML) notation.
- Aligning the CIM Framework representation of equipment and interfaces for interactions with equipment automation software with emerging standards in areas such as Object-Based Equipment Model (OBEM) and Automated Material Handling Systems (AMHS).
- Modifying the CIM Framework use of the “in” parameter mode and operation return value to include also the “out” and “inout” modes to better accommodate implementations based on Microsoft DCOM and IDL enhancements for pass-by-value of objects.

- Adjusting the functional partitioning of the Domain Architecture to reflect the final positioning of sub-components in the anticipated revisions of the other CIM Framework specifications.

5.1.15 *WIP* — Work In Process

5.2 *Definitions*

5.2.1 *abstract interface* — an interface defined outside any component that generalizes common features of the CIM Framework. The abstract interfaces are intended for use in multiple components via interface inheritance mechanisms.

5.2.2 *application* — 1. One or more programs consisting of a collection of interoperating objects which provide domain specific functionality to an end user or other applications. 2. Functionality provided by one or more programs consisting of a collection of interoperating objects.

5.2.3 *application framework* — a framework that constitutes an application or a set of applications for a domain area.

5.2.4 *application interface* — the interface provided by an application or application program.

5.2.5 *application object* — an object implementing an application interface.

5.2.6 *architecture* — the structure of the components of a program/system, their interrelationships, and principles and guidelines governing their design and evolution over time.

5.2.7 *attribute* — an identifiable association between an object and a value. An attribute may have functions to set and retrieve its value.

5.2.8 *behavior* — the effects of performing a requested service including its results.

5.2.9 *binding* — a specific choice of platform technologies and other implementation-specific criteria.

5.2.10 *class* — the shared common structure and common behavior of a set of objects. Class often implies an implementation of the common structure and behavior while interface represents a specification of those common features.

5.2.11 *client* — an object that uses the services of another object by operating upon it or referencing its state.

5.2.12 *collection* — an object containing references to (collections of) other objects with services for managing them and providing access to them as a related group of objects.

5.2.13 *component* — a reusable package of encapsulated objects and/or other components with well-specified interfaces. The component is the element of standardization and substitutability in the CIM Framework.

5.2.14 *Computer Integrated Manufacturing (CIM)* — an approach that leverages the information handling capability of computers to manage manufacturing information and support or automate the execution of manufacturing operations.

5.2.15 *conformance* — adherence to a standard or specification in the implementation of a product, process, or service.

5.2.16 *conformance requirement* — identification in the specification of behavior and/or capabilities required by an implementation for it to conform to that specification.

5.2.17 *conforming implementation* — an implementation that satisfies all relevant specified conformance requirements.

5.2.18 *distributed system* — an integrated collection of several processing and memory components whose distribution is transparent to the user so that the system appears to be local.

5.2.19 *domain interface* — an interface specific to an application subject area.

5.2.20 *domain object* — an object implementing a domain interface.

5.2.21 *events* — an asynchronous message denoting the occurrence of some incident of importance. For example, state change or new object created.

5.2.22 *event channel* — the intermediate object that forwards published events to interested subscribers.

5.2.23 *exception* — an infrastructure mechanism used to notify a calling client of an operation that an unusual condition occurred in carrying out the operation.

5.2.24 *extensibility* — the ability to extend or specialize existing components and add new object classes or components while preserving architectural integrity and component conformance to standards.

5.2.25 *framework* — a collection of classes or components that provide a set of services and functionality for a particular domain.

5.2.26 *implementation* — the internal view of a class, object or module, including any non-public behavior. The specific code and functionality that implements an interface.

5.2.27 *infrastructure* — the services, facilities, and communications mechanisms that support the collaboration between and lifecycle of distributed objects.

5.2.28 *inheritance* — a relationship among classes wherein one class (a subclass) shares the structure or behavior defined in one or more other classes (superclass). A subclass typically specializes its superclasses by augmenting or redefining existing structure and behavior.

5.2.29 *instance* — a software entity that has state, behavior and identity. The terms instance and object are interchangeable. An object is an instance of an interface if it provides the operations, signatures and semantics specified by that interface. An object is an instance of an implementation if its behavior is provided by that implementation.

5.2.30 *interface* — the external view of a class, object, or module that emphasizes its abstraction while hiding its structure and internal behavior. An interface definition ideally includes the semantics.

5.2.31 *interface inheritance* — the construction of an interface by incremental modification of other interfaces (see implementation inheritance). The CIM Framework specifies interface inheritance but not implementation inheritance.

5.2.32 *interoperability* — the ability for two applications or the parts of an application to cooperate. In the CIM Framework, interoperability requires that application components be able to share data, invoke each others' behavior (services), exchange events, and publish service exceptions.

5.2.33 *job* — some system level operation whose execution may be requested by an entity whose responsibility it is to manage jobs. The job concept is analogous to operations performed on the "factory floor" in a physical factory. There, operators are requested to perform operations (jobs) requested by their managing supervisors or some other managing source. A job often spans a significant amount of time and multiple resources within the system. In the CIM Framework, the job construct is intended for specialization to enable specific job supervisors and jobs to provide system solutions.

5.2.34 *lifecycle* — the life of an object, including creation, deletion, copy, and equivalence.

5.2.35 *method* — an operation upon an object defined as part of the declaration of a class. In general, the terms message, method and operation can be used interchangeably. Technically, a method is defined within a class and an operation is defined within the IDL. An operation is implemented by a method.

5.2.36 *object* — an identifiable encapsulated entity that implements one or more services that can be requested by a client. An instance of a class.

5.2.37 *object services* — interfaces for general services that are likely to be used in any program based on distributed objects.

5.2.38 *Object Management Group (OMG)* — an international consortium dedicated to the development of open specifications for distributed, heterogeneous, object-oriented systems.

5.2.39 *operation* — an operation is an entity, identified by an operation identifier that denotes a service that can be requested. An operation has a signature that describes the legitimate values of request parameters and returned results, including any exceptions.

5.2.40 *persistent object* — an object that can survive the process or thread that created it. A persistent object exists until it is explicitly deleted.

5.2.41 *process definition* — information characterizing manufacturing processes including an estimate for the time a process resource will be engaged in the process; process resource settings; and the process capabilities required for the process.

5.2.42 *process flow* — the part of a product specification that defines the sequence of process steps for the manufacturing of a specific product. The data structure for representing a process flow is the directed graph; specifically, a tree structure. The nodes of the tree are called process flow nodes (see below). Services are required to navigate the process flow.

5.2.43 *process flow context* — navigational information pertaining to a product's progress as it traverses its context process flow.

5.2.44 *process step* — the smallest unit of processing activity that can be defined in a process flow. One or more process steps are sequenced to define an operation set.

5.2.45 *recipe* — the pre-planned and reusable portion of the set of instructions, settings and parameters that determine how a job is to be performed. For example, recipes are used to describe Process Steps and are typically contained within a Product Specification.

They determine the processing environment seen by a manufactured product (e.g., wafer). Processing recipes may be subject to change between product runs or processing cycles.

5.2.46 *sub-component* — a component that is fully contained within a larger component. The interfaces of the sub-component may be exposed or hidden by the encapsulating component.

5.2.47 *substitutability* — the ability to replace a given component from one supplier with a functionally equivalent component from another supplier without impacting the other components or its clients in the system.

5.2.48 *type* — a declaration that describes the common properties and behavior for a collection of objects. Types classify objects according to a common interface; classes classify objects according to a common implementation.

6 Overview

6.1 This section provides background information that will help readers get the most from the content of this specification.

6.2 *Intended Audience*

6.2.1 The framework specification is intended to address the needs of the following CIM technologists:

- Technical CIM managers.
- System architects and engineers.
- Application developers and integrators.
- Standards developers.

6.2.2 These groups may be found in a variety of organizations, including semiconductor manufacturers, software product suppliers, system integrators, equipment suppliers, standards organizations, universities, national laboratories, and other research organizations.

6.2.3 *Technical CIM Managers*

6.2.3.1 Technical CIM managers are responsible for managing the development, delivery, and integration of complex manufacturing software applications. They can use the CIM Framework specification to plan and organize the development activities and guide component testing and validation. Moreover, those who buy some of their software from external sources can use it as a purchasing guide when discussing system architecture and integration requirements with potential suppliers.

6.2.4 *System Architects and Engineers*

6.2.4.1 System architects and engineers are responsible for overall system design, including selection of industry standards for computing and communications infrastructure, software development processes, product roadmaps, and related topics. They can make extensive use of the CIM Framework as a starting point for many of their activities, including the

- partitioning and allocation of application functions to specific modules,
- definition of the boundary between the distributed system infrastructure and the rest of the system, and
- specification of open interfaces between the portions of the system they are designing and the external environment.

6.2.4.2 They can also use the CIM Framework specifications to define a strategic system roadmap for migration to an open, distributed system environment.

6.2.5 *Application Developers and Integrators*

6.2.5.1 Application developers and integrators must produce, install, and support software applications for semiconductor manufacturing. The CIM Framework specification, in conjunction with a specific framework "binding" (i.e., target computer system hardware and software technologies), represents a set of detailed design requirements for the application developer. At a minimum, the CIM Framework defines the scope and boundaries of the essential standard components of a manufacturing execution system, and can be used principally as an interface specification. The object models can also be used in the internal design of new applications and/or legacy integration "wrappers," accelerating the development process even further. Finally, the specification can form the basis for creating an independent set of tests necessary to verify conformance.

6.2.6 *Standards Developers*

6.2.6.1 Developers of CIM software standards are responsible for specifying the public interfaces and shared information models that allow the many software products found in a modern semiconductor factory to work together. They can use the CIM Framework as an open source of information for establishing precise definitions for the many items in a factory that must be represented in multiple suppliers' products, including

- standards for partitioning and communicating with complex equipment,
- product and raw material attributes and relationships,

- process definitions and routings,
- equipment data sampling schemes and storage schema,
- personnel qualifications,
- and many others.

6.3 *CIM Framework Foundational Concepts*

6.3.1 This section provides an explanation of the basic concepts of framework, component, and sub-component as used in the CIM Framework Domain Architecture.

6.3.2 *Framework*

6.3.2.1 A framework is a software infrastructure that provides a common environment for the development and integration of applications and sharing of information in a given problem domain. The CIM Framework is a particular type of framework based on an object-oriented model of semiconductor wafer manufacturing. It specifies manufacturing objects and object interaction protocols that enable building semiconductor CIM applications from a framework of compatible, substitutable application components.

6.3.2.2 The heart of the framework is a set of semiconductor manufacturing abstractions (e.g., Wafer, Specification, Machine) and services (e.g., get wafer location, set specification parameter, get machine utilization) that are typically embodied in applications (e.g., material management, specification management, machine control). The implementations of these abstractions are delivered on distributed computer platforms (e.g., workstations, servers) which use standard software system technologies (e.g., communications, database, and user interface). The current CIM Framework is specifically targeted at manufacturing information management and control for both the planning and operational phases of semiconductor wafer fabrication.

6.3.3 *Component Architecture*

6.3.3.1 The CIM Framework specifies software functions that are common across MES applications and serve to integrate those MES applications into a coherent system. The CIM Framework software architecture is based on components. Components are software building blocks—"chunks" of functionality that make up software applications. By specifying standard interfaces and behavior of common MES components, manufacturers can assemble systems from components from multiple suppliers and they can evolve those systems by extending the common components and by substituting old components with improved components that implement the same interfaces and behavior in improved and extended ways. The CIM Framework defines a manufacturing execution system architecture whose components can be assembled in many ways and driven by many business processes and operational policies.

6.3.3.2 Figure 1 shows the CIM Framework architecture as a layered system, with the CIM Framework covering the middle layer of that system. Figure 2 details the layers, showing the components and their interaction and extension. The following subsections provide an introduction to the CIM Framework architecture.

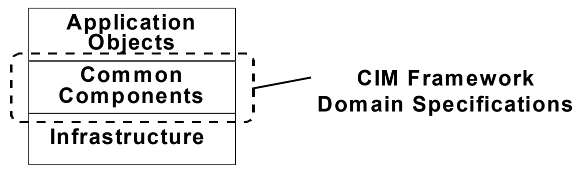

Figure 1
CIM Framework Layering

6.3.3.3 *Infrastructure*

6.3.3.3.1 The infrastructure provides the distributed computing environment for the application. These services include operating system, communications, data storage, user interface, event distribution, exception management, etc. The CIM Framework assumes infrastructure services and facilities defined by the Object Management Group®'s (OMG) Object Management Architecture (OMA) or by the Microsoft® DCOM and COM+ architecture and it can be mapped to other infrastructures such as those for Java™. SEMI E96 addresses the infrastructure layer.

6.3.3.4 *Common Components*

6.3.3.4.1 Common components are the functional entities common across MES applications. For example, material tracking, machine management, and scheduling applications all need a common, shareable concept of wafer groups (lots), machines, and process recipes. The common components provide a shared model for these entities, enabling quicker development and integration of material tracking, machine management, scheduling and other applications. They specify the data and behavior of these components required for interoperability between the applications.

6.3.3.5 *Application Objects*

6.3.3.5.1 The application objects provide the application functionality beyond the common components. These application objects provide application-specific data and behavior (such as the specific scheduling algorithms or the specific recipe management functions), building on the common component data and behavior that allows the application to interoperate with other applications. The application objects also define the business process workflows, business logic and user interfaces for the applications. They provide functionality that is often product- or site-specific. This functionality should not be included in an industry-wide standard for common components. Rather, it should be accommodated through the extendibility and reuse mechanisms of the common components.

6.3.3.6 *Component Granularity and Incremental Standard Conformance*

6.3.3.6.1 The CIM Framework components are the smallest elements of standardization of functional interface and behavior. The CIM Framework specifies relatively fine-grained components (in terms of their functional scope) as in the SEMATECH CIM Framework Specification Version 2.0 [CIMFW]. These components are larger than objects (their specification is in terms of an object model with typically three to five objects) but more fine-grained than traditional MES applications. However, the initial SEMI CIM Framework standards also identify components that are more coarse-grained, aligning with current MES product boundaries. These coarse-grained components contain fine-grained sub-components in their specifications, as in Figure 3 (typically two to four sub-components per coarse-grained component).

6.3.3.6.2 The coarse-grained components encapsulate the detail of the internal objects, relationships and sub-components by selectively exposing, hiding or abstracting some object methods and relationships. The coarse-grained components are specified with the detail of the sub-component and object interfaces and behavior, but standard conformance is in two levels; first-level conformance is to the interfaces of the coarse-grained components (not requiring exposure of the encapsulated detail), and second-level conformance is to the detail of the sub-components.

6.4 *CIM Framework Functional Scope*

6.4.1 The term Manufacturing Execution System (MES) represents an abstraction for a *collection* of software implementations. While there are examples of implementations that provide significant coverage of MES functionality, the industry trend is toward supplier focus on areas of core competency. In many cases this will result in a supplier offering for a subset of the MES domain, or a partitioned offering of separable products by a single source. Large, more monolithic implementations are gradually evolving toward this model of component packaging for smaller implementations. Ideally, MES scoping should correspond to natural boundaries that have emerged in representative products that border the “In MES”/“Outside MES” dividing line. It is that capability within MES scope that will be provided by the CIM Framework.

6.4.2 The following list identifies some criteria that may be used to help scope MES within the larger context of manufacturing enterprise systems often called Computer Integrated Manufacturing.

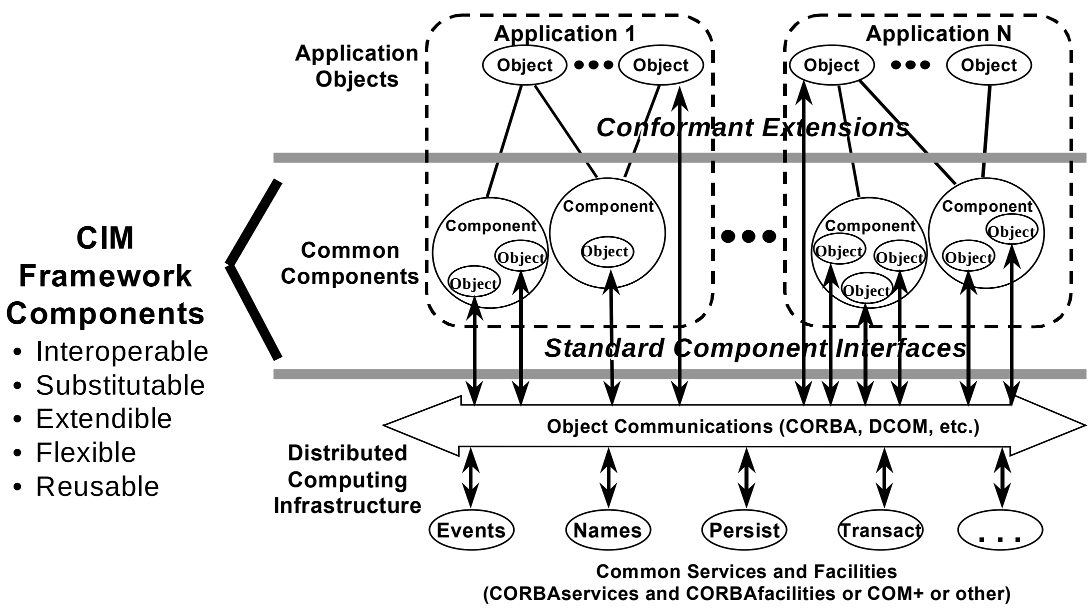

Figure 2
CIM Framework Component Architecture

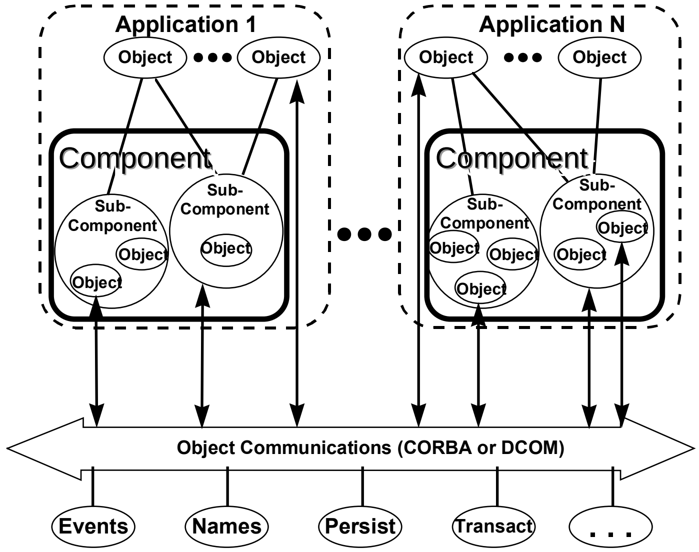

Figure 3
Components and Sub-Components

6.4.3 Thus, a component is "In MES" scope and within the CIM Framework scope, if

- it provides a job abstraction to manage work currently in progress across the manufacturing facility,
- it represents the convergence of product and process specifications, material, and manufacturing resources through execution of production jobs,
- it provides facility level planning and scheduling of manufacturing production activities,
- it provides access to historical data and reporting of occurrences that changed the state of the products, the production facility or its resources,
- it allows coordinated actions to control factory resources,
- it allows abstraction representations of production facilities and their resources,
- it enables automated update of manufacturing parameters (settings) through data collection and analysis of manufacturing processes, and
- it supports quality management through capture of key metrics (e.g., yield, throughput, cycle-time and utilization).

6.4.4 A component is "Outside MES" scope, thus outside CIM Framework scope, if

- it controls or manipulates the internal state or operation of a piece of manufacturing equipment,
- it deals with the business interactions between the manufacturing enterprise and external enterprises such as customers or suppliers,
- it manipulates the product or process definition with a focus on product design rather than execution of the manufacturing process,
- it focuses on the creation and manipulation of what-if models of factory or product state,
- it isn't directly concerned with transforming material from an initial (raw or partially completed) state to a more valuable product, and
- it is primarily used in support of laboratory analysis that is not directly integrated into the manufacturing process (e.g., off-line metrology).

6.4.5 Examples applying the MES definition and scoping criteria might be derived from the following high-level interactions.

6.4.5.1 *"In MES" Scope*

- A product request for production of goods (partial or finished) is offered to one facility which responds with a delivery commitment.

- A production job is created, along with a grouping structure for the target product.
- A production job is split into subjobs and maybe merged again.
- A production job is rerouted to a different resource due to specific circumstances.
- A production job is assigned to a set of resources, allocated required material, and dispatched for execution.
- A change in state of product, resources or material resulting in a change to delivery commitments is reported.
- A change to a manufacturing process results in alteration of the execution of a production job.
- A production job is assigned to specific set of manufacturing machines due to their machine resource capabilities.
- A value for a process specification is changed due to gathered values of a influencing quality control process.
- Material is made available for use or is moved to a new physical location within the facility.
- Material is exchanged between different positional containers due to e.g., contamination control (cleaning of a positional container).
- A manufacturing machine is taken down for maintenance and becomes unavailable for job execution.
- A resource of a multiple resource machine is taken down and becomes unavailable, but not the whole machine.

6.4.5.2 *"Outside MES" Scope*

- A product is defined and engineered for production — Product and Process Engineering.
- A facility is qualified to produce a given product — Release for Production.
- An order is released for production — represented as a demand from Order Management System.
- A consumable is running out of stock — an order is released for delivery to the facility — Enterprise Resource Tracking.
- The facilities (or series of facilities) capable of producing the needed product are analyzed and the demand is matched with available supply (including capacity for future production) — Enterprise Planning System.
- A piece of manufacturing equipment obtains a recipe and enacts a manufacturing process on material — Equipment Automation.
- Material movement equipment controls the transport of material to a specified destination — Equipment Automation.
- Modeling data representing a hypothetical change in factory state is manipulated and analyzed to determine the effects of the changes — Modeling and Simulation.
- Material is packed for transport from the front-end facility to the back-end facility and a carrier is notified of shipping order — Transportation Logistics.
- A customer order is divided into two product requests involving two facilities to meet the requested delivery date — Release for Production.
- The layout of equipment locations within the factory is modified to accommodate a new tool — Factory Design.

6.4.6 Multiple levels of packaging framework functionality are supported by the specification so that a variety of applications from multiple suppliers with potentially intersecting capabilities can be accommodated. This means that, given a specific framework binding to a set of computer and software system technologies, an application can be instantiated and executed in this environment and will register itself as a set of well-known objects that provide a core set of framework specified services.

6.4.7 The CIM Framework specification defines a set of functional components designed to work together to form an integrated manufacturing system. The CIM Framework components cover the functionality of Manufacturing Execution Systems (MES). MES is a factory-wide function that drives material processing on equipment to produce products, and it manages all the resources to accomplish this.

6.4.8 Figure 4 shows the functional scope of the CIM Framework. The left-hand side represents engineering aspects of manufacturing systems, such as configuration, while the right-hand side indicates where MES falls within manufacturing operations. The CIM Framework covers operations of manufacturing execution to a larger degree and configuration to a lesser degree.

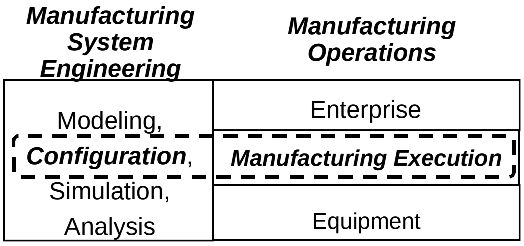

Figure 4
Boundaries of the CIM Framework: Manufacturing Execution

6.4.9 The CIM Framework specifies the MES functional responsibilities for semiconductor wafer fabrication. It does not include responsibilities for semiconductor packaging, assembly and test, but it was designed to accommodate extensions into this phase of semiconductor manufacturing.

6.4.10 Using the definition of component as found in Section 6.3.3, the components of the CIM Framework provide the following functionality found within MES configuration and execution:

- Product Management: manages product material and material groups.
- Durables Management: manages durable materials such as reticles and material carriers.
- Consumables Management: manages consumable materials such as gases and chemicals.
- Specification: manages product specifications and process flows.
- Factory Operations: drives efficient use of factory resources to manufacture products while meeting overall factory objectives.
- Scheduling: supports factory operations and other functions to optimize use of resources in manufacturing products and meeting factory objectives.
- Equipment Tracking and Maintenance: tracks equipment state and usage and manages equipment maintenance.
- Production Machine: manages execution of manufacturing process steps on process and metrology equipment.
- Recipe Management: provides factory-wide management and use of processing recipes.
- Advanced Process Control: executes run-to-run process control and fault detection strategies.
- Material Transport and Storage: moves and stores material.
- Factory Labor: manages labor resources and qualifications.
- Factory Services: provides support functions common across components, such as access security, document management/change control, and history storage and retrieval.

6.4.11 Section 7 lists the functional responsibilities of each of these components by MES configuration (called build-time) and execution (called run-time). The separation of the CIM Framework into components reflects anticipated boundaries of MES products, enabling integration of products from multiple suppliers into a coherent, integrated MES.

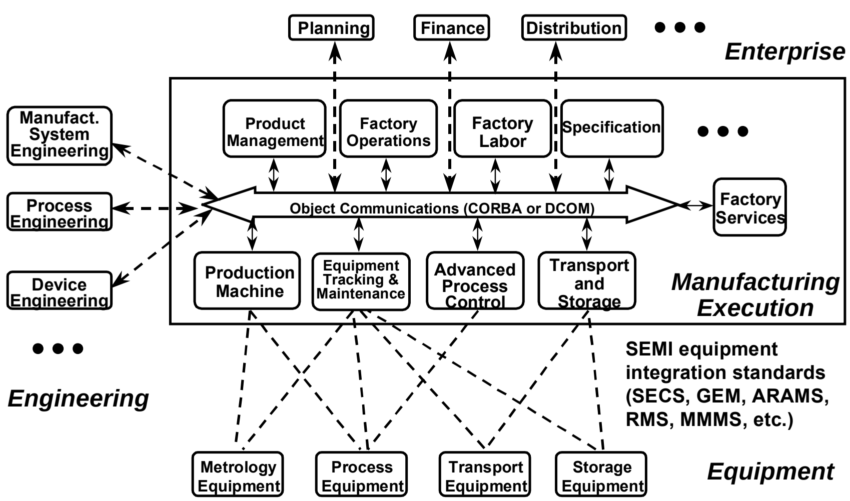

Figure 5
MES Component Integration

6.4.12 As Figure 5 shows, the CIM Framework specifies MES interfaces enabling integration between MES components, that is integration within the MES. The CIM Framework does not directly address integration between the MES and external functions. External functions, such as enterprise functions and engineering functions, can interact with the MES using the CIM Framework-specified intra-MES interfaces and communications mechanisms. Interaction between MES functions and manufacturing equipment can use existing SEMI equipment integration standards such as SECS II (SEMI E5), GEM (SEMI E30), ARAMS (SEMI E58), RMS (SEMI E42), and MMMS (SEMI E32). Equipment can also implement CIM Framework components such as Production Machine and Equipment Tracking and Maintenance within the equipment, integrating with the MES (the equipment host) through CIM Framework component interfaces.

6.4.13 The Object Management Group's Manufacturing Domain Task Force is adopting standards for Enterprise, MES, Machine Control and Engineering applications (MfgDTF). Other related activity within the OMG includes its efforts regarding workflow (Workflow) and component architectures. SEMI tracks these through a liaison with the OMG.

6.4.14 The CIM Framework focuses on the common software functions that serve to integrate MES. It specifies components for factory resources, materials, specifications and factory control, and it establishes a functional and technical architecture so the components can be assembled to meet many functional needs and driven by company-specific business process, workflows and operation rules. The CIM Framework enables, but does not define, workflow and business logic to drive component behavior, nor does it define user interfaces (including decision support and reporting). Workflow, business logic and user interface are considered use-specific and thus outside an industry consensus standard. In addition, the CIM Framework specifies application interfaces to the MES functions, but does not specify the implementation of those functions.

6.4.15 *What Is in the CIM Framework Specification*

6.4.15.1 This section provides additional information about the CIM Framework suite of documents. A brief description of each document is given below.

6.4.15.2 *Specification for CIM Framework Domain Architecture (this document)*

- Contains introductory information and an overview of the CIM Framework specifications.
- Specifies the functional partitioning and functional responsibilities of CIM Framework components.
- Specifies common architecture patterns that functionally integrate CIM Framework components.
- Provides graphical and textual specification notation conventions for all CIM Framework components.
- Provides citations for related specifications or documents referenced within the CIM Framework.

6.4.15.3 *SEMI E96, Guide for CIM Framework Technical Architecture*

- documents the CIM Framework component interoperability architecture based on distributed computing standards including OMG CORBA® and Microsoft DCOM.

6.4.15.4 Additional documents detail the CIM Framework specifications. The document structure will reflect the functional partitioning of the domain architecture. Except for reorganization, the details will remain substantially the same as contained within the CIM Framework Blue Ballots with some requested extensions. The structure of these documents has been influenced by SEMATECH's CIM Framework Specification [CIMFW]. These companion documents represent the actual specification; whereas this document serves primarily as their introduction.

7 Requirements

7.1 This section specifies the functional requirements of CIM Framework components. It establishes a functional partitioning of CIM Framework components and it defines functional architectures for resource tracking and maintenance and for factory control. It also establishes the graphical and textual notations required to specify the CIM Framework components. The list below is a short overview of this section.

- Global and Abstract Definitions Group
- Factory Services Group
- Product Management Component
- Durables Management Component
- Consumables Management Component
- Specification Component
- Factory Operations Component
- Scheduling Component
- Equipment Tracking and Maintenance Component
- Production Machine Component
- Recipe Management Component

- Advanced Process Control Component
- Material Transport and Storage Component
- Factory Labor Component

7.2 *Functional Partitioning*

7.2.1 This section overviews the functional responsibilities of the CIM Framework domain components. Details of the responsibilities are specified in the individual CIM Framework domain component specifications.

7.2.2 The domain component responsibilities cover two types of functions:

- Build-time, or configuration aspect of manufacturing systems engineering in Figure 4, which defines and configures the specific entities in the component, such as the specific machines and their state models or the wafer carriers and their initial locations.
- Run-time, or the execution aspect of manufacturing operations in Figure 4, which executes the component behaviors, maintains inter-component relationships, maintains component state and history and provides run-time access to component state and behavior.

7.2.3 The initial CIM Framework domain standards do not address the build-time functions of the components. These will be added as the standards move from provisional status to full standards. However, this functional partitioning section does identify build-time responsibilities, permitting these build-time functions to be properly allocated to the correct component as the CIM Framework evolves.

7.2.4 The components partition CIM Framework functionality. The components are designed to be exclusive: no functionality exists in more than one component. The only exception is that there are some cross-system functions that are used, specialized or implemented by most or all of the other components. These cross-component domain functions are in separate groups, called Global and Abstract Definitions Group and Factory Services Group.

7.2.5 The list of responsibilities for a complete MES solution is far more than the responsibilities of the CIM Framework components. The CIM Framework focuses on those functions that serve to integrate applications. Suppliers and users will provide functional responsibilities in addition to the standard responsibilities. The CIM Framework component responsibilities are also limited by focusing the scope of the CIM Framework on the run-time needs for wafer fabrication MES but to not cover the full scope of CIM solutions for the full semiconductor manufacturing process.

7.2.6 Sections 7.2.7 through 7.2.20 present the responsibilities for each of the CIM Framework components and the groups. Example terminology specific to semiconductor manufacturing is provided for clarity. It does not preclude application specialization for other industries.

7.2.7 *Responsibilities of Global and Abstract Definitions Group*

7.2.7.1 The Global and Abstract Definitions group (defined in SEMI E97) specifies the definitions of abstract data types and abstract interfaces used throughout the CIM Framework. These specifications are separated into a distinct group to enable them to be specified once and then logically included or inherited wherever they are subsequently needed.

7.2.7.2 *Global Definition Responsibilities*

- Provide type definitions for common data structures to ensure consistent representation. These items include data types for common concepts such as coordinates, priorities, timestamps, and sequences of basic data types.
- Provide type definitions for representations of historical occurrences.
- Provide definitions for common exceptions used consistently throughout the CIM Framework.

7.2.7.3 *Abstract Interface Responsibilities*

- Material architecture: the functions common to identifying, grouping, moving, locating and tracking material in the factory. The architecture is specialized for product material, durables and consumables. See Section 7.3.2.
- Factory resource architecture: the functions common to defining, organizing, tracking usage of and maintaining factory resources including equipment, sensors, durables, and people. See Section 7.3.3.
- Job architecture: the functions common to creating, executing and managing work in the factory. The job architecture is specialized for material processing jobs, material transport jobs, resource maintenance jobs and factory jobs that drive product material through their process flows. See Section 7.3.4.

7.2.8 *Responsibilities of Factory Services Group*

7.2.8.1 The Factory Services group (which is not actually a component) specifies domain facilities to support all domain components. The components can separately implement these facilities for their own use, they can share a common facility across components, or use a combination of separate and shared implementations.

7.2.8.2 *Services in Factory Services Group*

- Document management and version management: functions common to creating, storing, retrieving, and changing (under change control and version management) documents such as process recipes, process flow specifications, and maintenance specifications.
- Event broker: support for components to publish, subscribe to and filter events.
- Access security control: support for components to limit access of system functions to authorized users and applications.
- Component management: functions for CIM Framework component registration, start-up, shutdown, etc.
- History: supports the ability of factory objects to configure and maintain histories (time-based sequences of data and events) and to support access to those histories.
- Data collection: the functions common to data collectors, including equipment, sensors, and manual data entry.

7.2.9 *Responsibilities of Product Management Component*

7.2.9.1 The Product Management component captures the state of all product material (work in progress). For wafer fabrication, this includes wafer and die-level tracking to support multiple products on a single wafer and to track known-good-die through wafer probe. The component also tracks engineering wafers and test wafers, even though they may not become “product.” The component implements the common material architecture functions so product material can be identified, grouped (product groups, lots, process groups, transport groups), moved and located in the factory.

7.2.9.2 *Build-time Responsibilities of Product Management Component*

- Configure inventory regions.
- Configure product tracking histories, including what data to store and data archival mechanisms.

7.2.9.3 *Run-time Responsibilities of Product Management Component*

- Record and support access to current and historical product information, including:
  - Where material is (and has been) in its process flow.

    NOTE 2: The decision to advance material along its process flow is in the Factory Operations component.
  - Product state (processing, on hold, scrapped, etc.).
  - Material type (product, engineering, filler, etc.).
  - User-defined product information.
  - Genealogy, batching, allocation to product requests, the number of times reworked, etc.
  - Historical information on what equipment processed the material, when, with what process flow specification, recipe and durables, and by what operator.
  - Relations and history to related information in other components, including material location, material container, process flow specification, inventory region, process run data, recipe, etc.
- Notify other components of material information changes.
- Support creation, maintenance and historical recording of product groups and relationships among product groups (such as lots, transport groups and process batches) including splits and joins (and resulting product genealogy), experiments (planned future splits and processing changes), hold, rework, etc.

  NOTE 3: The decision to split, join, batch, move, rework, etc. is a responsibility outside of the Product Management component. Product Management records the results of the decisions.
- Record and support access to material location at multiple levels of detail: an area, a specific machine, a specific load port on a machine, a specific zone in a stocker, a specific wafer slot in a carrier, or a specific wafer coordinate of a die.
  - Including reference to material containers (cassettes, pods, etc.) holding the product (the containers are managed by the Durables Management component).

    NOTE 4: Material location is served by the Product Management component and the Material Transport and Storage component. The Material Transport and Storage component is responsible for physically moving material and recording its location, and the

Product Management component is responsible for keeping its material location consistent with Material Transport and Storage material location information.

- Account for and track material loss.
- Support inventory regions: monitor, report and capture history of material movement through physical and logical regions of the factory.

7.2.10 *Responsibilities of Durables Management Component*

7.2.10.1 The Durables Management component manages the durable resources used in wafer manufacturing, including material containers (cassettes, SMIF pods, etc.), reticles, fixtures, test probes, etc. The component implements the generic resource tracking and maintenance architecture specialized for durables. The component also implements the common material architecture behavior so durables can be identified, grouped and located in the factory.

7.2.10.2 *Build-time Responsibilities of Durables Management Component*

- Define the specific durables in the factory (the inventory of carriers, reticles, etc.).
- Define inventory regions that track the use and movement of various durable types in a factory (for example, the reticles assigned to and existing in a lithography bay).
- Define relationships between durables and the process steps that use them.
- Define maintenance tasks for durables and what triggers them.

7.2.10.3 *Run-time Responsibilities of Durables Management Component*

- Track durable attributes (location, usage, contamination exposure, etc.) and state (available, not available, in use, etc.).
- Maintain relations between durables and other CIM Framework objects (such as product material contained in a wafer carrier, the reticles in a reticle carrier, the process step a reticle is used for, etc.).

  NOTE 5: The Material Transport and Storage component has some responsibility for managing material containers, such as to move and allocate empty pods, gas purge and clean pods, etc.

- Maintain, report and record history of durable attributes, state and relations.
- Support assignment of durables to factory jobs (e.g. supporting the scheduling of a reticle for use in a production machine job) and monitor and record job progress (from the perspective of the durable's role).
- Monitor durable maintenance triggers (such as excessive exposure to contaminants) and recommend durable maintenance jobs.
- Execute triggered durable maintenance jobs.
  - Change durable capabilities.
  - Execute durable maintenance jobs (pod cleaning, reticle inspection and repair, etc.) and report job progress.
  - Record durable maintenance triggers and job results in resource maintenance histories.
- Collect and report durable utilization and effectiveness measures.

7.2.11 *Responsibilities of Consumables Management Component*

7.2.11.1 The Consumables Management component manages consumable materials, including gases, chemicals, etc. The component implements the generic resource tracking and maintenance architecture to track consumable usage and quality (e.g., expired resist) and to enable maintenance based on replenishment levels and quality expiration. The component also implements the common material architecture behavior so consumables can be identified, grouped and located in the factory.

7.2.11.2 *Build-time Responsibilities of Consumables Management Component*

- Define the specific consumables in the factory (the types of gases, chemicals, etc.).
- Define inventory regions that track the use and movement of consumable types in a factory (for example, the equipment fed by a common gas bottle and feeders).
- Define relationships between consumable types and the process steps that use them.
- Define maintenance tasks and triggers for testing the quality of and replacing consumables.

7.2.11.3 *Run-time Responsibilities of Consumables Management Component*

- Track consumable attributes and state (supplier's lot number, quantity available, usage rate, expiration date, etc.).
- Maintain relations between consumables and other CIM Framework objects (the product groups a particular consumable was used on, the equipment fed by a common gas bottle, etc.).

- Maintain, report and record history of consumable attributes, state and relations.
- Support assignment of consumables to factory jobs (e.g., the scheduling of a gas feed pressure for use in a production machine job) and monitor and record job progress (from the perspective of the consumable's role).
- Monitor consumable maintenance triggers (quality checks and replenishment levels) and recommend consumable maintenance jobs.
- Execute triggered consumable maintenance jobs.
- Change consumable capabilities.
- Execute consumable maintenance jobs and report job progress.
- Record consumable maintenance triggers and job results in resource maintenance histories.
- Collect and report consumable utilization and effectiveness measures.

7.2.12 *Responsibilities of Specification Component*

7.2.12.1 The Specification component supports definition and use of process specifications, product specifications and bill of materials. Process specifications define process flows (the process steps to manufacture a product, along with supporting material movement, advance process control, equipment maintenance and other tasks). Product specifications relate product types to the process flows to build them.

7.2.12.2 The CIM Framework does not specify a fully-detailed representation of process flows. At run-time, it views a specification as a current operation (the Process Flow Context) and a view of potential next steps (the Process Flow Iterator). Although a complete MES solution must build and provide process flow details, the CIM Framework standard does not require this detail for component integration.

7.2.12.3 Recipes, process capabilities, maintenance specifications, document management and version control services are the responsibilities of other components. The Specification component references and uses these services.

7.2.12.4 *Build-time Responsibilities of Specification Component*

- Build process operation specifications.
  - Specify a processing step as a relationship between a combination of recipes, data collection plans, advanced process control strategies, process capabilities, processing constraints (timing dependencies, contamination constraints, qualified machines, etc.), operator qualifications, durables, consumables and other elements.

    NOTE 6: At run-time, a process operation specification is fully bound to create a process operation (a specific machine is selected, recipe parameters are set, specific support resources are named, etc.).
- Build manufacturing process flows.
  - Specify a process flow as a combination of material processing steps, material movement tasks, equipment qualification and maintenance tasks and other tasks.

    NOTE 7: Process flows are primarily a combination process operation specifications, but the process flow should allow inclusion of explicit steps for material movement, metrology, equipment calibration, etc.
  - Define process flow traversal logic (rework decisions, metrology sampling decisions, alternate path decisions, parallel assembly routes, etc.).
    - preconditions for beginning a step.
    - postconditions for completing a step.
    - logic to enable selecting appropriate next steps.
  - Support recursive (nested) composition of simple process flows (partial flows or mini-flows) into complex process flows.
- Support a library of configurable, reusable process operation specifications and process flows.
- Build product specifications.
  - The process flow to build the product.
  - Product-specific run-time parameters.
    - Reticle and other required resources.
    - Quality/metrology sampling plans.
    - Required manufacturing technologies.

      NOTE 8: This is not a full product specification. It is only those elements needed to select and initialize the manufacturing process.
- Define and maintain relationships between process flow specifications and product specifications which use them.
- Use document and version management for specification change control.

7.2.12.5 *Run-time Responsibilities of Specification Component*

- Create a fully-bound process operation from a process operation specification.
- Create a Process Flow Context (PFC) from a product specification (create the initial process flow for a product).

  NOTE 9: The PFC is the "pointer" marking the current step in a process flow.

- Transition the PFC from the current process operation to the next process operation in the flow (move along the process flow).

  NOTE 10: The decision to move is the responsibility of other components. The Specification component records the decision.

- Create a PFC from an existing PFC (for example, to support splitting of a product group).
- Create a Process Flow Iterator (PFI) from a product specification (create an initial process flow iterator for a product).

  NOTE 11: The PFI is a process flow navigation aid to look ahead or look behind at steps in a process flow without actually incrementing the PFC. This allows scheduling and other functions to determine what steps are possible and to use processing history in determining what steps to take next.

- Create a PFI from an existing PFI (for example, to support evaluating among alternatives).
- Use the PFI to traverse forward and backward through a process flow.
  - Using the results of executing process flow traversal logic (the factory job control or process job control does the actual execution of traversal logic to decide among alternate paths).
- Provide query support for the contents and relationships of process operation specifications and process operations.
- Maintain relationships of active process flows to the factory jobs, production machine jobs, and transport jobs that are implementing the process flow.
- Maintain relationships of active process flows (process flow contexts) to product groups (e.g. process groups, transport groups, etc.) and product group histories for recording the results of executing process flow steps.
- Maintain relationships of process flow specifications to process capabilities and process resources.
- Support effectivity changes to process flows and process operation specifications (if the process flow version changes for the current product group on the flow, be responsive to those changes).

7.2.13 *Responsibilities of Factory Operations Component*

7.2.13.1 The Factory Operations component provides support for maximizing factory effectiveness through efficient use of factory resources to satisfy product demand and planned objectives. Examples of overall factory effectiveness measures are on-time delivery, profit margin, profit rate, cost per wafer, yield, overall equipment effectiveness, cycle time, etc. The Factory Operations component also provides the interface to the enterprise planning systems to commit the factory to fulfill product requests and to communicate factory capacity and production capability to enterprise planning. The product requests also provide a placeholder for order information (such as quantity, due date, priority, etc.) and are part of the link to material tracking at the enterprise level. Given the factory-wide scope of Factory Operations, this component owns the overall factory resource model of machines, areas, inventory regions, etc.

7.2.13.2 Factory Operations may not have exclusive responsibility for maximizing all factory objectives. The Production Machine component maximizes the use of process resources (chambers, internal storage, production batching, etc.), the Material Transport and Storage component maximizes the use of transport and storage resources (transport vehicles, transport paths, storage locations, etc.), the Equipment Tracking and Maintenance component maximizes equipment availability and capability, etc. The business logic and decision-making methods may be distributed to improve overall enterprise effectiveness (Enterprise functions), overall factory effectiveness (Factory Operations functions) and overall equipment effectiveness (Production Machine, Material Transport and Storage and other functions). The CIM Framework provides flexibility, enabling the spectrum from centralized, enterprise-wide or factory-wide operations to distributed, resource-focused operations with coordination to achieve factory-wide effectiveness. The CIM Framework Job Architecture is critical to enabling this flexibility (see Section 7.3.4).

7.2.13.3 *Build-time Responsibilities of Factory Operations Component*

- Define the factory model of resources (machines, people, durables, etc.), areas (bays, lines, cells, etc.), and inventory regions (see Section 7.3.3 for a description of the factory model of resources).

- Define the (initial or nominal) capabilities of the factory and area resources, including factory capacity, area capacity and process capability (detailed capabilities of the machines, people, etc. are the responsibility of other components).

7.2.13.4 *Run-time Responsibilities of Factory Operations Component*

- Dynamically receive product requests (from the enterprise or internally) and map them to product work-in-progress and planned material release (lot starts).
  - Associate material to a process flow (in the Specification component) for the product.
  - Consolidate product demand in the factory.
  - Request Factory Jobs or modify existing Factory Jobs to drive material through its process flows, in response to product requests.
    - New Factory Jobs for new material release,
    - Modify existing Factory Jobs (and associated material model and assigned process flow) for assigning new or modified product requests to material in process.
  - Set or modify product material quantity and due date(s) and other scheduling support information (such as priority and planned profit margin).
- Execute Factory Jobs to drive material through its process flow, using scheduling and dispatching services of the Scheduling component and requesting work from Production Machine, Material Transport and Storage, Equipment Tracking and Maintenance, and Factory Labor components.
  - Based on factory state (material process state, material due date and priority, material location, equipment state, equipment process capability, operator availability and qualification, etc.) and where the material is in its process flow, request and track Production machine jobs, transport jobs, maintenance jobs and other jobs that implement and enable the process steps in the process flow.
  - Based on success, failure or partial failure of production machine jobs and transport jobs, and based on metrology results and other information, determine the next activities for material and factory resources. This may include splitting or joining product groups, scrapping material, downgrading or changing the product type of material, and other actions responsive to job performance and resource availability. Once split, scrap and other decisions are made, Factory Operations may use scheduling utilities to select the next activities for the material and resources.
- Record and report factory job status and decisions in factory job histories.
- Report status and progress on enterprise product requests.
- Manage assignment of human resources to other factory resources.

7.2.14 *Responsibilities of Scheduling Component*

7.2.14.1 The Scheduling component supports Factory Operations, Material Movement, Production Machine and other components by ordering, in time, jobs that process material on equipment, move material, maintain equipment, etc. The scheduler uses knowledge of product demand, equipment and material state, process flows, throughput bottlenecks, operational policy and constraints, and other information to recommend jobs that maximize effective utilization of factory resources to satisfy product demand and planned objectives.

7.2.14.2 The CIM Framework specifies a dispatching function to support Factory Operations. Dispatching provides an answer to questions of the form, "What is next for this material or resource?" The answer may be based on any number of current or future constraints and objectives, but the dispatcher does not typically define a sequence of jobs projected into the future. Scheduling functions in the Scheduling component provide this future job sequencing function. Separate scheduler and dispatcher utilities can also provide resource-focused utilities, such as scheduling of process resources within a production machine or scheduling of material transport and storage resources and internal material movements within the factory-wide material transport and storage system.

7.2.14.3 *Build-time Responsibilities of Scheduling Component*

- Configure scheduling and dispatching decision mechanisms (for example, define scheduling goals and constraints, rules for resolving conflicting constraints, etc.).

7.2.14.4 *Run-time Responsibilities of Scheduling Component*

- Monitor resource and material state and apply scheduling and dispatching decision mechanisms to recommend the next task (dispatching) or a sequence of tasks (scheduling) for factory resources.

7.2.15 *Responsibilities of Equipment Tracking and Maintenance Component*

7.2.15.1 The Equipment Tracking and Maintenance component implements the Factory Resource architecture (see Section 7.3.3) specialized for production equipment (process and metrology tools and material handling and storage equipment).

7.2.15.2 Note that the machine is the software representation of physical equipment and should reflect the state of that equipment. The functionality can be implemented within the equipment, within the MES, or in a separate system such as a cell controller, station controller or equipment integration solution.

7.2.15.3 *Build-time Responsibilities of Equipment Tracking and Maintenance Component*

- Configure production machines as a combination of, or relationship to, process resources (such as process chambers) and support resources (loadports, add-on sensors, internal material buffers and transport, etc.).
- Configure material handling resources as a combination of transport machines and storage machines and relations to support resources (loadports, add-on sensors such as automatic material identification, etc.).
- Configure equipment state models compatible with SEMI E10 (at the machine level and/or at the machine resource level).
- Configure (initial or nominal) production machine capabilities.
- Configure the (initial) recipe namespaces that production machines use and manage.
- Configure the (initial) material locations that material transport equipment is able to reach and the locations it is authorized to reach.
- Define equipment maintenance tasks and what triggers them.
  - Tasks: repair, calibration, qualification, etc.
  - Triggers: failures, usage, elapsed time, need by another related maintenance task, etc.
- Use document management and version control for maintenance specification change control.

7.2.15.4 *Run-time Responsibilities of Equipment Tracking and Maintenance Component*

- Track the equipment state and update the machine state, accordingly.
  - Keep the machine state model current.
  - Report and record equipment and machine state changes, alarms and events in machine history.
  - Support query of machine state and history.
  - Update machine and machine resource process capabilities to reflect machine state and capability and machine assigned capabilities.
- Drive the equipment to a requested state.
- Collect and report machine performance according to SEMI E58 and other utilization and effectiveness measures.
- Monitor equipment maintenance triggers.
- Execute and monitor triggered maintenance jobs.
  - Update equipment state and resource capability (before and after maintenance).
  - Recommend maintenance jobs for scheduling.
  - Execute maintenance jobs and report job progress.
  - Record maintenance triggered and maintenance job results in equipment maintenance history.
- Manage the relationships between production machines that have specific process capabilities and process flows that need specific process capabilities.
- Manage the material locations that material transport equipment is capable of reaching and is authorized to reach.

7.2.16 *Responsibilities of Production Machine Component*

7.2.16.1 The Production Machine component supports execution of production machine jobs on process equipment and interaction with material handling equipment for material input/output at the machine. The functionality can be implemented within the equipment and/or in a separate system such as a cell controller, station controller or equipment integration solution.

7.2.16.2 *Build-time Responsibilities of Production Machine Component*

7.2.16.2.1 Note that the configuration of the machine is the responsibility of the Equipment Tracking and Maintenance component.

7.2.16.3 *Run-time Responsibilities of Production Machine Component*

- Initiate and execute production machine jobs to perform specific process operations (and recipes) on specific material (process groups). Here are the steps to initiating and executing production machine jobs:

  1) Validate the production machine job: compatibility and availability of the material in the process group, process capability of the equipment, proper machine state, valid and available recipe or process specification, necessary operator skills, etc.

  2) Equipment setup: recipe download and select, launch advanced process control (APC) calculation, make operator and APC-recommended adjustments, configure equipment and sensors according to data collection plans.

  3) Initiate processing.

  4) Monitor process operation:

    - Collect process run data from equipment, add-on sensors and operator entry according to data collection plans.
    - per machine and per process resource.
    - Store in process run histories.
    - Event management: capture, interpret, record and respond to equipment events, fault detection events and other process anomalies.
    - Monitor equipment operation and state (from the equipment tracking and maintenance component) as another source of information on process operation.
    - Generate MES-level (machine) events and alarms.
    - Track material within machine and record with process run histories and product histories.

  5) Complete processing.

    - Execute post-processing tasks for the process operation.
    - Generate job completed events and invoke "inform job completed" method on job requestor.

- Sequence steps between machines and machine resources (for that sequence logic that is not covered by embedded equipment control).
- Implement recipe control and recipe agent functionality as defined in SEMI E42 - Recipe Management Standard. Integrate with factory-level recipe namespace functionality in the CIM Framework Recipe Management component.
- Job accountability: account for and report material yield loss in material management component and equipment productivity loss in equipment tracking component.
- Interact with Material Transport and Storage component and loadport for material hand-off handshake protocols.
- Manage and monitor equipment when idle.

7.2.17 *Responsibilities of Recipe Management Component*

7.2.17.1 The Recipe Management component provides a capability for applying machine recipes across the factory. Recipes for multiple machines of the same process capability using the same recipe syntax are managed by specializing the recipes based on specific machine settings. The Production Machine component is responsible for merging the recipe with machine-specific data and run-time data (such as Advanced Process Control component recommendations for recipe settings) into an executable recipe and for downloading it to the equipment or selecting and modifying it in the equipment. The Recipe Management component also works with Recipe Executors and Recipe Agents (terminology from SEMI E42) implemented in the Production Machine component, in the equipment, or elsewhere.

7.2.17.2 *Build-time Responsibilities of Recipe Management Component*

- Build process recipes.
  - Generic.
  - Specific to a machine type (same process capability and recipe syntax).
  - Including identification of variable parameters in recipe.
  - Use document management and version control for change management and effectivity.
- Define, configure and initialize recipe namespaces.

  NOTE 12: Including this responsibility under "build time" does not imply that all recipes are built at MES system build time. Recipes may be built after the MES system is running.

7.2.17.3 *Run-time Responsibilities of Recipe Management Component*

- Work with Production Machine component and other recipe controllers to select, download and modify recipes.
- Implement resource effectivity control (manage when and to what material and machines to apply recipe changes).

7.2.18 *Responsibilities of Advanced Process Control Component*

7.2.18.1 The Advanced Process Control component (defined in SEMI E93) supports the Production Machine component execution of production machine jobs by optimizing machine-specific settings for the current material and machine state to achieve desired process effects. It also detects faults in processing and recommends an appropriate response to the Production Machine component. Advanced Process Control strategies can include statistical process control, model-based process control, multi-variate analysis, trace analysis, fault pattern matching, or any other appropriate mechanism. The internal design of the Advanced Process Control component allows integrating different types of analysis and computation mechanisms and their execution environments into a single control strategy.

7.2.18.2 *Build-time Responsibilities of Advanced Process Control Component*

- Define control strategies and associated sensor processing algorithms, fault detection algorithms and optimal process control algorithms.
- Define real-time control data structures to support control algorithms.
- Define data collection plans to acquire control data.
- Define control strategy selection logic.

7.2.18.3 *Run-time Responsibilities of Advanced Process Control Component*

- Select a control strategy and associated sensor processing and analysis algorithms to optimize processing and detect faults.
- Launch, coordinate and monitor the execution of data collection plans and control processing and analysis algorithms.
- Apply algorithm results to recommend process settings and detected fault response actions (recipe adjustment, equipment shutdown, maintenance, rework, etc.).
- Update control data with algorithm results.
- Update control data with equipment and product material data (current equipment state, material state, process operation, etc.).
- Record and report control strategy and algorithm results and recommendations in process run histories.

7.2.19 *Responsibilities of Material Transport and Storage Component*

7.2.19.1 The Material Transport and Storage component (defined in SEMI E102) supports active and manual material movement and active and passive material storage (active storage: stockers, smart racks, equipment buffers; passive storage: tables, racks). It executes Transport Jobs and interacts with the Production Machine components for material handoff to and from process equipment. The component tracks and reports on material location and material movement history. The equipment configuration, tracking and maintenance functions are the responsibility of the Equipment Tracking and Maintenance component. For complicated interbay and intrabay material transport and storage, there may be multiple instances of the component -- one for each material movement area -- that cooperate to provide factory-wide material movement functions.

7.2.19.2 *Build-time Responsibilities of Material Transport and Storage Component*

7.2.19.2.1 Note that configuration of the material transport and storage equipment and its capabilities is the responsibility of the Equipment Tracking and Maintenance component.

7.2.19.3 *Run-time Responsibilities of Material Transport and Storage Component*

- Support scheduling of material movement and processing by predicting time for material delivery to specific locations.
- Execute and monitor transport jobs to move material groups (transport groups) to specific locations.
    - Validate that the job can be done: the material is available, the destination is reachable and has available storage or loadport capacity, there are sufficient material movement resources (cars, storage space, etc.) to implement the job.
    - Implement the job by scheduling and enacting actions on internal material movement and storage resources (cars, turntables, stocker shelves, etc.).
    - Collect and record data on transport job execution and history.

- Capture, record, interpret and respond to equipment events and fault detection.
- Generate MES-level job status events and material location change events.

- Record and report on material locations and material movement histories for material in the system.
- Interact with Production Machine component and loadport for material hand-off handshake protocols.

7.2.20 *Responsibilities of Factory Labor Component*

7.2.20.1 The Factory Labor component (defined in SEMI E86) implements the generic Factory Resource architecture (see Section 7.3.3) applied to factory personnel resources. It represents personnel, their capabilities (skills) and skill maintenance (training), and their assignment to other factory resources (to machines and areas) and jobs. The Factory Labor component integrates with access security services (in the Factory Services group) to associate personnel with roles, identity authentication (e.g. system login passwords) and access authorization.

7.2.20.2 *Build-time Responsibilities of Factory Labor Component*

- Configure the Person resource model.
  - Each Person's name, identification, department, role, etc.
  - Each Person's initial skills and authorization to perform jobs and access data.
  - Each Person's initial assignment to other factory resources (such as specific machines or factory areas).
  - Each Person's medical qualifications.
- Define skill maintenance tasks and what triggers them.

7.2.20.3 *Run-time Responsibilities of Factory Labor Component*

- Track and report the Person skills, authorization and assignments and record these in Person histories.
- Support assignment of Persons to factory jobs and monitor and record job progress (from the perspective of the Person's role).
- Monitor skill maintenance triggers (such as expired skill certification) and recommend skill maintenance jobs.
- Execute triggered skill maintenance jobs.
  - Change Person capabilities (before and after training).
  - Execute and monitor skill maintenance jobs (training, certification testing) and report job progress.
  - Record skill maintenance triggers and job results in person skill maintenance histories.
- Collect and report person and skill performance (utilization and effectiveness).
- Maintain relationships between persons and system security for identity authentication and authorization.

7.3 *Common Architectural Patterns*

7.3.1 This section documents architecture patterns that serve to functionally integrate CIM Framework components. The material architecture defines functionality common to Product Management, Durables Management and Consumables Management components. The factory resource architecture defines relationships and common functionality of factory resources. The job architecture defines a factory-wide model of controlling factory operations.

7.3.2 *Material Architecture*

7.3.2.1 The Product Management, Durables Management and Consumables Management components all share a common architecture for identifying, grouping and locating materials. Figure 6 illustrates the common material interface architecture.

7.3.2.2 Material has an identification, history, location, inventory region and associations to material containers that may contain it. Material can also be in multiple material groups that physically (same location or carrier) or logically (same lot, same process batch, same product family, etc.) associate material. Specializations of material include products, durables and consumables. Specializations of material groups include product groups, lots, process groups and transport groups.

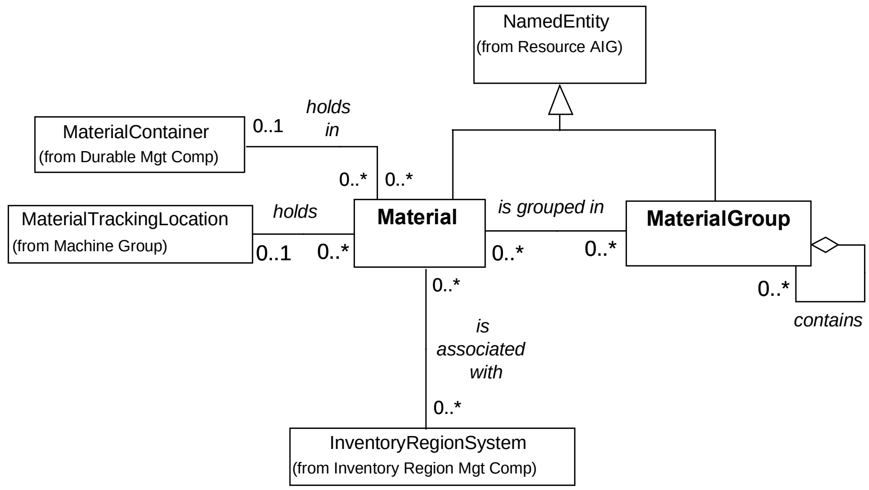

Figure 6
Material Interface Architecture

7.3.3 *Factory Resource Architecture*

7.3.3.1 Factory resources, such as machines, people and reticles, are the entities that participate in transforming material into products. The CIM Framework defines an overall domain architecture for factory resources that supports

- resource tracking and maintenance (resource usage counters, maintenance procedures, etc.),
- hierarchical organization (e.g., a factory is organized into areas which group machines and people),
- composition of resources (e.g., a machine is composed of chambers, load ports and sensors), and
- an object-oriented type structure (transport machines and production machines are types of machines; machines, ports, durables and people are support resources, etc.).

7.3.3.2 This section defines the CIM Framework resource architecture.

7.3.3.3 *Factory Resource Hierarchy*

7.3.3.3.1 A factory is usually viewed as a hierarchy of resources organized in groups, as in Figure 7. Each level or portion of the hierarchy has an associated task scope.

- An enterprise often includes multiple factories. The task of the enterprise is to deliver products to customers.
- A factory is made up of areas and bays with interbay material handling systems. The task of the factory is to manufacture product in response to product requests.
- Areas or bays are made up of processing and metrology equipment with intrabay material handling systems. The task of the areas or bays is to perform a group of process operations on groups of materials, move material to the processing equipment, and perform maintenance and other supporting tasks. For a simple factory, the area level is optional. For a complex factory, there may be multiple area levels, with areas made up of sub-areas.
- Complex processing equipment (such as a cluster tool) is made up of processing chambers and internal material handling and storage resources. The task of the processing equipment is to perform a process or metrology step or a closely related group of steps on a material lot or process group. The task of the processing resource in the processing equipment (such as a chamber in a cluster tool) is to perform a single process step on a single wafer or on a collection of wafers in a process resource group.
- Material handling and transport systems are made up of interconnected stockers, tracks, conveyers, robotic handlers and other material storage and movement equipment. The task of the material handling systems is to store and move materials in transport groups.

- Manufacturing operators and other factory personnel are important resources to facilitate and supervise material processing and handling, preventive maintenance, and in some cases, perform manufacturing steps such as moving material or performing a visual inspection.
- Other factory resources include durables (reticles, cassettes, pods, etc.) and consumables (gases, utilities, etc.).
- The information model in Figure 8 shows the CIM Framework Resource Composition Architecture. The interfaces in the box labeled Resource Abstract Interface Group define the generic resource architecture. In general, resources can be composed of other resources. In particular, at the factory and area levels, Factory can be composed of Areas and an Area can be composed of other Areas. Areas group Support Resources, such as machines and persons. This is not a strict composition so that support resources can be in more than one Area grouping. At the machine level, Machine Resources are composed of other Machine Resources, in general. In particular, Production Machines are composed of Process Resources.

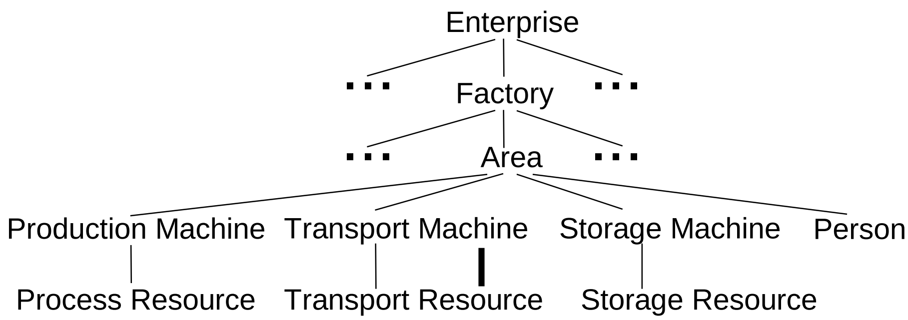

Figure 7
Factory Resource Hierarchy Model

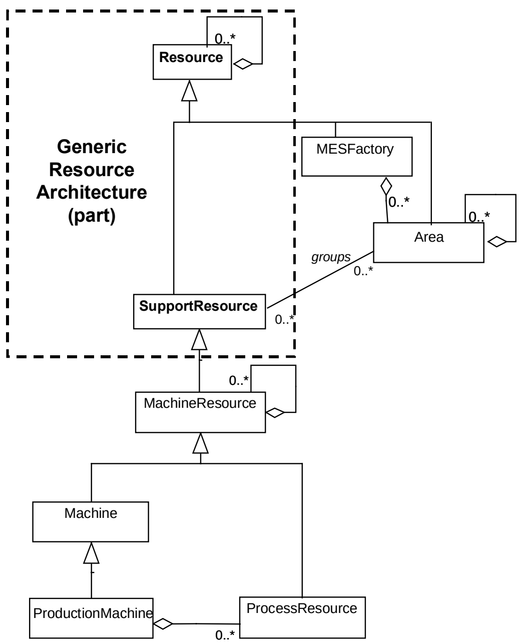

Figure 8
Resource Composition Architecture

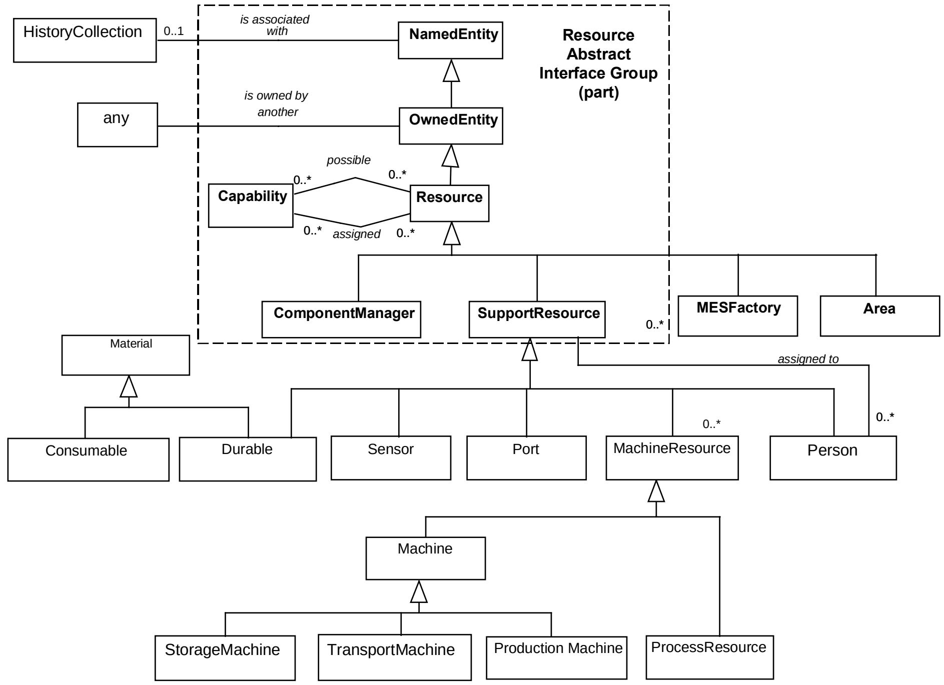

Figure 9
Resource Type Architecture

7.3.3.3.2 Figure 9 shows the CIM Framework Resource Type Architecture. Specializations of these interfaces, such as Machine Resource and Durable, provide component-specific details that extend the generic resource architecture. The functions added at each level of type specialization are discussed next.

7.3.3.3.3 *Named Entity*

7.3.3.3.3.1 The CIM Framework Named Entity interface provides for names and histories to be associated with any CIM Framework entity, including resources.

7.3.3.3.4 *Owned Entity*

7.3.3.3.4.1 The Owned Entity interface provides for resources to be organized into hierarchies.

7.3.3.3.5 *Resource*

7.3.3.3.5.1 The Resource interface provides for

- composition of subresources into complex resources,
- representing resource capabilities (such as capacity or process capability) (See Section 7.3.3),
- a simple state model (available, not available) and services to startup and shutdown the resource, and
- modeling of resource levels as in Figure 7 and Figure 8.

7.3.3.3.5.2 Each Resource has an attribute called resourceLevel to support the factory resource composition hierarchy of Figure 8. The CIM Framework defines the following resource levels: Factory (called MESFactory so as not to be confused with the OMA's object Factory type), Area, Machine and Machine Resource. The Area level is optional, or it may have multiple levels (such as an area called LithoBay with sub-areas called Zone1 and Zone2). Other levels can be defined. The resourceLevel concept, combined with the Named Entity and Owned Entity, also provide a name scoping facility.

7.3.3.3.6 *Support Resource*

7.3.3.3.6.1 The Support Resource interface provides services for reserving resources (to support scheduling, for example) and to track resource utilization and effectiveness and associate maintenance tasks with resources (see Figure 10 and Section 7.3.3.5). The support resources include machine resources, material load ports, sensors, durables and people.

7.3.3.3.7 *Machine Resource*

7.3.3.3.7.1 The Machine Resource interface provides attributes for machine description, serial number, model number, vendor, software version, etc. The interface extends resource composition to provide machine resources as composites of machine (sub)resources and specialized process resources with associated process capabilities. The Machine Resource interface also extends the resource state model to include the states and substates of SEMI E10 and SEMI E58. Specific subtypes of Machine Resource and Machine are possible. The CIM Framework defines the subtypes for Production Machine and Process Resource. Additional subtypes to support Transport Machine and Storage Machine interfaces are also possible if there are additional attributes or behaviors required that Machine and Machine Resource interfaces do not already provide.

7.3.3.3.8 *Port, Sensor, Durable, Consumable, Person, etc.*

7.3.3.3.8.1 The other support resource subtypes provide additional, resource-specific, attributes and behavior. Note that durables are also subtypes of Material so they can be moved and tracked as material. Consumables are not currently considered as resources, but a given implementation of the CIM Framework could have consumables be support resources to track their consumption and replenish them as regular maintenance. Persons are considered support resources to schedule them and associate them with machines and other resources and to have associated "maintenance" schedules for training and certification.

7.3.3.4 *Resource Capabilities*

7.3.3.4.1 Resources have associated capabilities, as Figure 9 shows. Factory operations and scheduling use capabilities to identify resources with the capability to perform a specific task. A CIM Framework capability is represented as a text string, providing flexibility to define types of capabilities appropriate for a variety of resources. For example, an MESFactory resource may have capabilities defined in terms of its capacity and the product families it can produce, and a Process Resource may have capabilities that define its C_{pk} process capability and its throughput.

7.3.3.4.2 The Capability interface maintains a list of Resources which have that specific capability, and the associated Resource interface maintains a list of its overall possible capabilities and the subset of possible capabilities that resource is assigned to perform.

7.3.3.4.3 The Capability interface is specialized for Process Capabilities associated with Process Resources. This provides an association to the Process Operation Specifications a Process Resource can perform and the Process Durables and the person Skills needed to support the Process Capability. Other Resources can specialize the Capability interface.

7.3.3.5 *Resource Tracking and Maintenance*

7.3.3.5.1 Support Resources have an associated resource tracking and maintenance management function, as Figure 10 shows. A Resource Tracking Supervisor for a Resource monitors and records resource usage and status and creates Maintenance Jobs according to Maintenance Specifications. Factory Operations, with the aid of a scheduler or dispatcher, assigns Persons and other support resources defined in the Maintenance Specification and initiates Maintenance Job execution. The Resource Tracking Supervisor then supervises Maintenance Job execution. The Maintenance Job and Resource Tracking Supervisor specialize the Job/Job Supervisor pair as Section 7.3.4.6 describes. The Resource Tracking Supervisor also records appropriate history, such as maintenance logs and resource utilization and state, in the Named History Collection for the Resource (inherited from Named Entity). Resource type-specific specializations of the resource tracking and maintenance interfaces are possible.

7.3.4 *Job Architecture*

7.3.4.1 This section describes the job management and control architecture of the CIM Framework. It defines a hierarchical job supervision and control structure that manages factory-level jobs (create product material to fill enterprise product requests) and implements these factory-level jobs by creating and managing machine-level process jobs and transport jobs, coordinated with maintenance jobs and other support jobs. The job control architecture defines and manages relationships between manufacturing resources (process equipment, transport equipment, people), material groups (lots, product groups, process groups, transport groups) and specifications (product specifications, process flows and recipes). This is the central functional architecture which integrates the CIM Framework components into a coherent manufacturing execution system architecture. The concepts are derived from existing standards and related standards efforts [ANSI], [ALBUS], [OMA], [WfMC].

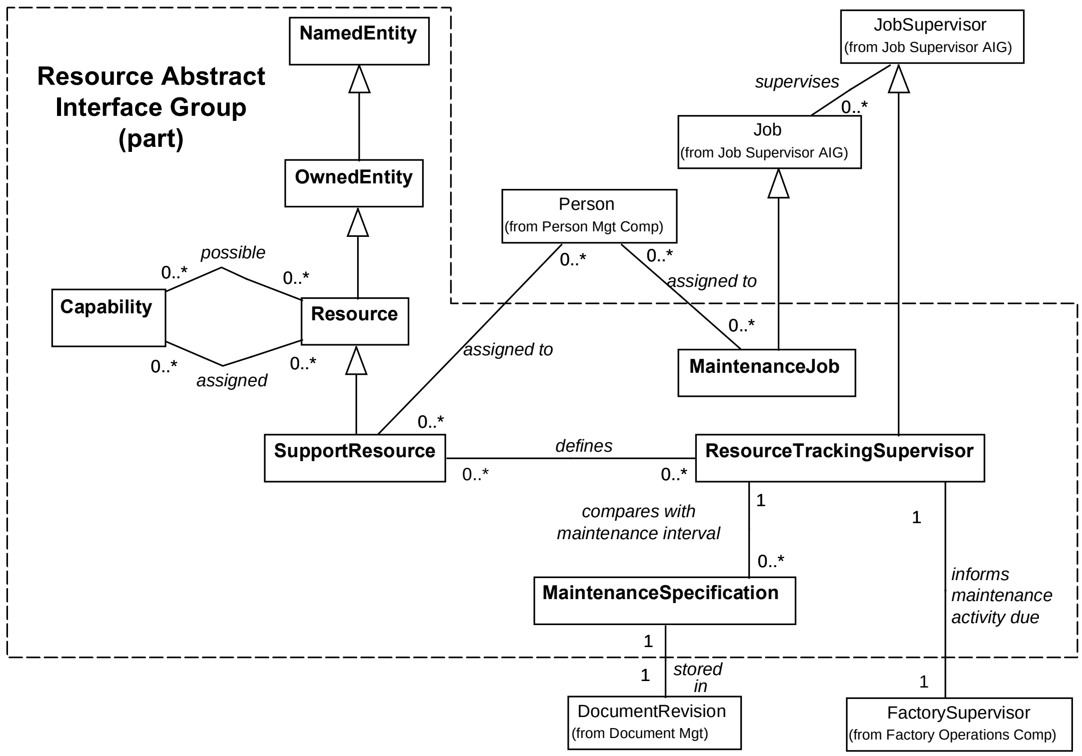

Figure 10
Resource Tracking and Maintenance Architecture

7.3.4.2 *Job Architecture Concepts*

7.3.4.2.1 A job represents a unit of work requested of and performed (or facilitated) by a factory entity that results in some change to the overall factory state. There are several important aspects of a job within the CIM Framework:

- A job typically takes a non-zero time to perform and has a non-zero chance of refusal or failure.
- A job may encapsulate a decomposition into a combination of jobs/tasks/activities.
- There is a notion of higher-level jobs and lower-level jobs. Coordination of lower-level jobs are delegated to other job supervisors to ensure that the higher-level job is completed.
- There is a job requestor.

7.3.4.2.2 The CIM Framework specifies a number of structures for job control. The complexity and variability of the factory requires some organizational structure and separation of manufacturing tasks. Breaking up a complex task into a coordinated interoperation of simpler tasks enables practical solutions to complex problems (the principle of "divide and conquer"). This results in a key organizational structure based on the factory resource hierarchy of Figure 7 and Figure 8 , with the separation of tasks summarized in Section 7.3.3.3. The job control architecture defines how tasks are assigned and coordinated across the hierarchy of factory resources.

7.3.4.2.3 Another key job structure is the relationship between manufacturing tasks and the material and resources used to carry out the task. For example, Factory Operations is responsible for efficiently allocating machine resources with the required processing capability to the material work-in-progress to drive the material through its process flow. A job is a combination of a requested task and the material and resources needed to execute that task (see Figure 13). The relationship between task, material and resource, combined with a hierarchical job structure (based on a hierarchical resource structure) results in complex relationships between tasks, material, and resources at multiple levels.

7.3.4.2.4 Given the complexity, scope and variability (chance of failure or partial success) of jobs, the CIM Framework separates job control into explicit functions.

It does not bury job control into material management functions for driving process flows, nor does it bury job control into machine management functions for driving process operations. The CIM Framework makes job control explicit, providing an architectural structure to attach decision support logic (such as scheduling utilities), business processes (workflow) and business rules that enforce operational policy. Further, the CIM Framework distributes and coordinates job control among factory jobs, production machine jobs, transport jobs, and maintenance jobs. This allows job control to manage "local" complexity while coordinating factory-wide operations toward "global" objectives.

7.3.4.3 *Hierarchical Task Structure*

7.3.4.3.1 At the lowest level of the factory hierarchy (the resource level in Figure 7), the tasks are single process or metrology operations or material movements. Through a complex, context-dependent combination of single tasks, products are manufactured and delivered to customers. This complex combination of single tasks is a task structure as shown in Figure 11. In manufacturing operations, these structures are pre-defined as task procedures, work flows, process specifications, etc. To accommodate manufacturing variability and exceptions, though, the structures must also be adjusted and modified as they are executed. For example, as factory operations selects specific machine resources to perform process steps, it may insert machine-dependent setup tasks and operation sequences, it may modify step specifications (recipes) with machine-dependents settings, or it may insert transport steps to get the material to the machine.

7.3.4.3.2 Notice in Figure 11 that tasks of a higher level are decomposed into combinations of tasks for lower level resources. Each manufacturing resource has a thread of tasks that must be coordinated with the tasks of other resources. The higher level task is completed when the combination of lower level tasks is completed. Figure 11 illustrates this with the coordination of material movement and processing operations and with the coordination of operations within the processing equipment. Resource maintenance, advanced process control calculations and other tasks must also be coordinated with material processing, inspection and movement tasks. The role of job control is to decompose, coordinate, monitor, adjust, and report on this hierarchical structure of tasks.

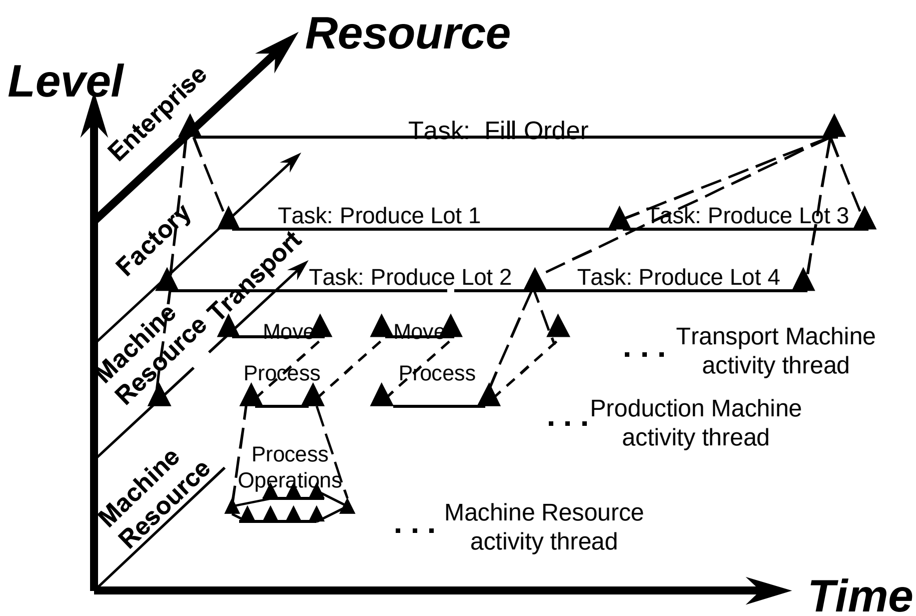

Figure 11
Hierarchical Task Structure

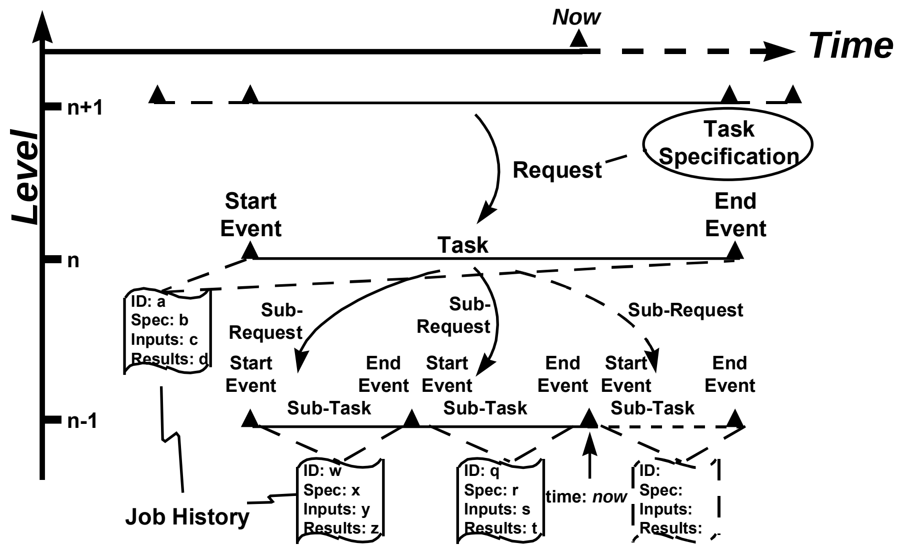

Figure 12
Elements of a Hierarchical Task

7.3.4.4 *Elements of a Task*

7.3.4.4.1 The Hierarchical Task Structure of Figure 11 defines the requirements for a multi-level task model. Figure 12 shows the elements of a hierarchical task, indicating some of the additional data for an overall job control structure. A task is requested from a superior level. Along with the request is a task specification, which is often a template or procedure for how to carry out the task, including a combination of subtasks and monitor and adjustment checkpoints along the way.

7.3.4.4.2 As each task is started, completed, modified or aborted, the job control for the task publishes appropriate events or other notifications. The task endpoints illustrated in Figure 12 as triangles represent factory states or some specific aspect of a factory state. When a task is completed, the factory state is changed in the specified way. For example, after a wafer deposition task, the product state is changed, with a layer of oxide deposited on all the wafers in a lot. When a movement task is completed, the product location state is changed to the load port for a machine to perform the next process operation. These intended factory states often have side effects on other factory states. For example, after a process operation, the equipment state changes to reflect its utilization, consumables consumption, etc. Job control achieves orderly, coordinated, efficient changes to factory state that result in products, that is, that efficiently turn raw wafers into product wafers.

7.3.4.4.3 As the job control executes the task, task results are collected in a job history that includes a job identifier, the (modified) specification used, and recorded inputs and results. Higher level job results could be a roll-up, an abstraction, or simply pointers to lower level job results.

7.3.4.5 *Job Structure*

7.3.4.5.1 A job is a relationship between all the elements necessary to perform a task with specific control functionality to carry out the task in light of manufacturing variability. A job implements a specified task on specified material using specific resources. The job structure of Figure 13 is the relationship mechanism for controlling and changing factory material and resource states and recording job results in associated job histories. That is, the job instantiates and manages the relationships in the structure of Figure 13.

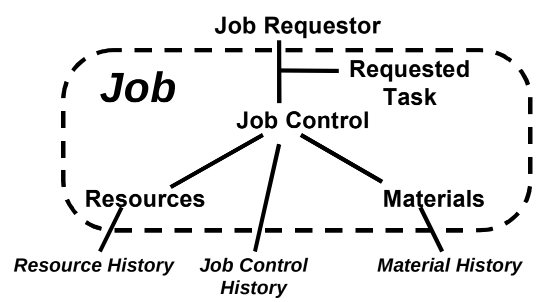

Figure 13
Job Structure

7.3.4.6 *Jobs and Job Supervisors*

7.3.4.6.1 Jobs are transient entities. They are created to perform a task and go away when the task is complete. A job supervisor is the persistent object that responds to job requests by creating jobs. Figure 14 shows an information model for the generic Job Supervision architecture.

7.3.4.6.2 There is a corresponding job supervisor which specializes the generic job supervisor; a Factory Job Supervisor manages Factory Jobs; an Area Job Supervisor manages Area Jobs; and a Production Machine Job Supervisor manages Production Machine Jobs. There is also a Maintenance Job Supervisor and an Advance Process Control job supervisor (the Control Execution Manager in the Advanced Process Control component).

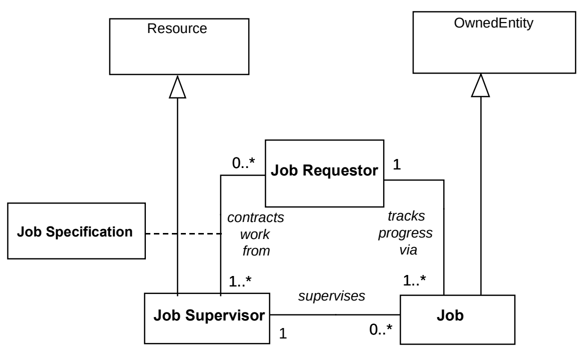

Figure 14
Job Requestors, Job Supervisors, and Jobs

7.3.4.6.3 The entities in Figure 14 are as follows:

- Job.
    - A unit of work that takes time and may fail.
    - Has state (see Figure 15).
- Job Supervisor.
    - Receives requests for work, facilitates creation of a job for the task and returns a reference to that job to the requestor.
    - Manages all jobs within the component that implements it.
- Job Requestor.
    - Requests work.
    - Receives job progress through interface methods (informJobStarted, informJobCompleted, informJobTerminated) and published events.
- Job Specification.
    - Job description (process flow, recipe, transport destination, maintenance spec, etc.).
    - Priority and deadline.

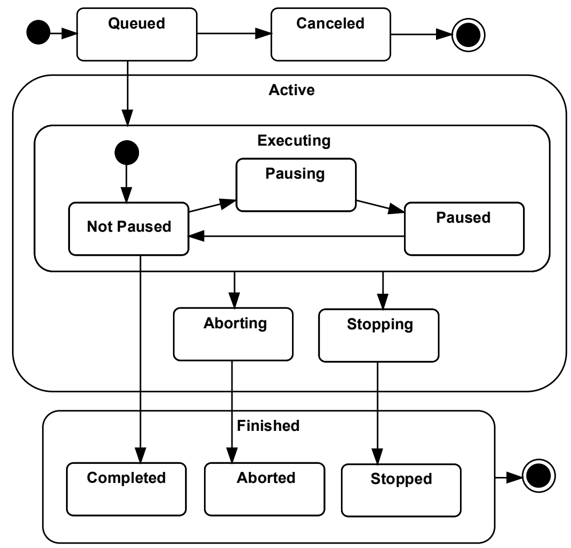

Figure 15
Job State Model (CIMFW)

7.3.4.7 *Job Supervision Design Principles*

7.3.4.7.1 Jobs and Job Supervision are encapsulated within a component. Their interaction and the division of responsibility between them is hidden. At any level, the requestor of activity will request work of a Job Supervisor and receive in return the handle to a Job which represents this work. This requestor will not have visibility to how the Job Supervisor performs the work beyond what is specified in the original activity specification and what is reported later as data. Not visible or accessible are the Job Supervisor's internal and lower-level activity requests (and resulting jobs).

7.3.4.7.2 A job requestor does not micromanage the job. Instead, the job requestor creates a specification of the work to be done and hands it to the Job Supervisor when requesting the work. Once the work request is accepted, the Job Supervisor's component controls the execution of that job within the limitations of the job specification and its business rules. The only exceptions are coarse commands such as job abort or pause. The responsibility of the Job Supervisor and Job is to perform the activity and report back to the requestor on the success or failure of the effort.

7.3.4.7.3 There is no predefined limitation on the facilities within the factory that may be used to satisfy a job request. However, a Job Supervisor may be configured to be limited to specific factory resources that it can call on to perform work.

7.3.4.7.4 The job requestor has an interface so the Job/Job Supervisor can report overall job progress. The Job Requestor interface includes the methods requesting that it be notified that a job has started, completed, or been terminated. The requestor or other components can subscribe to job state change events and other events for a more detailed job status.

7.3.4.7.5 The Job Supervisor interface provides high level information about the jobs it is currently managing. The details of any specific job are provided by the Job itself, not the Job Supervisor. From the Job Supervisor, the Job Requestor is able to

- request activity,
- locate jobs that meet certain criteria,
- request lists of all jobs being performed, and
- control all the jobs as a group (e.g. "abort all jobs"), but not individually (not "abort job X"— this would be a responsibility of the Job interface).

NOTE 13: Much thought should be given to the use of these "all jobs" commands since they can cause a great deal of harm if not designed and used properly.

7.3.4.7.6 The Job interface is the sole source of all public information about a job. It also provides all specific control of the job (pause, abort, etc.).

7.3.4.8 *Hierarchical Job Structure*

7.3.4.8.1 The factory and task hierarchy of Figure 11 and Figure 12 results in a multi-level (hierarchical) job control structure, with a given Job/Job Supervisor requesting work through other (sub)Jobs. As Figure 16 illustrates, higher level job controllers specify and request work from any number of lower level job controllers and monitor job progress through status and external feedback. At the lowest level, job control results in directly manipulating equipment actuators based on real-time sensor feedback. (Note, this lowest level of job control is outside the MES scope of the CIM Framework—it is within the scope of the equipment control.) The job request, status, and feedback information are all candidates for storage in job history.

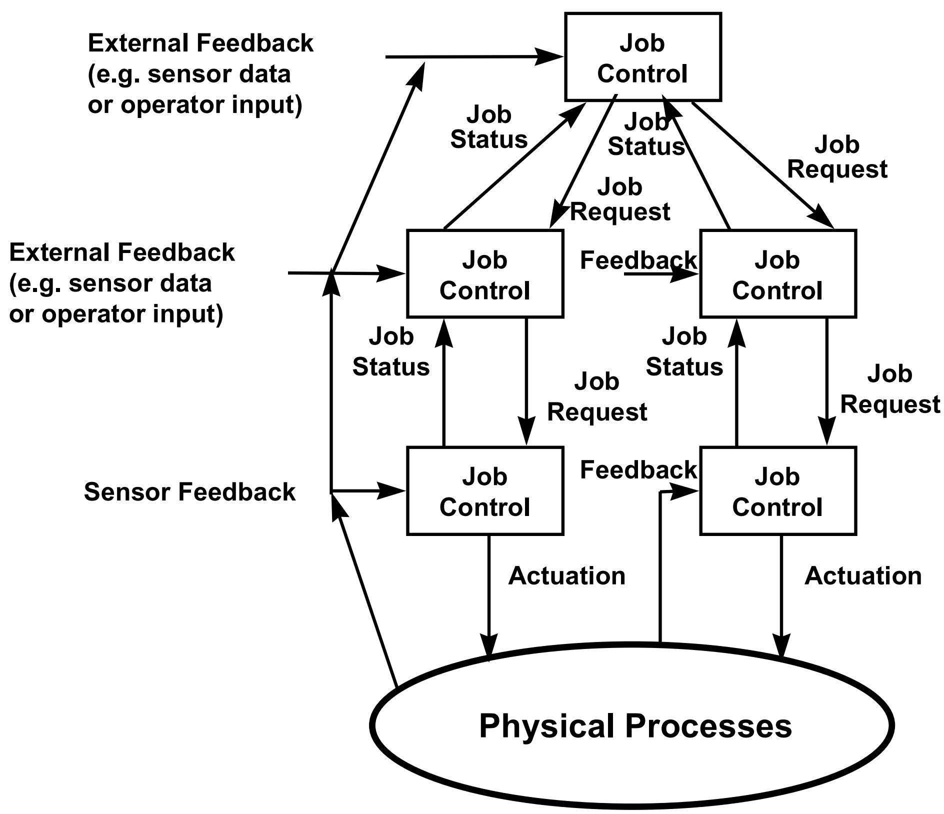

Figure 16
Hierarchical Job Control

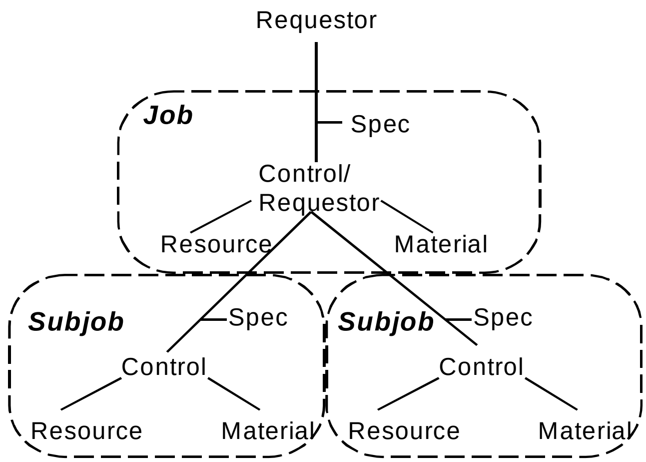

Figure 17
Hierarchical Job Control Pattern

7.3.4.8.2 Placing the job structure template of Figure 13 into the job control hierarchy of Figure 16 results in the hierarchical job control pattern of Figure 17.

7.3.4.8.3 At each level, the job control

- Receives job requests with associated job specifications,
- Decomposes the job into subjobs,
- Defines resource relations between the job and subjob (e.g., selects and schedules resources for subjobs within the scope of the job supervisor, such as machines assigned to an area or process chambers in a production machine),
- Defines material relations between the job and subjob (e.g. how lots are assigned to transport groups and process groups, including decisions on batching, splits, joins, etc.),
- Requests the subjobs and provides associated subjob specifications,
- Monitors subjob progress,
- Reports job progress to the job requestor and other interested functions,
- Records job history.

7.3.4.9 *CIM Framework Job Structure Summary*

7.3.4.9.1 Figure 18 shows the job hierarchy pattern applied to the material movement resources of Figure 7. Figure 19 shows the pattern of Figure 17 applied to the material processing resources of Figure 7 (branching to multiple lower-level resources is not shown). Figure 20 summarizes how the CIM Framework components come together into an integrated manufacturing execution system.

- The product material hierarchy and genealogy is modeled in the Product Management components of the CIM Framework Specification.
- The task specification hierarchy is modeled in the Specification Definition and Recipe Management components.
- The resource hierarchy is modeled in the Factory Operations (for Factory and Area levels), Equipment Tracking and Maintenance, Durables and Consumables Management, and Factory Labor components.
- The control hierarchy is modeled in the Factory Operations (Factory Jobs), Production Machine (Production Machine Jobs), Material Transport and Storage (Transport Jobs), and the maintenance job supervision aspects of the various Resource Tracking and Maintenance specializations (Maintenance Jobs).

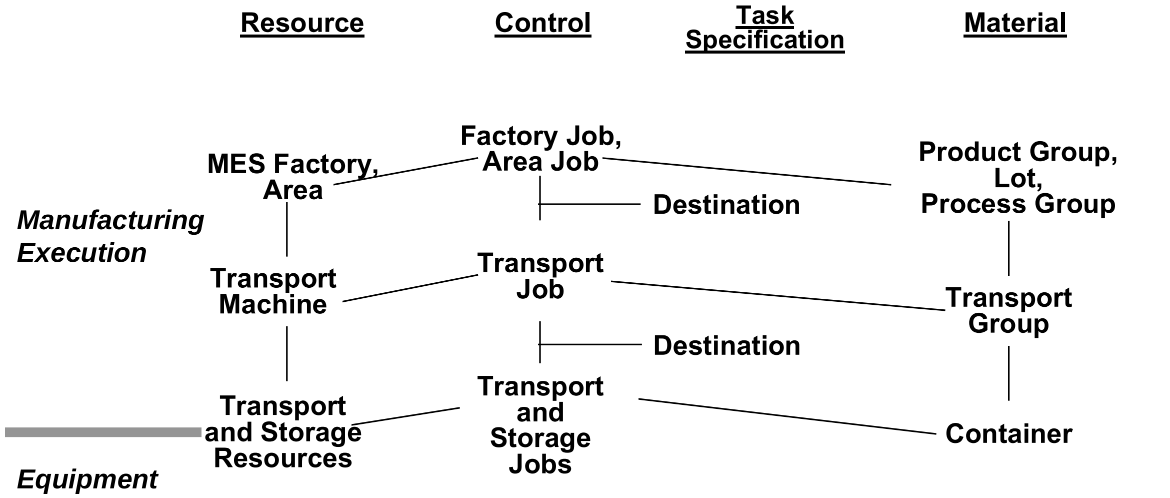

Figure 18
Hierarchical Job Control - Material Transport Aspects

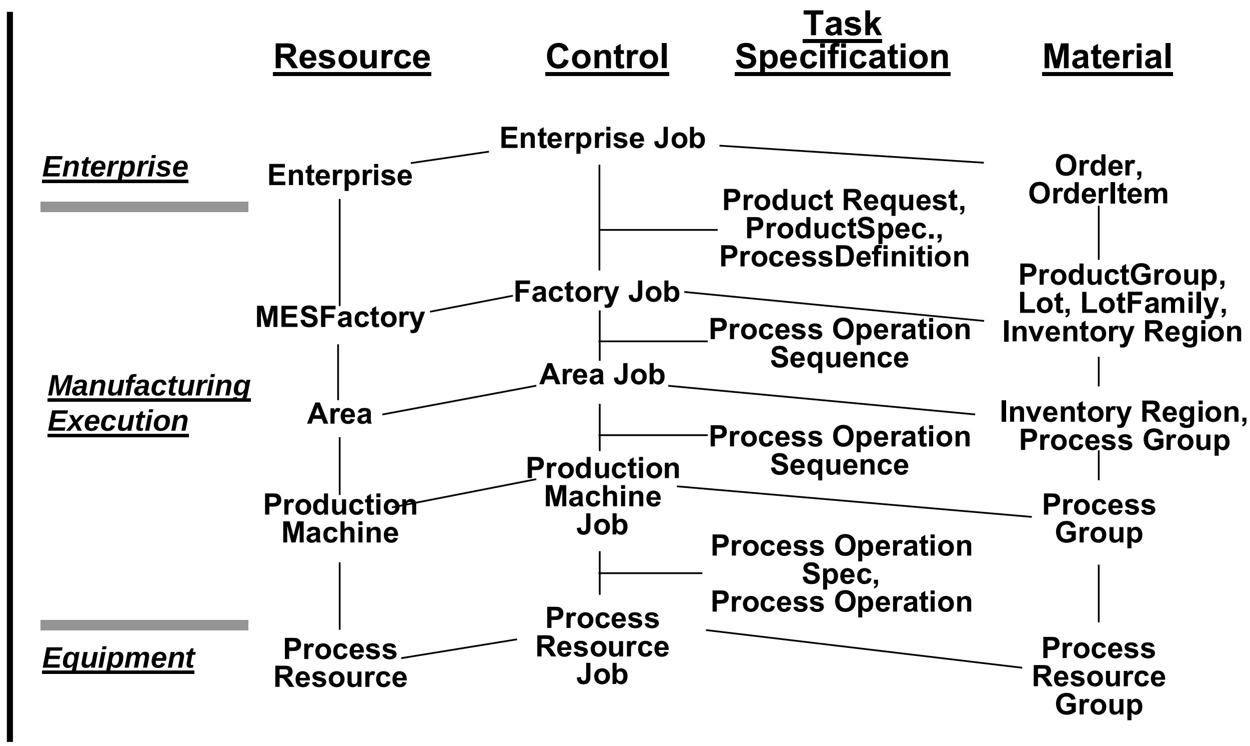

Figure 19
Hierarchical Job Control - Material Processing Aspects

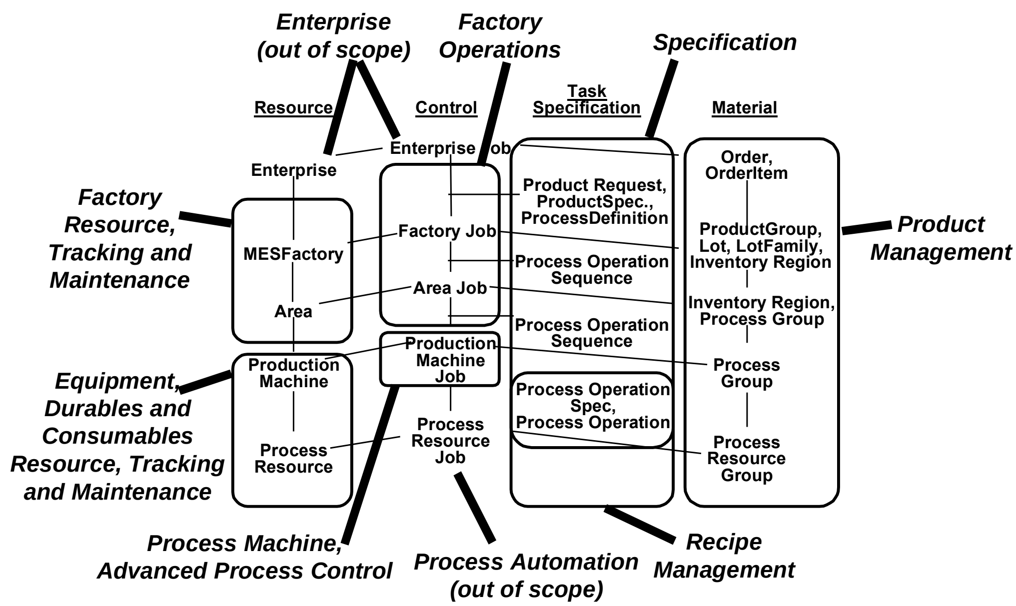

Figure 20
Integrated Hierarchical Job Control

7.3.4.9.2 As Section 7.3.3.3 describes, each of these job control views shows a job supervision function that performs the tasks for each level of the factory resource hierarchy.

7.3.4.9.2.1 Factory Job Supervision: Factory Operations satisfies enterprise product requests. It releases material and creates Factory Jobs which drive material work-in-progress through its process flow. The Factory Job Executor requests, schedules, monitors and coordinates supporting jobs: production machine jobs, transport jobs, maintenance jobs, etc.

7.3.4.9.2.2 Area Job Supervision: This optional level serves Factory Operations and is responsible for multiple machine activities (areas may map to bays, cell controllers, linked lithography, etc.). This level is not required, but is available for organizing large factories. Area job supervision could support factories that have a factory within a factory model with separate but integrated operations management for separate units of manufacturing capacity. It could also support factories transitioning from legacy systems, with parts of the factory under a CIM Framework-conformant MES and other parts under a legacy MES that is fronted or wrapped by a CIM Framework conformant Area Job Supervisor component. Another example could be a factory that provides a pseudo-cluster cell controller to group stand-alone process equipment into an integrated workcell that behaves like a cluster tool. The CIM Framework does not specify separate Area Job Supervision interfaces. These functions are met by the Production Machine Job interfaces with no change—the same interface serves both functional roles. Areas typically receive a sequence of process jobs as a request (implemented by requesting lower-level process jobs and material transport jobs), whereas simple machines usually receive a single process job (implemented through direct interaction with process equipment).

7.3.4.9.2.3 Machine Job Supervision: This level lies within the CIM Framework Production Machine component. It accepts activities that apply to a single Machine. It delegates work directly to the physical equipment, either through some equipment interface driver or directly through the GEM/SECS interface.

7.3.4.9.2.4 Transport Job Supervision: This level lies within the Material Transport and Storage component. It takes requests to move material from one location to another. While the CIM Framework provides for layers of Transport Job Supervisors in a complex interbay and intrabay material handling system, today's typical installation has a single material handling system controller (a single Transport Job Supervisor). Complex production machines with internal material handling and storage may also be Transport Job Supervisors.

7.3.4.9.2.5 Maintenance Job Supervision: Maintenance is a preventive (scheduled) or reactive (repair on failure) activity on specific resources (machines, durables, etc.) using labor resources and materials. Maintenance job progress is reported and tracked and maintenance job history is stored. The generic Resource Tracking and Maintenance component defines the overall maintenance job supervision functions (see Section 7.3.3.5), and the various resource types implement these functions in the Equipment Tracking and Maintenance, Durables Management, Consumables Management, and Factory Labor components.

7.3.4.9.2.6 Advanced Process Control (APC): APC includes lengthy calculation activities that may not succeed and which impact the performance of other jobs. For example, an algorithm may not converge, a sensor may emit bad data, or process recipes and job specifications may be modified. The CIM Framework APC component leverages the overall job architecture, where control strategies and scripts are the job specifications, sensor analysis and control execution environments are scheduled resources, and the state of process specifications (machine settings, modified process flows) are the result of APC job execution.

7.3.4.9.2.7 Enterprise and Process Resource: The job control hierarchy of Figure 19 provides interfaces to the enterprise at the top level and the equipment at the bottom level. The enterprise level is the requestor of work for the factory. Enterprise control is outside the MES functional scope of the CIM Framework. The equipment level is also outside the scope of control of the CIM Framework. It is usually implemented by process controllers embedded in or piggyback on equipment. The equipment level is modeled for the MES to allow process data to be collected and organized for specific equipment resources such as a specific chamber in a cluster tool.

7.3.4.10 *Job History*

7.3.4.10.1 Any entity can have an associated CIM Framework History. The CIM Framework defines some specific named histories, as Figure 21 illustrates. Product-oriented data is captured in production history associated with the material hierarchy and is used, for example, for material traceability and defect analysis. Process-oriented data is captured in process history associated with the job supervision hierarchy and is used, for example, for run-to-run process control. Equipment and other resource-oriented data is captured in resource history associated with the resource hierarchy and is used, for example, for preventive maintenance and warranty tracking.

7.3.4.10.2 As jobs are executed (and possibly broken down into sub-tasks as shown in Figure 12), their results are captured as various types of histories. For example, an Area Job's history may be captured within an InventoryRegionHistory. A Resource Level Job's history may be captured within an E10PerformanceHistory or within a ResourceMaintenanceLogHistory.

7.3.4.11 *Task Specification and Workflow*

7.3.4.11.1 The specification of a task takes various forms. For Factory Jobs, the specification is the process flow defining the process steps to transform material into products. For Production Machine Jobs, the specification is the specific steps in the process flow that this production machine is to perform, along with process recipes. For Transport Jobs, the specification defines the destination location for the material transport group. For maintenance jobs, the specification defines the specific maintenance tasks for the resource. For advanced process control jobs, the specification defines a script that includes the sensor processing and algorithm steps of a control strategy.

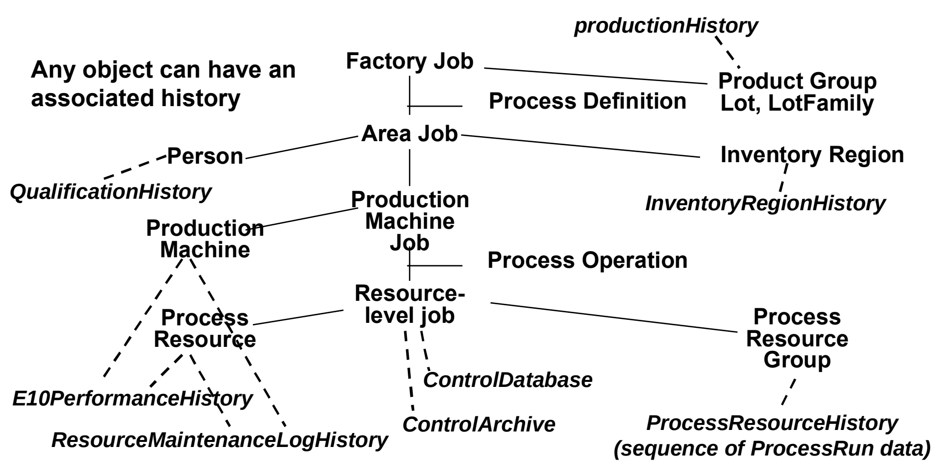

Figure 21
History Structure

7.3.4.11.2 In general, each task specification is a definition of a business process and a task workflow to carry out that business process. There is a diversity of information that could appear in a business process, including associated operational business rules and constraints, workflow traversal logic, and data structures for tasks, recipes, steps, etc. There is not industry consensus on representing these generic task specification details. For each specific job type, the CIM Framework defines some specification structure, but leaves room for suppliers and users to define additional data and behavior and to leverage workflow engines and evolving workflow standards [Workflow, WfMC].

7.4 *Specification Conventions*

7.4.1 This section provides an overview of the notations required to express the CIM Framework specifications. These notations provide the representational formalisms for all CIM Framework specifications. This section is a reference rather than a tutorial. Hence, those unfamiliar with these topics are strongly encouraged to consult the materials listed in the references for a more thorough explanation.

7.4.2 CIM systems requirements and the architectural principles upon which the CIM Framework was founded were derived through use of industry standards, practices reported in the literature, and other state-of-the-art information. The requirements of the CIM Framework are specified using a combination of graphical and textual notations. Where applicable, methods were employed and notations applied that were supported by the automation of computer-aided software engineering tools.

7.4.3 *Model Specification and Graphical Notation Usage*

7.4.3.1 This section briefly describes the graphical notations used to specify the semantics of the framework, including the following:

- Component Relationship Model.
- Component Information Model.
- Component Interaction Diagram.
- State Model.

7.4.3.2 *Component Relationship Model*

7.4.3.2.1 The Component Relationship Model was developed specifically for the framework specification as a mechanism to show relationships among framework components. It shows the logical combination of components and the relationships among the component parts. Figure 22 depicts the Component Relationship Model.

7.4.3.2.2 This model is based on the Unified Modeling Language (UML) Class Diagram [UML] with added stereotypes to represent the components. The UML Association concept is abstracted to represent the high-level relationships between components of the framework.

7.4.3.3 *Component Information Model*

7.4.3.3.1 The Component Information Model shows the specified CIM Framework interfaces along with the relationships between those interfaces. This model is based on the UML Class Diagram [UML] with the stereotype «Interface» to indicate that the classes are interfaces rather than implementation artifacts. This model shows generalization as applied to interface inheritance, aggregation of interfaces, and the use of an Association Class to represent data associated with an association between two interfaces. The associations also capture specific semantics of the relationship, including multiplicity and optionality as shown in Figure 23.

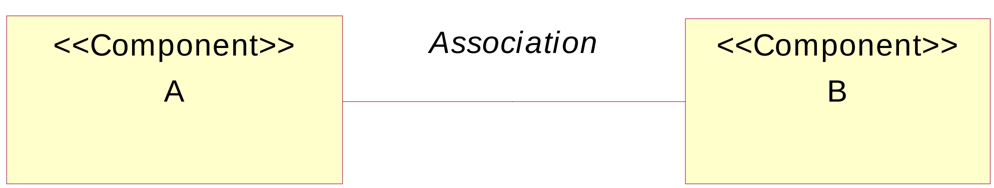

Figure 22
Component Relationship Model

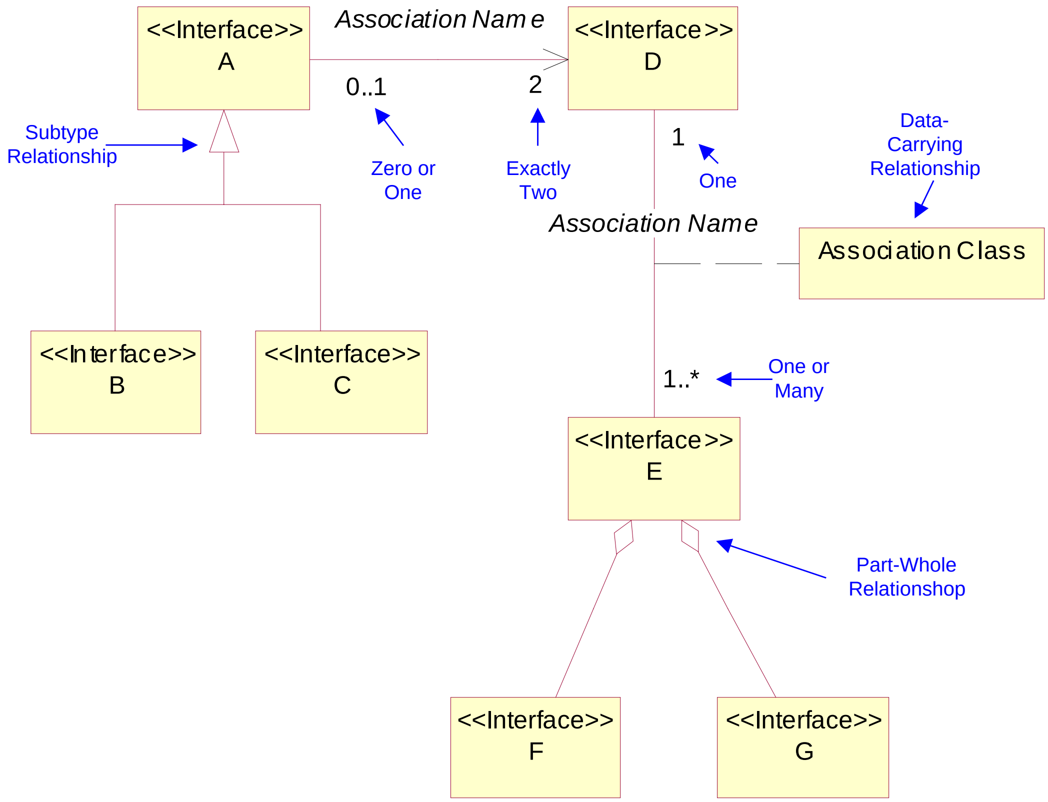

Figure 23
Information Model Example

7.4.3.4 *Component Interaction Model*

7.4.3.4.1 The Component Interaction Model expresses framework dynamics by describing the sequence of collaborations between objects supporting CIM Framework interfaces. This model is represented using the UML Sequence Diagram [UML]. The vertical lines each represent an object that conforms to a role specified by a CIM Framework interface. This is called a “lifeline.” The connecting arrows represent messages that flow between these objects and the data they convey. Each message must map to a defined operation on the interface of the message recipient. The example shown in Figure 24 of a Sequence Diagram models a portion of the interaction between a bank customer and an Automated Teller Machine (ATM).

7.4.3.5 *State Model*

7.4.3.5.1 The State Model shows behavior associated with CIM Framework interfaces as changes in state that result from specific events. The required behavior for an interface is conveyed through UML State Diagrams [UML] and textual tables that offer supporting details. Under this notation which is based on Harel Statecharts, states may be divided into substates, thereby forming a hierarchy of states. Substates must be one of two types, termed AND substates (representing concurrency) and exclusive OR substates (representing a finer breakdown of a parent state).

7.4.3.5.2 Object State Tables provide supplementary (to the State Diagram) state information including descriptive state definitions, state query mechanisms, the triggers effecting state transition, and the actions resulting from state transitions.

7.4.3.5.3 *Object State Definitions and Query Table*

7.4.3.5.3.1 The Object State Definition and Query Table provide supplementary information to the State Diagram.

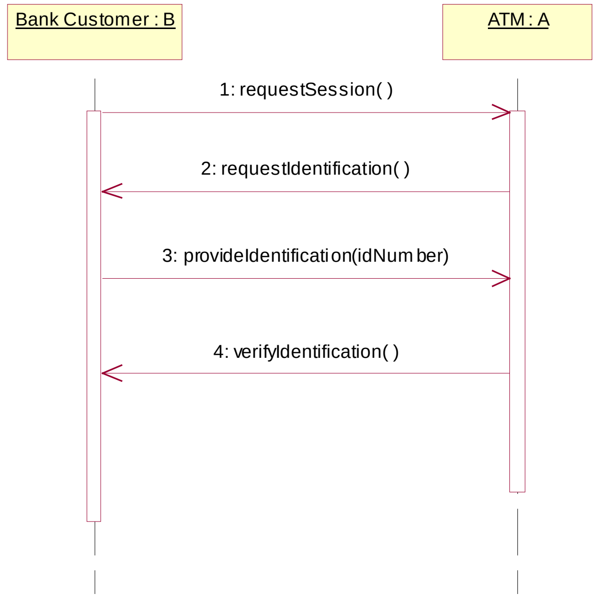

Figure 24
Component Interaction Model Example

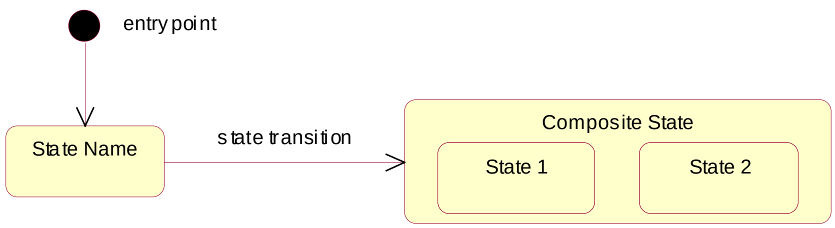

Figure 25
State Diagram

7.4.3.5.3.2 Table 1 provides a detailed description of each object state and identifies the query mechanism for determining if the object is in that state. Given the example provided in this section, an entry in the State Definitions and Query Table would appear as shown.

7.4.3.5.4 *Object State Transition Tables*

7.4.3.5.4.1 Another supplement to the state model is the Object State Transition Table (Table 2).

7.4.3.5.4.2 It lists the transition from the state diagram identified by the starting and ending states, and the event that causes the transition between these states.

7.4.3.5.4.3 Within the CIM Framework specification, only those triggers and state changes relevant to external interfacing are shown to help define how an external entity (in this case a driver) interoperates with an object (in this example an automobile).

7.4.3.5.4.4 While this table defines triggers for state transitions, there is no guarantee that the transition will take place in response to the trigger. In the above example, if the car is out of gas the engine will not go to the running state; if the light is burned out, it will not transition to the on state; depressing the accelerator pedal when the auto is in the off state will have no effect, etc. In the CIM Framework, object state can be queried to ensure successful transitioning in response to a triggering message. Events are also used in some cases to inform the client of a transition or change of state.

Table 1 Object State Definitions and Query Table Example

State	*Definition*	*Query for State Via*
ENGINE RUNNING	In this state, the automobile's engine is running.	boolean isEngineRunning ( ); sent to instance of Automobile. Returns true.

Table 2 Object State Transition Table Example

Current State	*Trigger*	*New State*	*Action*
ENGINE STOPPED	turn ignition key to right	ENGINE RUNNING	tachometer indicates positive RPM
ENGINE RUNNING	turn ignition key to left	ENGINE STOPPED	tachometer indicates zero RPM
LIGHTS OFF	turn light switch on	LIGHTS ON	driving at night is enabled
LIGHTS ON	turn light switch off	LIGHTS OFF	driving at night disabled

7.4.4 *Textual Specification Language*

7.4.4.1 The textual notations used to specify the framework in this specification, include the following:

- Interface Definition Language (IDL).
- Interface Definition Format.

7.4.4.2 *Interface Definition Language (IDL)*

7.4.4.2.1 Specifications of CIM Framework components are composed mainly of interfaces. The specifics of each interface, while also represented in the UML-based Component Information Model, are rigorously specified using OMG IDL. The IDL for CIM Framework interfaces shall be complete and consistent as verified by automated IDL compilers. The IDL portion of SEMI specifications will be available in a text file format to facilitate such validation and use with IDL compiler technologies.

7.4.4.2.2 This explanation of IDL is addressed to its use as a rigorous specification tool. The considerations of mapping the specifications to an implementation infrastructure are addressed in SEMI E96.

7.4.4.2.3 *Common Object Broker Architecture (CORBA)* [CORBA][CIMArch] defines the architecture which enables and regulates interoperability between objects and applications across heterogeneous languages and computer boundaries. In all Object Management Group (OMG) specifications, services are defined as object interfaces expressed in the OMG's *IDL*. *CORBA* standards define *IDL* and its mapping to implementation languages (for example, *C*, *C++*, *Smalltalk*, and *Java*).

7.4.4.2.4 *IDL* is a compilable language that describes the operations that are specified for an interface. The notation is independent of the language in which the methods that implement an interface's operations are written. This goal is achieved by mapping between the *IDL* syntax and whatever language is used to implement client and server objects. Because *IDL* is designed purely for interface specification, it omits the flow control and operator constructs of an implementation language. Object classes can implement an interface differently as long as their behavior conforms to the interface specification.

7.4.4.2.5 *IDL* obeys the same lexical rules as *C*, while introducing a number of keywords specific to a distributed system. As *IDL* is mapped to object-oriented languages, new constructs will appear. A brief discourse on some of the keywords and concepts used in this specification follows. In the examples, words in italics are user supplied, others are *IDL*-defined keywords.

7.4.4.3 *Interface Specification Format*

7.4.4.3.1 The OMG defines an object's interface as "a listing of the operations and attributes that an object provides. This includes the signatures of the operations, and the types of the attributes. An interface specification ideally includes the semantics as well" [OMA]. The CIM Framework Specification builds upon this definition to provide additional semantic information for an interface. These semantics are captured in an interface description. This section describes the format of an interface. Each description of an interface follows this format. The format includes the following:

- Name — The capitalized noun following the word "Interface:"
- Inherited Interface — The capitalized noun after the words "Inherited Interface:"
- Description — A definition of the interface giving its form and function.

- Exceptions — An IDL specification for reporting user-defined, framework-related error conditions.
- Published Events — The name of the event structure that must be placed on an event channel. The event structure identifies the event through a subject field. The subject is composed of the component and interface issuing the event and data describing the event, and filterable and non-filterable information. Events are defined at the interface level; neither posting services nor subscribers are identified. Thus, events are not tied to specific services and may be the result of an internal (to the component) computation.
- Provided Services — A list of publicly available services provided by this interface. In other words, a list of non-private, named operations. Each is given by a description in comment form (i.e., /*....*/) followed by its representation in the IDL syntax.
- Contracted Services — A table of framework services provided by other interfaces that are being used by public and/or private services in this interface. These methods must be available in order for the documented interface to provide its described services. Changes to contracted services may result in changes to the behavior of the interface making use of these services.
- State Model — See Section 7.4.3.5 for details.

7.4.4.3.2 If no Provided Services are defined for a particular category, then “No public interfaces” will appear after the category identifier. If no Exceptions, Published Events, Contracted Services, or Dynamic Model are provided, then the word “None” will appear. State Transition Tables occur only in conjunction with Dynamic Models.

7.4.4.4 *Interface Specification Example*

7.4.4.4.1 Table 3 provides a complete illustration of *IDL* and CIM Framework interface specification format usage within this specification. Words in italics are user-supplied, others are either *IDL* or CIM Framework-defined keywords.

8 Conformance to CIM Framework Domain Specifications

8.1 The objective of the CIM Framework is to speed the creation, use and improvement of a manufacturing execution system for a semiconductor wafer fabrication factory by enabling the integration of disparate components into a cohesive system. The CIM Framework achieves this objective by specifying a domain model for MES components. MES component suppliers use the specification to help establish the boundaries and interfaces of their components. Component customers first use the specification to assess the capabilities of individual components and then to facilitate the integration of components into a working system.

8.2 The CIM Framework increases the value of the MES components by enhancing their qualities of interoperability, substitutability and extensibility.

- Interoperability is the ability of components to work together through compatible interfaces.
- Substitutability implies the option to swap one component with another because they support the same interfaces.
- Extensibility means the planned capability to add functionality to a component, again by leveraging the support for predefined interface specifications.

8.3 Given both the scope and objectives of the CIM Framework, conformance to the Framework can not be reduced to a simple “yes or no” proposition. Rather, component customers must assess component conformance on a case-by-case basis. Potential buyers assess conformance in terms of how well a component supplier demonstrates use of the CIM Framework specification to enable rapid component integration.

8.4 With this background, here then are factors for consumers to consider in assessing MES components and for suppliers to comprehend when building components. These factors form the basis for communication between buyers and sellers of components regarding conformance to the CIM Framework specifications.

Table 3 Interface Specification Example

/* Comments are set between slashes and asterisks */

Interface: *FrameworkObject2*

Inherited Interface: *FrameworkObject1*

Description: The example defines the interface for *FrameworkObject2*, which inherits from *FrameworkObject1*.

Exceptions:

/* The following portrays the syntax used to describe exceptions for this interface. *ObjectType* and *instanceName* specify an object instance (supplementary information) returned with the exception. */

```
exception ExceptionName { ObjectType instanceName };
```

Published Events: *NamedEvent*

Provided Services:

/* The following defines the read/write methods for AttributeName1. */

```
ObjectType getAttributeName1 ( );
void setAttributeName1 (in ObjectType parameterName);
```

/* The following defines a method for readonly *AttributeName2* */

```
ObjectType getAttributeName2 ( );
```

/* The following says operationName1 is a local operation returning an object of the class ObjectTypeReturned. */

```
ObjectTypeReturned operationName1 ( );
```

/* The following says *operationName2* is a local operation returning an object of the class *ObjectTypeReturned* with an argument *instanceName* of the object type *ObjectType*. In addition, there is an operation-specific exception, *E*, that may be raised by this operation. */

```
ObjectTypeReturned operationName2 (in ObjectType instanceName)
          raises (E);
```

The type definitions follow the following format:

/* Type Declarations: */

/* The following specifies (types) the *ObjectType* for the named *datatype*. */

```
typedef ObjectType datatype ;
```

/* The following specifies a sequence (collection) of *ObjectType* for *ObjectTypeSequence*. */

typedef sequence<*ObjectType*> *ObjectTypeSequence* ;

- **CIM Framework component packaging:** Component suppliers must explain how their component is packaged relative to the corresponding CIM Framework component(s). Note, however, that suppliers may choose to provide multiple CIM Framework components as an integrated package. In this case the complete package can be assessed relative to the combination of services provided by the combined set of CIM Framework components. Obviously, a consumer must also assess the benefits of the integrated component relative to the reduction in the ability to substitute components within the integrated package.
- **CIM Framework objects and interfaces:** Component suppliers must describe how their objects and methods support the CIM Framework component interfaces. This includes describing the object methods available in comparison to the interfaces specified in the CIM Framework. Note that this interface specification question encompasses specific operations, the operations' arguments, the exceptions returned, and the events published.
- **Object behavior:** Component suppliers must document object behavior so component consumers can understand the purpose and consequences of specific methods. The CIM Framework specifies behavioral semantics for components using a variety of representations such as state models, information models showing relationships, interaction models, and text-based

comments. Component suppliers need to explain how their objects conform to the CIM Framework behavioral semantics.

8.5 As these factors indicate, assessing the CIM Framework conformance of supplied components takes more than just verifying the existence of specific objects and methods. The key issue is whether a component supplier provides both the software and its associated conformance information needed to enable the use and integration of the component.

SEMI E82-0302
SPECIFICATION FOR INTERBAY/INTRABAY AMHS SEM (IBSEM)

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on October 14 and November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published September 1999; previously published November 2001.

This document replaces SEMI E30.4 in its entirety.

1 Purpose

1.1 This standard establishes a Specific Equipment Model (SEM) for interbay and intrabay AMHS transport equipment (IBSEM). The model consists of equipment characteristics and behaviors that are to be implemented in addition to the SEMI E30 fundamental requirements and selected additional capabilities. The intent of this standard is to facilitate the integration of IBSEM equipment into an automated (e.g., semiconductor fabrication and flat panel display) factory. This document accomplishes this by defining an operational model for IBSEM equipment as viewed by a factory automation controller (Host). This definition provides a standard host interface and equipment operational behavior (e.g., control, state models, data reports, and reporting levels). Several topics require additional activity that are within the scope of this standard: traffic management characteristics (queuing), parallel interface for carrier transfer (SEMI E23), transport system controller architecture, and delivery of the transfer unit.

2 Scope

2.1 The scope of this standard is limited to the usage and description of interbay and intrabay AMHS transport equipment (OHT, OHS, RGT, AGT, DWC) as perceived by a SEMI Equipment Communications Standard 2 (SECS-II) host that complies with the GEM model (as specified in Section 13). It defines the view of the equipment through the SECS communication link. It does not define the internal operation of the equipment. It includes a specific transfer command state model and transport system controller state model as the basis for all equipment of this class.

2.2 This document assumes that the GEM fundamental requirements and selected additional capabilities (as specified in Section 13) have been implemented on the IBSEM equipment. It expands the GEM standard requirements and capabilities in the areas of state models (TSC, transfer command, vehicle and carrier state models), collection events, alarm documentation, remote commands, data item variables, and material movement.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 *Evaluation of SEMI E32 (MMM)*

3.1.1 The concepts defined in SEMI E32 were analyzed and included where applicable to the IBSEM, but the GEM model was used as the basis for IBSEM requirements definition.

3.2 *Interbay and Intrabay AMHS Transport Equipment Types*

3.2.1 This standard is targeted at the different types of 300 mm and interbay and intrabay AMHS transport equipment. The term *IBSEM equipment* refers to all types of transport equipment. The equipment types have fundamental mechanical differences:

3.2.1.1 *Overhead Hoist Transport (OHT)* — An overhead rail guided transport system positioned for vertical access to SEMI E15.1 compliant ports.

3.2.1.2 *Over Head Shuttle (OHS)* — An overhead rail guided transport system (monorail) positioned for access to stocker automated interbay input and output ports. The OHS vehicle may or may not contain a transfer agent.

3.2.1.3 *Rail Guided Transport (RGT)* — A ground-based rail guided transport system positioned for access to SEMI E15.1 compliant ports.

3.2.1.4 *Automated Guided Transport (AGT)* — A ground-based transport system with automated guidance (i.e., no rail guidance). Automated guidance system allows vehicles to access SEMI E15.1 compliant ports.

3.2.1.5 *Direct WIP Conveyer (DWC)* — An overhead transport system, based on direct WIP roller conveyers. No vehicles are used for point to point delivery. The conveyers are positioned for vertical access to SEMI E15.1 ports.

3.2.2 Transport vehicles may contain zero or more internal buffers for carrier transport. If mechanically feasible, the transport system may acquire or deposit carriers simultaneously. If transported in a safe manner, carrier transport may occur while occupying the acquire/deposit transfer port(s) of the transport vehicle (e.g., a single position hoist vehicle). In the context of this standard, a "vehicle" on a DWC is defined as a single carrier in the transport system.

3.3 *Physical Layout Limitations*

3.3.1 The equipment controlled by a single TSC must allow for a carrier to be transported from any given source port to any destination port via a single transfer command without the assistance of an external device (manual or automated). In other words, if a source port and a destination port are controlled by a TSC, there must not exist a physical or logical barrier that prevents a carrier from being moved between the two ports. This assumes that the type of carrier (FOUP, Reticle Pod, etc.) is permitted at the source and destination ports.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AGT* — Automated Guided Transport

5.1.2 *AMHS* — Automated Material Handling System

5.1.3 *DWC* — Direct WIP Conveyor

5.1.4 *FOUP* — Front Opening Unified Pod

5.1.5 *GEM* — Generic Equipment Model

5.1.6 *ITS* — Interbay or Intrabay Transport System

5.1.7 *OHS* — Over Head Shuttle

5.1.8 *OHT* — Overhead Hoist Transport

5.1.9 *PGV* — Person Guided Vehicle

5.1.10 *RGT* — Rail Guided Transport

5.1.11 *TCP/IP* — Transmission Communication Protocol/ Internet Protocol

5.1.12 *TSC* — Transport System Controller

5.2 *Definitions*

5.2.1 *active vehicle* — a vehicle in the transport system that contains a robot or other transfer agent for providing the acquiring (loading) and depositing (unloading) actions.

5.2.2 *buffer* — a set of one or more locations for holding carriers at the production equipment.

5.2.3 *carrier* — a container with one or more fixed positions for holding substrates. Examples of carriers include FOUPs and open cassettes.

5.2.4 *FOUP* — a closed carrier for holding wafers.

5.2.5 *host* — the factory computer system, or an intermediate system, that represents the factory and the user to the equipment. Refers to the system that controls or supervises the Transport System Controller (TSC) throughout this document.

5.2.6 *internal buffer* — locations within the equipment to store carriers. These locations exclude load ports.

5.2.7 *load port* — the interface location on the equipment where carriers are delivered.

5.2.8 *open cassette* — an open structure that holds one or more wafers.

5.2.9 *passive vehicle* — a vehicle in the transport system that does not contain a robot or other transfer agent for providing the acquiring (loading) and depositing (unloading) actions. The vehicle simply contains a position(s) to carry the transfer unit. The loading and unloading action must be accomplished at the load or unload port by a different system (e.g., stocker port robot).

5.2.10 *process equipment* — equipment used to make semiconductor devices. This excludes metrology and material handling equipment.

5.2.11 *production equipment* — equipment used to produce semiconductor devices, including wafer sorting, process, and metrology equipment and excluding material handling equipment.

5.2.12 *transfer port* — point on the transport system at which a change of equipment ownership of the carrier occurs.

5.2.13 *transfer unit* — the element of movement (assemblage of carriers) of the ITS that consists of a maximum num-ber of carriers allowed in a specific transfer command:

- AA is the maximum number of carriers allowed for acquire at the transfer source.
- BB is the maximum number of carriers allowed for deposit at the transfer destination.
- CC is the maximum number of carriers allowed for transfer in one transport vehicle.
- The maximum size of the transfer unit is the minimum of AA, BB, and CC.

5.2.14 *Transport System* — a transport system dedicated to one or more bays in the factory and responsible for transferring carriers to production equipment, from production equipment, from production equipment to production equipment or from stocker to stocker. TS consists of the physical units of the system (e.g., vehicles, nodes, docking stations), the low-level unit controllers, and a system-level controller. TS excludes factory floor storage systems (stockers), but includes any short-term storage integral to the system, such as storage locations within an overhead track system that are accessible only to units of the particular TS.

5.2.15 *Transport System Controller* — interbay or intrabay Transport System Controller that communicates with the Factory Host and represents the system as the equipment.

5.2.16 *Transport System Equipment* — an individual transport system viewed as a single piece of equipment, with distributed components and distributed control. The TS controller communicates with the host using HSMS and GEM and represents the system as an equipment. The factory may require more than one type of transport system.

5.2.17 *transport unit* — a physical component of a transport system, such as a vehicle, node, or docking unit.

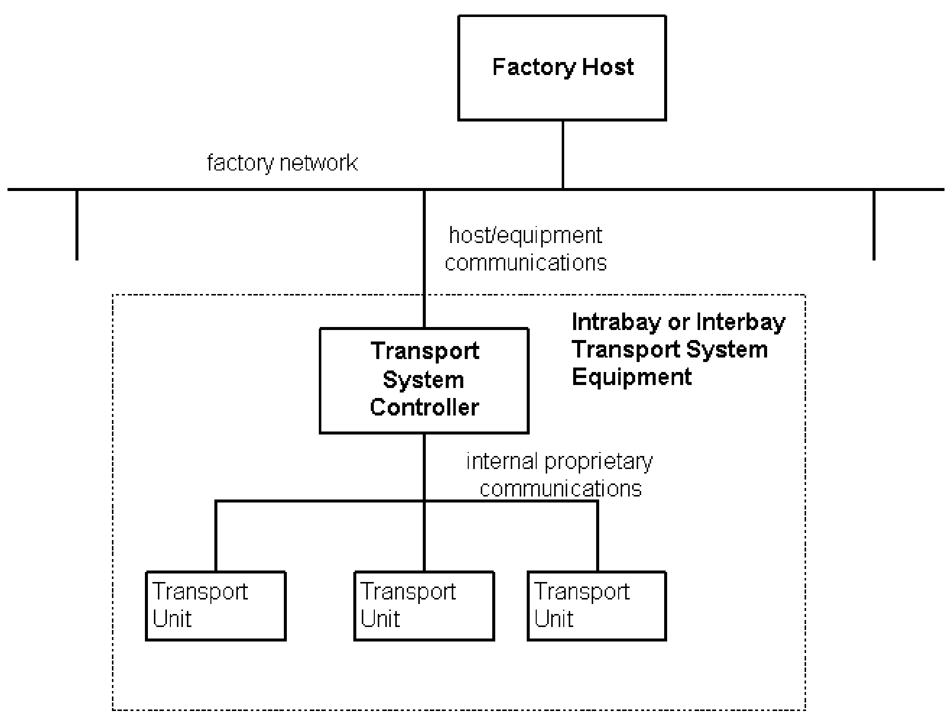

Figure 1
Example of Transport System Equipment

6 Communication Requirements

6.1 It is required that any IBSEM compliant equipment follow the Communications State Model in SEMI E30. In addition, IBSEM compliant equipment shall support either the High-speed SECS Message Services Single-Session Mode (SEMI E37 and SEMI E37.1, HSMS and HSMS-SS) communication standard or SEMI Equipment Communications Standard 1 Message Transfer (SEMI E4, SECS-I) communication standard.

7 State Models

7.1 *State Model Requirements*

7.1.1 The state models included in this standard are a requirement for IBSEM equipment. This standard requires implementation of all SEMI E30 state models (such as control, communication, on-line/off-line, etc. according to the GEM capabilities required per Section 13). A state model consists of a state model diagram, state definitions, and a state transition table. All state transitions in this standard, unless otherwise specified, shall correspond to collection events.

7.1.2 A state model is the host's view of the equipment, and does not necessarily describe the internal equipment operation. All IBSEM state model transitions shall be mapped sequentially into the appropriate internal equipment events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the IBSEM state model for transition to another state. The equipment makes the required transition without any additional actions in this situation.

7.1.3 Some equipment may need to include additional substates other than those in this standard. Additional substates may be added, but shall not change the IBSEM defined state transitions. All expected transitions between IBSEM states shall occur.

7.2 *TSC State Model*

7.2.1 *TSC State Model Requirements*

7.2.1.1 The purpose of the Transport System state model is to provide information to the host regarding the overall status of the Transport System. The TSC state model is valid when the SEMI E30 (GEM) state is ON-LINE. The TSC state model is **not** valid when the SEMI E30 (GEM) state is OFF-LINE. Since a transport system may consist of many components (e.g., vehicle, robot arm, ID reader, etc.), it may be possible to continue ON-LINE operation when the operation mode of some transport components (as viewed by the TSC) is a manual state. The details of what happens when individual components of the transport system enter a manual state are specific to the IBSEM equipment supplier. When the SEMI E30 Control state changes from OFF-LINE to ON-LINE, the TSC State Model is started from the TSC INIT state.

7.2.2 *TSC State Model*

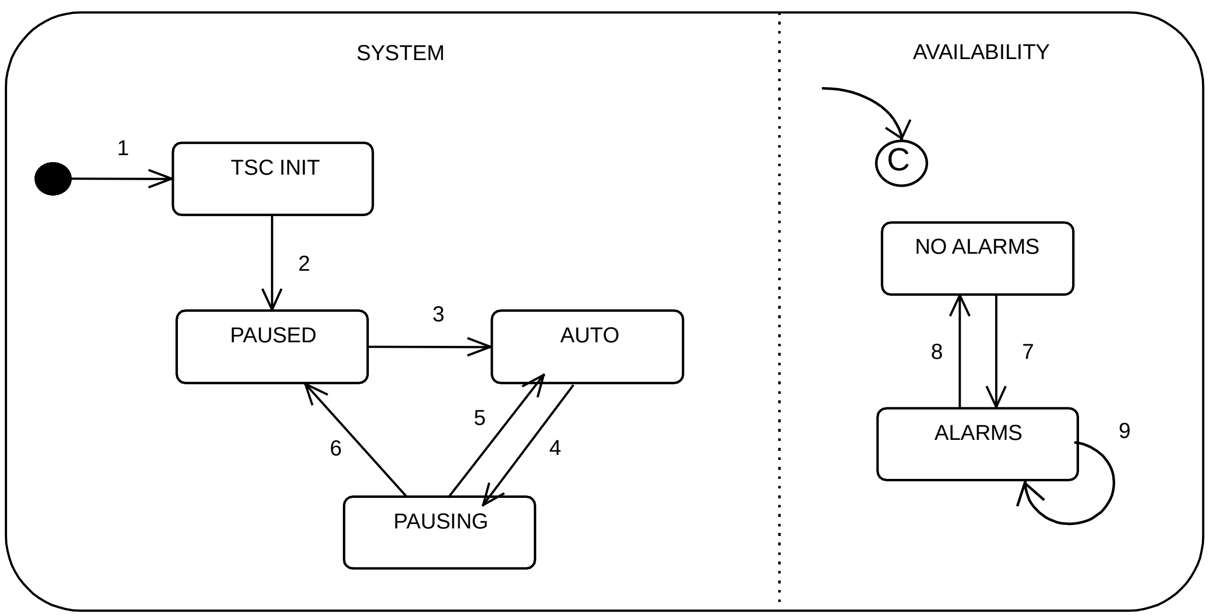

Figure 2
Generic IBSEM TSC State Model Diagram

7.2.3 *TSC State Definitions*

7.2.3.1 *TSC INIT* — TSC initialization of TS components is occurring. This is a non-operational state. No commands from the host will be processed or queued. The system will not move out of this state if there are vehicles actively loading or unloading carriers at ports. These vehicles must be manually or automatically recovered before moving on to the next state.

7.2.3.2 *PAUSING* — A system PAUSE command has been received and is being processed. All vehicles that are currently loading or unloading will continue until the load/unload is complete. Vehicles that are currently moving may continue to move but they must not begin a load or unload. TRANSFER commands are accepted and queued. All status requests will be processed. The RESUME command will also be processed.

7.2.3.3 *PAUSED* — No vehicles are in the process of loading or unloading a carrier at a port, but vehicles may still be moving. TRANSFER commands are accepted and queued.s All status requests will be processed. The RESUME command will also be processed.

7.2.3.4 *AUTO* — System is in the normal operational state. Commands are actively processed.

7.2.3.5 *NO ALARMS* — There are no alarms present in the system.

7.2.3.6 *ALARMS* — There are one or more alarms present in the system, but the TSC is still capable of normal processing since several components may remain unaffected by the alarm situation.

7.2.4 *TSC State Transition Table*

Table 1 TSC State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	None	TSC Initiation	TSC INIT	S6F11 TSCAutoInitiated	System runs through its startup sequence.
2	TSC INIT	System started up successfully. All loads and unloads are complete.	PAUSED	S6F11 TSCPaused	System ready
3	PAUSED	TSC is resumed.	AUTO	S6F11 TSCAutoCompleted	System will now perform all commands.
4	AUTO	TSC is requested to pause.	PAUSING	S6F11 TSCPauseInitiated	Vehicles that are stopped stay stopped. Vehicles that are moving stop at the next logical point without proceeding.
5	PAUSING	TSC is resumed.	AUTO	S6F11 TSCAutoCompleted	System will now perform all commands.
6	PAUSING	All carrier loads and unloads are completed. No new acquires or deposits will occur. Outstanding acquires and deposits will complete.	PAUSED	S6F11 TSCPauseCompleted	System will accept and queue new commands but will not execute them.
7	NO ALARMS	Alarm Set	ALARMS	S6F11 AlarmSet	System can process normally for transport components that are unaffected by the alarm.
8	ALARMS	Last remaining alarm cleared.	NO ALARMS	S6F11 AlarmCleared	
9	ALARMS	Alarm Set	ALARMS	S6F11 AlarmSet	Alarm occurs when there is already an outstanding alarm.

7.3 *TRANSFER Command State Model*

7.3.1 *TRANSFER Command State Model Requirements*

7.3.1.1 The TRANSFER command state model serves as the SEMI E30 Processing State Model. The purpose of the TRANSFER command state model is to provide information to the host regarding the control of the TRANSFER command. The TRANSFER command allows the host to manage interbay or intrabay delivery and scheduling. The control of each TRANSFER command must independently support the TRANSFER command state model.

7.3.2 *TRANSFER Command State Model Diagram*

7.3.2.1 The TRANSFER command state model is detailed for IBSEM equipment in Figure 3.

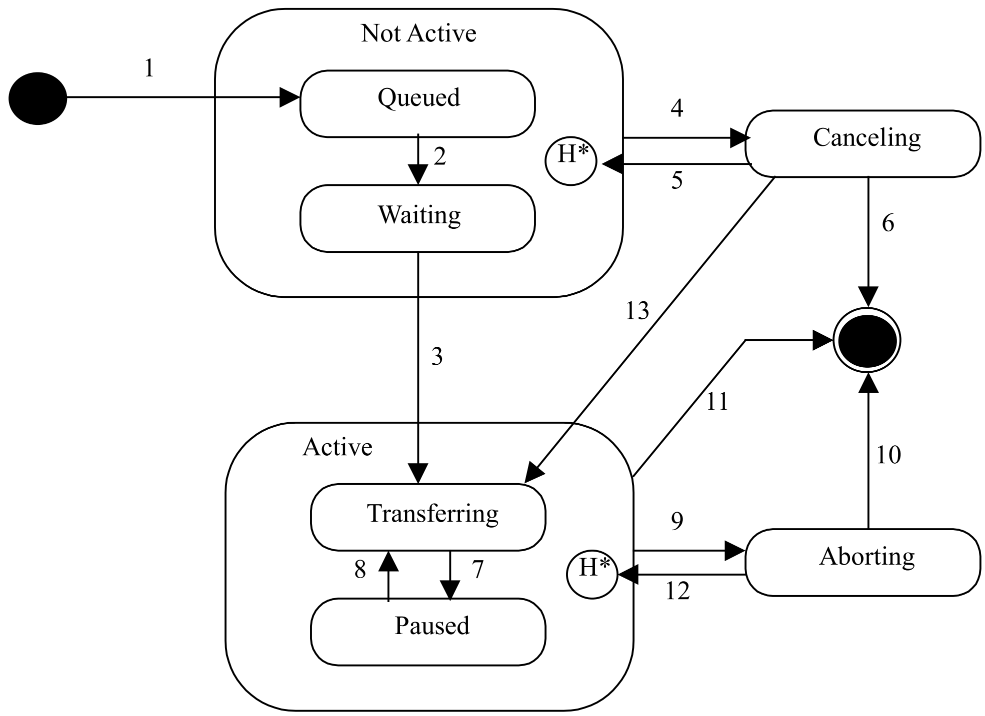

Figure 3
Generic IBSEM TRANSFER Command State Model Diagram

7.3.3 *TRANSFER Command State Definitions*

7.3.3.1 *NOT ACTIVE* — The transfer unit is not involved in the physical aspect of the TRANSFER command. It is denoted by the time spanned by the queuing of the TRANSFER command to the moment just prior to the acquire of the first carrier in the transfer unit.

7.3.3.2 *QUEUED (NOT ACTIVE sub-state)* — TSC has acknowledged and queued the TRANSFER command. TRANSFER command has not been initiated.

7.3.3.3 *WAITING (NOT ACTIVE sub-state)* — TRANSFER command has been initiated. A vehicle is on its way to the source location to acquire the transfer unit.

7.3.3.4 *ACTIVE* — The transfer unit is involved in the physical aspect of the TRANSFER command. It is denoted by the time spanned by the acquire of the first carrier in the transfer unit to the deposit of the last carrier in the transfer unit.

7.3.3.5 *TRANSFERRING (ACTIVE sub-state)* — The transfer command is actively being executed by the transport equipment.

7.3.3.6 *PAUSED (ACTIVE sub-state)* — The transfer command is not actively being executed by the transport equipment.

7.3.3.7 *CANCELING* — The TRANSFER command cancel procedure is being performed to terminate a transfer command which never entered the ACTIVE state (either QUEUED or WAITING). This state is entered via a CANCEL remote command. An unsuccessful transfer command completion will ultimately result.

7.3.3.8 *ABORTING* — The TRANSFER command abort procedure is being performed to terminate a transfer command which has entered the ACTIVE state. This state can only be entered via an ABORT remote command. An unsuccessful transfer command completion will ultimately result from this state.

7.3.4 *TRANSFER Command State Transition Table*

Table 2 Transfer Command State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	None	The Host generated TRANSFER command is successfully acknowledged by the TSC.	QUEUED		
2	QUEUED	The TRANSFER command has been initiated by the TSC.	WAITING	S6F11 Transfer-Initiated	Transport vehicle is dispatched to acquire the transfer unit.
3	WAITING	The acquire of the first carrier of the transfer unit begins.	TRANSFERRING	S6F11 Transferring	
4	NOT ACTIVE	Host issued cancel for the TRANSFER command is accepted by the TSC.	CANCELING	S6F11 TransferCancel-Initiated	A CANCEL remote command was issued to terminate a TRANSFER command that has not entered the physical aspect of the command.
5	CANCELING	Transport system is unable to cancel the TRANSFER command.	Previous NOT ACTIVE sub-state	S6F11 TransferCancel-Failed	The ability of the equipment to successfully complete a cancel of the TRANSFER command is specific to the IBSEM equipment supplier.
6	CANCELING	The cancel procedure for the TRANSFER command has completed by the transport system and TSC.	None	S6F11 TransferCancel-Completed	The transfer unit will still be situated at the transfer source location. The carriers in the transfer unit may now be included in a future transfer (either AMHS or PGV based).
7	TRANSFERRING	The TSC pauses execution of the TRANSFER command due to an anomaly condition.	PAUSED	S6F11 TransferPaused	It is an important distinction to make that the TRANSFER command is paused even though the vehicle may not be.
8	PAUSED	The TSC resumes execution of the TRANSFER command since the anomaly condition has been cleared.	TRANSFERRING	S6F11 Transfer-Resumed	

Tran-sition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
9	ACTIVE	Host initiates an abort of a TRANSFER command.	ABORTING	S6F11 TransferAbort-Initiated	An ABORT remote command was issued to terminate a TRANSFER command.
10	ABORTING	The abort procedure for the TRANSFER command has completed by the transport system and TSC.	None	S6F11 TransferAbort-Completed	Transfer unit could be located at any location or port located along the path of the ACTIVE transfer. The location of the carrier(s) associated with the aborted transfer command must be legal SourcePort(s) for issuing a new TRANSFER command.
11	ACTIVE	The TRANSFER command has completed by the transport system and TSC (either successfully or unsuccessfully).	None	S6F11 TransferCompleted sent to Host with appropriate ResultCode ResultCode = 0 if successful ResultCode Not = 0 if unsuccessful	Carrier(s) could be located at any location or port located along the path of the transfer if the TRANSFER command completed unsuccessfully. The location of the carrier(s) associated with an unsuccessful transfer command must be legal SourcePort(s) for a new TRANSFER command.
12	ABORTING	Transport system is physically unable to abort the TRANSFER command.	Previous ACTIVE sub-state	S6F11 TransferAbort-Failed	The ability of the equipment to successfully complete an ABORT of the TRANSFER command is specific to the IBSEM equipment supplier.
13	CANCELING	Transport system is unable to cancel the TRANSFER command because the transfer is now ACTIVE.	TRANSFERRING	S6F11 Transferring	The ability of the equipment to successfully complete a cancel of the TRANSFER command is specific to the IBSEM equipment supplier.

7.4 *Vehicle State Model*

7.4.1 *Vehicle State Model Requirements*

7.4.1.1 The purpose of the vehicle state model is to provide information to the host for use of transport vehicle information and metric tracking (i.e., the Host will not control vehicles). Each vehicle must individually comply with the vehicle state model. Implementation of this state model, along with associated events and variables, is not a requirement for Transport Systems which do not have vehicles. An example of such a Transport System is a DWC. The Host should not be dependent on any events from the vehicle state model.

7.4.2 *Vehicle State Model*

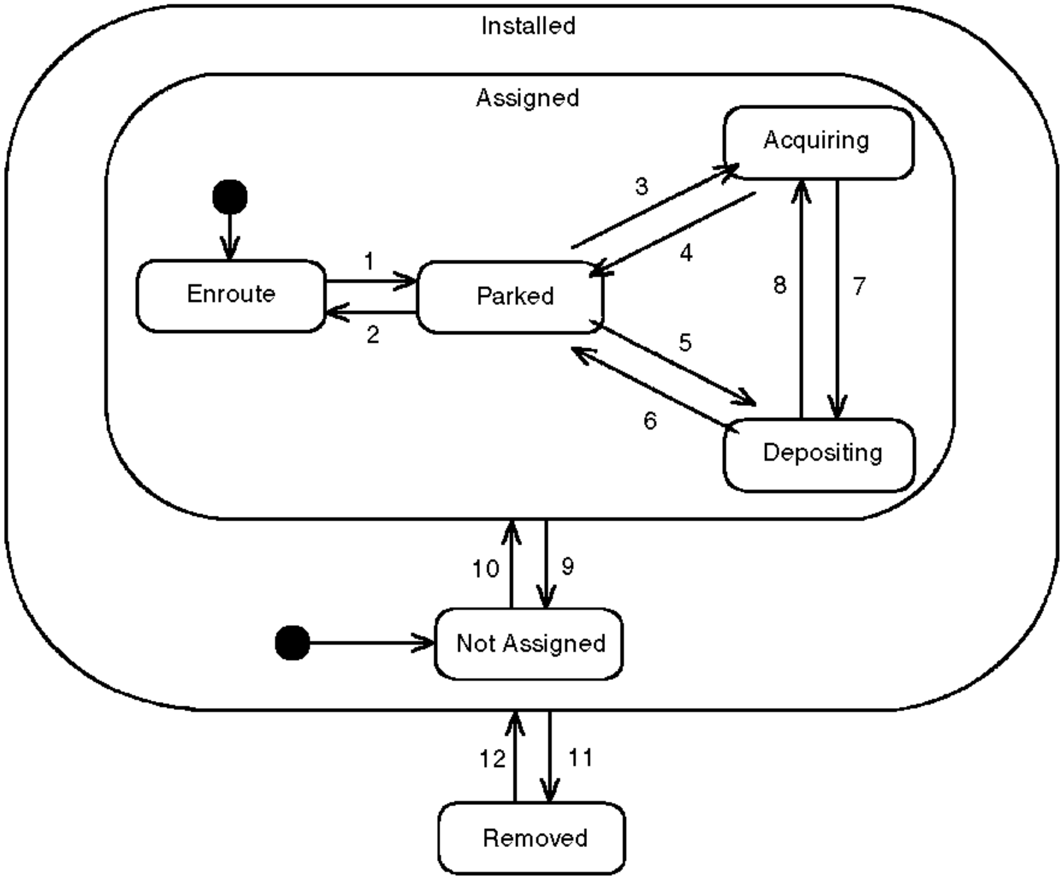

Figure 4
Generic IBSEM Vehicle State Model Diagram

7.4.3 *Vehicle State Definitions*

7.4.3.1 *INSTALLED* — The vehicle is available or being used for TRANSFER commands. All enabled collection events and alarms will be sent to the Host for vehicles in this state.

7.4.3.2 *REMOVED* — The vehicle is not available for Host initiated TRANSFER commands. No collection events or alarms will be sent to the Host for vehicles in this state.

7.4.3.3 *ASSIGNED (INSTALLED sub-state)* — Vehicle is allocated to a TRANSFER command.

7.4.3.4 *NOT ASSIGNED (INSTALLED sub-state)* — Vehicle is not allocated to a TRANSFER command. The vehicle may contain a carrier as the result of a command being aborted.

7.4.3.5 *ENROUTE (ASSIGNED sub-state)* — The vehicle is on its way to a transfer port. This is the default entry into the ASSIGNED state since it must be entered for the host to track vehicle metrics completely and adequately.

7.4.3.6 *PARKED (ASSIGNED sub-state)* — This state occurs when the vehicle is in the following conditions:

- After the arrival of the vehicle is completed and before the action of the transfer agent is started.
- After the action of the transfer agent has completed and before the departure of the vehicle.
- After continuous actions of the transfer agent (e.g., acquire/acquire and deposit/deposit) are completed.

7.4.3.7 *ACQUIRING (ASSIGNED sub-state)* — The vehicle is currently involved in carrier acquire (one or more carriers possible depending on vehicle limitations).

7.4.3.8 *DEPOSITING (ASSIGNED sub-state)* — The vehicle is currently involved in carrier deposit (one or more carriers possible depending on vehicle limitations).

7.4.4 *Vehicle State Transition Table*

Table 3 Vehicle State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
1	ENROUTE	Vehicle arrives at a transfer port associated with an ACTIVE transfer command.	PARKED	S6F11 VehicleArrived	
2	PARKED	Vehicle departs a transfer port associated with an ACTIVE transfer command.	ENROUTE	S6F11 VehicleDeparted	
3	PARKED	The carrier handoff parallel I/O starts for the vehicle to acquire (load) the transfer unit.	ACQUIRING	S6F11 VehicleAcquire-Started	If the vehicle is a passive type then the acquire occurs by the robot on the other equipment loading the transfer unit to the vehicle.
4	ACQUIRING	The carrier handoff parallel I/O completes for the vehicle to acquire (unload) the transfer unit.	PARKED	S6F11 VehicleAcquire-Completed	
5	PARKED	The carrier handoff parallel I/O starts for the vehicle to deposit (unload) the transfer unit.	DEPOSITING	S6F11 VehicleDeposit-Started	If the vehicle is a passive type then the deposit occurs by the robot on the other equipment unloading the transfer unit from the vehicle.
6	DEPOSITING	The carrier handoff parallel I/O completes for the vehicle to deposit (unload) the transfer unit.	PARKED	S6F11 VehicleDeposit-Completed	
7	ACQUIRING	The carrier handoff parallel I/O completes for the vehicle to acquire (load) the transfer unit and starts for the vehicle to deposit (unload) the carrier.	DEPOSITING	S6F11 VehicleDeposit-Started	Carrier Replace See scenario for an example.
8	DEPOSITING	The carrier handoff parallel I/O completes for the vehicle to deposit (unload) the transfer unit and starts for the vehicle to acquire (load) the carrier.	ACQUIRING	S6F11 VehicleAcquire-Started	Carrier Replace See scenario for an example.
9	ASSIGNED	Vehicle is no longer being utilized for the specified command.	NOT ASSIGNED	S6F11 Vehicle-Unassigned	This could be the result of the command being completed or aborted. It could also be the result of the TSC scheduling algorithms assigning this vehicle to another command and/or another vehicle being assigned to this command.
10	NOT ASSIGNED	Vehicle is allocated to a TRANSFER command.	ASSIGNED	S6F11 VehicleAssigned	
11	INSTALLED	Vehicle is removed from use of transfer commands.	REMOVED	S6F11 VehicleRemoved	

Tran-sition #	Previous State	Trigger	New State	Actions	Comment
12	REMOVED	Vehicle is installed for use of transfer commands.	INSTALLED	S6F11 VehicleInstalled	

7.5 *IBSEM Carrier State Model*

7.5.1 *IBSEM Carrier State Model Requirements*

7.5.1.1 The purpose of the carrier state model is to provide information to the host regarding carrier tracking (the Host will not control carriers). Each carrier must comply with the carrier state model.

7.5.2 *IBSEM Carrier State Model*

Figure 5
Generic IBSEM Carrier State Model Diagram

7.5.3 *Carrier State Definitions*

7.5.3.1 *INSTALLED* — A TSC database entry exists for the carrier.

7.5.4 *Carrier State Transition Table*

Table 4 Carrier State Transition Table

Transition #	Previous State	Trigger	New State	Actions	Comments
1	None	A TSC database entry is created for the carrier.	INSTALLED	S6F11 CarrierInstalled	
2	INSTALLED	A TSC database entry is removed for the carrier.	None	S6F11 CarrierRemoved	

7.6 *Port Transfer State Model*

7.6.1 *Port Transfer State Model Requirements*

7.6.1.1 The purpose of the port transfer state model is to provided information to the host for the use in accessing ports. This may permit the host and stocker to utilize ports that are in service while avoiding the use of ports that are not in service.

7.6.2 *Port Transfer State Model*

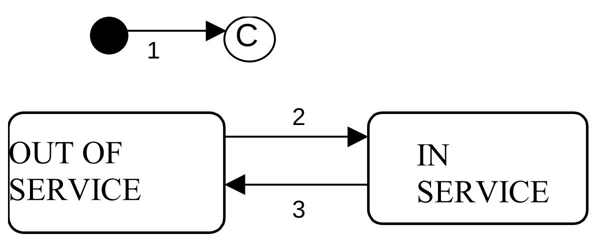

Figure 6
Port State Model Diagram

7.6.3 *Port Transfer State Definitions*

7.6.3.1 *OUT OF SERVICE* — Transfer to/from this port is disabled and the port should not be used in any Transfer command issued by the host. If a command is issued by the host which uses this port, it will not be rejected simply because the port is in this state.

7.6.3.2 *IN SERVICE* — Transfer to/from this port is enabled.

7.6.4 *Port Transfer State Transition Table*

Table 5 Port Transfer State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Action*	*Comments*
1	None	System reset.	OUT OF SERVICE Or IN SERVICE	S6F11 PortOutOfService Or S6F11 PortInService	The new state is based on the current status of the port or the state prior to system reset.
2	OUT OF SERVICE	The equipment has determined that the port can be utilized for transfers.	IN SERVICE	S6F11 PortInService	
3	IN SERVICE	The equipment has determined that the port should not be used for transfers.	OUT OF SERVICE	S6F11 PortOutOfService	This could be the result of an alarm condition.

8 Collection Event List

8.1 This section identifies data collection events and defines (Stream 6) suggested associated variable data items. The host can use the report definition scenario defined in SEMI E30 to define reports at IBSEM defined levels. The intent of this section is to demonstrate that certain suggested data is available at specific events.

8.2 *Requirements*

8.2.1 This standard requires all collection events listed in the SEMI E30 standard (according to the GEM capabilities required per Section 13).

8.3 *Collection Event Table*

Table 6 Collection Event Table (State Transition Based)

Collection Event Name	*From State*	*To State*	*Required DVVAL's*

8.4 *Non-Transition Collection Event Table*

Table 7 Non-Transition Collection Event Table

Collection Event Name	*Event Description*	*Required DVVALs*
OperatorInitiatedAction	The operator initiated an action from the Stocker Controller. The related State Transition Events defined in Table 6 shall be required after this "OperatorInitiatedAction" event.	CommandID CommandType CarrierID SourcePort DestPort Priority

9 Variable Data Items

9.1 The purpose of this section is to define the list of variable data item requirements for IBSEM equipment. Values of these variables will be available to the host via collection event reports and host status queries.

9.2 *Requirements*

- All variable data items defined in GEM and data item restrictions defined in SEMI E30 are required on IBSEM equipment (according to the GEM capabilities required per Section 13).
- All variable data items in the IBSEM Variable Data Item Dictionary for specific equipment classifications are required for IBSEM equipment. The data item restrictions are also required.
- Some SV's in the Variable Data Item Dictionary are referenced by an "i" subscript (e.g., $CarrierID_i$). The "i" subscript denotes a specific instance of the SV. This is necessary since there is usually more than one instance of such an SV active in the system at the same time (e.g., if there are 20 carriers active at the same time then "i" could range from 1 to 20 for $CarrierID_i$). Variable Data Items containing the "i" subscript should not have Variable ID's assigned to them.

9.2.1 Variable data items are documented in the IBSEM Variable Data Item Dictionary using the following format:

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*

Where:

Variable Name: A unique name for the variable data item.

Type: CV – meaning common variables, variables that are general to all vehicles.
CSV – meaning configuration specific variables.

Description: If class is DVVAL, then the description shall contain a statement of when data is valid in terms of IBSEM events.

Class: The data type of the item.

Format: < SECS Message Language (SML) mnemonic > acceptable formats are SEMI E5 lists, ASCII, floating point, unsigned integer or signed integer. A description of "ANY", indicates that only the above formats are acceptable and is left to the supplier to decide.

Comments: Any additional information pertinent to the variable name.

9.3 *Variable Data Item Types*

9.3.1 *Equipment Constants (ECV)* — The value can be changed by the host using S2F15. The operator may have the ability to change some or all of the values. The value of an equipment constant may be queried at any time by the host using the S2F13/14 transaction or Stream 6 reports.

9.3.2 *Status Variables (SV)* — The values are valid at all times. A SV may not be changed by the host or operator, but may be changed by the equipment. A host or operator command may change an equipment status thus changing a SV. The value of status variables may be queried by the host at any time using the S1F3/4 or Stream 6 reports.

9.3.3 *Data Variables (DVVAL)* — These are variables which are valid upon the occurrence of a specific collection event, and may or may not be valid at other times depending upon the equipment. An attempt to read a variable data item when it's invalid will not result in an error, but the data reported may not have relevant meaning.

9.3.4 *Variable Data (V)* — This is a class of variable data which includes all the previously defined types of variables.

9.4 *Variable Data Item Dictionary*

Table 8 Variable Data Item Dictionary

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*
ActiveCarriers	CV	List current status of all carrier information in the TSC database.	SV	L,n 1. <CarrierInfo$_1$> . . n. <CarrierInfo$_n$>	
ActiveTransfers	CV	List current status of all ACTIVE TRANSFER commands.	SV	L,n 1. <TransferCommand$_1$> . . n. <TransferCommand$_n$>	
ActiveVehicles	CV	List current status of all vehicles available or being used for TRANSFER commands.	SV	L,n 1. <VehicleInfo$_1$> . . n. <VehicleInfo$_n$>	
CarrierID	CV	ID of the carrier being moved.	DVVAL	A[1–64]	If an Id is created by the equipment (not obtained via an id reader, the host interface, or the user interface) it must be of the following format: UNKNOWNEqpNameSeq Where: UNKNOWN are the exact characters "UNKNOWN" EqpName is the value of the EqpName ECV (truncated if required) Seq is a unique sequence identifier determined by the vendor.
CarrierID$_i$	CV	ID of the i^{th} carrier.	SV	A[1–64]	See comment for CarrierID.
CarrierIDList	CV	The Ids of the Carriers being moved.	DVVAL	L,n 1.<CarrierID$_1$> . . n.<CarrierID$_n$>	'n' is the number of carriers being simultaneously transferred.
CarrierInfo	CV	All database information associated with a particular carrier generating an event.	DVVAL	L,3 1. <CarrierID> 2. <VehicleID> 3. <CarrierLoc>	

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*
$CarrierInfo_i$	CV	All database information associated with the i^{th} carrier.	SV	L,3 1. <$CarrierID_i$> 2. <$VehicleID_i$> 3. <$CarrierLoc_i$>	
CarrierLoc	CSV	Unique location of the carrier within ITS as reported by the TSC.	DVVAL	A[1–64]	For multiple position vehicles, the "CarrierLoc" must be unique for each position on the vehicle and must be distinct from a location on any other vehicle.
$CarrierLoc_i$	CSV	Unique Location of the ith carrier within ITS as reported by the TSC.	SV	A[1–64]	
CommandName	CV	Host command issued to controller.	DVVAL	A[1–20]	
CommandID	CV	Remote Command ID Command ID generated by TSC.	DVVAL	A[1–64]	Used to subsequently refer to a specified remote command (e.g., to cancel a remote command). If a command is generated by the Transport System Controller using Non-Transition Collection Event "OperatorInitiatedAction", the commandId must begin with the string 'MANUAL' followed by any arbitrary sequence identifier.
$CommandID_i$	CV	The i^{th} Remote Command ID. The i^{th} Command ID generated by TSC.	SV	A[1–64]	Used to subsequently refer to a specified remote command (e.g., to cancel a remote command).
CommandInfo	CV	Command information associated with a particular transfer command.	DVVAL	L,3 1. <CommandID> 2. <Priority> 3. <Replace>	
$CommandInfo_i$	CV	Command information associated with the i^{th} transfer command.	SV	L,3 1. <$CommandID_i$> 2. <$Priority_i$> 3. <$Replace_i$>	
CommandType	CV	The type of Command being initiated	DVVAL	A[1-20]	Valid Values are 'TRANSFER' 'CANCEL' 'ABORT'
CurrentPortStates	CV	Current State of all the ports	SV	L,n 1. <$PortInfo_1$> . . n. <$PortInfo_n$>	
DestPort	CV	Destination port unique identifier	DVVAL	A[1–64]	Must be the name of the port not the corresponding transport system node name or number.

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*
DestPort$_i$	CV	The i[th] Destination port unique identifier	SV	A[1–64]	Must be the name of the port not the corresponding transport system node name or number.
EnhancedCarriers	CV	List Current status of all carrier information in the TSC database. This includes all carriers for which there are Transfer commands.	SV	L,n 1. <EnhancedCarrierInfo$_1$> . . n. <EnhancedCarrierInfo$_n$>	
EnhancedCarrier-Info$_i$	CV	All database information associated with a particular carrier.	SV	L,4 1. <CarrierID$_i$> 2. <VehicleID$_i$> 3. <CarrierLoc$_i$> 4. <InstallTime$_i$>	
EnhancedTransfers	CV	List current status of ALL transfer commands.	SV	L,n 1. <EnhancedTransferCommand$_1$> . . n. <EnhancedTransferCommand$_n$>	
EnhancedTransfer Command$_i$	CV	Information associated with a particular Transfer command.	SV	L,3 1. <CommandInfo$_i$> 2. <TransferState$_i$> 3. L,n 1. <TransferInfo$_1$> . n. <TransferInfo$_n$>	
EnhancedVehicles	CV	List current status of all vehicles available or being used for TRANSFER commands.	SV	L,n 1. <EnhancedVehicle$_1$-Info> . . n.<EnhancedVehicle-Info$_n$>	
EnhancedVehicle-Info$_i$	CV	Information associated with a particular vehicle.	SV	L,3 1. <VehicleID> 2. <VehicleState> 3. <VehicleLocation>	
EqpName	CV	Unique ID of the TSC	ECV	A[1–80]	Like a device name
InstallTime$_i$	CV	Time the carrier was created in the TSC database.	SV	TIME (A16)	yyyymmddhhmmsscc
PortID	CV	ID of the port	DVVAL	A[1–64]	
PortID$_i$	CV	ID of the port	SV	A[1–64]	
PortInfo$_i$	CV	Port information associated with a particular port.	SV	L,2 1. <PortID$_i$> 2. <PortTransferState$_i$>	
PortTransferState$_i$	CV	Port Transfer State	SV	U2	1 – OutOfService 2 – InService

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*
Priority	CV	Remote command priority	DVVAL	U2	0 is not valid. 1 is the LOWEST priority, 99 is the highest priority.
$Priority_i$	CV	The i^{th} Remote command priority	SV	U2	0 is not valid. 1 is the LOWEST priority, 99 is the highest priority.
Replace	CV	Flag to denote if a transfer command involves a carrier replace at the DestPort.	DVVAL	U2	0 = OFF > 0 = ON
$Replace_i$	CV	The i^{th} flag used to denote if a transfer command involves a carrier replace at the DestPort.	SV	U2	0 = OFF > 0 = ON
ResultCode	CV	Result Code of a transport system command. Associated with the command completion event.	DVVAL	U2 Successful = 0 Unsuccessful ≠ 0 ResultCode's that must be implemented are: Canceled Aborted	Values of ResultCode will correspond to meaningful completion results (0 always signifies normal successful completion).
SourcePort	CV	Source port unique identifier	DVVAL	A[1–64]	Must be the name of the port not the corresponding transport system node name or number.
$SourcePort_i$	CV	The i^{th} Source port unique identifier	SV	A[1–64]	Must be the name of the port not the corresponding transport system node name or number.
SpecVersion	CV	Version of SEMI E82 to which the equipment is compliant.	SV	A[0–20]	Example values are: E82-0999, E82-0301. If the equipment is not compliant, a zero length value may be specified.
TransferCommand	CV	Information associated with a particular TRANSFER command.	DVVAL	L,n 1. <CommandInfo> 2. <$TransferInfo_1$> . . . n. <$TransferInfo_m$>	m ≤ Number of carriers in the Transfer Unit
$TransferCommand_i$	CV	Information associated with the i^{th} TRANSFER command.	SV	L,2 1. <$CommandInfo_i$> 2. L, m 1. <$TransferInfo_1$> . . . m. <$TransferInfo_m$>	m = Number of carriers in the Transfer Unit

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*
TransferComplete-Info	CV	Carrier information associated with a transfer.	DVVAL	L,n 1.<L,2 1. <TransferInfo$_1$> 2. <CarrierLoc$_1$(*1)> : : n.<L,2> 1. <TransferInfo$_n$> 2. <CarrierLoc$_n$(*1)>	N : size of Transfer Unit
TransferInfo	CV	Carrier information associated with a particular transfer command.	DVVAL	L,3 1. <CarrierID> 2. <SourcePort> 3. <DestPort>	
TransferInfo$_i$	CV	Carrier information associated with the ith transfer command.	SV	L,3 1. <CarrierID$_i$> 2. <SourcePort$_i$> 3. <DestPort$_i$>	
TransferPort	CV	Transfer Port unique identifier	DVVAL	A[1–64]	Must be the name of the port where the transfer is taking place, not the corresponding transport system node name or number.
TransferPortList	CV	Transfer Port information associated with a particular vehicle arrival or departure event.	DVVAL	L,n 1. <TransferPort$_1$> 2. <TransferPort$_2$> . . . n. <TransferPort$_n$>	n > 1 for simultaneous transfers
TransferState$_i$	CV	State of Transfer Command	SV	U2	1. Queued 2. Transferring 3. Paused 4. Canceling 5. Aborting 6. Waiting
TSCState	CV	TSC State (SYSTEM)	SV	U2	1 = SC Init 2 = Paused 3 = Auto 4 = Pausing
VehicleID	CV	Unique identification of a vehicle associated with an event.	DVVAL	A[1–32]	
VehicleID$_i$	CV	Unique identification of the ith vehicle.	SV	A[1–32]	
VehicleInfo	CV	Information associated with a particular vehicle.	DVVAL	L,2 1. <VehicleID> 2. <VehicleState>	

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comment*
$VehicleInfo_i$	CV	Information associated with the ith vehicle.	SV	L,2 1. <$VehicleID_i$> 2. <$VehicleState_i$>	
VehicleLocation	CV	Location of the Vehicle	DVVAL	A[0-64]	The vehicle's port location. The data is only valid if the vehicle is Parked, Acquiring, or Depositing.
$VehicleLocation_i$	CV	Location of the Vehicle	SV	A[0-64]	The vehicle's port location. The data is only valid of the vehicle is Parked, Acquiring, or Depositiong.
VehicleState	CV	The state of the vehicle	DVVAL	U2	1 = Removed 2 = Not Assigned 3 = Enroute 4 = Parked 5 = Acquiring 6 = Depositing
$VehicleState_i$	CV	The state of the ith vehicle	SV	U2	See VehicleState above.

(*1) Current location (port or vehicle id) of the carrier is reported in 'CarrierLoc'. This may be used as a source port in a following transfer command.

10 Alarm List

10.1 Since each model of IBSEM equipment differs in configuration, it is not practical to provide an exhaustive list of all possible alarms. Instead, the IBSEM is requiring the two tables provided as described in SEMI E30 (Document Section). Alarm List Table which is intended to provide for equipment configuration specific alarms and Alarm ID, Alarm Set/Cleared Event Table. Any alarm that is displayed locally at the equipment, if enabled, is required to be sent to the host. To be compliant, Tables 9 and 10 must be completed by the supplier, documenting all alarms.

10.2 *Alarm List Table*

10.2.1 The alarm list table contains examples of alarms that pertain to various configuration aspects of equipment. These examples are intended to illustrate that alarms pertain to situations in which there exists a potential for exceeding physical safety limits associated with people, equipment, and material being transported as per the SEMI E30 definition of an alarm. See SEMI E30 for further reference. The supplier is responsible for supplying documentation associated with these alarm definitions. Each alarm will have an associated alarm text (ALTX) and alarm identifier (ALID). Table 9 contains example alarm list information that is intended to be augmented when the IBSEM equipment supplier documents its interface. Examples highlighted by (*) are required by IBSEM.

Table 9 Alarm List Table

Equipment Cfg.	*Alarm Text*	*ALID*	*Danger*		*Affected*		
			Potential	*Imminant*	*Operator*	*Equipment*	*Material*
OHT, OHS, RGT, AGT, and DWC	vehicle obstruction* (exceeded timeout)		X			X	
	transport system equipment failure*		X			X	X
	Carrier Handoff Parallel I/O failure*		X		X	X	X
	database error*		X			X	

10.3 *Alarm ID, Alarm Set/Cleared Event Table*

10.3.1 The Alarm ID, Alarm Set/Cleared Event table documents the association of each ALID to a set and cleared event as required by SEMI E30. See SEMI E30 for further reference. The supplier is responsible for supplying documentation associated with these alarm definitions. Each alarm will have associated alarm set and cleared collection event identifiers ($CEID_{set}$ and $CEID_{clear}$). Table 10 contains example alarm event information that is intended to be replaced when the IBSEM equipment supplier documents its interface.

Table 10 Alarm ID, Alarm Set/Cleared Event Table

Alarm ID (ALID)	*Alarm SET Event ($CEID_{set}$)*	*Alarm CLEARED Event ($CEID_{cleared}$)*

11 Remote Commands

11.1 The purpose of this section is to identify remote commands, command parameters, and valid commands versus states pertinent to the SEM. All remote commands identified in this section follow the format of the S2,F41 Host Command Send SECS-II message except for the TRANSFER command which follows the S2,F49 Enhanced Remote Command Send SECS-II message.

11.2 *Requirements*

- The equipment shall support the SEMI E30 (according to the GEM capabilities required per Section 13) required remote commands.
- All the remote commands defined by IBSEM are required to be implemented as specified.
- The alphanumeric strings defined by IBSEM for RCMD and CPNAME are required.
- A completed table must be generated where an “X” is placed in the table for each state that a given command is valid.
- If additional remote commands are supported then a “remote commands versus valid states” matrix must be generated for these additional commands.
- For additional commands, a table must be generated similar to the remote command descriptions summary.

11.3 *Remote Commands Description*

11.3.1.1 *ABORT* — This command terminates the activity of a specific TRANSFER command based on CommandID while the command is in the ACTIVE state. This command may not be accepted due to mechanical issues if the vehicle is in a specific condition (e.g., depositing a carrier). The exact conditions surrounding when the ABORT command is not accepted by the TSC must be documented by the IBSEM equipment supplier.

11.3.1.2 *CANCEL* — This command terminates the activity of a specific TRANSFER command based on CommandID while the command is in either the QUEUED or WAITING state. This command must always be accepted by the TSC when in the QUEUED or WAITING state.

11.3.1.3 *PAUSE* — This command puts the TSC in the PAUSING state.

11.3.1.4 *RESUME* — This command puts the TSC in the AUTO state.

11.3.1.5 *TRANSFER* — This is a SECS-II Enhanced Remote Command instead of a SECS-II Host Command Send (S2,F49 instead of S2,F41). See the examples in Related Information 1 for details.

11.3.1.5.1 This command is used to perform the entire transfer command for the carrier(s) to be transferred between transfer ports. The execution of this command will include allocation of a vehicle, acquiring the carrier(s), moving the carrier(s) to the destination port(s), depositing the carrier(s), and returning the vehicle for other use. The number of carriers in the TRANSFER command is less than or equal to the number of carriers in the transfer unit (see Section 5.2 for definition of the transfer unit). It is recommended that the Carrier already be at the SOURCEPORT upon the issue of the TRANSFER command, otherwise, it is possible that the TRANSFER command can fail on "empty acquire" when no carrier is present on the SOURCEPORT when the acquire is started.

11.3.2 *Remote Commands and Associated Host Command Parameters*

11.3.2.1 This table describes the allowable command parameters (CPNAME) for each remote command (RCMD). Equipment shall support all parameters. The column marked Req/Opt, specifies which parameters are required to be sent by the host and which parameters may be optionally sent by the host.

Table 11 Allowable Command Parameters

Remote Command	*Parameters*		
	Cpname	*Req/opt*	*Comment*
ABORT	"COMMANDID"	R	Must specify the commandID that was used for the TRANSFER command that is being ABORT'ed.
CANCEL	"COMMANDID"	R	Must specify the commandID that was used for the TRANSFER command that is being CANCEL'ed.
PAUSE	None	NA	Once received by the TSC, the TSC will queue any TRANSFER commands until the TSC receives and successfully executes the RESUME command. Once in the AUTO state the TSC will process the TRANSFER commands in its queue.
RESUME	None	N/A	Returns the PAUSEd TSC to the AUTO state.
TRANSFER	"COMMANDINFO" "TRANSFERINFO"*	R R	* TRANSFER commands are allowed a maximum of |transfer unit| TRANSFERINFO's.

11.3.3 *Host Command Parameters Name and Values*

Table 12 Host Command Parameters CPNAMES

Cpname	*Parameter Value*		
	Description	*Range*	*Format*
CARRIERID	ID of the carrier being moved.		A[1–64]
COMMANDID	Unique command identifier created by the Host.		A[1–64]
COMMANDINFO	L,3 COMMANDID PRIORITY REPLACE		L,3
DESTPORT	Destination port unique identifier.		A[1–64]
PRIORITY	Remote command priority	0 is not valid. 1 is the LOWEST priority, 99 is the highest priority.	U2
REPLACE	Flag to denote a TRANSFER replace carrier. Replace a carrier already on the port with the one on the vehicle.	0 is OFF > 0 is ON	U2
SOURCEPORT	Source port unique identifier.		A[1–64]
TRANSFERINFO	L,3 CARRIERID SOURCEPORT DESTPORT		L,3

11.3.4 *Remote Commands versus TSC and TRANSFER Command States*

11.3.4.1 The following table indicates TSC and TRANSFER Command States where the remote commands are allowed. This is indicated with a “X” mark. Remote commands act independently of other state models (e.g., Vehicle States and Carrier States are independent from the IBSEM remote commands). “N/A” (Not Applicable) means that States and Remote Commands have no direct relationship.

Table 13 Remote Commands versus TSC and TRANSFER Command States

	COMMAND				
	TRANSFER	RESUME	PAUSE	CANCEL	ABORT
TSC STATE					
AUTO	X		X	X	X
ALARMS	X	X	X	X	X
NO ALARMS	X	X	X	X	X
INIT					
PAUSED	X	X		X	X
PAUSING	X	X		X	X
TRANSFER COMMAND STATE					
QUEUED	N/A	N/A	N/A	X	
WAITING	N/A	N/A	N/A	X	
ACTIVE (PAUSED or TRANS.)	N/A	N/A	N/A		X
ABORTING	N/A	N/A	N/A		
CANCELING	N/A	N/A	N/A		

12 Scenarios

12.1 The following scenarios represent Application Notes. In the scenarios, all unique Remote Command ID's must initially be created and sent by the Host. Subsequent event reports sent from the equipment referring to the status of a particular remote command must return the applicable CommandID. All collection events identified in Table 6 are assumed to be enabled (per the SEMI E30 definition/scenario) throughout the following scenarios. Variable data specified in the Host commands has been chosen arbitrarily for the purpose of demonstrating message structure/content. The Collection Event Report definitions contained in the scenarios are examples that could be defined by the Host.

12.2 *Normal Transport*

12.2.1 *Single Carrier Transfer — Transfer Unit Size is Equal to 1 Carrier*

12.2.1.1 A carrier is transported from a source port to a destination port.

12.2.3 *Continuous Multiple Carrier Transfer – Transfer Unit Size is Equal to 2 Carriers*

12.2.3.1 Two carriers are transported from a single source port to a single destination port. This scenario is used to demonstrate how the TSC would handle a continuous load/unload request. It also shows the sequence of events associated with the continuous case. It is assumed that the source and destination ports must be the same equipment.

STEP	COMMENTS	HOST	TSC	COMMENTS
1.	The carriers are prepared for a TRANSFER command. They are sitting sequentially at the single pickup point source output. 123456 is at the vehicle accessible source port for the first acquire of two. 654321 is sitting right behind it, and it will be shuttled out after 123456 is acquired by the vehicle. The vehicle will then acquire 654321 once in position. The depositing order depends on the IBSEM supplier’s functional specification.

12.2.4 *Carriers Replace*

12.2.4.1 One carrier is transported from the source port (e.g., stocker output port) to the destination port (e.g., process equipment port-1) and the other carrier is transported from the same port (process equipment port-1) to the destination ports (e.g., stocker input port) by the same vehicle. The transport vehicle is capable of acquiring and depositing these two carriers sequentially. This function is used for the depressuring process equipment with door, because the door opening time should be shorten for this type of equipment.

STEP	COMMENTS	HOST	TSC	COMMENTS
1.	Both carriers are prepared for a TRANSFER command at the source ports.

12.3 *Anomaly Transport*

12.3.1 *Host-Initiated CANCEL of a TRANSFER Command*

12.3.1.1 The Host wishes to terminate a previously issued TRANSFER command. This could be done so that the Host could issue another TRANSFER command with new command parameter values or so that a PGV could transfer the carriers. A Host initiated ABORT scenario would be similar to this scenario except that the remote command would be ABORT instead of CANCEL and the states when it is accepted by the TSC are different.

STEP	COMMENTS	HOST	TSC	COMMENTS
1.	The Host desires to CANCEL a particular TRANSFER command that it had previously issued to the TSC. Outstanding TRANSFER command has CommandId = "111111"			
2.	Host Command Send (HCS) **CANCEL** • COMMANDID = "111111" The COMMANDID must match that of the TRANSFER command that is being CANCEL'ed	S2,F41->		
3.			<-S2,F42	Host Command Acknowledge (HCA) This is the point where the TSC would reject the CANCEL command if not in the QUEUED or WAITING state.
4.			<-S6,F11	Event Report Send (ERS) TransferCancelInitiated • CommandID = "111111"
5.	Event Report Acknowledge (ERA)	S6,F12->		

STEP	COMMENTS	HOST	TSC	COMMENTS
6.			<-S6,F11	Event Report Send (ERS) TransferCancelCompleted • CommandID = "111111"
7.	Event Report Acknowledge (ERA)	S6,F12->		
8.			<-S6,F11	Event Report Send (ERS) VehicleUnassigned • VehicleID = "CARXX" • CommandID = "111111"
9.	Event Report Acknowledge (ERA)	S6,F12->		
10.	The host may now initiate another TRANSFER command for the carrier(s) from the TRANSFER command that was canceled or allow a PGV to deliver the carriers. If there were multiple carriers in the CANCEL'ed TRANSFER then the Host may elect to issue one TRANSFER command for all carriers or individual TRANSFER commands for each carrier. The SOURCEPORT in the resulting TRANSFER command(s) will be the same as when the original TRANSFER was issued since the carriers have not moved.			

12.3.2 *Host-Initiated Override of a TRANSFER Command*

12.3.2.1 The Host wishes to override the destination of a previously issued TRANSFER command after the command has entered the ACTIVE state. This could be done so that the Host could issue another TRANSFER command with a new destination.

STEP	COMMENTS	HOST	TSC	COMMENTS
1.	The Host desires to ABORT a particular TRANSFER command that it had previously issued to the TSC. The outstanding TRANSFER command has CommandID = "111111"			
2.	Host Command Send(HCS) **ABORT** • COMMANDID = "111111" The COMMANDID must match that of the TRANSFER command that is being ABORT'ed	S2,F41->		

STEP	COMMENTS	HOST	TSC	COMMENTS
3.			<-S2,F42	Host Command Acknowledge (HCA) This is the point where the TSC would reject the ABORT command if it is not possible for the transport system to abort the ACTIVE TRANSFER command.
4.			<-S6,F11	Event Report Send (ERS) TransferAbortInitiated • CommandID = “111111”
5.	Event Report Acknowledge (ERA)	S6,F12->		
6.			<-S6,F11	Event Report Send (ERS) TransferAbort-Completed • CommandID = “111111” • CarrierLoc = “LOC1” • TransferInfo
7.	Event Report Acknowledge (ERA)	S6,F12->		
8.			<-S6,F11	Event Report Send (ERS) VehicleUnassigned • VehicleID = “CARXX” • CommandID = “111111”
9.	Event Report Acknowledge (ERA)	S6,F12->		
10.	The host will now initiate another TRANSFER command for the carrier(s) from the TRANSFER command that was aborted.			
11.	Enhanced Remote Command(ERC) **TRANSFER** • COMMANDID = “111112” • PRIORITY = 5 • REPLACE = 0 • TRANSFERINFO$_1$ - L,3 1. CARRIERID = “123456” 2. SOURCEPORT = The current location of the carrier as sent from the TSC to the Host in the TransferCompleted for the failed TRANSFER command(an example is a port on a vehicle). The Host does not have to know the difference of whether the carrier is still on the car or not to send another TRANSFER command. 3. DESTPORT = “PORTYY”	S2,F49->		
12.			<-S2,F50	Enhanced Remote Command Acknowledge (ERCA)
13.	Scenario will now follow 12.1.1			

12.3.3 *Unsuccessful Completion of a TRANSFER Command*

12.3.3.1 The TSC must unsuccessfully complete a previously issued TRANSFER command due to an unrecoverable transport system error. Although this scenario follows the GEM defined scenario for Alarm handling, it was included to define the specifics of an IBSEM alarm and subsequent unsuccessful TRANSFER command completion. The abort of TRANSFER command should be performed by host as described in Section 12.2.2.

12.			<-S6,F11	Event Report Send (ERS) AlarmCleared • All VID's necessary to fully describe the nature of the unrecoverable error must be sent to the Host in this event.
13.	Event Report Acknowledge (ERA)	S6,F12->		
14.	The host may now initiate another TRANSFER command for the carrier(s) from the TRANSFER command that was completed unsuccessfully. If there were multiple carriers in the unsuccessful TRANSFER then the Host may elect to issue one TRANSFER command for all carriers or individual TRANSFER commands for each carrier. The SOURCEPORT in the resulting TRANSFER command(s) may be an internal vehicle location or any other location along the path of the TRANSFER command.			

12.3.4 *Connection or Reconnection between TSC and Host*

12.3.4.1 The Factory Host System crashes (or loses communication with the TSC for a time exceeding all time-outs and retries) and must re-synchronize with the TSC in lieu of several events completing while the communication link between the two was down.

STEP	COMMENTS	HOST	TSC	COMMENTS
1.	Communication session between host and TSC (re)established. Host establishes communication with the TSC per the GEM standard scenario (e.g., S1F13, etc).			
2.	Host Command Send (HCS) **PAUSE**	S2,F41->		
3.			<-S2,F42	Host Command Acknowledge (HCA)
4.			<-S6,F11	Event Report Send (ERS) TSCPauseInitiated

7.		S6,F12->		

STEP	COMMENTS	HOST	TSC	COMMENTS
8.	Selected Equipment Status Request (SSR) • ActiveCarriers • ActiveVehicles • ActiveTransfers	S1,F3->		HOST asks for carrier and vehicle information
9.			<-S1,F4	Selected Equipment Status Data (SSD) • CarrierInfo - L,3 . . (one CarrierInfo for each carrier) . • VehicleInfo - L,2 . . (one VehicleInfo for each vehicle) . • TransferCommand - L,n . . (one TransferCommand for each . Active TRANSFER command)
10.	The HOST updates it's model of the system with the information from the vehicle and carrier status data.			
11.	Host Command Send (HCS) **RESUME**	S2,F41->		HOST enables the system to continue operations.
12.			<-S2,F42	Host Command Acknowledge (HCA)
13.			<-S6,F11	Event Report Send (ERS) TSCAutoCompleted
14.	Event Report Acknowledge (ERA)	S6,F12->		
15.				System continues processing all commands that were in process or queued before/during the Host crash or communication loss/initialization. System will also now process new commands.

13 GEM Capabilities

13.1 The purpose of this section is to specify any SEMI E30 additional capabilities that are required to be supported by this class of equipment.

13.2 *Requirement*

13.2.1 This standard requires that the SEMI E30 fundamental requirements and additional capabilities have been implemented on the IBSEM equipment with the exception of Trace Data Collection, Remote Control, Process Program Management, and Limits Monitoring and Spooling. The TRANSFER Command State Model will serve as the Equipment Processing State Model specified in SEMI E30. If these capabilities are implemented, they will be implemented as required by SEMI E30. The SEMI E30 additional capabilities required by IBSEM are:

- Establish Communications
- Dynamic Event Report Configuration
- Variable Data Collection
- Status Data Collection
- Alarm Management
- Equipment Constants
- Material Movement
- Equipment Terminal Services
- Clock
- Control (host-initiated)

RELATED INFORMATION 1
IBSEM UNIQUE CAPABILITIES

NOTE: This related information is not an official part of SEMI E82, but was approved for publication by full letter ballot procedures on April 15, 1999.

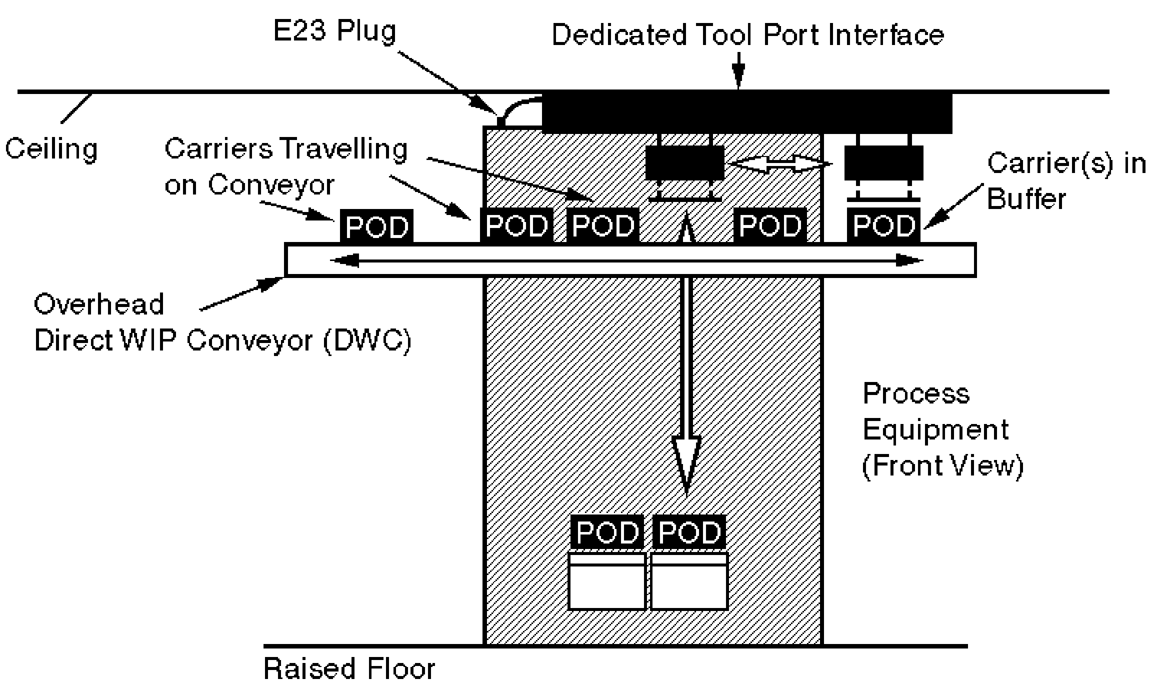

Figure R1-2
SEMI E23 Example Diagram for DWC

R1-3 Hardware Architecture

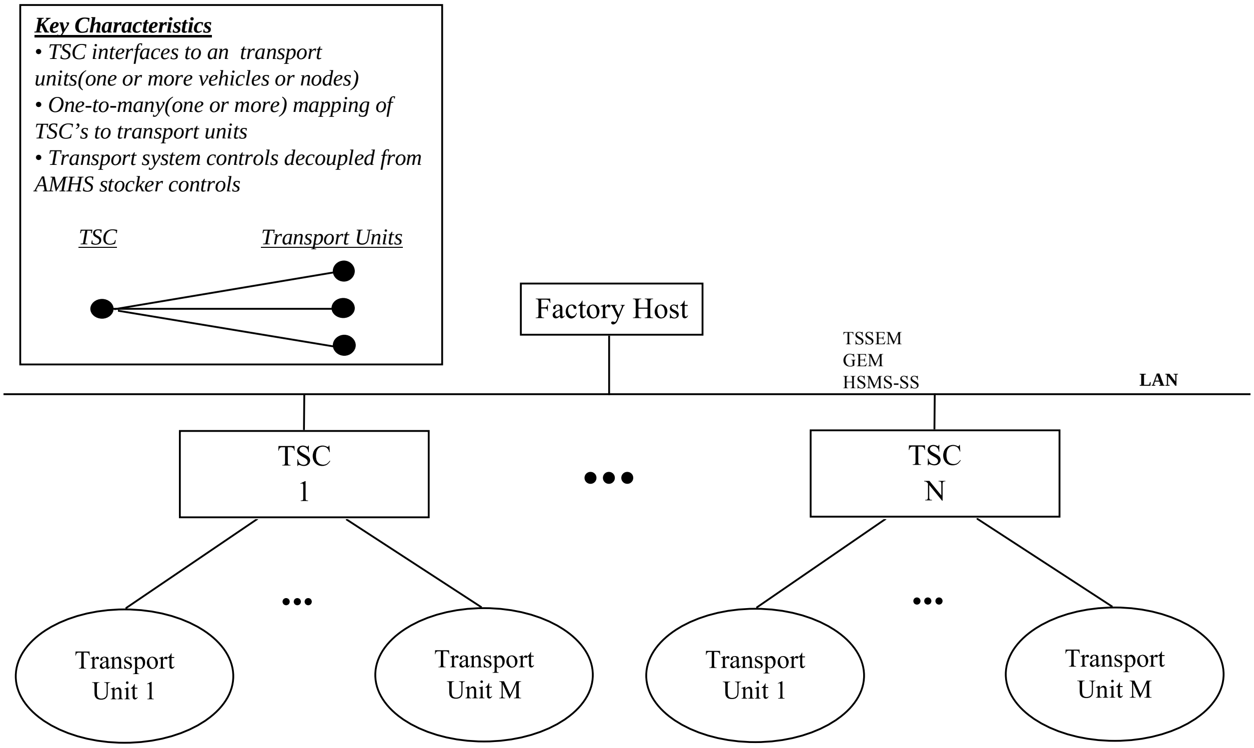

Figure R1-3
Configurable Centralized TSC Architecture (Logical View)

R1-4 Traffic Management Characteristics

R1-4.1 At a minimum, the TSC must offer Priority-based First-In-First-Out (FIFO) queuing of TRANSFER commands. In other words, all TRANSFER commands which have yet to be processed by the transport system must be serviced in the order in which they are received by the TSC based on the priority given in the host command. The minimum priority levels required to be available on IBSEM equipment are “Normal” and “High.” “Normal” and “High” priorities will be denoted by U2 compatible numbers as per the definition of the priority in the Variable Data and Remote Command sections of this document. Other options may be implemented, but to be an IBSEM equipment it must at a minimum have the ability to be configured to perform Priority-based FIFO queuing of TRANSFER commands. Additionally, the command priorities are to be utilized during execution of the commands to the following level: any “High” priority command will cause all other commands that are not “High” priority to be usurped. That is to say that all other commands will modify the execution steps to allow the “High” priority commands to be completed in the minimal elapsed time possible. Multiple “High” priority commands will act upon each other according to the same rules as “Normal” commands act on each other.

The following TRANSFER commands are received by the TSC in top to bottom order:

TRANSFER Command	Priority
1	Normal
2	Normal
3	High
4	Normal
5	High

Corresponding TSC processing queue for outstanding TRANSFER commands :

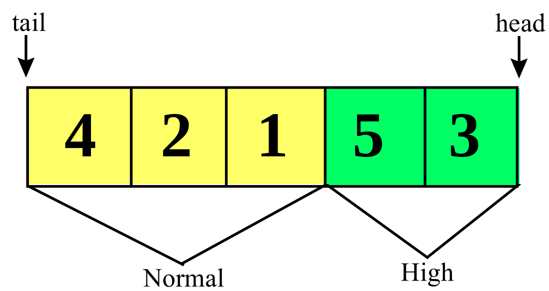

Figure R1-4
TSC Priority-based FIFO TRANSFER Command Processing Example

R1-4.2 The TSC must manage the vehicles so that TRANSFER requests are queued for later service if all vehicles are currently utilized.

R1-5 Transport System Handling and Delivery of the Transfer Unit

R1-5.1 A transfer unit must always be delivered by the same vehicle simultaneously. A transfer unit cannot be split between multiple vehicles.

SEMI E86-0200
PROVISIONAL SPECIFICATION FOR CIM FRAMEWORK FACTORY LABOR COMPONENT

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on October 21, 1999. Initially available at www.semi.org January 2000; to be published February 2000. Originally published September 1999.

1 Purpose

1.1 The Factory Labor Component provides the capability to support the qualification and management of available, qualified human resources for manufacturing operations.

1.2 The technical content of this ballot addresses the portion of the CIM Framework domain specified in SEMI E81, Provisional Specification for CIM Framework Domain Architecture, concerned with management of the availability of qualified factory personnel. This specification provides the interfaces required by Manufacturing Execution Systems to:

- Configure the Person resource model.
  - Each Person's name (or appropriate alias), identification, department, role, etc. There may be cases where identifying information should not be used to associate a person with the required factory labor records.
  - Each Person's initial skills and authorization to perform jobs and access data.
  - Each Person's initial assignment to other factory resources (such as specific machines or factory areas).
  - Each Person's medical qualifications.
- Define skill maintenance tasks and what triggers them.
- Track and report the Person's skills, authorization, and assignments and record these in the Person's histories.
- Support assignment of Persons to factory jobs and monitor and record job progress (from the perspective of the Person's role).
- Monitor skill maintenance triggers (such as expired skill certification) and recommend skill maintenance jobs.
- Execute triggered skill maintenance jobs.
  - Change Person capabilities (before and after training).
  - Execute and monitor skill maintenance jobs (training, certification testing) and report job progress.
  - Record skill maintenance triggers and job results in Person's skill maintenance histories.
- Collect and report Person and skill performance (utilization and effectiveness).
- Maintain relationships between Persons and system security for identity authentication and authorization.

2 Scope

2.1 Specifically, this component provides the services to:

- Manage the assignment of qualified and available labor resources for factory operations.
- Manage the training and medical requirements for factory operations.
- Support the maintenance of personnel information (full name, employee number, department, shift assignment, machines qualified to operate, course and medical examination records).
- Support the maintenance of personnel skill qualification histories (courses and medical examinations successfully completed) of factory personnel.

2.2 The Factory Labor Component is divided into two subcomponents:

- Person Management, which tracks, logs, and maintains availability and task assignment for factory operations personnel within the manufacturing facility. Also provides support for the management of personnel information, training, and medical qualifications.
- Skill Management, which provides support for the management of training and medical requirements for factory operations.

2.3 Figure 1 depicts the relationships between these two components and their interaction with other CIM Framework components defined in the Section 7.2 Functional Partitioning of SEMI E81, Provisional

Specification for CIM Framework Domain Architecture.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification is designated as provisional due to known areas that need to be completed. The following items summarize the deficiencies of the provisional specification to be addressed before a subsequent ballot to upgrade it to full standard status.

3.2 *Provisional Status*

3.2.1 The following items need to be completed before conducting a subsequent ballot to upgrade the Factory Labor Component to full standard status.

- Define skill maintenance tasks and what triggers them.
- Monitor skill maintenance triggers (such as expired skill certification) and recommend skill maintenance jobs.
- Maintain relationships between persons and system security for identity authentication and authorization.

3.2.2 It is anticipated that a future document defining the Resource Abstract Interface will satisfy the first two items.

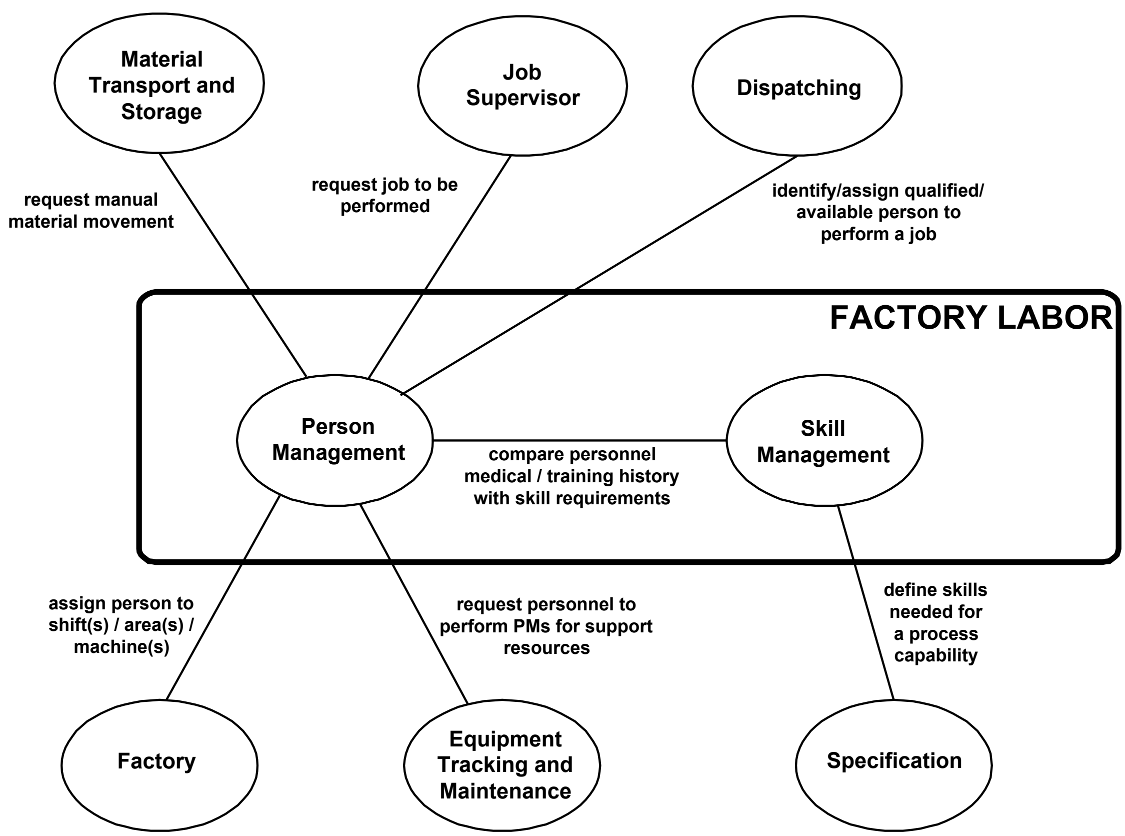

Figure 1
Factory Labor Component Relationships

4 Referenced Standards

4.1 *SEMI Standard*

SEMI E81 — Provisional Specification for CIM Framework Domain Architecture

4.2 *ISO/IEC Standard*[1]

ISO/IEC 14750 (also ITU-T Recommendation X.920) — Information Technology – Open Distributed Processing – Interface Definition Language

4.3 *OMG Standard*[2]

UML Notation Guide, Version 1.1, document number ad/97-08-05

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *person* — personnel performing manufacturing operations within a factory.

5.2 *person responsibility* — the concept of "responsibility" implies that factory personnel are authorized to perform, operate or access a specific factory object (but it does not imply ownership).

5.3 *skill* — skill is an attribute of factory personnel denoting that they are qualified to assist a process resource or job in the performance of a process capability or some other factory operation.

5.4 *skill qualification* — a skill qualification indicates that factory personnel meet a requirement (or all requirements) necessary to perform some factory operation.

5.5 *skill requirement* — a skill requirement is the training or medical examination(s) required to achieve a specific skill.

6 Requirements

6.1 The following sections provide the specification of interfaces that comprise the Factory Labor Component. The model notation used is the Unified Modeling Language (UML). UML is documented in the UML Notation Guide. The details of each interface are supplied using standard IT-ODP-IDL. Conformant implementations of the Factory Labor Component shall provide support for all elements of the IDL specifications and the semantics provided in the UML models. Conformant implementations are not constrained to any specific implementation approach, provided that a mapping is provided to the IDL specification.

6.2 *External Interfaces, Global Type Definitions, Global Exceptions and Events*

6.2.1 The following interfaces (external to this component), global type definitions, global exceptions, and events are required to support the Factory Labor component specification.

6.2.2 *Abstract and Base Interfaces*

6.2.2.1 Base interfaces provide a suite of interfaces that are used throughout the CIM Framework Specification. The Abstract Interfaces provide a hierarchy of abstract interfaces that are used as "Inherited Interfaces" in the rest of the framework. These interfaces are expected to be specialized in a specific implementation.

6.2.2.2 This section identifies base and abstract interfaces required by the Factory Labor component specification.

```
interface NamedEntity {
};

interface OwnedEntity : NamedEntity {
};
```

1 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland

2 Object Management Group, Inc., Framingham Corporate Center, 492 Old Connecticut Path, Framingham, MA 01701, 1.508.820.4300, [*http://www.omg.org/cgi-bin/doclist.pl*](http://www.omg.org/cgi-bin/doclist.pl)

```
interface Resource : OwnedEntity {
};

interface ComponentManager : Resource {
};

interface Job {
} ;
```

6.2.3 *Other CIM Framework Interfaces*

6.2.3.1 This section identifies interfaces within other CIM Framework components that are needed to satisfy relationships with the Factory Labor component.

```
interface HistoryCollection { // from Factory Services
} ;

interface History { // from Factory Services
} ;

interface MESFactory { // from Factory Management
} ;
```

6.2.4 *Global Type Definitions*

6.2.4.1 The CIM Framework uses IT-ODP-IDL *typedefs* in two ways:

- To define aliases for compound object types (*structs*), which can then be used in IDL specifications and
- To define aliases for basic object types, but with additional implied semantics. (e.g., the *units* typedef defines a *string*, whose contents conform to definitions found in SEMI E5).

6.2.4.2 This section identifies the global type definitions required by the Factory Labor component specification.

```
typedef sequence<string> stringSequence ;

typedef struct HistoryEvent_body {
        string subject ;
} HistoryEvent ;

struct ulonglong {
        unsigned long low ;
        unsigned long high ;
} ;

typedef ulonglong TimeT ;

typedef TimeT TimeStamp ;

struct IntervalT {
        TimeT lower_bound ;
        TimeT upper_bound ;
} ;
```

```
typedef IntervalT TimeWindow ;

typedef struct Shift_Structure {
        string name ;
        // ...
} Shift ;

typedef struct PersonResponsibilitystruct {
        string responsibilityCategory ;
        any responsibility ;
} PersonResponsibility;

typedef sequence<ProcessCapability> ProcessCapabilitySequence ;
typedef stringSequence CategorySequence ;
typedef sequence<HistoryEvent> HistoryEventSequence ;
typedef sequence<Job> JobSequence ;
typedef sequence<Machine> MachineSequence ;
typedef sequence<Person> PersonSequence ;
typedef sequence<QualificationData> QualificationDataSequence ;
typedef sequence<Resource> ResourceSequence ;
typedef sequence<SkillRequirement> RequirementSequence ;
typedef sequence<PersonResponsibility> ResponsibilitySequence ;
typedef sequence<Skill> SkillSequence ;

typedef string PropertyName;
struct Property
    {
    PropertyName property_name;
    any property_value;
    };
typedef sequence<Property> Properties;
```

6.2.5 *Global Exception Declarations*

6.2.5.1 An exception is an infrastructure mechanism used to notify a calling client of an operation that an unusual condition occurred in carrying out the operation. This section identifies the global exception declarations required by the Factory Labor component specification.

```
exception FrameworkErrorSignal {
        unsigned long errorCode ;
        any errorInformation ;
} ;

exception InvalidStateTransitionSignal {
} ;

exception SetValueOutOfRangeSignal {
} ;
```

6.2.6 *Events*

6.2.6.1 An event is an asynchronous message denoting the occurrence of some incident of importance. For example, state change or new object created. This section identifies the events defined by the Factory Labor component specification. Note that “//” or “/* ....*/” infers a comment.

```
/* Person lifecycle event definition. */
const string PersonLifecycleSubject =
        "/PersonManagement/PersonManager/PersonLifecycle" ;
typedef struct PersonLifecycleFilters_Structure {
        Property        name;           // “Name”, aPerson’s name
        Property        lifecycleEvent; // “LifecycleEvent”, LifecycleState
} PersonLifecycleFilters;
typedef struct PersonLifecycleEvent_Structure {
        string                          eventSubject;
        TimeStamp                       eventTimeStamp;
        PersonLifecycleFilters          eventFilterData;
        Properties                      eventNews;
        Person                          aPerson;
                        // Except when “Delete” where value will be nil
} PersonLifecycleEvent;

/* Person capacity changed event definition. */
const string PersonCapacityChangedSubject =
        "/PersonManagement/Person/CapabilityChanged" ;
typedef struct PersonCapacityChangedFilters_Structure {
        Property        name;           // “Name”, aPerson’s name
} PersonCapacityChangedFilters;
typedef struct PersonCapacityChangedEvent_Structure {
        string                          eventSubject;
        TimeStamp                       eventTimeStamp;
        PersonCapacityChangedFilters    eventFilterData;
        Properties                      eventNews;
        Person                          aPerson;
} PersonCapacityChangedEvent;

/* Person state changed event definition. */
const string PersonStateChangedSubject = "/PersonManagement/Person/StateChanged";
enum PersonState {PersonDefined, PersonOffShift, PersonOnShift,
PersonAvailableForWork, PersonNotAvailableForWork, PersonUnassignedToMachines,
PersonAssignedToJobs, PersonAssignedToMachines, PersonAvailableForMoreAssignments,
PersonAssignmentAtCapacityExceeded, PersonIdleWithJob, PersonBusyWithJob };
typedef struct PersonStateChangedFilters_Structure {
        Property        name;           // “Name”, aPerson’s name
        Property        formerState;    // “FormerState”, PersonState
        Property        newState;       // “NewState”, PersonState
} PersonStateChangedFilters;
typedef struct PersonStateChangedEvent_Structure {
        string                          eventSubject;
        TimeStamp                       eventTimeStamp;
        PersonStateChangedFilters       eventFilterData;
        Properties                      eventNews;
        Person                          aPerson;
} PersonStateChangedEvent;

/* Person shift worked changed event definition. */
const string PersonShiftChangedSubject = "/PersonManagement/Person/ShiftChanged";
typedef struct PersonShiftChangedFilters_Structure {
        Property        name;           // “Name”, aPerson’s name
        Property        fromShift;      // “FromShift”, former shift
```

```
        Property        toShift;        // "ToShift", new shift
} PersonShiftChangedFilters;
typedef struct PersonShiftChangedEvent_Structure {
        string                          eventSubject;
        TimeStamp                       eventTimeStamp;
        PersonShiftChangedFilters       eventFilterData;
        Properties                      eventNews;
        Person                          aPerson;
} PersonShiftChangedEvent;
```

6.3 *Person Management Component*

6.3.1 This component defines factory personnel (Person interface) to a CIM system. Persons are viewed as resources in the manufacturing environment, are assigned to a factory area, and own a detailed training and medical examination history (which qualifies them to perform a skill or set of skills). For example, there may be a requirement that an operator periodically completes specific training or medical testing. Qualifications would include verification that required training had occurred within the specified time limit. The associated skill would identify the process capability enabled for this person through that qualification. At any given time, a Person may be assigned to one or more factory jobs associated with other factory resources or operations.

6.3.2 The Component Information Model for Person Management is shown in Figure 2.

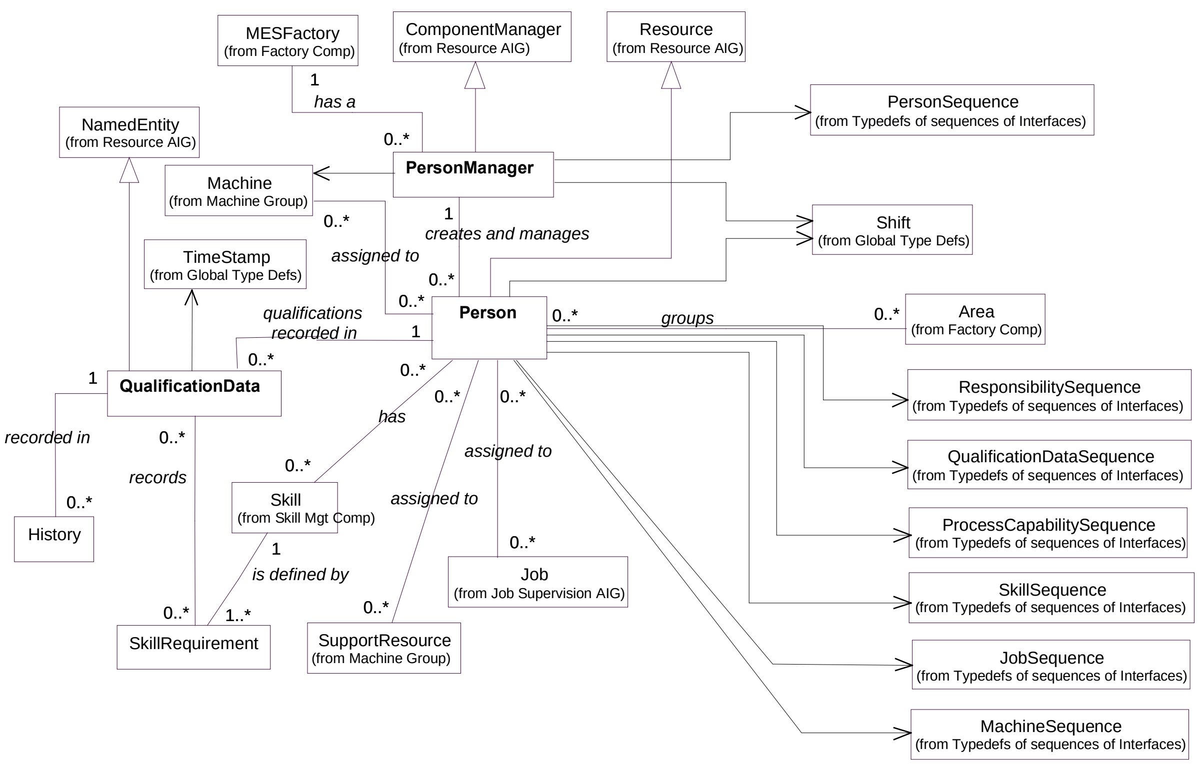

Figure 2
Person Management Component Information Model

6.3.3 *PersonManager Interface*

Interface: PersonManager

Inherited Interface: ComponentManager

Description: This is the interface between the Person Management Component and the rest of the CIM environment. The PersonManager creates instances of Persons within the factory and manages those Persons (shift, job assignment and status information). There are no limitations to the number of PersonManagers within a factory.

Exceptions:

/* This signal is raised with attempted creation of Person through the use of a Person identifier that already exists. */

```
exception PersonDuplicateSignal {string identificationNumber;};
```

/* This signal is raised when a retrieval operation fails because the Person specified by the argument could not be located. */

```
exception PersonNotFoundSignal {string identificationNumber;};
```

/* This signal is raised when a removal operation fails because the Person specified by the argument is not assigned to the PersonManager. */

```
exception PersonNotAssigned { Person unknownPerson;};
exception PersonRemovalFailedSignal { };
```

Published Events:

```
PersonLifecycleEvent
```

Provided Services:

/* Create an instance of Person with a unique identifier and add to the list managed by PersonManager. */

```
Person createPersonWithIdentifier (in string identificationNumber)
        raises (FrameworkErrorSignal, PersonDuplicateSignal);
```

/* Delete the Person identified by the argument from the list managed by PersonManager. */

```
void removePerson (in Person aPerson)
        raises (FrameworkErrorSignal, PersonRemovalFailedSignal,
                PersonNotAssignedSignal);
```

/* Return a set of Persons managed by the PersonManager. */

```
PersonSequence allPersons ( ) raises (FrameworkErrorSignal);
```

/* Search for an instance of Person using its unique identifier. Raises an exception if the Person is not found. */

```
Person findByIdentifier (in string identificationNumber)
        raises (FrameworkErrorSignal, PersonNotFoundSignal);
```

/* Return a set of all Persons logged on to the specified shift. */

```
PersonSequence allOnShiftPersons (in shift aShift) raises (FrameworkErrorSignal);
```

/* Return a set of all Persons available for work. */

```
PersonSequence allAvailableForWorkPersons ( ) raises (FrameworkErrorSignal);
```

/* Return a set of all Persons not available for work. */

```
PersonSequence allNotAvailableForWorkPersons ( ) raises (FrameworkErrorSignal);
```

/***** Manage Person / Machine relationship. *****/

/* Return a set of Persons qualified to operate a process or material handling machine. The Person is qualified to operate the machine if the machine is noted in the Person's skill list or if a comparison of the person's course and medical exam histories satisfy the requirements defined within the Skill Management Component for the noted machine. This method does not check the availability of the person to actually perform a task. */

```
PersonSequence allPersonsWithSkill (in Skill aSkill) raises (FrameworkErrorSignal);
```

/* Return a set of Persons available ("on duty" on the current shift) to operate the specified machine. This service assumes that a Person is qualified to operate the machine. */

```
PersonSequence allPersonsAvailableForMachine (in Machine aMachine)
        raises (FrameworkErrorSignal);
```

/* Return a set of all Persons currently assigned to the specified machine. */

```
PersonSequence allPersonsAssignedToMachine (in Machine aMachine)
        raises (FrameworkErrorSignal);
```

/* Return a set of all Persons currently assigned to machines. */

```
PersonSequence allAssignedToMachinesPersons ( ) raises (FrameworkErrorSignal);
```

/***** Manage Person/Job relationship. *****/

/* Return a set of Persons qualified to perform a process or material handling job. The Person is qualified for the job if the job qualification is noted in the person's skill list or if a comparison of the person's course and medical exam histories satisfy the requirements defined within the Skill Management Component for the noted job. This method does not check the availability of the person to actually perform a task. */

```
PersonSequence allPersonsQualifiedForJob (in Job aJob)
        raises (FrameworkErrorSignal);
```

/* Return a set of Persons available ("on duty" on the current shift) to perform a process or material movement job. This service assumes that a Person is qualified to perform the job. */

```
PersonSequence allPersonsAvailableForJob (in Job aJob)
        raises (FrameworkErrorSignal);
```

/* Return a set of Persons currently assigned to the specified job. */

```
PersonSequence allPersonsAssignedToJob (in Job aJob) raises (FrameworkErrorSignal);
```

/* Return a set of all Persons currently assigned to jobs. */

```
PersonSequence allAssignedToJobsPersons ( ) raises (FrameworkErrorSignal);
```

Contracted Services: None.

Dynamic Model: Same as inherited interface (Component Manager).

6.3.4 *Person Interface*

Interface: Person

Inherited Interface: Resource

Description: This interface represents factory personnel. As currently defined, Person refers specifically to operating personnel within the manufacturing facility. Instances of this interface hold the following information pertaining to these individuals: employee information (full name, identification number, department, shift assignment); training and medical certification; and factory operations (e.g., operate a machine, perform a process) qualified to perform.

Exceptions:

/* This signal is raised when an addition operation fails because the Qualification specified by the argument already exists. */

```
exception QualificationDuplicateSignal {
        QualificationData qualificationInformation;};
```

/* This signal is raised when a removal operation fails because the Qualification specified by the argument could not be located. */

```
exception QualificationNotAssignedSignal {string identificationNumber;};
```

/* This signal is raised when a retrieval operation fails because the Qualification specified by the argument could not be located. */

```
exception QualificationNotFoundSignal {string identificationNumber;};
```

/* This signal is raised when an addition operation fails because the Responsibility specified by the argument already exists. */

```
exception ResponsibilityDuplicateSignal {any responsibility ;
        string responsibilityCategory;};
```

/* This signal is raised when an operation fails because the Responsibility category specified by the argument could not be located. */

```
exception ResponsibilityCategoryNotFoundSignal {
        string responsibilityCategory;};
exception ResponsibilityCategoryRemovalFailedSignal { };
```

/* This signal is raised when a removal operation fails because the Responsibility specified by the argument could not be located. */

```
exception ResponsibilityRemovalFailedSignal {
        any responsibility;
        string responsibilityCategory;};
```

/* This signal is raised when an addition operation fails because the skill specified by the argument already exists. */

```
exception SkillDuplicateSignal {Skill aSkill;};
```

/* This signal is raised when a removal operation fails because the skill specified by the argument could not be located. */

```
exception SkillRemovalFailedSignal {Skill aSkill;};
exception SkillNotAssignedSignal {Skill aSkill;};
```

Published Events:

/* This event is posted when a Person's capacity to do work has changed. This includes assignment to/deassignment from machines and jobs. It also includes changing the number of jobs and/or machines to which a Person may be assigned. */

```
        PersonCapacityChangedEvent
```

/* This event is posted when a Person's availability has changed. This includes logging on/off a shift, leaving/returning to a work station, or capacity exceeded. */

```
        PersonStateChangedEvent
```

/* This event is posted when a Person has been reassigned to a different shift. */

```
        PersonShiftChangedEvent
```

Provided Services:

/* Set and get the Person's department. */

```
void setDepartment (in string department)
        raises (SetValueOutOfRange, FrameworkErrorSignal);
string getDepartment ( ) raises (FrameworkErrorSignal);
```

/* Set and get the Person's name. */

```
void setFullname (in string fullname)
         raises (SetValueOutOfRange, FrameworkErrorSignal);
string getFullname ( ) raises (FrameworkErrorSignal);
```

/* Set and get the Person's identification number. */

```
void setIdentificationNumber (in string idNumber)
         raises (SetValueOutOfRange, FrameworkErrorSignal);
string getIdentificationNumber ( ) raises (FrameworkErrorSignal);
```

/* Set and get the maximum number of jobs to which a Person can be assigned simultaneously. */

```
void setMaximumAssignedJobs (in long maximumJobs)
         raises (SetValueOutOfRange, FrameworkErrorSignal);
long getMaximumAssignedJobs ( ) raises (FrameworkErrorSignal);
```

/* Set and get the maximum number of machines to which a Person can be assigned simultaneously. */

```
void setMaximumAssignedMachines (in long maximumMachine)
        raises (SetValueOutOfRange, FrameworkErrorSignal);
long getMaximumAssignedMachines ( ) raises (FrameworkErrorSignal);
```

/* Set and get the Person's shift assignment. */

```
void setShift (in shift aShift) raises (SetValueOutOfRange, FrameworkErrorSignal);
shift getShift ( ) raises (FrameworkErrorSignal);
```

/* Add an object within the factory to a Person's responsibility category. The concept of "responsibility" implies that a Person is authorized to perform, operate or access the factory object. It does not imply ownership. The first argument represents the responsibility (object within the factory) which is associated with a responsibility category, while the second argument is the category. If the specified category does not exist, it is created. The service returns the added factory object. For example, add a machine to the Person's "maintenance responsibilities" category. Another example: add a change notice to a Person's "signoff responsibility" category. */

```
any addResponsibility_toCategory (in any responsibility,
        in string responsibilityCategory)
        raises (FrameworkErrorSignal, ResponsibilityDuplicateSignal,
                ResponsibilityCategoryNotFoundSignal );
```

/* Remove an object within the factory from a Person's responsibility category. If the specified category, or responsibility does not exist, then an exception is raised. */

```
void removeResponsibility_fromCategory (in any responsibility,
        in string responsibilityCategory)
        raises (FrameworkErrorSignal, ResponsibilityRemovalFailedSignal,
                ResponsibilityCategoryRemovalFailedSignal);
```

/* Return the responsibilities (objects within a factory) which are assigned to a Person's responsibility category. For example, return all of the specifications in the category "specification management." A dictionary of key/value pairs is returned that represents these responsibility associations. The key is the "responsibility category name" while the value is the set of factory objects associated with that category. */

```
ResponsibilitySequence responsibilities ( ) raises (FrameworkErrorSignal);
```

/* Add the skill (qualification to operate a specific machine) to the Person's list of skills. Skills may be assigned or obtained through the completion of specified course (s) and medical examination (s). This service does not detail specific course and medical examination requirements. */

```

Contracted Services: None.

Dynamic Model:

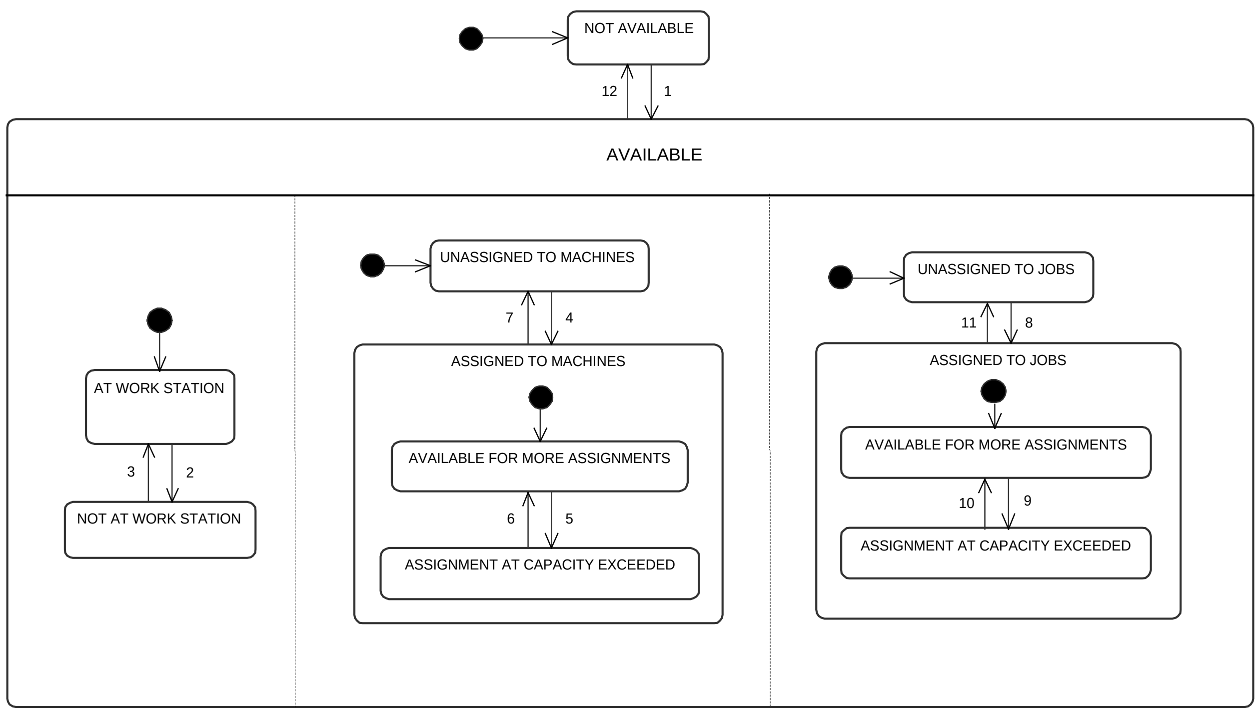

Figure 3
Person Dynamic Model

6.3.4.1 Object State Tables

Table 1 Person State Definitions and Query

State	*Definition*	*Query for State via*
NOT AVAILABLE	In this state, a Person is not clocked on to shift and cannot perform work.	boolean isOnShift ( ) sent to instance of Person returns FALSE. Person **NOT** included in set returned by PersonManager services. PersonSequence allOnShiftPersons (in Shift aShift) or allAvailableForWorkPersons ( ).
AVAILABLE	In this superstate, a Person is clocked on to a shift and is ready to perform work.	boolean isOnShift ( ) sent to instance of Person returns TRUE. Person included in set returned by PersonManager services PersonSequence allOnShiftPersons (in Shift aShift) or PersonSequence allAvailableForWorkPersons ( ).
AT WORK STATION	A Person is available to perform some manufacturing task; that is, the Person is physically present at his or her work site.	boolean isAtWorkStation ( ) sent to instance of Person returns TRUE.
NOT AT WORK STATION	A Person is not available to perform any manufacturing task; that is, the Person is physically absent from his or her work site.	boolean isAtWorkStation ( ) sent to instance of Person returns FALSE.
UNASSIGNED TO MACHINES	In this state, a Person has not been assigned to any machines. A Person may or may not be assigned to a job(s).	boolean isAssignedToMachines ( ) or boolean isAssignedToMachine (in Machine aMachine) [for all Machines] sent to instance of Person returns FALSE. Person **NOT** included in set returned by PersonManager services PersonSequence allPersonsAssignedToMachine (in Machine aMachine) [for all Machines] or PersonSequence allAssignedToMachinesPersons ( ). Empty set returned by Person service MachineSequence assignedMachines ( );
ASSIGNED TO MACHINES	In this parent state, a Person has been assigned to one or more machines.	boolean isAssignedToMachines ( ) or boolean isAssignedToMachine (in Machine aMachine) sent to instance of Person returns TRUE. Person included in set returned by PersonManager services PersonSequence allPersonsAssignedToMachine (in Machine aMachine) or PersonSequence allAssignedToMachinesPersons ( ). Non-empty set returned by Person service MachineSequence assignedMachines ( );
AVAILABLE FOR MORE ASSIGNMENTS	In this substate, a Person is available for assignments to more machines.	boolean isAvailableForMoreMachineAssignments ( ) sent to instance of Person returns TRUE.
ASSIGNMENT AT CAPACITY EXCEEDED	In this substate, a Person can no longer be assigned to another machine; that is, they are AT CAPACITY with regard to machine assignment.	boolean isAvailableForMoreMachineAssignments ( ) sent to instance of Person returns FALSE.

State	*Definition*	*Query for State via*
UNASSIGNED TO JOBS	In this state a Person has not been assigned to any jobs. A Person may or may not be assigned to job(s).	boolean isAssignedToJobs ( ) or boolean isAssignedToJob (in Job aJob) [for all Jobs] sent to instance of Person returns FALSE. Person **NOT** included in set returned by PersonManager services PersonSequence allPersonsAssignedToJob (in Job aJob) [for all Jobs] or PersonSequence allAssignedToJobsPersons ( ). Empty set returned by Person service JobSequence assignedJobs( );
ASSIGNED TO JOBS	In this parent state, a Person has been assigned to one or more job(s).	boolean isAssignedToJobs ( ) or boolean isAssignedToJob (in Job aJob) sent to instance of Person returns TRUE. Person included in set returned by PersonManager services PersonSequence allPersonsAssignedToJob (in Job aJob) or PersonSequence allAssignedToJobsPersons ( ). Non-empty set returned by Person service JobSequence assignedJobs ( );
AVAILABLE FOR MORE ASSIGNMENTS	In this substate, a Person is available for assignments to more jobs.	boolean isAvailableForMoreJobAssignments ( ) sent to instance of Person returns TRUE. Person included in set returned by PersonManager service PersonSequence allPersonsAvailableForJob (in Job aJob).
ASSIGNMENT AT CAPACITY EXCEEDED	In this substate, a Person can no longer be assigned to another job; that is, they are AT CAPACITY with regard to job assignment.	boolean isAvailableForMoreJobAssignments ( ) sent to instance of Person returns FALSE. Person not included in set returned by PersonManager service PersonSequence allPersonsAvailableForJob (in Job aJob).

Table 2 Person State Transitions

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
	non-existent	createPersonWithIdentifier (in string identificationNumber); sent to an instance of PersonManager.	NOT AVAILABLE		
1	NOT AVAILABLE	makeOnShift( ); sent to instance of Person.	AVAILABLE	PersonShiftChanged event posted by instance of Person. PersonStateChanged event posted by instance of Person.	Person logged on to shift. Person is assumed to be initially available for work (at work station) and not assigned to machines or jobs.
2	AT WORK STATION	makeNotAtWorkStation ( ); sent to instance of Person.	NOT AT WORK STATION	PersonStateChanged event posted by instance of Person.	Typically used for situation where Person is not physically present at work site (e.g., on a break). Person is still assigned to machine(s) and/or job(s). Person may be busy with a job.

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
3	NOT AT WORK STATION	makeAtWorkStation ( ); sent to instance of Person.	AT WORK STATION	PersonStateChanged event posted by instance of Person.	Person is physically present at work site.
4	UNASSIGNED TO MACHINES	assignToMachine (...); sent to instance of Person.	ASSIGNED TO MACHINES	PersonCapacityChanged event posted by instance of Person.	Person assigned to a machine. For example, a Scheduling Component might assign an operator to a machine.
5	AVAILABLE FOR MORE ASSIGNMENTS	Sending assignToMachine (...); to instance of Person increments number of machine assignments to AT CAPACITY level.	ASSIGNMENT AT CAPACITY EXCEEDED	PersonStateChanged event posted by instance of Person.	
6	ASSIGNMENT AT CAPACITY EXCEEDED	Sending deassignFromMachine (...); to instance of Person decrements number of machine assignments below AT CAPACITY level.	AVAILABLE FOR MORE ASSIGNMENTS	PersonStateChanged event posted by instance of Person.	
7	ASSIGNED TO MACHINES	Sending deassignFromMachine (...); decrements number of machine assignments to nil.	UNASSIGNED TO MACHINES	PersonCapacityChanged event posted by instance of Person.	Person not assigned to any machines.
8	UNASSIGNED TO JOBS	assignToJob (...); sent to instance of Person.	ASSIGNED TO JOBS	PersonCapacityChanged event posted by instance of Person.	Person assigned to job. Allocates a Person to a manufacturing task. A Person may be allocated to more than one task at a time.
9	AVAILABLE FOR MORE ASSIGNMENTS	Sending assignToJob (...); to instance of Person increments number of job assignments to AT CAPACITY level.	ASSIGNMENT AT CAPACITY EXCEEDED	PersonStateChanged event posted by instance of Person.	
10	ASSIGNMENT AT CAPACITY EXCEEDED	Sending deassignFromJob (...); to instance of Person decrements number of job assignments below AT CAPACITY level.	AVAILABLE FOR MORE ASSIGNMENTS	PersonStateChanged event posted by instance of Person.	
11	ASSIGNED TO JOBS	Sending deassignFromJob (...) decrements number of job assignments to nil.	UNASSIGNED TO JOBS	PersonCapacityChanged event posted by instance of Person.	Person not assigned to any jobs.
12	AVAILABLE	makeOffShift ( ); sent to instance of Person.	NOT AVAILABLE	PersonShiftChanged event posted by instance of Person. PersonStateChanged event posted by instance of Person.	Person logged off of shift.

6.3.5 *QualificationData Interface*

Interface:	QualificationData
Inherited Interface:	NamedEntity
Description:	This interface represents the record of training and medical examinations taken by factory personnel. Successful completion of training and medical examinations qualifies personnel for a factory operation (a skill). It is anticipated that a Factory Labor application will specialize and instantiate this interface to maintain the training and medical examination histories of factory personnel. For example, CourseQualificationData and MedicalQualificationData sub-interfaces could be defined. These sub-interfaces would exhibit most of the interesting behavior for this interface. For instance, each sub-interface could be compared with a corresponding sub-interface of the Skill Management Component interface SkillRequirement to determine certification (qualification for a skill). The attribute QualificationHistory indicates that either a specific course or a medical examination was taken; information regarding the date and time the Person tested for the qualification (when testing for a course or a medical examination occurred); and the results of that test or examination.
Exceptions:	None.
Published Events:	None.

Provided Services:

/* Set and get the qualification descriptor (an abbreviated string which serves as a "short-hand" notation for identifying the course or examination; e.g., a course number.) */

```
void setQualificationDesignator (in string designator)
        raises (FrameworkErrorSignal);
string getQualificationDesignator ( ) raises (FrameworkErrorSignal);
```

/* Set and get the history for a qualification event. Historical information indicates that either a specific course or a medical examination was taken; information regarding the date and time the Person tested for the qualification (when testing for a course or a medical examination occurred); and the results of that test or examination. */

```
void setQualificationHistory (in History qualificationHistory)
        raises (FrameworkErrorSignal);
History getQualificationHistory ( ) raises (FrameworkErrorSignal);
```

/* Return the date and time of qualification (when certification was made.) */

```
TimeStamp certificationDate ( ) raises (FrameworkErrorSignal);
```

Contracted Services: None.

Dynamic Model: None.

6.4 *Skill Management Component*

6.4.1 This component supports the management of the skill or skill set required to qualify personnel for a factory operation. Specifically, the skills required in order that personnel can assist a process resource or job in the performance of a process capability. Support is provided through association of skill requirements (training and medical examinations which must be completed) with a specific skill or skill set. Some personnel management aspect of the factory (e.g., training department) will interface with this component to define the training interface and medical examination roadmaps to achieve certification for factory operations.

6.4.2 The Skill Management Component Information Model is shown in Figure 4.

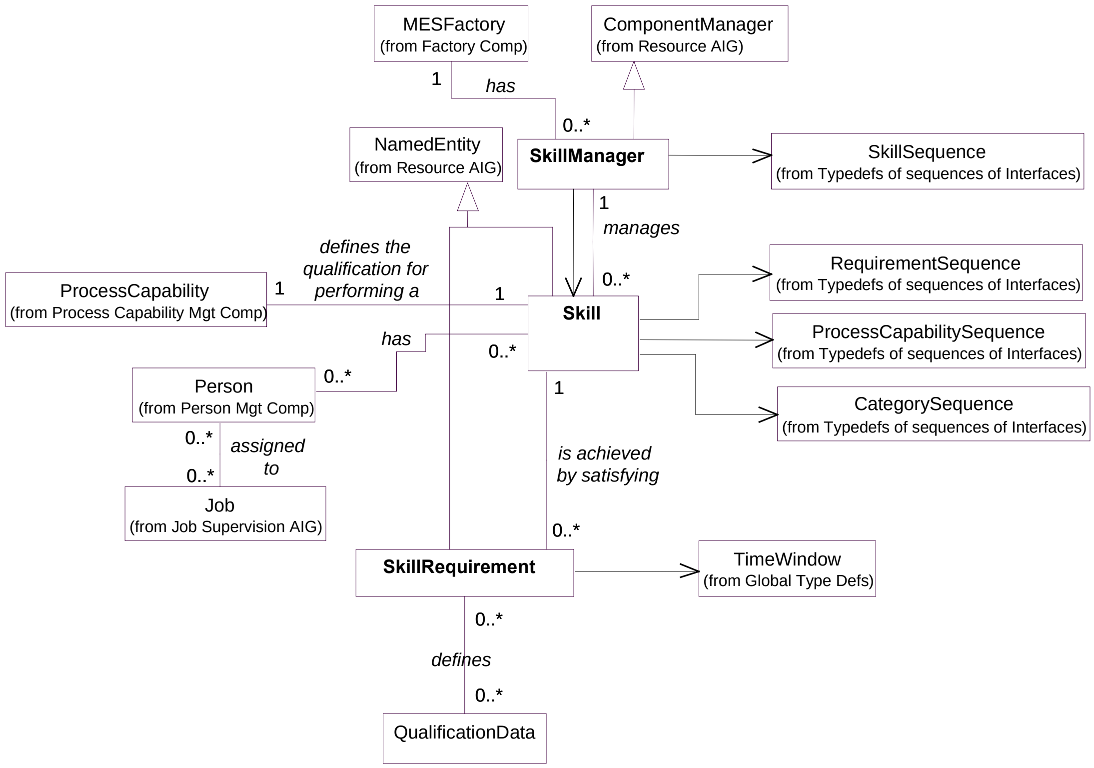

Figure 4
Skill Management Component Information Model

6.4.3 *SkillManager Interface*

Interface: SkillManager

Inherited Interface: ComponentManager

Description: This is the interface between the Skill Management Component and the rest of the CIM environment. This interface manages the skills or skill sets that personnel must possess before they are permitted to operate factory equipment. There are no limitations to the number of SkillManagers within a factory.

It is anticipated that a Factory Labor application would maintain the appropriate order (if required) of the qualifications related to a specific skill.

Exceptions:

/* This signal is raised with attempted creation of a duplicated Skill name. */

```
exception SkillDuplicateSignal {string skillName;};
```

/* This signal is raised when a removal operation fails because the Skill specified by the argument could not be located. */

```
exception SkillNotAssignedSignal {string skillName;};
exception SkillRemovalFailedSignal {string skillName;};
```

/* This signal is raised when a retrieval operation fails because the Skill specified by the argument could not be found. */

```
exception SkillNotFoundSignal {string skillName;};
```

Published Events: None.

Provided Services:

/* Create an instance of Skill and add to the list managed by this SkillManager. */

```
Skill createSkillNamed (in string skillName)
        raises (FrameworkErrorSignal, SkillDuplicateSignal);
```

/* Delete a specific skill from the list managed by this SkillManager. */

```
void removeSkillNamed (in string skillName)
        raises (FrameworkErrorSignal, SkillNotAssignedSignal,
                 SkillRemovalFailedSignal);
```

/* List the skills managed by this SkillManager. */

```
SkillSequence skills ( ) raises (FrameworkErrorSignal);
```

/* Search for an instance of Skill using its name. Raises an exception if the Skill is not found. */

```
Skill findSkillNamed (in string skillName)
        raises (FrameworkErrorSignal, SkillNotFoundSignal );
```

Contracted Services: None.

Dynamic Model: Same as inherited interface.

6.4.4 *Skill Interface*

Interface: Skill

Inherited Interface: NamedEntity

Description: This interface describes the specific Skill or set of Skills required to be held by personnel pursuant to performing factory operations. Specifically, a Skill is required in order that a Person can assist a process resource or job in the performance of a process capability. Each Skill is associated with one or more medical examination and/or training course requirements. A Skill may be associated with one or more process capabilities.

A Skill may represent a singular entity, it may categorize other Skills, or it might be categorized with other Skills. It is anticipated that a Factory Labor training application would maintain the appropriate order (if required) of a set of Skills.

Exceptions:

/* This signal is raised when a definition operation fails because the SkillRequirement specified already exists. */

```
exception SkillRequirementDuplicateSignal {string requirementName;};
```

/* This signal is raised when a removal operation fails because the SkillRequirement specified by the argument could not be located. */

```
exception SkillRequirementRemovalFailedSignal {SkillRequirement aRequirement;};
exception SkillRequirementNotFoundSignal {SkillRequirement aRequirement;};
```

/* This signal is raised when a retrieval operation fails because the SkillRequirement specified by the argument could not be located. */

```
exception SkillRequirementNotFoundSignal {string requirementName;};
```

Published Events: None.

Provided Services:

/* Get and set the Skill categories to which this Skill is associated. */

```
void setSkillCategories (in CategorySequence Categories)
        raises (FrameworkErrorSignal);
CategorySequence getSkillCategories ( ) raises (FrameworkErrorSignal);
```

/* Define a training course or medical examination necessary for obtaining an instance of Skill. */

```
SkillRequirement createSkillRequirementNamed (in string requirementName)
        raises (FrameworkErrorSignal, SkillRequirementDuplicateSignal);
```

/* Delete a training course or medical examination required for an instance of Skill. */

```
void removeSkillRequirement (in SkillRequirement aRequirement)
        raises (FrameworkErrorSignal, SkillRequirementRemovalFailedSignal,
                SkillRequirementNotFoundSignal);
```

/* Search for an instance of SkillRequirement using its name. Exception if the SkillRequirement is not found. */

```
SkillRequirement findSkillRequirementNamed (in string requirementName)
        raises (FrameworkErrorSignal, SkillRequirementNotFoundSignal);
```

/* Return the set of ProcessCapabilities to which this Skill is associated. */

```
ProcessCapabilitySequence processCapabilities ( ) raises (FrameworkErrorSignal);
```

/* List the training course or medical examination requirements that must be completed in order to be qualified for an instance of Skill. */

```
RequirementSequence requirements ( ) raises (FrameworkErrorSignal);
```

Contracted Services: None.

Dynamic Model: None.

6.4.5 *SkillRequirement Interface*

Interface: SkillRequirement

Inherited Interface: NamedEntity

Description: This interface defines training and medical examinations required to achieve a specific skill. The collection of these requirements associated with a specific skill constitutes the “roadmap” for acquiring the skill.

It is anticipated that a Factory Labor training application will specialize and instantiate this interface to maintain the training and medical examination requirements for skills. For example, CourseSkillRequirement and MedicalSkillRequirement sub-interface could be defined.

Exceptions: None.

Published Events: None.

Provided Services:

/* Set and get the complete description of this requirement. The requirement is either a training course which must be successfully completed or a medical examination that must be taken and passed. */

```
void setDescription (in string description) raises (FrameworkErrorSignal);
string getDescription ( ) raises (FrameworkErrorSignal);
```

/* Set and get the requirement descriptor. (An abbreviated string which serves as a “short-hand” notation for identifying a training course or examination; e.g., “OPS-ORIENT-1.”) */

```
void setDesignator (in string designator) raises (FrameworkErrorSignal);
string getDesignator ( ) raises (FrameworkErrorSignal);
```

/* Set and get the required training course grade which must be received or medical examination result which must be achieved for the requirement. */

```
void setRequiredResult (in string result) raises (FrameworkErrorSignal);
string getRequiredResult ( ) raises (FrameworkErrorSignal);
```

/* Return the information pertaining to the period of time in which this requirement is in effect. The information includes a starting time and a duration, from which expiration date can be computed. */

```
TimeWindow effectivity ( ) raises (FrameworkErrorSignal);
```

Contracted Services: None.

Dynamic Model: None.

SEMI E87-0702
SPECIFICATION FOR CARRIER MANAGEMENT (CMS)

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published September 1999; previously published March 2002.

1 Purpose

1.1 This document provides a standardized behavior for host view communication with production equipment during the coordination, execution, and completion of automated and manual carrier transfers to and from the equipment and, if it exists, its internal buffer space.

2 Scope

2.1 This is a standard that covers host and equipment communication for SEMI E15.1 300 mm load ports.

2.2 The scope of this document is to define standards that facilitate the host's knowledge and role in automated and manual carrier transfers, as well as internal buffer equipment carrier transfers. Specifically, this document provides state models and scenarios that define the host interaction with the equipment for the following:

- Carrier transfer between AMHS vehicles and production equipment load ports.
- Carrier transfers to/from production equipment internal buffer space.
- Equipment and load port access mode switching.
- Carrier to load port association.
- CarrierID verification and Carrier slot map verification.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard applies to semiconductor equipment with SEMI E15.1 compliant load ports. It may also be applied to other manufacturing equipment that supports automated carrier transfers, and/or contains an internal buffer. This standard is intended to be used for production equipment. It may or may not be applied to other types of equipment. Also, stocker load ports are not addressed by this standard.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Provisional Specification for 300 mm Tool Load Port

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E39 — Object Services Standard: Concept, Behavior, and Services

SEMI E41 — Exception Management (EM) Standard

SEMI E53 — Event Reporting

SEMI E62 — Provisional Specification for 300 mm Front-Opening Interface Mechanical Standard (FIMS)

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O Interface

SEMI E90 — Specification for Substrate Tracking

SEMI E99 — Carrier ID Read/Write Functional Standard

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AGT* — Automated Guided Transport

5.1.2 *AGV*— Automated Guided Vehicle

5.1.3 *AMHS* — Automated Material Handling System

5.1.4 *FIMS* — Front-Opening Interface Mechanical Standard

5.1.5 *FOUP* — Front Opening Unified Pod

5.1.6 *GEM* — Generic Equipment Model

5.1.7 *OHT* — Overhead Hoist Transport

5.1.8 *PGV* — Person Guided Vehicle

5.1.9 *PIO* — Parallel Input/Output Interface

5.1.10 *RGT* — Rail Guided Transport

5.1.11 *RGV* — Rail Guided Vehicle

5.2 *Definitions*

5.2.1 *Automated Material Handling System* — an automated system to store and transport materials within the factory.

5.2.2 *automation* — the degree to which activities of machines or production systems are self-acting. In this standard automation provides methods that will reduce the amount of operator intervention required.

5.2.3 *buffer* — a set of one or more locations for holding carriers at/inside the production equipment.

5.2.4 *carrier* — a container, such as a FOUP or open cassette, with one or more positions for holding substrates.

5.2.5 *CarrierID* — a readable and unique identifier for the carrier.

5.2.6 *CarrierID read* — the process of the equipment reading the CarrierID from the carrier.

5.2.7 *carrier ID tag (tag, ID tag)* — a physical device for storing Carrier ID and other information. There are two basic types of tags, read-only tags and read/write tags. [SEMI E99]

5.2.8 *Collection Event* — a collection event is an event (or grouping of related events) on the equipment that is considered to be significant to the host.

5.2.9 *docked position* — the position where the carrier is ready for substrate extraction or insertion.

5.2.10 *FIMS port* — the substrate access port where the FOUP is opened and closed.

5.2.11 *fixed buffer equipment* — production equipment that has only fixed load ports and no internal buffer for carrier storage. Substrates are loaded and unloaded directly from the carrier at the load port for processing.

5.2.12 *host* — the factory computer system or an intermediate system that represents the factory and the user to the equipment.

5.2.13 *internal buffer* — a set of locations within the equipment to store carriers. These locations exclude load ports.

5.2.14 *internal buffer equipment* — equipment that uses an internal buffer.

5.2.15 *load* — the operation of placing a carrier on a load port.

5.2.16 *load port* — the interface location on the equipment where carriers are loaded and unloaded.

5.2.17 *object instantiation* — the act of storing of information related to a physical or logical entity so that it can be recalled on demand based on its public identifier.

5.2.18 *on-line equipment* — equipment that is connected to, and able to communicate fully with, the host.

5.2.19 *process equipment* — equipment used to produce product, such as semiconductor devices. This excludes metrology and material handling equipment.

5.2.20 *production equipment* — equipment used to produce product, such as semiconductor devices, including substrate sorting, process, and metrology equipment and excluding material handling equipment.

5.2.21 *properties* — a set of name value pairs assigned to an object or used in a service message to include additional information about the object (i.e., carrier, port, etc.).

5.2.22 *re-initialization* — a process where production equipment is either powered off then on or when some kind of hardware or software reset is initiated to cause the equipment to reset and possibly reload its software. On production equipment that contains some kind of mass storage device this can also be called a “reboot”.

5.2.23 *read position* — any position on a load port or in an internal buffer from which the tag on a carrier can be read.

NOTE 2: This position may vary on any particular equipment depending on the read technology selected by the end user. Some technology/load ports may allow the carrier to be moved during reading. Equipment may have more than one read position.

5.2.24 *single communication connection* — exactly one physical connection using exactly one logical session and a standard set of messages.

5.2.25 *slot map* — the information that relates which slots in a carrier hold substrates, both correctly and incorrectly.

5.2.26 *slot map read* — the process of the equipment reading the slot map for substrate position and placement within the carrier.

5.2.27 *standard message set* — messages conforming to standard message specifications.

5.2.28 *substrate* — material held within a carrier. This can be product, or durables such as reticles.

5.2.29 *substrate port* — the carrier location from which substrates are accessed by the equipment.

5.2.30 *transfer unit* — maximum number of carriers allowed in a specific transfer service:

- AA is the maximum number of carriers allowed for acquisition at the transfer source.

- BB is the maximum number of carriers allowed for deposit at the transfer destination.
- CC is the maximum number of carriers allowed for transfer in one transport vehicle.

The transfer unit is the minimum of AA, BB, and CC.

5.2.31 *undocked* — the status of a carrier on a load port or in an internal buffer that is not at the docked position.

5.2.32 *unload* — the operation of removing a carrier from a load port.

5.2.33 *write position* — any position on a load port or in an internal buffer from which the tag on a carrier can be written to. This position may vary on any particular equipment depending on the write technology selected by the end user. Some technology/load ports may allow the carrier to be moved during writing. The read position and the write position may or may not be the same position.

6 Requirements

6.1 Carrier Management Standard (CMS) compliant equipment is required to provide certain capabilities defined by other standards: accessibility to status information, event reporting, alarm management, and equipment control. These requirements shall be satisfied through compliance to the following sets of standards:

6.2 Generic Equipment Model Standard (GEM) SEMI E30

- Event Notification
- Status Data Collection
- Equipment Constants
- Alarm Management
- Equipment Control

6.3 Object-Based Standards

- Object Services Standard (SEMI E39)
- Event Reporting (SEMI E53)
- Exception Management (SEMI E41)

7 Conventions

7.1 *Objects*

7.1.1 Whenever the equipment is required to know about specific kinds of entities, and required to manage information concerning these entities, it is useful to treat these entities as objects that comply with the basic requirements of SEMI E39 Object Services Standard (OSS). This is especially true whenever there are a large number of objects of a given type or when the entities are transient rather than permanent. In both cases, it is difficult to describe a general way for the host and equipment to specify which particular entity is referenced and to get information related only to a specific one out of many.

7.1.2 By defining these entities as objects that comply with OSS, it is only necessary for the host to specify the type of object and its specific identifier in order to inquire about one or more properties of the specific entity of interest.

7.1.3 *Object Properties*

7.1.3.1 A property (attribute) is information about an individual object that is presented as a name/value pair. The name is a formally reserved text string that represents the property, and the value is the current setting for that property.

7.1.3.2 Properties shall be accessible to the host via the service GetAttr and SetAttr for the Carrier and Carrier Location objects. Using SEMI E39 Object Services Standard, for example, it is possible to:

- get the list of IDs for the current carriers at the equipment, and
- get the specified properties for one or more individual carriers.

7.1.4 *Rules for Object Properties*

- Attributes with RO access can not be changed using SetAttr service as defined in OSS.
- Attributes with RW access can be changed using SetAttr service as defined in OSS.
- Additional attributes may be specified by the user or the equipment supplier by using an attribute name starting with “UD” (User Defined). Care should be taken to ensure the name of the attribute is unique.

7.1.5 *Object Attribute Table*

7.1.5.1 The object attribute table is used to list all the attributes related to the defined object as shown below the access is defined as Read only (RO) or Read/Write (RW). The REQD column is used to specify whether the attribute is required for implementation. Finally, the Form column is used to specify the format of that particular attribute.

Table 1 Object Attribute Table

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text = "Carrier"

7.2 *State Model Methodology*

7.2.1 A state model has three elements: definitions of each state and sub-state, a diagram of the states and the transitions between states, and a state transition table. The diagram of the state model uses the Harel State Chart notation. An overview of this notation is presented in an Appendix of SEMI E30. The definition of this notation is presented in Science of Computer Programming 8, "Statecharts: A Visual Formalism for Complex Systems", by D. Harel, 1987.[1]

7.2.2 *State Model Requirements*

The state models included in this standard are a requirement for CMS compliance. A state model consists of a state model diagram, state definitions, and a state transition table. All state transitions in this standard, unless otherwise specified, shall correspond to collection events. More explicitly, there must be a unique collection event for each state transition.

7.2.2.1

7.2.2.2 Equipment must maintain state models for each of the required state models as defined in this document. Equipment shall maintain individual and unique state models for each logical entity instantiated or physical entity in the equipment that has state models associated with it. The event identifier reported during a particular state transition change for each of these state models shall be shared for all associated state models but unique for each transition. For example, if the equipment has two load ports and the load port state model defines 10 transitions, there must be exactly 10 event identifiers for each load port transfer state model but not 10 for each physical load port. The information identifying the physical entity or logical entity undergoing the transition will be contained within the associated event report.

7.2.2.3 A state model represents the host' s view of the equipment, and does not necessarily describe the internal equipment operation. All CMS state model transitions shall be mapped sequentially into the appropriate internal equipment collection events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the CMS state model for transition to another state. In this case, the equipment makes the required transition without any additional actions in this situation.

7.2.2.4 Some equipment may need to include additional sub-states other than those in this standard. Additional sub-states may be added, but shall not change the CMS defined state transitions. All expected transitions between CMS states shall occur.

7.2.2.5 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition table contains columns for Transition number, Previous State, Trigger, New State, Actions, and Comments. The "trigger" (column 3) for the transition occurs while in the "previous" state. The "actions" (column 5) includes a combination of:

- Actions taken upon exit of the previous state.
- Actions taken upon entry of the new state.

---

1 Elsevier Science, P. O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.htt

- Actions taken which are most closely associated with the transition.

7.2.2.6 When a state model is defined with multiple AND sub-states, the equipment may report all state entry events with only one collection event. When conditional paths are defined in the state model, it is not necessary to report any state transition(s) until a terminal state is reached at which time each transition used to reach that state is reported.

Table 2 State Transition Table

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*

7.3 *Services*

7.3.1 Services are functions or methods that may be provided by either the equipment or the host. A service message may be either a request message, which always requires a response, or a notification message that does not require a response.

7.3.2 *Service Message Description*

7.3.2.1 A service message description table defines the parameters used in a service, as shown in the following table:

Table 3 Service Message Description Table

Service Name	*Type*	*Description*

Type can be either "N" = Notification or "R" = Request & Response.

7.3.2.2 Notification type messages are initiated by the service provider (e.g., the equipment) and the provider does not expect to get a response from the service user. Request messages are initiated by a service user (e.g., the host). Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

7.3.3 *Service Message Parameter Definition*

7.3.3.1 A service parameter dictionary table defines the description, range, and type for parameters used by services, as shown in the following table:

Table 4 Service Message Parameter Definition Table

Parameter Name	*Form*	*Description*

A row is provided in the table for each parameter used on a service.

7.3.4 *Service Message Definition*

7.3.4.1 A service message description table defines the parameters used in a service message. It also describes each message and its cause/effect to the equipment. The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message.

Service Parameter	*Req/Ind*	*Resp/Conf*	*Description*

7.3.4.2 The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication". The receiver may then send a "Response", which the original sender terms the "Confirmation".

7.3.4.3 The following codes appear in the Req/Ind and Rsp/Conf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M"	Mandatory Parameter – must be given a valid value.
"C"	Conditional Parameter – may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the values of other parameters.
"U"	User-Defined Parameter.
"-"	The parameter is not used.
"="	(for response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

7.4 *Alarm Requirements Definition*

7.4.1 An alarm requirements definition table defines the specific set of alarms required by CMS. The table is divided up by equipment configuration, and then by alarm. The danger and affected columns are marked with "X" characters to show each alarm and its possible impact to operators, equipment, and material. The table format is shown in the following example:

Equipment		*Danger*		*Affected*		
Configuration	*Alarm Text*	*Potential*	*Imminent*	*Operator*	*Equipment*	*Material*
Configuration 1	Alarm 1	X		X	X	X
	Alarm 2		X			X
Configuration 2	Alarm 3	X		X	X	
	Alarm 4	X			X	X

8 Overview

8.1 CMS defines the behavior, data, and services required for equipment supporting automated carrier transfer. This document provides a standard interface for host/equipment communications regarding the transfer of carriers. The standardized carrier transfer host interface includes not only transfers to and from the external load ports, but also transfers to and from the internal buffer positions on internal buffer type equipment.

8.2 *Single Connection Requirement*

8.2.1 The expectation of the production equipment supplier is that this standard be implemented in conjunction with the GEM interface to their production equipment and without the use of a separate communication connection.

9 Load Port

9.1 A load port (port) is used by the factory to load and unload carriers to and from production equipment. A load port may be used as an input load port, an output load port, or as an input/output load port, depending upon equipment type, configuration and/or factory practices. This classification may be fixed or it may be programmable by the user. A load port is generally designed to handle one specific carrier type, such as substrate cassettes, leadframe magazines, SMIF pods, or FOUPs.

9.2 *Load Port Numbering*

9.2.1 The load port number shall be assigned incrementally from the bottom left to bottom right, then top left to top right when facing the front of the equipment. The load port numbering requirement is to provide a common reference base to external entities, such as humans.

9.3 *Carrier Slot Numbering*

9.3.1 The slot numbers for a carrier shall be assigned incrementally from the bottom, starting with "1."

9.4 *Load Port Resource Sharing*

9.4.1 A model of a load port must account for any mechanical assemblies that are either active during carrier transfer or are capable of interacting with the transfer. The load port is responsible for such mechanisms when the load port is in the TRANSFER READY state. If these mechanisms are shared with other load ports, then the sharing must be coordinated.

9.5 *Load Port Transfer State Model*

9.5.1 The purpose of the Load Port Transfer State Model is to define the host view of a carrier transfer, which includes the host interactions with the equipment necessary to transfer carriers to and from equipment load ports. Each load port on the equipment shall maintain an independent instance of this state model.

9.5.2 *Load Port Transfer State Model Diagram*

9.5.2.1 Figure 1 is the diagram for the Load Port Transfer State Model.

9.5.3 *Load Port Transfer State Definitions*

9.5.3.1 LOAD PORT TRANSFER — The super state for the IN SERVICE and OUT OF SERVICE states.

9.5.3.2 OUT OF SERVICE — Transfer to/from this load port is disabled. A transition to IN SERVICE is required to continue using this load port for transfers.

9.5.3.3 IN SERVICE — Transfer to/from this load port is enabled. A transition to OUT OF SERVICE disables the load port for transfer use.

9.5.3.4 TRANSFER READY — A sub-state of IN SERVICE. The load port is available for carrier transfer. The transfer can either be manual or automated, and can be a load or an unload. This state contains two sub-states, which are used depending on whether or not a carrier is present on the load port (READY TO LOAD and READY TO UNLOAD).

9.5.3.5 READY TO LOAD — A sub-state of TRANSFER READY. When transitioning to the TRANSFER READY state, if a carrier is not present on the specified load port, this is the active sub-state. In this state, the load port is available to be loaded with an external carrier, or with a carrier that is currently located inside the equipment (i.e. internal buffer).

9.5.3.6 READY TO UNLOAD — A sub-state of TRANSFER READY. When transitioning to the TRANSFER READY state, if a carrier is present on the specified load port, this is the active sub-state. In this state, the load port is available for unloading of a carrier from the loadport to material handling equipment. When the load port is being used by the equipment, the state shall transition to TRANSFER BLOCKED.

9.5.3.7 TRANSFER BLOCKED — The carrier transfer state is neither READY TO LOAD nor READY TO UNLOAD. Because of load port related activity being performed, transfer is not available to/from this load port at this time.

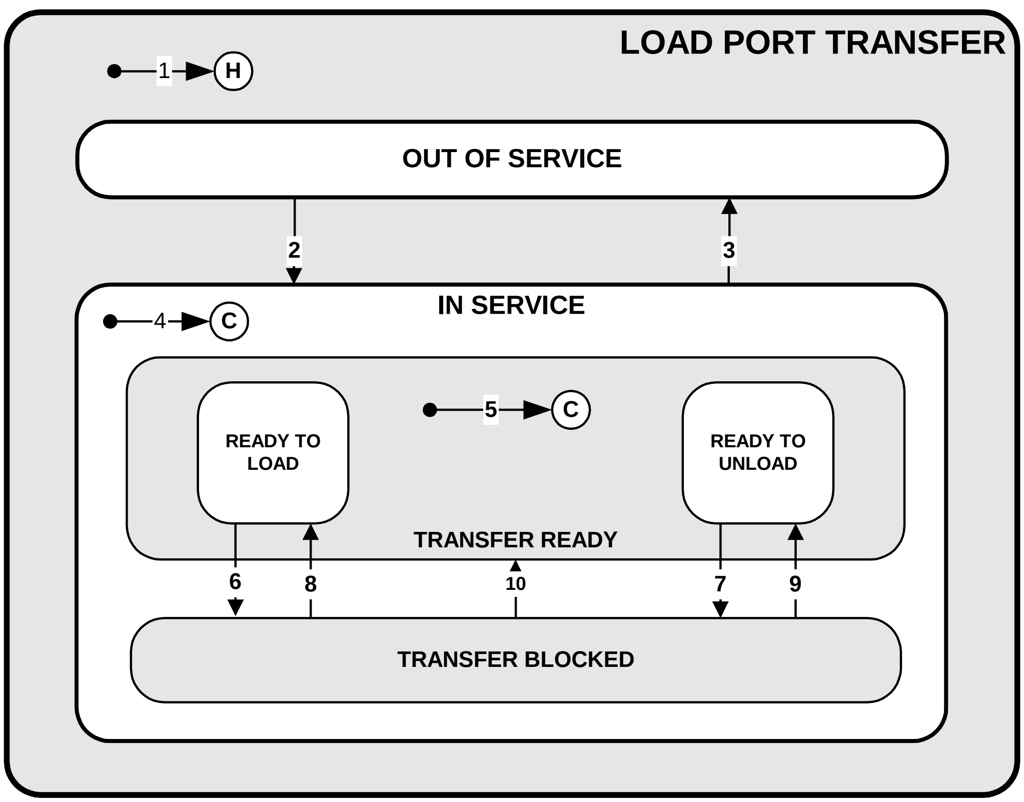

Figure 1
Load Port Transfer State Model Diagram

9.5.4 *Load Port Transfer State Transition Table*

Table 5 Load Port Transfer State Transition Definition

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(no state)	System reset.	OUT OF SERVICE or IN SERVICE (History)		This transition is based on what the current transfer status was prior to system reset. Data required to be available for this event report: PortID PortTransferState
2	OUT OF SERVICE	The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of IN SERVICE.	IN SERVICE		Load port is now usable for transfer. Data required to be available for this event report: PortID PortTransferState
3	IN SERVICE	The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of OUT OF SERVICE.	OUT OF SERVICE		Load port is now rendered unusable for transfer. Attempted usage of the load port for carrier transfer after the state transition results in an alarm. Data required to be available for this event report: PortID PortTransferState
4	IN SERVICE	*Service:* The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of IN SERVICE. *System Reset:* This transition can be activated by an equipment re-initialization.	TRANSFER READY or TRANSFER BLOCKED		This is the default entry into IN SERVICE. The state is TRANSFER BLOCKED if the carrier, or load port, is not available for carrier transfer. Otherwise, the state is TRANSFER READY. Data required to be available for this event report: PortID PortTransferState
5	TRANSFER READY	*Service:* The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of IN SERVICE. *System Reset:* This transition can be activated by an equipment re-initialization. *Failed Transfer:* If a transfer fails, this transition is activated by transition #10.	READY TO LOAD or READY TO UNLOAD		When entering the TRANSFER READY state, if a carrier is present, the sub-state is READY TO UNLOAD, else the sub-state is READY TO LOAD. If the state is READY TO LOAD, data required to be available for this event report: PortID If the state is READY TO UNLOAD, data required to be available for this event report: PortID CarrierID PortTransferState

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
6	READY TO LOAD	*Manual*: The equipment recognizes the logical indication of the start of a manual load transfer. This trigger is configurable by the user, examples are included in table 8. *Automated*: The PIO load transfer is beginning and the PIO "READY" signal is activated (see SEMI E84). *Internal Buffer:* A CarrierOut service has started for this load port.	TRANSFER BLOCKED		When a CarrierOut service is queued and the equipment load port is currently in the TRANSFER BLOCKED state, the equipment shall keep the load port in the TRANSFER BLOCKED state. Data required to be available for this event report: PortID PortTransferState
7	READY TO UNLOAD	*Manual*: The equipment recognizes the logical indication of the start of a manual unload transfer. This trigger is configurable by the user, examples are included in table 8. *Automated*: The PIO unload transfer is beginning and the PIO "READY" signal is activated (see SEMI E84). *Internal Buffer:* A CarrierIn service has started for this load port. *By CarrierReCreate Service:* A CarrierReCreate service command has been issued by host or operator on a carrier currently in the 'CarrierComplete' or 'Carrier Stopped' state.	TRANSFER BLOCKED		When a CarrierOut service is queued and the equipment load port is currently in the TRANSFER BLOCKED state, the equipment shall keep the load port in the TRANSFER BLOCKED state. Data required to be available for this event report: PortID PortTransferState
8	TRANSFER BLOCKED	*Manual:* The carrier unload transfer has completed, and the load port is now empty and ready for load transfer. This is indicated when two conditions are met, the presence signal indicates that no carrier is present and the operator has logically indicated that the transfer is complete. *Automated:* The PIO unload transfer ends with the PIO "COMPT" signal (see SEMI E84). *Internal Buffer:* The carrier has finished its move from the load port into the internal buffer, and no CarrierOut services are queued for this load port.	READY TO LOAD		A carrier can now be loaded onto the load port from either an external entity, or by the equipment's internal material handling resource. Data required to be available for this event report: PortID PortTransferState

Num	Previous State	Trigger	New State	Actions	Comments
9	TRANSFER BLOCKED	*Manual:* Processing for substrates contained within the carrier has completed, or a CancelCarrier/ CancelCarrierAtPort service has been issued, and the carrier has returned to the load/unload position on the load port. *Automated:* Processing for the substrates belonging to the carrier has completed, or a CancelCarrier/CancelCarrier-AtPort service has been received, and the carrier has returned to the load/unload position. *Internal Buffer:* A carrier has completed its move from the internal buffer to the load port.	READY TO UNLOAD		The carrier on the load port can now be unloaded from the load port to an external entity. Data required to be available for this event report: PortID CarrierID PortTransferState
10	TRANSFER BLOCKED	The transfer was unsuccessful, and the carrier was not loaded or unloaded.	TRANSFER READY		The sub-state of TRANSFER READY which is decided by transition #5. Data required to be available for this event report: PortID PortTransferState

10 Carrier Object

10.1 Information about a carrier is encapsulated as an object. This allows the host to exchange information with the equipment about one or more specific carriers using services defined in SEMI E39, Object Services Standard. A carrier has properties (attributes) that are defined in Table 6, Carrier Attribute Definition.

10.2 *Object Instantiation*

10.2.1 The carrier object is a software representation of the carrier in the equipment. Under normal circumstances this object is instantiated by the equipment when the host uses the Bind or Carrier Notification service or when the equipment successfully reads the carrierID from the carrier. A carrier object is instantiated by carrierID read only if there are no currently existing objects with the carrierID just read. A carrier object can also be instantiated by either the ProceedWithCarrier or CancelCarrier Services on an NOT ASSOCIATED port. (This implies a failed carrierID read event.) The ContentMap attribute will be an empty list (a list of zero) when the instantiation is done by CarrierID read. The SlotMap attribute should be a list consisting of all slots enumerated as “UNDEFINED” when the carrier object is instantiated by CarrierID read.

10.2.2 From the host point of view, an object is instantiated if the host is able to query the equipment about that object, it' s current state, and other attributes. Once instantiated, the object is considered destroyed (no longer instantiated) if the response to such queries is “unknown object”.

10.2.3 Summary of carrier object instantiation:

1. Bind or Carrier Notification or CarrierReCreate (with PropertiesList) service;
2. CarrierID read with no currently existing carrier objects having the carrierID just read; and
3. ProceedWithCarrier or CancelCarrier Service on an NOT ASSOCIATED port with a carrier.

10.2.4 *Carrier Object Identifier (ObjID)*

10.2.4.1 The purpose of an Object Identifier is to allow references to an object within the system. The object identifier is created when an object is instantiated and should be unchanged or persistent until the end of the object lifecycle. The Object Identifier shall be unique at the equipment during lifecycle of the object. The Carrier ID is the Carrier Object Identifier. The equipment is responsible for ensuring uniqueness of the Carrier ID prior to instantiation by the bind service.

10.2.5 *Carrier Object Destruction*

10.2.5.1 Normally, the Carrier Object reaches the end of its lifecycle when the carrier is unloaded from the equipment. Abnormally, the Carrier Object reaches the end of it’s lifecycle when a CancelBind or CancelCarrierNotification service is executed prior to the carrier being loaded, or when an equipment based carrier verification fails following carrier instantiation by the bind service.

10.2.5.2 Summary of carrier object destruction:

1. A carrier is unloaded from the equipment;
2. A CancelBind or CancelCarrierNotification service is received; and
3. An equipment based CarrierID verification fails after a carrier object was previously instantiated with a "Bind" service (Equipment initiated CancelBind).
4. The host or operator has issued a CarrierReCreate service.

10.3 *Carrier Attribute Definitions*

10.3.1 The following table contains the attributes that are of importance to the host and/or the equipment in order to manage the history and the reports about the carrier object.

10.3.2 *REQD Column*

10.3.2.1 All attributes in the following table are required to be associated with the carrier object and are always maintained and updated by the equipment (for example, if the equipment has a waferID reader, the equipment can determine the ContentMap).

10.3.3 *ACCESS Column*

10.3.3.1 Even though a value may be marked as RO (read only), the initial value for the attribute may be provided by the host when attached to either the Bind or ProceedWithCarrier services.

10.3.4 *Carrier Attribute Definition Table*

Table 6 Carrier Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
Capacity	Maximum number of substrates a carrier can hold.	RO	Y	Positive integer.
CarrierIDStatus	Current state of the carrier ID verification.	RO	Y	Enumerated: ID NOT READ, [ID] WAITING FOR HOST, ID VERIFICATION OK, ID VERIFICATION FAILED.
CarrierAccessingStatus	The current accessing state of the carrier by the equipment. The current substate of the CarrierAccessingStatus state model.	RO	Y	Enumerated: NOT ACCESSED, IN ACCESS, CARRIER COMPLETE, CARRIER STOPPED
ContentMap	Ordered list of lot and substrate identifiers corresponding to slot 1,2,3,…n	RO	Y	Ordered list of n structures, where n is equal to the value of "Capacity" above, and each structure consists of a LotID and SubstrateID. List of Structure LotID SubstrateID When no Lot ID is provided by the host, the LotID value should be null. When a slot has no substrate or the host does not know substrate identifier, the LotID and SubstrateID value should be null.
LocationID	Identifier of current location.	RO	Y	Text 1 to 80 characters.
ObjType	Object type.	RO	Y	Text 1 to 40 characters equal to "Carrier".
ObjID	Object identifier.	RO	Y	Text 1 to 80 characters equal to the CarrierID.

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
SlotMap	Ordered list of slot status as provided by the host and corresponding to slot 1,2,3‥n until a successful slot map read, then as read by the equipment.	RO	Y	Ordered list of n, where n is equal to the value of “Capacity” above, each value in the list is enumerated Enumerated Enumerated: UNDEFINED, EMPTY, NOT EMPTY, CORRECTLY OCCUPIED, CROSS SLOTTED, DOUBLESLOTTED. (NOT EMPTY provided for equipment that cannot detect incorrectly slotted substrates)
SlotMapStatus	Current state of slot map verification.	RO	Y	Enumerated: SLOT MAP NOT READ, [SLOT] WAITING FOR HOST, SLOT MAP VERIFICATION OK, SLOT MAP VERIFICATION FAILED.
SubstrateCount	The number of substrates currently in the carrier.	RO	Y	Non negative integer less than or equal to the Capacity.
Usage	The type of material contained in the carrier (i.e., TEST, DUMMY, PRODUCT, FILLER, etc.).	RO	Y	Text as defined by the Equipment.

NOTE 1: NOT EMPTY is included to indicate presence for equipment that is only able to detect substrate presence but not correct positioning of the substrate slot. For equipment that can detect incorrect positioning such as cross-slotted or double slotted, NOT EMPTY may not be applicable.

10.3.5 *Rules for Carrier Attributes*

- The equipment shall change object attributes, Capacity, ContentMap, SlotMap, Substrate count and Usage, provided by the host. All other attributes, such as LocationID, shall be set and maintained by the equipment.
- The attributes, Capacity, ContentMap, Substrate count and Usage, shall be provided with Bind, CarrierNotification, or ProceedWithCarrier service before or when SlotMap is provided.
- The SlotMap shall be provided with Bind, CarrierNotification, or ProceedWithCarrier to verify CarrierID, when the SlotMap verification is equipment based. And it shall not be provided when the SlotMap verification is host based.
- Carrier properties may be provided before the carrier arrives as part of the Bind service and should be retained until either a CancelBind service is received or the carrier is removed.
- Carrier properties may also be provided by the ProceedWithCarrier service. The carrier properties that are provided by the ProceedWithCarrier service may differ based whether or not the object is instantiated by the service.
- Carrier properties that are required shall be actively updated by the equipment.

10.3.6 *Carrier Location*

10.3.6.1 A carrier location, signified by LocationID, is used for tracking carriers as they move through the equipment. A carrier location is any physical area that is capable of holding a carrier. It is not intended to represent entire mechanisms, which may have a variety of other properties of interest, but only that portion where a Carrier may rest.

10.3.7 *Carrier Location Examples*

10.3.7.1 Carrier Locations include load port locations, substrate port locations, internal buffer locations, as well as grippers, conveyors, and elevators that are used internally for moving the carrier from one fixed location to another.

10.4 *Carrier Location Naming*

10.4.1 Carrier locations shall be assigned a unique name. Information about the carrier location can be obtained by querying the CarrierObject for the LocationID or by asking the equipment for the CarrierLocation-Matrix. The text form of the LocationID shall be descriptive of the location. For example, LocationID form for load port load/unload location might be “LPn”, where “n” equal is equal to the load port number (the load port number is determined through the numbering rule in Section 9.1). The LocationID form for the FIMS port location might be “FIMSn”. The LocationID form for a buffer location might be “BUFn”.

10.5 *Load Port Carrier Locations*

10.5.1 For fixed buffer equipment configured to handle FOUPs, a Load Port has two different Carrier Locations. One represents the place where a Carrier is delivered and picked up, while the other represents the place where the Carrier is docked and can be opened.

10.6 *Carriers Between Locations*

10.6.1 When the carrier is traveling from one location to another, the location attribute remains equal to the source location until the carrier movement is complete and the carrier is resting at the new carrier location (the destination location).

10.6.2 *Usage*

10.6.2.1 The Usage parameter indicates the type of substrate the carrier contains. All Usage values are equipment specific values. Some internal buffer equipment manages carriers by establishing logical partitions. This type of equipment shall use the Usage parameter to determine which logical partition where the carrier is held.

10.6.3 *SubstrateCount*

10.6.3.1 The SubstrateCount parameter can be sent to the equipment by the host in either the Bind service or the ProceedWithCarrier service. However the equipment shall update this parameter based on the results of the read slot map operation. Furthermore, the equipment shall update the parameter based on it's own actions of adding and removing a substrate to and from a carrier. If the equipment does not know the value of SubstrateCount prior to instantiation, the equipment shall instantiate the carrier object with the value of null for SubstrateCount.

10.6.4 *Lot information for ContentMap*

10.6.4.1 Lot is defined in SEMI E90 as a group of one or more substrates of the same type. It is organized external to the equipment. The Lot ID is the identifier of this group. If the equipment is informed of the Lot ID to which a substrate belongs, the equipment must maintain this information.

10.6.5 *Carrier Accessing Status*

10.6.5.1 The CarrierAccessingStatus is used by the host to know whether or not the carrier owned by the equipment can be moved out. If the carrier is within the internal buffer equipment, this status may be used by the host to issue CarrierOut service.

10.7 *Carrier State Model*

10.7.1 The purpose of the Carrier State Model is to define the host's view of a carrier. The equipment shall maintain a separate and independent state model for each carrier in/at the equipment.

10.7.2 *Carrier State Model Diagram*

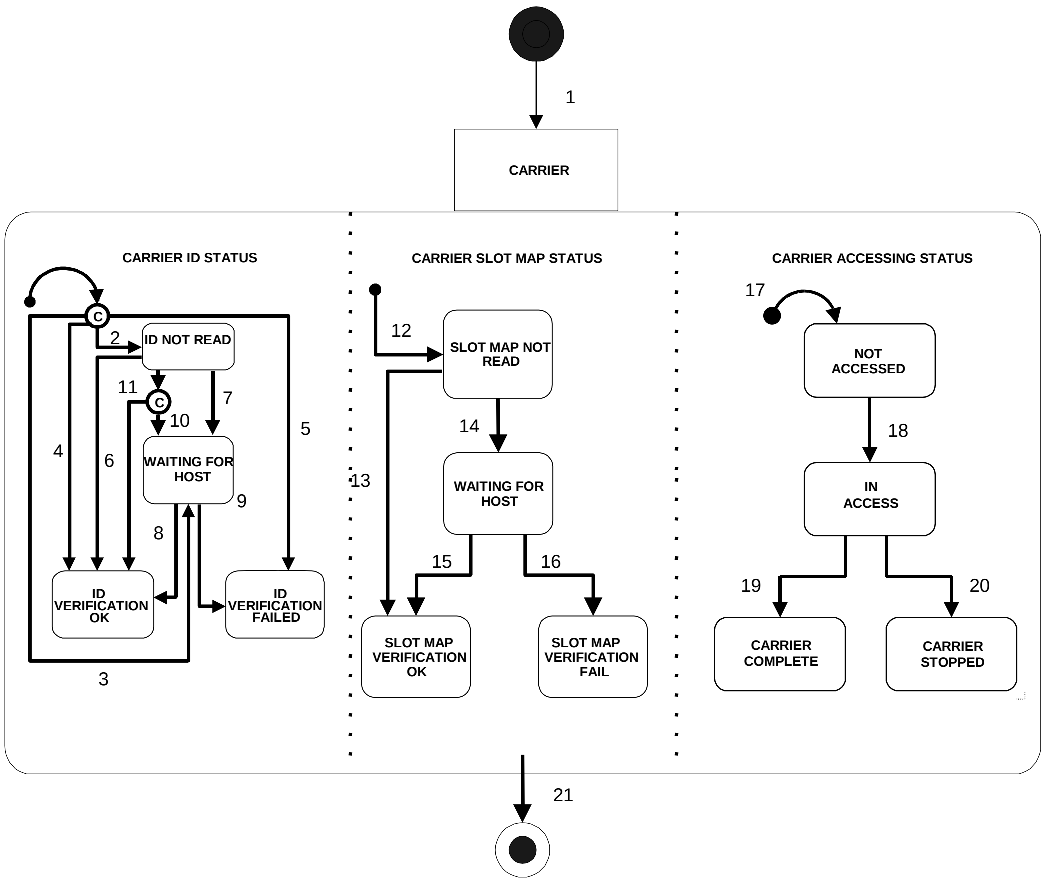

Figure 2
Carrier State Model Diagram

10.7.3 *Carrier State Definitions*

10.7.3.1 *CARRIER* — The CARRIER state has three ANDed (orthogonal) states: CARRIER ID STATUS, CARRIER SLOT MAP STATUS and CARRIER ACCESSING STATUS.

10.7.3.2 *CARRIER ACCESSING STATUS* — This is a substate of CARRIER and indicates the current accessing status of the carrier. It has four substates, NOT ACCESSED, IN ACCESS, CARRIER COMPLETE, and CARRIER STOPPED. The initial default entry substate is NOT ACCESSED.

10.7.3.2.1 *NOT ACCESSED* — This is a substate of CARRIER ACCESSING STATUS and is active when access by the equipment to the carrier has not been started. The carrier can be moved out.

10.7.3.2.2 *IN ACCESS* — This is a substate of CARRIER ACCESSING STATUS and is active when access by the equipment to the carrier has been started but has not been finished, and the carrier should not be moved out.

10.7.3.2.3 *CARRIER COMPLETE* — This is a substate of CARRIER ACCESSING STATUS and is active when the access by the equipment to the carrier has been finished, and the carrier should be moved out. This is a final state.

10.7.3.2.4 *CARRIER STOPPED* — This is a substate of CARRIER ACCESSING STATUS and is active when the access by the equipment to the carrier has been stopped abnormally, and the carrier should be moved out. This is a final state.

10.7.3.3 *CARRIER ID STATUS* — This is a substate of CARRIER and indicates the current status of the carrier with respect to its identifier. It has four substates, ID NOT READ, WAITING FOR HOST, ID VERIFICATION FAILED, ID VERIFICATION OK. The initial substate is conditional based on information the equipment has about the carrier. When the carrierID is provided by the Bind or the Carrier Notification service, the carrier object shall be instantiated in the ID NOT READ substate. When the carrierID is provided by the carrier ID reader, the carrier shall be instantiated in the WAITING FOR HOST substate. When the Carrier is instantiated by the ProceedWithCarrier service, the carrier shall be instantiated in the ID VERIFICATION OK substate. Finally when the carrier is instantiated by the CancelCarrier service, the carrier will be instantiated in the ID VERIFICATION FAILED substate.

10.7.3.3.1 *ID NOT READ* — This is a substate of CARRIER ID STATUS. This state is active whenever the CarrierID has not been read by the equipment.

10.7.3.3.2 *ID VERIFICATION FAILED* — This is a substate of CARRIER ID STATUS and is active when the carrierID has failed verification by the host following the CancelCarrier service. This is a final state.

10.7.3.3.3 *ID VERIFICATION OK* — This is a substate of CARRIER ID STATUS and is active as soon as the CarrierID has been accepted. The ID is determined to be accepted by either successful verification by the equipment or the host, or by bypassing ID read because a carrier ID reader is not available and the BypassReadID variable is set to true. This is a final state.

10.7.3.3.4 *WAITING FOR HOST* — This is a substate of CARRIER ID STATUS and is active during the period of time when the carrierID has been read by the equipment successfully or unsuccessfully and has not yet been verified by the host.

10.7.3.4 *CARRIER SLOT MAP STATUS* — This is a substate of CARRIER and indicates the current status of the carrier with respect to its slot map. It has four substates, SLOT MAP NOT READ, WAITING FOR HOST, SLOT MAP VERIFICATION FAILED, SLOT MAP VERIFICATION OK. The initial default entry sub-state is SLOT MAP NOT READ.

10.7.3.4.1 *SLOT MAP NOT READ* — This is a substate of CARRIER SLOT MAP STATUS and is the default entry state. It is active when the Carrier is first loaded at the equipment until the Slot Map has been read successfully by the equipment at the Substrate Port.

10.7.3.4.2 *SLOT MAP VERIFICATION FAIL* — This is a substate of CARRIER SLOT MAP STATUS and is active when the Slot Map has been read by the equipment and has failed verification by the host. This is a final state.

10.7.3.4.3 *SLOT MAP VERIFICATION OK* — This is a substate of CARRIER SLOT MAP STATUS and is active as soon as the slot map has been verified. This is a final state.

10.7.3.4.4 *WAITING FOR HOST* — This is a substate of CARRIER SLOT MAP STATUS and is active when the equipment is waiting for input from the host.

10.7.4 *Carrier State Transition Table*

10.7.4.1 Table 7 indicates the triggers and the expected behavior of the instantiated carrier object.

Table 7 Carrier State Transition Definition

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
1	(no state)	A carrier is instantiated.	CARRIER	None.	No event is required for this transition
2	(no state)	*Normal:* A Bind or Carrier Notification service is received.	ID NOT READ	None.	Data required to be available for this event report: CarrierID CarrierIDStatus
3	(no state)	*Normal:* A carrierID not currently existing at the equipment is successfully read. *Abnormal:* A carrierID is read successfully but an equipment based verification failed.	WAITING FOR HOST	None.	Data required to be available for this event report: CarrierID PortID CarrierIDStatus Normally, this transition will happen after a successful ID read if a bind service has not been issued (host based verification) or abnormally if a bind service is followed by a successful ID read and an unsuccessful equipment based verification.

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
4	(no state)	*ID Read fail*: A ProceedWithCarrier service is received.	ID VERIFICATION OK	A carrier is instantiated having the carrierID provided by the Proceed WithCarrier service.	Data required to be available for this event report: CarrierID CarrierIDStatus This transition can happen only if a bind service has not been received.
5	(no state)	*ID Read fail:* A CancelCarrier service is received.	ID VERIFICATION FAIL	A carrier is instantiated having the carrierID provided by the Cancel Carrier service.	Data required to be available for this event report: CarrierID CarrierIDStatus This transition can happen only if a bind service has not been received.
6	ID NOT READ	Carrier ID is read successfully and the equipment has verified the carrierID successfully.	ID VERIFICATION OK	None.	Data required to be available for this event report: PortID CarrierID CarrierIDStatus
7	ID NOT READ	Carrier ID is read unsuccessfully.	WAITING FOR HOST	None.	Data required to be available for this event report: PortID CarrierID CarrierIDStatus
8	WAITING FOR HOST	A ProceedWithCarrier service is received.	ID VERIFICATION OK	None.	Data required to be available for this event report: PortID CarrierID CarrierIDStatus
9	WAITING FOR HOST	A Cancel Carrier Service is received.	ID VERIFICATION FAIL	None.	Data required to be available for this event report: PortID CarrierID CarrierIDStatus
10	ID NOT READ	BypassReadID variable is set to FALSE, and a carrier is received when the id reader is not in service or not installed.	WAITING FOR HOST	Wait for ProceedWith-Carrier.	Data required to be available for this event report: PortID CarrierID CarrierIDStatus
11	ID NOT READ	BypassReadID variable is set to TRUE, and a carrier is received when the id reader is not in service or not installed.	ID VERIFICATION OK	None.	Data required to be available for this event report: PortID CarrierID CarrierIDStatus
12	(no state)	A carrier is instantiated.	SLOT MAP NOT READ	None.	No event is required for this transition.

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
13	SLOT MAP NOT READ	Slot Map is read and verified successfully by the equipment.	SLOT MAP VERIFICATION OK	None.	Data required to be available for this event report: PortID (if valid) CarrierID LocationID CarrierAccessingStatus SlotMapStatus
14	SLOT MAP NOT READ	*Normal host based verification:* Slot Map is read successfully and the equipment is waiting for host verification. *Equipment based verification fail:* Slot Map is read successfully but equipment based verification has failed. *Slot map read fail:* Slot Map cannot be read. *Abnormal substrate position within the carrier:* The Slot Map read has indicated an abnormal substrate position.	WAITING FOR HOST	Save new slot map in the SlotMap attribute.	Data required to be available for this event report: PortID (if valid) CarrierID LocationID SlotMap (if valid) Reason SlotMapStatus
15	WAITING FOR HOST	A ProceedWithCarrier service is received.	SLOT MAP VERIFICATION OK	Proceed with the Carrier as instructed.	Data required to be available for this event report: PortID (if valid) CarrierID LocationID SlotMapStatus
16	WAITING FOR HOST	A CancelCarrier service is received.	SLOT MAP VERIFICATION FAIL	Prepare the Carrier for Unload.	Data required to be available for this event report: PortID (if valid) CarrierID LocationID CarrierAccessingStatus SlotMapStatus
17	(no state)	A carrier object is instantiated.	NOT ACCESSED	None.	No event is required for this transition
18	NOT ACCESSED	The equipment starts accessing the carrier.	IN ACCESS	None.	Data required to be available for this event report: CarrierID CarrierAccessingStatus
19	IN ACCESS	The equipment finishes accessing the carrier normally.	CARRIER COMPLETE	None.	Data required to be available for this event report: CarrierID CarrierAccessingStatus
20	IN ACCESS	The equipment finishes accessing the carrier abnormally.	CARRIER STOPPED	None.	Data required to be available for this event report: CarrierID CarrierAccessingStatus

#	Previous State	Trigger	New State	Actions	Comment
21	CARRIER	*Normal:* The carrier is unloaded from the equipment. *Abnormal by service:* CancelBind or CancelCarrierNotification service is received prior to the carrier load. *Abnormal by equipment:* An equipment based verification fails and the equipment performs a self-initiated CancelBind service.	(no state)	The equipment destroys the instance of this carrier object.	Data required to be available for this event report: CarrierID

NOTE 1: Only one collection event report is required when entering the Carrier State Model (instantiating a carrier object). This event report shall include the entry state of the all the substates of Carrier State Model, (including CARRIER ID STATUS substate and the CARRIER SLOT MAP STATUS substate).

10.7.5 *Slot Map Read Details*

10.7.5.1 The Slot Map shall be read on all production equipment prior to removal of substrates from the carrier.

10.7.6 *Carrier Read Failure* — A carrier read failure occurs when the carrier ID reader is present, in service, and reports that it is unable to read the ID of a carrier. This represents a transient random failure rather than a steady condition.

10.7.7 *Bypass Read ID* — A carrier ID reader may be unavailable: either out of service, not installed, or otherwise malfunctioning and unable to execute a read operation. This represents a steady condition that often is known in advance. The equipment shall provide a user-configurable variable BypassReadID that the user is able to set to specify the action to take when a carrier is received to an ASSOCIATED loadport. In this case, the carrier object is instantiated in the ID NOT READ state, and when the carrier is received, the state model transitions to either WAITING FOR HOST or ID VERIFICATION OK, depending upon whether BypassReadID is FALSE (the default value) or TRUE. When TRUE, then the Carrier ID received in the Bind is used automatically. Otherwise, the carrier transitions to WAITING FOR HOST and waits for the host to send a ProceedWithCarrier. The ID used will be the ID included with the ProceedWithCarrier.

11 Access Mode

11.1 *Access Mode State Model*

11.1.1 The Access Mode State Model defines the host view of equipment access mode, as well as the host interactions with the equipment necessary to switch the access mode. Each Load Port has its own Access Mode State Model. There are two access mode states: MANUAL and AUTO. These are defined in Section 11.3.3.

11.1.2 The access mode for a load port may be switched at anytime by the host or the operator, except when the Load Port Reservation State Model for that Load Port is in the RESERVED state or during carrier transfer. Carrier transfer boundaries, for determining when access mode may be changed, are designated by Table 8, Carrier Transfer Boundaries.

Table 8 Carrier Transfer Boundaries

Transfer Type	*Transfer Method*	*Starting Boundary*	*Ending Boundary*
LOAD	MANUAL	This starting boundary is specified by the user. Known examples of the starting boundary include but are not limited to; the presence sensor detecting a carrier, a load port door opening, input to the equipment by the operator through a switch at the load port or the equipment console.	This ending boundary is specified by the user. Known examples of the ending boundary include but are not limited to; a preset configurable time following presence and placement sensor detecting a carrier, a load port door closing, or input to the equipment by the operator through a switch at the load port or the equipment console or a service message.
	AUTO	The PIO signal "READY" is active for load. See SEMI E84.	PIO signals a transfer complete signal "COMPT". See SEMI E84.
UNLOAD	MANUAL	This starting boundary is specified by the user. Examples of the starting boundary include but are not limited to presence and placement sensor no longer detecting a carrier, a load port door opening, or input to the equipment by the operator through a switch at the load port or the equipment console or a service message.	This ending boundary is specified by the user. Examples of the ending boundary include but are not limited to a preset configurable time following presence and placement sensor no longer detecting a carrier, a load port door closing, or input to the equipment by the operator through a switch at the load port or the equipment console, or a service message.
	AUTO	The PIO signal "READY" is active for unload. See SEMI E84.	PIO signals a transfer complete signal "COMPT". See SEMI E84.

11.2 *Manual Carrier Transfer Confirmation Trigger*

11.2.1 For a manual transfer completion confirmation, the production equipment supplier must implement a software or hardware mechanism for an operator to inform the equipment that the carrier transfer is complete.

11.3 *Access Mode Initial Value*

11.3.1 Also, when equipment re-initialization occurs, the access mode(s) must be remembered, and used as the initial value when initializing. Since the access mode is remembered through re-initializations, the initial value that is used the very first time the software is ever loaded is not important. The equipment supplier is free to set this default value.

11.3.2 *Access Mode State Model Diagram*

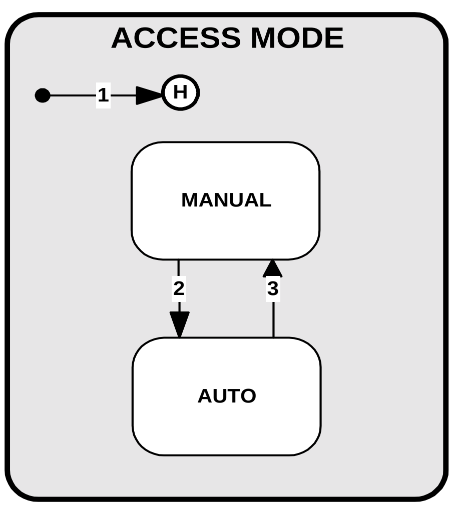

Figure 3
Access Mode State Model Diagram

11.3.3 *Access Mode State Definitions*

11.3.3.1 ACCESS MODE — The parent state for the MANUAL and AUTO sub-states.

11.3.3.2 MANUAL — A sub-state of ACCESS MODE. When the production equipment or specified load port is in this mode, only manual (non-AMHS) carrier transfers are allowed. The production equipment shall have the capability of generating an alarm if an automated (AMHS) delivery is attempted.

11.3.3.3 AUTO — A sub-state of ACCESS MODE. When the production equipment or specified load ports are in this mode, only automated (AMHS) carrier transfers are allowed. The production equipment shall have the capability of generating an alarm if a manual delivery is attempted.

11.3.4 *Access Mode State Transition Table*

11.3.4.1 Table 9 defines the transitions for the Access Mode State Model.

Table 9 Access Mode State Transition Definitions

#	*Previous State*	*Trigger*	*New state*	*Actions*	*Comments*
1	(no state)	System restart.	MANUAL or AUTO (History)	The access mode returns to the mode it was previous to the system reset.	Data required to be available for this event report: PortID AccessMode
2	MANUAL	The host or operator has executed a ChangeAccess service with the value of AUTO. This trigger can happen at anytime, except during a carrier transfer.	AUTO		Manual deliveries are not allowed after this state transition. The operator may also trigger this transaction from the production equipment console. Data required to be available for this event report: PortID AccessMode
3	AUTO	The host or operator has executed a ChangeAccess service with the value of MANUAL. This trigger can happen at anytime, except during carrier transfer.	MANUAL		The operator may also trigger this transaction from the production equipment console or a manual switch at the load port. Automated transfers are not allowed after this state transition. Data required to be available for this event report: PortID AccessMode

12 Reservation State Model

12.1 The purpose of the Reservation State Model is to define the host view of future activity at a specific load port.

12.1.1 The Reservation State Model, the ReserveAtPort service and CancelReserveAtPort enable the following items:

1. They enable the host to inform the equipment of a future carrier delivery without specifying the carrier ID and at the same time allow host based verification. (Equipment based verification is enabled via the Load Port/Carrier Association State Model, the Bind service, and the Carrier Notification service detailed in Sections 13, 15.4.2 and 15.4.11 of SEMI E87.)
2. They enable the equipment to send a state change event to the host if the operator (either local or remote) informs the equipment of a future carrier delivery to a port without specifying the carrier ID. Thus the host knows that the operator expects to use that port for something the host did not request for AMHS based delivery.
3. They enable internal buffer equipment to inform the host that it is physically initiating a carrier out operation (this carrier has a known or specified ID) and that no AMHS delivery should be scheduled.

4. The Bind and CancelBind services also trigger changes in the Load Port Reservation State Model. If the Load Port Reservation state model is in the NOT RESERVED state, the Bind service triggers a transition to the RESERVED state. If the Load Port Reservation is in the RESERVED State, the CancelBind service triggers a transition to NOT RESERVED.

12.1.2 For internal buffers equipment, the Reservation State Model, the ReserveAtPort service, the CancelReserveAtPort service, and all other associated functionality is necessary for fundamental compliance to this standard.

12.1.3 For fixed buffer equipment, the Reservation State Model, the ReserveAtPort service, the CancelReserveAtPort service, and all other associated functionality is a user option and not necessary for fundamental compliance.

12.1.4 For equipment implementing the reservation state model, the equipment shall provide a load port reservation state model for each load port.

12.2 *Reservation Visible Signal*

12.2.1 When a port reservation has taken place, the equipment shall display a visible signal indicating that the designated load port is in the Reserved State. Examples of visible signals for the associated load port are: Blinking LEDs, flags, color indicators, or other methods that allow easy recognition that the load port is reserved; proximity to or location on the load port is recommended. The visible signal shall remain present as long as the load port state remains RESERVED. When the state changes to NOT RESERVED the visible indicator shall cease. This capability is not required for fundamental compliance to CMS.

12.3 *Reservation State Model Diagram*

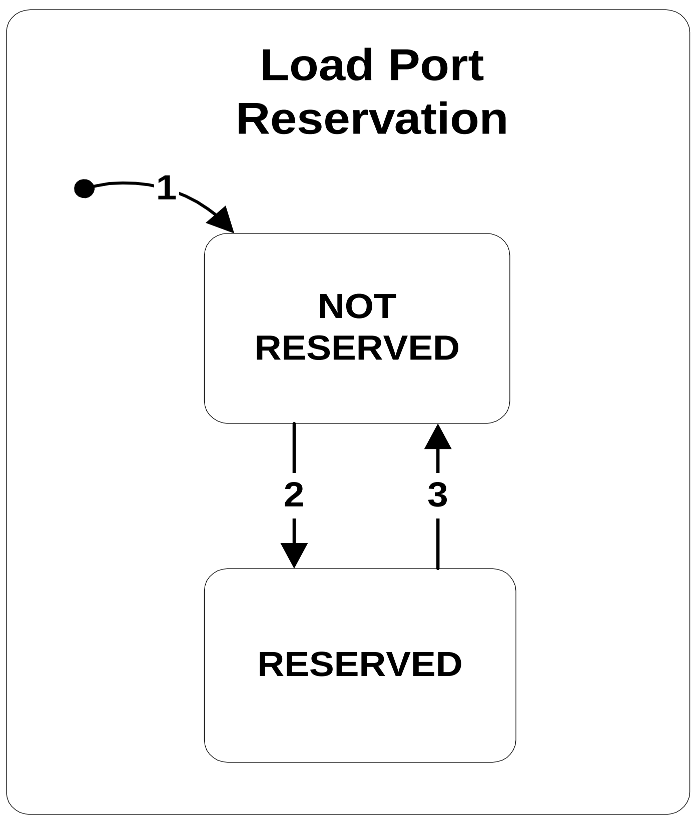

Figure 4
Reservation State Model Diagram

12.4 *Load Port Reservation State Definitions*

12.4.1 LOAD PORT RESERVATION — The super state of the substates NOT RESERVED and RESERVED.

12.4.2 NOT RESERVED — A substate of LOAD PORT RESERVATION, this state is active when there is no reservation existing at the load port.

12.4.3 RESERVED — A substate of LOADPORT RESERVATION, this state is active when there is a reservation for future activity at the load port. When in this state, the access mode for a load port may not be changed.

12.5 *Load Port Reservation State Transition Table*

Table 10 Load Port Reservation State Transition Table

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(no state)	System reset.	NOT RESERVED		No event report is required for this transition.
2	NOT RESERVED	*Service:* If reserved by service, the host or operator sends a ReserveAtPort or a Bind service to the production equipment. *CarrierOut:* This happens when the equipment physically initiates a CarrierOut operation.	RESERVED	If the user has configured the equipment to use the reservation visible signal indicator, it is activated for this load port.	Data required to be available for this event report: PortID LoadPortReservation-State CarrierID may be included when a carrier out or a bind service triggers this transition.
3	RESERVED	*Service:* If a reservation is cancelled by service, the host or operator sends a CancelBind or a CancelReservationAtPort. *Carrier arrival:* A carrier arrives at the reserved port.	NOT RESERVED	If the user has configured the equipment to use the reservation visible signal, the indicator is deactivated for this load port.	Data required to be available for this event report: PortID LoadPortReservation-State

12.6 *Relation of Reservation to Association*

12.6.1 The following figure indicates the relationship of Association to Reservation.

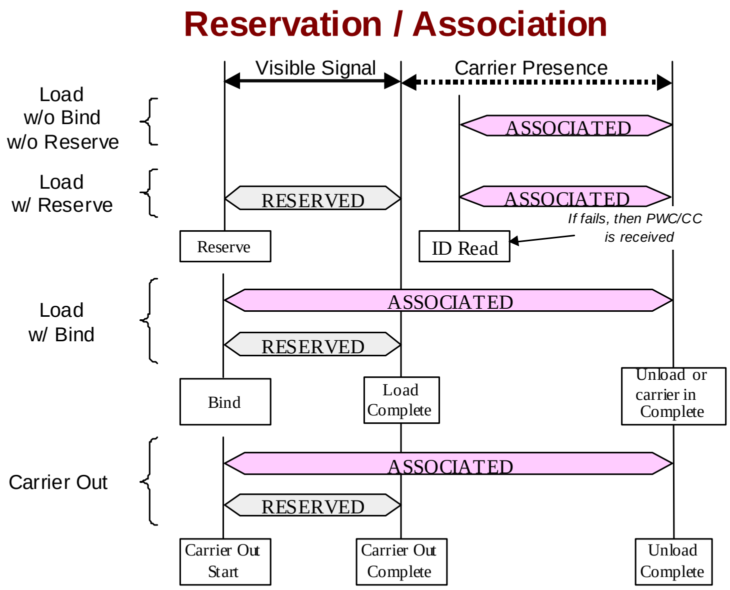

Figure 5
Relation of Reservation to Association

13 Load Port/Carrier Association State Model

13.1 The purpose of the Carrier Association State Model is to define the host view of carrier to load port association of the production equipment, as well as the host interactions with the production equipment necessary to associate a carrier to load port, and to perform equipment based carrier verification. Each load port shall maintain an independent instance of the Carrier Association State Model. Each instance of this state model must not influence the state of the same state model for a different load port.

13.1.1 This state model provides the ability to perform carrierID verification with two different methods. If the CarrierID is provided before the equipment reads the CarrierID, the CarrierID that becomes associated with the load port can be used later for equipment based carrier verification. If the association happens by CarrierID read (not by a service execution), then the production equipment shall report the CarrierID information in a data collection event.

13.2 *Load Port/Carrier Association State Model Diagram*

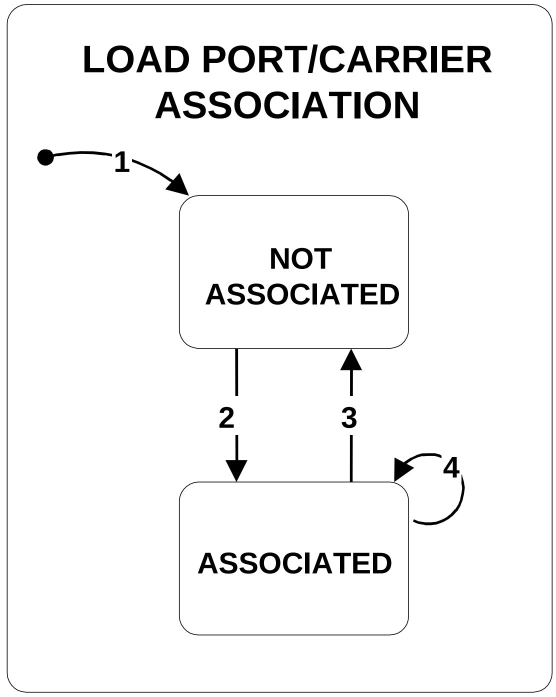

Figure 6
Load Port/Carrier Association State Model Diagram

13.2.1 *Load Port/Carrier Association State Definitions*

13.2.1.1 LOAD PORT/CARRIER ASSOCIATION — The parent state of the NOT ASSOCIATED and ASSOCIATED sub-states.

13.2.1.2 NOT ASSOCIATED — A sub-state of LOAD PORT/CARRIER ASSOCIATION. There is no carrier association present for this load port.

13.2.1.3 ASSOCIATED — A sub-state of LOAD PORT/CARRIER ASSOCIATION. A CarrierID has been associated with this load port. The load port is not available for a new carrier association.

13.2.2 *Load Port/Carrier Association State Transition Table*

13.2.2.1 Table 11 defines the transitions of the Load Port/Carrier Association State Model.

Table 11 Load Port/Carrier Association State Transition Definitions

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(no state)	System reset.	NOT ASSOCIATED		No event report is required for this transition
2	NOT ASSOCIATED	*Service Normal:* If associated by service in the noraml situation, the host sends a Bind service to the production equipment when the port is unoccupied. *Service Abnormal:* If associated with a service in an abnormal situation, the host sends a ProceedWithCarrierService to the production equipment when the load port is ocuupied. *CarrierID Read:* If associated by a CarrierID read, the production equipment creates the association at the time the CarrierID read is performed. *Known Carrier:* A carrier already known to the production equipment is being loaded onto the load port. This happens when the CarrierOut service is initiated.	ASSOCIATED		Once the CarrierID to load port association is complete, the load port is not available for association until the state returns to NOT ASSOCIATED again. Data required to be available for this event report: PortID CarrierID PortAssociationState
3	ASSOCIATED	*Service:* If cancellation of a load port association is required; then, this can be accomplished by sending a CancelBind service to the production equipment before the carrier arrives to the loadport or before a transfer sequence has started. *Carrier Unload:* An association cancellation may also be performed by removing the carrier from the load port or by the production equipment moving a carrier to an internal buffer position.	NOT ASSOCIATED		A carrier unload, may happen before or after processing occurs. The load port is available for another association once the carrier is removed. Data required to be available for this event report: PortID PortAssociationState

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
4	ASSOCIATED	Production equipment based carrier verification fails, and the carrier assumes the ID value from the carrier that is on the load port. *Internal buffer:* A carrier is unloaded and a queued CarrierOut service starts.	ASSOCIATED	The existing carrierID that was associated by a Bind service is unassociated by the production equipment and the new carrierID is now associated to the Load Port. The production equipment shall delay further action until receiving either a CancelCarrier or a ProceedWithCarrier command from the host.	This transition only occurs when the Bind command has been used. Data required to be available for this event report: PortID CarrierID PortAssociateState

14 Verification

14.1 Verification is the operation of comparing an actual value with an expected value. Verification may be performed by either the host or the equipment, depending upon whether the host is using the Bind service or not.

14.1.1 If the host provides the expected value before the actual value is obtained by the production equipment, then the production equipment shall perform the verification.

14.1.2 If the host does not provide the expected value, using the Bind service, before the actual value is read, then the production equipment shall provide to the host, the information necessary for host based verification.

14.1.3 There are two values that are defined by Carrier Management that require verification: Carrier ID and Carrier Slot Map.

14.2 *CarrierID Verification*

14.2.1 Table 12 defines the methods for verifying the Carrier ID.

Table 12 Carrier ID Verification Methods

Verification Method Desired	*Host Actions before Load*	*Equipment Action When Carrier Is Loaded*	*Host Actions after Load*
Production Equipment Based	*Bind Service:* The host executes the Bind service to associate a load port and a CarrierID.	*Bind Service:* The production equipment reads the Carrier ID from the carrier, compares it to the CarrierID supplied with the Bind service.	
		Verification Passed: Transition 6 of the Carrier State Model occurs. The production equipment proceeds with processing.	*Verification Passed:* None.
		Verification Failed: The equipment initiates by itself a CancelBind and destroys the carrier created with the “Bind” service and instantiates a new carrier with the newly read CarrierID. The carrier shall not be opened or moved to an internal buffer in the production equipment until and unless the ProceedWithCarrier service is received from the host.	*Verification Failed:* The host uses either the CancelCarrier service to force the carrier to the unload position, or indicates to the production equipment that it may proceed with the unexpected carrier, by sending the ProceedWithCarrier service. In both cases the carrierID specified in the service is equal to the one

Verification Method Desired	*Host Actions before Load*	*Equipment Action When Carrier Is Loaded*	*Host Actions after Load*
			determined by the carrierID read.
	Carrier Notification Service: The host executes the CarrierNotification service to inform the equipment of the future arrival of a carrier to an unspecified port.	*Carrier Notification Service:* The production equipment reads the Carrier ID from the carrier, compares it to the CarrierID supplied with a CarrierNotification service.	
		Verification Passed: Transition 6 of the Carrier State Model occurs. The production equipment proceeds with processing.	*Verification Passed:* None.
		Verification Failed: Not Applicable; because there is no association between a load port and a carrier, equipment based verification failure is not possible. If a carrier that has not been instantiated arrives at a load port, the equipment shall consider this as host based verification.	*Verification Failed:* Not Applicable, because there is no association between a load port and a carrier, equipment based verification failed is not possible. If a carrier that has not been instantiated arrives at a load port, the equipment shall consider this as host based verification." The host will respond with either a ProceedWithCarrier or a CancelCarrier Service. (See Host Based verification method).
Host Based	None required, the host may issue a ReserveAtPort service.	The production equipment reads the CarrierID and reports it to the host in an event report. Following carrierID read the equipment initiates Transition 3 of the Carrier State Model and a carrier object with the carrierID equal to the one determined by the carrierID read is instantiated. The carrier shall not be opened or moved to an internal buffer in the production equipment until and unless the ProceedWithCarrier service is received from the host.	*Verification Passed:* The host sends a ProceedWithCarrier service indicating the verification passed.
			Verification Failed: The host uses the CancelCarrier or CancelCarrierAtPort service to force the carrier to the unload position.

14.3 *Slot Map Verification*

14.3.1 Table 13 defines the methods for verification of the Carrier Slot Map. Some user's factory operations may not require strict management of the slot map. In this case the user may use the host based verification method.

Table 13 Slot Map Verification Methods

Verification Method Desired	*Host Actions Before Verification*	*Equipment Action When Carrier is Loaded*	*Host Actions After Load*
Production Equipment Based	The host provides a Slot Map with the Bind service or	The production equipment checks the carrier slot map and compares it to the slot	*Verification Passed:* None, the production equipment proceeds with the carrier. *Verification Failed:* If the host decides to cancel

Verification Method Desired	*Host Actions Before Verification*	*Equipment Action When Carrier is Loaded*	*Host Actions After Load*
	the ProceedWithCarrier service.	map supplied by the host. Either transition 13 or 14 of the Carrier State Model occurs.	processing, the host issues the CancelCarrier service. If the host decides to continue processing, the host issues the ProceedWithCarrier service.
Host Based	None.	The production equipment checks the carrier slot map and reports it to the host in an event report. The host has the responsibility for verifying the slot map.	*Verification Passed:* The host sends a ProceedWithCarrier indicating the verification passed. *Verification Failed:* If the host decides to cancel processing, the host issues the CancelCarrier service. If the host decides to continue processing, the host issues the ProceedWithCarrier service.

14.4 This table clarifies the relation of the reservation and verification to the related services.

Table 14 Reservation and Verification Relation to Service

	Reser-vation	*CarrierID Verification*	*Carrier SlotMap Verification*	*Service Used*	*Information Provided with Service*		
					Port ID	*Carrier ID*	*Carrier SlotMap*
1	Yes	Equipment based	Equipment based	Bind	Yes	Yes	Yes
2	Yes	Equipment based	Host based	Bind	Yes	Yes	No
3	Yes	Host based	Host based	ReserveAtPort	Yes	No	No
				ProceedWithCarrier (following ID read and host verification)	No	Yes	No
4	Yes	Host based	Equipment based	ReserveAtPort	Yes	No	No
				ProceedWithCarrier to provide slotmap (following ID read and host verification)	No	Yes	Yes
5	No	Equipment based	Equipment based	CarrierNotification	No	Yes	Yes
6	No	Equipment based	Host based	CarrierNotification	No	Yes	No
7	No	Host based	Equipment based	ProceedWithCarrier to provide slotmap (following ID read and host verification)	No	Yes	Yes
8	No	Host based	Host based	ProceedWithCarrier (following ID read and host verification)	No	Yes	No

15 Carrier Release Control

15.1 For both fixed buffer and internal buffer equipment, where Carrier Read/Write technology is used, the carrier must remain at the write position where the tag may be accurately written on until the Host has completed all of its read and write operations. For this purpose, a variable that affects the equipment releasing a carrier is defined.

15.2 *Carrier Hold Trigger* — Both fixed buffer equipment and internal buffer equipment shall allow the user to select a trigger to release the carrier when reading/writing is complete. Carrier release does not mean the equipment must move the carrier from the location it currently occupies, only that it is permissible to do so.

15.2.1 *CarrierHold Trigger set to Host Release* — If the Carrier Hold trigger is set to Host Release, both fixed buffer and internal buffer equipment shall hold the carrier at the write position until the CarrierRelease service is received.

15.2.2 *CarrierHold Trigger set to Equipment Release* — If the Carrier Hold trigger is set to Equipment Release, the equipment shall release the carrier based on the Carrier Object state model transition to CARRIER COMPLETE or CARRIER STOPPED.

15.3 For fixed load port equipment in AUTO access mode, it may be desirable to leave a completed carrier clamped, locked, or at the docked position until the AMHS arrives to pick it up. This reduces the chance that an operator may remove it. For this purpose, a variable that affects UnClamp Control is provided to allow the user to select the desired behavior. When the equipment finishes with a carrier, the Carrier State transitions from ACCESSING to CARRIER COMPLETE (normal) or CARRIER STOPPED (abnormal) and the equipment sends either the CarrierComplete event (normal) or the CarrierStopped event (abnormal). If the carrier has a door, the door shall be closed by this point.

15.4 Fixed buffer equipment shall allow the user to select a trigger to unclamp the carrier based on AMHS arrival at the equipment. If the access mode is MANUAL, the unclamp control trigger has no effect.

15.4.1 *UnclampControl trigger set to CARRIERCOMPLETE/CARRIERSTOPPED Triggered Unclamp* — The equipment automatically unclamps the carrier when the Carrier Status transitions to CARRIERCOMPLETE or CARRIERSTOPPED.

15.4.2 *UnclampControl trigger set to AMHS Triggered Unclamp* — The equipment behavior depends upon the Load Port Access State. If the Loadport Access State is AUTO, the carrier remains clamped, locked, or at the docked position (it will remain at the docked position only if that is the only position on which the carrier can be clamped) until AMHS has arrived. The AMHS arrives and begins a PIO unload sequence. The carrier must be at or moved to the pickup position and any additional clamp mechanisms must be released by the appropriate point of the sequence.

NOTE 3: It may be necessary to adjust timeouts for the AMHS to allow a few more seconds to move the carrier into the pickup position.

16 Services

16.1 The purpose of this section is to define the message services required to support CMS functionality.

16.1.1 This message service definition has four parts:

- A service description table.
- A service parameter table.
- A service parameter value table that specifies the type and range of the parameters.
- A service state mapping table that defines the states in which each service is valid.

16.2 *Service Message Description*

16.2.1 There are two types of services:

- An initial message and response between the service user and the service provider.
- A notification message from the service provider to the service user that does not require a response.

16.2.2 The "TYPE" column in the following table is used to indicate whether the service consists of a request/response message pair, "R", or a single notification message, "N".

Table 15 Service Message Description

Service Name	*Type*	*Description*
Bind	R	This service shall associate a CarrierID to a load port and shall cause the load port to transition to the RESERVED state..
CancelAllCarrierOut	R	This service shall cause all CarrierOut services to be removed from the queue.
CancelBind	R	This service cancels a CarrierID to load port association and shall cause the load port to transition to the NOT RESERVED state.
CancelCarrier	R	This service shall Cancel the current carrier related action, and the production equipment shall return the carrier to the unload position of the load port, or an internal buffer position, depending on the carrier's position in the production equipment.
CancelCarrierAtPort	R	This service shall Cancel the current carrier related action, and the production equipment shall return the carrier to the unload position of the load port.
CancelCarrierNotification	R	This service shall cause the equipment to destroy a carrier object instantiated through a prior CarrierNotification.
CancelCarrierOut	R	This service shall cause a specified CarrierOut service to be removed from the queue by the production equipment.
CancelReservationAtPort	R	This service shall cause the equipment to remove the reservation at the specified Port and to deactivate the visible signal.
CarrierIn	R	This service shall cause a carrier to be moved from a load port to an internal buffer location. Used in anomaly situations.
CarrierNotification	R	This service shall cause the equipment to instantiate a carrier object.
CarrierOut	R	This service shall cause a carrier to be moved from the internal buffer to a load port. This service can be queued by the production equipment.

Service Name	*Type*	*Description*
CarrierReCreate	R	This service shall cause the carrier object (and consequently, associated state models of the object) specified by the service to be recreated. This service shall be accepted only if the carrier accessing state is “Carrier Complete” or “Carrier Stopped” and the load port is in the “Ready to Unload” state.
CarrierRelease	R	Release the carrier from Carrier Hold
CarrierTagReadData	R	Read data from carrier ID tag.
CarrierTagWriteData	R	Write data to the carrier ID tag.
ChangeAccess	R	This service shall change the access mode of the specified Ports at the production equipment. If the service parameters include more than one load port and one of the load ports cannot be changed for any reason, the service request shall be rejected entirely. This means the Access mode shall not be changed for any load ports.
ChangeServiceStatus	R	This service shall change the transfer status of a specified load port at the production equipment.
ProceedWithCarrier	R	This service shall instruct the production equipment to proceed with using the specified carrier.
ReserveAtPort	R	This service shall cause the equipment to reserve the specified Port and activate a visible signal. This service is a Transfer boundary.

16.3 *Service Message Parameter Definition*

16.3.1 The following is a list of required parameters used in conjunction with service messages.

Table 16 Service Message Parameter Definition

Parameter Name	*Form*	*Description*
AccessMode	Enumerated AUTO, MANUAL.	The desired access mode of the ports specified.
AttributeData	Could be several different data types.	The data value associated with AttributeID.
AttributeID	Text 1 to 40 characters.	Identifier of the object attribute in the PropertiesList.
CarrierID	Text Conforms to ObjID as defined in SEMI E39.	Identifier of a carrier.
CMAcknowledge	Enumerated: • Acknowledge, command has been performed • Invalid command • Cannot perform now • Invalid data or argument • Acknowledge, request will be performed with completion signaled later by an event • Rejected, invalid state	Acknowledgement of request. Some services are commanding a certain task to be performed. This task is only completed if the expected end-condition is reached or has failed. A number of services only have effect on a ‘logical’ level (e.g. Bind, CancelReservationAtPort). Those services in general can be acknowledged right away after having performed the task. Other services that include triggering of physical movements (e.g. CarrierOut, CancelCarrier) most likely will be interpreted as “request action to be initiated” rather than “do action”. The equipment will reply in those cases the command “is going to be performed”. This alleviates transaction timeouts for these services that may take a long time to perform. It is however up to the supplier to decide if this is applicable. The completion of the task initiated by the services commanding some task to be performed (either acknowledged or going to be performed) must result in either a state transition or other action that generates a collection event upon normal / abnormal completion.
CMStatus	A structure consisting of CMAcknowledge and Status	Return information for a service.

Parameter Name	*Form*	*Description*
Data	Text	User data.
DataSeg	Protocol-specific.	Indicates specific section of data to read or write.
DataSize	Unsigned integer	Indicates the number of bytes of data to read or write.
ErrorCode	Enumerated: *Valid for all services listed below* Unsupported option [service] requested Command not valid for current state Insufficient parameters specified Parameters improperly specified *Bind* Load port does not exist Load port already in use Object identifier in use, Duplicate CarrierID Invalid attribute value Unknown attribute name *CancelAllCarrierOut* (none) *CancelBind* Load port does not exist Unknown object instance – Unknown CarrierID *CancelCarrier* Load port does not exist Unknown object instance – Unknown CarrierID Missing Carrier *CancelCarrierAtPort* Load port does not exist *CancelCarrierNotification* Unknown object instance – Unknown CarrierID *CancelCarrierOut* Unknown object instance – Unknown CarrierID *CancelReservationAtPort* Load port does not exist *CarrierIn* Unknown object instance – Unknown CarrierID *CarrierNotification* Object identifier in use, Duplicate CarrierID Invalid attribute value Unknown attribute name *CarrierOut* Load port does not exist Unknown object instance – Unknown CarrierID *CarrierReCreate* Unknown object instance – Unkown CarrierID Invalid attribute value Unknown attribute name Command not valid for current state *ChangeAccess* Load port does not exist *ChangeServiceStatus* Load port does not exist *ProceedWithCarrier* Load port does not exist Unknown object instance – Unknown CarrierID Invalid attribute value Unknown attribute name	Contains the code for the specific error found.

Parameter Name	*Form*	*Description*
	ReserveAtPort Load port does not exist Load port already in use	
ErrorText	Text	Text in support of the error code.
PortID	Integer 1 to n.	ID number of a load port. The PortID number should be the same as the load port number.
PortList	List 1 to n items.	List of n items $PortID_1$ . . n $PortID_n$
PropertiesList	List 1 to n name/value pairs.	List of n items 1. $AttributeID_1$ $AttributeData_1$ . . n. $AttributeID_n$ $AttributeData_n$
ServiceStatus	Enumerated: IN SERVICE, or OUT OF SERVICE.	The desired transfer service status of the specified list of load ports.
Status	A list of ErrorCode/ErrorText pairs.	Reports any errors found.

16.3.2 The "Acknowledge, request will be performed with completion signaled by a later event" response to a service, may apply to services listed in the table below. If this does apply, the supplier must document the event that signals completion. Any service not included in Table 17 shall respond with "Acknowledge, command has been performed."

16.3.2.1 Events that may signal completion are listed in Table 17.

Table 17 Deferred Completion Events

Service	*Events that may signal completion*
CarrierOut	CarrierLocation Changed Event Load Port State Change Event (transition 9)
CarrierIn	CarrierLocation Change Event Load Port State Change Event (transition 8)
CancelCarrier	CarrierLocation Changed Event Load Port State Change Event (transition 9)
CancelCarrierAtPort	CarrierLocation Changed Event Load Port State Change Event (transition 9)
ChangeService	LoadPortTransferState Change Event (transition 2 and 3)

16.4 *Service Message Definitions*

16.4.1 The following tables specify the allowable/required parameters for each service. The column marked "REQ/IND" specifies which parameters are required to be supported for CMS compliance (see Section 7.3.4.3).

16.4.2 *Bind*

16.4.2.1 The Bind service is used to associate a CarrierID with a load port. The Bind can contain a PropertiesList of carrier object attributes that are supplied by the host. A carrier object is instantiated when this service is used successfully. The Bind service will be rejected if the carrier specified has already been instantiated through the Bind or CarrierNotification service, or a carrierID read. The Bind service also triggers a transition in the Load Port Reservation state model from NOT RESERVED to RESERVED.

Table 18 Bind Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	The PortID where a carrier is expected.
CarrierID	M	—	The expected CarrierID.
PropertiesList	C	—	A list of name value pairs providing attributes for the carrier object being instantiated with the Bind service.
CMStatus	—	M	Information concerning the result of the service.

16.4.3 *CancelAllCarrierOut*

16.4.3.1 The CancelAllCarrierOut service is sent to internal buffer production equipment to cancel all CarrierOut services in queue.

Table 19 CancelAllCarrierOut Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CMStatus	—	M	Information concerning the result of the service.

16.4.4 *CancelBind*

16.4.4.1 The CancelBind request is used to cancel the association between a port and a Carrier ID. The carrier object is destroyed when this service is used successfully. The CancelBind service also triggers a transition in the Load Port Reservation state model from RESERVED to NOT RESERVED.

Table 20 CancelBind Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	C	—	The PortID for which to cancel the load port to carrier association. Either PortID or CarrierID must be specified.
CarrierID	C	—	The CarrierID for which to cancel the load port to carrier association. Either PortID or CarrierID must be specified.
CMStatus	—	M	Information concerning the result of the service.

16.4.5 *CancelCarrier*

16.4.5.1 The CancelCarrier request is used to stop a carrier. If the carrier is at a load port, then it shall be returned to the load/unload location of the load port and made ready for unload. If the carrier is at an internal location the carrier will return to an internal buffer location. A subsequent CarrierOut request is required for the production equipment to move the carrier to the external load port. The production equipment shall reject this service if issued after substrates have been removed for processing.

Table 21 CancelCarrier Service Parameters

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	—	The carrierID to cancel.
CMStatus	—	M	Information concerning the result of the service.
PortID	C	—	The PortID where the carrier object is located. This parameter is not required if the carrier object has been previously instantiated.

16.4.6 *CancelCarrierAtPort*

16.4.6.1 CancelCarrierAtPort is used to abort any carrier at a designated port. This service can be used when the carrierID of the carrier at the designated port is unknown.

Table 22 CancelCarrierAtPort Service Parameters

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	Any carrier that exist on the load port specified shall be made ready for unloading.
CMStatus	—	M	Information concerning the result of the service.

16.4.7 *CancelCarrierNotification*

16.4.7.1 The CancelCarrierNotification is used by the host to request the equipment cancel a previous CarrierNotification service. This service shall cause the equipment to destroy the carrier object specified.

Table 23 CancelCarrierNotification Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	—	The CarrierID of the carrier object to destroy.
CMStatus	—	M	Information concerning the result of the service.

16.4.8 *CancelCarrierOut*

16.4.8.1 The CancelCarrierOut service is sent to internal buffer production equipment to cancel a queued CarrierOut.

Table 24 CancelCarrierOut Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	—	CarrierID for the CarrierOut service that is being cancelled.
CMStatus	—	M	Information concerning the result of the service.

16.4.9 *CancelReservationAtPort*

16.4.9.1 The CancelReservationAtPort service is sent by the host to cancel a reservation at the load port. The load port will enter the UNRESERVED State after receiving this service.   A Port reserved by the physical initiation of a carrier out operation may not be cancelled by this service.

Table 25 CancelReservationAtPort Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	The Port ID to reserve
CMStatus	—	M	Information concerning the result of the service.

16.4.10 *CarrierIn*

16.4.10.1 The CarrierIn service is only used to request the internal buffer equipment internalize a carrier that has been moved to the load port via a previous CarrierOut service. When using host based verification, the production equipment shall move the carrier in to the internal buffer for the first time after receiving the ProceedWithCarrier request. If the CarrierIn service is received by the production equipment without previously having received a CarrierOut service for the carrier, the service will be refused.

Table 26 CarrierIn Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	—	The CarrierID for the carrier to internalize.
CMStatus	—	M	Information concerning the result of the service.

16.4.11 *CarrierNotification*

16.4.11.1 The Carrier Notification service is used by the host to inform the equipment that a Carrier with the ID specified will be arriving at the equipment. The load port is not specified; therefore no carrier to load port association takes place. A carrier object with the ObjID equal to the carrierID specified in the service is instantiated. "The CarrierNotification service will be rejected if the carrier specified has already been instantiated through the Bind or CarrierNotification service, or a carrierID read.

Table 27 CarrierNotification Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	—	The CarrierID of the carrier object to instantiate.
PropertiesList	C		The PropertiesList of the carrier to instantiate.
CMStatus	—	M	Information concerning the result of the service.

16.4.12 *CarrierOut*

16.4.12.1 The CarrierOut service is sent to internal buffer production equipment, to request that the equipment move the specified carrier to a load port, as soon as the carrier is completed. When the CarrierOut service is started, the destination load port state becomes TRANSFER BLOCKED, and the load port's association state becomes ASSOCIATED.

16.4.12.2 *CarrierOut Queuing*

16.4.12.2.1 This service request can be queued by the production equipment. The production equipment is required to support a queue of n size, where n is equal to the sum of the number of internal buffer locations and the number of internal FIMS ports. The order of the queue is FIFO for each load port. If the load port is not specified in service request, the equipment chooses which load port queue to place the CarrierOut service. The queued service does not take effect until the current substrate handling action is complete (i.e., filling, emptying of the carrier) and the load port is in the NOT ASSOCIATED state. When a CarrierOut service is queued and the production equipment load port is currently in the TRANSFER BLOCKED state, the production equipment shall keep the load port in the TRANSFER BLOCKED state. Then, after the port is cleared, the CarrierOut service shall begin.

Table 28 CarrierOut Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	—	CarrierID for the carrier to be moved out.
PortID	C	—	If omitted, the production equipment shall select an appropriate port at the time the carrier is ready to be moved.
CMStatus	—	M	Information concerning the result of the service.

16.4.13 *CarrierRelease*

16.4.13.1 CarrierRelease request is used to tell the equipment that the carrier is ready to be moved away from the read or write position. Equipment shall deny the request if LocationID and CarrierID are mismatched.

Table 29 CarrierRelease Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
LocationID	C	—	The ID for the location of the carrier. Either LocationID or CarrierID must be used.
CarrierID	C	—	The CarrierID of the carrier. Either LocationID or CarrierID must be used.
CMStatus	—	M	Information concerning the result of the service.

16.4.14 CarrierReCreate

16.4.14.1 CarrierReCreate request is used to re-create the carrier object specified by the service. This will allow a repeated introduction of the same carrier on the loadport. After the service is issued, the equipment shall treat the carrier occupying the respective loadport identically to one that was physically removed and replaced, deleting the original carrier and then re-instantiating it. If no PropertiesList is provided with the service, then the host verification scenarios for re-instantiating the carrier object shall be followed. For example, the carrier ID would be re-read (at which point Carrier State transition #3, (no state) to Waiting for Host occurs) and subsequently verified by host, followed by slot map re-read and verification by host. Alternatively, if PropertiesList is provided with this service, then the equipment shall follow the equipment based verification steps. For example, the carrier object is re-instantiated with the CarrierID (and possibly content/slot map) information provided within the CarrierReCreate Service. In this equipment based verification scenario, the equipment is responsible for verifying the contents of the carrier against the received information. If the equipment supports other SEMI standards (i.e.- SEMI E40/E90/E94), then from the perspective of those standards, when CarrierReCreate service is received, the scenario would resemble that of a carrier being removed and a new carrier placed. The service shall be accepted only if the current carrier Accessing Status is either “Carrier Complete” or “Carrier Stopped” and the load port is in the “Ready to Unload” state.

Table 30 CarrierReCreate Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CarrierID	M	-	Carrier ID for the carrier object the service is to be performed upon
PropertiesList	C	-	If sent by the host, then equipment based verification scenario. If not, then host based verification scenario.
CMStatus	-	M	Information concerning the result of the service

16.4.15 *CarrierTagReadData*

16.4.15.1 CarrierTagReadData is used to request a block of data from the carrier ID tag. Equipment shall deny the request if LocationID and CarrierID are mismatched.

Table 31 CarrierTagReadData Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
LocationID	C	—	The ID for the location of the carrier. Either LocationID or CarrierID must be used.
CarrierID	C	—	The CarrierID of the carrier. Either LocationID or CarrierID must be used.
DataSeg	C	—	Indicates a specific section of data.
DataSize	C	—	Indicates the number of bytes to read.
Data	—	C	Data from the carrier ID tag. May be NULL if no data exists for the given section.
CMStatus	—	M	Information concerning the result of the service.

16.4.16 *CarrierTagWriteData*

16.4.16.1 CarrierTagWriteData is used to request that a block of data be written to the carrier ID tag. Equipment shall deny the request if LocationID and CarrierID are mismatched.

Table 32 CarrierTagWriteData Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
LocationID	C	—	The ID for the location of the carrier. Either LocationID or CarrierID must be used.
CarrierID	C	—	The CarrierID of the carrier. Either LocationID or CarrierID must be used.
DataSeg	C	—	Indicates a specific section of data.
DataSize	C	—	Indicates the number of bytes to read.

Parameter Name	Req/Ind	Rsp/Conf	Description
Data	M	—	Data from the carrier ID tag. May be NULL if no data exists for the given section.
CMStatus	—	M	Information concerning the result of the service.

16.4.17 *ChangeAccess*

16.4.17.1 The ChangeAccess message requests a change of access mode for the load ports specified in the PortList.

Table 33 ChangeAccess Service Parameter Definitions

Parameter Name	Req/Ind	Rsp/Conf	Description
AccessMode	M	—	The new desired access mode.
PortList	M	—	The list of ports to use the new access mode.
CMStatus	—	M	Information concerning the result of the service.

16.4.18 *ChangeServiceStatus*

16.4.18.1 The ChangeServiceStatus service is used to request the production equipment change a load port service state.

Table 34 ChangeServiceStatus Parameter Definitions

Parameter Name	Req/Ind	Rsp/Conf	Description
PortID	M	—	PortID to designate the new service status.
ServiceStatus	M	—	The new service state.
CMStatus	—	M	Information concerning the result of the service.

16.4.19 *ProceedWithCarrier*

16.4.19.1 The ProceedWithCarrier service is sent by the host to indicate that the carrier operations may continue. When using host based verification it is used by the host to indicate to the production equipment that the verification of Carrier ID and/or the Carrier Slot Map is correct. For successful production equipment based verification the production equipment shall not require this message before proceeding with the carrier. For failed production equipment based verification the production equipment shall require either a CancelCarrier or ProceedWithCarrier service.

16.4.19.2 Using Table 34, for the Host based CarrierID verification case, the ProceedWithCarrier service sent by the host after the first carrier ID read is referred to as ProceedWithCarrier #1, the ProceedWithCarrier service sent after slot map read is referred to as ProceedWithCarrier #2.

Table 35 ProceedWithCarrier Service Parameter Definitions

Parameter Name	Req/Ind	Rsp/Conf	Description
PortID	C	—	The PortID for which processing may proceed.
CarrierID	M	—	The CarrierID for which processing may proceed.
PropertiesList	C	—	A list of name value pairs providing attributes for the carrier object.
CMStatus	—	M	Information concerning the result of the service.

16.4.20 *ReserveAtPort*

16.4.20.1 The ReserveAtPort service is sent by the host to indicate future activity at the load port. This allows for reserving the port but doing host based ID verification. The load port will enter the RESERVED State after receiving this service. The equipment shall move a carrier to a reserved load port.

Table 36 ReserveAtPort Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	The Port ID to reserve
CMStatus	—	M	Information concerning the result of the service.

17 Carrier Tag Read/Write

17.1 Some technologies allow data to be stored on a carrier ID tag where it can be subsequently read and/or modified. In this case, it is the host that specifies when this data is written and read, because the equipment has no knowledge of the contents of the data. The read operations shall be performed only when the carrier is at the read position. The write operations shall be performed only when the carrier is at the write position. NOTE: The read and write positions may be the same position. The host shall be able to both read and write whenever CarrierHold switch is set to Host Release and the carrier is at the respective read or write position. Once the host has completed all of its read and write operations for that carrier, then the host sends the CarrierRelease request to the equipment. In all cases, the CarrierAccessingStatus state shall be set to either CARRIER COMPLETE or CARRIER STOPPED before the carrier may be undocked. The CarrierRelease service informs the equipment that carrier read or carrier write is complete. For internal buffer equipment the CarrierRelease service shall allow the equipment to move the carrier away from the read or write position.

NOTE 4: The CarrierRelease service has a different purpose from the CarrierOut service. The intent of the CarrierOut service request is to move the carrier to a loadport, while the intent of the CarrierRelease service request is to inform equipment that it may move the carrier away from the read or write position. Therefore, CarrierOut may also be used with the CarrierRelease command. If CarrierHold is Host Release, then the carrier shall be kept at the write position until an CarrierRelease service request is received, regardless of when a CarrierOut is sent. If CarrierHold is set to Equipment Release, then the CarrierRelease request has no effect.

18 Additional Events

18.1 This section identifies data collection events that are not related to State transitions for variable data items. The intent of this section is to ensure certain data is available for specific events that are not related to state transitions, not to define all the additional collection events for CMS. Also, all state transitions in CMS state models are required to have associated event reports.

18.2 *Buffer Capacity Changed Event*

18.2.1 An event shall be generated whenever Buffer Capacity changes. This applies to all internal buffers and internal buffer partitions.

18.2.2 Data required to be available for this event report:

- BufferPartitionInfo.

18.3 *Carrier Approaching Complete Event*

18.3.1 In some cases, for carrier transfer efficiency, the host needs to know carrier completion timing a little faster than actual. For example:

- If the equipment is internal buffer type, QTAT carriers need to be moved out directly from internal FIMS to a load port to shorten moving out time.
- If the equipment uses non-product carriers, such as dummy, they need to be changed before it becomes not reusable to prevent stopping the equipment operation.
- If the equipment uses non-product carriers, such as test, reject, they need to be changed before it becomes empty or full to prevent stopping the equipment operation.

18.3.2 This event shall be generated when the access by the equipment to the carrier is approaching complete. How the timing of the event is determined shall be configurable.

18.3.3 Detailed definition of the event timing depends upon the type of usage of the carrier. Some examples of event timing for different types of usage are shown below.

18.3.3.1 *PRODUCT* — When remaining time until the carrier starts moving from internal FIMS to internal buffer reaches the configurable variable time (internal buffer equipment only).

18.3.3.2 *DUMMY* — When remaining times until substrates of the carrier becomes not reusable reaches the configurable variable times.

18.3.3.3 *TEST* — When remaining substrates until the carrier becomes empty reaches the configurable variable number.

18.3.3.4 *REJECT* — When remaining slots until the carrier becomes full reaches the configurable variable number.

18.3.4 Suppliers shall document the interpretation and the configurable variable(s) in the equipment specification document.

18.3.5 Data required to be available for this event report:

- CarrierID

18.4 *Carrier Clamped Event*

18.4.1 An event shall be generated whenever a carrier is clamped. Clamped means the load port has engaged a device that would inhibit removal or movement of the carrier by any entity external to the load port. Some load ports may include more than one clamping device. This event should be generated only when the first clamping is engaged. This applies to all load ports.

18.4.2 There is no standard for when load ports clamp a carrier. Therefore the IC makers host systems and personnel will need some signal from the equipment to know if a carrier is clamped. This event provides that signal. This applies to all load ports that provide clamping. If a load ports does not clamp the carrier no event is required.

18.4.3 Data required to be available for this event report:

- Port ID,
- Carrier ID (if available), and
- Location ID.

18.5 *Carrier Closed Event*

18.5.1 If the carrier is equipped with a door, an event shall be generated when a carrier door has been closed.

18.5.2 Data required to be available for this event report:

- CarrierID,
- LocationID, and
- PortID (if valid).

18.6 *Carrier Location Change Event*

18.6.1 An event shall be generated whenever a carrier has changed location. This applies to both load ports, substrate ports, and internal buffer locations.

18.6.2 Data required to be available for this event report:

- CarrierID,
- LocationID (new destination location), and
- CarrierLocationMatrix.

18.7 *Carrier Opened Event*

18.7.1 If the carrier is equipped with a door, an event shall be generated when a carrier door has been opened.

18.7.2 Data required to be available for this event report:

- CarrierID,
- LocationID, and
- PortID (if valid).

18.8 *Carrier Unclamped Event*

18.8.1 An event shall be generated whenever a carrier is unclamped. Unclamped means that the load port has disengaged any devices that would inhibit removal or movement of the carrier by any entity external to the load port. Some load ports may include more than one clamping device. This event should be generated only when all clamping or locking devices are disengaged.

18.8.2 There is no standard for when load ports unclamp a carrier. Therefore the IC makers host systems and personnel will need some signal from the equipment to know if a carrier is unclamped. This event provides that signal. This applies to all load ports that provide clamping and unclamping. If a load ports does not clamp and unclamp the carrier no event is required.

18.8.3 Data required to be available for this event report:

- Port ID,
- Carrier ID (if available), and
- Location ID.

18.9 *CarrierID Read Fail Event*

18.9.1 An event shall be generated when the equipment attempts to read a carrierID and fails at a port in the NOT ASSOCIATED STATE.

18.9.2 Data required to be available for this event report:

- PortID

18.10 *ID Reader Available Event*

18.10.1 An event shall be generated whenever an id reader becomes available. This applies to all load ports.

18.10.2 Data required to be available for this event report:

- Port ID

18.11 *ID Reader Unavailable Event*

18.11.1 An event shall be generated whenever an id reader becomes unavailable for any reason. This applies to all load ports.

18.11.2 Data required to be available for this event report:

- Port ID

19 Variable Data

19.1 The purpose of this section is to define the list of variable data requirements for CMS equipment. Values of these variables are available to the host via collection event reports and host status queries. Some of the data items listed are valid for internal buffer production equipment only, and are marked as such.

19.2 *Variable Data Definitions*

19.2.1 The following table defines variable data that shall be provided by the production equipment. Also, for the objects defined by Carrier Management, the identifier of that object and all of the attributes of that object shall be available for inclusion in event reports associated with that object. Subscripted variables are used either as items within a list or to differentiate data representing different entities. Subscripted variables are always valid.

Table 37 Variable Data Definitions

Variable Name	*Description*	*Type*	*Access*	*Comment*
AccessMode	The access mode of the loadport.	Enumerated: MANUAL, AUTO	RO	
$AccessMode_i$	The access mode for the i^{th} load port.	Enumerated: MANUAL, AUTO	RO	
AvailPartitionCapacity	The current available buffer capacity for a logical partition inside internal buffer equipment (PartitionCapacity - # of carriers in partition).	Non-negative integer	RO	Only applicable to internal buffer production equipment.
AvailPartition-$Capacity_i$	The AvailPartitionCapacity for the i^{th} PartitionID within the internal buffer.	Non-negative integer	RO	Only applicable to internal buffer production equipment.
BufferCapacityList	The current PartitionType, AvailPartitionCapacity, and PartitionCapacity for all logical buffer partitions.	List of n groups of items 1. $BufferPartitionInfo_1$ . . n. $BufferPartitionInfo_n$	RO	Only applicable to internal buffer production equipment.
BufferPartitionInfo	The related information for a logical buffer partition.	Structure of 5 items PartitionID PartitionType AvailPartitionCapacity PartitionCapacity UnallocatedPartition-Capacity	RO	Only applicable to internal buffer production equipment.
$BufferPartitionInfo_i$	The related information for the i^{th} buffer partition.	Structure of 5 items $PartitionID_i$ $PartitionType_i$ $AvailPartitionCapacity_i$ $PartitionCapacity_i$ UnallocatedPartition-$Capacity_i$	RO	Only applicable to internal buffer production equipment.
BypassReadID	Enables or disables automatic ID acceptance when the carrier ID reader is unavailable.	Boolean.	RW	If TRUE, the ID provided with Bind is used automatically.

Variable Name	*Description*	*Type*	*Access*	*Comment*
CarrierAccessing-Status	The state of the carrier accessing status.	Enumerated: NOT ACCESSED, IN ACCESS, CARRIER COMPLETE, CARRIER STOPPED	RO	
CarrierID	The ID of the carrier.	Text	RO	
$CarrierID_i$	The CarrierID at the i^{th} locationID.	Text	RO	
CarrierIDStatus	State of the carrier ID status.	Enumerated: ID NOT READ, [ID]WAITING FOR HOST, ID VERIFICATION OK, ID VERIFICATION FAILED	RO	
CarrierLocationMatrix	A list all the carriers at/in the equipment. Both internal to the equipment, and on equipment load ports.	List of n pairs of items 1. $LocationID_1$ $CarrierID_1$ . . n. $LocationID_n$ $CarrierID_n$	RO	The $CarrierID_i$ shall be null if there is no carrier at the $locationID_i$. If a carrier is at $LocationID_i$, but the $CarrierID_i$ is not known, the value of $CarrierID_i$ shall be "UNKNOWN".
LocationID	The ID of a carrier location.	Text	RO	Carrier locations are any location at/in the production equipment where a carrier may rest.
$LocationID_i$	The LocationID of the i^{th} carrier location.	Text	RO	Carrier locations are any location at/in the production equipment where a carrier may rest.
LoadPortReservation-State	The reservation state of a Load Port.	Enumerated: NOT RESERVED, RESERVED	RO	
LoadPortReservation-$State_I$	The reservation state of the i^{th} Load Port.	Enumerated: NOT RESERVED, RESERVED	RO	
LoadPortReservation-StateList	The current reservation state of all the load ports.	A list of n items 1. $LoadPortReservationState_1$ . . n.$LoadPortReservationState_n$	RO	This can be used to resynchronize the host.
PartitionCapacity	The total PartitionCapacity for a logical internal buffer partition.	Non-negative integer	RO	Only applicable to internal buffer production equipment.
$PartitionCapacity_i$	The PartitionCapacity for the i^{th} PartitionID of the internal buffer.	Non-negative integer	RO	Only applicable to internal buffer production equipment.
PartitionID	The ID of a logical internal buffer partition.	Text	RO	Used to identify separate material types in an internal buffer.
$PartitionID_i$	The ID of the i^{th} logical partition of the internal buffer.	Text	RO	Used to identify separate material types in an internal buffer.

Variable Name	*Description*	*Type*	*Access*	*Comment*
PartitionType	The type of a logical partition within an internal buffer.	Text	RO	Only applicable to internal buffer production equipment. Some examples of logical buffer PartitionType are Product, Dummy, Substrate, and Seed.
PartitionType_i	The PartitionType corresponding with the i^{th} PartitionID.	Text	RO	Only applicable to internal buffer production equipment. Some examples of logical buffer PartitionType are Product, Dummy, Substrate, and Seed.
PortAssociationState	The association state of a load port.	Enumerated: ASSOCIATED, NOT ASSOCIATED	RO	
$\text{PortAssociationState}_i$	The association state of the i^{th} load port.	Enumerated: ASSOCIATED, NOT ASSOCIATED	RO	
PortAssociationState-List	The current association state for all load ports.	A list of n items 1. $\text{PortAssociationState}_1$ . . n. $\text{PortAssociationState}_n$	RO	This can be used to re-synchronize the host.
PortID	ID of a load port.	Positive integer	RO	
PortID_i	ID of the load port where the carrier transfer is taking place. One PortID exists for each load port.	Positive integer	RO	
PortStateInfo	The PortAssociationState combined with the PortTransferState.	List of 2 items PortAssociationState PortTransferState	RO	A combination of both port states.
PortStateInfo_i	The PortAssociationState combined with the PortTransferState for the i^{th} load port.	List of 2 items $\text{PortAssociationState}_i$ $\text{PortTransferState}_i$	RO	A combination of both port states.
PortStateInfoList	List of PortStateInfo for all load ports.	List of n items 1. PortStateInfo_1 . . n PortStateInfo_n	RO	A list of all the port states for all the ports.
PortTransferState	The current transfer state of a load port.	Enumerated: OUT OF SERVICE, TRANSFER BLOCKED, READY TO LOAD, READY TO UNLOAD	RO	Super states are not included, only sub states.
$\text{PortTransferState}_i$	The current transfer state of the i^{th} load port.	Enumerated: OUT OF SERVICE, TRANSFER BLOCKED, READY TO LOAD, READY TO UNLOAD	RO	Super states are not included, only sub states.
PortTransferStateList	The current Load Port Transfer State for all load ports.	A list of n items 1. $\text{PortTransferState}_1$ . . n. $\text{PortTransferState}_n$	RO	This can be used to re-synchronize the host.

Variable Name	*Description*	*Type*	*Access*	*Comment*
Reason	The reason for transition 14, SLOT MAP NOT READ to WAITING FOR HOST	Enumerated: VERIFICATION NEEDED, VERIFICATION BY EQUIPMENT UNSUCCESSFUL, READ FAIL, IMPROPER SUBSTRATE POSITION	RO	Information to aid host in deciding appropriate action.
SlotMapStatus	State of the carrier slot map status.	Enumerated: SLOT MAP NOT READ, [SLOT]WAITING FOR HOST, SLOT MAP VERIFICATION OK, SLOT MAP VERIFICATION FAILED	RO	
UnAllocatedPartition-Capacity	The current unallocated capacity for a logical partition inside internal buffer equipment, (PartitionCapacity - # of carriers in partition - # of carriers allocated for the partition (via reception of a Bind, CarrierIn, Carrier-Notification, ReserveAtPort, or ProceedWithCarrier service)). Any carriers allocated for a partition will be de-allocated if the corresponding Cancel service is received (for example Bind-CancelBind, CarrierNotification – CancelCarrierNotification, ReserveAtPort – CancelReservationAtPort, ProceedWithCarrier – CancelCarrier).	Non-negative integer	RO	Only applicable to internal buffer equipment.
UnAllocatedPartition-$Capacity_i$	The UnallocatedPartition-Capacity for the i^{th} Partition ID within the internal buffer	Non-negative integer	RO	Only applicable to internal buffer equipment.

20 Alarms

20.1 This section includes specific alarms that are required to be implemented by CMS compliant equipment.

20.2 *Alarm List Table*

20.2.1 Table 37 is a listing of required alarms for both fixed buffer and internal buffer equipment. This list is only a subset of the carrier transfer alarms. There may be more carrier transfer related alarms that are not listed here.

Table 38 Alarm List

Equipment		*Danger*		*Affected*		
Configuration	*Alarm Text*	*Potential*	*Imminent*	*Operator*	*Equipment*	*Material*
Fixed & Internal Buffer Equipment	PIO Failure	X		X	X	X

Equipment		*Danger*		*Affected*		
Configuration	*Alarm Text*	*Potential*	*Imminent*	*Operator*	*Equipment*	*Material*
	Access Mode Violation	X		X	X	X
	Carrier Verification Failure	X				X
	Slot Map Read Failed	X		X	X	X
	Slot Map Verification Failed	X			X	X
	Attempt To Use Out Of Service Load Port	X			X	X
	Carrier Presence Error	X		X	X	X
	Carrier Placement Error	X		X	X	X
	Carrier Dock/UnDock Failure	X			X	X
	Carrier Open/Close Failure	X			X	X
Fixed and Internal Buffer	Duplicate CarrierID	X				X
Internal Buffer Equipment Only	Internal Buffer Carrier Move Failure	X			X	X
Fixed & Internal Buffer Equipment	Carrier Removal Error	X		X	X	X

20.3 *Duplicate CarrierID*

20.3.1 If the equipment receives a carrier with a CarrierID that is the same as that of another carrier present at the equipment, the following rules shall apply:

1. The second carrier with a CarrierID shall not be processed.
2. If processing on the first carrier with the CarrierID has not begun, it should not be processed.
3. If processing on the first carrier has begun a Duplicate Carrier ID In Process event shall be issued to notify the host.

21 Requirements for Compliance

21.1 Table 38 provides a checklist for CMS compliance.

Table 39 CMS Compliance Statement

Fundamental CMS Requirements	*CMS Section*	*Implemented*	*CMS Compliant*
Load Port Numbering	9.1	☐ Yes ☐ No	☐ Yes ☐ No
Carrier Slot Numbering	9.2	☐ Yes ☐ No	☐ Yes ☐ No
Load Port Transfer State Model	9.3–9.4.3	☐ Yes ☐ No	☐ Yes ☐ No

RELATED INFORMATION 1
CARRIER OBJECT ID

NOTE: This related information is not an official part of SEMI E87, but was approved for publication by full letter ballot procedures on December 15, 1999.

R1-1 Carrier Object ID

R1-1.1 The Carrier Object ID is derived as stated in the Table R1-1 Carrier ID derivation.

Table R1-1 CarrierID Derivation

	Method of Original Instantiation	*CarrierID Read*	*ID Verifi-cation*	*Following Actions*	*CarrierID =*	*Parameter Required by Service*
1	Bind	Success-ful	Successful and equipment based	Production equipment continues with the carrier.	CarrierID in Bind service.	*Bind:* CarrierID, PortID, and PropertiesList
2	Bind	Success-ful	Fails	The carrier object instantiated via the Bind message is destroyed and a new carrier object with the carrierID equal to the one determined by the carrierID is instantiated. ProceedWithCarrier service is received.	CarrierID provided by the CarrierID read.	*ProceedWith-Carrier:* CarrierID, PropertiesList
3	Bind	Success-ful	Fails	The carrier object instantiated via the Bind message is destroyed and a new carrier object with the carrierID equal to the one determined by the carrierID is instantiated. CancelCarrier service is received.	CarrierID provided by the CarrierID read.	*CancelCarrier*: CarrierID
4	Bind	Fails	NA	ProceedWithCarrier service is received and the carrierID matches the carrierID provided by the Bind service.	CarrierID provided by the Bind service.	*ProceedWith-Carrier*: CarrierID
5	Bind	Fails	NA	CancelCarrier service is received and the carrierID matches the carrierID provided by the Bind service.	CarrierID provided by the Bind service.	*CancelCarrier*: CarrierID
6	Carrier-Notification	Success-ful	Successful and equipment based	Production equipment continues with the carrier.	CarrierID in Carrier-Notification.	*Carrier-Notification:* CarrierID and PropertiesList
7	Carrier ID read	Success-ful	Successful and Host based	ProceedWithCarrier service is received and the carrierID matches the carrierID read by the production equipment.	CarrierID read by production equipment.	*ProceedWith-Carrier*: CarrierID and PropertiesList, PortID may be included.
8	CarrierID read	Success-ful	Fails and Host based	A CancelCarrier service is received and the carrierID matches the carrierID read by the production equipment.	CarrierID read by production equipment.	*CancelCarrier*: CarrierID

	Method of Original Instantiation	*CarrierID Read*	*ID Verifi-cation*	*Following Actions*	*CarrierID =*	*Parameter Required by Service*
9	The method of original instantiation is defined following the carrierID read fail and is described in column titled following actions.	Fails	NA	A ProceedWithCarrier service is received and the carrierID is provided in the service.	CarrierID provided by the Proceed-WithCarrier service.	*ProceedWith-Carrier* : CarrierID, PortID, PropertiesList
10	The method of original instantiation is defined following the carrierID read fail and is described in the column titled *Following Actions*.			A CancelCarrier service is received and the carrierID is the one provided by the CancelCarrier.	CarrierID provided by the Cancel-Carrier service.	*CancelCarrier*: CarrierID, PortID

R1-2 Scenarios

R1-2.1 The scenarios listed here are not a requirement of this standard. They are provided to aid in the understanding of the document. These scenarios are not an exhaustive set of all possible scenarios. The scenarios presented are typical or common scenarios encountered when using this standard.

R1-2.2 *Normal Roundtrip 1*

R1-2.2.1 Assumptions: Fixed buffer production equipment, FOUP, Host based verification

R1-2.2.2 Indicated states: LTS = Load Port Transfer State, LCAS = Load Port/Carrier Association State, CIDS = Carrier ID Status, CSMS = Carrier Slot Map Status

Table R1-2 Normal Roundtrip 1

#	*Comment*	*Dir*	*Message*	*LTS*	*LCAS*	*CIDS*	*CSMS*
0	Initial condition.			RTL	NA	(T)	(T)
1	Loading transfer starts.	H<-E	TransferBlocked	TB			
2	Loading transfer completes.						
3	CarrierID is read.	H<-E	WaitingForHost		A	WFH	SNR
4	CarrierID is verified by host, and result is OK.						
5	Host commands to proceed.	H->E	ProceedWithCarrier			IVO	
6	Carrier is docked.						
7	Slot map is read.	H<-E	WaitingForHost				WFH
8	Slot map is verified by host, and result is OK.						
9	Host commands to proceed.	H->E	ProceedWithCarrier				SVO
10	Process starts.						
11	Process completes.						
12	Carrier is undocked.	H<-E	ReadyToUnload	RTU			
13	Unloading transfer starts.	H<-E	TransferBlocked	TB			
14	Unloading transfer completes.	H<-E	ReadyToLoad	RTL	NA	(T)	(T)

R1-2.3 *Normal Roundtrip 2*

R1-2.3.1 Assumptions: Fixed buffer production equipment, FOUP, Production equipment based verification, Bind Service received

R1-2.3.2 Indicated states: LTS = Load Port Transfer State, LRS = Load Port Reservation State LCAS = Load Port/Carrier Association State, CIDS = Carrier ID Status, CSMS = Carrier Slot Map Status

Table R1-3 Normal Roundtrip 2

#	*Comment*	*Dir*	*Message*	*LTS*	*LRS*	*LCAS*	*CIDS*	*CSMS*

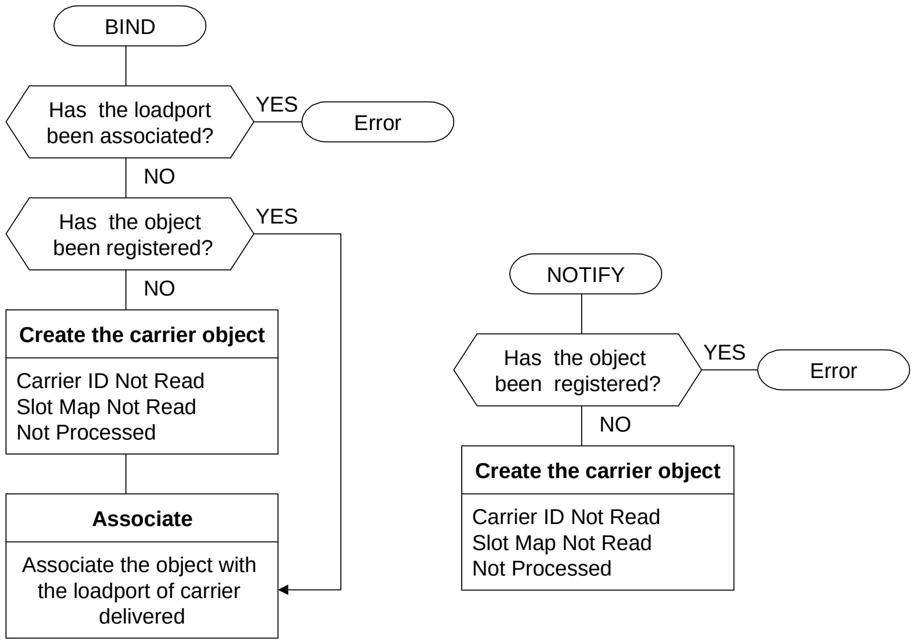
R1-3 Example Equipment Logic for Carrier Delivery

R1-3.1 To summarize the CMS carrier object behavior, following flow-charts are provided. The charts show the example of an equipment logic for the CMS definitions.

R1-3.2 *Bind and Notify*



R1-3.2.1 *Bind Service Request From the Host*

R1-3.2.1.1 Verify no object has been associated with designated loadport. If it is associated the Bind service shall be failed.

R1-3.2.1.2 Verify no object having the same ID specified in Bind service has been registered.

R1-3.2.1.2.1 If it is registered, the Bind service shall associate the object that is already registered with the designated loadport.

R1-3.2.1.2.2 If it is not registered, then create the object and associate it to the loadport. The initial states of the object are Carrier ID Not Read, Carrier Slot Map Not Read, Carrier Not Processed and Associated to the loadport.

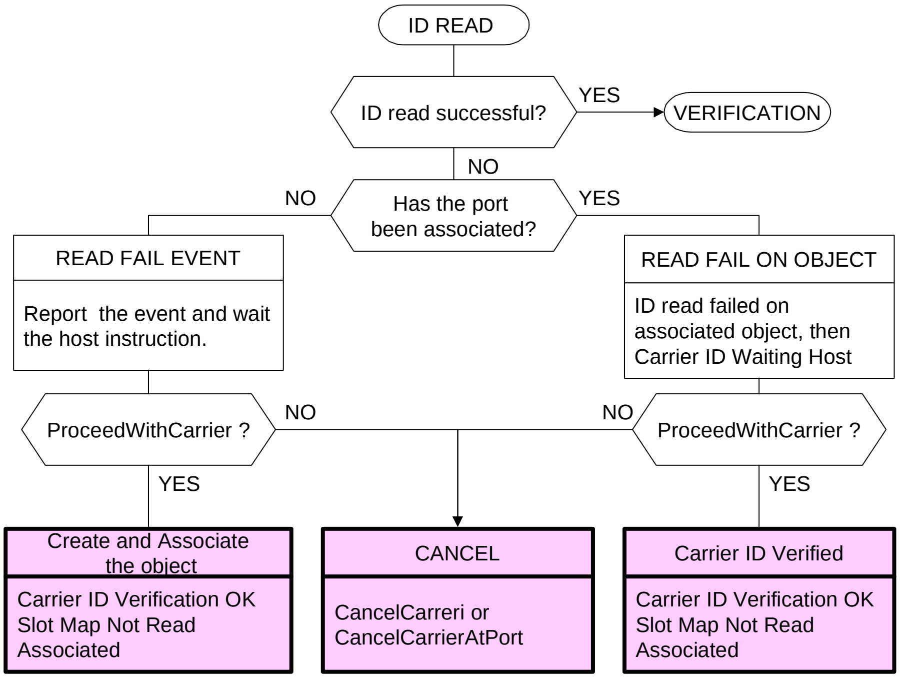
R1-3.2.2 Notify service request from the host

R1-3.2.2.1 Verify no object having the same ID specified in Notify service has been registered.

R1-3.2.2.1.1 If it is registered, the Notify service shall be failed.

R1-3.2.2.1.2 If it is not registered, then create the carrier object. The initial states of the object are Carrier ID Not Read, Carrier Slot Map Not Read, Carrier Not Processed and Not Associated.

R1-3.3 *Carrier ID Read*



R1-3.3.1 *Carrier ID Read Event*

R1-3.3.1.1 If carrier ID has been read successfully then ID DETERMINATION (ID DET) is executed.

R1-3.3.1.2 If carrier ID has been failed to be read and the port is not associated with any object;

R1-3.3.1.2.1 Report the host the event to inform Carrier ID read fail when the loadport has no Bind.

R1-3.3.1.2.2 If the host requests ProceedWithCarrier service, then create the object and associate it with the loadport. Carrier ID state shall be changed to Carrier ID Verification OK.

R1-3.3.1.2.3 If the host requests CancelCarrierservice, then create the object and associate it with the loadport. Carrier ID state shall be changed to Carrier ID Verification Fail. Take the carrier to Ready to Unload.

R1-3.3.1.2.4 If the host requests CancelCarrierAtPort service, no objet is created. Take the carrier to Ready to Unload.

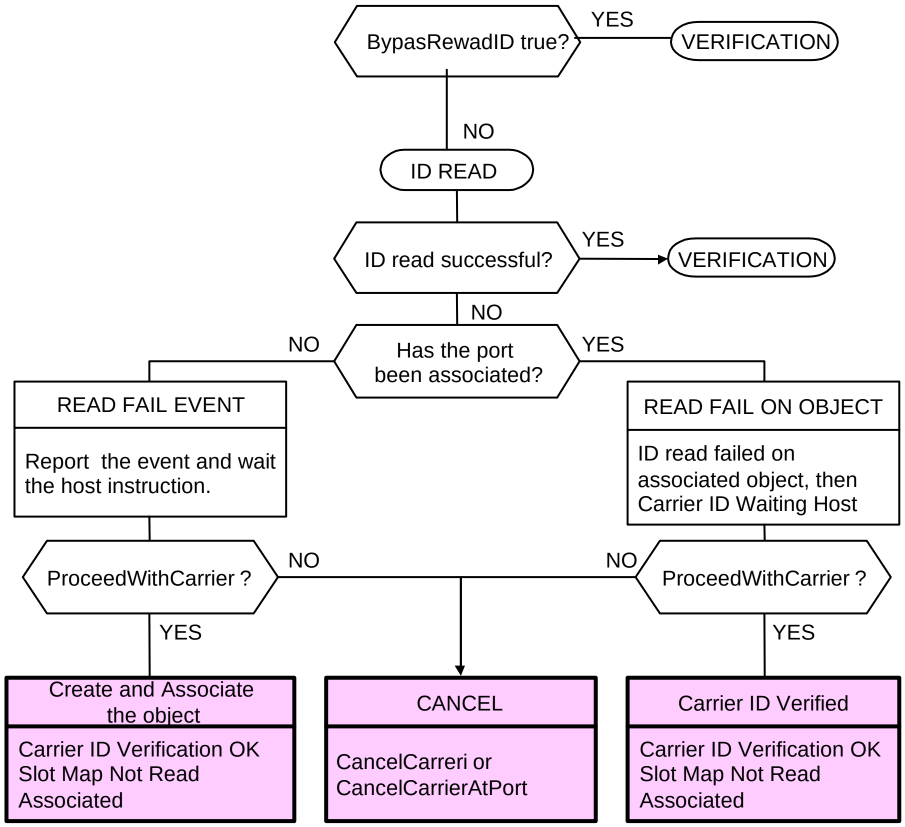
R1-3.3.1.3 If carrier ID has been failed to be read and the port is associated with any object;

R1-3.3.1.3.1 Change the Carrier ID status of the associated object to Waiting for Host. The event shall be reported to indicate carrier ID read for associated object has been failed.

R1-3.3.1.3.2 If the host requests ProceedWithCarrier service, then change the Carrie ID status of the associated object to Carrier ID Verification OK.

R1-3.3.1.3.3 If the host requests CancelCarrier service, then change the Carrie ID status of the associated object to Carrier ID Verification Fail. Take the carrier to Ready to Unload.

R1-3.4 *BypassReadID*



R1-3.4.1 *BypassReadID*

R1-3.4.1.1 If Bind has been received, then decision should be made if ID read is necessary.

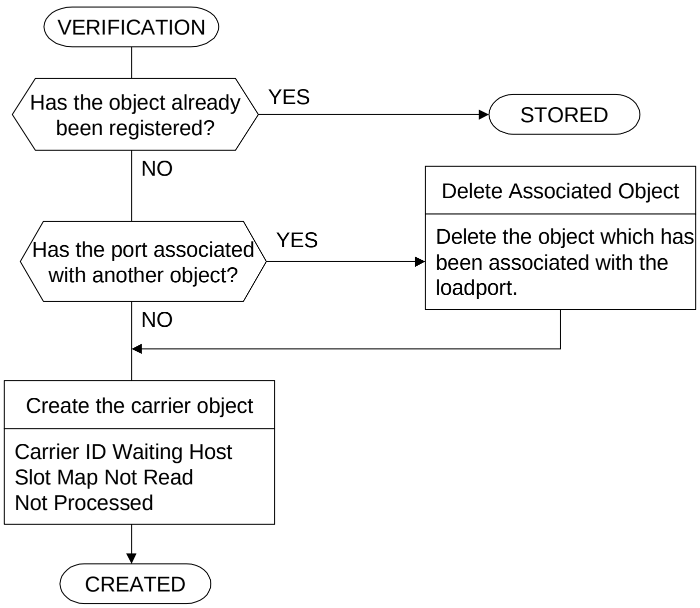
R1-3.4.1.2 If BypassReadID is equal to True

R1-3.4.1.2.1 No ID read is required and carrier object enters ID Verification OK state

R1-3.4.1.3 If BypassReadID is equal to False

R1-3.4.1.3.1 ID Read is required

R1-3.5 *Carrier Object Verification*



R1-3.5.1 If the object having the ID read from the carrier has been registered, then STORED object logic shall be executed.

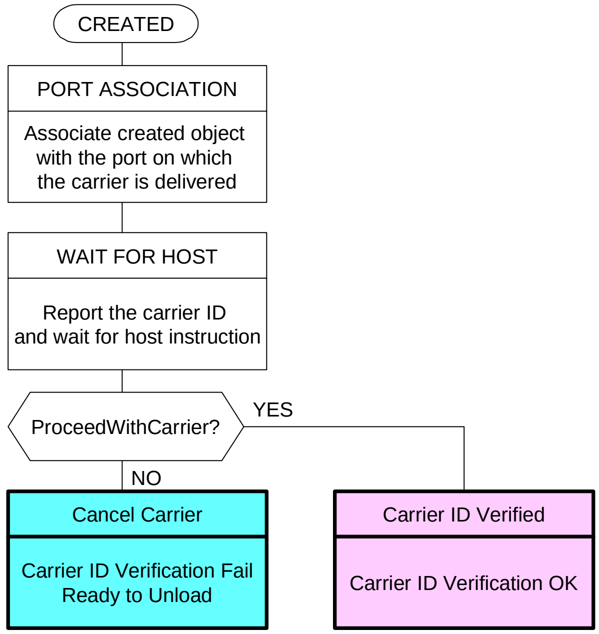
R1-3.5.2 If no object having the ID read from the carrier has been registered;

R1-3.5.2.1 Create the object.

R1-3.5.2.2 If an object has been associated with the loadport on which the carrier is delivered, the event means the carrier delivered is not expected by the associated object. That is Carrier ID verification fail. Then, delete the asoociated object.

R1-3.5.2.3 CREATED logic shall be executed.

R1-3.6 *CREATED*



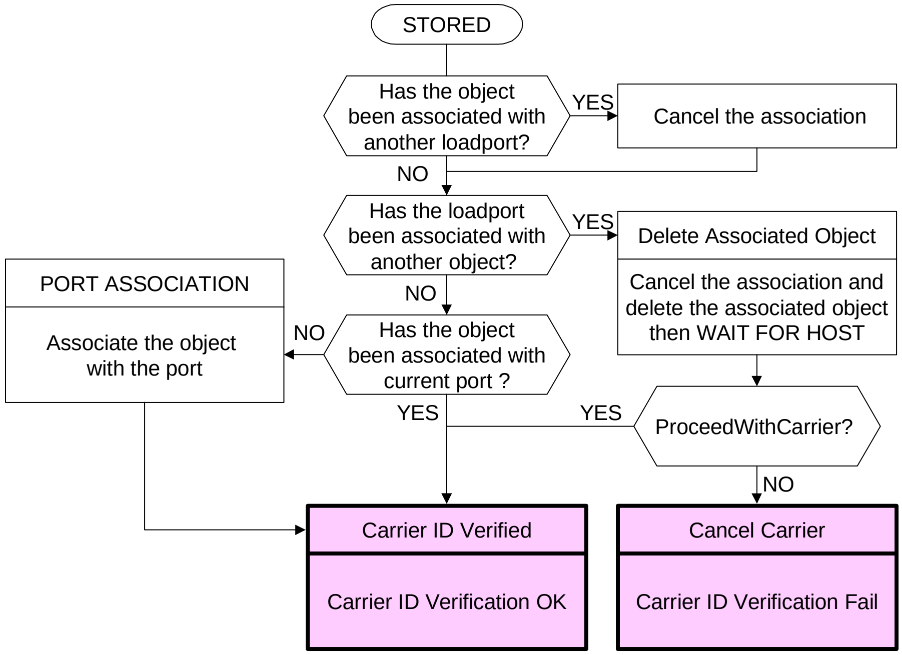
R1-3.6.1 Associate the object just created with the loadport on which the carrier is delivered.

R1-3.6.2 Report the carrier ID and wait for host instruction.

R1-3.6.3 If the host requests ProceedWithCarrier service, change the Carrier ID Status to Carrier ID Verification OK.

R1-3.6.4 If the host requests CancelCarrier service, change the Carrier ID Status to Carrier ID Verification Fail. The carrier shall be taken to Ready to Unload.

R1-3.7 *STORED*



R1-3.7.1 If the object has been already associated with the loadport other than the carrier is delivered;

R1-3.7.1.1 This is the case for misloading to a wrong loadport.

R1-3.7.1.2 Cancel the association.

R1-3.7.2 And If the loadport on which the carrier has been delivered is associated to another object, then delete the object associated with the port on which the carrier is delivered.

R1-3.7.2.1 This is the case for equipment base ID VERIFICATION FAIL.

R1-3.7.2.2 Associate the object with the loadport on which the carrier has been delivered.

R1-3.7.2.3 Then enter WAITING FOR HOST.

R1-3.7.2.4 If ProceedWithCarrier is given, then the carrier is verified.

R1-3.7.2.5 If CancelCarrier is given, then the carrier verification is failed.

R1-3.7.3 If the object has been associated with the loadport on which the carrier is delivered, the carrier is verified. Change the Carrier ID status to Carrier ID Verified.

R1-3.7.4 If no object has been associated with the loadport on which the carrier is delivered, associate the object with the loadport. This is the case for associating object created by Notify.

SEMI E87.1-0702
PROVISIONAL SPECIFICATION FOR SECS-II PROTOCOL FOR CARRIER MANAGEMENT (CMS)

This provisional specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on April 30 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published February 2000; previously published March 2002.

1 Purpose

1.1 This document maps the services and data of SEMI E87 to SECS-II streams and functions, and data definitions.

2 Scope

2.1 This is a provisional specification covering equipment supporting automated access to load ports from the host point-of-view. The provisional status is required because of the immaturity of implementations of integrated equipment with AMHS, and additional specifications may yet be defined. Also, further exception handling and error recovery scenarios need to be defined.

2.2 This document applies to all implementations of SEMI E87 that use the SECS-II message protocol (SEMI E5). Compliance to this standard requires compliance to both SEMI E87 and SEMI E5.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification applies to semiconductor equipment with SEMI E15.1 compliant load ports. It may also be applied to other manufacturing equipment that supports automated carrier transfer and or contains an internal buffer.

3.2 This is a provisional specification. The following areas must be completed before the provisional status is removed:

1) Any additional services, or changes to existing services, in Carrier Management must be mapped to SECS-II messages.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI 15.1 — Provisional Specification for 300 mm Tool Load Port

SEMI E39.1 — SECS-II Protocol for Object Services Standard (OSS)

SEMI E87 — Specification for Carrier Management (CMS)

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Services Mapping

5.1 This section shows the specific SECS-II streams and functions that shall be used for SECS-II implementation of the services defined in SEMI E87, as well as the parameter mapping for data attached to services.

5.2 *Services Message Mapping*

5.2.1 Table 1 defines the relationships between SEMI E87 services and SECS-II messages.

Table 1 Services Message Mapping Table

Service Name	*Stream, Function*	*SECS-II Message Name*
Bind	S3,F17/18	Carrier Action Request/Acknowledge
CancelBind	S3,F17/18	Carrier Action Request/Acknowledge
CancelAllCarrierOut	S3,F19/20	Cancel All Carrier Out Request/Acknowledge
CancelCarrier	S3,F17/18	Carrier Action Request/Acknowledge
CancelCarrierAtPort	S3,F17/18	Carrier Action Request/Acknowledge
CancelCarrierNotification	S3,F17/18	Carrier Action Request/Acknowledge
CancelCarrierOut	S3,F17/18	Carrier Action Request/Acknowledge
CancelReservationAtPort	S3,F25/26	Port Action Request/Acknowledge
CarrierIn	S3,F17/18	Carrier Action Request/Acknowledge
CarrierNotification	S3,F17/18	Carrier Action Request/Acknowledge
CarrierOut	S3,F17/18	Carrier Action Request/Acknowledge
CarrierReCreate	S3,F17/18	CarrierReCreate Rquest/Acknowledge
CarrierRelease	S3,F17/18	Carrier Action Request/Acknowledge
CarrierTagReadData	S3,F29/30	Carrier Tag Read Data Request/Acknowledge
CarrierTagWriteData	S3,F31/32	Carrier Tag Write Data Request/Acknowledge

ChangeServiceStatus	S3,F25/26	Port Action Request/Acknowledge
ProceedWithCarrier	S3,F17/18	Carrier Action Request/Acknowledge
ReserveAtPort	S3,F25/26	Port Action Request/Acknowledge

5.3 *Services Parameter Mapping*

5.3.1 Table 2 maps the SEMI E87 service parameters to SECS-II Data Items.

NOTE 2: Use of parameters not specified for a given message in SEMI E87 is prohibited. SECS-II data items not used for a given message shall be sent as zero-length items.

Table 2 Service Parameters to SECS-II Data Items Mapping

Parameter Name	*Range*	*SECS-II Data Item*
AccessMode	Enumerated: MANUAL, AUTO	PORTACCESS
AttributeData	Any	CATTRDATA
AttributeID	Text format restrictions per SEMI E39.1, Section 6.	CATTRID
CarrierID	1 to 80 characters	CARRIERID
CMAcknowledge	Enumerated	CAACK
CMStatus	Structure	L,2 1. <CAACK> 2. Status
Data	ASCII (20)	DATA
DataLength	Integer (Un or Sn)	DATALENGTH
DataSeg	ASCII (20)	DATASEG
ErrorCode	Enumerated	ERRCODE
ErrorText	1 to 80 characters	ERRTEXT
LocationID	ASCII (20)	LOCID
PropertiesList	Non-identifier properties	L,n 1. L,2 1. <CATTRID$_1$> 2. <CATTRDATA$_1$>

Parameter Name	*Range*	*SECS-II Data Item*
		. . n. L,2 1.< CATTRID $_n$> 2. <CATTRDATA $_n$>
PortID	U1 (1–255)	PTN
ServiceStatus	Enumerated: IN SERVICE, OUT OF SERVICE	U1 0 = OUT OF SERVICE 1 = IN SERVICE
Status	n errors	L,n 1. L,2 1. <ERRCODE$_1$> 2. < ERRTEXT $_1$> . . n. 1.< ERRCODE $_n$> 2. <ERRTEXT $_n$>

5.4 *SECS-II Data Items Without Corresponding SEMI E87 Parameters*

5.4.1 Table 3 contains the SECS-II data items that do not correspond to SEMI E87's service parameter.

Table 3 Additional Data Item Requirements Table

Function	*SECS-II Data Item*
Used by S3,F17 to differentiate between Bind, CancelCarrierOut, CancelCarrierAtPort, CancelBind, CarrierIn, ProceedWithCarrier, CancelCarrierNotification CarrierNotification services, and CarrierReCreate.	CARRIERACTION
Used to satisfy SECS-II conventions for linking a multi-block inquiry with a subsequent multi-block message. Neither required nor specified by CMS.	DATAID
Used to inform receiver of total message length size for SECS-II multi-block conventions. May also be used to indicate the length of a section of data being transmitted to or from a carrier tag.	DATALENGTH
Used to satisfy SECS-II multi-block requirements. Neither required nor specified by SEMI E87.	GRANT
Used by S3,F25 to differentiate between port related, CancelReservationAtPort, and ReserveAtPort services.	PORTACTION
Used by S3F27 to specify desired Port Access Mode.	ACCESSMODE

6 Variable Data Item Mapping

6.1 This section shows the specific SECS-II data classes, and formats needed for SECS-II implementations of SEMI E87 variable data items.

Table 4 Variable Data Item Mapping Table

Variable Name	*Class*	*Format*
AccessMode	DVVAL	51 (U1) Enumerated: 0 = MANUAL 1 = AUTO
AccessMode$_i$	SV	51 (U1) Enumerated: 0 = MANUAL 1 = AUTO

Variable Name	*Class*	*Format*
PortStateInfo$_i$	SV	L,2 1. <PortAssociationState$_i$> 2. <PortTransferState$_i$>
PortStateInfoList	SV	L,n 1. <PortStateInfo$_1$> . n. <PortStateInfo$_n$>
PortTransferState	DVVAL	51 (U1) Enumerated as: 0 = OUT OF SERVICE 1 = TRANSFER BLOCKED 2 = READY TO LOAD 3 = READY TO UNLOAD
PortTransferState$_i$	SV	51 (U1) Enumerated as: 0 = OUT OF SERVICE 1 = TRANSFER BLOCKED 2 = READY TO LOAD 3 = READY TO UNLOAD
PortTransferStateList	SV	L,n 1. <PortTransferState$_1$> . . n. <PortTransferState$_n$>
Reason	DVVAL	51 (U1) Enumerated as: 0 = VERIFICATION NEEDED 1 = VERIFICATION BY EQUIPMENT UNSUCCESSFUL 2 = READ FAIL 3 = IMPROPER SUBSTRATE POSITION
SlotMapStatus	DVVAL	51 (U1) Enumerated as: 0 = SLOT MAP NOT READ 1 = [SLOT] WAITING FOR HOST 2 = SLOT MAP VERIFICATION OK 3 = SLOT MAP VERIFICATION FAILED
SlotMap	DVVAL	L, n n= capacity (1...25) 1. Enumerated 2. Enumerated 3. . . n Each as 51 (U1) Enumerated as: 0 = UNDEFINED 1 = EMPTY 2 = NOT EMPTY 3 = CORRECTLY OCCUPIED 4 = DOUBLE SLOTTED 5 = CROSS SLOTTED
UnAllocatedPartitionCapacity	DVVAL	51
UnAllocatedPartitionCapacity$_i$	SV	51

7 SECS-II Attribute Definitions

7.1 *Carrier Object SECS-II Attributes Definitions*

7.1.1 The following are the SECS-II structure definitions for the E87 Carrier Object.

Table 5 Carrier Object Attribute Definitions

Attribute Name	*Attribute Data Form: SECS-II Structure*
"ObjType"	1. "Carrier"
"ObjID"	1. <CARRIERID> (Conforms to the restrictions of ObjID as specified in SEMI E39.1, Section 6.)
"Capacity"	51 (U1) Capacity Capacity Range: 1..25 Capacity Examples: 1, 13, 25
"CarrierAccessingStatus"	51 (U1) CarrierAccessingStatus CarrierAccessingStatus enumerated per Variable CarrierAccessingStatus
"CarrierIDStatus"	51 (U1) CarrierIDStatus CarrierIDStatus enumerated per Variable CarrierIDStatus
"ContentMap"	L, n n=Capacity 1. L,2 1. 20 (A) LotID 2. 20 (A) SubstID … n. L,2 1. 20 (A) LotID 2. 20 (A) SubstID SubstID conform to the restrictions of ObjID as specified in SEMI E39.1, Section 6.
"LocationID"	20 (A) LocationID LocationID conforms to the restrictions of ObjID as specified in SEMI E39.1, Section 6.
"SlotMap"	L, n n=Capacity 1. 51 (U1) enumerated … n. 51 (U1) enumerated enumerated per variable SlotMap
"SlotMapStatus"	51 (U1) SlotMapStatus SlotMapStatus enumerated per Variable SlotMapStatus.
"SubstrateCount"	51 (U1) SubstrateCount SubstrateCount Range: 0..25 SubstrateCount Examples: 1, 3, 21, 25
"Usage"	20 (A) Usage Usage is equipment defined, examples: "TEST", "DUMMY", "PRODUCT"

SEMI E88-0702
SPECIFICATION FOR AMHS STORAGE SEM (STOCKER SEM)

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published September 1999; previously published March 2002.

1 Purpose

1.1 This standard establishes a Specific Equipment Model (SEM) for AMHS storage equipment (Stocker SEM). The model consists of equipment characteristics and behaviors that are to be implemented in addition to the SEMI E30 fundamental requirements and selected additional capabilities. The intent of this standard is to facilitate the integration of Stocker SEM equipment into an automated (e.g., semiconductor fabrication and flat panel display) factory. This document accomplishes this by defining an operational model for Stocker SEM equipment as viewed by a factory automation controller (Host). This definition provides a standard host interface and equipment operational behavior (e.g., control, state models, and data reports). Several topics require additional activity that are within the scope of this standard: queuing, parallel interface for carrier transfer (SEMI E23), stocker controller architecture, and scheduling and transport of the transfer unit.

2 Scope

2.1 The scope of this standard is limited to the usage and description of AMHS storage equipment (Stockers) as perceived by a SEMI Equipment Communications Standard 2 (SECS-II) host that complies with the GEM model (as specified in Section 13). It defines the view of the equipment through the SECS communication link. It does not define the internal operation of the equipment. It includes a specific transfer command state model and stocker controller state model as the basis for all equipment of this class.

2.2 This document assumes that the GEM fundamental requirements and selected additional capabilities (as specified in Section 13) have been implemented on the Stocker SEM equipment. It expands the GEM standard requirements and capabilities in the areas of state models (stocker controller, transfer command, carrier and stocker crane state models), collection events, alarm documentation, remote commands, data item variables, and material movement.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 *SEMI Standards Alignment*

3.1.1 The GEM (SEMI E30) model was used as the basis for Stocker SEM requirements definition in alignment with existing AMHS SEM Specifications.

3.2 *AMHS Storage Equipment Description*

3.2.1 This standard is targeted at the different types/configurations of 300 mm AMHS storage equipment. The term Stocker SEM equipment refers to all the types of AMHS storage equipment. The equipment types may have fundamental mechanical differences.

3.2.2 *Stocker (configuration)*

3.2.2.1 Generally an AMHS automated storage and retrieval device used to provide temporary storage of carriers. The device is not required to provide temporary storage of carriers when used as a device to connect multiple IBSEM devices or as a lifter (Floor to Floor Transport). Additionally, any number of physical interfaces may exist to connect the stocker with external devices such as: Interbay and/or Intrabay Transport Systems, Process Equipment, other StockerSEM devices, Operator ports, etc.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AMHS* — Automated Material Handling System

5.1.2 *BP* — Buffer Port

5.1.3 *FOUP* — Front Opening Unified Pod

5.1.4 *GEM* — Generic Equipment Model

5.1.5 *IBSEM* — InterBay/IntraBay Specific Equipment Model

5.1.6 *ITS* — Interbay or Intrabay Transport System

5.1.7 *LP* — Loading Port

5.1.8 *OP* — Output Port

5.1.9 *PGV* — Person Guided Vehicle

5.1.10 *SC* — Stocker Controller

5.1.11 *TCP/IP* — Transmission Control Protocol/Internet Protocol

5.1.12 *TSC* — Transport System Controller

5.2 *Definitions*

5.2.1 *Automated Material Handling System* — an automated system to store and transport materials within the factory.

5.2.2 *automation* — the capability of managing material and data within the factory.

5.2.3 *bidirectional load port* — a load port used for loading and unloading carriers.

5.2.4 *buffer* — a set of one or more locations for holding carriers at the production equipment.

5.2.5 *buffer port* — special buffer port location on a stocker output shuttle. Contains carrier presence sensors so that the host can be notified when a carrier is situated at this position.

5.2.6 *carrier* — a container with one or more fixed positions for holding substrates. Examples of carriers include FOUPs and open cassettes.

5.2.7 *carrier ID* — a readable and unique identifier for the carrier.

5.2.8 *FOUP*—a closed carrier for holding wafers.

5.2.9 *host* — the factory computer system, or an intermediate system, that represents the factory and the user to the equipment. Refers system that controls or supervises the Stocker Controller (SC) throughout this document.

5.2.10 *independent port* — a load port on the stocker that is dedicated to input or output. It is considered that the carriers can only be transferred in one direction.

5.2.11 *interbay transport system* — a transport system used to move work-in-process between stockers in different parts of the factory.

5.2.12 *Intrabay Transport System* — a transport system dedicated to one or more bays in the factory and responsible for transferring carriers to and from production equipment. ITS consists of the physical units of the system (e.g., vehicles, nodes, docking stations), the low-level unit controllers, and a system-level controller. ITS excludes factory floor storage systems (stockers), but includes any short-term storage integral to the system, such as storage locations within an overhead track system that are accessible only to units of the particular ITS.

5.2.13 *load port* — the interface location on the equipment where carriers are transferred.

5.2.14 *loading port* — user or vehicle accessible port location on a stocker output shuttle. Contains carrier presence sensors so that the host can be notified when a carrier is situated at this position.

5.2.15 *output port* — stocker crane accessible port location on a stocker output shuttle. Contains carrier presence sensors so that the host can be notified when a carrier is situated at this position.

5.2.16 *process equipment* — equipment used to make semiconductor devices. This excludes metrology and material handling equipment.

5.2.17 *production equipment* — equipment used to produce semiconductor devices, including wafer sorting, process, and metrology equipment and excluding material handling equipment.

5.2.18 *Stocker Controller* — stocker Equipment Controller that communicates with the host and represents the system as the equipment.

5.2.19 *stocker crane* — stocker transfer agent specialized for the movement of carriers between shelves and input and output port locations.

1 Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.htt

5.2.20 *stocker equipment* — an individual stocker viewed as a single piece of equipment, with distributed components and distributed control, as illustrated in Figure 1. The stocker controller communicates with the host using HSMS and GEM and represents the system as an equipment. The factory may require more than one type of stocker.

5.2.20.1 Communications with transport system equipment may require a low-level handshake with a transport unit directly involved in the transfer of material (such as a vehicle or a docking station on an overhead track).

5.2.20.2 Communications between the various stocker units and controllers are proprietary to the supplier.

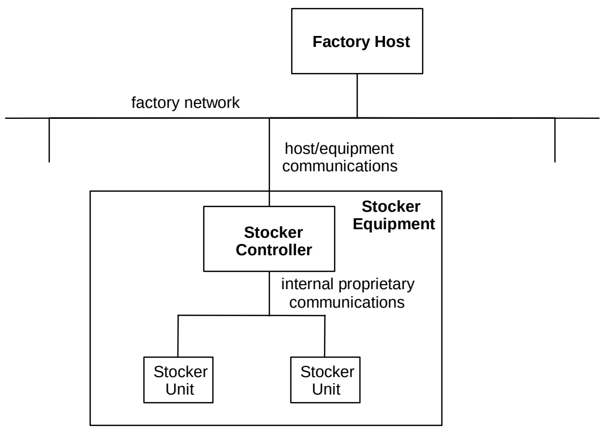

Figure 1
Example of Stocker Equipment

5.2.21 *stocker shelf* — locations within the stocker equipment to store carriers. These locations exclude load ports.

5.2.22 *stocker unit* — a physical component of the stocker system, such as a stocker crane, ID reader, wafer sensor, shuttle port, etc.

5.2.23 *swapping port* — a load port on the stocker capable of handling single load and unload of carriers or simultaneous replace of carriers.

5.2.24 *transfer agent* — a component of equipment specialized to the movement of transfer objects from place to place within a factory. May be of different types with widely-differing characteristics. Examples are fixed-arm robots, robot arms on fixed tracks, overhead gantries or even systems containing a heterogeneous collection of other transfer agents. Humans may also act as transfer agents.

5.2.25 *transfer completed port* — the destination port specified in a transfer command.

5.2.26 *transfer port* — point on the transport system at which a change of equipment ownership of the carrier occurs.

5.2.27 *transfer unit* — the element of movement (assemblage of carriers) of the ITS that consists of a maximum number of carriers allowed in a specific transfer command:

- AA is the maximum number of carriers allowed for acquire at the transfer source.
- BB is the maximum number of carriers allowed for deposit at the transfer destination.
- CC is the maximum number of carriers allowed for transfer in one transport vehicle.

5.2.27.1 The maximum size of the transfer unit is the minimum of AA, BB, and CC.

5.2.27.2 For purposes of the Stocker SEM, the transfer unit is limited to one carrier.

5.2.28 *transport system* — the component of AMHS that moves material from one part of the factory to another.

5.2.29 *transport unit* — a physical component of a transport system, such as a vehicle, node, or docking unit.

5.2.30 *zone* — a logical assignment referencing a set of one or more locations. A stocker can have several logical zone assignments. For example, a specific stocker may have 2 zones defined as LEFT_ZONE and RIGHT_ZONE. The assignment of zones is specific to the Stocker SEM equipment supplier and it may be desirable for the supplier to remain flexible in the assignment of zones so that it could be configured to meet the specific requirements of different users. A specific zone may only contain shelf locations or ports, but not both.

6 Overview and Assumptions

NOTE 2: This section has been included as background information to help clarify requirements.

6.1 *Destination Control (to Shelf or to Output Port)*

6.1.1 The destination is controlled by Host when the carrier is input to the stocker (i.e., the carrier enters the stocker domain). The destination of the transfer command is required. It would be invalid for the Host to issue a transfer command to the SC without including a valid destination.

6.1.2 *Output to the Interbay Output Port*

6.1.2.1 The destination for a transfer command to move a carrier to an interbay output port must be a loading port. It is the responsibility of the Host to ensure that sufficient capacity exists in the destination stocker when delivering from a source stocker to a destination stocker (i.e., an interbay move). For example, it would be the responsibility of the Host to check the remaining capacity of the destination stocker prior to issuing the transfer command to send the carrier to the interbay output port of the source stocker.

6.1.3 *Output to the Intrabay Output Port*

6.1.3.1 The destination for a transfer command to move a carrier to an intrabay output port must be a loading port.

6.1.4 *Store to the Stocker Shelf*

6.1.4.1 The specific stocker shelf location is to be controlled by the Stocker Controller (SC). The Host does not specify a shelf ID in a transfer command. The Host sends the name of a zone as the destination in the transfer command

6.1.4.2 The carrier is stored to a stocker shelf temporarily when the Host requested output port destination is occupied. This is the responsibility of the Stocker Controller. The carrier count of the stocker is incremented due to this temporary storage (i.e., the current capacity decreases).

6.2 *Quantity Control in the Stocker (Capacity Planning)*

6.2.1 The number of carriers in the stocker is controlled by the Host. A list of carrier database entries in the specified stocker's SC database will be available to the Host upon request via a remote command.

6.3 *Number of Stocker Cranes*

6.3.1 No Limitation. Host does not control the stocker crane directly.

6.4 *Port Type*

6.4.1 The independent input port and the independent output port are required for the Stocker SEM. The swapping type is considered as an independent port.

6.5 *Plural Sets of Input/Output Ports*

6.5.1 Plural sets of Input/Output ports connected to the interbay or intrabay transport system must be considered. (This would be considered a Multi-loop type interface connection to the stocker.) Examples of plural sets of interfaces are as follows:

- Main Loop/Sub Loop,
- Right-handed rotation/Left-handed rotation, and
- Double Track (i.e., Stacked Track).

6.6 *Carrier ID Reader*

- Manual Input Port: Carrier ID Reader is mandatory.
- Automated Input Port: Carrier ID Reader is a customer option.
- Carrier ID Reader at any output port: Carrier ID Reader is a customer option.

6.6.1 The intrabay automated input port is sometimes used as the manual Input Port. If one port is used for both an automated and a manual, the Carrier ID Reader is mandatory for this port. If there is a Carrier ID Reader, the scenario for a stocker transfer without a Carrier ID Reader is not applicable.

6.7 *Tag*

6.7.1 Same assumptions as Carrier ID Reader.

6.8 *Carrier Exchanger/Gas Purger*

6.8.1 Out of scope of Stocker SEM.

6.9 *Robot Arm in the Passive Type Stocker*

6.9.1 No assumption is made regarding the passive type stocker.

6.10 *Empty or Not Empty Carriers*

6.10.1 No assumption is made regarding empty and not empty carriers.

6.11 *Monitor/Dummy*

6.11.1 No assumption.

6.12 *Operation Mode*

6.12.1 No assumption.

6.13 *Transfer Completed Port*

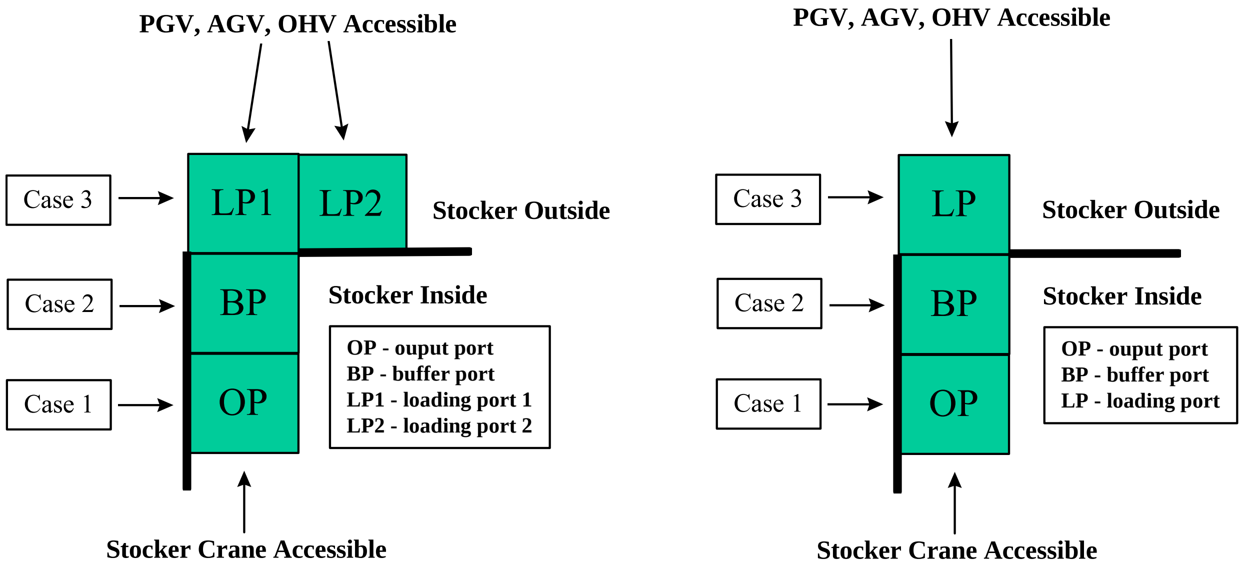

Figure 2
Output Shuttle Examples: L-Shaped Shuttle on Left, I-Shaped Shuttle on Right

6.13.1 The Transfer Completed Port is always the LoadingPort (LP) specified in the transfer command. If the end user desires that the Host issue a transfer to the TSC prior to the carrier arriving at the LP, the states defined in the Stocker Carrier State Model may be utilized.

7 Communication Requirements

7.1 It is required that any Stocker SEM compliant equipment follow the Communications State Model in SEMI E30. In addition, Stocker SEM compliant equipment shall support either SEMI E37 and SEMI E37.1 or SEMI E4.

8 State Models

8.1 *State Model Requirements*

8.1.1 The state models included in this standard are a requirement for Stocker SEM equipment. This standard requires implementation of all SEMI E30 state models (such as control, communication, on-line/off-line, etc. according to the GEM capabilities required per Section 13). A state model consists of a state model diagram, state definitions, and a state transition table. All state transitions in this standard, unless otherwise specified, shall correspond to collection events.

8.1.2 A state model is the host's view of the equipment, and does not necessarily describe the internal equipment operation. All Stocker SEM state model transitions shall be mapped sequentially into the appropriate internal equipment events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the Stocker SEM state model for transition to another state. The equipment makes the required transition without any additional actions in this situation.

8.1.3 Some equipment may need to include additional substates other than those in this standard. Additional substates may be added, but shall not change the Stocker SEM defined state transitions. All expected transitions between Stocker SEM states shall occur.

8.2 *SC State Model*

8.2.1 *SC State Model Requirements*

8.2.1.1 The purpose of the SC state model is to provide information to the host regarding the overall status of the stocker system. The SC state model is valid when the SEMI E30 (GEM) state is ON-LINE. The SC state model is **not** valid when the SEMI E30 (GEM) state is OFF-LINE. Since a stocker may consist of many components (e.g., stocker crane, conveyor, ID reader, etc.), it may be possible to continue ON-LINE operation when the operation mode of some stocker components (as viewed by the SC) is a manual state. The details of what happens when individual components of the stocker enter a manual state are specific to the Stocker SEM equipment supplier. When the SEMI E30 Control state changes from OFF-LINE to ON-LINE, the SC State Model is started from the SC INIT state.

8.2.2 *SC State Model*

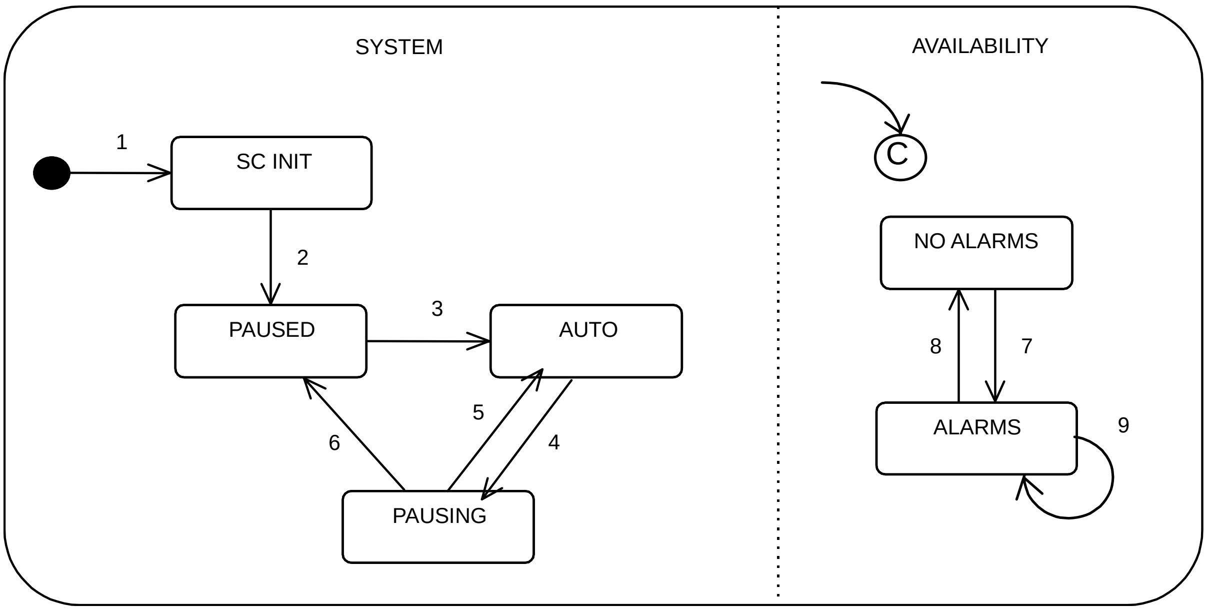

Figure 3
Generic Stocker SEM SC State Model Diagram

8.2.3 *SC State Definitions*

8.2.3.1 SC INIT — SC initialization of stocker components is occurring. This is a non-operational state. No commands from the host will be acknowledged, queued or processed. The system will not move out of this state if there are carriers moving on any of the stocker units controlled by the SC. Such devices must be manually or automatically recovered before transitioning to the next state.

8.2.3.2 PAUSING — A system PAUSE command has been received and is being processed. All carriers that are currently moving will continue until complete. Carriers that are currently moving may continue to move but they must not begin another movement. TRANSFER commands are accepted and queued. All status requests will be processed. The RESUME, INSTALL, REMOVE, and LOCATE commands will also be processed.

8.2.3.3 PAUSED — No carriers are in the process of moving on any of the stocker units controlled by the SC. TRANSFER commands are accepted and queued. All status requests will be processed. The RESUME, INSTALL, REMOVE, and LOCATE commands will also be processed.

8.2.3.4 AUTO — Stocker is in the normal operational state. Commands are actively processed.

8.2.3.5 NO ALARMS — There are no alarms present in the system.

8.2.3.6 ALARMS — There are one or more alarms present in the system.

8.2.4 *SC State Transition Table*

Table 1 SC State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	none	SC Initiation	SC INIT	S6F11 SCAutoInitiated	System runs through its startup sequence.
2	SC INIT	System started up successfully. All carrier movement stopped.	PAUSED	S6F11 SCPaused	System ready.
3	PAUSED	RESUME command	AUTO	S6F11 SCAutoCompleted	System will now execute remote commands.
4	AUTO	PAUSE command	PAUSING	S6F11 SCPauseInitiated	Carriers that are not moving remain there. Carriers that are moving must stop at the next logical stopping point.
5	PAUSING	All carrier movement has completed.	PAUSED	S6F11 SCPauseCompleted	System will accept and queue new commands but will not execute them. No new movement will occur. Outstanding moves/commands will remain NOT ACTIVE.
6	PAUSING	RESUME command	AUTO	S6F11 SCAutoCompleted	System will now execute remote commands.
7	NO ALARMS	Alarm Set	ALARMS	S6F11 AlarmSet	
8	ALARMS	All Alarms cleared.	NO ALARMS	S6F11 AlarmCleared	
9	ALARMS	Alarm Set	ALARMS	S6F11 AlarmSet	Alarm occurs when there is already an outstanding alarm.

8.3 *TRANSFER Command State Model*

8.3.1 *TRANSFER Command State Model Requirements*

8.3.1.1 The TRANSFER command state model serves as the SEMI E30 Processing State Model. The purpose of the TRANSFER command state model is to provide information to the host regarding the control of the TRANSFER command. The TRANSFER command allows the host to manage carrier movement and scheduling. The control of each TRANSFER command must independently support the TRANSFER command state model.

8.3.2 *TRANSFER Command State Model Diagram*

8.3.2.1 The TRANSFER command state model is detailed for Stocker SEM equipment in Figure 4.

8.3.3 *TRANSFER Command State Definitions*

8.3.3.1 QUEUED — SC has acknowledged and queued the TRANSFER command. TRANSFER command has not been initiated.

8.3.3.2 ACTIVE — The carrier is involved in the physical aspect of the TRANSFER command. It is denoted by the time spanned by command initiation to command completion.

8.3.3.3 TRANSFERRING (ACTIVE sub-state) — The transfer command is actively being executed by the stocker.

8.3.3.4 PAUSED (ACTIVE sub-state) — The Transfer command is not actively being executed by the stocker. This may be due to an internal equipment error that does not immediately terminate the Transfer command unsuccessfully. This would allow the Host or Operator the opportunity to retry the transfer.

8.3.3.5 CANCELING — The TRANSFER command cancel procedure is being performed to terminate a transfer command which never entered the ACTIVE state (currently QUEUED). This state is entered via a CANCEL remote command.

8.3.3.6 ABORTING — The TRANSFER command abort procedure is being performed to terminate a transfer command which has entered the ACTIVE state. This state can only be entered via an ABORT remote command. An unsuccessful transfer command completion will ultimately result from this state.

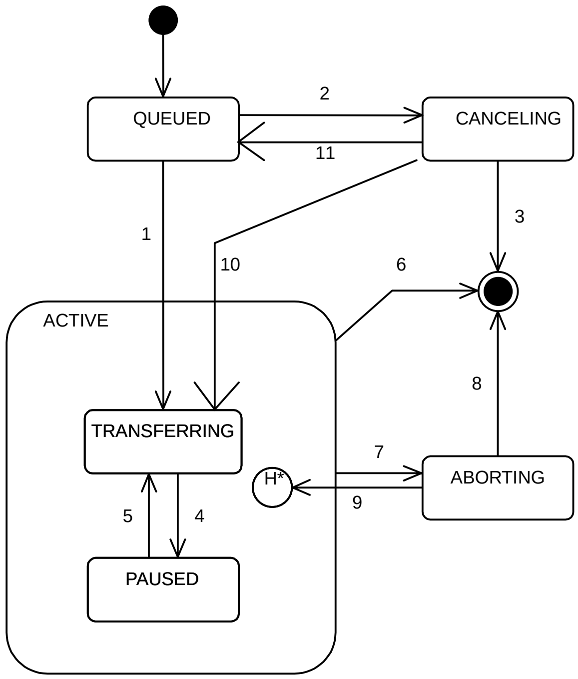

Figure 4
Generic Stocker SEM TRANSFER Command State Model Diagram

8.3.4 *TRANSFER Command State Transition Table*

Table 2 Transfer Command State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	QUEUED	The TRANSFER command has been initiated by the SC.	TRANSFER-RING	S6F11 TransferInitiated	
2	QUEUED	Host sends CANCEL command for a specified TRANSFER command to SC.	CANCELING	S6F11 TransferCancel-Initiated	TRANSFER command is to be removed from the TRANSFER command queue.
3	CANCELING	The cancel procedure for the TRANSFER command has completed by the stocker and the SC.	None	S6F11 TransferCancel-Completed	The carrier will still be situated at the transfer source location. The carrier may now be included in a future transfer.
4	TRANSFER-RING	The SC pauses execution of the TRANSFER command due to an anomaly condition.	PAUSED	S6F11 TransferPaused for a specific CommandID	It is an important distinction to make that the TRANSFER command is paused and not just the transfer agent. The Stocker Controller state will be ALARM.

Tran-sition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
5	PAUSED	The SC resumes execution of the TRANSFER command since the anomaly condition has been cleared.	TRANSFER-RING	S6F11 TransferResumed for a specific CommandID	If this was the only remaining stocker alarm, the Stocker Controller state will transition to NO ALARMS.
6	ACTIVE	The TRANSFER command has completed by the stocker and SC (either successfully or unsuccessfully).	None	S6F11 TransferComplete d sent to Host with appropriate ResultCode ResultCode = 0 if successful ResultCode is nonzero if unsuccessful	Carrier(s) could be located at any location or port located along the path of the transfer, if the TRANSFER command completed unsuccessfully. **Supplier Option** — The location of the carrier(s) associated with an unsuccessful transfer command must be a legal SourcePort for a new TRANSFER command.
7	ACTIVE	Host sends ABORT command for a specified TRANSFER command to SC.	ABORTING	S6F11 TransferAbort-Initiated	
8	ABORTING	The abort procedure for the TRANSFER command has completed by the stocker and SC.	None	S6F11 TransferAbort-Completed	Carrier could be located at any location or port located along the path of the ACTIVE transfer. **Supplier Option** — The location of the carrier associated with the aborted transfer command must be a legal SourcePort for issuing a new TRANSFER command.
9	ABORTING	TRANSFER command cannot be aborted.	ACTIVE	S6F11 TransferAbort-Failed	TRANSFER command could not be aborted due to the physical state of the equipment. Such conditions must be documented by the Stocker SEM equipment Supplier.
10	CANCELING	Transport system is unable to cancel the TRANSFER command because the transfer is now ACTIVE.	TRANSFER-RING	S6F11 TransferInitiated	
11	CANCELING	Transport system is unable to cancel the TRANSFER command and it is still queued.	QUEUED	S6F11 TransferCancel-Failed	

8.4 *Stocker Carrier State Model*

8.4.1 *Stocker Carrier State Model Requirements*

8.4.1.1 The purpose of the stocker carrier state model is to provide information to the host regarding carrier tracking (the Host will not control carriers) while the carrier is in the domain of the stocker. The carrier is in the domain of the stocker when it is in storage or transport internal to the stocker or on a stocker interface port (manual, interbay, or intrabay). The equipment shall track each carrier in compliance with the Stocker Carrier State Model.

8.4.2 *Stocker Carrier State Model*

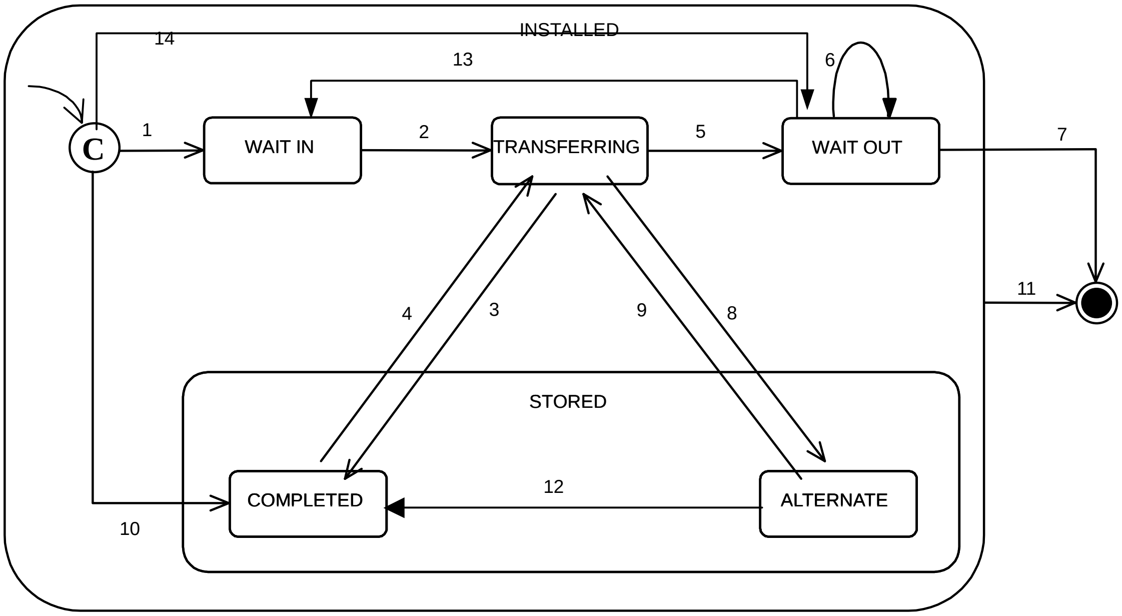

Figure 5
Generic Stocker SEM Carrier State Model Diagram

8.4.3 *Stocker Carrier State Definitions*

8.4.3.1 INSTALLED — Carrier in stocker database.

8.4.3.2 WAIT IN (INSTALLED sub-state) — Carrier at an internal input location in the stocker ready to be moved to a storage or output location.

8.4.3.3 WAIT OUT (INSTALLED sub-state) — Carrier is at an Output, Buffer, or Loading Port.

8.4.3.4 TRANSFERRING (INSTALLED sub-state) — Carrier moving between locations in the stocker.

8.4.3.5 STORED (INSTALLED sub-state) — Carrier is sitting at a storage location.

8.4.3.6 COMPLETED (STORED sub-state) — The carrier is stored at a shelf location as a result of completing a transfer for which this shelf represents the destination of the transfer command.

8.4.3.7 ALTERNATE (STORED sub-state) — The carrier is temporarily stored at a shelf location. The transfer command completion is pending until the destination becomes available.

8.4.4 *Stocker Carrier State Transition Table*

Table 3 Stocker Carrier State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Action*	*Comments*
1	none	Carrier is registered into stocker.	WAIT IN	S6F11 CarrierWaitIn	
2	WAIT IN	Stocker is executing a TRANSFER command for the carrier.	TRANSFER-RING	S6F11 Carrier-Transferring	

Transition #	*Previous State*	*Trigger*	*New State*	*Action*	*Comments*
3	TRANSFER-RING	Completion of a TRANSFER command with a DEST of internal stocker storage.	COMPLETED	S6F11 CarrierStored	Carrier is at an internal storage destination.
4	COMPLETED	Stocker is executing a TRANSFER command for the carrier.	TRANSFER-RING	S6F11 Carrier-Transferring	
5	TRANSFER-RING	Carrier has arrived at the output port.	WAIT OUT	S6F11 CarrierWaitOut	
6	WAIT OUT	Carrier has advanced (automatically) on a port beyond the output port.	WAIT OUT	S6F11 CarrierWaitOut	
7	WAIT OUT	Carrier is removed from the stocker domain (removed from the output LP).	None	S6F11 CarrierRemoved	
8	TRANSFER-RING	The destination of the move command is occupied.	ALTERNATE	S6F11 CarrierStoredAlt	SC is waiting for the Destination to become available.
9	ALTERNATE	The port becomes available and transfer command is first in queue.	TRANSFER-RING	S6F11 CarrierResumed	Carrier continues with move to the Destination.
10	None	Carrier entry is created or modified in the SC database.	COMPLETED	S6F11 CarrierInstall-Completed	Could be due to an INSTALL remote command.
11	INSTALLED	Carrier entry is removed from the SC database.	None	S6F11 CarrierRemove-Completed	Could be due to a REMOVE remote command.
12	ALTERNATE	Transfer command is Aborted	COMPLETED	S6F11 CarrierStored	
13	WAIT OUT	Carrier on a bi-directional port is ready to be moved to a storage or output location.	WAIT IN	S6F11 CarrierWaitIn	Examples of a trigger could be the operator pressing a button or the host issuing a transfer command for the carrier.
14	None	The result of ID read at an output port that did not match the expected ID.	WAITOUT	S6F11 CarrierInstall-Completed	

8.5 *Stocker Crane State Model*

8.5.1 *Stocker Crane State Model Requirements*

8.5.1.1 The purpose of the stocker crane state model is to provide information to the host for use of stocker crane information and metric tracking (i.e., the Host will not control the stocker crane). If it is possible for the stocker to continue operation while the stocker crane is not operational then the Stocker Crane State Model will retain its current state and the SC State Model will be ALARM. When the stocker crane becomes operational again, the state of the Stocker Crane State Model will transition to the new state. Whether it is possible to continue operation while the stocker crane is not operational is specific to the stocker SEM equipment supplier. If a single stocker contains multiple stocker cranes, each stocker crane must comply with the stocker crane state model. The Host should not be dependent on any events from the stocker crane state model.

8.5.2 *Stocker Crane State Model*

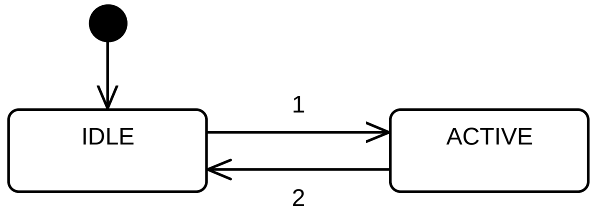

Figure 6
Generic Stocker SEM Stocker Crane State Model Diagram

8.5.3 *Stocker Crane State Definitions*

8.5.3.1 IDLE — The stocker crane is not performing Host or SC initiated work.

8.5.3.2 ACTIVE — The stocker crane is busy performing Host or SC initiated work.

8.5.4 *Stocker Crane State Transition Table*

Table 4 Stocker Crane State Transition Table

Transi-tion #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	IDLE	Crane is requested to perform host or SC initiated work.	ACTIVE	S6F11 CraneActive	
2	ACTIVE	Crane completes host or SC initiated work.	IDLE	S6F11 CraneIdle	

8.6 *Port Transfer State Model*

8.6.1 *Port Transfer State Model Requirements*

8.6.1.1 The purpose of the port state model is to provided information to the host for the use in accessing ports. This may permit the host and stocker to utilize ports that are in service while avoiding the use of ports that are not in service.

8.6.2 *Port Transfer State Model*

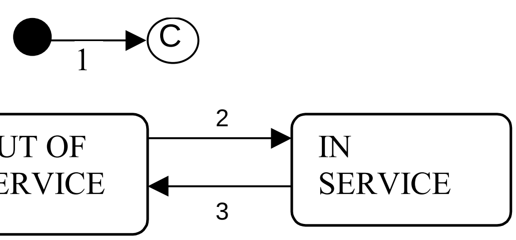

Figure 7
Port State Model Diagram

8.6.3 *Port Transfer State Definitions*

8.6.3.1 OUT OF SERVICE — Transfer to/from this port is disabled and the port should not be used in any Transfer command issued by the host. If a command is issued by the host which uses this port, it will not be rejected simply because the port is in this state.

8.6.3.2 IN SERVICE — Transfer to/from this port is enabled.

8.6.3.3 *Port Transfer State Transition Table*

Table 5 Port Transfer State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Action*	*Comments*
1	None	System reset.	OUT OF SERVICE Or IN SERVICE	S6F11 PortOutOfService Or S6F11 PortInService	The new state is based on the current status of the port or the state prior to system reset.
2	OUT OF SERVICE	The equipment has determined that the port can be utilized for transfers.	IN SERVICE	S6F11 PortInService	
3	IN SERVICE	The equipment has determined that the port should not be used for transfers.	OUT OF SERVICE	S6F11 PortOutOfService	This could be the result of an alarm condition.

9 Collection Event List

9.1 This section identifies data collection events and defines (Stream 6) reporting levels for variable data items. The host can use the report definition scenario defined in SEMI E30 to define reports at Stocker SEM defined levels. The intent of this section is to demonstrate that certain suggested data is available at specific events. The collection events are grouped according to whether or not they are associated with a state change (according to the state models defined within this document).

9.2 *Requirements*

9.2.1 This standard requires all collection events listed in the SEMI E30 standard (according to the GEM capabilities required per Section 14). There are cases where specific collection event names are designated for GEM defined collection events. Such collection event names are denoted by “Y” in the GEM column.

9.3 *State Transition Collection Event Table*

Table 6 State Transition Collection Event Table

Collection Event Name	*From State*	*To State*	*Required DVVAL’s*	*GEM*

9.4 *Non-Transition Collection Event Table*

Table 7 Non-Transition Collection Event Table

Collection Event Name	*Event Description*	*Required DVVAL's or Reports*
CarrierIDRead	A carrier identification has been performed by the stocker system. It was deemed unnecessary to represent this simple event with a state model. This event is always sent to the Host immediately following the actual ID read by the stocker.	CarrierID CarrierLoc IDReadStatus
CarrierLocateCompleted	A LOCATE remote command has completed.	CarrierLocations
IDReadError	All carriers related to an ID error situation have been dispositioned. This event occurs automatically when the stocker places the carrier that experienced the ID error to the pickup port (See Section 13.3.3).	CarrierID CarrierLoc IDReadStatus

Collection Event Name	*Event Description*	*Required DVVAL's or Reports*
OperatorInitiatedAction	The operator initiated an action from the Stocker Controller.	CommandID CommandType CarrierID Source Dest Priority

10 Variable Data Items

10.1 The purpose of this section is to define the list of variable data item requirements for Stocker SEM equipment. Values of these variables will be available to the host via collection event reports and host status queries.

10.2 *Requirements*

- All variable data items and data item restrictions defined in SEMI E30 are required on Stocker SEM equipment (according to the GEM capabilities required per Section 13).
- All variable data items in the Stocker SEM Variable Data Item Dictionary for specific equipment classifications are required for Stocker SEM equipment. The data item restrictions are also required.
- Some SV's in the Variable Data Item Dictionary are referenced by an "i" subscript (e.g., $CarrierID_i$). The "i" subscript denotes a specific instance of the SV. This is necessary since there is usually more than one instance of such an SV active in the system at the same time (e.g., if there are 20 carriers active at the same time then "i" could range from 1 to 20 for $CarrierID_i$). Variable Data Items containing the "i" subscript should not have Variable ID's assigned to them.

10.2.1 Variable data items are documented in the Stocker SEM Variable Data Item Dictionary using the following format:

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*

Where:

Variable Name: A unique name for the variable data item.

Type: CV – meaning common variables, variables that are general to all vehicles.

CSV – meaning configuration specific variables.

Description: If class is DVVAL, then the description shall contain a statement of when data is valid in terms of Stocker SEM events.

Class: The data type of the item.

Format: <SECS Message Language (SML) mnemonic>acceptable formats are SEMI E5 lists, ASCII, floating point, unsigned integer or signed integer. A description of "ANY", indicates that only the above formats are acceptable and is left to the supplier to decide.

Comments: Any additional information pertinent to the variable name.

10.3 *Variable Data Item Types*

10.3.1 *Equipment Constants (ECV)* — The value can be changed by the host using S2F15. The operator may have the ability to change some or all of the values. The value of an equipment constant may be queried at any time by the host using the S2F13/14 transaction or Stream 6 reports.

10.3.2 *Status Variables (SV)* — The values are valid at all times. A SV may not be changed by the host or operator, but may be changed by the equipment. A host or operator command may change an equipment status thus changing a SV. The value of status variables may be queried by the host at any time using the S1F3/4 or Stream 6 reports.

10.3.3 *Data Variables (DVVAL)* — These are variables which are valid upon the occurrence of a specific collection event, and may or may not be valid at other times depending upon the equipment. An attempt to read a variable data item when it's invalid will not result in an error, but the data reported may not have relevant meaning.

10.3.4 *Variable Data (V)* — This is a class of variable data which includes all the previously defined types of variables.

10.4 *Variable Data Item Dictionary*

Table 8 Variable Data Item Dictionary

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*
ActiveCarriers	CV	List current status of all carrier information in the SC database.	SV	L,n 1. <$CarrierInfo_1$> . . n. <$CarrierInfo_n$>	
ActiveTransfers	CV	List current status of all ACTIVE TRANSFER commands.	SV	L,n 1. <$TransferCommand_1$> . . n. <$TransferCommand_n$>	
ActiveZones	CV	List current status associated with all zones being used by the SC.	SV	L,n 1. <$ZoneData_1$> . . n. <$ZoneData_n$>	
CarrierID	CV	Unique ID of the carrier.	DVVAL	A[1–64]	If an Id is created by the equipment (not obtained via an id reader, the host interface, or the user interface) it must be of the following format: UNKNOWNEqpNameSeq Where: UNKNOWN are the exact characters “UNKNOWN” EqpName is the value of the EqpName ECV (truncated if required) Seq is a unique sequence identifier determined by the vendor.
$CarrierID_i$	CV	Unique ID of the carrier.	SV	A[1–64]	See comment for CarrierID.
CarrierInfo	CV	All database information associated with a particular carrier.	DVVAL	L,2 1. <CarrierID> 2. <CarrierLoc>	
$CarrierInfo_i$	CV	All database information associated with a particular carrier.	SV	L,2 1. <$CarrierID_i$> 2. <$CarrierLoc_i$>	
CarrierLoc	CV	Unique location of the carrier within the stocker as reported by the SC.	DVVAL	A[1–64]	It is important to note that this is the unique location within the stocker (i.e., 2 carriers cannot be stored at the same CarrierLoc, but 2 carriers can be stored at the same ZoneName).

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*
CarrierLoc$_i$	CV	Unique location of the carrier within the stocker as reported by the SC.	SV	A[1–64]	It is important to note that this is the unique location within the stocker (i.e., 2 carriers cannot be stored at the same CarrierLoc, but 2 carriers can be stored at the same ZoneName).
CarrierLocationInfo$_i$	CV	Carrier Location Information	DVVAL	L,3 1. <CarrierID$_i$> 2. <CarrierLoc$_i$> 3. <CarrierZoneName$_i$>	
CarrierLocations	CV	Carrier Location Information for the 'LOCATE' host command	DVVAL	L,n 1. <CarrierLocationInfo$_1$> . . n. < CarrierLocationInfo$_n$ >	'n' number of carriers
CarrierState$_i$	CV	The Carrier State	SV	U2	1 = Wait In 2 = Transferring 3 = Completed 4 = Alternate 5 = Wait Out
CarrierZoneName	CV	The name of the zone associated with the carrier's current location.	DVVAL	A[0–64]	A location may not be associated with a particular zone. This would be the case if ports are not assigned to a zone.
CarrierZoneName$_i$	CV	The name of the zone associated with the carrier's current location.	SV	A[0–64]	A location may not be associated with a particular zone. This would be the case if ports are not assigned to a zone.
CommandName	CV	Name of Host issued remote command.	DVVAL	A[1–20]	
CommandID	CV	Remote Command ID	DVVAL	A[1–64]	Used to subsequently refer to a specified remote command (e.g., to cancel a remote command). If a command is generated by the Stocker Controller, the commandid must begin with the string 'MANUAL' followed by any arbitrary sequence identifier.
CommandID$_i$	CV	Remote Command ID	SV	A[1–64]	Used to subsequently refer to a specified remote command (e.g., to cancel a remote command).
CommandInfo	CV	Command information associated with a particular transfer command.	DVVAL	L,2 1. <CommandID> 2. <Priority>	
CommandInfo$_i$	CV	Command information associated with a particular transfer command.	SV	L,2 1. <CommandID$_i$> 2. <Priority$_i$>	
CommandType	CV	The type of Command being initiated	DVVAL	A[1–20]	Valid Values are 'TRANSFER' 'CANCEL' 'ABORT'

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*
CurrentPortStates	CV	Current State of all the ports	SV	L,n 1. <$PortInfo_1$> . . n. <$PortInfo_n$>	
Dest	CV	Destination location identifier.	DVVAL	A[1–64]	Can either be a CarrierLoc or a ZoneName.
$Dest_i$	CV	Destination location identifier.	SV	A[1–64]	Can either be a CarrierLoc or a ZoneName.
EmptyCarrier	CV	Flag which denotes whether the carrier is empty or not empty.	DVVAL	U2	Empty = 0 Not Empty = 1
EnhancedCarriers	CV	List Current status of all carrier information in the SC database.	SV	L,n 1. <$EnhancedCarrierInfo_1$> . . n. <$EnhancedCarrierInfo_n$>	
$EnhancedCarrierInfo_i$	CV	All database information associated with a particular carrier.	SV	L,5 1. <$CarrierID_i$> 2. <$CarrierLoc_i$> 3. <$CarrierZoneName_i$> 4. <$InstallTime_i$> 5. <$CarrierState_i$>	
EnhancedTransfers	CV	List current status of all transfer commands.	SV	L,n 1. <$EnhancedTransferCommand_1$> . . n. <$EnhancedTransferCommand_n$>	
EnhancedTransfer-$Command_i$	CV	Information associated with a particular Transfer command.	SV	L,3 1. <$TransferState_i$> 2. <$CommandInfo_i$> 3. <$TransferInfo_i$>	
EnhancedActive-Zones	CV	List current status associated with all zoned being used by the SC.	SV	L,n 1. <$EnhancedZoneData_1$> . n. <$EnhancedZoneData_n$>	
$EnhancedZoneData_i$	CV	Information associated with a particular zone.	SV	L,4 1. <$ZoneName_i$> 2. <$ZoneCapacity_i$> 3. <$ZoneSize_i$> 4. <$ZoneType_i$>	
EqpName	CV	Unique ID of the SC	ECV	A[1–32]	

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*
ErrorID	CV	Unique ID of an error	DVVAL	A[1–64]	Used to subsequently refer to a specified stocker error (e.g., to RETRY a stocker operation). The following values are required: "DestOcuupied" – Double Store "SourceEmpty" – Empty Retrieve Other values may be used as required.
HandoffType	CV	Denotes the type of handoff that occurred at the equipment ownership transfer point (e.g., from loading port to vehicle).	DVVAL	U2	MANUAL = 1 means that no handoff handshake occurs (e.g., PGV handoff). AUTOMATED = 2 means that a handshake occurs (e.g., SEMI E84).
IDReadDuplicate-Option	CV	Indicates manner in which Duplicate ID reads must be processed.	ECV	U1	0=Reject 1=HostControlled See Carrier ID Error Scenarios (Table 14) for detailed information.
IDReadFailureOption	CV	Indicates manner in which IDRead Failures must be processed.	ECV	U1	0=Reject 1=HostControlled See Carrier ID Error Scenarios (Table 14) for detailed information.
IDReadMismatch-Option	CV	Indicated manner in which Mismatch ID reads must be processed	ECV	U1	0=Reject 1=HostControlled See Carrier ID error Scenarios (Table 14) for detailed information.
IDReadStatus	CV	Result Code of an ID read event.	DVVAL	U2	Success = 0 Failure = 1 Duplicate = 2 Mismatch = 3
$InstallTime_i$	CV	Time the carrier was created in the SC database.	SV	TIME (A16)	yyyymmddhhmmsscc
PortID	CV	ID of the port	DVVAL	A[1–64]	
$PortID_i$	CV	ID of the port	SV	A[1–64]	
$PortInfo_i$	CV	Port information associated with a particular port.	SV	L,2 1. <$PortID_i$> 2. <$PortTransferState_i$>	
$PortTransferState_i$	CV	Port Transfer State	SV	U2	1 – OutOfService 2 – InService
PortType	CV	Definition of the type of port associated with the carrier's current location.	DVVAL	A[1–32]	"OP" = output port "BP" = buffer port "LP" = loading port
Priority	CV	Remote command priority	DVVAL	U2	0 is not valid. 1 is the LOWEST priority, 99 is the highest priority.

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*
$Priority_i$	CV	Remote command priority	SV	U2	0 is not valid. 1 is the LOWEST priority, 99 is the highest priority.
RecoveryOptions (Supplier Option)	CV	List of options that the Host may use to try to recover a specific stocker error.	DVVAL	A[1–64] blank RETRY ABORT	This variable will enumerate the possible Host command responses to the error associated with the event. If blank, Host cannot do anything.
ResultCode	CV	Result Code of a stocker system command. Associated with the command completion event.	DVVAL	U2	Values of ResultCode will correspond to meaningful completion results (0 always signifies normal successful completion). The following Result Codes are required: 0=Success 1=Other Error 2=Shelf Zone is FULL 3=Duplicate ID 4=Mismatch ID
SCState	CV	SC State (SYSTEM)	SV	U2	1 = SC Init 2 = Paused 3 = Auto 4 = Pausing
Source	CV	Source location unique identifier.	DVVAL	A[1–64]	
$Source_i$	CV	Source location unique identifier.	SV	A[1–64]	
SpecVersion	CV	Version of SEMI E88 to which the equipment is compliant.	SV	A[0–20]	Example values are: E88-0999, E88-0301. If the equipment is not compliant, a zero length value may be specified.
StockerCraneID	CV	The id of the stocker crane	DVVAL	A[1–64]	Generally only used when there are multiple cranes in a stocker.
StockerUnitID	CV	Unique identification of a stocker unit (e.g., port, transfer agent, etc.).	DVVAL	A[1–32]	
$StockerUnitID_i$	CV	Unique identification of a stocker unit (e.g., port, transfer agent, etc.).	SV	A[1–32]	
StockerUnitInfo	CV	Information associated with a particular stocker unit.	DVVAL	L,2 1. <StockerUnitID> 2. <StockerUnitState>	
$StockerUnitInfo_i$	CV	Information associated with a particular stocker unit.	SV	L,2 1. <$StockerUnitID_i$> 2. <$StockerUnitState_i$>	
StockerUnitState	CV	The state of the stocker unit.	DVVAL	U2	The State of the component will be specific to the stocker configuration.
$StockerUnitState_i$	CV	The state of the stocker unit.	SV	U2	The State of the component will be specific to the stocker configuration.

Variable Name	*Type*	*Description*	*Class*	*Format*	*Comments*
TransferCommand	CV	Information associated with a particular TRANSFER command.	DVVAL	L,2 1. <CommandInfo> 2. <TransferInfo>	
TransferCommand_i	CV	Information associated with a particular TRANSFER command.	SV	L,n 1. <CommandInfo_i> 2. <TransferInfo_i>	
TransferInfo	CV	Carrier information associated with a particular transfer command.	DVVAL	L,3 1. <CarrierID> 2. <CarrierLoc> 3. <Dest>	
TransferInfo_i	CV	Carrier information associated with a particular transfer command.	SV	L,3 1. <CarrierID_i> 2. <CarrierLoc_i> 3. <Dest_i>	
TransferState	CV	State of Transfer Command	SV	U2	1. Queued 2. Transferring 3. Paused 4. Canceling 5. Aborting
ZoneCapacity	CV	Available capacity (in carriers) of a particular zone.	DVVAL	U2	Example: If a stocker zone can store 100 carriers and 25 of the locations are currently occupied, then the ZoneCapacity is 75.
ZoneCapacity_i	CV	Available capacity (in carriers) of a particular zone.	SV	U2	Example: If a stocker zone can store 100 carriers and 25 of the locations are currently occupied, then the ZoneCapacity is 75.
ZoneData	CV	Information associated with a particular zone.	DVVAL	L,2 1. <ZoneName> 2. <ZoneCapacity>	
ZoneData_i	CV	Information associated with a particular zone.	SV	L,2 1. <ZoneName_i> 2. <ZoneCapacity_i>	
ZoneName	CV	Alphanumeric name of a particular zone.	DVVAL	A[1–64]	
ZoneName_i	CV	Alphanumeric name of a particular zone.	SV	A[1–64]	
ZoneSize_i	CV	Size (in carriers) of a particular zone.	SV	U2	The physical size of the zone.
ZoneType_i	CV	Type of the Zone	SV	U2	1: Shelf 2: Port 3: Other

11 Alarm List

11.1 Since each model of Stocker SEM equipment differs in configuration, it is not practical to provide an exhaustive list of all possible alarms. Instead, the Stocker SEM is requiring the two tables provided as described in SEMI E30 (Section 8.4). Alarm List Table which is intended to provide for equipment configuration specific alarms and Alarm ID, Alarm Set/Cleared Event Table. Any alarm that is displayed locally at the equipment, if enabled, is required to be sent to the host. To be compliant, Tables 9 and 10 must be completed by the supplier, documenting all alarms.

11.2 *Alarm List Table*

11.2.1 The alarm list table contains examples of alarms that pertain to various configuration aspects of equipment. These examples are intended to illustrate that alarms pertain to situations in which there exists a potential for exceeding physical safety limits associated with people, equipment, and material being transported as per the SEMI E30 definition of an alarm. See SEMI E30 for further reference. The supplier is responsible for supplying documentation associated with these alarm definitions. Each alarm will have an associated alarm text (ALTX) and alarm identifier (ALID). Table 9 contains an example of alarm list information that is intended to be augmented when the Stocker SEM equipment supplier documents their interface. Examples highlighted by (*) are required by Stocker SEM.

Table 9 Alarm List Table

Equipment Cfg.	*Alarm Text*	*ALID*	*Danger*		*Affected*		
			Potential	*Imminent*	*Operator*	*Equipment*	*Material*
Stocker	stocker unit error*		X			X	X
	handoff error*		X		X	X	X
	database error*		X			X	

11.3 *Alarm ID, Alarm Set/Cleared Event Table*

11.3.1 The Alarm ID, Alarm Set/Cleared Event table documents the association of each ALID to a set and cleared event as required by SEMI E30. See SEMI E30 for further reference. The supplier is responsible for supplying documentation associated with these alarm definitions. Each alarm will have associated alarm set and cleared collection event identifiers ($CEID_{set}$ and $CEID_{clear}$).

Table 10 Alarm ID, Alarm Set/Cleared Event Table

Alarm ID (ALID)	*Alarm SET Event ($CEID_{set}$)*	*Alarm CLEARED Event ($CEID_{cleared}$)*

12 Remote Commands

12.1 The purpose of this section is to identify remote commands, command parameters, and valid commands versus states pertinent to the Stocker SEM.

12.2 *A. Requirements*

- The equipment shall support the SEMI E30 (according to the GEM capabilities required per Section 13) required remote commands.
- All the remote commands defined by Stocker SEM are required to be implemented as specified.
- The alphanumeric strings defined by Stocker SEM for RCMD and CPNAME are required.
- A completed table must be generated where an “X” is placed in the table for each state that a given command is valid.
- If additional remote commands are supported then a “remote commands versus valid states” matrix must be generated for these additional commands.
- For additional commands, a table must be generated similar to the remote command descriptions summary.

12.3 *Remote Commands Description*

12.3.1 ABORT — This command terminates the activity of a specific TRANSFER command based on CommandID while the command is in the ACTIVE state. This command might not be accepted due to mechanical issues if the stocker is in a specific con-dition (e.g., moving a carrier). The exact conditions surrounding when the ABORT command is not ac-cepted by the SC must be documented by the Stocker SEM equipment supplier.

12.3.2 CANCEL — This command terminates the activity of a specific TRANSFER command based on CommandID while the command is in the QUEUED state. This command must always be accepted by the SC when in the QUEUED state.

12.3.3 INSTALL — This is used to update the SC database by adding a specified CarrierID record to a specified CarrierLoc. If the CarrierID specified by the Host is already in the SC database then the additional fields will be updated based on the information contained in this command.

12.3.4 LOCATE — This command is used by the Host to query the SC for database carrier information.

12.3.5 PAUSE — This command puts the SC in the PAUSING state.

12.3.6 REMOVE — This is used to update the SC database by deleting a specified carrier. This command would be used for database recovery.

12.3.7 RESUME — This command puts the SC in the AUTO state.

12.3.8 RETRY (Supplier Option) — This command may be used by the Host when an error is encountered by the stocker. The Host would use this command to allow the stocker to retry the movement which gener-ated the error condition.

12.3.9 TRANSFER — This is a SECS-II Enhanced Remote Command instead of a SECS-II Host Command Send (S2,F49 instead of S2,F41). See the examples in Section 15.1 for details.

12.3.10 This command is used to perform the entire transfer command for the carrier to be transferred between stocker locations. The execution of this com-mand will include allocation of resources, acquiring the carrier, moving the carrier to the destination, queuing the carrier at an alternate destination (if needed), depositing the carrier, and returning the resources for other use. The number of carriers in the TRANSFER command is always equal to one (i.e., the size of the transfer unit is always equal to one carrier).

12.3.11 *Remote Commands and Associated Host Command Parameters*

12.3.11.1 This table describes the allowable command parameters (CPNAME) for each remote command (RCMD). Equipment shall support all parameters. The column marked Req/Opt, specifies which parameters are required to be sent by the host and which parameters may be optionally sent by the host.

Table 11 Allowable Command Parameters

Remote Command	*Parameters*		
	Cpname	*Req/Opt*	*Comment*
ABORT	"COMMANDID"	R	Must specify the commandID that was used for the TRANSFER command that is being ABORT'ed.
CANCEL	"COMMANDID"	R	Must specify the commandID that was used for the TRANSFER command that is being CANCEL'ed.
INSTALL	"CARRIERID" "CARRIERLOC"	R R	

Remote Command	*Parameters*		
	Cpname	*Req/Opt*	*Comment*
LOCATE	"CARRIERID" or "ZONENAME" or "CARRIERLOC"	O	SC will check its database and return the carrier information to the Host with a single 'CarrierLocateCompleted' event for all relevant carriers. If the Host issues the LOCATE command with CARRIERID then SC returns information associated with the carrier specified by the Host. If the Host issues the LOCATE command with ZONENAME or CARRIERLOC, all carrier information in the specified area (ZONENAME or CARRIERLOC) will be returned. If the Host issues the LOCATE command without a Cpname, all carrier information in the SC database will be returned.
PAUSE	None	N/A	Once received by the SC, the SC will queue any TRANSFER commands until the SC receives and successfully executes the RESUME command. Once in the AUTO state the SC will process the TRANSFER commands in its queue.
REMOVE	"CARRIERID"	R	
RESUME	None	N/A	Returns the PAUSEd TSC to the AUTO state.
RETRY Supplier Option	"ERRORID"	R	Since more than one error can occur for the same TRANSFER command, an ERRORID must be used to identify the ERRORID to apply the RETRY to.
TRANSFER	"COMMANDINFO" "TRANSFERINFO"	R R	

12.3.12 *Host Command Parameters Name and Values*

Table 12 Host Command Parameters CPNAMES

Cpname	*Parameter Value*		
	Description	*Range*	*Format*
CARRIERID	Unique ID of the carrier.		A[1–64]
CARRIERLOC	Unique carrier location within the stocker.		A[1–64]
COMMANDID	Unique command identifier created by the Host.		A[1–64]
COMMANDINFO	L,2 COMMANDID PRIORITY		L,2
DEST	Destination location identifier	Must be a valid ZoneName. Must be a loading port for a move to an output shuttle (DEST = LP).	A[1–64]
ERRORID	Unique error identifier created by the stocker.		A[1–64]
PRIORITY	Remote command priority	0 is not valid. 1 is the LOWEST priority, 99 is the highest priority.	U2
SOURCE	Unique source location identifier	Stocker Robot/Crane is a valid SOURCE (Supplier Option).	A[1–64]
TRANSFERINFO	L,3 CARRIERID SOURCE DEST	SOURCE may intentionally be left blank by the Host. If this is true, the stocker must determine the carrier's current location by checking its database for the specified CARRIERID.	L,3

12.3.13 *Remote Commands versus SC, Transfer Command and Stocker Carrier States*

12.3.13.1 The following table indicates SC, TRANSFER Command and Stocker Carrier States where the remote commands are allowed. This is indicated with a “X” mark. Remote commands act independently of other state models (e.g., Stocker Crane States are independent from the Stocker SEM remote commands). “NA” (Not Applicable) means that States and Remote Commands have no direct relationship.

Table 13 Remote Commands versus SC and TRANSFER Command States

	COMMAND								
	TRANSFER	*RETRY*	*RESUME*	*REMOVE*	*PAUSE*	*LOCATE*	*INSTALL*	*CANCEL*	*ABORT*
SC STATE									
AUTO	X	X		X	X	X	X	X	X
ALARMS	X	X	X	X	X	X	X	X	X
SC INIT									
NO ALARMS	X		X	X	X	X	X	X	X
PAUSED	X	X	X	X		X	X	X	X
PAUSING	X	X	X	X		X	X	X	X
TRANSFER COMMAND STATE									
ACTIVE (PAUSED)	NA	X	NA		NA	X			X
ACTIVE (QUEUED AT ALT.)	NA		NA		NA	X			X
ACTIVE (TRANSFERRING)	NA		NA		NA	X			X
ABORTING	NA		NA		NA	X			
CANCELING	NA		NA		NA	X			
QUEUED	NA		NA		NA	X		X	
STOCKER CARRIER STATE									
STORED (ALTERNATE)		NA	NA		NA	X		NA	X
STORED (COMPLETED)	X	NA	NA	X	NA	X	X	NA	
TRANSFERRING		NA	NA		NA	X		NA	NA
WAIT IN	X	NA	NA	X	NA	X	X	NA	NA
WAIT OUT		NA	NA	X	NA	X	X	NA	NA

12.4 *Remote Command Relies*

12.4.1 For a TRANSFER remote command the HCACK in the reply message must return an error 6 (No such Object Exists) if the SOURCE is not specified and the CARRIERID is not in the SC database.

13 Scenarios

13.1 The scenarios that follow represent Application Notes. In the scenarios, all unique Remote CommandID’s must initially be created and sent by the Host. Subsequent event reports sent from the equipment referring to the status of a particular remote command must return the applicable CommandID. All collection events identified in Table 6 are assumed to be enabled (per the SEMI E30 definition/scenario) throughout the following scenarios. Variable data specified in the Host commands has been chosen arbitrarily for the purpose of demonstrating message structure/content. The Collection Event Report definitions contained in the scenarios are examples that could be defined by the host.

13.2 *Normal Operation*

13.2.1 *Carrier Transfer from an Input to a Storage Location (No ID Reader at Input Port)*

13.2.1.1 The carrier is transferred from a stocker input port to a storage location. The SC inserts the carrier into the database based on the CarrierID sent by the Host in the TRANSFER command. This is the scenario when the stocker does not have a carrier ID reader at the input port. A good example of this would be for a interbay transport input port.

STEP	COMMENTS	HOST	SC	COMMENTS
1.	Carrier 123456 enters the domain of the stocker			
2.	Since there is no ID reader, the SC can choose any arbitrary CarrierID to internally track the carrier; However, the SC must send the empty string as the CarrierID to the Host so that the Host can distinguish this condition. It is the Host responsibility to recognize that the empty string "" for the CarrierID denotes that a carrier ID reader does not exist at this input port.		←S6,F11	Event Report Send (ERS) CarrierWaitIn · CarrierID = "" /* Empty String */ · CarrierLoc · CarrierZoneName

13.2.2 *Carrier Transfer from an Input to a Storage Location (ID Reader at Input Port)*

13.2.2.1 The carrier is transferred from a stocker input port to a storage location. The carrier is automatically inserted into the SC database by the SC based on the carrier ID read which occurs on the stocker input port.

STEP	COMMENTS	HOST	SC	COMMENTS

13.2.5 *Carrier Transfer to an Automated Stocker Output with Multiple Loading Ports*

13.2.5.1 Three carriers are requested to the stocker output. The output shuttle consists of multiple carrier positions including the stocker crane set down port (OP – location 03) and two AGV accessible port locations (LP's – locations 05 and 06). The port shuttle also has a BP (location 04) that is the location reached by a carrier before reaching the LP positions. The BP is configured to be the transfer completed port for this scenario. The Host sends the three Transfer commands to the stocker and they are queued. The first two Transfer commands send carriers to LP locations 05 and 06 respectively. These carriers are to be loaded by the same AGV. The third carrier is also requested to LP 05. Each carrier is transferred to the OP where it then automatically travels forward on the shuttle toward the BP and LP's (see figure in Section 6.16). The first two carriers arrive at the LP's. The vehicle removes the two carriers from the LP's. The third carrier then shuttles forward to the LP location 05.

STEP	COMMENTS	HOST	SC	COMMENTS
5.	Event Report Acknowledge (ERA)	S6,F12→		
6.			←S6,F11	Event Report Send (ERS) CarrierTransferring · CarrierID = '123456' · CarrierLoc · CarrierZoneName
7.	Event Report Acknowledge (ERA)	S6,F12→		
			←S6,F11	Event Report Send (ERS) ZoneCapacityChange
	Event Report Acknowledge (ERA)	S6,F12→		
8.			←S6,F11	Event Report Send (ERS) CraneActive
9.	Event Report Acknowledge (ERA)	S6,F12→		
10.				The stocker attempts to place the carrier to the storage location but finds the location to be full.
11.			←S5,F1	Alarm Report Send (ARS) · ALCD(Alarm Set) · ALID · ALTX
12.	Alarm Report Acknowledge (ARA) · ACKC5	S5,F2→		
13.			←S6,F11	Event Report Send (ERS) AlarmSetEvent · CommandID · ErrorID = DestOccupied · StockerDeviceInfo · RecoveryOptions = RETRY, ABORT /* Supplier Option */
14.	Event Report Acknowledge (ERA)	S6,F12→		
15.	Supplier Option The Host may choose to disposition the error as follows: 1. Retry the TRANSFER · The stocker attempts to place the carrier to the dest location again			This is a Supplier Option to implement this Host initiated recovery method.
16.	If the ABORT command is issued by the Host, an unkown carrier is created in the SC database at the physical location responsible for the error. This generates a CarrierInstalledCompleted event for the newly created carrier. The newly created carrier is NOT automatically sent to the LP of the manual output port. The host can issue a new TRANSFER command for the carrier currently on the crane as well as the recently created unkown carrier.			

STEP	COMMENTS	HOST	SC	COMMENTS
17.	If the operator indicates, via the stocker console (supplier option), that the SC should select another shelf location, an unknown carrier is created in the SC database at the physical location responsible for the error. This generates a CarrierInstalledCompleted event for the newly created carrier. The newly created carrier is NOT automatically sent to the LP of the manual output port. The host can issue a new Transfer command for the recently created unknown carrier. The original transfer command for the carrier on the crane completes with success at the other shelf location.			

13.3.3 *Carrier ID Errors*

13.3.3.1 A carrier ID error occurred. See table below for possible Carrier ID errors and resolutions.

Table 14 Carrier ID Error Scenarios at Stocker Ports

ID Error	*Error Description*	*Input Port Action*	*Intrabay Output Port Action**
Failure	ID read fails Examples of reasons for failure are: · Bad bar code reader · Bad bar code label · Obstruction of bar code read · Other	If IDReadFailureOption is 'Reject' Option 1 1. CarrierIDRead event sent 2. Carrier automatically sent to LP of manual output port 3. IDReadError event sent when carrier arrives at LP of manual output port Option 2 - manual input port only 1. CarrierIDRead event sent 2. Stocker automatically sends carrier back to operator accessible location of input port(if necessary) 3. IDReadError event sent Person picks up carrier from input port with the PGV If IDReadFailureOption is 'HostControlled' 1. CarrierIDread event sent 2. CarrierWaitIn event sent with unkown carrier ID 3. Host issues Transfer Command	1. CarrierIDRead event sent 2. Carrier automatically sent to LP of this output port 3. IDReadError event sent when carrier arrives at LP of this output port

ID Error	*Error Description*	*Input Port Action*	*Intrabay Output Port Action**
Duplicate	The carrier ID read results in an ID that matches another entry already in the SC database at a different physical location. Example at Input – Carrier 123 read at ID reader, but there is already a database entry for a carrier with CarrierID 123. Example at Output - Carrier 456 requested to ID reader but CarrierIDRead result is 123, but there is already a database entry for a carrier with CarrierID 123. DuplicateIDs are a subset of unkownIDs with the following format: UNKNOWNDUP-oldid-Seq. Where Seq is a unique sequence identifier.	1. CarrierIDRead event sent for 123 2. If existing carrier 123 has a TransferCommand, send TransferCompleted with 'Duplicate ID' ResultCode. 3. SC automatically Deletes carrier 123 from SC database and sends CarrierRemovedCompleted. 4. SC automatically creates an DuplicateID carrier at shelf location and sends CarrierInstallCompleted event. 5. CarrierWaitIn event for 123 at the port. If IDReadDuplicateOption is 'Reject' EITHER Option 1 6a. Carrier 123 automatically sent to LP of manual output port. 7a. IDReadError event sent for 123 when carrier arrives at LP of manual output port 8a. Host or manual maintenance required to disposition the carrier that SC thought was 123 that is now a Duplicate. OR Option 2 – manual input port only 6b. Stocker automatically sends carrier back to operator accessible location of input port(if necessary) 7b. IDReadError event sent 8b. Person picks up carrier from input port with the PGV 9b. Host or manual maintenance required to disposition the carrier that SC thought was 123 that is now a Duplicate. If IDReadDuplicateOption is 'HostControlled' 6c. Host responsible for sending appropriate Transfer Commands for both carriers.	If IfReadDuplicateOption is 'Reject' or 'HostControlled' and carrier's previous location is a shelf 1. CarrierWaitOut event for 456 2. CarrierIDRead 123 event sent 3. If carrier ID has a TransferCommand, send TransferCompleted with 'Duplicate ID' ResultCode. 4. SC automatically deletes carrier 123 from SC database and sends CarrierRemoveCompleted event. 5. SC automaically creates a DuplicateID carrier at shelf location and sends CarrierInstallCompleted event. 6. SC automatically deletes carrier 456 from SC database and sends CarrierRemoveCompleted event. 7. TransferCompleted for 456 with duplicate ID ResultCode. 8. SC automatically creates an carrier123 at the port location and sends CarrierInstallCompleted event. 9. Carrier continues to LP of this output port. (CarrierWaitOut for 123 at each position) 10. IDReadError event sent when carrier arrives at the LP of this output port 11. Host or manual maintenance required to disposition the carrier that SC thought was 123 (now a duplicate). Note: The TransferCompleted events may come anywhere from step 3 to step 8.

ID Error	*Error Description*	*Input Port Action*	*Intrabay Output Port Action**
Mismatch	The carrier ID read results in an ID that does not match any entries in the SC database. Example - Carrier 456 requested to ID reader but CarrierIDRead result is 123, but there is no SC database entry for a carrier with CarrierID 123.		1. CarrierWaitOut event for 456 2. CarrierIDRead 123 event sent 3. TransferComplete for 456 with mismatch error. 4. SC automatically deletes carrier 456 from SC database and send CarrierRemoveCompleted event. 5. SC automatically creates carrier 123 at the port and sends CarrierInstallCompleted event 6. Carrier continues to LP of this output port. (CarrierWaitOut for 123 at each position) 7. IDReadError event sent when carrier arrives at the LP of this output port. Note: Optionally step 3 may come after step 4 or 5.

13.3.3.2 The following scenario represents a carrier ID *failure* at the stocker *input port* with *option 1* implemented.

STEP	COMMENTS	HOST	SC	COMMENTS
1.	The SC assigns an arbitrary CarrierID based on the failure. An example of such an arbitrary CarrierID would be “FAILURE001” Note: IDReadStatus = 1 means that a Carrier ID Read failure occurred.		←S6,F11	Event Report Send (ERS) CarrierIDRead · CarrierID = “FAILURE001” · PortID · IDReadStatus = 1

8.	Event Report Acknowledge (ERA)	S6,F12→		

13.3.5 *Host Initiated ABORT of a TRANSFER Command*

13.3.5.1 The Host wishes to abort a previously issued transfer command. The assumption is that the carrier is currently in the ALTERNATE substate of STORED.

STEP	COMMENTS	HOST	SC	COMMENTS
1.	Assumption is that a TRANSFER command (CommandID = 111111) is in the ACTIVE state.			
2.	Host Command Send (HCS) ABORT · CARRIERID = "111111"	S2,F41→		
3.			←S2,F42	Host Command Acknowledge (HCA)
4.				The stocker must abort the transfer command if the carrier was in the ALTERNATE sub-state. Other INSTALL stocker carrier states may cause ABORT command rejection. The latter scenario is supplier specific.
5.			←S6,F11	Event Report Send (ERS) TransferAbortInitiated · CommandID = "111111" · CarrierID = "123456" · CarrierLoc = "STOCKER CRANE" · CarrierZoneName
6.	Event Report Acknowledge (ERA)	S6,F12→		
7.			←S6,F11	Event Report Send (ERS) TransferAbortCompleted · CommandID = "111111" · CarrierID = "123456" · CarrierLoc = "STOCKER CRANE" · CarrierZoneName
8.	Event Report Acknowledge (ERA)	S6,F12→		
9.	Event Report Acknowledge (ERA)	S6,F12→		
10.	Two options may be available for recovery: 1. Manual Recovery 2. Host Initiated Recovery The host would have to issue a TRANSFER command to dispose of the carrier on the stocker crane end-effector for the crane to be utilized for future transfers. This is a Supplier Option			

13.3.6 *Connection or Reconnection between SC and Host*

13.3.6.1 The Host System crashes (or loses communication with the SC for a time exceeding all time-outs and retries) and must re-synchronize with the SC with the possibility of several events completing while the communication link was lost.

STEP	COMMENTS	HOST	SC	COMMENTS
1.	Communication session between host and SC (re)established. Host establishes communication with the SC per the GEM standard scenario (e.g., S1F13, etc).

16.	Event Report Acknowledge (ERA)	S6,F12→		
17.				System continues processing all commands that were in process or queued before/during the Host crash or communication loss/initialization. System will also now process new commands.

14 GEM Capabilities

14.1 The purpose of this section is to specify any SEMI E30 additional capabilities that are required to be supported by this class of equipment.

14.2 *Requirement*

14.2.1 This standard requires that the SEMI E30 fundamental requirements and additional capabilities have been implemented on the Stocker SEM equipment with the exception of Trace Data Collection, Process Program Management, Remote Control, Limits Monitoring and Spooling. If these capabilities are implemented, they will be implemented as required by the SEMI E30 document. The Stocker SEM Transfer Command State Model serves as the SEMI E30 Processing State Model. The SEMI E30 additional capabilities required by Stocker SEM are:

- Establish Communications
- Dynamic Event Report Configuration
- Variable Data Collection
- Status Data Collection
- Alarm Management
- Equipment Constants
- Material Movement
- Equipment Terminal Services
- Clock
- Control (host-initiated)

R1-2 *Parallel Interface for Carrier Handoff*

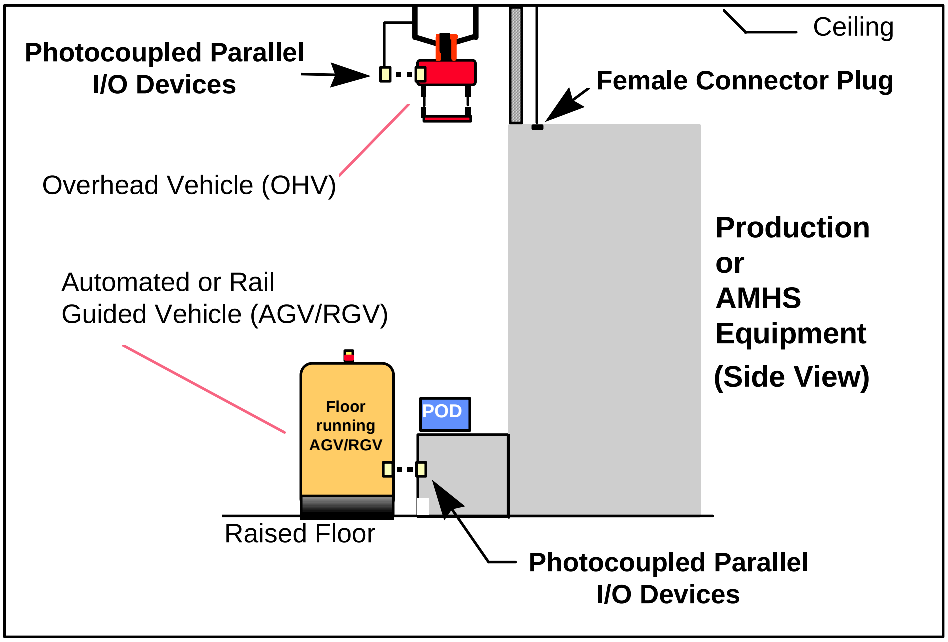

Figure R1-1
Carrier Handoff Example Diagram for OHV/AGV/RGV

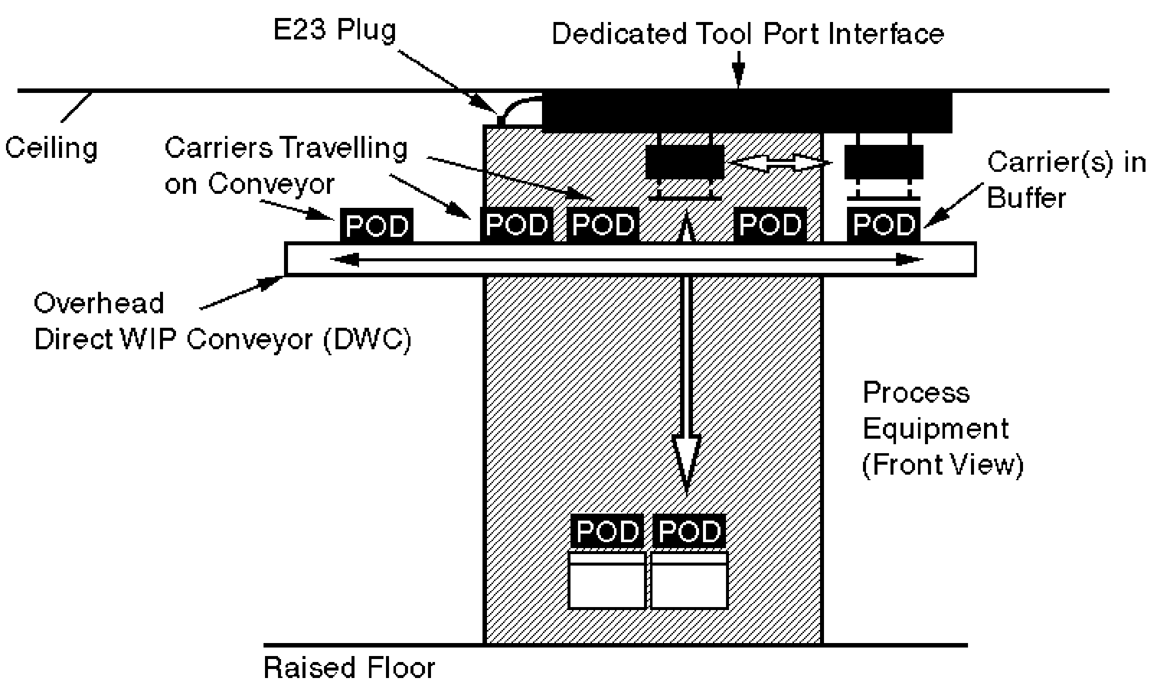

Figure R1-2
Carrier Handoff Example Diagram for DWC

R1-3 *Hardware Architecture*

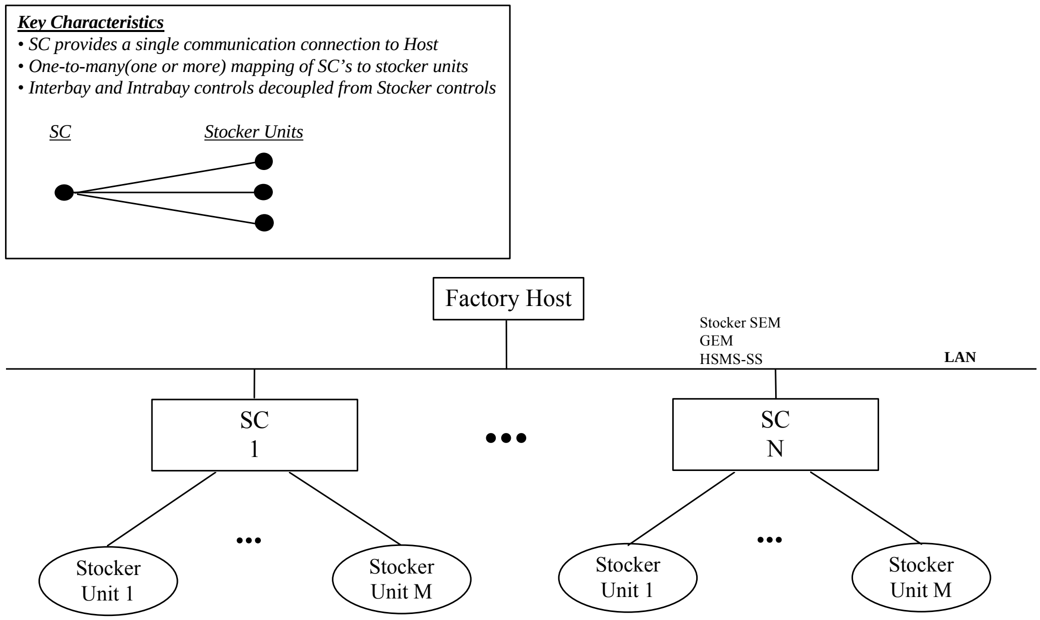

Figure R1-3
SC Architecture (Logical View)

R1-4 *Stocker Command Scheduling Characteristics*

R1-4.1 At a minimum, the SC must offer Priority-based First-In-First-Out (FIFO) queuing of TRANSFER commands. In other words, all TRANSFER commands which have yet to be processed by the SC must be serviced in the order in which they are received by the SC based on the priority given in the host command. The minimum priority levels required to be available on Stocker SEM equipment are “Normal” and “High” (refer to Figure R1-4 for an example). “Normal” and “High” priorities will be denoted by U2 compatible numbers as per the definition of the priority in the Variable Data and Remote Command sections of this document. Other options may be implemented, but to be a Stocker SEM equipment it must at a minimum have the ability to be configured to perform Priority-based FIFO queuing of TRANSFER commands. Additionally, the command priorities are to be utilized during execution of the commands to the following level: any “High” priority command will cause all other commands that are not “High” priority to be usurped. That is to say that all other commands will modify the execution steps to allow the “High” priority commands to be completed in the minimal elapsed time possible. Multiple “High” priority commands will act upon each other according to the same rules as “Normal” commands act on each other.

The following TRANSFER commands are received by the SC in top to bottom order:

TRANSFER Command	Priority
1	Normal
2	Normal
3	High
4	Normal
5	High

Corresponding SC processing queue for outstanding TRANSFER commands :

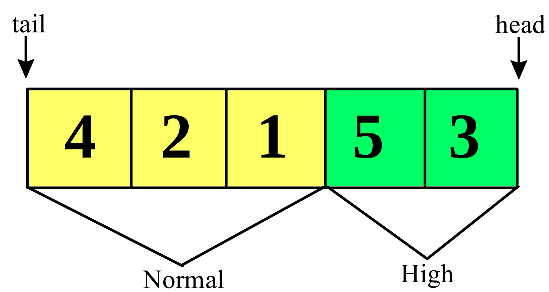

Figure R1-4
SC Priority-Based FIFO TRANSFER Command Processing Example

R1-4.2 The SC must manage the resources so that TRANSFER requests are queued for later service if all resources are currently utilized.

SEMI E90-0702
SPECIFICATION FOR SUBSTRATE TRACKING

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published September 1999; previously published March 2002.

1 Purpose

1.1 The purpose of this standard is to provide the standard services of equipment to track substrates (manufactured product) in manufacturing equipment. This standard defines the concepts and behaviors for the information management of substrates, as well as the messages/services.

2 Scope

2.1 Essentially, information about substrates must be managed by the factory system, while the equipment is required to provide the services for the substrate information management. This standard addresses the requirement for the equipment services to manage information of substrates that reside in the equipment.

2.2 The scope of this standard is to define the information services of equipment that can be requested by the user. To clarify required services, the concepts and behaviors of the substrate and the substrate location are defined.

2.3 This standard is applicable to any manufacturing equipment that handles substrates. To implement these services, the equipment and factory system must be integrated by means of a communication link.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard assumes that the substrate(s) to be managed has been resident in the equipment and has been given a substrate identifier.

3.2 The service for a substrate is valid while the substrate is registered in the equipment. That is, the service is available from the moment that the substrate is registered into the equipment and, to the moment that the substrate is removed from the equipment.

3.3 This standard is only for information services. It does not address any mechanism to read or write information from/to the substrate.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E53 — Event Reporting

SEMI E87 — Specification for Carrier Management (CMS)

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Definitions*

5.1.1 *carrier ID* — the name to identify a specific substrate carrier.

5.1.2 *carrier slot* — physical location capable of holding a substrate within cassette type carrier.

5.1.3 *carrier slot map* — the registry of substrates to the substrate carrier slots.

5.1.4 *carrier substrate location* — a substrate location within a substrate carrier capable of holding a substrate.

5.1.5 *default substrate ID (default ID)* — the substrate ID assigned to the substrate when no substrate ID information is given by the user but the carrier ID for the source carrier is known. The default ID is the combined text of the source carrier ID and the slot number.

5.1.6 *equipment substrate location* — a substrate location on a equipment resource.

5.1.7 *location ID* — the name of a material location.

5.1.8 *lot* — a group of one or more substrates of the same type. A lot must be organized by the user. The group may be referred to for tracking of substrates in the factory.

5.1.9 *material location* — an identifiable place within the equipment or carrier where material can be held.

5.1.10 *register* — an operation that adds the substrate object to the equipment's database. This operation is performed automatically when the equipment receives both a carrier and information from the host about the contents of the carrier. The operation is also performed automatically when the equipment detects the substrate ID.

5.1.11 *remove* — the operation that removes a substrate from the equipment.

5.1.12 *service* — represents a function offered to a user by a provider. A service consists of a sequence of service primitives, each described by a list of parameters.

5.1.13 *substrate* — the basic unit of material on which work is performed to create a product. Examples include wafers, die, plates used for masks, flat panels, circuit boards, and leadframes.

5.1.14 *substrate carrier* — a carrier to hold substrates to be transferred to/from the equipment. A substrate carrier has one or more position to hold substrates (carrier substrate location).

5.1.15 *substrate history* — ordered set of information about the locations visited by the substrate.

5.1.16 *substrate ID* — identifier of a substrate.

5.1.17 *substrate location* — a material location which is capable of holding a substrate. For example, but not limited to, process modules, transfer subsystems, wafer chucks, robot end effecter, and carrier slots.

5.1.18 *substrate type* — represents the type of the substrate, such as wafers, CDs, flat panels, or masks.

5.2 *Data Type*

5.2.1 *Boolean* — may take on one of two possible values, equating to TRUE or FALSE.

5.2.2 *enumerated* — may take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type except floating point.

5.2.3 *floating point* — may take on any single numeric value, positive or negative. Messaging protocol may impose a limit on the range of possible values.

5.2.4 *form* — type of data: positive integer, unsigned integer, integer, floating point, enumerative, Boolean, text, formatted text, structure, list, and ordered list.

5.2.5 *formatted text* — text with an imposed format. This could be by position, by use of special characters, or both.

5.2.6 *integer* — may take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

5.2.7 *list* — a set of one or more items that are all of the same form (one of the above forms).

5.2.8 *ordered list* — a list for which the order in which items appear is significant.

5.2.9 *positive integer* — may take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

5.2.10 *structure* — a complex set of information consisting of specific sets of items of possibly mixed data types, in a specified arrangement.

5.2.11 *text* — a text string. The message protocol restricts its length or ASCII representation. Messaging protocol may impose restrictions, such as length or ASCII representation.

5.2.12 *unsigned integer* — may take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

6 Convention

6.1 *Harel State Model*

6.1.1 This document uses the Harel state chart convention for describing dynamic operation of defined objects. The outline of this convention is described in an attachment of SEMI E30. The official definition of this convention is described in “Statecharts: A Visual Formalism for Complex Systems” written by D. Harel in Science of Computer Programming 8, 1987.[1]

6.1.2 A transition table is used with the state chart for clearly describing the character of each state transition. The table contains the folllowing: a transition number, current state, trigger, new state, and operation in transition.

6.1.3 The state models included in this standard are a requirement for Substrate Tracking compliance. A state model consists of a state model diagram, state definitions, and a state transition table. When using collection events, all state transitions in this standard, unless otherwise specified, shall correspond to collection events.

1 Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.htt

6.1.4 A state model represents the host's view of the equipment and does not necessarily describe the internal equipment operation. When using collection events, all Substrate Tracking state model transitions shall be mapped sequentially into the appropriate internal equipment collection events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the Substrate Tracking state models for transition to another state. In this case, the equipment makes the required transition without any additional actions.

6.2 *OMT Object Information Model*

6.2.1 The object models are represented using the Object Modeling Technique (OMT) developed by Rumbaugh, James, et al, in Object Oriented Modeling Design, Prentice Hall, Englewood Cliffs, NJ, 1991.[2]

6.2.2 An overview of this notation is provided in the Appendix 1 of SEMI E39.

6.3 *Object Attributes Representation*

6.3.1 The object information model for standardized objects will be supported by an attribute definition table with the following column headings:

Attribute Name	*Definition*	*Access*	*Reqmt*	*Format*
The formal text name of the attributes.	Description of information contained.	RO or RW	Y or N	Refer to the description below.

6.3.1.1 The Access column uses RO (read only) or RW (read/write) to indicate the access that a service user has to the attribute.

6.3.1.2 A "Y" or "N" in the Requirement (Reqmt) column indicates if this attribute must be supported in order to meet the fundamental requirement for the service.

6.3.1.3 The Format column is used for showing the data type of the attribute. (See Section 5.2.)

6.4 *Service Message Representation*

6.4.1 *Service Resource Definition* — A service resource definition table defines the specific sets of messages for a service group, as shown in the following table:

Message Service Name	*Type*	*Description*
Message name	N or R	Purpose of the service

6.4.1.1 Type can be either N = Notification or R = Request. Notification type messages are initiated by a service provider and the provider does not expect to get the response from the service user or requester.

6.4.1.2 Request messages are initiated by a service user or requester. The Request message asks for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message context).

6.4.2 *Service Parameter Dictionary* — A service parameter dictionary table defines the parameters for one or more services, as shown in the following table:

Parameter	*Form*	*Description*
Parameter X	Data type	The parameter called X is B in A.

6.4.2.1 A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing form and contents of the corresponding primitive.

6.4.2.2 The Form column is used to indicate the type of data contained in a parameter. (See Section 5.2 for definitions.)

2 Prentice Hall, Inc., Upper Saddle River, NJ 07458, http://www.prenhall.com/divisions/ecs/cscat.html

6.4.2.3 The Description column in the Service Parameter Dictionary table describes the meaning of the parameter, the values it can assume, and any interrelationships with other parameters.

6.4.2.4 To prevent the definition of numerous parameters named "XxxList", this document adopts the convention of referring to the list as "(List of) Xxxx". In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type. Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element unless zero elements are specifically allowed.

6.4.3 *Service Message Definition* — A service message definition table defines the parameter used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Parameter X	see below	see below	A description of the service.

6.4.3.1 The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication". The receiver may then send a "Response", which the original sender terms the "Confirmation".

6.4.3.2 The following codes appear in the Req/Ind and Rsp/Conf columns, and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M" — Mandatory Parameter – must be given a valid value.

"C" — Conditional Parameter – may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the values of other parameters.

"U" — User-Defined Parameter

"-" — The parameter is not used.

"="— (for response only) Indicates that the value of this parameter in the response shall match the value in the primary (if defined).

7 Overview

7.1 *Purpose of Substrate Tracking*

7.1.1 Substrate tracking consists of two kinds of capabilities, as described below:

7.1.2 *Substrate Location Tracking* — Substrate Location Tracking provides the capability to determine the current location of substrates in the equipment. The indication of the substrate location will help the user to understand the environment to which the substrate is exposed in the equipment.

7.1.3 *Substrate History Record* — Substrate History Record provides the capability to read the history of substrates in the equipment. The user can inquire about the history of a particular substrate or substrate location. A history includes the series of locations that the substrate has visited in the equipment.

7.1.4 *Substrate Process Tracking* — Substrate Process Tracking provides the capability of tracking current substrate processing state. For example, the user may determine whether a substrate is processed or not by requesting its state when the process has been completed abnormally. The user may use the state transitions to trigger wafer level data collection.

7.2 *View of Substrate Tracking*

7.2.1 Figure 1 shows the view of Substrate Tracking using the OMT representation. It is assumed that substrates are available before usage of the services. Substrate carriers may or may not be used to load the substrates to the equipment. Substrates are loaded into the equipment and travel through substrate locations. The equipment must maintain all information necessary to track substrates in the equipment.

7.3 *Substrate Location*

7.3.1 A substrate location is a discrete position that can hold a substrate in the equipment. This document will not define where the substrate location exists. Substrate locations shall be determined by the design of equipment and the applications. For example, to track the order of process chambers that is applied to a substrate process in a multi-chamber equipment, it is appropriate to designate process chambers for substrate locations. All substrate locations shall be documented by the equipment supplier.

7.3.2 Figure 2 shows the concept of the substrate location using OMT representation. This figure is provided to clarify the definition of locations.

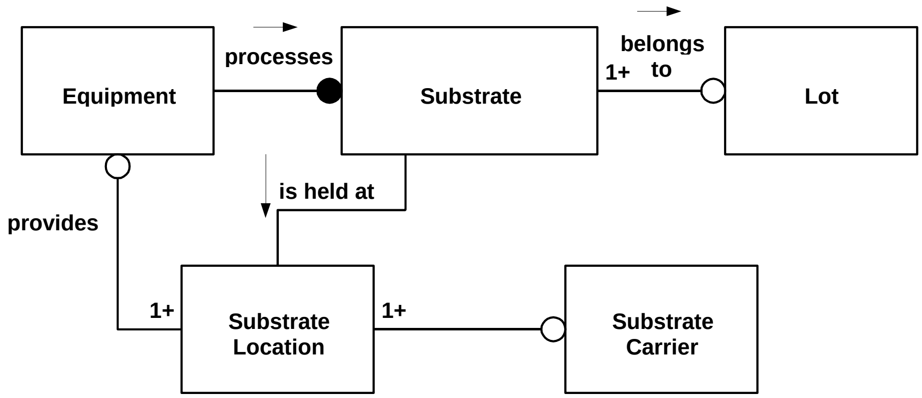

Figure 1
Overview of Substrate Tracking

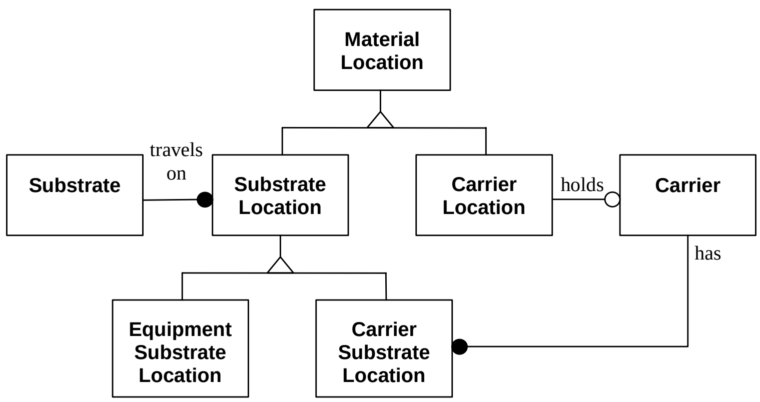

Figure 2
Concept of Substrate Location

7.3.3 Material Location is classified into Substrate Location and Carrier Location. A Carrier Location may hold a carrier and a Substrate Location may hold a substrate.

7.3.4 Substrate Location is classified into Equipment Substrate Location and Carrier Substrate Location. Carrier has Carrier Substrate Locations. A Carrier Substrate Location is the location which can hold a substrate in a carrier. An Equipment Substrate Location is the location which can hold a substrate on the equipment resource.

7.3.5 Substrate travels on substrate locations.

7.4 *Identification of Substrate*

7.4.1 Substrate shall be identified by substrate ID. There are options for assigning substrate ID to a substrate.

- When a carrier is used for loading substrates and the carrier is given its carrier ID, substrate IDs can be obtained by utilizing the carrier ID and carrier substrate location. This standard will define the requirement for the substrate ID assignment to the substrates in a carrier.
- Substrate ID may be read from the substrate directly by a substrate ID reader. The substrate ID read from the substrate can be used for the identification.

- Substrate ID may be assigned by the user (i.e., host or operator). The substrate ID can be used for the identification. This standard will define the service for registering substrates.

7.4.2 The recommendation of a particular option for assigning substrate IDs is not within the scope of this standard. It must be selected based on the equipment design and applications.

8 Substrate Tracking Requirement

8.1 Compliance to Substrate Tracking Service (STS) requires that an implementation also provide certain capabilities that are defined in other standards.

- STS requires compliance to SEMI E39 (OSS) for Substrate objects. The attributes of these objects may be accessed through use of the GetAttr and SetAttr services.
- STS requires an event reporting capability. This capability may be satisfied by the Event Reporting capability in SEMI E30 (GEM) or by SEMI E53 (ERS).

8.2 STS compliant equipment must implement capabilities defined in the following sections of this document:

- Section 9, Substrate Object Definition,
- Section 10, Substrate Location Object Definition,
- Section 11, Substrate Tracking Services, and
- Section 12, Variable Data, if SEMI E53 is not implemented.

8.3 Suppliers shall document the method by which the equipment identifies individual substrates. If the equipment has implemented a substrate ID reading capability, then the equipment shall provide the capability to assign the ID read from the substrate to the substrate object. Otherwise, the equipment shall provide the capability to assign substrate ID to the substrate object by the information provided by the host with the source carrier, either in ContentMap, where provided (see SEMI E87), or the default substrate ID. The default substrate ID shall be represented in text as the carrier ID, a period ".", and a two-digit slot number combined, as in "carrier ID" + "." + "slot number". For example, if CarrierID = "xyz" and SlotNumber = 5, then the substrate ID would be "xyz.05".

8.4 All state transitions defined for the two state models specified in this document must be reportable via discrete collection events as defined in Section 6.1, Harel State Model. The two state models are the Substrate Object State Model (Figure 3) and the Substrate Location State Model (Figure 4).

8.4.1 The following data is required to be available, at a minimum, for the Substrate Object State Model transition collection events:

- SubstID or SubstIDList
- SubstState or SubstStateList
- SubstProcState or SubstProcStateList
- SubstLocID or SubstLocIDList

An equipment may support both SubstID and SubstIDList, but depending on equipment type, one or the other must be supported in the following manner: Fixed buffer equipment must, at a minimum, support the SubstID variable, whereas internal buffer equipment must, at a minimum, support the SubstIDList variable. SubstID is valid at collection events triggered by discrete state model transitions, whereas SubstIDList is valid at collection events triggered by a group of related state model transitions.

8.4.2 The following data is required to be available, at a minimum, for the Substrate Location State Model transition collection events:

- SubstLocID or SubstLocIDList
- SubstLocState or SubstLocStateList
- SubstID or SubstIDList

An equipment may support both SubstLocID and SubstLocIDList, but depending on equipment type, one or the other must be supported in the following manner: Fixed buffer equipment must, at a minimum, support the SubstLocID variable, whereas internal buffer equipment must, at a minimum, support the SubstLocIDList variable. SubstLocID is valid at collection events triggered by discrete state model transitions, whereas SubstLocIDList is valid at collection events triggered by a group of related state model transitions.

8.5 The minimum data required to be valid at each state model transition event is defined in Table 10, Variable Data Definitions for Substrate, of this document. The host may assign other variables, as applicable, from other equipment variable data items.

8.6 Each Substrate Object instantiated on the equipment must maintain an independent instance of the Substrate Object State Model. When discrete and unrelated state transitions occur for Substrate Object models, each shall trigger a separate collection event. However, when related state transitions occur for a group of Substrate Object models (such as with internal buffer equipment material transfers), each model does not trigger a separate collection event. Instead, a single collection event shall be triggered (for all related Substrate Objects in the group). The data items defined in Table 10 are required to be valid for collection events triggered by discrete state model transitions as well as those triggered by a group of related state model transitions, with one exception. SubstID must be valid for collection events triggered by discrete state transitions, but SubstIDList must be valid for collection events triggered by a group of related state transitions. The value of SubstIDList shall be the list of SubstID data items that identify the Substrate Objects related by the collection event.

8.7 Each Substrate Location Object instantiated on the equipment must maintain an independent instance of the appropriate state Substrate Location Object Model. Each Substrate Location Object shall trigger a separate collection event for each state transition. The data items defined in Table 10 are required to be valid for collection events triggered by each state model transition.

9 Substrate Object Definition

9.1 A substrate is a base upon which a product unit is built in the manufacturing equipment. Wafers and flat panel displays are examples of substrates. A substrate may be associated with a lot, which the factory uses for tracking purposes.

9.1.1 The substrate object shall be created when the substrate is registered by the equipment. There are two possible ways of registering the substrate.

(1) The substrate is registered by the equipment when the information for the carrier containing the substrate is registered. The information required to create a substrate object must be provided with the carrier. However, the specification of carrier management services is outside the scope of this standard. Substrate Tracking implementations shall be consistent with the Carrier Management standard. For instance, if the Carrier Management standard specifies the method of identifying the substrates in a carrier, then Substrate Tracking shall recognize those identifiers.

(2) The substrate is registered when the substrate is transferred directly (not in a carrier) to the equipment by the Create service defined in SEMI E39 to inform the equipment of this event.

9.2 *Substrate Object State Model*

9.2.1 A substrate has both a state indicating where it is located and a state indicating the progress of processing. These states are represented by the SUBSTRATE TRANSPORT and the SUBSTRATE PROCESSING states, which are concurrent substates of the SUBSTRATE State Model shown in Figure 3.

9.3 *Substrate Object State Definitions*

9.3.1 ABORTED — The process has been aborted during the processing. The substrate will require special treatment.

9.3.2 AT DESTINATION — The substrate has been placed at its designated destination substrate location. The substrate may have been placed at a carrier substrate location when the carrier is used to unload the substrate from the equipment, or at an equipment substrate location when the substrate is to be removed by itself from the equipment.

9.3.3 AT SOURCE — The state which the substrate is originally received. The substrate is held at carrier substrate location when a carrier is used to supply the substrate.

9.3.4 AT WORK — The substrate has been taken from the original substrate location or destination substrate location, and is traveling on intermediate equipment substrate locations. The substrate has been taken out of the carrier and placed into the equipment when a carrier is used to supply the substrate.

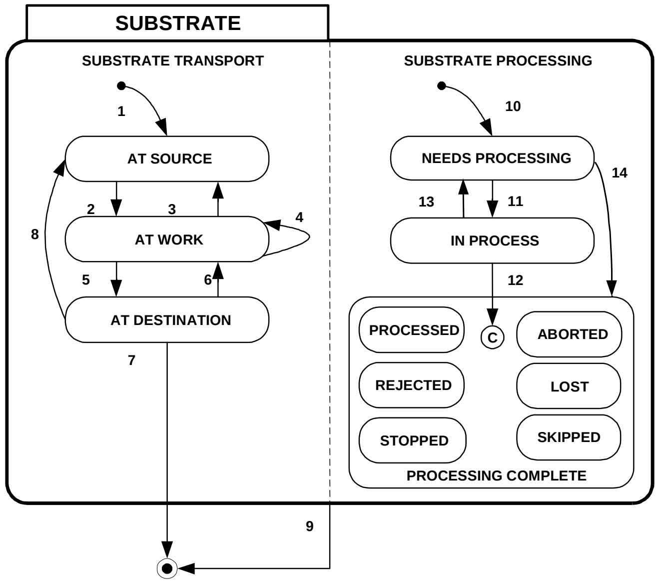

Figure 3
Substrate Object State Model

9.3.5 IN PROCESS — The processing for the substrate has begun and not completed. The processing is effecting on that substrate. The nature of the process depends upon the substate usage.

9.3.6 LOST — The terminal state when the substrate has been broken and/or removed from the equipment by an external entity and it no longer exists at the equipment.

9.3.7 NEEDS PROCESSING — Processing requirements exist that have not yet been fulfilled. This is the default entry state when the substrate is originally received. In some cases, the substrate may return to this state while it waits for additional processing to be performed.

9.3.8 PROCESSED — All substrate processing has successfully completed. No further processing will be performed by the equipment.

9.3.9 PROCESSING COMPLETE — The superstate of PROCESSED, ABORTED, REJECTED, LOST, STOPPED, SKIPPED which the substrate has completed the processing.

9.3.10 REJECTED — The state which the substrate has been processed completely; however, the result of the processing may have a problem. The substrate will require special treatment. This substate is not required for equipment that is unable to identify rejected substrates.

9.3.11 SKIPPED — As directed by an operator or a host, the substrate was not processed.

9.3.12 STOPPED — The process has been stopped during the processing. The substrate will require special treatment.

9.3.13 SUBSTRATE — The superstate of the SUBSTRATE TRANSPORT and SUBSTRATE PROCESSING. SUBSTRATE TRANSPORT and SUBSTRATE PROCESSING are concurrent substates. The state is created when the substrate is initially registered to the equipment, and deleted when the substrate is removed from the equipment.

9.3.14 SUBSTRATE PROCESSING — The superstate of NEEDS PROCESSING, IN PROCESS, PROCESSING COMPLETE which represents the processing state of the substrate.

9.3.15 SUBSTRATE TRANSPORT — The superstate of the AT SOURCE, AT WORK, AT DESTINATION which represents the transport state of the substrate within the equipment.

9.4 *Substrate State Transition*

Table 1 Substrate State Model Transition Table

No.	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	no state	The substrate is registered.	AT SOURCE		
2	AT SOURCE	The substrate is taken from the source substrate location and placed into the equipment.	AT WORK	Update substrate location history.	Substrate tracking through the equipment substrate locations begin.
3	AT WORK	The substrate has moved to the source substrate location.	AT SOURCE	Update substrate location history.	This transition is not required for compliance to this standard.
4	AT WORK	The substrate has moved out from current equipment substrate location towards a new equipment substrate location.	AT WORK	Update substrate location history.	The substrate has moved between equipment substrate locations. This transition is not required for compliance to this standard. This transition is not required if the equipment only provides a single Equipment Substrate Location.
5	AT WORK	The substrate is moved to the destination substrate location.	AT DESTINATION	Update substrate location history.	
6	AT DESTINATION	The substrate is taken from the destination substrate location and placed into the equipment.	AT WORK	Update substrate location history.	This transition is not required for compliance to this standard.
7	AT DESTINATION	The substrate is removed from the equipment by a normal transfer sequence.	(Extinction)	The substrate object is deleted in the equipment.	
8	AT DESTINATION	The user informs or the equipment detects that the substrate is AT SOURCE.	AT SOURCE	Update substrate location history.	This transition is not required for compliance to this standard.
9	Any SUBSTRATE substate	The equipment detects or is informed by the user that a substrate has been removed.	(Extinction)	The substrate object is deleted in the equipment.	The removal may be detected by the equipment or in-formed by the user. This transition would not occur during normal wafer movement. So if transition 7 occurs, there is no need to report a transition 9.
10	no state	The substrate object is created.	NEEDS PROCESSING		
11	NEEDS PROCESSING	The processing to the substrate starts.	IN PROCESS		
12	IN PROCESS	The processing to the substrate completes.	PROCESSING COMPLETE	One of the substates PROCESSED, ABORTED, STOPPED, REJECTED, LOST, SKIPPED is determined.	
13	IN PROCESS	The substrate is requested to be processed again.	NEEDS PROCESSING		This transition is not required for compliance to this standard.
14	NEED PROCESSING	The substrate has been removed from the equipment by an external agent or it is physically missing (LOST) or the substrate has been not processed (SKIPPED).	PROCESSING COMPLETE	One of the substrates LOST, SKIPPED, is determined.	

9.5 *Substrate Object Attribute Definition*

9.5.1 Table 2 defines attributes for substrate objects. These attributes can be accessed by using GetAttr and SetAttr messages as defined in SEMI E39 (OSS).

Table 2 Substrate Object Attribute Table

Attribute Name	*Definition*	*Access*	*Reqmt*	*Format*
LotID	Identifier of the lot associated with the substrate by the user.	RW	N	Text
MaterialStatus	Current status of the substrate that represents criteria of the processing quality. The criteria is equipment design dependent.	RO	N	Enumerated: equipment dependent
ObjID	Object Identifier	RO	Y	Text equal to the Substrate ID
ObjType	Object type	RO	Y	Text = "Substrate"
SubstDestination	Identifier of the substrate location on which the substrate shall be finally restored. When a carrier is used for restoring the substrate, the value shall be the concatenation of carrier identifier (carrier ID) string and a numeric string representing the substrate position in the carrier to represent the carrier and position of the substrate restored.	RO	Y	Text If empty string, then same as source substrate location
SubstHistory	History of locations visited.	RO	Y	List of structures consisting of SubstLocID, TimeIn, TimeOut
SubstLocID	Identifier for current equipment substrate location.	RO	Y	Text
SubstProcState	Processing state of the substrate. "NEEDS PROCESSING": initial value to indicate that processing in the equpment is required and has not started. "IN PROCESS": processing has started. "PROCESSED": processing has completed normally. "ABORTED": processing has terminated abnormally. "STOPPED": processing has terminated at completion of certain processing step. "REJECTED": the substrate has been identified as needing special treatment. "LOST": the substrate has been removed from the equipment by an external agent or it is physically missing. "SKIPPED": the substrate was not processed.	RO	N	Enumerated: NEEDS PROCESSING IN PROCESS PROCESSED ABORTED STOPPED REJECTED LOST SKIPPED
SubstSource	Identifier of the substrate location on which the substrate has been initially registered. When a carrier is used for registering the substrate, the value shall be the concatenation of carrier identifier (carrier ID) string and a numeric string representing the substrate position in the carrier to represent the carrier and position of the substrate registered.	RO	Y	Text
SubstState	Transport state of the substrate.	RO	Y	Enumerated: AT SOURCE AT WORK AT DESTINATION
SubstType	The type of the substrate. It includes wafers, flat panels, CD's or masks.	RW	N	Enumerated: WAFER FLAT PANEL CD MASK

Attribute Name	Definition	Access	Reqmt	Format
SubstUsage	How the substrate is used, such as “product”, “test”, “filler” and “cleaning”.	RW	N	Enumerated: PRODUCT TEST FILLER CLEANING

9.5.2 SubstHistory attribute is a composite data type. The constitute data is defined in Table 3.

Table 3 Attribute Data Definition

Data Identifier	Description	Form
SubstLocID	Equipment substrate location on which the substrate has visited. Must be copied from SubstLocID of which the substrate has visited.	Text
TimeIn	Actual arrival time of the substrate on the substrate location.	The format of the timestamp defined by the protocol for implementation.
TimeOut	Actual departure time of the substrate from the substrate location.	The format of the timestamp defined by the protocol for implementation.

10 Substrate Location Object Definition

10.1 A Substrate Location Object (SLO) provides a model for identifying substrate locations. Each SLO on an equipment is assigned a substrate location ID to uniquely identify it. The assignment shall be docu-mented by the equipment supplier. There are two types of substrate locations: carrier substrate location, which is the location or position (e.g., slot) in the carrier, and equipment substrate location, which is on the equip-ment resource. The equipment substrate location is a persistent object, while the carrier substrate locations are dynamic objects that shall be created or deleted by the placement or removal of carriers on the equipment.

10.1.1 Source substrate locations and Destination substrate locations are the points at which substrates transfer to/from the equipment’s internal substrate locations (often locations at which processing occurs). A carrier substrate location is the Source or Destination substrate location when a carrier is used to transfer the substrate. An equipment substrate location can be the Source or Destination substrate location when the substrate is transferred directly (without a carrier).

10.2 *Substrate Location State Model*

Figure 4 shows the dynamic behavior of the substrate location using the Harel state chart representation.

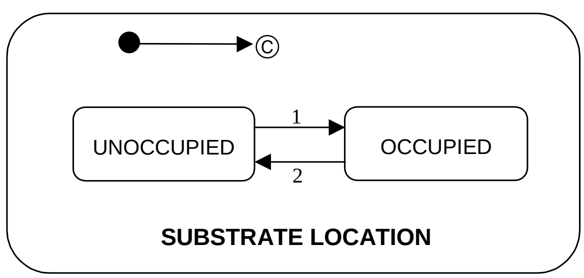

Figure 4
Dynamic Behavior Model of Substrate Location

10.3 *Substrate Location State Definitions*

10.3.1 SUBSTRATE LOCATION — the superstate of UNOCCUPIED and OCCUPIED.

10.3.2 UNOCCUPIED — the state in which the substrate location does not hold or have a substrate.

10.3.3 OCCUPIED — the state in which the substrate location holds a substrate.

10.4 *Substrate Location State Transition*

Table 4 Substrate Location State Model Transition Table

No.	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	UNOCCUPIED	Substrate moves onto the substrate location.	OCCUPIED	None.	
2	OCCUPIED	Substrate moves off the location.	UNOCCUPIED	Update substrate tracking history.	

10.5 *Substrate Location Object Attributes*

10.5.1 Table 5 defines attributes for substrate location objects. These attributes can be accessed by using GetAttr and SetAttr messages as defined in SEMI E39 (OSS).

Table 5 Substrate Location Object Attribute Table

Attribute Name	*Definition*	*Access*	*Reqmt*	*Format*
ObjID	Object Identifier	RO	Y	Text equal to the Substrate Location ID
ObjType	Object type	RO	Y	Text = "SubstLoc"
SubstID	Substrate Identifier relevant to the location	RO	Y	Text
SubstLocState	Substrate Location state	RO	Y	Enumerated: UNOCCUPIED, OCCUPIED

11 Substrate Tracking Services

11.1 *Creating and Deleting Substrate Objects*

11.1.1 Substrates may be registered at the equipment through the Create service defined in SEMI E39. Table 6 defines the attribute settings that may be initialized through this service.

11.1.2 In general, it depends on the application whether or not attributes are initialized by the user of the create service. In some situation, it may be necessary to match the new substrate with a location, for example, while in other situations it would be unnecessary. Each application must specify its own requirements.

11.1.3 ObjType is a required argument of the Create service and should not be reset by including it as an attribute setting. In the table, M indicates Mandatory, O indicates Optional, and R specifies Restricted (shall be ignored if used).

Table 6 Substrate Attributes Settable through Create

Substrate Attribute Name	*Use as AttrSetting in Create Service*
LotID	O
MaterialStatus	O
ObjID	M
ObjType	R
SubstDestination	O
SubstHistory	O
SubstLocID	O
SubstProcState	O
SubstSource	O

11.1.4 Use of attribute settings for the Delete service are optional and specific to the application.

11.2 Table 7 defines services required for substrate tracking. These services must be supported with substrate object.

Table 7 Substrate Tracking Service Message Definition Table

Message Service Name	*Type*	*Description*
Change substrate state	R	Request to change substrate state. This message can be used to inform the equipment that external intervention has occurred and the state of the substrate (SubstState) must be corrected. For example, changing from AT DESTINATION state to AT SOURCE state.

11.3 *Substrate Tracking Service Parameter Dictionary*

Table 8 Substrate Tracking Service Parameter

Dictionary Parameter	*Form*	*Description*
ErrorCode	Enumerated	Contains the code for the specific error found.
ErrorText	Text	Text in support of the error code.
STAcknowledge	Enumerated	Acknowledge of request
Status	A list of ErrorCode/ErrorText pairs	Report any errors found
STStatus	A structure consisting of STAcknowledge and Status	Return information for a service.
SubstID	Text	Identifier of a substrate.
SubstLocID	Text	Identifier of substrate location.
SubProcState	Enumerated	Processing State of a substrate.
SubstState	Enumerated	Transport State of a substrate

Table 9 Change Substrate State Message Pararmeter Table

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
(list of) SubstID	M	=	
(list of) SubstState	C (See NOTE 1.)	-	The order of SubstStates corresponds to the order of SubstID list.
(list of) SubstProcState	C (See NOTE 1.)	-	The order of SubstStates corresponds to the order of SubstID list.
Status	-	M	Information about the results.

12 Variable Data

12.1 The host may inquire about any data related to specific substrates at any time by using the OSS service GetAttr. However, in order for the host to be able to specify the data of interest for building event reports, it must be possible for the host to indicate any of the attributes of the specific instance of substrate associated with an event. To satisfy this need, implementations of STS that are not compliant with SEMI E53 are required to provide variables defined in Table 10.

12.1.1 Variables are presented in alphabetical order.

Table 10 Variable Data Definitions for Substrate

Variable Name	*Description*	*Access*	*Form*	*Comment*
LotID	A tracking ID for the substrate associated with the last event.	RO	Text	
SubstDestination	Destination Carrier Substrate Location for the substrate associated with the last event.	RO	Text	If empty string, then same as source carrier position.
SubstHistory	List of history of locations visited for the substrate associated with the last event.	RO	List of structures consisting of Location ID, Time In, and Time Out.	

Variable Name	*Description*	*Access*	*Form*	*Comment*
SubstID	Identifier of substrate associated with last event.	RO	Text	
SubstIDList	A list of substrate identifiers related by the same Substrate Object State Model or Substrate Location Object State Model state transition that triggered a collection event with which this variable was associated.	RO	Ordered list of SubstID	When a group of substrates have a related state model transition, only one collection event is triggered.
SubstLocID	Identifier for equipment substrate location associated with the last event.	RO	Text	
$SubstLocID_i$	Identifier of the ith equipment substrate location.	RO	Text	
SubstLocIDList	A list of substrate location identifiers related by the same Substrate Object State Model or Substrate Location Object State Model state transition that triggered a collection event with which this variable was associated.	RO	Ordered list of SubstLocID	When a group of substrates have a related state model transition, only one collection event is triggered.
SubstLocState	State of substrate location associated with the last event.	RO	Enumerated: OCCUPIED UNOCCUPIED	
$SubstLocState_i$	State of ith equipment substrate location.	RO	Enumerated: OCCUPIED UNOCCUPIED	
SubstLocStateList	A list of substrate location states related by the same Substrate Location Object State Model state transition that triggered a collection event with which this variable was associated.	RO	Ordered list of SubstLocState	When a group of substrates have a related state model transition, only one collection event is triggered.
$SubstrLocSubstrID_i$	Substrate ID of the substrate at the ith equipment substrate location, when occupied.	RO	Text	
SubstMtrlStatus	Processing quality criteria associated with the last event.	RO	Enumerated (equipment specific)	
SubstProcState	Processing state of the substrate associated with the last event.	RO	Enumerated: NEEDS PROCESSING IN PROCESS PROCESSED ABORTED STOPPED REJECTED	May not be implemented when the equipment does not have capability of process.
SubstProcStateList	A list of substrate process states related by the same Substrate Object State Model state transition that triggered a collection event with which this variable was associated.	RO	Ordered list of SubstProcState	When a group of substrates have a related state model transition, only one collection event is triggered.
SubstSource	Source Carrier Substrate Location for the substrate associated with the last event.	RO	Text	
SubstState	The current state of the substrate associated with the last event.	RO	Enumerated: AT SOURCE AT WORK AT DESTINATION	

Variable Name	*Description*	*Access*	*Form*	*Comment*
SubstStateList	A list of substrate states related by the same Substrate Object State Model state transition that triggered a collection event with which this variable was associated.	RO	Ordered list of SubstState	When a group of substrates have a related state model transition, only one collection event is triggered.
SubstType	Substrate subtype for the substrate associated with the last event.	RO	Enumerated: wafer, disc, flat panel, reticle	SEMI E5, Section 9.2 contains a dictionary of units.
SubstUsage	Description of the substrate associated with the last event.	RO	Enumerated: PRODUCT TEST FILLER CLEANING	Indicates how the substrate is used.

13 Requirements for Compliance

13.1 Table 11 provides a checklist for Substrate Tracking (STS) compliance.

Table 11 STS Compliance Statement

Fundamental STS Requirements	*STS Section*	*Implemented*	*STS Compliant*
Subtrate Tracking	8 (except 8.4)	☐ Yes ☐ No	☐ Yes ☐ No
Substrate Object and State Model	9	☐ Yes ☐ No	☐ Yes ☐ No
Substrate Location Object and State Model	10	☐ Yes ☐ No	☐ Yes ☐ No
Service Message Implementation	11	☐ Yes ☐ No	☐ Yes ☐ No
Variable Data	12	☐ Yes ☐ No	☐ Yes ☐ No
Events	8.4	☐ Yes ☐ No	☐ Yes ☐ No
Additional STS Capabilities	*STS Section*	*Implemented*	*STS Compliant*
None			

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E90. This related information was approved for publication by full letter ballot procedures on January 14, 2000.

R1-1 Substrate State Model Implementation

R1-1.1 The Substrate Object State Model defined in Section 9.1 is a generic representation of the substrate object state model that includes standard transitions for various equipment types.

R1-1.2 Some equipment may not be able to implement all of the transitions defined in this model. For example, the transition from AT WORK to AT SOURCE (Transition Number 3) represents the case where the substrate returns to the original (source) location, typically for further processing. If the equipment is unable to implement this return, then the transition would never occur, and it should be omitted from the implemented state model.

R1-1.3 The state model shall be implemented based on the definition of the state model; however, substates and transitions that cannot occur for a particular equipment design may be omitted where the model allows.

R1-2 Example of Substrate Object State Model for Simple Equipment

R1-2.1 This section shows an example of Substrate Object State Model for simple equipment. (See Figure R1-1.)

R1-2.2 The equipment transports the substrate only in a forward direction, so that the Substrate Transport Substate takes straight forward transitions from AT SOURCE to AT WORK and then to AT DESTINATION. For example, the wirebonder removes leadframes from a magazine and carries them on a transport mechanism but is unable to return them to the magazine.

R1-2.3 Also, the equipment processes the substrate only in forward steps so that the Substrate Processing Substate takes straight forward transitions from NEED PROCESSING to IN PROCESS and then to PROCESSING COMPLETE. The REJECTED state is not applied to this equipment.

Substrate State Model for Simple Equipment

SEMI E90.1-0702
PROVISIONAL SPECIFICATION FOR SECS-II PROTOCOL SUBSTRATE TRACKING

This provisional specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published March 2001, previously published July 2001.

1 Purpose

1.1 This document maps the services and data of SEMI E90 to SECS-II streams and functions, and data definitions.

2 Scope

2.1 This is a specification covering equipment supporting automated substrate tracking.

2.2 This document applies to all implementations of SEMI E90 that use the SECS-II message protocol (SEMI E5). Compliance to this standard requires compliance to both SEMI E90 and SEMI E5.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2.4 This standard is provisional. To have the provisional status removed, the following must be completed:

- Table 1, Services Message Mapping Table
- Table 3, Services Parameters to SECS-II Data Items Mapping

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39.1 — SECS-II Protocol for Object Services Standard (OSS)

SEMI E53 — Event Reporting

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Mapping

4.1 This section shows the specific SECS-II streams and functions that shall be used for SECS-II implementation of the services defined in SEMI E90, as well as the parameter mapping for data attached to services.

4.2 *Message Mapping*

4.2.1 *Services Message Mapping* — Table 1 defines the relationships between SEMI E90 services and SECS-II messages.

4.2.2 *Event Message Mapping* — Table 2 defines the relationships between SEMI E90 collection events and SECS-II messages.

Table 1 Services Message Mapping Table

Service Name	*Stream, Function*	*SECS-II Message Name*
change substrate state	(not yet defined)	(not yet defined)
register substrate	S14,F9/10	Create Object Request/Acknowledge (E39.1)
remove substrate	S14,F11/12	Delete Object Request/Acknowledge (E39.1)

Table 2 Event Message Mapping Table

Event Name	*Stream, Function*	*SECS-II Message Name*
All state model transitions	If SEMI E30 style events: S6F11/12 If SEMI E53 style events: S6F11/12 S6F13/14	If SEMI E30 style events: Event Report Send/Acknowledge If SEMI E53 style events: Event Report Send/Acknowledge Annotated Event Report Send/Ack

4.3 *Parameter Mapping* — Table 3 defines the relationships between SEMI E90 service parameters and SECS-II data definitions.

Table 3 Service Parameters to SECS-II Data Items Mapping

Parameter Name	*Range*	*SECS-II Data Item*
ErrorCode	Enumerated	ERRCODE
ErrorText	1 to 80 characters	ERRTEXT
STAcknowledge	0 if success; 1 if error (Conforms to ObjAck in SEMI E39.1)	OBJACK
Status	List of error information	L,n n=number of errors 1. L,2 1. <ErrorCode$_1$> 2. <ErrorText$_1$> . . n. L,2 1. <ErrorCode$_n$> 2. <ErrorText$_n$>
STStatus	STAcknowledge and Status	L,2 1. <STAcknowledge> 2. <Status>
SubstID	1–80 characters (Conforms to ObjID in SEMI E39.1)	OBJID
SubstIDList (ordered list of)	List of Substrate ID' s	L,n n=number of substrate identifiers 1. <SubstID$_1$> . . n. <SubstID$_n$>
SubstLocID	1–80 characters (Conforms to ObjID in SEMI E39.1)	OBJID
SubstLocIDList (ordered list of)	List of Substrate Location ID's corresponding to the SubstIDList (ordered list of).	L,n n=number of substrate identifiers in SubstIDList (ordered list of) 1. <SubstLocID$_1$> . . n. <SubstLocID $_n$>
SubstProcState	Enumerated per Variable SubstProcState.	U1
SubstProcStateList (ordered list of)	List of Substrate Processing States corresponding to the SubstIDList (ordered list of).	L,n n=number of substrate identifiers in SubstIDList (ordered list of) 1. <SubstProcState$_1$> . . n. <SubstProcState $_n$>
SubstState	Enumerated per Variable SubstState	U1
SubstStateList (ordered list of)	List of Substrate Transport States corresponding to the SubstIDList (ordered list of).	L,n n=number of substrate identifers in SubstIDList (ordered list of) 1. <SubstState$_1$> . . n. <SubstState $_n$>

4.4 *SECS-II Data Items without Corresponding SEMI E90 Parameters* — Table 4 contains the SECS-II data items that do not correspond to SEMI E90's service parameter.

Table 4 Additional Data Item Requirements Table

Function	*SECS-II Data Item*

SEMI E91-0600
SPECIFICATION FOR PROBER SPECIFIC EQUIPMENT MODEL (PSEM)

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the Japanese Communications Committee. Current edition approved by the Japanese Regional Standards Committee on January 14, 2000. Initially available at www.semi.org March 2000; to be published June 2000. Originally published September 1999.

1 Purpose

1.1 This document establishes a Specific Equipment Model for prober equipment (PSEM). The PSEM consists of equipment characteristics and behaviors that apply to this class of equipment and are required to be implemented in addition to the fundamental requirements and additional capabilities specified in SEMI E30 (GEM). The intent of this document is to facilitate the integration of prober equipment into an automated semiconductor factory. This document accomplishes this by defining an operational model for prober equipment as viewed by a factory automation controller. This definition provides a standard host interface and equipment operational behavior.

2 Scope

2.1 The scope of this document is limited to the definition of prober equipment behavior as perceived by a Semiconductor Equipment Communications Standard (SECS-II) (SEMI E5) host that complies with GEM. The document defines the view of the equipment through the SECS communications link, but does not define the internal operation of the equipment. It includes a specific processing state model as the basis for the behavior of all equipment of this class.

2.2 This document requires that the GEM fundamental requirements and applicable additional capabilities have been implemented on the prober equipment. This document expands GEM Standard requirements and capabilities in the areas of the processing state model, collection events, remote commands, data item variables and process program management, and adds Prober Job state model to GEM Standard requirements and capabilities. This document does not include the definition of the treatment of Multiple Stage.

2.3 This document applies to the class of prober equipment in which the wafer is unloaded from the same slot in the same carrier which loaded the wafer after processing.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI M20 — Specification for Establishing a Wafer Coordinate System

SEMI M21 — Specification for Assigning Addresses to Rectangular Elements in a Cartesian Array

3.2 *Other Documents*

Harel, D., "Statechart: A Visual Formalism for Complex Systems", Science of Computer Programming 8 (1987) 231-274.[1]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *alignment* — a procedure in which a coordinate system is established on a substrate.

4.2 *bin* — categorized data of die as a result of measurement.

4.3 *cassette* — a physical object containing one or more substrate locations (see slot). For example, a SEMI standard cassette is a carrier with 25 substrate slot locations.

4.4 *die* — 1. A field sub-unit. 2. An area of substrate that contains the device being manufactured.

4.5 *execution area* — the area from which a current copy of the process program instructions are executed.

4.6 *inker* — a resource of the prober. The electromechanical units to put ink mark on die.

4.7 *instruction data* — the Result Data to refer on the inspection process.

1 Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.htt

4.8 *job* — a lot, processed with a single process program on PSEM equipment.

4.9 *load* — move material to the probing or marking location from the cassette.

4.10 *lot* — a group of one or more substrates of the same type (e.g., wafers, masks, CDs).

4.11 *map* — a list of coordinate positions of die on a substrate. MAP is defined in accordance with SEMI M21 in this document.

4.12 *map data* — the categorized data of die as a result of measurement associated with coordinates. Map data also have an information that identifies origin die.

4.13 *marking* — the process of the prober that making an ink mark on a die using the inker.

4.14 *material* — 1. The basic unit of process, physically a cassette or some cassettes. 2. A lot.

4.15 *measurement* — making a test, contacting the probe card and the die. The tester sends to the prober a categorized data as a result of test.

4.16 *probe card* — the electromechanical interface necessary to enable temporary electrical contact between the substrate to be tested and the tester resource. May consist of multiple components.

4.17 *re-inspection* — a process where the same substrate is tested again by using the inspected map data.

4.18 *slot* — a physical location within a cassette capable of containing a substrate. (Also referred to as a carrier location).

4.19 *state* — 1. A static set of conditions. If the conditions are met, the state is current (SEMI E30). 2. A state reacts predictably to specific stimuli.

4.20 *substrate* — 1. The basic unit of material, processed by PSEM equipment such as wafers.

4.21 *testing equipment* — an equipment class generally consisting of integrated mechanisms and controls for performing electrical tests of packaged devices and or wafer die during the manufacturing process.

4.22 *unload* — remove materials to the cassette slots from the probing or marking location.

4.23 *wafer end* — the end of measuring process of a wafer.

5 State Model

5.1 The purpose is to define the equipment-specific processing state model and Prober Job state models necessary to portray the expected operational states of the equipment to enable host tracking and control in place of a local operator.

5.1.1 The processing state models in this document are required for implementing an PSEM-compliant prober, in addition to the required state models in SEMI E30. A state model consists of a state model diagram, state definitions, and a state transitions' table. A state model represents the host's view of the prober, but not necessarily the actual prober operations. All PSEM state model transitions shall be mapped sequentially into the actual equipment events that satisfy the requirements of those transitions. In certain implementations, the prober may enter a state and has already satisfied all of the conditions required by the PSEM state model for transition to another state. In this situation, the prober makes the required transition without any additional actions.

5.1.1.1 Various symbols used in a state diagram are described in Figure 1.

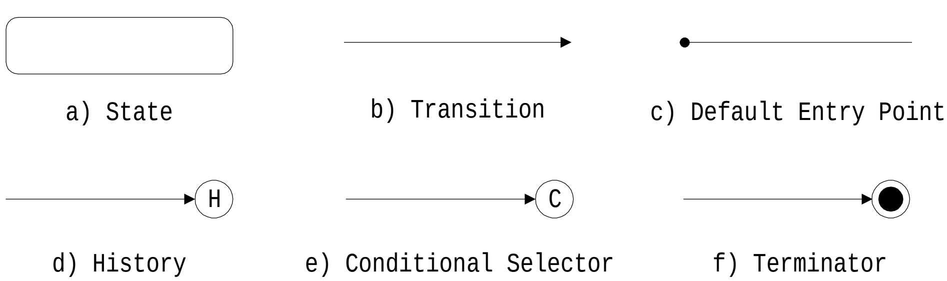

Figure 1
Various Symbols Used in a State Diagram

5.1.2 Some equipment may need to include additional states. However, any additional states must not change the PSEM-defined state transitions. All expected transitions between PSEM states must occur.

5.2 *PSEM Processing State Model*

5.2.1 *Purpose*

5.2.1.1 The purpose of the PSEM Processing State Model is to make an accurate model for the behavior of the PSEM prober from Processing State Model defined in SEMI E30.

5.2.2 *PSEM Processing State Model Diagram*

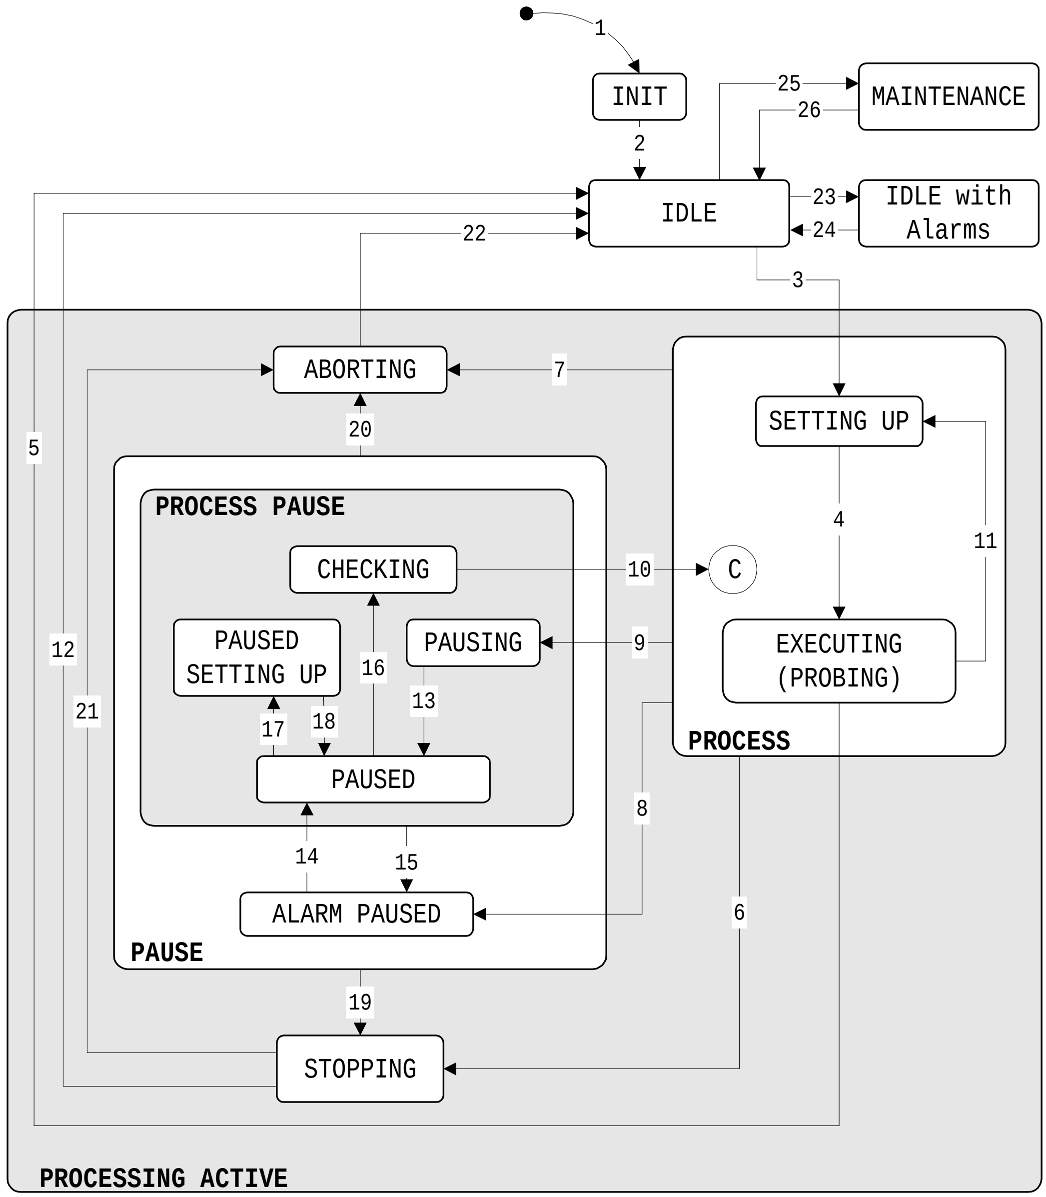

Figure 2
PSEM Processing State Model Diagram

5.2.3 *Description of Prober Processing States*

5.2.3.1 *ABORTING (PROCESSING ACTIVE Sub-state)* — The prober has received ABORT command. All activities are suspended. The prober is taking an appropriate action to ensure possible safe state for the prober itself and materials. Wafer data or lot data may be unavailable.

5.2.3.2 *ALARM PAUSED (PAUSE Sub-state)* — An alarm has occurred in PROCESS or PROCESS PAUSE state. The prober is waiting for the alarm to be cleared.

5.2.3.3 *CHECKING (PROCESS PAUSE Sub-state)* — The prober verifies that a process program update performed is valid. This is a procedure same with that taken in SETTING UP state before the prober is ready to transit to READY state. Upon completion of verification, an event will be created if the verification is successfully ended. A transition is made to the process state, based on the process model condition table.

5.2.3.4 *EXECUTING (PROCESS Sub-state)* — The prober is processing material automatically and can continue to do so without external intervention. This state may include interaction with the host or operator.

5.2.3.5 *IDLE* — The prober is waiting for an instruction. IDLE is free of ALARMS and error conditions.

5.2.3.6 *IDLE with ALARMS* — An alarm has occurred in the IDLE state and the prober is waiting for all alarms to be cleared.

5.2.3.7 *INIT* — Prober is in the course of initialization.

5.2.3.8 *MAINTENANCE*

5.2.3.8.1 The operator's instruction has disabled production by the prober.

5.2.3.8.2 Maintenance and inspection of the prober are executed in this state.

5.2.3.9 *PAUSE (PROCESSING ACTIVE Sub-state)* — PROCESS state is interrupted when the processing can be paused. An action to ensure safety of the prober is taken. The prober waits for a command (RESUME, STOP or ABORT) or the alarm to be cleared.

5.2.3.10 *PAUSED (PROCESS PAUSE Sub-state)* — In this state an operator can correct an error as far as the current process program selection is not affected. PROCESS state is suspended and the prober waits for a command (RESUME, STOP or ABORT). In this state, the operator is allowed to correct an error conditions that does not affect the current process program selected. One of such corrective actions that can be taken by the operator is manual alignment of the wafer in process.

5.2.3.11 *PAUSED SETTING UP (PROCESS PAUSE Sub-state)* — When PROCESS state is suspended, the prober is made to perform simple set-up operations. Probe card replacing work and inker replacing work are included in those operations.

5.2.3.12 *PAUSING (PROCESS PAUSE Sub-state)* — PROCESS state is interrupted when the processing can be paused. The prober cannot transit to PAUSED state until safe state is ensured.

5.2.3.13 *PROCESS (PROCESSING ACTIVE Sub-state)* — This state is the parent of those sub-states that refer to the preparation and execution of a process program.

5.2.3.14 *PROCESS PAUSE (PAUSE Sub-state)* — The prober is free of alarm conditions in the PAUSE state.

5.2.3.15 *PROCESSING ACTIVE* — The state in which the prober is processing materials.

5.2.3.16 *SETTING UP (PROCESS Sub-state)* — The prober is trying to satisfy requirements to be able to start processing. This is the state under which the prober has already received a process program and materials to be processed, then has received START command from the host or the operator and is making preparation for the processing according to the process program.

5.2.3.17 *STOPPING (PROCESSING ACTIVE Sub-state)* — The prober has received STOP command and sets up for the stop. All necessary cleanup is completed within this state with regard to material, data, control system, etc. Data is preserved. Any error condition is cleared before exiting from this state.

5.2.4 *PSEM Processing State Transition Table*

Table 1 Processing State Transition Table

No.	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	Undefined	After turning the power on, the operator has commanded the prober to perform initialization.	INIT	The prober executes initialization.	None
2	INIT	Initialization of all probers completes without an alarm or error.	IDLE	The prober is waiting for a command by the host or the operator.	None
3	IDLE	Prober Job has been created, and the prober has already received a process program and materials, then has received START command from the host or the operator.	SETTING UP	The prober is set up according to the process program.	None
4	SETTING UP	All set-up performance has completed.	EXECUTING	The prober executes wafer transfer and measuring.	None
5	EXECUTING	Material processing completes.	IDLE	None	None
6	PROCESS	The prober received STOP command.	STOPPING	The prober completes the current wafer or the current die under EXECUTING state and unloads it in accordance with the setting of ECV "StopUnit".	The prober starts clearing data. Whether or not unloading is executed after the completion of the current wafer or the current die depends on the specification.
7	PROCESS	The prober received ABORT command from operator, host or self generated.	ABORTING	The prober is placed in a safe state.	Wafer data or lot data may be invalid or not available.
8	PROCESS	An alarm occurs.	ALARM PAUSED	PROCESS activity is suspended, the prober is waiting for all alarms to be cleared, STOP or ABORT command.	ALARM PAUSED is PAUSE sub-state.
9	PROCESS	The prober received PAUSE command from the host or the operator.	PAUSING	PROCESS state is suspended when the processing can be stopped. All operations required to put the prober in safe condition are performed.	PAUSING is PROCESS PAUSE sub-state.
10	CHECKING	Parameter checking ends normally.	Previous PROCESS state.	Processing re-starts from the previously suspended state.	None

No.	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
11	EXECUTING	Processing of the last wafer of a current lot completed. The prober has received START command for next lot.	SETTING UP	None	None
12	STOPPING	The prober completes clearing of data and no alarm remains.	IDLE	None	None
13	PAUSING	The prober stopped the processing of the current wafer which was in EXECUTING state at a possible stop breakpoint and attained a safe state.	PAUSED	The prober is waiting for command (RESUME, STOP or ABORT).	None
14	ALARM PAUSED	Alarm is cleared.	PAUSED	The prober is waiting for command (RESUME, STOP or ABORT).	None
15	PROCESS PAUSE	An alarm occurs in the prober.	ALARM PAUSED	The prober is waiting for all alarms to be cleared, STOP or ABORT command.	None
16	PAUSED	RESUME command was received.	CHECKING	Verification of process program parameters.	Before continuing processing, the host or operator is required to issue RESUME command.
17	PAUSED	The operator instructed a state transition.	PAUSED SETTING UP	Probe card replacement or inker replacement is carried out by operator's instruction.	None
18	PAUSED SETTING UP	The operator instructed a state transition.	PAUSED	None	None
19	PAUSE	The prober received STOP command.	STOPPING	The prober starts clearing data.	Data is saved and valid.
20	PAUSE	The prober received ABORT command.	ABORTING	If possible, unsafe condition is reset.	Wafer data or lot data may be invalid or not available.
21	STOPPING	The prober received ABORT command.	ABORTING	If possible, unsafe condition is reset.	Wafer data or lot data may be invalid or not available.
22	ABORTING	An abort performance has completed.	IDLE	None	Only a state transition to IDLE is permitted.
23	IDLE	An alarm occurs.	IDLE with ALARMS	The prober is waiting for all alarms to be cleared.	None
24	IDLE with ALARMS	All alarms were cleared.	IDLE	None	The IDLE state is free of alarms.
25	IDLE	The operator instructed a state transition.	MAINTEN-ANCE	None	Maintenance and inspection of the prober modules and creation, change and deletion of process programs are possible.
26	MAINTEN-ANCE	The operator instructed a state transition.	IDLE	None	None

5.2.5 *The Process Model Condition Table*

5.2.5.1 Undermentioned Table 2 is an explanation of the transition condition of transition No. 10 in PSEM Processing State Model diagram.

Table 2 The Process Model Condition Table

Conditions	*Next State*
The check approves that the process program is changed.	SETTING UP
The check approves that the process program is **not** changed.	
The previous state was SETTING UP.	SETTING UP
The previous state was EXECUTING.	EXECUTING

5.3 *Prober Job State Model*

5.3.1 *Purpose*

5.3.1.1 The Prober Job state model is defined for the purpose of keeping track of its processing state of the material to be processed by the prober in every material. The host can give instructions on how to process which material by creating Prober Job to the equipment. Prober Job is created by the JOB CREATE command. Prober Job state exists in each Prober Job. It occurs upon creation of Prober Job and is deleted upon its completion. The host can control progress of material processing which is requested to the equipment according to an event report accompanied by progress of Prober Job.

5.3.2 *Prober Job State Model Diagram*

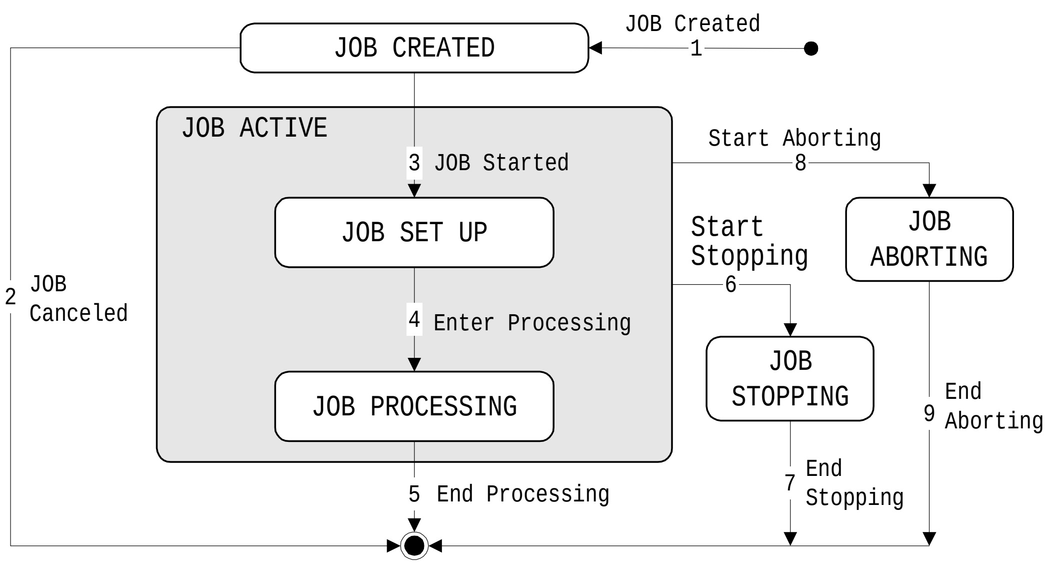

Figure 3
Prober Job State Model Diagram

5.3.3 *Description of Prober Job State*

5.3.3.1 *JOB CREATED* — State where Prober Job is created to the equipment Prober Job has not processed yet. It has nothing to do with whether material reached the equipment or not.

5.3.3.2 *JOB ACTIVE* — State where normal Prober Job processing operation is performed It consists of two sub-states.

5.3.3.3 *JOB SET UP (JOB ACTIVE Sub-state)* — State that waits for condition to be ready for processing such as Equipment preparation.

5.3.3.4 *JOB PROCESSING (JOB ACTIVE Sub-state)* — State where this processing is performed.

5.3.3.5 *JOB STOPPING* — State where attempts are made to stop Prober Job.

5.3.3.6 *JOB ABORTING* — State where attempts are made to abort Prober Job.

5.3.4 *Prober Job State Transition Table*

Table 3 Prober Job State Transition Table

No.	*Current State*	*Trigger*	*New State*	*Action*	*Comments*
1	Undefined	JOB_CREATE command was received from host or the Job Create operation was instructed by operator when Processing State is neither INIT nor MAINTENANCE state.	JOB CREATED	Create Prober Job.	None.
2	JOB CREATED	JOB_CANCEL command from host or operator.	Undefined	Cancel Prober Job.	None.
3	JOB CREATED	START command from host or the Start operation was instructed by operator.	JOB SET UP	Prepare for processing of Prober Job and wait for processing to be possible.	None.
4	JOB SET UP	Prober Job processing conditions were established.	JOB PROCESSING	Start processing of the main unit.	None.
5	JOB PROCESSING	Processing of Prober Job was normally completed.	Undefined	Delete Prober Job.	None.
6	JOB ACTIVE	STOP command was received from host or the stop operation was instructed by operator.	JOB STOPPING	Start stop processing.	A trigger may be caused by error detection of the equipment itself as well as by instruction from outside.
7	JOB STOPPING	The stop operation was completed.	Undefined	Delete Prober Job.	None.
8	JOB ACTIVE	ABORT command was received from host of the Abort operation was instructed by operator.	JOB ABORTING	Start abort processing.	A trigger may be caused by error detection of the equipment itself as well as by instruction from outside.
9	JOB ABORTING	Abort processing was completed.	Undefined	Delete Prober Job.	None.

6 Collection Event List

6.1 *Requirements*

6.1.1 All GEM-required Events are required by the PSEM. Since Processing State Model is required by the PSEM, all state transitions are required Events.

6.1.2 All GEM-required Events associated with the GEM Control, Communications, Alarm, and Spooling State Models are required. This section of the PSEM lists only those collection events that are not associated with a change of state or those requiring specific data variables (DVVALs) or Reports defined in the PSEM.

6.2 *Collection Event Tables*

6.2.1 Table 4 shows events and reports required for the PSEM process state transition. Table 5 shows events and reports required for the Prober Job state transition. Table 6 shows other collection events.

Table 4 Collection Events Required by Process State Transition

Transition	*Transition No.*	*Current State*	*New State*	*Typical Variable Data*
Start INIT	1	Undefined	INIT	Previous Process State
Into IDLE	2	INIT	IDLE	
	5	EXECUTING		
	12	STOPPING		
	22	ABORTING		
	24	IDLE with ALARMS		
	26	MAINTENANCE		
Into IDLE with ALARMS	23	IDLE	IDLE with ALARMS

Table 5 Collection Events Required by Prober Job State Transition

Transition	*Current State*	*New State*	*Typical Variable Data*
JOB Created	Undefined	JOB CREATED	EventJobID
JOB Canceled	JOB CREATED	Undefined	
JOB Started	JOB CREATED	JOB SET UP	
Enter Processing	JOB SET UP	JOB PROCESSING	
End Processing	JOB PROCESSING	Undefined	
Start Aborting	JOB SET UP, JOB PROCESSING	JOB ABORTING	
End Aborting	JOB ABORTING	Undefined	
Start Stopping	JOB SET UP, JOB PROCESSING	JOB STOPPING	
End Stopping	JOB STOPPING	Undefined	

Table 6 Other Collection Events

Event Name	*Contents*	*Typical Variable Data*
Wafer Start	Wafer processing was started.	WaferStartJobID, WaferStartWaferID
Wafer End	Wafer processing was completed.	WaferEndJobID, WaferEndWaferID
Ready to Receive Previous Data	Waits for reception of instructed data for wafer.	WaitPreDataJobID, WaitPreDataWaferID

7 Data Item Variables

7.1 The purpose of this section is to define the list of data item variables required by the PSEM. Values of these variables will be available to the host through collection event reports and host status queries.

7.2 *Requirements*

7.2.1 All generic variable data items defined in GEM are required by all PSEM equipment. Any supplier-defined variables shall be documented in the same format used by this document. The following minimum information is required:

<variable name> Class: <ECV, SV, or DVVAL>

Format: <SML>

Description: <if class=DVVAL, description must contain statement of when data is valid>.

<If format = ASCII then a length is required. It is assumed to be left-justified unless otherwise noted. >

7.3 *Data Types*

7.3.1 Equipment Constants (ECVs) can be changed by the host using S2F15. The operator may be able to change some values, but the equipment does not change the values on its own. The value of an equipment constant may be queried by the host at any time, using the S2F13/14 transaction. They reside in non-volatile memory of the equipment. Equipment constants remain in effect until they are overwritten either by manual entry or by a NEW EQUIPMENT CONSTANT SEND. Equipment constants have various uses in PSEM, including the following:

- Equipment offsets that match the performance of several pieces of equipment that would otherwise perform differently due to inherent manufacturing differences. Examples are home values and motion axis scaling factors.
- Setting the configuration of the equipment to allow for different material specifications, equipment options, material flows, frequency of automatic functions, etc. Examples are yield check frequency.
- Managing optional machine features. Examples are constants that tell the system whether optional features such as automated media stackers are present and control the configuration and function of these optional subsystems when they are present.

7.3.2 Status Variables (SVs) are valid at all times. A SV may not be changed by the host but may be changed by the equipment or operator. The value of status variables may be queried by the host at anytime using the S1,F3/4 or S6,F19/20 transactions. DVVALs are variables that are valid only upon the occurrence of specific collection events. An attempt to read a data variable at the wrong time will not generate an error, but the data reported may not have relevant meaning.

7.4 *Data Item Variable Table*

Table 7 Data Item Variable Table

Variable Name	*Description*	*Class*	*Format*	*Comments*
StopUnit	Constant which specifies separation of stop operation in probing.	ECV	U1	0=Unit of Die 1=Unit of Wafer 2=Unit of Cassette 3=Unit of Lot
EventJobID	Prober Job ID which occurs Prober Job state transition.	DVVAL	A[30]	Valid when Prober Job state transition occurs.
EventJobState	Current state of Prober Job whose state changed.	DVVAL	U2	Valid in event of Prober Job state transition.
ResultData	Processing result in unit of one wafer.	DVVAL	L[n]	Valid only in wafer end event.

8 Process Program Management

8.1 PSEM explains how to specify a process program for the prober and the process program control between the host and prober.

8.2 *Process Program Requirements*

8.2.1 The PSEM requires that the GEM capability of process program management be fully supported for this class of prober.

8.3 *Process Program*

8.3.1 The process program of the prober consists of the main process program and two or more sub process programs that are referred to by the main process program.

Table 8 Kinds and Descriptions of Process Programs

Kind	*Description*
Product type master record	Master process program for processing.
Sub-parameter record	Sub-process program for processing. Various kinds of parameter records that consist main process program for processing.

8.3.2 These process programs are controlled by the prober with grouped into different categories according to application purposes and structures. The prober defines PPID with "structure class name/class name/process program record name." The number of PPID digits is defined by an equipment supplier. If the number of the digits is less than a default value, left-justify and fill in space after PPID. Do not use space at some midpoint in PPID. At present, the prober practically uses the structure class name and class name as shown in the table given below.

Table 9 How to Operate Class Name and Structural Class Name

Classification	*Operation*	*Remarks*
Structural class name	Class name indicating major classification of process program record.	Defined by supplier.
Class name	Class name indicating attribute of process program record.	Defined by supplier.

8.4 *Master Process Program Record*

8.4.1 The master process program record is a plain text (ASCII) record like below:

DEVICE:xxxxxxxx

WAFER_SIZE:xx

DIE_SIZE:xxxxxx,xxxxxx

....

PARAM_RECORD00:structure class name/class name/process program record name

....

PARAM_RECORDnn:structure class name/class name/process program record name

8.4.1.1 Each line has a structure:

TAG + ":" + parameter(s) + line terminator

8.4.1.2 The line terminator is some of CR+LF (0x0d0a), CR (0x0d), LF (0x0a).

8.4.1.3 Specific parameters of equipment supplier may be put between "HOT_CHUCK_TOLE" and "PARAM_FILE00".

Table 10 Tag Parameters in Master Process Program

Tag	*Description*	*Format*	*Unit*
PRODID	Product name (i.e., Device type)	A[1,24]	-
WAFER_SIZE	Wafer size	A[1,3]	mm
DIE_SIZE_X	Die size X	A[1,6]	micron
DIE_SIZE_Y	Die size Y	A[1,6]	micron
MULTI_DIE	Multi probing number	A[1,3]	-
REFERENCE_DIE_COORD_X	Reference die coordinator X	A[1,4]	-
REFERENCE_DIE_COORD_Y	Reference die coordinator Y	A[1,4]	-
OVER_DRIVE	Over drive value	A[1,4]	micron
FLAT_ANGLE	Flat orientation	A[1,3]	degree
FLAT_TYPE	FLAT or NOTCH	A[1,5]	-
HOT_CHUCK	Flag of hot chuck usage	A[2,3] “ON” or “OFF”	-
HOT_CHUCK_TEMP	Hot chuck temperature	A[1,4]	Celsius
HOT_CHUCK_TOLE	Hot chuck tolerance	A[1,3]	Celsius
PARAM_RECORDnn	Sub-parameter record nn	A[ ]	-

9 Map Data

9.1 This section defines handling of map data in the PSEM equipment. The contents of map data are not defined here. The specification in this section is provisional. This will be revised in the near future.

9.2 *Use of Map Data*

9.2.1 Map data is divided into two groups: result data which is reported to the host when processing of each wafer is completed and instruction data which is instructed by the host in a unit of wafer at the time of re-inspection or marking.

9.3 *Structure of Map Data*

9.3.1 The map data has a list structure and the result data is defined by class <DVVAL> and the instruction data is defined by <CEPVAL>.

9.3.1.1 Example:

<ResultData>

L,n

1. <Data$_1$>

```
:
n. <Datan>
```

9.4 *Uploading (Reporting) Result Data*

9.4.1 Result Data is reported by S6,F11 upon completion of the inspection in each wafer.

9.4.1.1 Example:

```
L,3
  1. <DATAID>
  2. <CEID>:Wafer End
  3. L,a
       1. L,2
            1. <RPTID1>
            2. L,7
                 1. <LOTID>
                 2. <PROCID>
                 3. <IDTYP>
                 4. <MID>
                 5. <ROWCOLCT>
                 6. <REFDIEPOS>
                 7. <ResultData>
       :
       a. L,2
            1. <RPTIDa>
            2. L,b
                 1. <LOC>
                 2. <PRODID>
                 3. <WAFSIZE>
                 4. <FLATTYPE>
                 5. <FLATANGL>
                 6. <REFDIECOORD>
                 7. <BINLIST>
                 :
                 b. <Vb>
```

9.5 *Downloading Instruction Data*

9.5.1 If the past inspection result is required in processing a wafer, the equipment obtains instructed data from the host in the following procedure.

Comment	*Host*		*Equipment*	*Comment*
				Transfer a wafer. The equipment is ready to receive previous result data for a wafer concerned.
		←	S6,F11	“Waiting Previous Data (wait for reception of previous result data)” event report.
Check event.	S6,F12	→		
Instruction data download (PRE-DATA_DOWNLOAD)	S2,F49	→		
		←	S2,F50	Reception response. The processing is performed based on instruction data.

9.5.2 An example of Waiting Previous Data event report S6,F11 in the procedure above is shown below:

9.5.2.1 Example:

S6,F11
    L,3
        1. <DATAID>
        2. <CEID> :Waiting Previous Data
        3. L,2
            1. <RPTID1>
            2. L,4
                1. <LOTID> :Prober Job ID
                2. <PROCID>
                3. <MID>
                4. <IDTYP>

9.5.3 An example of remote command S2,F49 used in the procedure above is shown below.

9.5.3.1 Example:

S2,F49
    L,4
        1. <DATAID>
        2. <OBJSPEC> :a null length item.
        3. < RCMD> :“PRE-DATA_DOWNLOAD”
        2. L,n
            1. L,2
                1. <CPNAME$_1$>
                2. <CEPVAL$_1$>
            :
            n. L,2
                1. <CPNAME$_n$> :PreviousResultData
                2. L,b
                    1. <CPVAL$_{n1}$>
                    :
                    b. <CPVAL$_{nb}$>

9.6 *Map Data Item Variable Table*

Table 11 Map Data Item Variable Table

Variable Name	*Description*	*Format*	*Comments*
LOTID	Lot ID (Prober Job ID)	A[30]	
PROCID	Process ID	A[20]	
LOC	Cassette location	U1	
PRODID	Product name (i.e., Device type)	A[24]	
SLOTNO	Slot position in the cassette	A[2]	MID
WAFERNO	Wafer number	A[2]	MID
WAFERID	Wafer ID	A[32]	MID
IDTYP	ID type to recognize a wafer.	A[8]	“SLOTNO” or “WAFERNO” or “WAFERID”
WAFSIZE	Wafer size	A[3]	Unit is mm
FLAT	Flat or Notch	A[5]	“FLAT” or “NOTCH”
FLATANGLE	Flat angle	A[3]	Range from “000” to “359”. Unit is degree.
ROW	Row count	U2	
COLUMN	Column count	U2	

DIESIZE_X	Die Size X	A[1,6]	Unit is micron
DIESIZE_Y	Die Size X	A[1,6]	Unit is micron
REFDIECOORD_X	X coordinator of reference die	A[1,4]	
REFDIECOORD_Y	Y coordinator of reference die	A[1,4]	
REFDIEPOS_X	X address of reference die from wafer center	I4	Unit is micron
REFDIEPOS_Y	Y address of reference die from wafer center	I4	Unit is micron
BINLIST	Bin value array containing pass/fail information.	B[n]	
ResultData	Result data	B[m]	

NOTE 1: One of these three OPT items needs to be specified.

9.6.1 The data structure of ResultData is selectable with soft-switch as below:

(i) X,Y,BIN,...,X,Y,BIN

(ii) X,Y,N,BIN,BIN,...,BIN

(iii) BIN,BIN,...,BIN

9.6.2 The BIN data is a binary array and defined by an equipment supplier. For example, BIN data may include an attribute of die (skip, on-wafer, etc.), pass or fail information and bin code.

9.7 *Data Item Variable Table*

Table12 Data Item Variable Table

Variable Name	*Description*	*Class*	*Format*	*Comments*
BinType	Constant which specifies the kind of the data structure of ResultData.	ECV	U1	0= X, Y, BIN, ..., X, Y, BIN 1= X, Y, N, BIN, BIN, ..., BIN 2= BIN, BIN, ..., BIN

10 Remote Commands

10.1 The purpose of this section is to identify remote commands, command parameters, and valid commands versus states in the processing state models. The specification in this section is provisional. This will be revised in the near future.

10.2 *Requirements*

10.2.1 The prober must support the GEM-required remote commands. (Some of the GEM required remote commands are restated here to define PSEM specific requirements.)

10.2.2 All the remote commands defined by PSEM are required.

10.2.3 The alphanumeric strings defined by PSEM for remote commands (RMCD) and command parameter (CPNAME) are required.

10.2.4 If additional remote commands are supported, then the “Remote Command Versus Valid States” matrix must be generated for these additional commands. Place an “X” in the table for each state in which a given command is valid.

10.3 *Remote Commands Descriptions*

10.3.1 *ABORT* — This command terminates the current processing. ABORT makes no guarantee about completion of the current process.

10.3.2 *JOB_CANCEL* — Instruct to delete Prober Job before starting processing.

10.3.3 *JOB_CREATE* — Instruct to create Prober Job in batch processing unit (usually, unit of one cassette). This allows management data for batch processing unit to be instructed to the prober.

10.3.4 *PRE-DATA_DOWNLOAD* — Downloads previous result data which instructs the details of processing for a wafer.

10.3.5 *ONLINE-LOCAL* — Change the control state from On-Line Remote to On-Line Local.

10.3.6 *ONLINE-REMOTE* — Change the control state from On-Line Local to On-Line Remote.

10.3.7 *PAUSE* — Instructs the equipment to pause the processing. This command puts the prober into PAUSING state when the current operation is completed.

10.3.8 *PP-SELECT* — This command instructs the prober to copy the indicated Process Program from non-volatile storage to the prober's Process Program execution area.

10.3.9 *RESUME* — Instructs the equipment in pause to resume operation. This command makes the equipment resume the processing from a point where the processing PAUSED.

10.3.10 *START* — Instructs to start Prober Job.

10.3.11 *STOP* — Instructs the equipment to stop the processing. This command completes the current processing unit, stops the equipment in safe state, and puts the equipment back to IDLE state. STOP has an intention of causing a normal completion after the current unit is completed. Also, whether the processing unit is die or wafer can be specified by the equipment constant Stop Unit.

10.4 *Parameter Related to Remote Command*

Table 13 Description of Remote Command

Command Name	*Command Parameter*			
	Name	*OPT/REQ*	*Description*	*Format*
ABORT			No parameter.	
JOB_CANCEL	ProberJobID	REQ.	ID of deleted Prober Job	A[30]
JOB_CREATE	ProberJobID	REQ.	ID of created Prober Job (Used as lot ID.)	A[30]
	LOC	REQ.	Location number of the cassette in which processed wafers are placed.	B
	PRODID	OPT	Product name i.e., Device type	A[24]
	PPID	OPT	Product type master record name. Unless otherwise specified, use the current PPID.	A[]
	NO-OF-WAFER	OPT	Number of wafers held in the cassette (regardless of whether the wafers are subject to processing or not).	A[20]
	SLOT-ORD	OPT	Specify the wafer pick-up order from the cassette.	BOOL
	SLOT-INFO	OPT	Set a wafer ID and whether a wafer is subject to processing or not. Example: L[25,26] 1. L[2] 1. A[1,28] ; wafer ID 2. B ; whether a wafer is subject to processing or not. : n. L[2] 1. A[1,28] ; wafer ID 2. B ; whether a wafer is subject to processing or not. (Notes) n = 25 or 26	L[25,26]

Command Name	Command Parameter			
	Name	*OPT/REQ*	*Description*	*Format*
PRE-DATA_DOWNLOAD	ProberJobID	REQ.	Prober Job ID	A[30]
	PROCID	REQ.	Process ID	A[20]
	LOC	OPT	Port number of the cassette in which wafers to be processed are placed.	B
	PRODID	OPT	Product name (i.e., Device type)	A[24]
	SLOTNO	OPT (See NOTE 1.)	Slot number in which the wafer is held.	A[2]
	WAFERNO	OPT (See NOTE 1.)	Wafer number set by the host or operator.	A[2]
	WAFERID	OPT (See NOTE 1.)	Wafer ID read by OCR.	A[28]
	IDTYP	REQ.	ID type to recognize a wafer.	A[8]
	WAFSIZE	OPT	Wafer size	A[3]
	FLAT	OPT	Flat or Notch	A[5]
	FLATANGLE	OPT	Flat angle	A[3]
	ROW	REQ.	Row count	U2
	COLUMN	REQ.	Column count	U2
	DIESIZE_X	OPT	X die size	A[6]
	DIESIZE_Y	OPT	Y die size	A[6]
	REFDIECOORD_X	REQ.	X coordinator of reference die	A[4]
	REFDIECOORD_Y	REQ.	Y coordinator of reference die	A[4]
	REFDIEPOS_X	REQ.	X address of reference die from wafer center	I4
	REFDIEPOS_Y	REQ.	Y address of reference die from wafer center	I4
	BINLIST	OPT	Bin value array containing pass/fail information.	B[n]
	PreviousResultData	REQ.	Previous result data information	L[n]
ONLINE-LOCAL			No parameter	
ONLINE-REMOTE			No parameter	
PAUSE			No parameter	
PP-SELECT	PPID	REQ.	Product type master record name.	A[]
RESUME	Resume-Die	OPT	Specify which die to restart the processing (e.g., last die, current die, next die).	B
START	ProberJobID	REQ.	ID of Prober Job to be started.	A[30]
STOP			No parameter	

NOTE 1: At least one of <SLOTNO>, <WAFERNO>, and <WAFERID> need to be set.

10.5 *Remote Commands and PSEM Process Model Mapping*

10.5.1 Each remote command either can or cannot be executed depending on a state other than the control state.

10.5.2 The following table shows remote commands and the relationship between process state to be operated by these commands and Prober Job state.

Table 14 Remote Command vs. Process State/Prober Job State

	Command Name										
	STOP	START	RESUME	PP-SELECT	PAUSE	ONLINE-REMOTE	ONLINE-LOCAL	PRE-DATA_DOWNLOAD (See NOTE 3.)	JOB_CREATE	JOB_CANCEL	ABORT
PROCESSING STATE											
INIT											
IDLE				X (See NOTE 1.)		X (See NOTE 2.)	X (See NOTE 2.)				
IDLE with ALARMS											
MAINTENANCE											
PROCESSING ACTIVE											
...PROCESS											
......SETTING UP	X				X						X
......EXECUTING	X				X						X
...PAUSE											
......PROCESS PAUSE											
.........PAUSING	X										X
.........PAUSED	X		X								X
.........CHECKING	X										X
.........PAUSED SETTING UP	X										X
......ALARM PAUSED	X										X
...STOPPING											X
...ABORTING											
Prober Job STATE											
Undefined				X (See NOTE 1.)		X (See NOTE 2.)	X (See NOTE 2.)		X		
JOB CREATED		X								X	
JOB ACTIVE											
...JOB SET UP								X (See NOTE 3.)			
...JOB PROCESSING								X (See NOTE 3.)			(X)
JOB STOPPING											
JOB ABORTING											

NOTE 1: Both IDLE and Undefined need hold true for PP-SELECT.

NOTE 2: Both IDLE and Undefined need hold true for ONLINE-REMOTE and ONLINE-LOCAL.

NOTE 3: PRE-DATA_DOWNLOAD is valid when Ready to Receive Previous Data event is reported.

10.6 *Restriction on the Operator by Control States*

10.6.1 For the remote commands, the operator of the prober or the host is restricted by the control states of the equipment.

Table 15 Table of Restrictions on the Operator by Control States

Remote Commands	*Operator*		*Host*	
	LOCAL	*REMOTE*	*LOCAL*	*REMOTE*
JOB_CREATE	O	X	O	O
PP-SELECT	O	X	O	O
PRE-DATA _DOWNLOAD	X	X	O	O
JOB_CANCEL	O	X	O	O
START	O	X	X	O
PAUSE	O	O	X	O
RESUME	O	O	X	O
STOP	O	O	X	O
ABORT	O	O	X	O
ONLINE-LOCAL	X	O	X	O
ONLINE-REMOTE	O	X	O	X

O: Operation is allowed.
X: Operation is prohibited.

11 Scenario

11.1 The purpose of this section is to document a typical PSEM specified operation scenario.

11.2 *From Power-On to Online Remote*

11.2.1 A typical scenario of transition from equipment power-on to online remote is shown below.

Comment	*Host*		*Equipment*	*Comment*
				(Equipment power-on)
				(Equipment initialization operation)
		←	S1,F13	Communication establishment request
Communication establishment request confirmation	S1,F14	→		
				(Press the online transition switch.)
		←	S1,F1	Are You There Request
Online data	S1,F2	→		
				(Online transition is completed.)
		←	S6,F11	Send ONLINE-REMOTE transition event report
Confirm event report	S6,F12	→		
		←	S6,F11	Send IDLE transition event report
Confirm event report S6,F12	S6,F12	→		

11.3 *1 Lot Processing in Online Remote*

11.3.1 A typical scenario from 1 lot processing instruction to processing completion in online remote is shown below.

Comment	*Host*		*Equipment*	*Comment*
				ONLINE-REMOTE IDLE
Send JOB_CREATE command	S2,F49	→		
		←	S2,F50	Confirm host command
		←	S6,F11	Send Prober Job Created event report
Confirm event report	S6,F12	→		
				(Carry in cassette)
		←	S6,F11	Send material carry-in event report
Confirm event report	S6,F12	→		
Send START command	S2,F49	→		
		←	S2,F50	Confirm host command
		←	S6,F11	Send Prober Job Started event report
Confirm event report	S6,F12	→		
		←	S6,F11	Send SETTING UP transition event report
Confirm event report	S6,F12	→		
				(Equipment setup is started.)
				(Equipment setup is completed.)
		←	S6,F11	Send Enter Processing event report
Confirm event report	S6,F12	→		
		←	S6,F11	Send EXECUTING transition event report
Confirm event report	S6,F12	→		
				[DO] "wafer count times"
				(Wafer load is completed.)
				[IF]
				Is Instruction data required?
				[THEN]
		←	S6,F11	Send Waiting Previous Data event report
Confirm event report	S6,F12	→		
Send PRE-DATA_DOWNLOAD command	S2,F49	→		
		←	S2,F50	Confirm host command
				[END_IF]
				(Wafer processing is started.)
				(Wafer processing is completed.)
		←	S6,F11	Send wafer end event report (Result Data)
Confirm event report	S6,F12	→		
				(Wafer unload is completed.)
				[END_DO]
		←	S6,F11	Send End Processing event report
Confirm event report	S6,F12	→		
		←	S6,F11	Send IDLE transition event report
Confirm event report	S6,F12	→		
				(Carry out cassette)
		←	S6,F11	Send material carry-out event report
Confirm event report	S6,F12	→		

NOTE 1: Each event report send order in Prober Job Started and SETTING UP transition, Enter Processing and EXECUTING transition, and End Processing and IDLE transition may be inverted.

12 GEM Addition Request

12.1 The purpose of this section is to specify all GEM addition requests which are required to support the equipment of this class.

12.2 *Requirements*

12.2.1 GEM addition requests required of PSEM are as shown below:

- Establish Communications,
- Dynamic Event Report Configuration,
- Variable Data Collection,
- Status Data Collection,
- Alarm Management,
- Remote Control,
- Equipment Constants,
- Process Program Management,
- Equipment Terminal Services,
- Clock,
- Spooling, and
- Control (host-initiated).

SEMI E93-0200
PROVISIONAL SPECIFICATION FOR CIM FRAMEWORK ADVANCED PROCESS CONTROL COMPONENT

This provisional specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on October 21, 1999. Initially available at www.semi.org January 2000; to be published February 2000. Originally published September 1999.

1 Purpose

1.1 The Advanced Process Control (APC) component supports the Process Machine component's execution of process machine jobs by optimizing machine-specific settings for the current material and machine state to achieve desired process effects. It may also detect faults in processing and recommend an appropriate response to the Process Machine component. An APC component may include statistical process control, model-based process control, multi-variate analysis, trace analysis, fault pattern matching, or other analysis techniques.

1.2 The Advanced Process Control component specification does not constrain implementation approaches. However, subcomponents are defined to enable integration with different types of analysis and computation mechanisms, specifically those provided in other software systems. The subcomponents are defined principally along boundaries expected to align with products addressing process control in the factory. The number of subcomponents offered by suppliers may vary, with some suppliers supporting all of the subcomponent interfaces and others focusing on a specific subset of subcomponents. These subcomponent boundaries provide the customer with added flexibility to integrate and use multiple suppliers' products.

1.3 This specification provides the interfaces required by Manufacturing Execution Systems to:

- Define control data structures to support control algorithms.
- Launch, coordinate, and monitor the execution of control processing and analysis algorithms.

2 Scope

2.1 The technical content of this ballot addresses the portion of the CIM Framework domain concerned with Advanced Process Control (APC). Compliant implementations are free to use other components defined in the CIM Framework via their standard interfaces. They are also free to use components that are not defined by the CIM Framework standards as long as they don't conflict with the standard. The specific details of these interactions are implementation level choices. The key elements of the APC Component shown here are:

2.1.1 *APC Control Execution Component* — The component that executes control strategies.

2.1.2 *Algorithm Execution Interface Group* — The group of interfaces that abstracts external computation facilities which perform processing or calculations. The execution model abstracts an Algorithm, representing a computation, and an Algorithm Executor, responsible for performing the computation.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The CIM Framework Advanced Process Control Component is at the supervisory level, meaning this is a MES specification, not a specification for tool-level, real-time control. For example, the proposed interfaces support a control granularity no finer than wafer-to-wafer adjustments. The interfaces support APC applications such as fault detection and classification, run-to-run feedback, and feed-forward control spanning one or more process tools. The interfaces are very high-level such that a factory CIM system can communicate with a tool or set of tools providing process control while remaining unaware of the details of how that control is carried out.

3.2 *Provisional Status*

3.2.1 This specification is designated as provisional due to known areas that need to be completed. The following items summarize the deficiencies of the provisional specification to be addressed before a subsequent ballot to upgrade it to full standard status.

3.2.2 *Dependence on Global Declarations and Abstract Interfaces* — Components of this document depend on global declarations and on abstract interfaces for material, resource, and job concepts. Work is currently underway to standardize these declarations and interfaces.

3.2.3 This specification will require alignment with future specifications from SEMI expected to specify standards for data collection.

3.2.4 This specification will require a standard service for document management that provides operations for the manipulation of versioned documents containing stored forms of APC objects. This service is anticipated as part of a future CIM Framework ballot. When a document management specification is adopted by SEMI, the APC Component can be enhanced to use the standard document management interfaces.

3.2.5 This specification will require additional operations for interactions with a component for MES-level access to data collection plans. Interfaces for manipulating data collection plans are anticipated as part of a future CIM Framework ballot. When they are adopted by SEMI, this specification can be enhanced to use those standard data collection plan interfaces.

3.2.6 This specification will require additional operations for interactions with a component to manage the flow of data from the sources where the data is collected to the data sinks where that data is used. These data flow interfaces are anticipated as part of a future CIM Framework ballot. When they are adopted by SEMI, this specification can be enhanced to use those standard data flow interfaces.

3.2.7 Parts of this specification will require additional declarations of the specific property names and value datatypes for arguments that include name-value pairs.

3.2.8 The events identified in Section 6.1 require more detailed specification to identify the event subject strings, filterable data, and event news contents.

3.2.9 The Algorithm Execution interfaces will require alignment with future architecture extensions for CIM Framework services that are provided without full component management lifecycle support.

4 Referenced Standards

4.1 *SEMI Standard*

SEMI E81 — Provisional Specification for CIM Framework Domain Architecture

4.2 *Other Standards*

ISO/IEC International Standard 14750 (also ITU-T Recommendation X.920): Information Technology – Open Distributed Processing – Interface Definition Language[1]

UML Notation Guide, Version 1.1, document number ad/97-08-05, Object Management Group[2]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Advanced Process Control (APC)* — the manufacturing discipline for applying control strategies employing analysis and computation mechanisms to recommend optimized machine settings and detect faults in processing.

5.2 *control strategy* — a sequence of actions performed in response to a factory event to achieve an Advanced Process Control objective of process optimization or fault detection. Control Strategies are implementation specific.

6 Requirements

6.1 The following sections provide the interface design and description of the interfaces that comprise the APC Component. The model notation used is the Unified Modeling Language (UML). UML is documented in the *UML Notation Guide*. The details of each interface are supplied using standard IT-ODP-IDL. Conformant implementations of the APC Component or the Algorithm Execution interfaces shall provide support for all elements of the IDL specifications and the semantics provided in the UML models. Conformant implementations are not constrained to any specific implementation approach, provided that a mapping to the IDL specification is documented.

6.1.1 Figure 1 shows the Advanced Process Control Control Execution component and the Algorithm Interface Group in the context of other CIM Framework components. The Process Machine component will be the primary client of APC services, requesting APC results as part of process setup and monitoring. The Data Collection Plan and Dataflow components provide mechanisms to specify APC data collection needs and to supply collected information to APC. APC can be a client of other CIM Framework components, such as Product Management and Specification Management for modifying APC behavior based on prior and planned subsequent processing for the process material.

1 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland

2 UML Notation Guide v1.1 is available to the general public at http://www.omg.org/cgi-bin/doclist.pl, +1.508.820.4300, Object Management Group, Inc., Framingham Corporate Center, 492 Old Connecticut Path, Framingham, MA 01701.

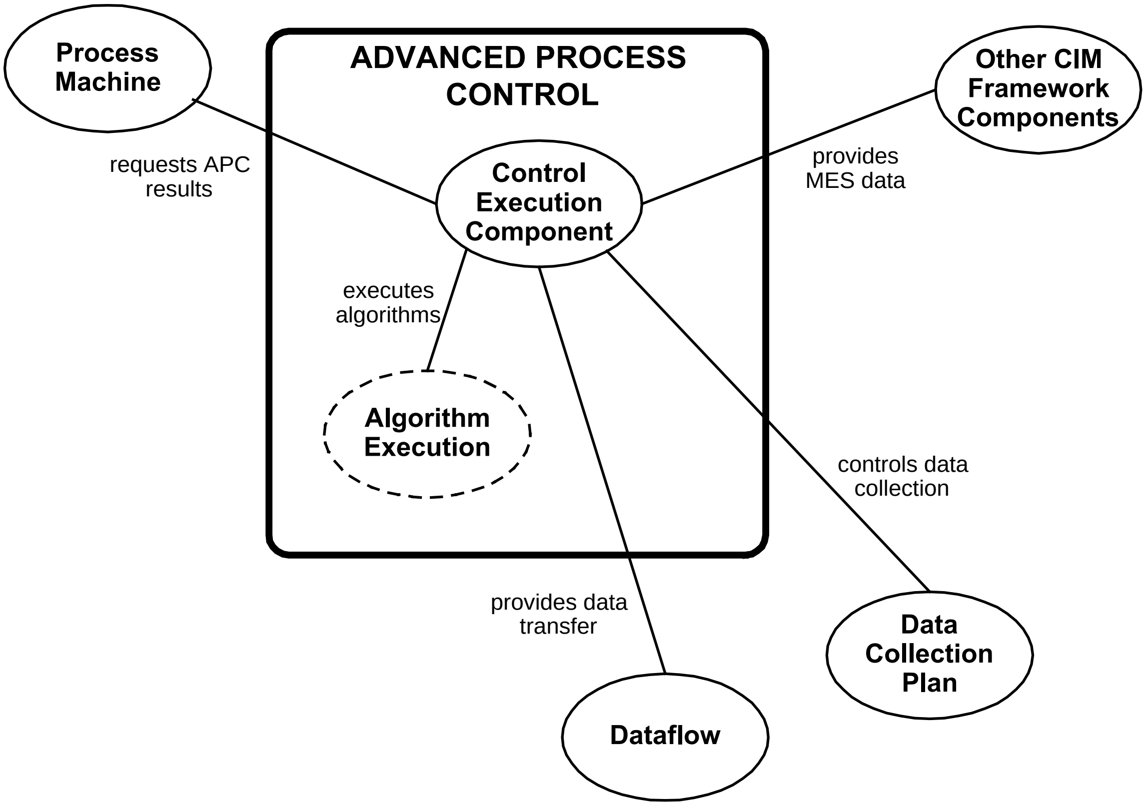

Figure 1
Advanced Process Control Component Context

6.1.2 The Algorithm Execution interface group is shown in dotted lines to indicate that the Algorithm Execution interface group is not a *component*, but rather a collection of interfaces that can be used in the specification of other components.

6.2 *APC Control Execution Component*

6.2.1 This component contains the main interfaces used to invoke APC functionality and the objects that describe and direct process control. Through the control component a client such as another MES component can request APC actions and receive results based on the execution of the APC action.

6.2.2 The APC Control Execution Component uses the CIM Framework job architecture, which is characterized by a JobSupervisor that handles requests to run Jobs. In the APC's Control Execution Component, Jobs typically return results. Results are represented by the Results type defined in the Job Architecture.

6.2.3 The major concepts defined by the APC Control Execution Component derive the following interfaces:

6.2.3.1 *ControlExecutionManager* — The interface used to initiate APC actions. A typical use would be by a process machine as part of its setup for a process job. The ControlExecutionManager creates and implicitly starts ControlStrategyJobs.

6.2.3.2 *ControlStrategyJob* — A unit of work performed by the APC Control Execution Component. The ControlStrategyJob performs some or all of the actions that make up an APC control strategy. The ControlStrategyJob is central to the APC Control Execution Component. It logically orchestrates interaction with other framework services such as AlgorithmExecutors. Dependencies on other interfaces, such as Algorithm Execution or access to process data, are implementation defined.

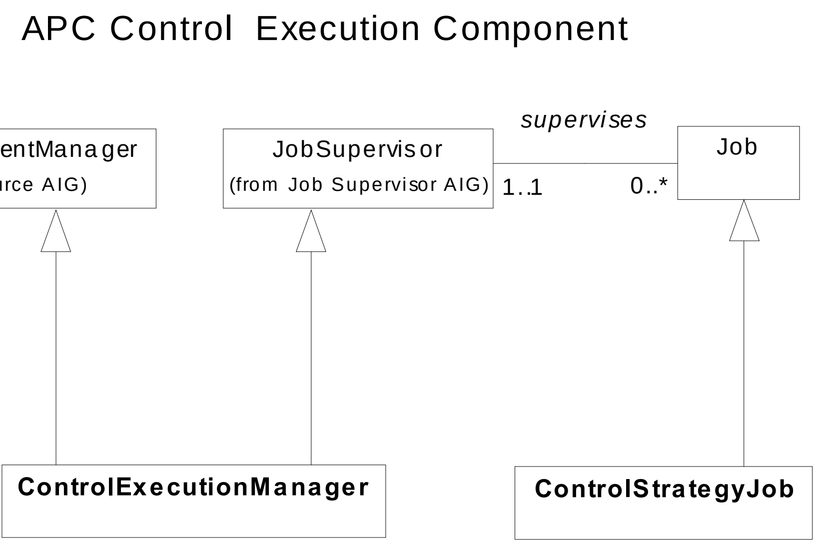

Figure 2
APC Control Execution Information Model

6.2.4 The following subsections define the interfaces for the APC Control Execution Component.

6.2.5 *ControlExecutionManager Interface*

Module:	APCControlExecution
Interface:	ControlExecutionManager
Inherited Interface:	AbstractIF::JobSupervisor, FactoryOperations::ComponentManager

```
interface ControlExecutionManager : AbstractIF::JobSupervisor,
        FactoryOperations::ComponentManager {
```

Description:	The ControlExecutionManager creates and manages ControlStrategyJobs. The behavior of the Control Execution Manager is specified by the inherited operations from JobSupervisor and Component Manager. Calls to the inherited requestJob and runJob operations from JobSupervisor shall include the value “ControlStrategyJob” for the JobType property of the JobSpecification.
Type Declarations:	None.
Exceptions:	None.
Published Events:	None.
Provided Services:	None.
Contracted Services:	None.
Dynamic Model:	None.

```
}; // ControlExecutionManager
```

6.2.6 *ControlStrategyJob Interface*

Module:	APCControlExecution
Interface:	ControlStrategyJob
Inherited Interface:	AbstractIF::Job

```
interface ControlStrategyJob : AbstractIF::Job {
```

Description: The ControlStrategyJob executes control actions such as settings, calculations, fault detection, or data collection. It is a “Job,” executing whatever actions are specified by a control strategy.

A ControlStrategyJob may return results which are accessed with the inherited operation getJobResults or through a ControlStrategyJobStatusEvent that contains the results.

Exceptions: None.

Published Events: This section describes the intent of the APC events and the data that should be provided in the APC events. Specific declaration of these events will be added in a future revision of this standard.

Information specified for an event is not required. The events will be flexible and allow additional fields to be added. An implementation may choose to provide more or less information for these events.

ControlStrategyJobStatusEvent

The ControlStrategyJobStatusEvent is issued by ControlStrategyJobs (refer to definition in Section 6.2) to indicate a change in job status. The event would contain a reference to the ControlStrategyJob that initiated the event so that clients can query the Job for additional information as well as an indication of the type of status change that occurred. The status change could indicate the availability of results, in which case the event would contain the Job results. The status change could indicate a change in Job state, in which case the event would contain an indication of the Job state change.

ApplicationEvent

An ApplicationEvent is an Event published by a ControlStrategyJob to indicate an important milestone or status during the execution of the control strategy. ApplicationEvents can be used to indicate the detection of a fault or provide other kinds of notification. ApplicationEvents provide a mechanism to convey application information that goes beyond the specifics of the ControlStrategyJob state changes.

Provided Services: None.

Contracted Services: None.

Dynamic Model: None.

```
}; // ControlStrategyJob
```

6.3 *Algorithm Execution Interface Group*

6.3.1 The Algorithm Execution Interface Group provides interfaces that encapsulate interaction with computational services. Typically these services are to provide an APC compliant interface to a non-APC compliant computational service. The Algorithm Execution Interface Group defines a synchronous “call/return” style interaction for an Algorithm. The requestor of the algorithm execution calls the interface and waits for the completion of the calculation and the return of the results. This interaction pattern is the most common form of interaction between an APC application and an Algorithm. Support for other forms could be vendor defined or added in future revisions of this standard.

6.3.2 Within the Algorithm Service the following concepts are defined:

6.3.2.1 *AlgorithmExecutor* — A wrapper for an external computation engine. The AlgorithmExecutor creates AlgorithmJobs to perform calculations within the computation engine.

6.3.2.2 *AlgorithmJob* — Responsible for translating the specifications defined within an Algorithm into a form that is usable by the wrapped application.

6.3.2.3 *Algorithm* — A specification of actions that is interpreted by an AlgorithmJob. An Algorithm has a collection of AlgorithmContents that define the algorithm.

6.3.2.4 *AlgorithmContents* — AlgorithmContents are specific attributes of an Algorithm. AlgorithmContents can be such things as a command script to be dynamically interpreted by an application, configuration values used for calculations, and capabilities required from the AlgorithmExecutor in order to execute the Algorithm.

6.3.3 Executing an Algorithm requires two operations. The first is to create an AlgorithmJob with the AlgorithmExecutor. The client supplies the Algorithm. Once the AlgorithmJob is created it is assumed to be initialized and ready to run. *AlgorithmJob.execute* causes the Algorithm to be interpreted with the results of the calculations being returned.

6.3.4 The AlgorithmExecutor is isolated from the APC Component to allow suppliers of Algorithm products to build custom versions to enable their products for framework applications. In a typical APC scenario the ControlStrategyJob would be a client of the AlgorithmExecutor. ControlStrategyJobs would invoke AlgorithmExecutors, passing them Algorithms.

6.3.5 This specification requires any implementation of a conformant Algorithm to support an AlgorithmExecutor interface. The AlgorithmExecutor interface would be implemented by an external component that provides the operations enabling the execution of an Algorithm.

6.3.6 Specification of the AlgorithmContents, management of Algorithms and AlgorithmContents and how clients locate AlgorithmExecutors is vendor defined. This specification intends that Algorithms and AlgorithmContents be managed through separate document management and version control components as they become available.

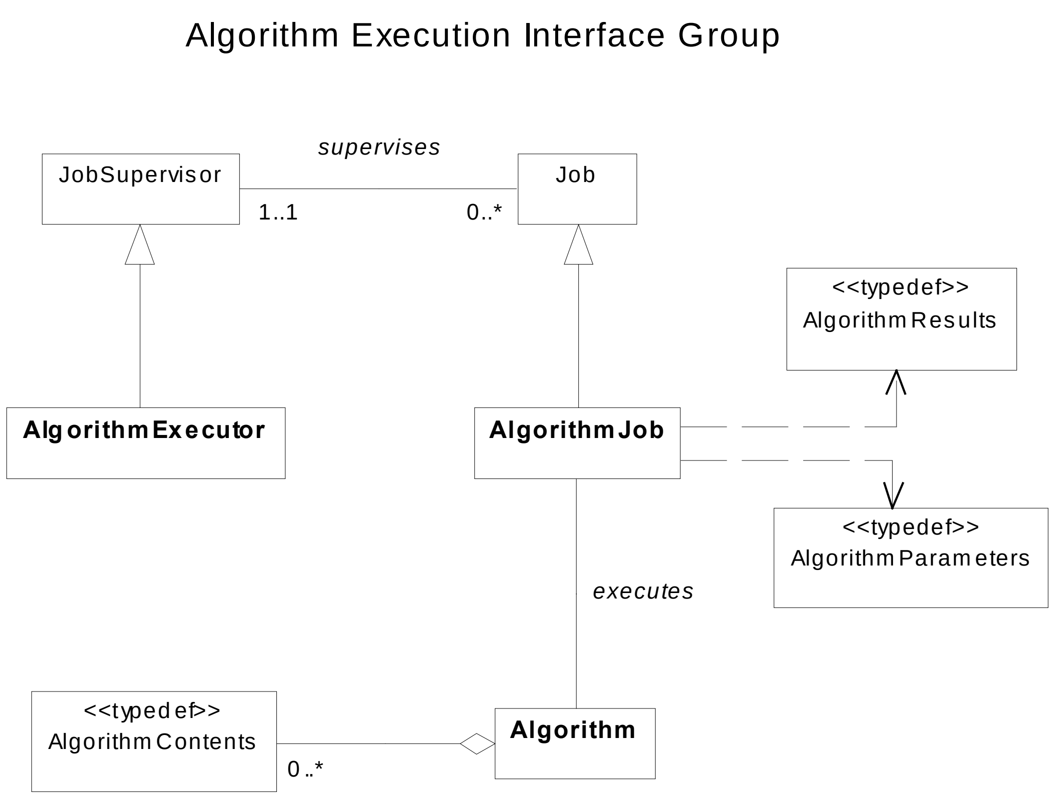

Figure 3
Algorithm Execution Information Model

6.3.7 *APCAlgorithm Declarations*

Module: APCAlgorithm

Description: These declarations are used by the Algorithm Execution Interfaces.

Declarations:

/* Data values returned by an Algorithm */

```
typedef any AlgorithmResults ;
```

/* Data values input to an Algorithm */

```
typedef any AlgorithmParameters ;
```

/* An attribute of the Algorithm. Could represent an algorithm source, compiled algorithm, etc. */

```
typedef any AlgorithmContents ;

typedef Global::Properties AlgorithmContentsSequence ;
```

/* A specification of the AlgorithmContents Type. */

```
typedef string AlgorithmContentsType;
```

/* Indicates the Algorithm did not contain content with the type */

```
exception NoContentForTypeSignal {
        string errorMessage;
        AlgorithmContentsType aType; } ;

typedef sequence <Algorithm> AlgorithmSequence;
```

6.3.8 *AlgorithmExecutor Interface*

Module: APCAlgorithm

Interface: AlgorithmExecutor

Inherited Interface: AbstractIF::JobSupervisor

```
interface AlgorithmExecutor : AbstractIF::JobSupervisor {
```

Description: The AlgorithmExecutor provides execution environments for application Algorithms. Execution of the Algorithm is performed by the AlgorithmJob. The behavior of the AlgorithmExecutor is specified by the inherited operations from JobSupervisor. Calls to the inherited requestJob and runJob operations from JobSupervisor shall include the value "AlgorithmJob" for the JobType property of the JobSepecification.

AlgorithmExecutor::requestAlgorithmJob provides the same functionality as AlgorithmExecutor::requestJob except requestAlgorithmJob returns a Job with a type of AlgorithmJob and requestJob returns a Job with the type AbstractIF::Job.

Exceptions: None.

Published Events: None.

Provided Services:

/* Creates a new AlgorithmJob to execute the Algorithm

A Job Property with the tag "Algorithm" and a value with type Algorithm is required.

A Job Property with the tag "Parameters" and a value AlgorithmParameters is optional.

*/

```
AlgorithmJob requestAlgorithmJob (
        in Global::Properties aJobSpecification,
        in AbstractIF::JobRequestor aJobRequestor)
        raises (Global::FrameworkErrorSignal,
        AbstractIF::JobSuperviso::JobRejectedSignal);
```

/* Creates an AlgorithmJob and performs execute. The Job is managed internal to the AlgorithmExecutor.

A Job Property with the tag "Algorithm" and a value with type Algorithm is required.

A Job Property with the tag "Parameters" and a value AlgorithmParameters is optional. If Parameters are provided, the AlgorithmJob execute operation is performed on behalf of the client. No explicit call to execute is required in this case.

*/

```
AlgorithmResults runAlgorithmJob (
        in Global::Properties aJobSpecification )
        raises (UnableToExecuteSignal,
        Global::FrameworkErrorSignal,
        AbstractIF::JobSupervisor::JobRejectedSignal );
```

Contracted Services: None.

Dynamic Model: None.

```
}; // AlgorithmExecutor
```

6.3.9 *AlgorithmJob Interface*

Module: APCAlgorithm

Interface: AlgorithmJob

Inherited Interface: AbstractIF::Job

```
interface AlgorithmJob : AbstractIF::Job {
```

Description: The AlgorithmJob is responsible for execution of an Algorithm. The AlgorithmJob is initiated by an AlgorithmExecutor. The behavior of the AlgorithmJob is specified by the inherited operations from Job along with the operation defined below.

Exceptions: None.

Published Events: None.

Provided Services:

/* Executes the Algorithm and returns the result. Note: successful return from "execute" does not imply that the Job has completed. Execute is a valid operation whenever the Job is in the EXECUTING state. */

```
AlgorithmResults execute (
        in AlgorithmParameters parameters )
        raises (UnableToExecuteSignal,
        Global::FrameworkErrorSignal );
```

Contracted Services: None.

Dynamic Model: None.

```
}; // AlgorithmJob
```

6.3.10 *Algorithm Interface*

Module: APCAlgorithm

Interface: Algorithm

Inherited Interface: None.

```
interface Algorithm {
```

Description: The Algorithm encapsulates the code instructions or settings to perform a specific control calculation as specified by a specific algorithm. The Algorithm is used to incorporate algorithms developed on third-party platforms into the CIM environment for use in process control applications.

Contents of the Algorithm are defined according to the specific implementation. The format is designed to give ControlStrategies a flexible way to interact with a wide range of external applications while maintaining a simple interface.

As an example, an Algorithm could define an AlgorithmContentsType of “Data File” with a value of a string. A second AlgorithmContentsType could be “long parameter” with a value of a numeric long.

Exceptions: None.

Published Events: None.

Provided Services:

/* Returns a copy of the Algorithm “contents” (executable algorithm, source algorithm, etc.). */

```
AlgorithmContentsSequence getAllContents ()
        raises (Global::FrameworkErrorSignal);
```

/* Retrieves the “content” with the given contents type. */

```
AlgorithmContents getContentByType (
        in AlgorithmContentsType aAlgorithmContentType)
        raises (Global::FrameworkErrorSignal,
        NoContentForTypeSignal);
```

Contracted Services: None.

Dynamic Model: None.

```
}; // Algorithm
```

APPENDIX 1
COMPLETE IDL LISTING

NOTE: The material in this appendix is an official part of SEMI E93 and was approved by full letter ballot procedures on July 15, 1999.

SEMI E94-0702
PROVISIONAL SPECIFICATION FOR CONTROL JOB MANAGEMENT

This provisional specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on March 17, 2002. Initially available at www.semi.org June 2002, to be published July 2002. Originally published February 2000; previously published March 2002.

1 Purpose

1.1 This specification describes equipment provided services to the factory that supports a high level of factory automation. These services provide capabilities for the host to coordinate processing and disposition of materials on production equipment.

2 Scope

2.1 This specification may be applied to equipment that is compliant to SEMI E30 (GEM). However, it is also intended that this standard will be useful for future generation equipment interfaces that supercede SEMI E30, such as SEMI E53.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard presents a model of the ControlJob. The model delineates the services (messages) and behavior of the ControlJob. The model is protocol independent. Thus, an ancillary standard must be selected in order to provide a complete implementation.

3.2 This standard should not be applied to non-production equipment, such as, material transport systems or facilities (environmental) controllers.

3.3 *Provisional Status*

3.3.1 For this standard specification to be complete (removal of provisional status) the following areas need to be completed:

1) ControlJob to assure equivalent processing regardless of module used in multi-module equipment.

2) Complete specification of relationship to Carrier Management.

3) Standardized support for the parallel execution of ControlJobs.

4) Support for processing materials on equipment that have batch sizes that are not either multi-carrier or on which the carrier substrate location count is not an integer multiple of the batch size.

5) Possible linkages between ControlJob, material, and substrate tracking.

6) Complete work on the model for the control job queue. Additional functions and attributes for manipulating the job queue may be added.

3.4 This specification applies to equipment for which the atomic unit of material is the same for all input and output carriers on the equipment. It may not apply to equipment which would perform operations such as slicing or assembly that would require or result in different input and output material objects. This specification may not apply to equipment or equipment configurations where the equipment does not handle carriers, as in the case of a stepper or scanner in a linked photolithography cell.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E40 — Standard for Processing Management

SEMI E53 — Event Reporting

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Definitions*

5.1.1 *control job* — defines a unit of work on equipment for one or more carriers. The work is described by a set of one or more process jobs to be applied to the material contained in the carriers.

5.1.2 *de-queue* — the act of removing an item from a queue. The de-queue implies nothing about the status of the item after removal.

5.1.3 *equipment* — the intelligent system that communicates with the host.

5.1.4 *host* — the intelligent system that communicates with the equipment.

5.1.5 *life cycle* — the processes and activities of something from its beginning (creation) to its ending.

5.1.6 *multi-module equipment* — equipment that has more than one distinct processing resource (e.g., chamber).

5.1.7 *production equipment* — equipment that measures or adds value to the product.

5.1.8 *protocol independent* — for software, this means that the message descriptions are independent of delivery mechanisms.

5.1.9 *set-up* — a description of the current process capability of an equipment.

5.1.10 *substrate* — basic unit of material on which work is performed to create a product. Examples include wafers, lead frames, CD's, die, flat panel displays, circuit boards, and disks.

5.1.11 *substrate port* — the carrier location from which substrates are accessed by the equipment.

5.1.12 *uni-carrier* — term for an equipment mode of operation in which all material is returned to the source carrier after processing.

5.1.13 *user start* — activities that are initiated on a system by another system or operator.

6 Conventions

6.1 *Object Models*

6.1.1 This standard uses object models to specify the control job interface.

6.1.2 *Object Services Standard*

6.1.2.1 This document conforms to the conventions established by SEMI E39.

6.1.3 *Formal Name of an Object*

6.1.3.1 The text capitalizes formal object name references, similar to the way capitalization is normally used when discussing entities. When describing something in the general (like cities) lower case is used, but when a specific entity is of interest (New York City), then first letters are capitalized.

6.2 *State Model Methodology*

6.2.1 This document uses the Harel state chart convention for describing dynamic operation of defined objects. The outline of this convention is described in an attachment of SEMI E30. The official definition of this convention is described in "State Charts: A Visual Formalism for Complex Systems" written by D. Harel in Science of Computer Programming 8, 1987. [1]

6.2.2 The Harel convention does not have the concept of state models of "creation" and "extinction" for expressing a temporary entity. The "job" described in this document is such an entity, and a copy of the same state model is used for an independent job newly created. In this document, a circle with a black circle inside is used for expressing extinction of an entity. A filled, black circle denotes the entry to the state model (the entity creation).

6.2.3 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition table contains columns for Transition number, Previous State, Trigger, New State, Actions, and Comments. The "trigger" (column 3) for the transition occurs while in the "previous" state. The "actions" (column 5) includes a combination of:

1) Actions taken upon exit of the previous state.

2) Actions taken upon entry of the new state.

3) Actions taken which are most closely associated with the transition.

6.2.3.1 No differentiation is made between these cases.

6.2.4 The state models included in this standard are a requirement for Control Job Management compliance. A state model consists of a state model diagram, state definitions, and a state transition table. When using collection events, all state transitions in this standard, unless otherwise specified, shall correspond to collection events.

6.2.5 A state model represents the host's view of the equipment, and does not necessarily describe the internal equipment operation. When using collection events, all Control Job Management state model transitions shall be mapped sequentially into the appropriate internal equipment collection events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the Control Job Management state models for transition to another state. In the case, the equipment makes the required transition without any additional actions in this situation.

1 Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.htt

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*

6.3 *Service Message Representation*

6.3.1 Services are functions or methods that may be provided by either the equipment or the host. A service message may be either a request message, which always requires a response, or a notification message, that does not require a response.

6.3.2 *Service Definition*

6.3.2.1 A service definition table defines the specific set of messages for a given service resource, as shown in the following table:

Message Service Name	*Type*	*Description*

6.3.2.2 Type can be either "N" = Notification or "R" = Request & Response.

6.3.2.3 Notification type messages are initiated by the service provider (e.g., the equipment) and the provider does not expect to get a response from the service user. Request messages are initiated by a service user (e.g., the host). Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

6.3.3 *Service Parameter Dictionary*

6.3.3.1 A service parameter dictionary table defines the description, format and its possible value for parameters used by services, as shown in the following table:

Parameter Name	*Description*	*Format: Possible Value*

6.3.3.2 A row is provided in the table for each parameter of a service.

6.3.4 *Service Message Definition*

6.3.4.1 A service message definition table defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Res/Cnf*	*Comment*

6.3.4.2 The columns labeled REQ/IND and RSP/CNF link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication" or the request. The receiver may then send a "Response" which the original sender terms the " Confirmation".

6.3.4.3 The following codes appear in the REQ/IND and RSP/CNF columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

M	Mandatory Parameter — Must be given a valid value.
C	Conditional Parameter — May be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of the other parameter.
U	User-Defined Parameter.
-	The parameter is not used.
=	(For response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

7 Overview

7.1 This section provides an overview of the control job functionality. It does not contain the specifications which define that functionality.

7.1.1 Control jobs provide a supervisory level of control for process jobs on material processing equipment. They can be used to reduce the amount of host level interaction required for material processing. A factory host is provided with methods for instructing the equipment to provide only significant factory level events, such as, a carrier complete. The ControlJob also supplies methods for the disposition of material after processing.

7.2 *User Requirements*

7.2.1 To handle the complexity required for manufacturing, equipment must support the ability to coordinate its processing services with the factory's needs. The ControlJob provides the services that the factory needs to accomplish this coordination. The requirements that the ControlJob satisfies include: (1) a method by which the equipment coordinates related work, for instance, all process jobs associated with a carrier, and (2) a method by which the equipment can be informed of material destination after processing. The ControlJob is not a type of process job. It is not responsible for the coordination of the processing resource and the material to be processed.

7.2.2 *Initiate and Monitor Process Jobs*

7.2.2.1 ControlJobs are queued. ProcessJobs are not queued by equipment that supports control jobs, rather they are pooled waiting to be scheduled by their respective ControlJob. The ControlJob specifies the order for process jobs. The equipment follows that order as the equipment's resources become available (and when material is available).

7.3 *Supplier Requirements*

7.3.1 *Management of Process Materials*

7.3.1.1 Suppliers need to implement an operational model for managing material and processing in a manner consistent with factory expectations. For instance, the equipment must know when it is finished with a carrier so that it can either allow or signal the factory for the removal of the carrier. This standard provides mechanisms to meet this requirement. While the model implies some implementation it is only the external events that are required by this standard.

7.3.2 *Control Job Events*

7.3.2.1 Control jobs supply information to host systems as either responses to request messages or as events which are sent to the host. Typically the equipment can implement the event mechanisms either in GEM (SEMI E30) or the Event Reporting standard (SEMI E53).

7.3.2.2 All state transitions defined for state models in this document must be able to be reported by separate collection events as defined in section 6.2, State Model Methodology. The state model is the Control Job State Model (Figure 2). The data required for each state model transition event is defined per the following. This data is the minimum required per event. The host may assign other variable, as applicable, from Section 13, Variable Data, of this document, or from other equipment variable data.

7.3.2.3 The following data is required to be available for the Control Job State Model transition collection events:

CtrlJobID

7.4 *Operational Descriptions*

7.4.1 The ProcessJob as referenced in the specification of the control job model is the SEMI E40 process job. Within a ProcessJob the material processing order is managed by the equipment. For some equipment types, the user may be able to configure the material processing order. If available, this feature shall be fully documented by the supplier (see SEMI E40).

7.4.2 To support a simpler interface for single substrate processing, it is suggested to use the PRJobMultiCreate (see SEMI E40) service.

7.4.3 The use of control jobs restricts some SEMI E40 functionality. In particular, the equipment's queue management functionality for process jobs is superseded by the job order as defined in the control job.

7.4.4 The relationship between control jobs and process jobs varies by equipment type. The equipment supplier should document this relationship. In general aborting or stopping a process job does not stop or abort the control job. Equipment is responsible to disposition material correctly depending on how a process job ends. In the case of equipment types that always have a one to one relationship between a control job and a process job it may be convenient for a process job abort or stop to automatically abort the respective control job. In the same sense, if a control job specifies more than one process job, it may be convenient for an abort or stop of all process jobs to automatically abort or stop the respective control job.

8 ControlJob Object Model

8.1 This specification only standardizes the ControlJob object's interface. The other objects provide a context for the ControlJob interface. Since only the interface is standardized, it is not a requirement for equipment to implement a control job object, it is only required that the equipment provide an external interface that provides the services and behavior defined for the ControlJob.

8.2 *Material to Job Linkage*

8.2.1 The equipment has relationships with many other components not illustrated in Figure 1. In partic-ular, from its knowledge based on substrate and carrier tracking capabilities, the equipment shall connect the process job material list to the materials in the carriers that it has. It is the responsibility of the factory host to make sure that the description or identifiers of material contained in carriers can be mapped to the material identifiers in the process job definition.

8.3 *Control Jobs and Carriers*

8.3.1 A control job may specify work for several carriers. The supplier shall document the behavior of the equipment in the case where a carrier is specified for use in more than one control job.

8.4 *Attribute Definitions*

8.4.1 The attributes in Table 1 shall be accessible using the Object Services standard (SEMI E39). Object services is a set of messages which may be required of any service provider which is modeled by objects. An object model for a service provides a consistent naming convention for exchanging information between the service provider and user. Object services implementations shall be consistent with the service's object and state models. For instance, if an attribute can only be modified in a certain state, then a request to set that attribute when the model is in the wrong state shall be rejected (fail). ControlJob Attributes shall be modifiable if and only if the ControlJob is not in either the EXECUTING or COMPLETED states by using OSS to change them (see Section 14.3.1).

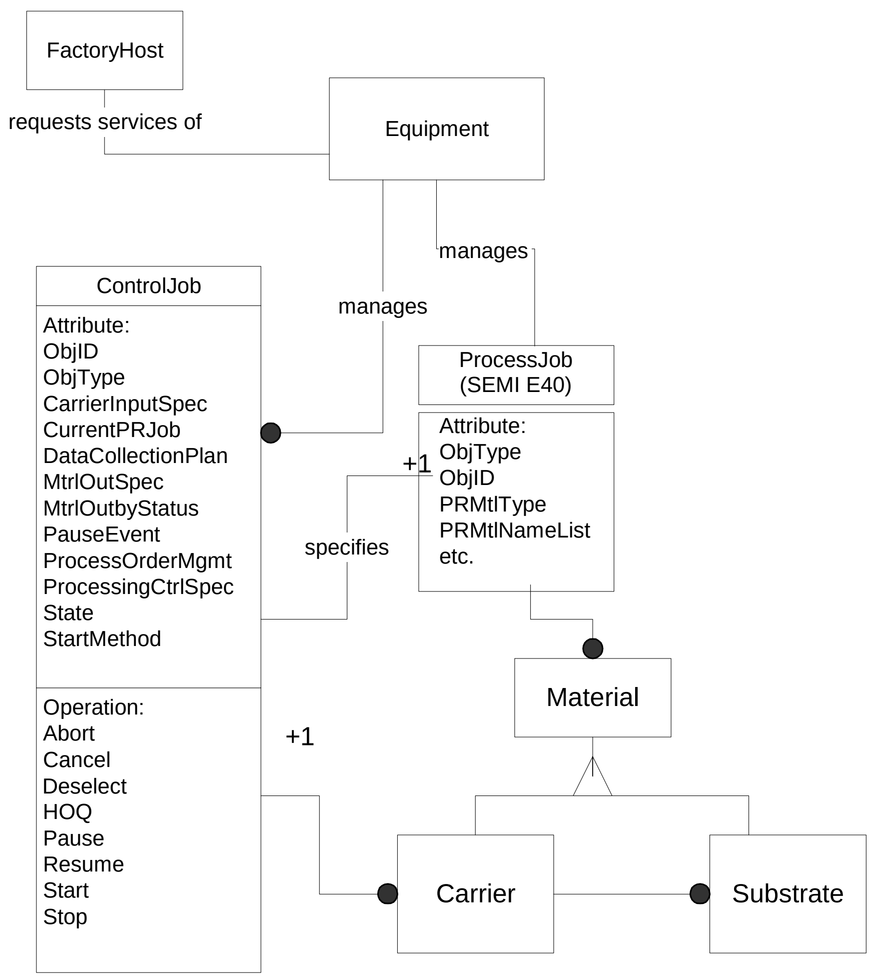

Figure 1
ControlJob Object Model

Table 1 ControlJob Attributes

Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjID	Host defined identifier of the control job.	Y	RO	Text
ObjType	Object type	Y	RO	Text = 'ControlJob'
CurrentPRJob	Holds the identifiers of any process job in the active state (i.e., in the Executing, Stopping, Aborting or Pause states).	Y	RO	(list of) PRJobID (see SEMI E40)
DataCollectionPlan	Identifier for a data collection plan to be used during execution of the control job.	N	RW	Text
CarrierInputSpec	A list of carrierID for material that will be used by the ControlJob. An empty list is allowed.	Y	RW	(list of) CarrierID
MtrlOutSpec	Maps material from source to destination after processing. For uni-carrier operation, the list shall be empty. The list shall also be empty, if CarrierInputSpec is an empty list.	Y	RW	List of Structure: SourceMap DestinationMap
MtrlOutByStatus	List structure which maps locations or Carriers where processed material will be placed based on material status.	N	RW	List of structure: MaterialStatus DestinationMap
PauseEvent	Identifier of a list of events on which the Control Job shall PAUSE.	N	RW	(list of) EventID
ProcessingCtrlSpec	A list of structures that defines the process jobs and rules for running each that will be run within this ControlJob.	Y	RW	(list of) Structure: PRJobID ControlRule OutputRule
ProcessOrderMgmt	Define the method for the order in which process jobs are initiated.	Y	RW	Enumeration: LIST ARRIVAL OPTIMIZE
StartMethod	A logical flag that determines if the ControlJob can start automatically. A user start may come through either the host connection or the operator console.	Y	RO	Boolean: TRUE – Auto FALSE – UserStart
State	The current state of the ControlJob.	Y	RO	Enumerated: per State Model

8.4.2 A number of the ControlJob attributes are composite data types. The constituent data is defined in Table 2.

Table 2 Attribute Data Definitions

Data Identifier	*Description*	*Form*
CarrierID	The identifier of a carrier that is the source or destination for substrates.	Text
ControlRule	Provides additional job control functionality. It is equipment type dependent. It may be used to modify processing based on processing results. Use of this attribute is not required for equipment, which does not support it. Suppliers shall document the use of this attribute when supported.	(list of) Structure: RuleName RuleValue
Destination	The identifier of a substrate location at which material can be placed. (Identifier should conform to standards for substrate tracking.)	Text
DestinationMap	Describes carrier positions into which finished material will be placed. If the list of carrier positions is empty, then follow sequential order of source.	Structure: CarrierID List of SubstrateLocation

Data Identifier	*Description*	*Form*
MaterialStatus	ControlJob processing assigns this value to finished material. The association of MaterialStatus to Destination enables ControlJob processing to put material at the desired destination.	Equipment dependent enumeration
OutputRule	Defines the MaterialStatus (such as Good, Reject, Aborted, Monitor, etc.) based on results of the process job.	Equipment dependent
PRJobID	A process job identifier as defined by SEMI E40. Host must supply same name in the ProcessingCtrlSpec as when it requested creation of process job. NOTE: SEMI E40 process jobs link material to a recipe.	See SEMI E40.
Rule Value	The value used by the equipment for execution of a control rule.	Equipment dependent
RuleName	Identifier of a control rule.	Text
SourceMap	Describes the locations from which material is taken for processing. If the list of location is empty, then assume the default of ascending order.	Structure: CarrierID List of SubstrateLocation
SubstrateLocation	A substrate position at a source and a destination. A carrier is an example of a multi-location destination. For a wafer carrier the SubstrateLocation is a slot number.	Numeric

8.4.3 *ControlRule*

8.4.3.1 For equipment that supports this attribute (field), the host sets this in order to achieve better host processing control capabilities. For example, the host may have previously measured characteristics of the material to be processed. A standard recipe is used based on the product and process step, but based on the measured characteristics, the application of the recipe is biased by the specified rule and the value that is passed to the rule (RuleValue). However, use of ControlRule should not be considered to be limited to only this type of application.

8.4.4 *DataCollectionPlan*

8.4.4.1 The DataCollectionPlan is a name given by the host to associate data collection activities to a specific control job. In general, it provides a way for the equipment to then inform and coordinate with the host to receive data collection requests. A DataCollectionPlan is generic and will be applied to many control jobs. The variable itself, DataCollectionPlan, will hold no significance for the equipment. It is simply a label the equipment reports back when requested by the host. Normally, the host upon receiving the ControlJob START event would include DataCollectionPlan as a data variable to be reported. The host then knows that the time is appropriate to set up various trace reports and event reports on the equipment. Potentially, all jobs that specify the same product type and process capability could specify the same DataCollectionPlan.

8.4.5 *OutputRule*

8.4.5.1 This attribute can only be supported by equipment that has some means to determine the status of material that it has processed. For equipment with that ability, the rule will usually take the form of a list of name value pairs. The names will be material status and the values will be measurement thresholds that correspond to the status category (such as, Good, Reject, Rework, etc.). Substrate (material) status changes should be recorded in substrate histories created by the equipment.

8.4.5.2 Equipment which also supports the MtrlOutbyStatus shall use the status determined by the OutputRule to place substrates at the Destination associated with MaterialStatus.

8.4.6 *PauseEvent*

8.4.6.1 For equipment which can support it, this attribute contains a list of equipment events, specified by the host, at which the host expects the equipment to PAUSE the ControlJob. Equipment suppliers shall document any events that can be used for the pausing of control jobs. Pausing a control job causes it to stop initiating process jobs. The host might use this to stop processing after one or more process jobs has started in order to await results before processing the rest of the material in the control job.

8.4.7 *ProcessOrderMgmt*

8.4.7.1 This is an enumerated attribute that defines the order in which processing will occur. This standard defines three enumerations. For some equipment other enumerations may be possible. If they are the supplier shall document them.

8.4.7.2 LIST

8.4.7.2.1 When ProcessOrderMgmt is set to this value, process jobs shall be initiated in the order of the list in ProcessingCtrlSpec.

8.4.7.3 ARRIVAL

8.4.7.3.1 When ProcessOrderMgmt is set to this value, process jobs shall be initiated as the material for the job arrives. Any jobs that do not require material will be initiated first.

8.4.7.4 OPTIMIZE

8.4.7.4.1 When ProcessOrderMgmt is set to this value, process jobs shall be initiated in an order to be determined by internal equipment algorithms, that optimize the throughput of material in the equipment.

9 Control Job State Model – Behavior

9.1 The following state chart defines the behavior of the ControlJob.

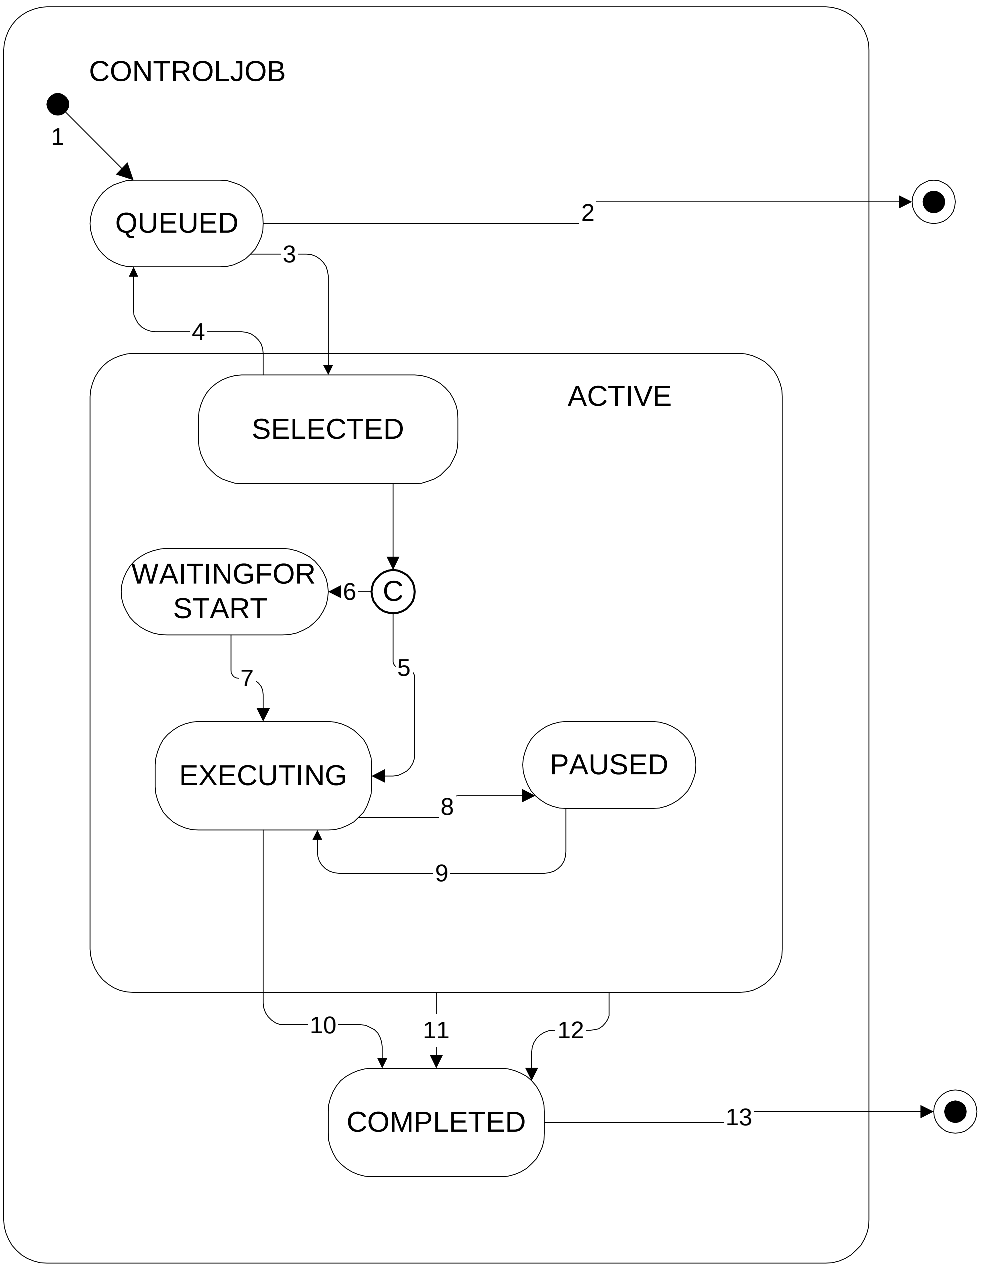

Figure 2
Control Job State Model

9.2 *State Definitions*

9.2.1 QUEUED — A ControlJob is queued after its creation or de-selection. A newly created ControlJob is placed at the tail of the queue.

9.2.2 SELECTED — In this state, the ControlJob does not initiate process jobs specified in it and therefore pre-defined (based on recipe variable parameters) process conditions can be modified. The processing resource is reserved (not available for any other jobs) by the ControlJob in the SELECTED state. If materials, required by the ControlJob, for processing have not arrived at the equipment, the ControlJob will stay in this state until materials arrive. If the ControlJob or the first process job in the ControlJob does not require material, this state is exited immediately. A SELECTED ControlJob can be de-selected if specified materials have not arrived.

9.2.3 WAITING FOR START — The ControlJob is waiting to receive a start command manually or remotely from the host. The ControlJob transitions to this state only if the StartMethod is set to FALSE (UserStart) and materials have arrived.

9.2.4 EXECUTING — In this state, each process job in the ProcessingCtrlSpec is initiated in order, based on the value of the ControlJob's ProcessOrderMgmt attribute as required resources become available and material for the job has been verified. Process jobs that have been initiated but that are WAITINGFORSTART or PAUSED shall block the availability of the resources that they require (see SEMI E40).

NOTE 2: Process jobs that have blocked available resources shall cause the ControlJob to stop initiating subsequent process jobs that use those resources.

9.2.5 PAUSED — When the ControlJob is paused it shall not commence the initiation of any more Process jobs. In this state, Process jobs that have not entered the "PROCESSING" state can be modified. Various attributes of the ControlJob can also be modified. This is equipment specific and shall be documented by the equipment supplier.

9.2.6 COMPLETED — A control job enters this state once all of its process jobs have been completed, stopped or aborted.

Table 3 ControlJob State Transition Table

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(No state)	Receive "Create" command from host or operator through operator console.	QUEUED	Create ControlJob and put it at the tail of a control job queue.	If job queue is full, "Create" request is rejected.
2	QUEUED	Receive "Cancel", "Abort", or "Stop" command from host or operator through operator console.	(No state)	De-queue and terminate the job. Send a "ControlJob Canceled" event to the host.	If other control jobs are waiting behind the canceled job in the queue, they are shifted forward to fill in the gap after the de-queuing of the canceled control job.
3	QUEUED	The processing resource has capacity to begin work on the next ControlJob.	SELECTED	Select and de-queue the job at the head of the queue. Send a "Selected" event to the host.	Materials are not necessarily at the equipment.
4	SELECTED	Receive "De-select" command from host or operator through operator console and materials for the control job have not arrived yet.	QUEUED	De-selected job moves to the head of the job queue and the job that was at the head becomes the SELECTED job.	The command shall be rejected if the resources for the job at the head of queue are not available. See the Queue Model.

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
5	SELECTED	Material for the first process job arrives or in the case where the first (or only) process job does not require material, this transition shall be taken as soon as the processing resource for that process job becomes available. "StartMethod" attribute in the ControlJob is set for Auto.	EXECUTING	Send "Execution began" event to the host.	Process jobs associated with a carrier will not initiate until the identifier and substrate slot map for the carrier have been verified. Process jobs that don't use material can be initiated immediately.
6	SELECTED	Same as for transition 5 except that the "StartMethod" attribute in the control job is set for user start.	WAITING FORSTART	Send a "JobWaiting for Start" event to host and/or operator.	
7	WAITING FORSTART	User START command received.	EXECUTING	Same as for transition 5.	Same as for transition 5.
8	EXECUTING	Received "Pause" message from host or operator through operator console or a ControlJob. PauseEvent has occurred.	PAUSED	Send a "Paused" event to the host.	Process jobs which have not started can be modified in this state.
9	PAUSED	Receive "Resume" message from host or operator through operator console.	EXECUTING	Commence initiating process jobs. Send a "Resumed" event to the host.	
10	EXECUTING	All the ProcessJobs specified for the ControlJob have completed.	COMPLETED	Send a "Complete" event to the host.	It may include post processing completion.
11	ACTIVE	Receive "CJStop" message from host or operator through operator console or all the process jobs under the ControlJob have been stopped and material processing is stopped.	COMPLETED	Send a "Stopped" event to the host.	
12	ACTIVE	Receive "CJAbort" command from host or operator through operator console or all the process jobs under the ControlJob have been aborted and material processing is aborted.	COMPLETED	Send "Aborted" message to the host.	
13	COMPLETED	The ControlJob is deleted.	(No state)		Equipment should perform this function automatically for COMPLETED jobs.

10 Control Job Queue Model

10.1 The Queuing mechanism for control jobs will generally operate under FIFO (First in- First Out) constraints. The commands used to monitor queue status and prevent deadlock conditions are specified here.

10.2 *Queue Integrity*

10.2.1 To maintain queue integrity, only one operation shall be performed at any given time (e.g., the "Create" request shall be rejected by the equipment if the CJHOQ service is being processed). The Queue is defined to be "locked" while it is performing an operation (and refusing any further operation until completion of the current operation).

10.3 *Head of Queue Service*

10.3.1 The Head of Queue service (CJHOQ) shall operate under the following rules:

1) All control jobs positioned between the specified control job and the head of the queue (including the job currently positioned at the head) will be moved back one position. The specified control job will then be moved into the head of queue position.

2) When the CJHOQ command is invoked, the queue will be "locked" to maintain integrity.

3) In the case where only one control job exists in the queue, the command will perform no action on the queue.

10.4 *DeadLocks*

10.4.1 The Head of Queue service (CJHOQ) requests a specific control job to be set as the next control job to be run. In order to prevent deadlock when the job at Head of Queue and the job in the SELECTED state are both awaiting material delivery, the CJHOQ command may be used to move a different job to the head of the queue position. The potential dead lock is then broken by issuing the DE-SELECT service request.

10.5 *Utilization of Queue for Control Job Priority Management*

10.5.1 Similar to Deadlock, certain cases may arise where a job at the head of the queue cannot be selected due to a lack of processing resources. In this case, DE-SELECT command shall be rejected and consequently a series of DE-SELECT and CJHOQ commands may be issued in an attempt to find a job which can transition to SELECTED state.

10.5.2 To force a "hot job" to be the next job run, it could be necessary to send the CJStop message to the SELECTED job. This case only happens when the job at the head of the queue (the hot job) does not yet have resources available.

NOTE 3: Most equipment where this is possible can support parallel execution of Control Jobs. Management of the queue(s) in this case is currently beyond the scope of this standard.

10.6 *Space in the Queue*

10.6.1 The QueueAvailableSpace variable data item is used to query the number of control job openings within the queue. The QueueAvailableSpace shall function according to the following rules:

1) This variable can only be guaranteed valid when no other operations are being performed simultaneously on the queue. For example, don't request this variable while a Create control job command is being processed by the equipment.

2) This variable shall be incremented whenever a control job in the queue is de-queued. That is, when a "Cancel", "Abort", or "Stop" command has been received and completed while the control job is queued. It should also be incremented when the SELECTED state is entered by a control job. However, if this transition occurs as a result of the "Deselect" command (at least one job in queue, and a control job in the SELECTED state), no change should be made to the variable value.

3) This variable should be decremented whenever a control job joins the queue. That is, when a "Create" command is received and accepted. It should also be decremented if a "Deselect" command is issued on a control job in the SELECTED state and no other jobs currently reside in the queue.

4) The equipment should reject the "Create" command when this variable is equal to zero.

10.7 *Getting a List of Queued Jobs*

10.7.1 The QueuedCJobs Variable Data Item is used to query the names of the control jobs currently residing in the queue. It lists items starting at the head of the queue.

10.7.2 The QueuedCJobs Variable Data Item shall function according to the following rules:

1) This variable can only be guaranteed valid when no other operations are being performed simultaneously on the queue.

2) This variable list will be modified whenever a successful "Create" command is received. Additionally, "Cancel", "Abort", and "Stop" commands issued on control jobs residing in the queue will modify this variable list. Any use of the "Deselect" command will also modify the variable list.

11 Properties for Carriers

11.1 Compliance to Control Job Management requires that the equipment track the status of individual carriers. In particular, the factory needs to know the status of carriers with respect to control jobs. Carriers may have various properties that are beyond the scope of this standard. However, there are specific properties that are needed for Control Jobs.

11.2 *Carrier Verification*

11.2.1 The equipment needs to know when a carrier has been verified as proper. Only process jobs associated with the carrier that has been verified shall be initiated by a control job. Depending on the equipment's capabilities, verification may include verification by an equipment read of the carrier's ID (identification) and the reading of the substrate (e.g., wafer) slot map. The ControlJob determines if the carrier is verified by checking the carrier's attributes that indicate the level to which a carrier has been verified. This section is reserved for further specification of this requirement.

11.3 *Carrier Completion for Control Jobs*

11.3.1 A carrier that has been loaded onto the equipment may go through three stages: first, it is in the "not accessed" stage until it is accessed by a control job. When the carrier is at the substrate port and unloading of the substrates within the carrier begins, the carrier enters the "in access" stage. Once it enters this stage, it remains in this stage until all material has been returned to the carrier, no active control job exists that is using it and no control jobs in the queue exist that reference it. The equipment shall provide a property of the carrier that shows the current stage of all carriers. The equipment shall provide a "CarrierComplete" or "CarrierStopped" event for each change in stage. The event when the carrier enters the "in access" stage informs the host that the carrier may not be removed from the equipment. The event when the carrier enters the "completed" stage informs the host that the carrier may be removed.

12 Requirements - Service Definitions

12.1 *Service Definitions*

Table 4 Service Definitions Table

Message Service Name	*Type*	*Description*
CJStart	R	To start a ControlJob.
CJPause	R	To request a ControlJob to pause.
CJResume	R	To request a PAUSED ControlJob to go to the EXECUTING state.
CJCancel	R	To request a ControlJob to be removed from the queue.
CJDeselect	R	To request a ControlJob to be deselected; it will no longer be the next job to run.
CJStop	R	To request a ControlJob to stop. Used to discontinue a job without risk to the material.
CJAbort	R	To request a ControlJob to abort. Used to discontinue a job on equipment that may be malfunctioning. Material is at risk when this command is issued.
CJHOQ	R	To request a particular ControlJob to be set as the next control job to be SELECT'ed.

12.2 *Parameter Definitions*

Table 5 Parameter Definitions Table

Parameter Name	*Description*	*Format: Possible Value*
ACKcode	To return indication of result of service call.	Enumeration: SUCCESS, FAILURE
Action	See Section 12.2.1	Enumeration: SAVEJOBS REMOVEJOBS
CtrlJobID	ObjID (object identifier) of a control job.	Text
ErrorCode	Contains the code for the specific error found.	Enumerated (ACKcode must equal FAILURE): *All services:* • Unknown object instance • Parameters improperly specified • Insufficient parameters specified *CJStart:* • Command not valid for current state *CJPause:* • Command not valid for current state *CJResume:* • Command not valid for current state *CJCancel:*

Parameter Name	Description	Format: Possible Value
		• Job cancelled • Command not valid for current state *CJDeselect:* • Command not valid for current state • Busy (when queue empty or resources for HOQ job would not be available) *CJStop:* • Job stopped *CJAbort:* • Job aborted *CJHOQ:* • Command not valid for current state
ErrorInfo	The parameter may be null or excluded on a SUCCESS.	(List of) ErrorCode ErrorText
ErrorText	Description of the error.	Text
Status	Information returned by service provider which indicates the result of the service call.	Structure: ACKcode ErrorInfo

12.2.1 *Action Parameter* — The Control Job services CJCancel, CJStop, and CJAbort can all cause Process Jobs to be terminated, as specified in SEMI E40. In these Control Job services, the parameter "Action" specifies the disposition of the Process Job objects for the terminated Process Jobs. "Action" specifies one of the following enumerated values: SAVEJOBS and REMOVEJOBS. This Action parameter only affects Process Jobs that are in the QUEUED/POOLED state.

12.3 *Message Details*

12.3.1 This section specifies parameter usage by the service messages.

12.3.2 *Creating ControlJobs* — ControlJobs shall be created by using the OSS (SEMI E39) Object Create message. The following table defines the use of the AttrSetting arguments to the Object Create service. Note: ObjType is a required argument of Object Create and therefore should not be reset by including it as an AttrSetting argument. In the table M indicates mandatory, O indicates optional, and R specifies restricted (shall be ignored if used).

12.3.3 The process jobs specified for a control job must exist prior to calling this message. If a process job does not exist, the Create service shall fail and the ObjStatus shall return a list of any PRJob identifiers that were not present. The Create request shall be rejected if the ControlJob queue is full. Newly created control jobs will be put at the end of the queue.

Table 6 SetAttr Arguments Table

Control Job Attribute Name	*Use as AttrSetting of Create Service*
ObjID	M
ObjType	R
CurrentPRJob	R
DataCollectionPlan	O
CarrierInputSpec	M
MtrlOutSpec	M
MtrlOutbyStatus	O
PauseEvent	O
ProcessingCtrlSpec	M

Control Job Attribute Name	*Use as AttrSetting of Create Service*
ProcessOrderMgmt	M
StartMethod	M
State	R

12.3.4 *CJStart* — Starts jobs that require a user start. The host sends this command only to a Control Job from which it has received a WAITINGFORSTART event.

Table 7 CJStart Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Status	-	M	Success or failure

12.3.5 *CJPause* — The ControlJob shall stop initiating process jobs. Process jobs in the EXECUTING state are not affected by this command.

Table 8 CJ Pause Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Status	-	M	Success or failure

12.3.6 *CJResume* — The ControlJob shall resume initiating process jobs.

Table 9 CJResume Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Status	-	M	Success or failure

12.3.7 *CJCancel* — Used to remove a ControlJob from the Queue. The command shall only succeed for jobs in the QUEUED state.

Table 10 CJCancel Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Action	M	-	
Status	-	M	Success or failure

12.3.8 *CJDeselect* — Shall only succeed for jobs in the SELECTED state. Deselected jobs must trade places with the job that is currently at the head of the queue. If the job at the head of the queue cannot transition to the SELECTED state, then the deselect request shall be rejected. See the section on Control Job Queue Model for information on breaking possible deadlocks.

Table 11 CJDeselect Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Status	-	M	Success or failure

12.3.9 *CJStop* — Stops the ControlJob from initiating any more process jobs. Equipment should issue a STOP command to all running process jobs. When the currently running process jobs have stopped, the ControlJob will send a complete event with a status code indicating the ControlJob has stopped. ControlJobStop shall only succeed on a job in the ACTIVE or QUEUED states. When CJStop is issued in the QUEUED state, its affect will be identical to that of CJCancel.

Table 12 CJStop Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Action	M	-	
Status	-	M	Success or failure

12.3.10 *CJAbort* — Stops the control job from initiating any more process jobs. The currently running process jobs are sent the Abort command by the equipment. When the equipment has detected the successful ABORT of currently running process jobs, the ControlJob shall send a complete event with a status code indicating the job was aborted. ControlJobAbort shall only succeed on a job in the ACTIVE or QUEUED states. When CJAbort is issued in the QUEUED state, its affect will be identical to that of CJCancel. The equipment due to a serious alarm situation (operator risk) may internally generate this command.

Table 13 CJAbort Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Action	M	-	
Status	-	M	Success or failure

12.3.11 *CJHOQ* — The other jobs in the queue are pushed back (rest of queue order remains unchanged).

Table 14 CJHOQ Service Parameter Definitions Table

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
CtrlJobID	M	M	Indicate which job
Status	-	M	Success or failure

13 Variable Data

13.1 For objects defined by Control Job Management, the identifiers of the objects and all of the attributes of the objects shall be available for inclusion in event reports associated with those objects. The following attribute is the most likely to be used: CtrlJobID.

13.2 The following table provides the definition of additional Variable Data that equipment shall support for Control Job Management.

Table 15 Variable Data Definitions Table

Variable Name	*Description*	*Type*	*Access*	*Comment*
CtrlJobID	Control job identifier, available to be used in control job related event reports.	Text	RO	
QueuedCJobs	This is an ordered list of control jobs currently in the Queue. The first job in the list is the job at the head of the Queue.	(list of) Text	RO	Each list item is a control job identifier.
QueueAvailableSpace	Indicates number of jobs which the Queue can accept.	Numeric	RO	This value cannot be negative. When it is zero it indicates that the queue is full.

Variable Name	Description	Type	Access	Comment
SetUpName	Host sets this to define the operational condition of the equipment.	Text	RW	If the equipment is manipulated locally, it should set this variable to "unknown", otherwise it returns the value set by the host (when requested).

14 Additional Requirements

14.1 *Serial Execution of Control Jobs*

14.1.1 Control jobs are initiated in sequential order by the equipment. The order is based on the queue. A ControlJob shall not issue a complete event (message) until all substrates have been placed in destination carriers. However, in many cases equipment must support multiple control jobs running at once; in order to support the factory requirement for equipment productivity. This will be particularly true for multi-module equipment. The next ControlJob in the queue shall start as soon as possible after processing has begun for the last ProcessJob in the previous ControlJob's processing control specification.

14.2 *Parallel Execution of Control Job*

14.2.1 Some equipment may be able to support parallel execution of control jobs. The supplier must fully document this behavior and any additional services needed to manage it.

14.3 *Modifying Control Jobs*

14.3.1 Control jobs shall be modifiable if and only if they are not in either the EXECUTING or COMPLETED states. Jobs shall be modified by using OSS to change their attributes. Modifications shall be rejected if the equipment is in the wrong state or requested value changes are out of range.

14.4 *Set-up, Pre- and Post-Conditioning*

14.4.1 Whenever equipment has completed some processing work, with or without material, the equipment can be considered to be "set-up" for a certain process capability. Information about the equipment's set-up is important to the factory in determining the best material routing. The SetupName variable defined in this standard is set by the host after host directed processing or changes to equipment constants. If the equipment is used for processing while off-line or not under host command, the value of the variable shall be set to "unknown". It shall also be set to "unknown" immediately after any changes to equipment constants.

14.5 *Event Relationships*

14.5.1 This section is reserved for specification of the relationship between process job events and control job events.

14.5.2 PRJob Paused

14.5.3 PRJob Aborted or Stopped

15 Compliance

15.1 Implementations compliant to this standard shall implement all the messages as specified in Section 12. All mandatory parameters must be supported. The supplier shall document support for any of the optional parameters. Any additional parameters and messages shall be fully documented by the supplier. Additional messages shall be used to support additional functionality and not as a replacement for any of messages specified herein.

15.2 Table 16 provides a checklist for Control Job Mangement (CJM) compliance.

Table 16 CJM Compliance Statement

Fundamental CJM Requirements	*CJM Section*	*Implemented*	*CJM Compliant*
Control Job Object	8	☐ Yes ☐ No	☐ Yes ☐ No

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: The material contained in these Applications Notes is not an official part of SEMI E94 and is not intended to modify or supersede the official standard. Rather, these notes are auxiliary information describing possible methods for implementing the protocol described by the standard and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

Service messages are presented with a "C" language style of application interface. For illustrative purposes values for variables may be included using the "=" in the argument list. If not used the optional arguments are not shown. Service names (e.g., PRJob) are prefixed to function name. The scenarios assume processing is for wafers. The services used in these scenarios are PRJob for Processing Management, ControlJob for Control Job Management, and CMS for Carrier Management Services.

R1-1 ControlJob for a Batch Processing Tool

R1-1.1 Tool processes the contents of a single carrier as a batch. This example demonstrates the simplicity of using control jobs for a simple situation. Wafer order is maintained, and material is returned to the source carrier.

#	*Comment*	*Dir*	*Message*	*CJS*	*PJS*

R1-6 Using Cleaning Wafers

R1-6.1 For this scenario we assume a single wafer processing tool, such as an RIE. The tool has three fixed load ports; two for product material, one for cleaning material. A cleaning wafer is run before the 1st and 13th wafer of each carrier of product wafers. Show the load and unload of the cleaning wafers and the running of the ControlJob for processing material. Note that control jobs do not provide functionality for dispositioning collateral material consumed during processing (the cleaning wafers). The equipment is responsible for providing mechanisms to determine when this collateral material has been consumed (should be replaced).

Step #	Comment	Dir	Message	CJS	PJS
1	Remove the previously spent wafers.	H<-E	Event (ReadytoUnload, PortID=Cleaning, CarrierID=CC01)	No state	No state
2	After host picks up the spent wafers, the equipment is ready to load.	H<-E	Event (ReadytoLoad, PortID=Cleaning)		
3	Delivered material is identified.	H<-E	Event (CarrierIDRead, CarrierID=CC02)

20		H<-E	Event (ReadytoUnload, CarrierID = CP01)		

SEMI E94.1-1101
SPECIFICATION FOR SECS-II PROTOCOL FOR CONTROL JOB MANAGEMENT (CJM)

This provisional specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001, to be published November 2001.

1 Purpose

1.1 This document maps the services and data of SEMI E94 to SECS-II streams and functions and data definitions.

2 Scope

2.1 This is a specification covering equipment supporting automated control job management.

2.2 This document applies to all implementations of SEMI E94 that use the SECS-II message protocol (SEMI E5). Compliance to this standard requires compliance to both SEMI E94 and SEMI E5.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification applies to semiconductor equipment that also use SEMI E40 Process Jobs.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39.1 — SECS-II Protocol for Object Services Standard (OSS)

SEMI E40 — Standard for Processing Management (PJM)

SEMI E53 — Event Reporting (ER)

SEMI E94— Provisional Specification for Control Job Management (CJM)

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Mapping

5.1 This section shows the specific SECS-II streams and functions that shall be used for SECS-II implementation of the services defined in SEMI E94, as well as the parameter mapping for data attached to services.

5.2 *Message Mapping*

5.2.1 *Services Message Mapping*

5.2.1.1 Table 1 defines the relationships between SEMI E94 services and SECS-II messages.

Table 1 Services Message Mapping Table

Service Name	*Stream, Function*	*SECS-II Message Name*
Create Object	S14,F9/10	Create Object Request/Acknowledge (SEMI E39.1)
CJAbort	S16,F27/28	Control Job Command Request/Acknowledge
CJCancel	S16,F27/28	Control Job Command Request/Acknowledge
CJDeselect	S16,F27/28	Control Job Command Request/Acknowledge
CJHOQ	S16,F27/28	Control Job Command Request/Acknowledge
CJPause	S16,F27/28	Control Job Command Request/Acknowledge
CJResume	S16,F27/28	Control Job Command Request/Acknowledge
CJStart	S16,F27/28	Control Job Command Request/Acknowledge
CJStop	S16,F27/28	Control Job Command Request/Acknowledge

5.2.2 *Event Message Mapping*

5.2.2.1 Table 2 defines the relationships between SEMI E94 collection events and SECS-II messages.

Table 2 Event Message Mapping Table

Event Name	*Stream, Function*	*SECS-II Message Name*
All state model transitions	If SEMI E30 style events: S6,F11/12 If SEMI E53 style events: S6,F11/12 S6,F13/14	If SEMI E30 style events: Event Report Send/Acknowledge If SEM E53 style events: Event Report Send/Acknowledge Annotated Event Report Send/Ack

5.2.3 *Parameter Mapping*

5.2.3.1 Table 3 defines the relationships between SEMI E94 service parameters and SECS-II data definitions.

Table 3 Parameter to SECS-II Data Items Mapping

Parameter Name	*Range*	*SECS-II Data Item*
ACKcode	TRUE, FALSE	ACKA
Action	SAVEJOBS, REMOVEJOBS	CPVAL (U1) 0 = SAVEJOBS. This command does not destroy the Process Jobs specified by this Control Job. 1 = REMOVEJOBS. This command destroys all Process Jobs specified by this Control Job.
CtrlJobID	1–80 characters (Conforms to ObjID in SEMI E39.1, Section 6.)	OBJID
ErrorCode	Enumerated	ERRCODE
ErrorInfo	Error	L,2 1. ErrorCode 2. ErrorText
ErrorText	1–80 characters	ERRTEXT
Status	Acknowledgement and error	L,2 1. ACKcode 2. ErrorInfo

5.2.4 *SECS-II Data Items without Corresponding SEMI E94 Parameters*

5.2.4.1 Table 4 contains the SECS-II data items that do not correspond to SEMI E94's service parameter.

Table 4 Additional Data Item Requirements Table

Function	*SECS-II Data Item*
Used to identify control job commands.	CTLJOBCMD
Used to satisfy SECS-II conventions for linking a multi block inquiry with subsequent multi block message.	DATAID

5.2.5 *Variable Data Item Mapping*

5.2.5.1 Table 5 shows the specific SECS-II data classes, and formats needed for SECS-II implementations of SEMI E94 variable data items.

Table 5 Variable Data Item Mapping

Variable Name	*Class*	*Format*
CtrlJobID	DVVAL	<OBJID>
QueueAvailableSpace	SV	5() (U1, U2, U4, U8)
QueuedCJobs	SV	L,n n = number of queued control jobs 1. <CtrlJobID$_1$> … n. <CtrlJobID$_n$>
SetUpName	ECV	20 (A[1..80]) Zero length string is used by the equipment to indicate “unknown”.

6 SECS-II Attribute Definitions

6.1 *ControlJob Object SECS-II Attributes Definitions*

6.1.1 The following are the SECS-II structure definitions for the E94 ControlJob Object.

Table 6 ControlJob Object Attribute Definitions

Attribute Name	*Attribute Data Form: SECS-II Structure*
“ObjType”	20 (A) “ControlJob”
“ObjID”	<OBJID> CtrlJobID (Conforms to the restrictions of ObjID as specified in SEMI E39.1, Section 6.)
“CarrierInputSpec”	L,n n = number of input carriers 1. <CARRIERID$_1$> … n. <CARRIERID$_n$>
“CurrentPRJob”	L,n n = number of process jobs 1. <PRJOBID$_1$> … n. <PRJOBID$_n$>
“DataCollectionPlan”	20 (A) DataCollectionPlan

Attribute Name	*Attribute Data Form: SECS-II Structure*
"MtrlOutByStatus"	L,n n = number of status dispositions 1. L,2 1. 51 (U1) MaterialStatus$_1$ 2. L,2 DestinationMap$_1$ 1. <CARRIERID$_{1,1}$> 2. L,m m = number of slots 1. <SLOTID$_1$> … m. <SLOTID$_m$> … n. L,2 1. 51 (U1) MaterialStatus$_n$ 2. L,2 DestinationMap$_n$ 1. <CARRIERID$_{n,1}$> 2. L,m m = number of slots 1. <SLOTID$_1$> … m. <SLOTID$_m$> If m = 0, the substrates may be placed by the equipment in any available slot.
"MtrlOutSpec"	L,p p = number of mapping source/destination pairs 1. L,2 1. L,2 SourceMap$_1$ 1. <CARRIERID$_{1,1}$> 2. L,m m = number of slots 1. <SLOTID$_1$> … m. <SLOTID$_m$> 2. L,2 DestinationMap$_1$ 1. <CARRIERID$_{1,2}$> 2. L,m m = number of slots 1. <SLOTID$_1$> … m. <SLOTID$_m$> … p. L,2 1. L,2 SourceMap$_p$ 1. <CARRIERID$_{p,1}$> 2. L,n n = number of slots 1. <SLOTID$_1$> … n. <SLOTID$_n$> 2. L,2 DestinationMap$_p$ 1. <CARRIERID$_{p,2}$> 2. L,n n = number of slots 1. <SLOTID$_1$> … n. <SLOTID$_n$>

Attribute Name	*Attribute Data Form: SECS-II Structure*
"PauseEvent"	L,n n = number of collection events 1. <CEID$_1$> … n. <CEID$_n$>
"ProcessingCtrlSpec"	L,p p = number of process jobs assigned to control job 1. L,3 1. <PRJOBID$_1$> 2. L,m ControlRule$_1$ 1. L,2 1. 20 (A) RuleName$_1$ 2. (Any format) RuleValue$_1$ … m. L,2 1. 20 (A) RuleName$_m$ 2. (Any format) RuleValue$_m$ 3. L,n OutputRule$_1$ 1. L,2 1. 51 (U1) MaterialStatus$_1$ 2. (Any format) OutputRuleValue$_1$ … n. L,2 1. 51 (U1) MaterialStatus$_n$ 2. (Any format) OutputRuleValue$_n$ … p. L,3 1. <PRJOBID$_p$> 2. L,m ControlRule$_p$ 1. L,2 1. 20 (A) RuleName$_1$ 2. (Any format) RuleValue$_1$ … m. L,2 1. 20 (A) RuleName$_m$ 2. (Any format) RuleValue$_m$ 3. L,n OutputRule$_p$ 1. L,2 1. 51 (U1) MaterialStatus$_1$ 2. (Any format) OutputRuleValue$_1$ … n. L,2 1. 51 (U1) MaterialStatus$_n$ 2. (Any format) OutputRuleValue$_n$ ControlRule 1) m = 0 indicates no ControlRule specified 2) RuleName and RuleValue are equipment specific OutputRule 1) n = 0 indicates no OutputRule specified 2) There is no defined OutputRuleValue. The content and format of OutputRuleValue is equipment dependent per SEMI E94 intent.

Attribute Name	*Attribute Data Form: SECS-II Structure*
"ProcessOrderMgmt"	51 (U1) ProcessOrderMgmt ProcessOrderMgmt is enumerated as follows: 1 = ARRIVAL 2 = OPTIMIZE 3 = LIST
"StartMethod"	11 (BOOLEAN) StartMethod StartMethod is as follows: TRUE – Auto FALSE – UserStart
"State"	51 (U1) State State is enumerated as follows: 0 = QUEUED 1 = SELECTED 2 = WAITINGFORSTART 3 = EXECUTING 4 = PAUSED 5 = COMPLETED

SEMI E95-1101
SPECIFICATION FOR HUMAN INTERFACE FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT

This specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published February 2000.

1 Purpose

1.1 This standard addresses the area of processing content with the direct intention of developing common software standards, so that problems involving operator training, operation specifications, and efficient development can be resolved more easily.

1.2 This standard is written to be "tool-neutral" without reference to, or reliance on, specific capabilities of platforms or operating systems. Neither is it intended that choices of software tools or detailed implementation strategies be dictated.

1.3 Note that all figures in this standard are schematic, are not drawn to scale, and unless otherwise specified, are not intended to provide implementation details about number of buttons, button sizes, panel sizes, etc.

2 Scope

2.1 This standard specification applies to manufacturing equipment used in the production of semiconductors.

2.2 This standard may be applicable to other areas such as the manufacture of flat panel displays, but specific application to these areas is outside the scope of this document.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

None.

4 Terminology

4.1 *condition* — a property of a displayed object or value (textual or numeric) that visually indicates, if applicable, whether the current state of an object or the current value violates the defined bounds of normal operational states or parameters, whether that violation is categorized as a minor exception (a caution) or a severe exception (an alarm), and provides no visual indication if no exception has occurred.

4.2 *display objects* — user interface elements displayed on the screen, such as function selection buttons, keyboard input buttons, graphics representing the equipment, etc.

4.3 *functional area* — a grouping of one or more views presenting information and control capabilities to the user.

4.4 *icon* — an icon (diagrammatic image) is a bitmap or other image used in GUI environments such as windowing systems to show different types of objects, improve operability, and help the user better understand the functionality underlying buttons.

4.5 *navigation model* — the navigation model determines how a user interacts with a system to access functionality and information.

4.6 *salience* — a salience is a solid (or textured), colored border shown around a display object to indicate an alarm, caution, or other condition, or to draw the user's attention to the display object.

5 Requirements

5.1 Each of the following sections is designated with one of the following labels:

5.1.1 Sections designated:

Description	provide background information and set the context for subsequent specifications;
Mandatory	provide a specification of a requirement which shall both be present and implemented as specified;
Conditional	provide a specification of a requirement which shall be implemented as specified if such a feature is implemented on the tool;
Recommended	provide a recommended capability and implementation of that capability, but neither their presence nor their implementation is required.

5.2 *Basic Display Objects* Description

5.2.1 This section specifies the general appearance and behavior of basic display objects used throughout the interface, including buttons, saliences, and dialog boxes. It is intended that the use of other types of display objects (choose lists, data display and data entry fields, scroll-bars, etc.) is specifically allowed, and their use is at the discretion of the implementers.

5.2.1.1 There are two types of display objects; selectable and non-selectable. Some are selectable by the user to initiate or execute an action. Non-selectable graphics and user interface elements (such as pipes and text field labels, respectively) are read only, and no action is initiated or executed.

5.2.2 *Buttons*

5.2.2.1 *Button Size* Mandatory

5.2.2.1.1 When a touchscreen device is used, button sizes must be large enough to ensure selection on the targeted display.

5.2.2.2 *Button Dimensions* Recommended

5.2.2.2.1 It is recommended that buttons shall have a minimum dimension of approximately 1.5 cm on the shortest side. If a smaller size is used, the space between buttons must be increased to avoid selection errors. For installations where a keyboard and a mouse, light pen or other pointing device is available, button sizes in the navigation panel and the command panel may be made somewhat smaller (approximately 1–1.25 cm), and the size of the information panel increased proportionally.

5.2.2.3 *Button Behavior* Mandatory

5.2.2.3.1 One type of button behavior is momentary; that is, user selection of a button causes a brief display of the down (selected) state of the button, followed immediately by a display of the up (unselected) state. The other button behavior is two-state; the button remains in the down state after user selection. User re-selection of the button, and/or selection of another button, and/or selection of another display object restores the display of the up state. In some cases, the software will control the display of the down state or restore the up state, without direct user interaction.

5.2.2.3.2 For 2-D buttons, the down state shall be indicated by hatching, cross-hatching, or otherwise texturing the button in such a manner that does not obscure the button label.

5.2.2.4 *Button Text* Mandatory

5.2.2.4.1 Text for all button labels shall have the first letter of words capitalized unless it is an article or preposition not occurring at the beginning or end of the label, or unless the word's conventional usage is not capitalized. Button labels that are all capital letters are harder to read than mixed case labels. Additionally, text in all capitals appears larger, and the user may attach more importance to the button than necessary simply because the label is visually distracting.

5.2.3 *Saliences* Conditional

5.2.3.1 Saliences, colored, textured, or both shall be displayed around buttons and other display objects to indicate their condition, which may include caution, alarm, user attention required or requested, processing, unfinished task notification, and other conditions.

5.2.3.2 A salience is displayed to draw the user's attention to a display object when its condition is *not* normal or OK (in this case, the absence of a displayed salience shall indicate a normal or OK condition), or when the salience provides information that benefits the user in the performance of tasks or the monitoring of equipment functions and operations.

5.2.3.3 A salience shall not hide the display object it surrounds. Saliences shall not be used to indicate the state (open, closed, on, off, etc.) of display objects.

5.2.3.4 On color displays, alarm saliences shall appear bright red, caution saliences shall appear bright yellow, and processing and unfinished task saliences shall appear medium blue. User attention required or requested saliences, (for example, "Ready to Load," or "Ready to Unload") shall appear medium green.

5.2.4 *Dialog Boxes* Description

5.2.4.1 Dialog boxes are secondary windows used to display supplemental information, solicit information from the user, or report errors.

5.2.4.2 Dialog boxes are used to provide additional information to the user; to display detailed information not shown on the information panel for controlling the system, and to display detailed information for monitoring system operation.

5.2.5 *Dialog Boxes* Mandatory

5.2.5.1 Dialog boxes (which are always temporary) are displayed in response to some action initiated by the user. When displayed, a dialog box shall overlay a portion of the information panel, and shall not obscure the title panel. If invoked by user selection of a display object on the information or command panels, all the display objects on those two panels shall be disabled until the dialog box is dismissed. The title and navigation panels remain enabled. At the explicit request of the user, the dialog box is dismissed, and the underlying information is refreshed.

5.2.5.2 Dialog boxes contain a title bar at the top, a display (free use) area, and one or more dialog box window control buttons arranged horizontally at the bottom. The title bar text reflects the command or the nature of the event that invoked the dialog box. Dialog box window control buttons are centered on the width of the dialog box, with any other buttons (Apply, Log-out, etc.) right-aligned and visually separated from the window control buttons. If the underlying operating system will not allow this alignment, then it is allowed that other alignments may be used, but only if the alignment is consistent across all dialog boxes.

5.2.5.2.1 User selection of a dialog box control button controls the dismissal of the dialog box and, when applicable, controls whether the user accepts or rejects information or choices displayed, or desires no action be performed.

5.2.5.2.1.1 An "OK" dialog box control button, when selected by the user, indicates acceptance of any choices or user inputs made, if any, and causes the dismissal of the dialog box. If no choices or user inputs were made, selecting this button indicates acceptance of any default values displayed. If user choices or inputs are required, this button shall be disabled until the choices or inputs are made.

5.2.5.2.1.2 A "Cancel" dialog box control button, when selected by the user, indicates no action should be taken, causes the dismissal of the dialog box, and returns the user to the state that existed prior to the invocation of the dialog box.

5.2.5.2.1.3 A "Yes" dialog box control button is displayed when the dialog box message is in the form of a question. User selection indicates a positive response to the question asked and causes the dismissal of the dialog box.

5.2.5.2.1.4 A "No" dialog box control button is displayed when the dialog box message is in the form of a question. User selection indicates no action should be taken, causes the dismissal of the dialog box, and returns the user to the state that existed prior to the invocation of the dialog box.

5.2.5.2.1.5 A "Close" dialog box control button is displayed (often as the only dialog box control button) when the dialog box message contains only information and does not require the user to make or accept choices, and shall be used instead of an "OK" dialog box control button in this case. The "Close" dialog box control button shall also be used instead of a "Cancel" dialog box control button when the user cannot be returned to the state that existed prior to the invocation of the dialog box. User selection indicates no action should be taken and causes the dismissal of the dialog box.

5.2.5.2.1.6 An "Apply" dialog box control button, when selected by the user, indicates acceptance of any choices or user inputs made, if any, but does not dismiss the dialog box. This button shall be disabled until one or more user choices or inputs are made. After user selection of this button, it shall be disabled until additional choices or user inputs are made, if any.

5.2.5.3 Dialog boxes may not be resized or moved, but may display a button equivalent to the Cancel button in the title bar.

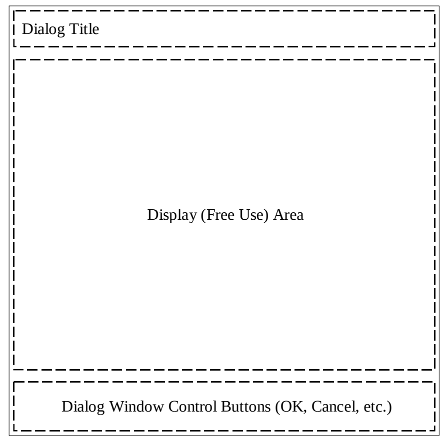

Figure 1
Dialog Box

5.2.5.4 Dialog boxes are classified into the following three types:

- Information dialog box
- Data input/selection dialog box
- Message dialog box

5.2.5.5 To be compliant with this specification, at least one of these dialog box types shall be supported.

5.2.6 *Information Dialog Box* — *Conditional*

5.2.6.1 This dialog box type is used to provide additional information to the user about some display object or topic addressed by the information panel. User selection of a display object on the information panel invokes an information dialog box, if appropriate for the display object selected. The window control button to dismiss the dialog box shall be the Close button. Use of an OK button in this case is not allowed.

5.2.6.2 Implementation of this dialog box type shall be conditional on the equipment having the capability of providing the required information.

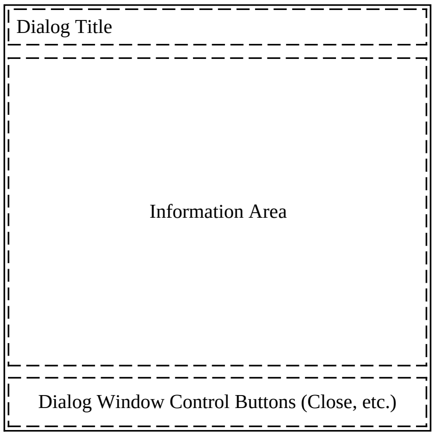

Figure 2
Information Dialog Box

5.2.7 *Input/Selection Dialog Box* Conditional

5.2.7.1 This dialog box type is used to request data input or selection from the user. If no keyboard or keypad is available, and the user must input characters, an on-screen representation ("mimic") of one or both shall be displayed as part of the dialog box. The window control buttons are the OK and Cancel buttons.

5.2.7.2 Implementation of this dialog box type shall be conditional on the presence of display objects that allow user input or selection.

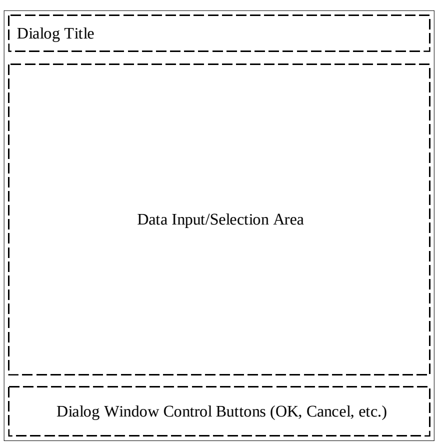

Figure 3
Data Input/Selection Dialog Box

5.2.8 *Message Dialog Box* Conditional

5.2.8.1 This dialog box type is used to provide a message to the user (including the reporting of errors) or to request confirmation of a user initiated action. The message text is located to the right of the icon. It is recommended that icons from the underlying operating system be used to represent the message type as follows:

- Information in the form of a simple message
- Progress, informing the user of an ongoing process
- Attention, alerting the user of possible danger, or inability to execute a command, or requesting confirmation (either as a statement or as a question)
- Error, informing the user of danger or inability to execute a command (if effect is severe)

5.2.8.2 Note that most style guides no longer recommend the use of a question mark icon when the message is phrased as a question, as its meaning could be ambiguous in some cases. The attention icon should be used instead.

5.2.8.3 The first two message types use the Close window control button. The second two use OK and Cancel, or Yes and No (and sometimes Cancel) if the message is phrased as a question. It is recommended that buttons or other display objects that would cause an error message be disabled in those circumstances.

5.2.8.4 Implementation of this dialog box type shall be conditional on the equipment having the capability of providing the required information.

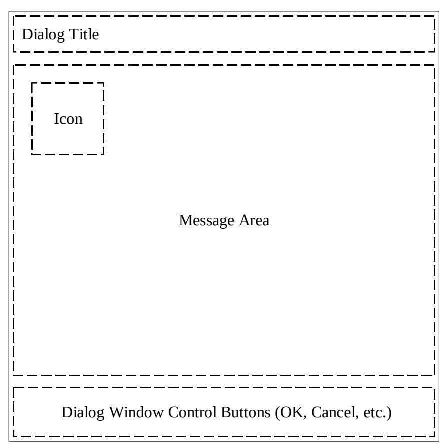

Figure 4
Message Dialog Box

5.3 *Basic Network Navigation Model* Mandatory

5.3.1 This standard specifies a simple navigation model designed specifically to minimize the number of actions and the amount of time required of the user.

5.3.2 The basic network navigation model is capable of displaying a number of views within a single level of hierarchy. The user does not have to traverse up and down menu or view "trees" when exercising control and monitoring tasks. As shown in the figure below, the basic navigation model is a network, supporting horizontal (lateral) transfer, at any time, between any of the functional areas in the interface. The basic network navigation model does not support more than one view in any functional area. Expansion of detail for views is typically implemented using dialog boxes.

5.3.3 Note that the diagram is schematic; it shows that user selection of a functional area shall display its associated information panel. Only one information panel shall be displayed at any time.

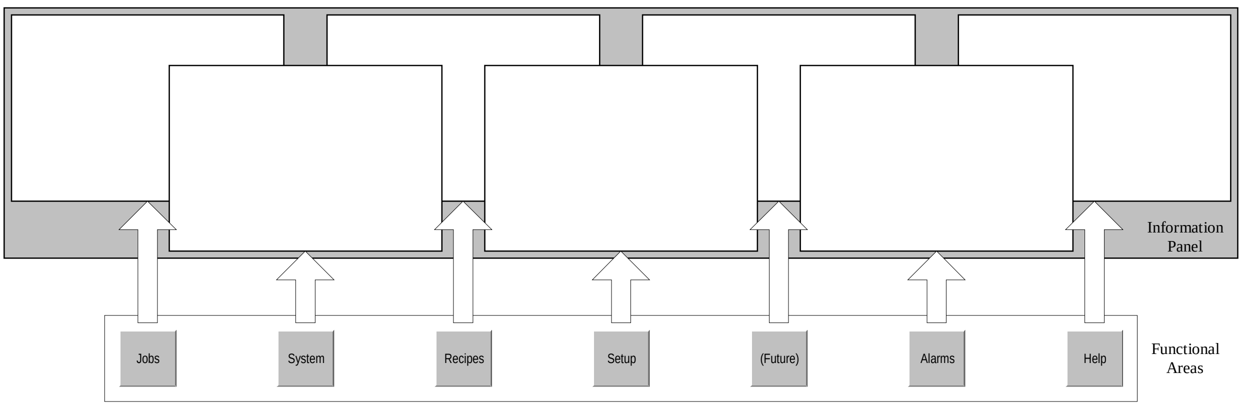

Figure 5
Basic Network Navigational Model

5.3.4 *Network Navigation Model with Sub-navigation* Conditional

5.3.4.1 While maintaining the same basic structure, this navigation model supports multiple views within functional areas on the network. If any functional area has more than one view, all functional areas in the interface shall consistently use one of the two view sub-navigation methods described below. Lateral transfer between any of the views within a functional area is supported either by providing a single row of tabs which may be selected to change views (Figure 6), or by providing view sub-navigation buttons (Figure 7) in a separate screen area dedicated solely to sub-navigation. Expansion of detail for each of these views is typically implemented using dialog boxes.

5.3.4.2 The grouping of tasks within functional areas reflects the natural flow of information, events, and tasks in a way that is familiar to the user and that directly supports the attainment of successful process and equipment performance goals. Functional areas are user task oriented, collecting together logically related monitoring and control functions, reducing the need to navigate between views.

5.3.4.3 Note that the diagrams are schematic; they show that user selection of a functional area shall display its associated information panel. Only one information panel shall be displayed at any time. Similarly, user selection of a tab or sub-navigation button displays only one of the views available at any time.

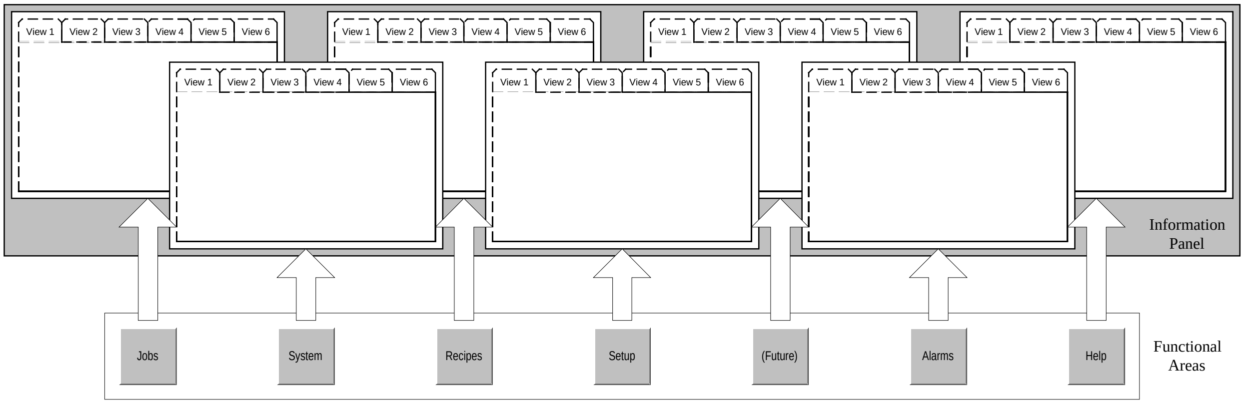

Figure 6
Network Navigation Model — Tab Sub-navigation

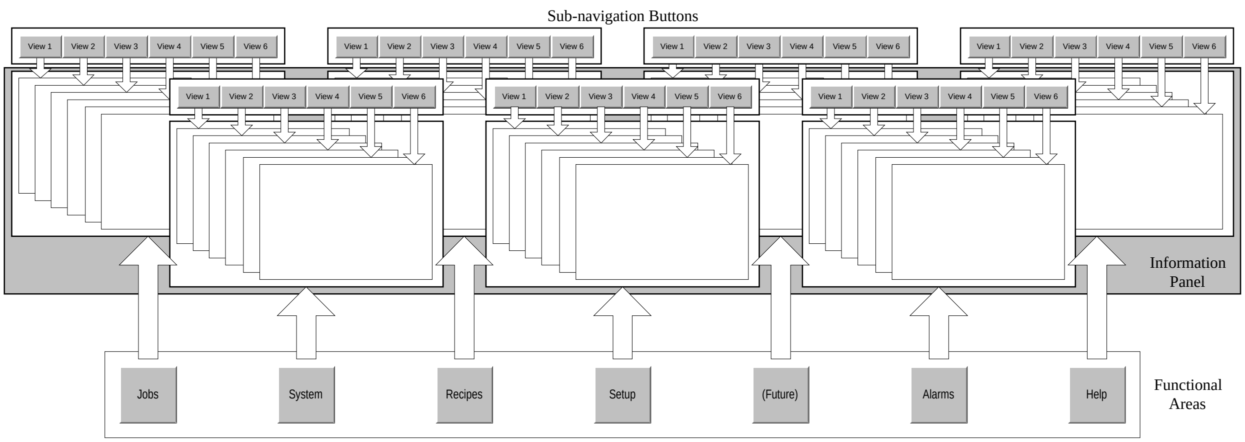

Figure 7
Network Navigation Model — Button Sub-navigation

5.3.5 *Display Layout* *Description*

5.3.5.1 The display layout is designed for ease of use with touchscreen input devices and does not require a keyboard or other pointing device. By dividing the screen into rectangular panels, provision is made to accommodate the display and input of information organized by the tasks users must accomplish in managing and monitoring processing, maintaining and repairing the equipment, and other relevant work.

5.3.6 *Basic Layout* *Mandatory*

5.3.6.1 The basic layout shall contain four panels as shown and oriented in Figure 8. At a minimum, the interface shall support the orientation of the command panel on the right-hand side, unless the enhanced layout (Section 5.3.7) is implemented.

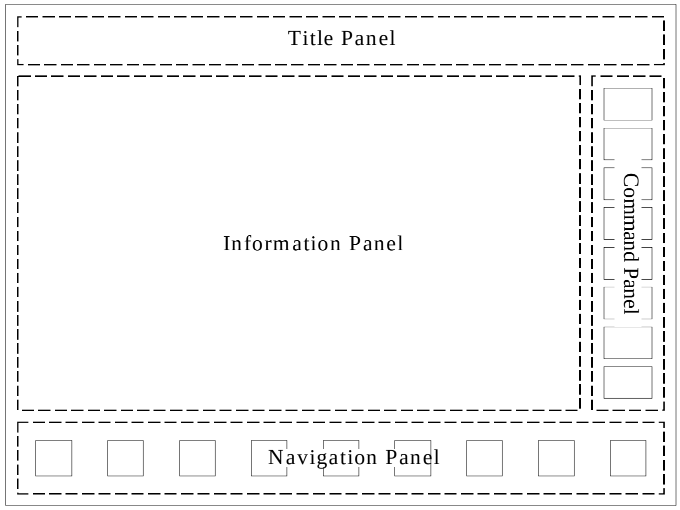

Figure 8
Basic Layout

5.3.6.2 All the panels are tiled edge to edge to create the display, and only the relative position of the panels is specified in this standard. Panels may or may not display a visible border. For an interface that is the primary display (typically, but not always at the front of equipment), an outer window frame allowing window resizing, closing, or positioning shall not be shown or enabled. This is to prevent the user from mistakenly “losing” the window, which may result in a dangerous condition. If desired, a logged-in user with sufficient privileges may be allowed to resize, but not minimize or close, the primary display window. Secondary instances of the interface (e.g., displayed at a maintenance node or displayed at a remote node) may show and enable the outer window frame.

5.3.7 *Enhanced Layout* *Recommended*

5.3.7.1 It is strongly recommended that left-handed users be allowed to change the location of the command panel to the left-hand side (see Figure 9(b)) to avoid obscuring the screen when reaching with their left hand to make selections on the command panel when it is located on the right-hand side of the screen.

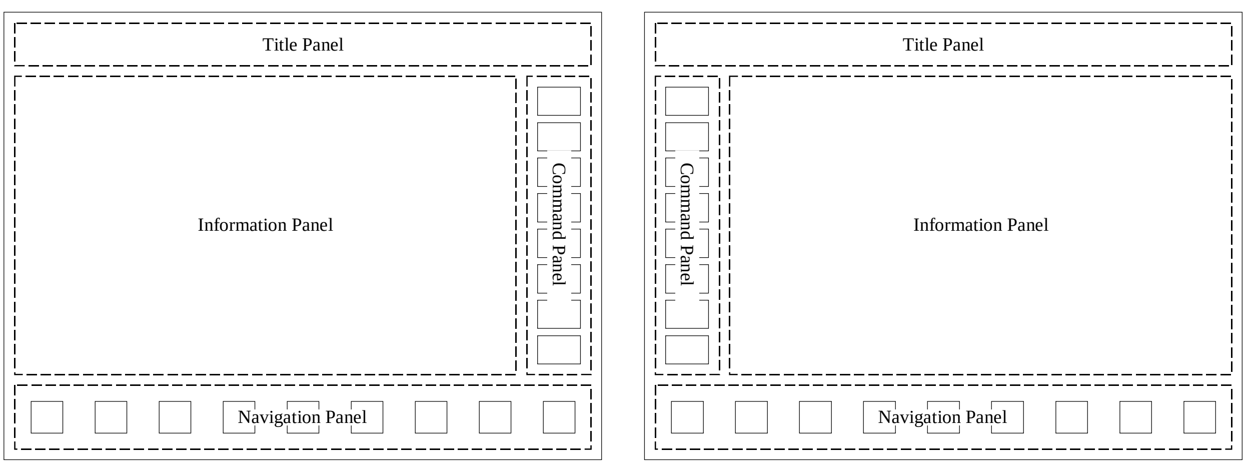

Figure 9
Enhanced Layout – Right and Left Command Panel Orientation

5.3.8 *Title Panel* — *Description*

5.3.8.1 The title panel is a horizontal area above the information and command panels, at the top of the interface window. It is always displayed and contains the host communications status display (if host communications is supported), date/time display, Login/Logout button (if security is supported), message display area, and the name of the current view. It may optionally contain a corporate identifier or logo, a display of critical parameters, an audible alarm silencing button, orientation graphics, a light tower representation, and other items that should always be displayed to ensure effective operation.

5.3.9 *Title Panel Basic Information* — *Mandatory*

5.3.9.1 Shown below is the title panel with the mandatory display objects. The relative positions shown, with the top portion of the title panel containing the date/time display at the left, the current view name to its right, and with the message area below the top portion, are mandatory.

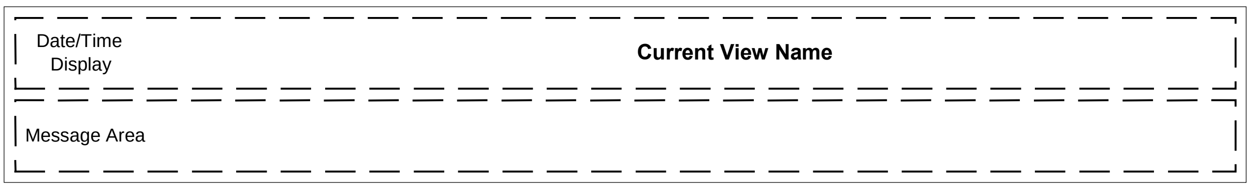

Figure 10
Title Panel

5.3.10 *Title Panel with Conditional Information* — *Conditional*

5.3.10.1 Shown below is the title panel with the mandatory display objects, plus the conditional host communications status display and the conditional Login/Logout button. The relative positions shown, with the host communications status display left-most, and the Login/Logout button at the upper right, are mandatory.

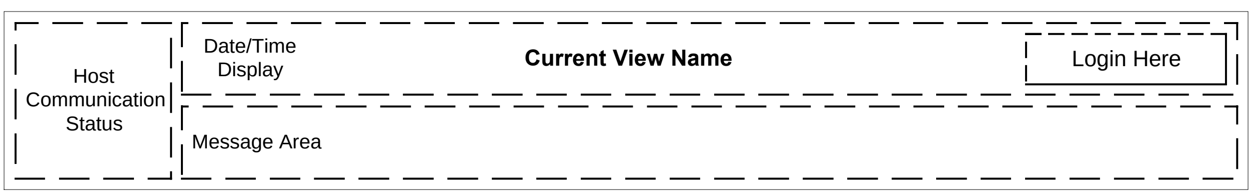

Figure 11
Title Panel

5.3.10.2 *Title Panel Host Communications Status* — *Conditional*

5.3.10.2.1 If the equipment supports host communication then status information shall be included in the title panel. Information such as communications status (i.e., whether communications is active), communications state (i.e., connected, disconnected, etc.), and whether the equipment is in a local or remote mode may be displayed here. The display of specific information is dependent on the host communication protocol which may impose additional specific requirements on what is displayed.

5.3.10.3 *Title Panel Login/Logout Button* — *Conditional*

5.3.10.3.1 The Login/Logout button label reads “Login Here” until a user is logged in, then displays a user identifier until the user logs out. User selection of the Login/Logout button invokes a dialog box where the user may enter a user identifier and password, or, if already logged in, may select a button to log out. If required by the implementation, when this dialog box is displayed, all other functions in the interface window may be disabled, including the navigation panel.

5.3.11 *Title Panel with Additional Information* | *Recommended*

5.3.11.1 Shown below is an example of a layout for the title panel incorporating some recommended display objects and their relative positions.

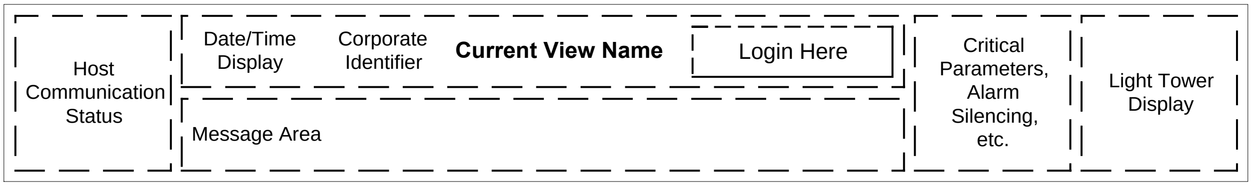

Figure 12
Title Panel with Some Additional Display Objects

5.3.11.2 *Title Panel Alarms Button* | *Recommended*

5.3.11.2.1 Although not recommended for new designs, the title panel may also contain an Alarms button that allows the user to respond to cautions and severe alarms. In this case, the Alarms navigation button in the navigation panel shall be omitted, and any alarms accessed through a title panel Alarms button shall be displayed in a dialog box, not as an information panel and its command panel.

5.4 *Navigation Panel* | *Mandatory*

5.4.1 Navigation buttons shall have a text label. In addition, they may also include an icon to graphically represent their function. When no icon is present, the button label shall be centered on the button. If an icon is present, the label shall be centered below the icon. Navigation buttons are arranged horizontally along the bottom of the display, in the navigation panel, which shall always be present.

5.4.2 *Required Navigation Functions* | *Mandatory*

5.4.2.1 At a minimum, the user shall always be able to immediately access and respond to alarm and caution notifications, even when a dialog box is displayed on the current view. Dialog boxes shall not obscure the navigation panel. Additionally, the user shall always be able to immediately access other parts of the interface if such access is required to ensure the safe operation of the equipment. Only when prohibited by the operating system or other implementation limitations such that a displayed dialog box cannot be maintained during, or redisplayed after navigation, it is allowed that such access may be accomplished by displaying another dialog box that completely covers the originally displayed dialog box. When the overlaying dialog box is dismissed, the underlying dialog box is redisplayed, in the same state it was in prior to the invocation of the overlying dialog box (i.e., given the stated prohibition or limitations, it is not mandatory that access be provided through navigation using the navigation panel). Immediate access shall mean that the user shall not have to dismiss or otherwise interact with any displayed dialog box in order to perform the required access. When the user navigates back or otherwise returns from the required access, the last selected view shall be displayed, along with any dialog box that was displayed, in the same state it was in. If no dialog box was displayed, the last selected view shall be displayed.

5.4.2.2 An allowed exception is a login and/or logout dialog box or screen if an implementation requires modal operation while logging in or out.

5.4.3 *Conditional Navigation Functions* | *Conditional*

5.4.3.1 Except when absolutely prevented by the operating system or implementation limitations, the navigation panel shall always be available for user selection, even when a dialog box is displayed on the current view. This makes it possible for the user to directly and immediately access any functional area from anywhere within the user interface. Immediate access shall mean that the user shall not have to dismiss or otherwise interact with any displayed dialog box in order to perform the required access. When the user navigates back to a functional area, the last selected view is displayed, along with any dialog box that was displayed, in the same state it was in.

5.4.3.2 An allowed exception is a login and/or logout dialog box or screen if an implementation requires modal operation while logging in or out.

5.4.4 *Navigation Panel Layout* Mandatory

5.4.4.1 The figure below shows the navigation panel, with three buttons labeled "(Future)" indicating the positions where buttons may be placed if required by the specific implementation of the interface, or as a result of modifications or enhancements in future releases of the software. It is recommended that the navigation panel contain no more than ten buttons.

5.4.4.2 The navigation buttons shall be sequenced from left to right in descending order of expected frequency of use. The most frequently selected navigation button shall be left-most within the navigation panel; and the least frequently selected button shall be right-most.

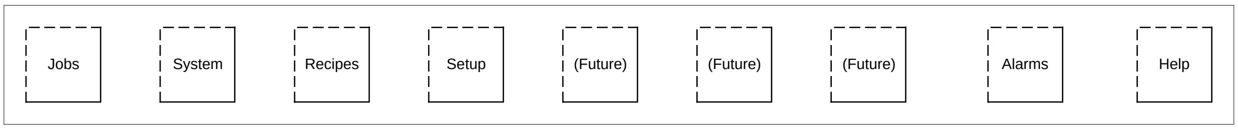

Figure 13
Navigation Panel

5.4.5 *Navigation Panel Alarm and Help Buttons* Conditional

5.4.5.1 The two exceptions to the above ordering are the Alarms and Help navigation buttons, which, when they are supported in an implementation, shall be the next to right-most and right-most buttons, respectively. This placement ensures that the position of these buttons shall remain unchanged, even if subsequent interface modifications or enhancements require additional buttons. The Alarm button shall be placed so that the spacing between it and adjacent buttons is larger than the spacing between other buttons, to allow its selection quickly, and without error.

5.4.6 *Navigation Button Labels* Conditional

5.4.6.1 For each functional area, there is a corresponding navigation button identified by a text label (mandatory) and icon (recommended) identifying the functionality and information provided. The table below shows text labels (conditional) for the navigation buttons, a description of each functional area, and some recommended alternative labels.

Table 1 Functional Areas

Navigation Button Label	*Description*	*Alternate Labels*
Jobs	Operations related to product processing, including any pre- and post-production equipment setup	Lot Operations, Operation, Operations, Processing, Main, Run
System	Equipment status, manual move, maintenance, service, calibration, & other engineering-level functions	Overview, Service, Status, System Status, Maintenance
Recipes	Recipe management, including creation, editing, storing, etc.	None
Datalog	Data histories, event logs, SPC functions (If supported)	History, Analysis, Logs, Data
Setup	User account administration, host communications control, user preferences, parameters, hardware configuration/options, light tower programming, etc.	Configuration, Options
Alarms	Alarm and caution summary to acknowledge and clear posted alarms, current event log	None (see Section 5.4.5)
Help	Help files on operations, procedures, and the interface	None (see Section 5.4.5)

5.4.6.2 The top to bottom ordering of the table reflects the left to right ordering of navigation buttons. Also allowed, but not recommended for new designs, is a left to right ordering of: System, Jobs, Equipment Setup, Recipes, History, Maintenance, and Configuration. The alternative labels specified in the table may be applied to this ordering also. Additional buttons, if required for a particular implementation, shall be added between the Setup and Alarm button positions.

5.4.7 *Navigation Panel Saliences* Conditional

5.4.7.1 Only one navigation button at a time shall display a pressed appearance. Additionally, navigation buttons shall display colored salience coding for a number of purposes: 1, to indicate the user is viewing a functional area (medium blue salience); 2, to indicate an unfinished task (typically an open dialog box) in a functional area not currently displayed (medium blue salience); and 3, to inform the user that there are new or unacknowledged cautions or alarms (saturated yellow or saturated red salience, respectively). The caution and alarm saliences are displayed on the Alarms navigation button only. As an example, if the user has opened a dialog box in the Jobs functional area, and then selects the Recipes navigation button, the Recipes button shall display a pressed (down) appearance *and* a medium blue salience, and the Jobs button shall display an unpressed (up) appearance *and* a medium blue salience (Figure 14). This reminds the user that there is an open dialog box in the Jobs functional area. More than one navigation button may display the unfinished task salience.

5.4.7.2 The Jobs button may also display a medium green salience (not shown) to notify the user that the equipment is “Ready to Load,” “Ready to Unload,” “Ready to Run,” or is in a similar state such that the user’s attention is requested in the Jobs functional area. This is useful when the user has navigated to another functional area of the interface. If there is an unfinished task, its medium blue salience shall remain displayed, even if the user’s attention is requested.

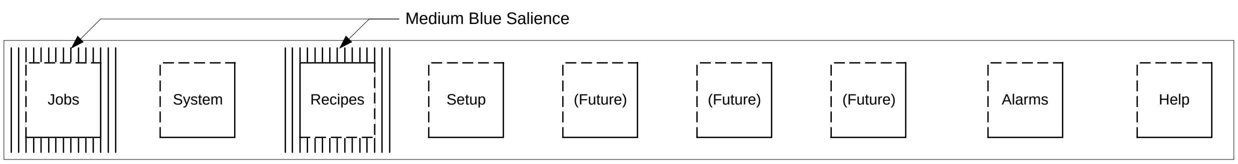

Figure 14
Navigation Button Saliences

5.4.7.3 The Alarm navigation button, in addition to the medium blue salience, displays a saturated (bright) yellow salience when there are new or unacknowledged cautions, or displays a saturated red salience when there are new or unacknowledged alarms. Only the severest level is displayed. That is, when there are both cautions and alarms, the red alarm salience shall be displayed. When there are no alarms and only cautions, the caution salience shall be displayed. The figures below show the same situation as Figure 14, with Figure 15 showing a caution salience, and Figure 16 showing an alarm salience. If there are no cautions or alarms, the Alarm button displays a medium blue salience if the user is viewing the Alarms functional area, or if there is an unfinished task and another functional area is being viewed. If a caution or alarm occurs, the medium blue salience is replaced with the appropriate salience, and is only re-displayed when all cautions and alarms have been acknowledged or cleared.

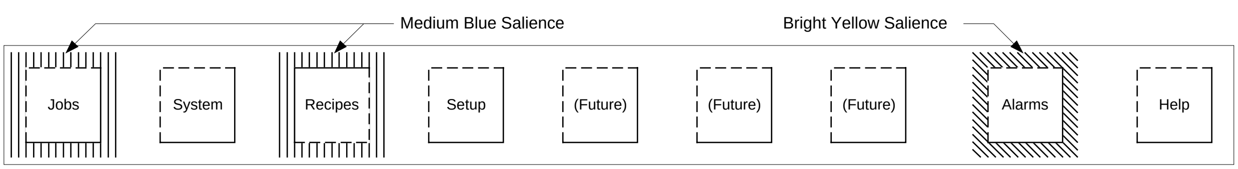

Figure 15
Warning Salience

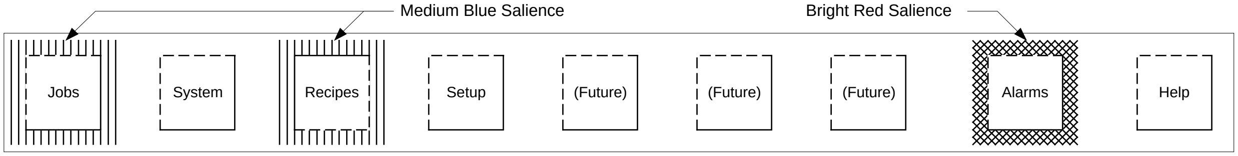

Figure 16
Alarm Salience

5.4.8 *Sub-navigation* *Conditional*

5.4.8.1 When sub-navigation is supported it shall be by a single row of tabs or buttons in a sub-navigation panel as shown below.

5.4.8.2 *Sub-navigation Layout A — Tabs*

5.4.8.2.1 Shown below are two orientations of the layout (right-hand and left-hand command panels), with sub-navigation using tabs. This is the preferred method for new designs where more than one view per functional area is needed. User selection of a tab brings the tab to the front, displays its information and command panel, and allows the user access to its display objects. Use of tabs in each functional area must be consistent throughout the interface, even if there is only one view in a functional area, and thus, one tab.

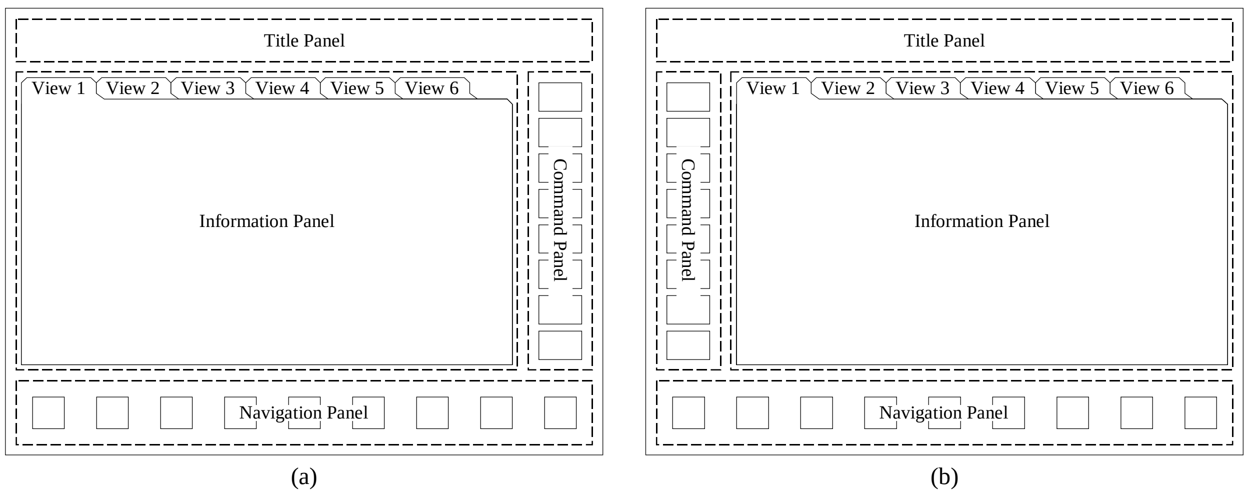

Figure 17
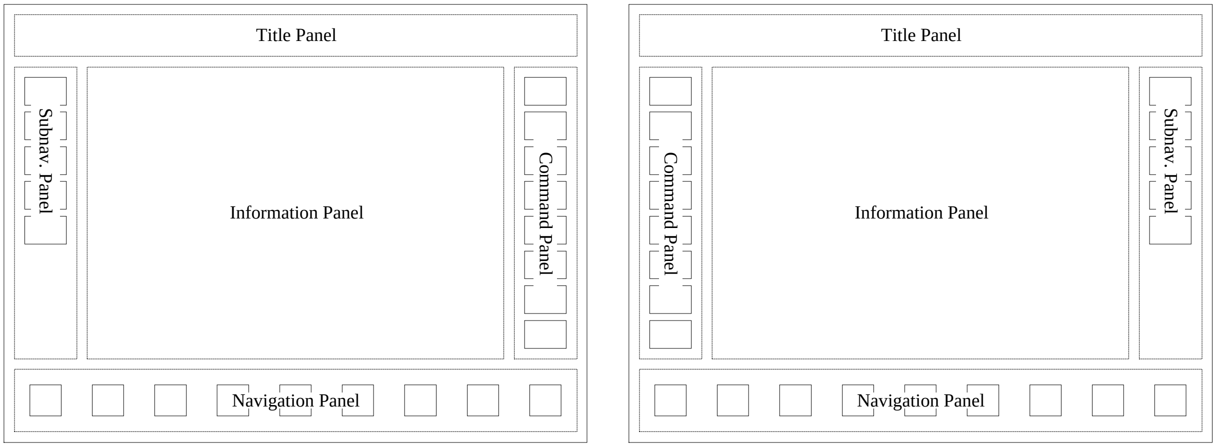
View Sub-navigation Using Tabs

5.4.8.3 *Sub-navigation Layout B — Sub-navigation Panel With Buttons*

5.4.8.3.1 Shown below are two orientations of the layout, with sub-navigation using view selection buttons in a sub-navigation panel. The figure shows one possible relative location for a sub-navigation panel, but is not intended to restrict implementation. Other arrangements are allowed. However, if a sub-navigation panel is used, its size and location in each functional area must be consistent throughout the interface, even if there is only one view in a functional area, and thus, no buttons in the panel.



(a) (b)

Figure 18
View Sub-navigation Using Buttons in Separate Panel

5.4.8.3.2 It is important in the layout to separate sub-navigation methods from the global commands in the command panel. This limits the number of buttons needed in the command panel; and reduces or eliminates the need for multiple columns of buttons, which would alter the information panel display aspect ratio. If an information panel has a different aspect ratio than the others, its contents may appear to "jump" sideways when navigating, distracting the user. The separation of sub-navigation from commands accomplishes two important objectives; a) users do not become confused trying to differentiate sub-navigation from commands, and b) the aspect ratio of the information panel display is consistent for all views across all functional areas.

5.5 *Information Panel* Mandatory

5.5.1 The information panel displays a view or views of the information and graphics for each functional area. Graphics and other display objects are placed in this panel to achieve the control and monitoring capabilities required. If necessary, multiple views of information may be displayed within a functional area, one at a time, in the information panel.

5.5.2 When any functional areas have more than one view, the user must be able to switch between those views while remaining within the context of the current functional area. The ways the user may select among multiple views presented in this standard are called sub-navigation methods to distinguish them from user navigation between functional areas using the navigation panel.

5.6 *Command Panel* Mandatory

5.6.1 The command panel is a vertical column of command buttons located to the right of the information panel (to the left if switched to accommodate left-handed users). Only buttons for common or global commands related to the current view displayed in the information panel shall be located in the command panel. If there are no common commands for an information panel, the command panel shall have no buttons. Each view in a functional area shall have its own command panel. To limit the number of command buttons needed in each command panel, user selection of a different view shall display that view and its associated command panel, with commands that apply only to the selected view. A command panel may be used for more than one view if it is suitable for that purpose. Command buttons or other display objects that have a more limited scope shall be located in the information panel. Restricting locally-acting commands and functions to the information panel makes clear to the user that only general, global commands are located in the command panel. Buttons for navigation (i.e., that invoke the display of another view in the information panel) shall not be located in the command panel. It is recommended that multiple columns of buttons in the command panel be avoided.

6 Compliance Statement

6.1 In order to be compliant with this specification, the documentation accompanying an equipment shall include a Human Computer Interface (HCI) Compliance Statement that accurately indicates compliance with the individual requirements defined in this document. Requirements and recommended capabilities are defined in Table 2.

6.2 In order to be compliant with HCI, equipment must meet all requirements in each of three categories, as follows:

6.2.1 Mandatory: In order to be compliant with this standard, all of the mandatory requirements shall be both implemented and compliant as defined in this specification.

6.2.2 Conditional: In order to be compliant with this standard, each conditional requirement shall either be implemented as defined in this specification or shall both not be implemented in the user interface and not be supported in some other way by the equipment. (i.e., no conditional capability which is present on the equipment shall be implemented in a manner other than as defined in this specification).

6.2.3 Recommended: Implementation of these features is at the discretion of the implementers. The only requirement for compliance with this specification for these capabilities is that they be accurately documented in the compliance statement for the equipment.

6.3 Each requirement/capability shall be marked "Yes" under "Implemented" if the equipment includes a feature which provides equivalent functionality as that defined in this specification even if that feature appears in a different form. Otherwise it shall be marked "No".

6.4 Each requirement/capability shall be marked "Yes" under "HCI Compliant" if the equipment includes a feature which conforms to all aspects of the requirement or recommended capability as defined in this specification. Otherwise it shall be marked "No".

Table 2 HCI Compliance Statement

HCI Compliance Statement			
Mandatory Requirements	*Reference*	*Implemented*	*HCI Compliant*
Button Size	5.2.2.1	Yes No	Yes No
Button Behavior	5.2.2.3	Yes No	Yes No
Button Text	5.2.2.4	Yes No	Yes No

SEMI E96-1101
GUIDE FOR CIM FRAMEWORK TECHNICAL ARCHITECTURE

This guide was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the European Regional Standards Committee on June 11, 2001, and by the North American Regional Standards Committee on July 19, 2001. Initially available at www.semi.org August 2001; to be published November 2001. Originally published February 2000. This document replaces PR5-0699 in its entirety.

1 Purpose

1.1 This guide describes technical architecture choices that enable application components to cooperate in a Computer Integrated Manufacturing (CIM) environment and reduce the effort required to integrate those components into a working solution. The CIM Framework technical architecture guide builds on publicly available specifications for distributed object computing. It defines manufacturing production systems requirements for the technical infrastructure needed for improved component interoperability, substitutability, and extensibility. It provides guidance for specifying components and addresses options for using an underlying distributed object communication infrastructure.

1.2 This guide provides guidance for the technical foundation of the SEMI Computer Integrated Manufacturing (CIM) Framework standards. It discusses a component-based architecture using object-oriented and framework technology that helps implementers achieve component interoperability and substitutability, application extensibility, and reuse. It establishes the role of distributed object communications infrastructure in providing necessary support for the framework technology. Specification methods for mapping a CIM Framework specification to alternative infrastructure technologies are also addressed by this technical architecture. However, these mappings are not intended to be prescriptive. Further work may be required to define additional mappings to emerging technologies. Many implementation issues that should be resolved for a particular software implementation are outside the scope of this guide.

1.3 Adhering to this guide for technical architecture alone does not provide interoperability between applications. While the technical architecture provides a foundation for interoperability, it is limited by the following factors:

- Multiple infrastructure implementation choices are possible, and interoperability across these environments is not guaranteed.
- The technical architecture intentionally limits its scope to only the most fundamental infrastructure requirements, leaving additional technical issues for future guide upgrades or for implementers' discretion.
- Conformance to a specification for CIM Framework Domain Architecture is also required for interoperability of domain components.
- More complete semantics (including behavioral constraints and collaboration patterns) for components are needed to ensure consistent interactions among components developed by separate suppliers.

1.4 A guide for technical architecture is a necessary, but not a sufficient, basis to achieve the goals of the CIM Framework specifications. It does not mandate specific solutions to address the identified technical requirements because there are multiple implementation choices that meet these requirements. Rather, the technical architecture identifies those crucial technical requirements that should be considered by both CIM software suppliers and consumers. The proposed standard identifies the technical capabilities implementations should provide, but leaves the implementation options open. It is the responsibility of suppliers to provide and explain an implementation of each capability, and the responsibility of consumers to assess particular implementations for use in their factories.

1.5 This guide provides guidance on the technical tradeoffs for services provided by the distributed computing infrastructure for the purpose of supporting and enabling the domain specifications of CIM Framework components. These areas are:

- *Distributed Object Communication* — Provides the basic services to enable implementations supporting the CIM Framework interfaces to transparently locate other, possibly distributed implementations and exchange messages requesting standard CIM Framework operations. Interface Definition Language provides a formal specification of the CIM Framework interfaces that can be automatically transformed into conformant implementations ready for integration and interoperation.
- *Exception Declarations* — Identify the form and structure of return messages that inform requestors that a requested operation resulted in an anticipated, but abnormal outcome.

- *Event Specification* — Establishes the delivery mechanism, identification conventions, and data structures for reporting the occurrence of anticipated state changes to CIM Framework objects.
- *Distributed Transactions* — Define mechanisms needed to coordinate the start, completion or rollback of units-of-work that cross CIM Framework component boundaries.
- *Component Manager Support* — Identifies the component-level operations needed to create, locate, or remove instances of objects (and manage collections of those objects) that support the CIM Framework specified interfaces.

2 Scope

2.1 *Intended Audience*

2.1.1 This document is intended for developers of components and applications, and integrators of MES systems that adhere to the CIM Framework specifications. It is also intended for system architects who contribute to the evolution of the CIM Framework architecture and guides based on implementation experience. A guide for technical architecture is focused on the software technologies that support the architectural goals for the CIM Framework rather than on the manufacturing domain concepts that the CIM Framework encompasses. The technical architecture perspective complements SEMI E81.

2.2 *Architectural Issues Not Covered*

2.2.1 A number of architectural issues are not covered within this document because they are beyond the scope of the CIM Framework standards and are not expected to come within the scope of the standards as they are revised. They are itemized here because a product architecture layered on the CIM Framework Technical Architecture should address these additional architecture issues. In these cases, other more general specifications emerging in the infrastructure technology areas are expected to provide these needed standards. The CIM Framework domain specifications do not require specific conformance in these areas to support component specifications.

2.2.2 *Persistence*

2.2.2.1 Persistence refers to the ability of an object to maintain a nonvolatile copy of its current state such that the object could recreate the state during a future initialization. There are various operations for object persistence, and problems can occur if objects with cross-references do not coordinate their persistence strategies and mechanisms. The CIM Framework excludes persistence as an implementation mechanism.

2.2.3 *System Performance*

2.2.3.1 System performance is highly dependent on the selection of hardware and software platforms for system execution. Tests should be performed to verify adequate system performance and scalability for the anticipated operating environment. Performance tuning mechanisms or measurement tools are excluded from the CIM Framework specifications as an implementation dependent mechanism.

2.2.4 *Data Replication*

2.2.4.1 Data replication is a technique used to provide additional fault tolerance or improve system performance in certain situations. The CIM Framework excludes specification of replication strategies as an implementation dependent mechanism.

2.2.5 *Change Management*

2.2.5.1 Change management is the ability to introduce and control changes to the system configuration. The CIM Framework encompasses change management in the domain context of document control, but the CIM Framework excludes the broader treatment of change management for the MES software configuration itself.

2.2.6 *Externalization*

2.2.6.1 Externalization can be used to provide a form of persistence or to transfer object state between disjoint implementations. The ability of an object to externalize its data and state supports recovery of data and state for objects that terminated from memory. The CIM Framework excludes externalization as an implementation dependent mechanism.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The CIM Framework should continue to evolve to meet the needs of a competitive and vital industry. The content of this framework represents a significant amount of real development experience from a number of commercial software suppliers and their customers. These specifications reflect the product architectures of those companies, as well as the requirements of their customers. This evolution process should continue as more products based on the CIM Framework are developed.

3.1.1 This guide acknowledges the following deficiencies that should be addressed in future revisions. These deficiencies are identified in the following sections.

3.2 *Mapping to Alternate Distributed Computing Infrastructures*

3.2.1 The CIM Framework provides a specification for MES software components, specified in terms of generalized manufacturing production systems requirements, that may be implemented using a variety of technical infrastructure foundations. While the intent of this guide is to provide both rigor in specification and flexibility to make infrastructure implementation choices, these goals often conflict. The use of mapping techniques complicates the task of integrating applications across technology boundaries.

3.2.2 While it is anticipated that a conformant implementation using either CORBA®[1] or the Microsoft®[2] Distributed Component Object Model (DCOM) is feasible by mapping the specifications to the implementation, it is recognized that cross-infrastructure integration is significantly more difficult (for example, merging transaction models). The mapping described here offers more diverse implementation choices, but it does not guarantee that all of those chosen technologies easily work together in a single heterogeneous implementation.

3.2.3 Although the DCOM mapping provides a straightforward transform from the OMG® Interface Definition Language (IDL)™[3] specifications for static invocation, the Microsoft OLE Automation interfaces may be required for dynamic invocation. There appears to be greater risk in being able to successfully map the CIM Framework to the OLE Automation interfaces. The requirement for dynamic invocation should be evaluated with this in mind.

3.2.4 Another issue with DCOM mapping concerns exceptions. DCOM returns exceptions using its return value HRESULT. Many CIM Framework operations already use return values and would not be able to return a HRESULT without restructuring the return mechanism for the operation results.

3.2.5 Finally, there has not yet been a detailed analysis of the CIM Framework interfaces to verify that they can be successfully mapped using the CORBA Interworking Architecture.[4] This is especially true of the OLE Automation mapping resolution.

1 CORBA is a registered trademark of Object Management Group, Inc. in the United States and other countries.

2 Microsoft is a registered trademark of Microsoft Corporation, Inc. in the United States and other countries.

3 OMG Interface Definition Language (IDL) is a trademark of Object Management Group, Inc. in the United States and other countries.

4 Object Management Group. The Common Object Request Broker: Architecture and Specification, Revision 2.2, Object Management Group, 492 Old Connecticut Path, Framingham, MA: Object Management Group, 1998.

3.3 *Business Rules*

3.3.1 The management of factory objects requires the use of a set of business rules; that is, procedures representing common business practices that should be applied under a given set of circumstances in response to some factory event. For instance, “Do not assign a process job to a machine which is scheduled for maintenance within 24 hours.” Factory systems implementations typically specify business rules as event-driven ECA (event-condition-action) or ECAA (event-condition-action-alternative action) rules. For example:

- *event* — request to edit a process specification;
- *condition* — invalid user access privilege;
- *action* — deny access;
- (*alternative action* — deny access and report breach of security).

3.3.2 Business rules can also be embodied in the sequencing logic of sequential process definitions. In this case the business rules define the criteria for making sequencing decisions that effect the flow of work through the factory.

3.3.3 Business rules are intended to be addressed in future revisions of this guide.

3.4 *Security and Access Control*

3.4.1 The management of sensitive information regarding business processes and product specifications requires that MES implementations (especially distributed systems) provide some level of security and access control services. Typically, such services:

- identify and authenticate any factory object seeking sensitive information,
- permit access to information or operations based upon identity and privilege,
- provide security-related audit trails,
- provide secure communications (not susceptible to being intercepted nor malicious or inadvertent modification), and
- administer an enterprise’s security policy.

3.4.2 Security and access control is intended to be addressed in future revisions of this guide.

3.5 *Internationalization*

3.5.1 Specifications that deal with issues related to internationalization are emerging from several sources, including the OMG. This guide should encompass the need and ability to incorporate internationalization features into the CIM Framework specifications.

3.5.2 Internationalization are intended to be addressed in future revisions of this guide.

3.6 *Object Properties*

3.6.1 Object properties refers to a technique that allows additional attributes (data) to be dynamically associated with an object without changing the interfaces of the objects to which the properties are attached. This can be used as a convenient dynamic extensibility mechanism that may be considered in future CIM Framework specifications.

3.6.2 Object properties are intended to be addressed in future revisions of this guide.

3.7 *Object Collections and Queries*

3.7.1 Object collections and queries allow flexible access to aggregate data for a group of objects. This capability may be a candidate to replace the limited operations for collections found in the component manager interface.

3.7.2 Object collections and queries are intended to be addressed in future revisions of this guide.

4 Referenced Standard

4.1 *SEMI Standard*

SEMI E81 — Provisional Specification for CIM Framework Domain Architecture

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *ACID* — Atomicity Consistency Isolation Durability

5.1.2 *CIM* — Computer Integrated Manufacturing

5.1.3 *ECA* — Event-Condition-Action (rule)

5.1.4 *ECAA* — Event-Condition-Action-Alternative Action (rule)

5.1.5 *ENS* — Event Notification System

5.1.6 *ERP* — Enterprise Resource Planning

5.1.7 *GUI* — Graphical User Interface

5.1.8 *MES* — Manufacturing Execution System

5.1.9 *ODL* — Object Definition Language

5.1.10 *OMA* — Object Management Architecture

5.1.11 *OTS* — Object Transaction Service

5.2 *Definitions*

5.2.1 *application* — 1. one or more programs consisting of a collection of interoperating objects which provide domain specific functionality to an end user or other applications. 2. functionality provided by one or more programs consisting of a collection of interoperating objects.

5.2.2 *application interface* — the interface provided by an application or application program.

5.2.3 *application object* — an object implementing an application interface.

5.2.4 *architecture* — the structure of the components of a program/system, their interrelationships, and principles and guidelines governing their design and evolution over time.

5.2.5 *attribute* — an identifiable association between an object and a value. An attribute may have functions to set and retrieve its value.

5.2.6 *behavior* — the effects of performing a requested service, including its results (e.g., changes in the state of an object).

5.2.7 *binding* — a specific choice of platform technologies and other implementation-specific criteria.

5.2.8 *class* — the shared common structure and common behavior of a set of object implementations.

5.2.9 *client* — an object that uses the services of another object by sending messages to it or referencing its state.

5.2.10 *collection* — an object containing references to (collections of) other objects with services for managing them and providing access to them as a related group of objects.

5.2.11 *component* — a reusable package of encapsulated objects and/or other components with well-specified, published interfaces. The component is the element of standardization and substitutability for the CIM Framework.

5.2.12 *Computer Integrated Manufacturing* — an approach that leverages the information handling capability of computers to manage manufacturing information and support or automate the execution of manufacturing operations.

5.2.13 *conformance* — adherence to a standard or specification in the implementation of a product, process, or service.

5.2.14 *conformance requirement* — identification in the specification of behavior and/or capabilities required by an implementation for it to conform to that specification.

5.2.15 *conforming implementation* — an implementation that satisfies all relevant specified conformance requirements.

5.2.16 *event* — an asynchronous message denoting the occurrence of some incident of importance. For example, state change or new object created.

5.2.17 *event channel* — the intermediate object that forwards published events to interested subscribers.

5.2.18 *exception* — an infrastructure mechanism used to notify a calling client of an operation that an unusual condition occurred in carrying out the operation.

5.2.19 *extensibility* — the ability to extend or specialize existing components and add new object classes or components while preserving architectural integrity and component conformance to standards.

5.2.20 *framework* — a collection of classes or components that provide a set of interoperable services and functionality for a particular domain.

5.2.21 *implementation* — the internal view of a class, object or module, including any non-public behavior. The specific code and functionality that implements an interface.

5.2.22 *implementation conformance statement* — a statement made by the supplier of an implementation or system claiming to conform to one or more specifications and stating which capabilities have been implemented. It specifically includes the relevant optional capabilities and limits.

5.2.23 *infrastructure* — the services, facilities, and communications mechanisms that support the collaboration between and lifecycle of distributed objects.

5.2.24 *inheritance* — the ability to derive new classes, types or interfaces from existing classes, types or interfaces. For example, a derived class ("subclass") inherits the instance variables and methods of the base class ("superclass") and may add new instance variables and methods. In the CIM Framework, inheritance applies to interfaces and their specification of operations rather than implementations of classes.

5.2.25 *instance* — a software entity that has state, behavior and identity. The terms instance and object are interchangeable. An object is an instance of an interface if it provides the operations, signatures, and semantics specified by that interface. An object is an instance of an implementation if its behavior is provided by that implementation.

5.2.26 *interface* — the external view of a class, object, or module that emphasizes its abstraction while hiding its structure and internal behavior. An interface definition ideally includes the semantics of attributes and operations.

5.2.27 *interoperability* — the ability for two applications or the parts of an application to cooperate. In the CIM Framework, interoperability requires that application components be able to support specified relationships, share data, invoke each others' behavior (operations), return exceptions, and exchange events.

5.2.28 *lifecycle* — the life of an object, including creation, deletion, copy, and equivalence.

5.2.29 *message* — in object oriented systems a message is the means by which a client object invokes the behavior specified by an operation of a server object.

5.2.30 *message bus* — a software infrastructure that provides distributed communication between objects in component implementations. It can refer to an Object Request Broker, Microsoft DCOM, Java Remote Method Invocation or other infrastructure for conveying messages between objects.

5.2.31 *name-value pair* — a data structure that associates a name with an arbitrary value, typically used as an extensibility mechanism for conveying information by name-based retrieval.

5.2.32 *namespace* — a namespace is a bounded collection of names with a constraint to ensure that each name is unique within the collection.

5.2.33 *object* — a software entity that has state, behavior, and identity. The terms instance and object are interchangeable. An object is an instance of an interface if it provides the operations, signatures, and semantics specified by that interface. An object is an instance of an implementation if its behavior is provided by that implementation.

5.2.34 *object services* — interfaces for general services that are likely to be used in any program based on distributed objects.

5.2.35 *operation* — an operation is a specification entity, identified by an operation identifier, that denotes a service that can be requested. An operation has a signature that describes the legitimate values of request parameters and returned results, including any exceptions.

5.2.36 *persistent object* — an object that can survive the process or thread that created it.

5.2.37 *productive entity* — productive entity is an abstraction of a physical unit, which is involved in any way in a production process (e.g. production or supporting equipment). A productive entity has its own internal logic and provides a software interface to access this logic

5.2.38 *query* — a message sent to a server (e.g. the productive entity) by a client interested in some information from the server (state of the productive entity). A query may or may not have arguments and it always has an answer. The semantics of a query is that some information from the server is returned, but the query cannot effect any change to the state of the server.

5.2.39 *service* — a function provided by a service provider that is performed through an operation specified by the provider.

5.2.40 *service provider, server* — an object providing services to other objects as specified by its published operations.

5.2.41 *signature* — a signature is the name, parameters, return values, and exceptions for a specific operation.

5.2.42 *substitutability* — the ability to replace a given component from one supplier with a functionally equivalent component from another supplier without impacting the other components or its clients in the system.

5.2.43 *trader service* — a collection of names with associated properties of features for each name and methods for manipulating and inspection that collection.

5.2.44 *type* — a declaration that describes the common properties and behavior for a collection of objects. Types classify objects according to a common interface; classes classify objects according to a common implementation.

6 Technical Architecture Guidance

6.1 The computing infrastructure provides the distributed computing environment for CIM Framework applications. This infrastructure includes the operating system, networking and communications, data storage and access, user interface and presentation services, event distribution, systems management, and many other elements. Of these many infrastructure elements, a guide for technical architecture specifies a small subset of key services that need to be standardized in order to facilitate and streamline system integration between conformant CIM Framework implementations.

6.2 The CIM Framework relies on publicly available specifications to define the use of infrastructure services wherever such published specifications exist. The largest single source for openly defined specifications for distributed object services is the Object Management Architecture.[5] Reference to this guide does not imply that CIM Framework conformant implementations should implement the referenced services. The implementations that realize these infrastructure technologies are outside the scope of this guide. The technology choices made by implementers should be kept transparent to the CIM Framework to the greatest extent possible.

6.3 *Distributed Object Communication*

6.3.1 The CIM Framework documents assume the use of software infrastructure to provide distributed communication between objects in an implementation. The acronym ORB was originated by the OMG to describe its distributed object communication infrastructure, but is sometimes used in a more general sense. In this document ORB is used only to refer to the OMG specified technology and the more general term "message bus" is used for the diverse class of distributed communication mechanisms for communication between objects. The message bus is used to allow objects to make requests and receive responses from other objects. An object can communicate through the message bus with objects that are local or remote. Location transparency allows the object to remain ignorant of the actual location of the object with which it communicates.

6.3.2 A primary criterion for a message bus implementation is its ability to deliver all messages specified by the interfaces of the CIM Framework components. To accomplish this, the message bus should provide the ability to support or map a specified interface, including its inherited features, data types, operations, object references, and exceptions to and from runtime marshaled transport formats.

6.3.3 Alternate message bus implementation technologies are supported by the CIM Framework by mapping the OMG IDL for the CIM Framework interfaces into a specific message bus implementation. The Common Object Request Broker: Architecture and Specification[4] contains sections that define this mapping from CORBA to COM and from CORBA to OLE Automation. These sections, called the "Interworking Architecture," cover detailed rules for mapping OMG IDL, types, and exceptions to compatible interfaces in COM and OLE Automation.

6.3.4 From a high level perspective, the DCOM and CORBA message buses are comparable. The DCOM capabilities are roughly equivalent to those of an ORB. However, with a lower level analysis, differences show up in data types, inheritance, object identity, and the handling of exceptions. The CORBA Interworking

5 Object Management Group. The Object Management Architecture Guide, Revision 3.0, John Wiley and Sons, New York NY, 1995.

Architecture[4] (Chapter 15, "Interworking Architecture," Chapter 16, "Mapping COM to CORBA," and Chapter 17, "Mapping OLE Automation to CORBA") defines mapping approaches covering:

Interface Mapping,

Interface Composition Mapping, and

Identity Mapping.

6.3.5 These areas should be addressed in order to provide a mapping between the OMG IDL used to specify CIM Framework interfaces and the message bus used for implementation. If the mapping is not specific (i.e., can occur in multiple ways) then two implementations may not necessarily be able to communicate even if they use the same message bus type. Although the CORBA Interworking Architecture is specific to Microsoft technologies, it could provide the foundation for future interworking mappings.

6.3.6 The current CIM Framework interfaces are specified in OMG IDL. The interfaces can be directly compiled and used with any of the available ORB implementations on the market.

6.3.7 The only way to provide such a direct solution using Microsoft DCOM would be to create additional CIM Framework interface specifications in DCOM MIDL and/or OLE Automation ODL. This would allow direct support for message bus functionality using DCOM. For example, the CIM Framework memory management requirement of "in" for parameter passing (see Section 6.3.15) would be directly supported by MIDL and DCOM but since the CORBA exception model is significantly richer than the DCOM exception model, mapping CORBA exceptions to COM would require an additional protocol to be defined for DCOM.

6.3.8 The CORBA Interworking Architecture supports mapping the current CIM Framework interfaces defined in OMG IDL to DCOM MIDL or OLE Automation ODL. This mapping is detailed enough that the mapping should always provide the same MIDL/ODL solution. Even though the current scope does not include interoperability between implementations on DCOM and CORBA (see Section 3.2), the issue of mapping the interface is still the same. This would also provide a step towards true interoperability using CORBA/ DCOM bridge products that are beginning to become available.

6.3.9 Microsoft also provides an extension called OLE Automation. These interfaces are described in Object Definition Language (ODL). The OLE interfaces can be invoked dynamically by a client with no compile-time interface knowledge. The OLE data types are a subset of the types supported in DCOM, and there is no support for user-defined constructed types. The mapping solution differs for the DCOM and the OLE Automation. OLE Automation does not provide as clean a mapping from OMG IDL as DCOM does. This limitation may not allow some of the interfaces to translate completely to an OLE Automation implementation. Thus, component suppliers using an OLE Automation implementation should explain impact on interfaces that were not fully supported due to the Automation restrictions.

6.3.10 The CORBA Interworking Architecture covers mapping issues for the major areas of concern for the CIM Framework. The areas of primary importance are the Interface mapping, Interface composition mapping, Identity mapping, and Exception mapping. The CORBA Interworking Architecture gives detailed mappings for each of these areas and deals with the DCOM and OLE Automation mappings separately. The following five subsections summarize these mapping issues.

6.3.11 *Interface Mapping*

6.3.11.1 The OMG IDL primitives, constructed data types, and object references map closely to DCOM. The inherited CORBA interfaces may be represented as multiple DCOM interfaces. The CORBA attributes may be mapped to get and set operations in DCOM interfaces.

6.3.11.2 The OMG IDL primitives map to OLE primitives except for special cases. The OLE interfaces do not support constructed data types and should be mapped to specially constructed interfaces. CORBA object references map to OLE Automation interface pointers. There are difficulties in mapping CORBA multiple inheritance to OLE Automation interfaces documented in the CORBA specification.[4] CORBA attributes may be mapped to get and set operations in OLE Automation interfaces.

6.3.12 *Aspects* — The total behavior of a piece of a productive entity in a factory can be viewed as the union of distinct behaviors. Each such isolated behavior (or functional area) is called an aspect of the productive entity.

6.3.12.1 There is great variety in productive entity behavior. There are generic aspects that are shared by all or most productive entities (such as recipe management or process state model or material tracking) and there are aspects that are specific to one productive entity type or to a particular productive entity model. The behavior of each productive entity is the union of the particular aspects of that productive entity.

6.3.12.2 Saying that two pieces of productive entities have a certain aspect does not necessarily mean that they behave absolutely the same way. There are two ways by which behavioral variation within an aspect can be modeled: Parameters and Variants.

6.3.13 *Parameterized Aspects* — An aspect can have parameters. Differences in productive entities behavior are modeled by assigning different values to the parameters. For example if a physical structure aspect of the productive entity specifies that the productive entity has a material buffer, the number of material units (buffer size) that can be placed on the buffer is a possible parameter. The number of buffers the productive entity has can be another parameter.

6.3.14 *Variants* — While parameterization is a very powerful tool, there are variations in behavior that cannot be simply modeled as different parameter values. In this case one can use variants. An aspect is said to have variants if there are some different behaviors related to the same aspect. For example the process control aspect can have a discrete variant and a continuous variant. In the discrete variant the productive entity processes discrete units of material (like the material within a magazine or a single wafer carrier), while in the continuous variant the productive entity processes continuously as long as there is material to be processed.

6.3.14.1 Differences between productive entities are best modeled as parameters when possible in order to avoid an explosion of the number of variants, while at the same time trying to maintain the clarity of the model.

6.3.14.2 A complete specification of the behavior of a piece of productive entity should specify variants for these aspects that have them.

6.3.15 Where do aspects and variants come from? — They leverage on previous work done by the industry. GEM (Generic Equipment Model, SEMI E30) is a primary source for identifying generic aspects. Various SEMs (Specific Equipment Models) are a source for specific aspects and very likely for variants. Other SEMI standards like SEMI E-40 (Standard For Processing Management) cover other aspects neglected by GEM.

6.3.16 *Specifying Productive Entity Interfaces in a Factory* — In order to specify the interface of a productive entity it is necessary first to identify the aspects (or variants of these aspects) supported by the productive entity, then to specify the interfaces associated with each aspect. The productive entity interface specification is then the sum of the interface specifications for all participating aspects.

6.3.16.1 The interface of an aspect (or variants of these aspects) is the sum of its Queries, Commands, Event Notifications and Service Requests and thus the problem of defining productive entity interface is reduced to the problem of defining the interfaces of individual aspects (or variants of these aspects).

6.3.17 *Architecture* — The productive entity in a factory is viewed as a composition of its aspects. The total productive entity behavior is therefore represented by the sum of all its aspects representing these behaviors. Each aspect specifies a specific behavior of productive entity and provides an interface for incoming messages (queries and commands).

6.3.17.1 An aspect has a name. The productive entity can answer a reference to one of its aspects given the aspect name:

```
AspectInterface aspectNamed(in string
aspectName);
```

6.3.17.2 An AspectInterface is a virtual interface that represents a generic aspect. All aspect interfaces inherit from the generic AspectInterface. When an aspect has variants, the aspect interface itself is virtual, and all its variant interfaces inherit from it.

6.3.17.3 Additionally the productive entity answers a list of the names of all its aspects:

```
StringList allAspectNames();
```

6.3.17.4 The usual scenario for a client is to acquire a reference to the productive entity. It then acquires references to the productive entity aspects of interest by querying the productive entity. The client then invokes methods on the aspect interfaces as required.

6.3.17.5 The client only needs to acquire aspect interfaces once when it first establishes communication with the productive entity. From then on it caches the productive entity interface as well as the references to the productive entity aspects for further use. The procedure of acquiring references needs to be repeated only in case the references become invalid (due to productive entity restart for example).

6.3.18 *How To Add A New Aspect* — The definition of an aspect follows the following aspect definition pattern. It includes the following items:

6.3.18.1 *Aspect Name* — Each aspect has a name that identifies it.

6.3.18.2 *Aspect Description* — The aspect description explains the productive entity behavior covered by the aspect. If the aspect has been derived from an existing standard, the description includes a reference to this standard. It explains the concepts and the used terminology, adds state models and state transition diagrams if required, and explains the interactions between the productive entity and the factory elements related to the aspect. If the interactions require certain sequences of messages, they are also described (as use cases or interaction diagrams).

6.3.18.3 The description also includes all the side effects and exceptions that can occur as a result of the interactions related to the aspect.

6.3.18.4 If the aspect has any relation or effects related to other aspects, they are also described here.

6.3.19 *Variants* — If the aspect has variants, each variant is named and described.

6.3.19.1 *IDL* — Usually the IDL will include a special module for the aspect. The module includes data type definitions specific to the aspect and usually a single interface that provides the various queries and commands of the aspect. An aspect that has variants has an interface per variant. The interfaces for the variants can be inherited from a common (abstract) aspect interface.

6.3.19.1.1 An aspect that deals with service requests should also include an IDL definition for the server that provides the services. Which is to be done in a separate module.

6.3.19.2 *Aspect Definition Example* — Here the Control State Aspect has been chosen as an example for aspect definition.

6.3.19.2.1 *Aspect Name* — Control State

6.3.19.2.2 *Aspect Description* — The definition of the Control State Aspect is based on Generic Equipment Model (GEM) SEMI standard E30.

NOTE 2: The state diagram presented here is simpler than the one in SEMI E30, since the internal sub-states are irrelevant to the productive entity interface, and the concept of HOST OFFLNE is obsolete in a distributed factory environment

6.3.19.2.2.1 The control state model defines the level of cooperation between the productive entity and the factory. It also specifies how the operator interacts in the different levels of factory control.

6.3.19.2.2.2 The control state model provides the factory with three levels of control over the productive entity:

6.3.19.2.3 *OFFLINE* — In the OFFLINE state, operation of the productive entity is done by the operator. In the OFFLINE state the productive entity accepts a query to find out the current control state and the command to change its control state, but rejects all other queries or commands (raising the rejected exception). While in the OFFLINE state the productive entity produces no events and no service requests.

6.3.19.2.4 *LOCAL* — In the LOCAL state the productive entity is operated by the operator.

6.3.19.2.4.1 In the LOCAL state the productive entity answers all queries from the factory and allows the factory to execute a limited set of commands. The commands that are prohibited are those that cause movement or directly affect the process. The productive entity sends events and asks for services from the factory.

6.3.19.2.5 *REMOTE* — In the REMOTE state the productive entity is controlled by the factory. The factory has full access to all the necessary commands to operate the productive entity through the full process cycle in an automated manner. The degree of automation can vary from productive entity to productive entity and from factory to factory. Generally operators are required to intervene in setup operations, operator assist situations, etc. Therefore when in REMOTE state, even though theoretically fully under control of the factory, the productive entity should not restrict the operator from executing essential operations such as selecting a recipe, pausing or resuming the process, operator assists, material movement to/from the productive entity, initiating recipe download and other productive entity specific commands on a command by command basis as needed. At the very least the operator should be able to change the control state, actuate an emergency stop and interrupt processing (stop, abort or pause).

6.3.19.2.6 The following diagram depicts the productive entity Control State model.

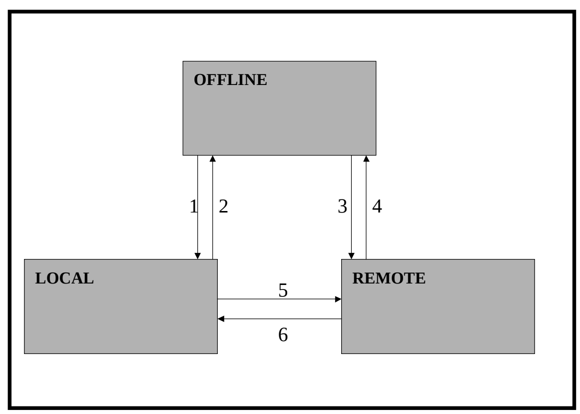

Figure 1

6.3.19.2.7 As can be seen from the diagram, transition from any state is allowed to the two others. The aspect provides the factory methods for querying the current state, for initiating a transition to any of the states, and for events when state transitions occur.

Variants : None

IDL

```
 module ControlStateModule {
   // Type Definitions
   enum ControlState {OFFLINE, LOCAL,
   REMOTE);

        interface ControlState {
         // Queries
         ControlState getControlState()
       raises (EqBasicTypesModule::
       CommunicationFailure);

         // Commands
      void changeControlStateToOffline()
       raises (EqBasicTypesModule::
       CommunicationFailure);
      void changeControlStateToLocal()
       raises (EqBasicTypesModule::
       CommunicationFailure);
      void changeControlStateToRemote()
       raises (EqBasicTypesModule::
       CommunicationFailure);
        };
};
```

6.3.19.2.8 The control state aspect can post the following events:

```
ControlStateChangedToLocal
ControlStateChangedToRemote
controlStateChangedToOffline
```

6.3.20 *Interface Composition Mapping*

6.3.20.1 The DCOM interfaces do not support multiple inheritance. When multiple inheritance is used to extend functionality, the mapping is not very difficult. When multiple inheritance is used to “mix in” orthogonal behavior the mapping is more difficult. The CIM Framework interfaces that only use single inheritance provide the most reliable mapping. Interfaces that use multiple inheritance should follow the detailed mapping rules and ordering provided in the CORBA Interworking Architecture.

6.3.20.2 OLE Automation also has problems directly supporting the multiple inheritance of CORBA. The CORBA Interworking Architecture[4] provides detailed mapping rules for making the conversion where multiple inheritance is used.

6.3.21 *Identity Mapping*

6.3.21.1 CORBA and DCOM/OLE Automation have different notions of what object identity means. CORBA defines an object as a combination of the state and a set of operations that explicitly define the instance. An object reference is defined as a name that reliably and consistently denotes an instantiated object. A CORBA object exists until it is destroyed; its lifecycle is controlled by the server.

6.3.21.2 DCOM does not provide the same mechanism for identifying a particular object. DCOM objects are usually created when used and their state does not persist as an object instance. DCOM objects exist while they are referenced; their lifecycle is controlled by the client. This is true of OLE Automation objects as well.

6.3.21.3 The CORBA Interworking Architecture provides mapping solutions for managing the object lifecycle. The lifecycle issues should be minimized with the CIM Framework use of component managers to control object lifecycles. The implementation of DCOM lifecycle mapping should be encapsulated in the component manager.

6.3.22 *Naming*

6.3.22.1 As a mechanism to support initialization between collaborating components, the name of each component manager should be registered in a publicly available *namespace* along with the object reference for the component manager. The same name may be reused unambiguously as long as all occurrences belong to distinct namespaces. Other objects should be able to obtain a handle (object reference) to each component manager by utilizing the namespace through the operations of a naming service. A *trader* service may also be used to perform lookup of component managers and other objects based on well documented search criteria. Additional objects may also be registered in the namespace or trader as appropriate. The component manager serves as the namespace for the objects it manages, providing object references for named objects. Implementations should provide documentation on how to obtain available object references in either the namespace or the trader.

6.3.23 *Memory Management*

6.3.23.1 ORB implementations’ memory allocation and deallocation services should handle all three types of OMG IDL parameter passing:

- *in* — Memory is caller-allocated and read-only. The caller is responsible for memory deallocation.
- *out* — Memory deallocation depends on the specific usage of the argument.
- *inout* — Memory allocation and deallocation depend on the specific usage of the argument.

6.3.23.2 The CIM Framework uses only the *in* parameter passing mechanism. Within operations that have had objects passed by reference, any modification of the object occurs by using the *in* parameter as a reference. Supplier provided extensions to the CIM Framework that use either the *out* or *inout* parameter passing mechanism should document the caller and callee responsibilities with respect to memory allocation and deallocation.

6.3.24 *Use of OMG IDL Module Packaging Constructs*

6.3.24.1 All IDL statements included as part of the specification of SEMI E81 should be contained within one or more CIM Framework defined modules.

6.3.24.2 *CIMFW Module Conventions*

6.3.24.2.1 Each CIM Framework sub-document that specifies IDL declarations should provide a full listing of the IDL statements in a compilable IDL file. This file may be presented as an appendix to the specification prior to final adoption and preparation for distribution with the standard. The IDL file should include module statements to enclose all IDL declarations for that specification.

6.3.24.2.2 IDL files (or appendices) should begin with a comment identifying the correct name of the file that contains the enclosed IDL specification. The following hypothetical example illustrates the form of this comment.

```
//File: CIMFactoryLabor.idl
//Part of the CIM Framework for the
Factory Labor Component
```

6.3.24.2.3 Every IDL appendix should contain the following statement identifying the top-level module that contains all CIM Framework declarations.

```
module CIMFW{

      ...

};
```

6.3.24.3 *Lower Level Modules within the CIM Framework Module*

6.3.24.3.1 The CIM Framework module should enclose second level modules that further package each partition of the CIM Framework specification as defined in SEMI E81. All IDL declarations should thus be scoped, first, to the CIM Framework, and second, to the specific component of the framework. The following example illustrates the positioning of elements of the Factory Labor component within a component module.

```
module CIMFW{

      module FactoryLabor{

            typedef ..., etc.

      };

};
```

6.3.24.3.2 Subsequent decomposition of CIM Framework specifications into a third level of module containment may be necessary in some places, but should be avoided where possible to keep fully qualified names from getting to an unworkable length.

6.3.24.4 *Conventions for CIM Framework Dependencies*

6.3.24.4.1 Each CIM Framework IDL file should include explicit statements identifying any other files in the CIM Framework specification set that contain modules that are referenced. These statements should be in the form of `#include` statements. In order to avoid circular references among related modules, a specification may need to partition a module into more than one file and include parts of the module at different points in the referencing file. This structure of IDL files is dependent on the specific implementation and which parts of the CIM Framework it implements and may be adjusted as needed to achieve successful compiles. The IDL files distributed with the standard should suggest a file structure to achieve a successful compile, but should not indicate that the file structure is specified as a part of the standard. The following example illustrates an include statement.

```
#include <CIMGlobal.idl>

module CIMFW{ ...
```

6.3.24.4.2 All references to elements of separate modules will then need to be fully qualified with the module scoping. For example, to reference a type defined in the CIMGlobal module, the reference should take a form similar to the following hypothetical example:

```
#include <CIMGlobal.idl>

module CIMFW{

      module FactoryLabor{ ...

            Global::MachineSequence
assignedMachines ( )

                  raises
(Global::FrameworkErrorSignal);

      };

};
```

6.3.24.4.3 Fully qualified names may also be automatically generated if the target programming language compiler supports the "namespace" concepts. For example, the C++ standard uses namespace and Java uses package to support namespaces.

6.3.24.5 *Guard Statements*

6.3.24.5.1 To avoid the possibility of the same CIM Framework file being included more than once and thus causing multiple definition errors, each module should be preceded by the following type of guard statement.

```
#ifndef _CIM_FACTORY_LABOR_IDL_

#define _CIM_FACTORY_LABOR_IDL_

module ...

};

#endif // _CIM_FACTORY_LABOR_IDL_
```

6.3.24.5.2 The guard name should be designated by the string that begins and ends with an underscore and includes an all caps version of the filename with embedded underscores to separate the parts of the name. The guard statement should be documented for each module.

6.3.24.6 *Naming Modules and IDL Files*

6.3.24.6.1 All Module names for CIM Framework specifications are scoped within the CIMFW module and need not use redundant prefixing of the name with CIMFW. The names should be derived as closely as possible from the name of the CIM Framework specification they represent.

6.3.24.6.2 All Names should be composed of one or more words, abbreviations or acronyms concatenated together with capital letters used as delimiters between parts.

6.3.24.6.3 Names should be kept as short as possible while still providing understandable semantic associations for the subject module.

6.3.24.6.4 IDL File names should be based on the second level module contained within the CIMFW module.

6.4 *Exception Declarations*

6.4.1 Exceptions provide an alternative return mechanism for operations. When performing a normal return, control is returned to the point of invocation and the provided return values and output parameters are valid. Abnormal operation results raise an exception, which causes control to return to the defined exception handler and breaks the flow of control. Any data defined as part of the exception and provided by the called operation is valid and available to the exception handler. When an exception is raised, normal output parameters defined in the operation signature are not valid and are not available in the exception handler.

6.4.2 Exceptions are not communicated as an operation return code. An exception signifies that the post-conditions for successful operation completion have not been satisfied. If, on the other hand, the operation merely needs to communicate which one of multiple post-conditions were met, then the operation should provide this information in a return code or return structure as part of the normal operation completion.

6.4.3 Exception declarations in OMG IDL follow a *C* struct-like data structure with the keyword *exception* taking the place of *struct*. It contains attributes that can be used to pass information about an exception condition to a service requester. An exception is declared with an identifier (*ExceptionNameSignal*, the exception name), which is accessible as a value when the exception is raised, allowing the client to determine which exception has been received. Data values associated with the exception, if declared, are accessible to the client. The keyword *raises* is used in the operation definition to specify that a user-defined exception may be raised (or thrown in implementation terminology). The CIM Framework specifications assume that an operation may raise a CORBA-defined standard system exception, thus these exceptions are not specified.

6.4.4 The following conventions are used when defining exceptions:

Exceptions are not reserved for system or programming errors or failures, but should be included for any abnormal application behavior in the called service. This is consistent with CORBA usage of exceptions for application errors.

Exception descriptions are shown as OMG IDL comments similar to descriptions for services.

Return values should, if necessary, be implemented as fields in the exception definition.

All state transition services (e.g., *makeXXX* services) should include the *InvalidStateTransition-Signal* exception in their list of raised exceptions.

Services that perform a “find” or “lookup” function raise an appropriate *<ObjectType> NotFound-Signal* exception: a null return value is not an appropriate response. However, services that return a collection of objects do not raise an exception but simply return an empty collection.

Services that perform “add” functions raise a *<ObjectType>DuplicateSignal* exception for the case where the object to be added is already in the target collection or logical set. The exception includes a field containing a reference to the currently existing object.

Services that perform “remove” functions raise a *<ObjectType>NotAssignedSignal* exception for the case when the given object is not in the collection it was to be removed from or *<ObjectType> RemovalFailedSignal* exception if the object could not be removed.

Boolean query services should rarely raise an exception unless conditions are such that neither a true or false return value can be determined.

6.4.5 User-defined exceptions can be defined for any operation specified in IDL. Only user-defined exceptions that are defined and listed in the *raises* clause of an operation should be thrown. Interface-defined or other standard system exceptions may be thrown without using a *raises* clause on an operation. The data contained in the user exception should help the caller interpret and deal with the exception. Specific data can be defined for each user exception. Any additional information that assists in debugging situations should be sent to a tracing or logging facility.

6.4.6 Operations should throw standard system exceptions when an error condition clearly matches the defined exception. This ability should be used judiciously as the receiver of the exception may not be able to distinguish between a system-thrown or user-thrown exception. If a system exception does not clearly fit the situation at hand, then a user exception should be defined. Use of user-defined exceptions is part of the binding that should be considered for interoperability and substitutability.

6.4.7 The mapping defined for exceptions should support both the system exceptions and user exceptions. The CORBA model uses the concept of exceptions being raised to report error information. There should be exception specific data associated with the exception. The DCOM model provides error information by returning an HRESULT type. There is no facility for returning user-defined exception data.

6.4.8 The CORBA Interworking Architecture provides a mapping for the CORBA System Exceptions to the DCOM HRESULT values. The additional exception information for User Exceptions can be returned in an exception structure and added as another parameter to methods that include the *raises* keyword. The OLE Automation mapping provides for the use of a Pseudo-Automation Interface called a pseudo-exception. This is included in the interface as an additional out parameter.

6.4.9 The mapping of exceptions from CORBA to DCOM is very complex and requires an added parameter on many of the interfaces. The complete mapping rules are defined in the CORBA Interworking Architecture.

6.5 *Event Specification*

6.5.1 This guide uses a publish/subscribe model of events. Published events are sent to subscribers of the event in an asynchronous manner. The identity and quantity of subscribers are not known by the publisher of an event. The publisher is also known as the "supplier" and the subscriber known as the "consumer" of the event. Although the receipt of an event can alter the flow of control in the consumer, they should typically be used primarily as an information broadcast mechanism. Direct operation requests to another object should be used when affecting changes to critical flow of control to ensure message receipt by the intended recipient.

6.5.2 This guide suggests the use of an event delivery mechanism called "event channels." Event channels can provide a coarse grain filtering capability for events. Consumers can subscribe to a specific event channel in order to receive a particular event type. The event broker specification of this guide extends this event channel capability by adding features for locating event channel, registering for event delivery, and filtering the events of interest to minimize performance penalties when large numbers of events are present.

6.5.3 This guide supports creating, posting, and subscribing to events. It also provides the mechanisms to support subject-based addressing. When a consumer subscribes to events for a particular subject, it should be notified whenever an event for the subject is posted by any supplier.

6.5.4 The event delivery requirements are summarized as follows:

Suppliers do not know who the consumers of news events are; therefore, suppliers do not need to get a "handle" for them.

No response or answer is sent back from the consumer(s) to the supplier once the post is completed.

Message delivery is based entirely on message context (subject).

6.5.5 *Event Content*

6.5.5.1 The specification of event content should have two parts: a header and a body. The header should consist of information of a general nature regarding the event, such as the name of its subject (a subject string used for identification); an aging factor (for determining event effectiveness and may be site specific); priority; and any filtering information relevant to event delivery at a general level. The event body should contain: the actual event message; the original time of the event; and data relevant to filtering by the consumer of the event. The body should also contain any information required by the consumer not used in the filtering process (called "News"). The body should be extended with object references as required to facilitate communication with any objects associated with the event.

6.5.5.2 The event header is constructed by the supplier of the event and is used by an Event Notification System (ENS) to route the event to any consumer registering interest in the event. Note that the structure of the header may be specific to a particular ENS. The body of the event is constructed by the event supplier and is intended for use by the event consumer. Consumers of events express interest in an event type by passing the subject name and associated filter data along to the ENS. The ENS returns an original connection, called an event channel, to the consumer.

6.5.5.3 Name-value pairs are one mechanism that should be used to define data either in the header or body. Specific information within the body varies according to event type; issues such as allocation are implementation dependent.

6.5.6 *Subject String*

6.5.6.1 The event subject string should be defined as a multi-level hierarchy to assist in event classification and filtering. The levels designate the CIM Framework issuing the event component, the issuing interface within that component, and the event type. Each level should be delimited by a special character (e.g., a forward slash: "/"). An example of this syntax is */RecipeManagement/MachineRecipe/ParameterChanged*.

6.5.7 *Filter Data and News*

6.5.7.1 Filter data are attribute names, values, and operators that are specified by the consumer and are used by the filter subsystem to further qualify an event. News consists of additional attributes and values that are received by the consumer but not used in the filtering process and thus are not specified by the consumer. The consumer specifies the attributes, values, and operators upon which the event data is filtered. The actual filtering is performed after the supplier sends an event but prior to the consumer receiving the event. The filterable data should be well known and standardized. News may be used by the consumer to further filter the event, but the attributes and values are not standardized. Additionally, news may be used to convey the identity of the object generating the event to any consumer of the event.

6.5.7.2 An Event Broker is required to support subscription to an event channel that has the specified subject and supports filtering. The actual filtering mechanism is an implementation dependency. Filter data is passed to the Event Broker by the consumer to qualify the particular events that the consumer is interested in receiving. The filter data specifies filterable items in which the consumer is interested plus operators and operands to perform the filtering. The filtering sub-system should use the filter data to ensure that a specific event is passed to the consumer. The interface is *simple* and does not try to construct advanced logic to build the filter. The results of the filtering are *anded* together, such that the passed event should meet all of the filter criteria. The need to specify logical operators (e.g., "or") on the filter criteria or the use of query languages should be evaluated. Extensions to the filter structures would be required to support these additional capabilities.

NOTE 2: The location of the filtering subsystem is an implementation detail.

6.6 *Distributed Transactions*

6.6.1 Many operations defined in the CIM Framework are related to one another in complex ways that require multiple operations to be treated as a single unit of work. For example, grouping operations are combined with the ability to make an explicit decision to commit the aggregation of changes, or to abort all of the operations and return to the prior state. These grouping of operations are consistent with the familiar concept of a transaction (most commonly encountered in the context of database management systems). CIM Framework objects should be capable of participating in transactions as described below. However, the choice of how an object participates is implementation specific. For example, the implementer chooses the implementation technology and whether a change in object state is recoverable (that is, whether a change in state can be rolled back).

6.6.2 A transaction is a contract between two or more objects to perform some action based upon one or more requests in some context and having the ACID properties as follows:[6]

- Atomicity — State changes are atomic; either all happen or none happen. These changes include database changes, messages and events.
- Consistency — A correct transformation of state. Actions taken as a group do not violate any of the integrity constraints associated with the state.
- Isolation — Even though transactions execute concurrently, it appears to each transaction T that others executed either before T or after T, but not both.
- Durability — Once a transaction completes successfully (commits), its changes to state survive failures.

6.6.3 For example, consider a lot that starts processing in a piece of equipment. The states of the lot and the

6 J. Gray, Transaction Processing Concepts and Techniques, Morgan Kaufmann Publishers/Harcourt Brace and Co., 6277 Sea Harbor Dr., Orlando, FL, 1993.

equipment should change in order to accurately track the state of the factory. Coordinating the lot and equipment state changes as a transaction guarantees that factory state can be recovered accurately.

6.6.4 Transactions are created by a user of a service (the client) requesting an operation from a provider of a service (the server). To maintain the ACID properties of a transaction, the server should be able to return to the state prior to the request for the operation in the event of a failure. In this sense, the server should be recoverable. Failures are either software or hardware events that prevent the completion of the transaction. The server is a recoverable server if it is able to maintain the ACID properties when faced with a failure.

6.6.5 Transactions should be designed in a manner such that they do not span a period of interaction with an external entity such as a person using a GUI or a piece of equipment. Waiting for the response from an external entity can result in locks being held for multiple seconds, minutes, or longer. This can adversely affect other transactions by causing time-outs or deadlocks. These types of transactions can usually be split into multiple serially executed transactions with some small amount of extra revalidation of current states at succeeding transactions.

6.6.6 Coordinating the completion of transactions may involve multiple servers and may entail either committing the successfully completed transaction or rolling back the unsuccessful transaction. This activity imposes additional overhead on a system. Suppliers and consumers should assess the impact of transactions on system performance during component design and selection of transactional events.

6.6.7 Transactions may cause physical effects in the manufacturing system that cannot simply be rolled back in accordance with the ACID properties. Application and system designers should include ways to modify the logical view of the system to match the physical reality of the manufacturing floor if such a mismatch occurs.

6.6.8 Transactions can create CIM Framework events as state changes occur. As the transaction may not be committed at the point of event creation, the event should not be visible outside the transaction until the final commit point. The details of performing this task are implementation dependent. For example, the event announcing the completion of a lot at a processing step should not be published until the processing step completion transaction is committed. Otherwise, the event could be published, but the transaction subsequently rolled back, creating a system inconsistency.

6.6.9 Transactions should be able to be *nested*, thus providing the ability to define transactions within other transactions. These sub-transactions can generate additional sub-transactions, thus forming a hierarchy of transactions. In the spirit of maintaining the ACID properties, each sub-transaction can issue a commit or rollback for its piece of work. The results of the sub-transaction are only available to the parent transaction. The sub-transactions commit becomes permanent only after it issues a local commit and all ancestors commit. If the parent transaction does a rollback, all descendent transactions are rolled back regardless of any local commits.

6.6.10 There are two types of transactions widely supported for distributed object infrastructures. The OMA support for transactions is described in the OMG's Object Transaction Service (OTS). Microsoft provides support for transactions with its Microsoft Transaction Server (MTS) product. The OTS closely aligns with other standards such as The Open Group *Distributed Transaction Processing (DTP)* model.[7] Using industry standard protocols as a base, the OTS supports interfacing with products from the major database suppliers. Using the provided OTS interfaces and information about The Open Group standards, non-ORB supplied database interfaces could be developed to allow for interoperability with other cooperating transaction services. MTS also supports transactions with major database suppliers through use of The Open Group XA interface. Using the MTS Software Developer Kit, transaction support can be extended to other resources.

6.6.11 Combining heterogeneous components based on a combination of OTS and MTS is not straightfor-ward. Although both rely on the XA interface for dis-tributed transaction coordination, they are not designed to operate with each other. Both OTS and MTS hide the details of transactions from users. This makes either solution very convenient, but makes linking them together more difficult. For example, suppose a CORBA-based component adhering to OTS should interact with an MTS-based component. The scenario calls for the CORBA based component to use the XA interface to work with the MTS provided transaction coordinator (see Gray[8] for additional information on distributed transactions). However, in hiding XA complexity, OTS also hides the ability to readily specify the transaction coordinator (OTS does this behind the scenes). CIM Framework component developers and consumers should determine the relative need for distributed transactions spanning OTS and MTS against the additional complexity of developing a XA-based mechanism for combined OTS and MTS transactions.

7 The Open Group, Distributed TP: The XA+ Specification, Version 2, The Open Group, 11 Cambridge Center, Cambridge MA, 1994.

6.6.12 The ACID properties provided by either OTS or MTS may be used for CIM Framework transactions. Many implementation details are supplier specific; however, the major architectural principles have been described above.

6.7 *Component Management*

6.7.1 A component refers to a collection of related interfaces that form a coherent subsystem. Components may have a component manager to assist in the tracking and management of the instantiated interfaces (objects). The objects that are managed by a component manager are called managed objects.

6.7.2 *Component Level Interface*

6.7.2.1 Component managers provide services such as reporting on the collection of instances they manage and creating object instances. The component manager provides the following:

Object references to managed objects.

Collective queries for some aspect (usually a state) across all the objects it manages.

Services for:

Creating a managed object and returning a reference to it, or receiving an object reference to a newly created object. The component manager then "registers" the object reference.

Removing managed objects.

Finding managed objects.

6.7.3 *Component Manager Classification*

6.7.3.1 Component Managers are classified by their allowable number of instances.

6.7.3.2 *Unique Component Managers*

6.7.3.2.1 A unique component manager describes a component manager for which there is only one running instance in an MES implementation. Unique component managers are used when a single point of factory level control or focus is required. An example use of this pattern might be an interface within a Dispatcher component called DispatchingManager. This might be a unique component manager because multiple dispatching systems on the factory floor could create problems with work scheduling.

6.7.3.3 *Non-Unique Component Managers*

6.7.3.3.1 A non-unique component manager describes a component manager for which multiple instances may be running in an installed MES system. The component manager instances are derived from the same code base, but have separate instance data for each running instance. Non-unique component managers should be registered with the factory with some selection criteria in order for a requester to be able to obtain a handle to the correct instance. An example use of this pattern is the scenario in which several ProductManagers are employed within a production system.

6.8 *Architecture For Service Requests*

6.8.1 Services are implemented by a factory object that is the service provider. The productive entity in a factory invokes the service methods on that factory object.

6.8.1.1 For example, a recipe server could offer the following interface:

```
interface RecipeManagementServer {
     // upload a recipe
     void acceptRecipe(
          in string recipeName,
          in Recipe recipe);
     // download a recipe
     Recipe provideRecipe(in string
     recipeName);
};
```

6.8.1.2 The problem with service requests is that they require a flow from the productive entity to the factory object that provides the service. This kind of reverse flow contradicts the principle of layered architecture by which the productive entity is supposed to be a more primitive entity, unaware of factory objects, their locations and their structures. The trading service addresses this problem.

6.8.2 *Trading Service*

6.8.2.1 *Using Trading Service*

6.8.2.1.1 A trading helps clients to locate services. An object that must locate a service must know how to access the trading service.

6.8.2.1.2 A trading service relies on the description of the service itself, rather than any attribute relating to the server that provides the service (such as the name of the server). It must be able to describe the service it requires. The trading server locates a server that fulfills the required service profile.

NOTE 3: The trading service described here is based on the CORBA COS Trading Object Service, implementations of which are available from vendors of CORBA environments. The solution however does not require the full generality of the COS Trading Object Service, and can be viewed as a strict subset of the latter.

6.8.2.2 *The Trading Concept*

6.8.2.2.1 A trading scenario is based on a server that exports a service to a trader. The client then imports the service from the trader, receiving a reference to the server on which it can invoke the service.

6.8.2.2.2 This is depicted in the following diagram:

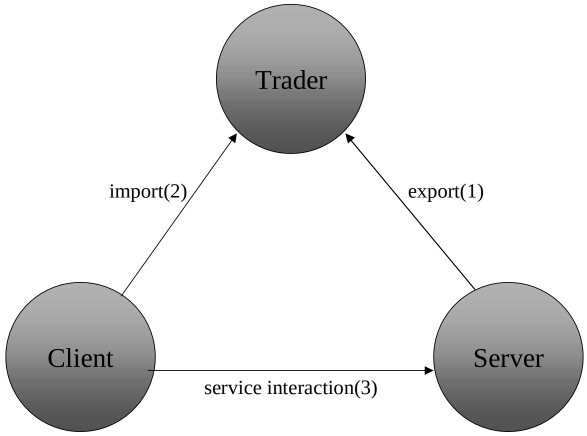

Figure 2

6.8.2.2.3 The diagram suggests that the server exports its service to the trader. In practice any object aware of the server and its provided services could assume this job. For example, a factory configuration object could be responsible for exporting all services to the trader.

6.8.2.3 *Trading Service Models*

6.8.2.3.1 The trader has to implement two interfaces:

- The Register interface allows other objects to register export service offers to the trader.

  NOTE 4: This interface is used e.g. by the service provider to inform the trader about the services the service provider offers.

- The Lookup interface allows other objects to lookup the trader for a required service.

  NOTE 5: This interface is used by e.g. the productive entity to find a service provider for a specific service.

6.8.2.4 *Export Use Cases*

6.8.2.4.1 The trader offers an interface named Register, that allows a server to register its services with the trader.

6.8.2.4.2 The IDL definitions given below are for illustrative purposes. They are extracted from the COS Trading Object Service specification [OMG]. For clarity, not all services are included here.

6.8.2.4.3 *Exporting a Service*

6.8.2.4.4 To export a service, the server uses:

```
OfferId export (
     in Object reference,
     in ServiceTypeName type,
     in PropertySeq properties
);
```

6.8.2.4.5 The server passes a reference to itself, and describes its offer by passing in a service type name and a list of properties of the service. The trader answers an offer id, through which the server can further manipulate its offer.

6.8.2.4.6 Factory service offers are described as follows:

6.8.2.4.6.1 *Service Type Name*

6.8.2.4.6.2 The type is a string naming the service itself. We are yet to agree upon the services supported by this specification. The following are obvious candidates:

- Recipe Service
- Wafer Map Service
- Fixtures Service[8]

6.8.2.4.6.3 *Properties*

6.8.2.4.6.3.1 Properties are used to characterize and specialize the service. A property is a name/value pair, where the name is a string naming the property, and the value specifies the property value offered by the server. The constraint language defined by the COS Trading Object Service [OMG] limits the type of values to the basic data types (such as numbers, chars, booleans and strings) and sequences of these.

6.8.2.4.6.3.2 The following properties are to be used for registering factory services:

- “Serviced Productive entities” — The value of this property is a list of the ids of the productive entities serviced by this server. This allows multiple servers of the same type to be installed, and partition the productive entity service among the available servers. Note that it does not require the server to know the productive entities it serves, since the server registration can be done by a factory configuration service.
- “Serviced Areas” — The value of this property is a string collection naming the factory areas serviced by the server. This property is another means of partitioning the service among multiple servers. The area could be a name of a cell controller if cellular manufacturing is practiced, or the name of any organizational unit implemented by the factory, and known to the factory configuration service.

6.8.2.4.7 *Withdrawing a Service*

6.8.2.4.7.1 To withdraw a registered service, the server (or the configuration service) uses:

```
void withdraw (
     in OfferId Id);
```

8 In back end fixtures is a generic name for durables and consumable materials

6.8.2.4.8 *Querying a Registered Service*

6.8.2.4.8.1 A server may query the trader the details of a registered service by passing in the offer id.

```
Struct OfferInfo {
     Object  reference;
     ServiceTYpeName  type;
     PropertySeq  properties;
};
OfferInfo describe (
     in OfferId  id);
```

6.8.2.4.9 *Modifying a Registered Service*

6.8.2.4.9.1 The server may modify the properties of a registered service. It may add new properties, delete existing properties, or modify the value of existing properties. This is done using the following method:

```
void modify (
     in OfferId  id,
     in PropertyNameSeq  del_list,
     in PropertySeq  modify_list
);
```

6.8.2.4.9.2 The properties named in the del_list are deleted. Properties in the modify_list that do not exist are added. Properties in the modify_list that exist, receive a new value.

6.8.2.4.9.3 The modify method can be used to support changes in the factory configuration, such as new productive entity being added or deleted, a productive entity being migrated from one cell to another, a new load balancing policy for the servers installed, etc.

6.8.2.5 *Import Use Cases*

6.8.2.5.1 *Importing a Service* — The trader offers an interface named Lookup that clients can use in order to locate a service:

```
void query (
in ServiceTypeName  type,
     in Constraint  constr,
     in Preference  pref,
     in PolicySeq  policies,
     in SpecifiedProps  desired_props,
     in unsigned long  how_many,
     out OfferSeq  offers,
     out OfferIterator  offer_itr,
     out PolicyNameSeq  limits_applied
);
```

6.8.2.5.1.1 The Query in Parameters — The “in” parameters are used by the client to specify the service it needs and the policies for searching it.

- The “type” parameter is key to the central purpose of trading. It specifies the name of the service type the client is interested in.
- The “constraint” guides the trader on how to select a server based on its registered properties. It is a string that describes the selection in some given constraint language. The typical constraints will select a server for a specific productive entity or for the area the productive entity belongs to. Both possibilities use the “in” operator for testing the inclusion of an element in a set. Some examples follow:

```
“DieAttachXYZ in ServicedProductive-
Entities”
“Cell22 in ServicedAreas”
```

6.8.2.5.1.2 “Preferences” specify how should a server be selected in case the query results in more than one answer. It is suggested that this parameter be ignored, which means that the default of first is always used.

6.8.2.5.1.3 The “policies” parameter guides the trader on how to choose a policy for performing the search. Search policies are a rather complicated issue, which can be ignored in the Simple Trader case.

6.8.2.5.1.4 The “desired_props” parameter instructs the trader which properties are to be returned as part of the answer (it does not affect the selection itself). This does not make much sense with the limited set of properties which has been defined, and can also be ignored (use none as the parameter value).

6.8.2.5.1.5 The “how_many” parameter is another way to restrict the number of answers. It is proposed that 1 always be used as the value of this parameter.

NOTE 6: Should areas be used as the selection criteria, the equipment must be aware of its area within the factory. This should be supported through the productive entity “Configuration” aspect.

6.8.2.5.1.6 *The Query out Parameters*

6.8.2.5.1.6.1 The query returns the selected servers in one of two forms: a collection of services or a reference to an iterator through which the returned servers can be obtained. The second method is designed for queries that may return a large number of offers. One can always assume that results are returned within the first out parameter (out OfferSeq offers*)*, namely a sequence of offers. Furthermore, having specified 1 as the value of the “how_many” parameter, it is ensured that the answered sequence contains at most one element.

6.8.2.6 *Locating the Trading Service*

6.8.2.6.1 The productive entity locates the services it requires using a trading service.

6.8.2.6.2 A client can obtain a reference to the trading service by invoking the following method on the ORB:

```
Object resolve_initial_references (
     in ObjectId identifier)^
     raises (InvalidName);
```

Where:

the reserved name “TradingService” is passed as the identifier.

6.8.2.7 *A Usage Scenario Example*

6.8.2.7.1 Here is an example of a usage scenario.

6.8.2.7.2 In common factory practice, cellular manufacturing has a factory configuration service responsible (among other things) for exporting the factory services to the trading service. The following are some typical use cases:

1. The factory configuration service registers a wafer map server to server two cells named CellA and CellB.

   The factory configuration service obtains an initial reference to the trading service from the ORB:

   ```
   trader =
        orb.resolve_initial_refer
        ences("TradingService");
   The trader answers its Register
   interface:
        traderRegistry =
        trader.register_if();
   ```

   The factory configuration service builds properties as a single-itemed sequence of containing one name/value pair whose name is "ServicedAreas" and whose value is a sequence of the cell names { "CellA", , CellB"} . It then uses the Register interface of the Trading Service to register the service offer:

   ```
   traderRegistry.export(
        waferMapServer,"Wafer Map
        Service", properties);
   ```

2. The configuration manager informs a Die Attach equipment that it belongs to CellA.

   ```
   ProductiveEntities.setArea("CellA");
   ```

3. The Die Attach needs a wafer map.

   It obtains an initial reference to the trading service from the ORB:

   ```
   trader =
        orb.resolve_initial_refer
        ences("TradingService");
   ```

   The trader answers its Lookup interface:

   ```
   traderLookup = trader.lookup_if();
   ```

   The productive entity looks up the trading service for the wafer map service:

   ```
   traderLookup.query(
        "Wafer Map Service",
        "CellA in ServicedAreas",
        pref, policies, desired_props,
        1, preference, offers,
        offers_itr, limits_applied);
   ```

   The wafer map server is returned as the first element of the offers sequence. The productive entity may keep the reference to the wafer map server for future use.

4. The Die Attach can now invoke the service on the wafer map server:

   ```
   waferMapServer.getWaferMap(…);
   ```

7 Technical Architecture Conformance

7.1 Conformance is defined as "adherence to a standard or specification in the implementation of a product, process, or service." A conforming implementation should have an associated implementation conformance statement that details the capabilities that have been implemented. While recognizing that the CIM Framework is, by definition, not a complete specification of a MES, a guide for technical architecture defines conformance for each of its major requirements as follows.

7.2 *Distributed Object Communications Conformance*

7.2.1 The CIM Framework object model is based on the ability to issue service requests to a component object and to subscribe to events published by the component object. Component suppliers should explain how these two forms of communications are accomplished so consumers can assess the ease and feasibility of integrating a component into the factory MES. Example terminology specific to semiconductor manufacturing is provided for clarity. It does not preclude application specialization for other industries.

7.3 *Exception Conformance*

7.3.1 Alerting operation requesters of abnormal outcomes is essential for robust implementations. Component suppliers should explain how their implementations support raising specified system and user-defined exceptions.

7.4 *Event Specification Conformance*

7.4.1 Notification of asynchronous occurrences is a cornerstone of distributed event-driven application domains such as MES. Suppliers should explain how their components support event delivery, including the registration of event suppliers, event consumers and the provision for Event Broker features for event filtering.

7.5 *Distributed Transaction Conformance*

7.5.1 Ensuring consistent state changes among components is a key concern in the integration of a factory MES. Component suppliers should explain how their components support transactional units of work.

7.6 *Component Management Conformance*

7.6.1 Component suppliers should explain how object instances are managed. This includes how the object is identified, constructed, accessed, and destroyed (or flattened in the case of a persistent object). It also includes mechanisms for query or lookup of specific managed object instances.

7.7 *General Rules for CIM Framework Conformance*

7.7.1 The following rules define the general expectations for technical conformance to any CIM Framework specification. Suppliers should provide documentation explaining any deviations from these general rules.

- All CIM Framework-defined operations for an interface should be supported.
- All exceptions and events for an interface should be supported.
- A component should use component manager interfaces for object instance creation and registration where these operations are specified.
- A component implementation should support all interfaces specified for that component.
- An application may not add states and transitions to the defined dynamic models that have external interfacing ramifications. The application may still further subdivide the states.
- A component implementation should explain how it supports substitutability. For example, it may support different degrees of substitutability between the following levels:
  - Strict — An application that supplies a CIM Framework component should be reconfigurable so it can use another supplier's implementation of that component. The application's interactions with the component are restricted to CIM Framework defined interfaces.
  - Weak — An application may use extended, pro-prietary, or private interfaces of a component. When the another supplier's implementation is substituted for an installed component, any components using the extended, proprietary, or private interfaces need to be reassessed and possibly modified. The use of the CIM Frame-work-defined interfaces does not change.

SEMI E97-0200A
PROVISIONAL SPECIFICATION FOR CIM FRAMEWORK GLOBAL DECLARATIONS AND ABSTRACT INTERFACES

This provisional specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on October 21 and December 15, 1999. Initially available at www.semi.org January 2000; to be published February 2000.

NOTE: This document was published twice during the February 2000 (0200) publishing cycle.

1 Purpose

1.1 This document defines the global declarations used by all other components of the CIM Framework and also specifies the common architecture patterns that serve to functionally integrate CIM Framework components. The material architecture defines functionality common to product management, durables management and consumables management components. The factory resource architecture defines relationships and common functionality of a variety of factory resources. The job architecture defines a factory-wide model for controlling factory jobs that drive a variety of manufacturing tasks. These specifications are separated into a distinct group to enable them to be specified once and then logically included or inherited wherever they are subsequently needed.

2 Scope

2.1 This specification provides the common interfaces required by Manufacturing Execution Systems to:

- Provide type definitions for common data structures to ensure consistent representation. These items include data types for common concepts such as coordinates, priorities, timestamps, and sequences of basic data types.
- Provide definitions for common exceptions used consistently throughout the CIM Framework.
- Provide the material architecture interfaces common to identifying, grouping, moving, locating and tracking material in the factory.
- Provide the factory resource architecture interfaces common to defining, organizing, tracking usage of and maintaining factory resources including equipment, sensors, durables, and people.
- Provide the job architecture interfaces common to creating, executing and managing work in the factory. The job architecture is specialized for material processing jobs, material transport jobs, resource maintenance jobs and factory jobs that drive product material through their process flows.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 *Provisional Status*

3.1.1 This specification is designated as provisional due to known areas that need to be completed. The following items summarize the deficiencies of the provisional specification to be addressed before a subsequent ballot to upgrade it to full standard status.

3.1.2 The specification uses the IDL typedef “any” in several places. While this usage provides flexibility, it can have the effect of reducing interoperability due to differences in interpretation of the value provided by separate implementations that interact through a standard interface. The “any” typedefs should be replaced with explicit data types prior to upgrade from Provisional to full Standard status.

3.1.3 The definition of interfaces for retrieval of history associated with CIM Framework objects may need to be added to abstract interfaces in this document after the complete specification for the history facility within the CIM Framework Factory Services Component.

3.1.4 The specification of CIM Framework states reported through published state change events is currently based on a type definition for an enumeration of state values. There may be alternate representations for states that are better able to capture the semantics of nested and parallel states. The state representation used for the CIM Framework will be reviewed and possibly changed before upgrade to full standard status.

3.1.5 The Resource model defined in SEMI E81 includes several extensions that are not yet included in this specification. These extensions include composition of resources from other resources, capabilities associated with resources, and associations with tracking and maintenance functions for resources.

These extensions will be addressed before upgrade to full standard status.

3.1.6 The interfaces specified for MESFactory, Area, and ComponentManager are included in the E81 responsibilities for the Factory Component within Factory Operations. These interfaces will need to be moved to that component when it is considered in a future ballot.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E81 — Provisional Specification for CIM Framework Domain Architecture

4.2 *Other Standards*

UML Notation Guide, Version 1.1, document number ad/97-08-05, Object Management Group[1]

ISO/IEC International Standard 14750 (also ITU-T Recommendation X.920) — Information Technology – Open Distributed Processing – Interface Definition Language [2]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *abstract interface* — an interface specified only for inheritance rather than for implementation in order to standardize common features shared by all specializations of the interface.

6 Requirements

6.1 *Global Type Definitions*

6.1.1 This section describes data type definitions and exceptions that are global in nature. By "global" it is meant that they are designed to be used by any component within the CIM Framework. This specification does not address how they are implemented within a CIM Framework conformant application; that level of detail is within the realm of the development effort.

6.1.2 Global type definitions are specified as IDL declarations which may be referenced by any CIM Framework interface. The CIM Framework uses the keyword *typedef* to define aliases for basic object types, but with additional implied semantics. (e.g., the *units* typedef defines a *string*, whose contents conform to definitions found in SEMI E5). The keyword *struct* begins the type declaration for record structures composed of a collection of named and typed values. The third form of type definition is an enumerated type beginning with the reserved word *enum*. Enumerated types are used to declare a list of tokens that can be used as values of that type. Enumerated types are mainly used to denote the states of an object for communication in CIM Framework events. Finally, collections of values are declared with the keyword *sequence*. This kind of type definition may or may not imply significance to the ordering of the members in the sequence. Where no ordering constraint is mentioned, the elements of the *sequence* are not assumed to be in any meaningful order.

NOTE 2: In the following definitions, "//" or "/* .... */" delimits a comment.

NOTE TO THE READER: The comments in the following sections (described in NOTE 2, above) appear to immediately precede, rather than follow, the items they discuss. — SEMI Staff

6.1.3 All CIM Framework specifications will be declared within the context of the CIMFW module which spans all of the components of the CIM Framework. Within the CIMFW module, the global type definitions will be declared within a second-level module called Global.

1 UML Notation Guide v1.1 is available to the general public at http://www.omg.org/cgi-bin/doclist.pl, +1-508-820 4300, Object Management Group, Inc. , Framingham Corporate Center, 492 Old Connecticut Path, Framingham, MA 01701.

Module: Global

```
typedef string Identifier;

typedef unsigned long Flags;

struct NamedValue {
        Identifier name;
        any argument;
        long len;
        Flags arg_modes;
};

typedef NamedValue NameValue;

typedef sequence <NamedValue> NameValueSequence;

typedef string PropertyName;

struct Property {
        PropertyName property_name;
        any property_value;
};

typedef sequence <Property> Properties;
```

/* This type definition represents units for factory parameters, measurements. etc., and conforms to the SEMI E5 standard for representation of units. In that standard, the string contains a code representing a value of the units. For example, "ns" would mean nano-seconds; "A" for ampere; and "wfr" for wafer. */

```
typedef string Unit;

typedef string Units;
```

/* This type definition represents a sequence of *string* values. */

```
typedef sequence <string> StringSequence;
```

/* This type definition represents a sequence of *any* values. */

```
typedef sequence <any> AnySequence;
```

/* This type definition represents a sequence of *long* values. */

```
typedef sequence <long> LongSequence;
```

/* This enumerated type identifies event priorities and is used in each event definition. */

```
enum PriorityOfEvent {
        Low,
        Medium,
        High,
        Alarm };
```

/* This enumerated type identifies the lifecycle states that an object may go through. It is used in event notifications of state changes. */

```
enum LifecycleState {
        Undefined,
        Created,
        Deleted,
        Moved,
        Copied };
```

/* This enumerated type identifies the states of objects that can be reserved (Lot, Durable and Machine). It is used in event notifications of state changes. */

```
enum ReservationState {
        UndefinedReservationState,
        Reserved,
        UnReserved };
```

/* This enumerated type represents the SEMI E10 states for Machines and Support Resources. It is used in event notifications of state changes. */

```
enum E10State {
        E10Productive,
        E10Standby,
        E10Engineering,
        E10ScheduledDowntime,
        E10UnscheduledDowntime,
        E10NonscheduledTime };
```

/* *TimeT* is a *ulonglong* value (64 bits) that represents the number of 100 nanosecond increments that have passed since a base time (October 15, 1582 at 00:00, the Universal Time Representation which refers to time in Greenwich Mean Time). The specification for *TimeT* is: */

```
struct ulonglong {
        unsigned long low;
        unsigned long high;
};
```

```
typedef ulonglong TimeT;
```

/* *TimeStamp* is mapped to the data type of *TimeT.* */

```
typedef TimeT TimeStamp;
```

```
typedef sequence <TimeStamp> TimeStampSequence;
```

/* The notion of a specific interval of time denoting a start time and an end time is represented as a struct called *IntervalT.* */

```
struct IntervalT {
        TimeT lower_bound ;
        TimeT upper_bound ;
};
```

/* *TimeWindow* is mapped to the data type *IntervalT.* */

```
typedef IntervalT TimeWindow;
```

/* Duration is mapped to the datatype TimeT. */

```
typedef TimeT Duration;
```

/* This structure is for the representation of a single schedule instance. It should be noted that “EndTime” should never proceed “StartTime.” */

```
struct ResourceSchedule {
        TimeStamp plannedStartTime;
        TimeStamp plannedEndTime;
        TimeStamp actualStartTime;
        TimeStamp actualEndTime;
};
```

/* The definition of a sequence of ResourceSchedules. This sequence is ordered in increasing time order and that order must be maintained in any manipulation of the sequence. */

```
typedef sequence <ResourceSchedule> ResourceScheduleSequence;
```

6.2 *Global Exception Declarations*

6.2.1 This section describes the standard CIM Framework exceptions that may be thrown by operations in any component.

Module: Global

/* This signal is raised when a lookup or find fails. */

```
exception NotFoundSignal { string errorMessage; };
```

/* This signal is raised when an add fails because an object already exists with the given identifier. Interfaces may also define and raise a <ObjectType>DuplicateSignal. */

```
exception DuplicateIdentifierSignal {
        string errorMessage;
        string duplicateIdentifier; };
```

/*This signal is raised when an invalid state transition request is made of an object. */

```
exception InvalidStateTransitionSignal {
        string errorMessage; };
```

/*This signal is raised when a "set" attribute contains a value out of range. */

```
exception SetValueOutOfRangeSignal {
        string errorMessage; };
```

/* This signal is raised when an incorrect TimePeriod is used. */

```
exception TimePeriodInvalidSignal {
        string errorMessage; };
```

/* This signal is raised when a Property name is not valid. */

```
exception InvalidPropertyNameSignal {};
```

/* This signal is raised when a a Property with this name is not defined. */

```
exception PropertyNotFoundSignal {};
```

/* This signal is raised when a Property is not supported. */

```
exception UnsupportedPropertySignal {};
```

/* This signal is raised when a Property is read-only and cannot be set. */

```
exception ReadOnlyPropertySignal {};
```

/* This signal is raised when no other defined signal matches the error condition. */

```
exception FrameworkErrorSignal {
        string errorMessage;
        unsigned long errorCode;
        any errorInformation; };
```

/* Definition of fields for FrameworkErrorSignal:

errorMessage	is a text field representing a description of the circumstances of the exception for use by developers in debugging the exception.
errorCode	is a numeric field representing the code for the given exception.
errorInformation	is any further debugging information related to the circumstances of the exception.

The errorCode has certain reserved values that are defined and standardized in the CIM Framework.

- 0000–0999 reserved for the CIM Framework.
- 1000–1999 reserved for extensions to the CIM Framework.
- 2000–2999 reserved for specializations of CIM Framework interfaces.
- 3000–maximum reserved for implementers. /*

/* This errorCode should be used for any operation where the supplier has chosen to not provide implementation, but needs to communicate to the user that nothing has happened as a result of this operation invocation. */

```
const unsigned long NOT_IMPLEMENTED = 0;
```

/* This errorCode should be used for any operation where the supplier assumes a specialization will implement this operation. If this exception is received, the user will realize that an interface has not been properly specialized. */

```
const unsigned long IMPLEMENTED_BY_SUBCLASS = 1;
```

/* This errorCode should be used for any operation where an unknown exception has been caught by the implementation and, rather than crashing, the implementation can map the “unknown” exception into this known exception. This probably does not aid in program debugging but does prevent program crashing. */

```
const unsigned long UNKNOWN_EXCEPTION = 2;
```

/* This errorCode should be used for any invocation where some unknown error has occurred that left the server object in an ambiguous state. */

```
const unsigned long COMPLETION_UNKNOWN = 3;
```

6.3 *Abstract Interface Type Definitions*

6.3.1 *Referenced Declarations*

6.3.1.1 The following declarations are not part of this specification, but are required for reference by Abstract Interface elements. These referenced declarations are defined in separate documents but are noted here as dependencies that appear in IDL compilations.

Module:	EquipmentTracking
Interface:	Machine

```
module EquipmentTracking {

interface Machine {}; // Stub

typedef sequence <Machine> MachineSequence;

exception MachineDuplicateSignal { };
```

```
exception MachineNotAssignedSignal { };

exception MachineRemovalFailedSignal { };

}; // module EquipmentTracking
```

Module: Labor

Interface: Person

```
module Labor {

interface Person {}; // Stub

typedef sequence <Person> PersonSequence;

exception PersonDuplicateSignal { };

exception PersonNotAssignedSignal { };

exception PersonRemovalFailedSignal { };

}; // module Labor
```

6.3.2 *Abstract Interface Declarations*

Module: AbstractIF

/* The following IDL interfaces will be fully defined in the sections below. They are declared here as forward references to support the sequence typedefs. */

```
interface Resource;

interface Material;

interface MaterialGroup;

interface JobSupervisor;

interface Job;

interface JobRequestor;
```

/* Type definitions for sequences of interfaces instances. */

```
typedef sequence <Resource> ResourceSequence;

typedef sequence <Material> MaterialSequence;

typedef sequence <MaterialGroup> MaterialGroupSequence;

typedef sequence <Job> JobSequence;

typedef sequence <JobSupervisor> JobSupervisorSequence;
```

6.4 *Resource Abstract Interface Group*

6.4.1 The Resource Abstract Interface Group provides a set of abstractions that are globally useful. Figure 1 is the Information Model for the Resource Abstract Interface Group.

Resource Abstract Interface Group

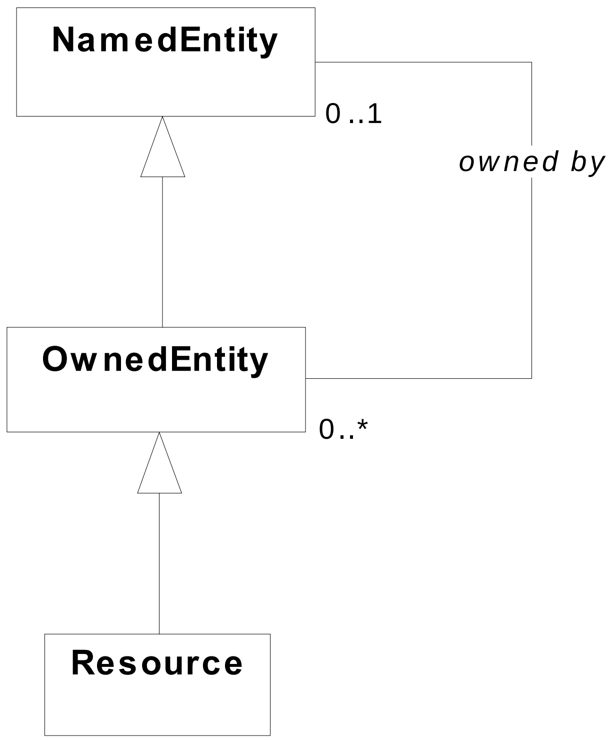

Figure 1
Resource Abstract Interface Group Information Model

6.4.1.1 All CIM Framework interfaces will inherit from one of the interfaces shown in Figure 1. NamedEntity provides the most basic naming functions. An OwnedEntity is a NamedEntity with functions supporting the concept of ownership. A Resource is an OwnedEntity which also takes an active role in product manufacturing.

6.4.2 *Named Entity Interface*

Module:	AbstractIF
Interface:	NamedEntity
Inherited Interface:	Implementation-dependent.
Description:	The abstract interface NamedEntity provides the concept of a named item. This allows for comparison and conversion of names via a standard object.
Exceptions:	None.
Published Events:	None.
Provided Services:	

```
interface NamedEntity {
```

/* Set and get the name. The NamedEntity interface does not specify scoping of names or enforce uniqueness of names. This could allow distinct instances of a NamedEntity to use the same string as a name. */

```
void setName (in string name)
        raises (Global::FrameworkErrorSignal);

string getName ( )
        raises (Global::FrameworkErrorSignal);
```

/* Tests the equality of the name with the name provided as an argument. */

```
boolean isNamed (in string testName)
        raises (Global::FrameworkErrorSignal);

}; // NamedEntity
```

Contracted Services: None.

Dynamic Model: None.

6.4.3 *Owned Entity Interface*

6.4.3.1 The concept of ownership in the CIM Framework relates to the hierarchical structure that may be defined where one object "owns" another object. This should not be confused with the business concept of ownership relating to an item's value as an asset.

Module: AbstractIF

Interface: OwnedEntity

Inherited Interface: NamedEntity

Description: The abstract interface OwnedEntity provides for the concept of an "owned" entity. There may be only one "owner" for each instance of an OwnedEntity. The OwnedEntity is able to communicate with the owner to request services, or forward information of interest. To build a "parts of" hierarchy, a series of ownerships can be established.

Exceptions: None.

Published Events: None.

Provided Services:

```
interface OwnedEntity : NamedEntity {
```

/* Set and get owner. */

```
void setOwner (in NamedEntity owner)
        raises (Global::FrameworkErrorSignal);

NamedEntity getOwner ( )
        raises (Global::FrameworkErrorSignal);

}; // OwnedEntity
```

Contracted Services: None.

Dynamic Model: None.

6.4.4 *Resource Interface*

Module: AbstractIF

Interface: Resource

Inherited Interface: OwnedEntity

Description: Resource is an abstract inherited interface for any entity in the factory that takes an active role in advancing a product along its manufacturing life cycle (adds value). This includes the factory itself, personnel, production, planning and scheduling resources, and all of the machines used for processing, transporting, and storing materials. Resource provides a common set of services for monitoring and control. Resource uses the NamedEntity and OwnedEntity characteristics together to allow for the building of resource hierarchies.

There must be a clear division between the state of the Resource and the condition of the physical entity which the Resource represents. For instance, a Machine is a resource, but the fact that it is “Out of Service” may not mean the physical equipment is shutdown on the shop floor. In fact, the equipment may be operating in manual mode. The Resource state represents the availability of the Resource object to accept work for the factory system.

Exceptions: None.

Published Events: None.

Provided Services:

```
interface Resource : OwnedEntity {
```

/* Perform the startup activities for this Resource. Should be implemented by Resource specializations. */

```
void startUp ( )
        raises (Global::FrameworkErrorSignal);
```

/* Perform normal shutdown activities for this Resource. Normal is defined as allowing the Resource to complete any current activities and “gracefully” shutdown. */

```
void shutdownNormal ( )
        raises (Global::FrameworkErrorSignal);
```

/* Perform immediate shutdown activities for this Resource. Immediate is defined as aborting or terminating any current activities and stopping activity as soon as possible. This should be implemented by Resource specializations. */

```
void shutdownImmediate ( )
        raises (Global::FrameworkErrorSignal);
```

/* Respond with the receiver’s level in the Resource hierarchy. Resource specifies that each different type of Resource provide a “resourceLevel” identifier.

```
string resourceLevel ( )
        raises (Global::FrameworkErrorSignal);
```

/* The following service provides name scoping for Resources. Resource name scoping makes use of the notion of “Resource level” and the ownership hierarchy. For example, unique identification of MachineResources within a Machine is possible, but to identify them outside the Machine additional information about their ownership will be required.

Thus: nameQualifiedTo (“Machine”) sent to the ProcessResource named “Chamber” answers

“TestMachine>Chamber”.

If the Machine was owned by a Factory named “TestFactory”, then:

nameQualifiedTo (“Factory”) sent to the ProcessResource answers

“TestFactory>TestMachine>Chamber”

where the ProcessResource has now been uniquely identified for the given Factory.

There is no limit to the number of levels that may be addressed this way. Based on the implementations of nameQualifiedTo (string); a name need not always be concatenated, if a particular Resource level is not applicable to identification. */

```
string nameQualifiedTo (in string resourceLevel)
        raises (Global::FrameworkErrorSignal);
```

/* Returns the set of subordinate Resources for a given Resource. */

```
ResourceSequence subResources ( )
        raises (Global::FrameworkErrorSignal);
```

/* Answer if the resource is in service. In service means the resource is functional and ready to accept and perform its normal tasks. Derivatives of Resource are expected to expand this state (e.g., add sub-interfaces) that explicitly deal with such additional issues as capacity, "normal" work versus maintenance, etc. */

```
boolean isInService ( );
```

/* Answer if the resource is out of service. Out of service means the resource is unable to accept or begin new tasks. Previously begun tasks may continue in some cases. */

```
boolean isOutOfService ( );
```

```
}; // Resource
```

Contracted Services: None.

Dynamic Model:

Implementations of Resource may extend the state model by providing additional sub-states that are wholly contained within a state defined here. Extending the state model by the addition of state transitions is also an option for subtypes of Resource.

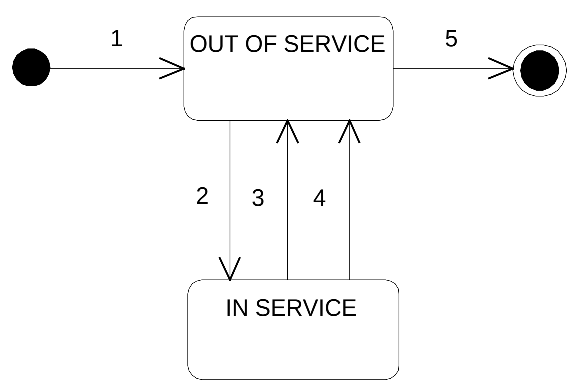

Figure 2
Resource Dynamic Model

Table 1 Resource State Definitions and Query Table

State	*Definition*	*Query for State via*
IN SERVICE	Resource is capable of interacting with other resources with its full service interface.	boolean isInService ( ); sent to the instance of Resource returns TRUE.
OUT OF SERVICE	Resource is not able to provide services	boolean isOutOfService ( ); sent to the instance of Resource returns TRUE.

Table 2 Resource State Transitions

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	Non Existent	Object creation.	OUT OF SERVICE	None.	Default entry.
2	OUT OF SERVICE	startUp ( ) or object initialization.	IN SERVICE	Initiate Resource and subresources.	startUp() service initiates the trigger.
3	IN SERVICE	shutdownNormal ( ).	OUT OF SERVICE	Complete current execution of resources normally.	shutdownNormal() service initiates the trigger.
4	IN SERVICE	shutdownImmediate ( ). Take resource out of service.	OUT OF SERVICE	Stop execution of resource immediately.	shutdownImmediate() service initiates the trigger.
5	OUT OF SERVICE	Resource removed.	Non Existent	None.	

6.5 *Material Abstract Interface Group*

6.5.1 The CIM Framework uses a common architecture for identifying, grouping and locating materials. Any material has an identification, history, location, and associations to any material containers that contain it. Material can also be in multiple material groups that physically (same location or carrier) or logically (same lot, same process batch, same product family, etc.) associate material. Specializations of material include products, durables and consumables. Specializations of material groups include product groups, lots, and process groups.

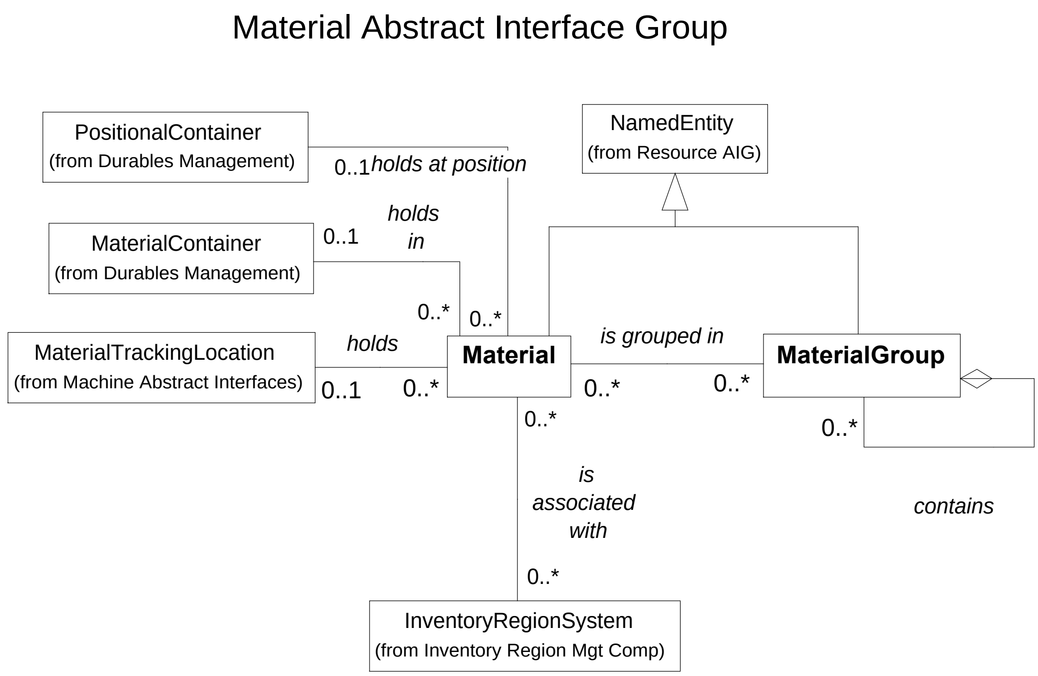

Figure 3
Material Abstract Interface Group Information Model

6.5.2 *Material Interface*

Module:	AbstractIF
Interface:	Material
Inherited Interface:	NamedEntity
Description:	Material is an abstract interface for physical items or substances that are required as inputs to the manufacturing process. This includes the product itself, consumables and durables used in the manufacturing process. It does not include the resources used to transform material into product.
Exceptions:	None.
Published Events:	None.
Provided Services:	

```
interface Material : NamedEntity {
```

/* Set and get the identifier for this material. The identifier is unique within the extent of all material for an MES Factory. */

```
string getIdentifier ( )
        raises (Global::FrameworkErrorSignal);

void setIdentifier (in string identifier)
        raises (Global::FrameworkErrorSignal,
        Global::DuplicateIdentifierSignal);
```

/* Returns the material groups of which the receiver is a member. */

```
MaterialGroupSequence materialGroups ( )
        raises (Global::FrameworkErrorSignal);
```

/* Answers whether the receiver is a member of the material group indicated by the argument. */

```
boolean isMemberOf (in MaterialGroup aMaterialGroup)
        raises (Global::FrameworkErrorSignal);
```

```
}; // Material
```

Dynamic Model: None.

6.5.3 *Material Group Interface*

Module: AbstractIF

Interface: MaterialGroup

Inherited Interface: NamedEntity

Description: MaterialGroup is the abstract interface for any aggregation of Material.

```
interface MaterialGroup : NamedEntity {
```

Exceptions:

/* Signals an attempt to add Material to the MaterialGroup that is already in the group. */

```
exception DuplicateMaterialSignal {Material aMaterial;};
```

/* Signals an attempt to add a MaterialGroup to a MaterialGroup that is already in the group. */

```
exception DuplicateMaterialGroupSignal {Material aMaterialGroup;};
```

/* Signals an attempt to remove Material that wasn't found in this MaterialGroup. */

```
exception MaterialRemovalFailedSignal {Material aMaterial;};
```

/* Signals an attempt to remove a MaterialGroup that wasn't found in this MaterialGroup. */

```
exception MaterialGroupRemovalFailedSignal {MaterialGroup aMaterialGroup;};
```

Published Events: None.

Provided Services:

/* Set and get the unique identifier for this group. */

```
string getIdentifier ( )
        raises (Global::FrameworkErrorSignal);

void setIdentifier (in string identifier)
        raises (Global::FrameworkErrorSignal,
        Global::DuplicateIdentifierSignal);
```

/* Adds the argument MaterialSequence to the collection of Matrial held by the receiver. */

```
void addMaterials (in MaterialSequence aMaterialSequence)
        raises (Global::FrameworkErrorSignal,
        DuplicateMaterialSignal);
```

/* Adds the argument Material to the collection of Material held by the receiver. */

```
void addMaterial (in Material aMaterial)
        raises (Global::FrameworkErrorSignal,
        DuplicateMaterialSignal);
```

/* Removes the Material indicated from the MaterialGroup. Throws the exception if not found. */

```
void removeMaterial (in Material aMaterial)
        raises (Global::FrameworkErrorSignal,
        MaterialRemovalFailedSignal,
        Global::NotFoundSignal);
```

/* Remove and return all Material from the MaterialGroup. */

```
MaterialSequence removeAllMaterials ( )
        raises (Global::FrameworkErrorSignal);
```

/* Add the argument MaterialGroup to this MaterialGroup. */

```
void addMaterialGroup (in MaterialGroup aMaterialGroup)
        raises (Global::FrameworkErrorSignal,
        DuplicateMaterialGroupSignal);
```

/* Removes the argument MaterialGroup from this MaterialGroup. */

```
void removeMaterialGroup (in MaterialGroup aMaterialGroup)
        raises (Global::FrameworkErrorSignal,
        MaterialGroupRemovalFailedSignal,
        Global::NotFoundSignal);
```

/* Remove and return all MaterialGroups from this MaterialGroup. */

```
MaterialGroupSequence removeAllMaterialGroups ( )
        raises (Global::FrameworkErrorSignal);
```

/* Returns the collection of material in this MaterialGroup. */

```
MaterialSequence allMaterials ( )
        raises (Global::FrameworkErrorSignal);
```

/* Returns all the MaterialGroups in this MaterialGroup. */

```
MaterialGroupSequence allMaterialGroups ( )
        raises (Global::FrameworkErrorSignal);
```

/* Returns the count of the items in the MaterialGroup. */

```
long count ( )
        raises (Global::FrameworkErrorSignal);

}; // MaterialGroup
```

Dynamic Model: None.

6.6 *Job Supervision Abstract Interface Group*

6.6.1 The Job Supervision Abstract Interface Group provides the abstractions common to creating, executing and managing a “job,” where a job can be defined as some system level operation which may be requested from the JobSupervisor. The job often spans a significant amount of time and multiple resources within the system. It is intended for specialization to provide specific job supervisors and jobs to provide system solutions.

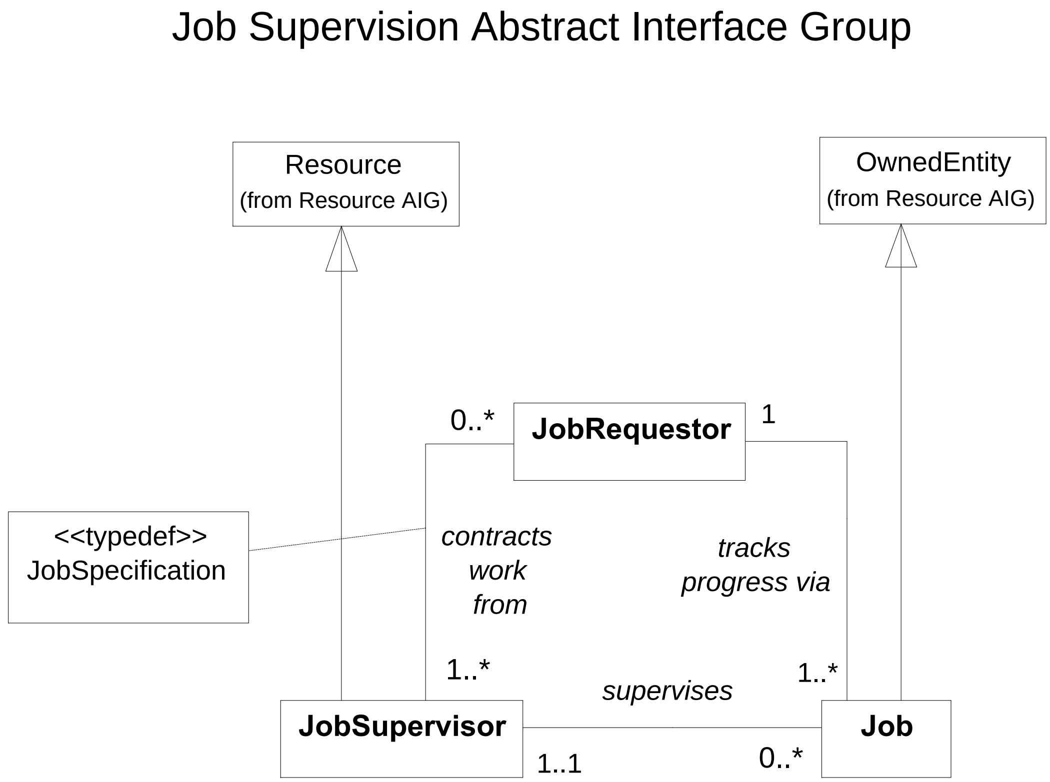

Figure 4
Job Supervision Abstract Interface Group Information Model

6.6.1.1 The basic Job Supervision Abstract Interface Group does not interact with other components, except to the extent that other components instantiate its interfaces. Figure 4 shows how the interfaces of Job Supervision relate to one another.

6.6.1.2 A Job Specification is a sequence of properties containing the parameters required to sufficiently define the work to be done. This sequence is passed by the JobRequestor to the JobSupervisor in the Job request message. See the JobSupervisor interface for more details.

6.6.1.3 JobSupervision levels are hierarchical. One level may accept a Job and delegate portions of that Job to lower levels. Jobs, however, are not purely hierarchical. A Job accepted by one JobSupervisor may be broken down, along with other Jobs of that component and reconstituted as needed to optimize the activities of the factory.

6.6.1.4 For example, a ProductRequest may ask for 15 wafers of a particular product. The ProductRequestManager may delegate a LotJob to Factory Operations with a Lot containing those 15 wafers and 10 more from a different ProductRequest. In the factory, this Lot may be split up and processed in smaller groups at various stages or, as scrap reduces the wafer count, combined with another small lot to create a more optimal process group. The Job Supervision implementation is allowed great latitude to optimize performance. Its only requirement is to fulfill the specification of the Job.

6.6.2 *JobSupervisor Interface*

Module:	AbstractIF
Interface:	JobSupervisor
Inherited Interface:	Resource

Description: The JobSupervisor manages all the Jobs being performed by the component which implements it. It receives the requests for work, facilitates the creation of a Job for the task and returns (a reference to) that Job.

A JobSupervisor will have a well defined domain which it can call on to perform work. These may be CIM Framework Resources if it delegates the work, or internal resources if it performs the work itself. Only activity requests which can be accomplished within the domain of a JobSupervisor should be issued to/accepted by that JobSupervisor.

Jobs, as subtypes of NamedEntity, are named by the JobSupervisor in such a way that their name attribute may be used to query for the Job. Jobs from different JobSupervisors may have the same name.

The definition of the work to be performed is the JobSpecification, a sequence of name/value pairs (see “Properties” definition). Specializations of Job Supervision may require certain properties in the JobSpecification. Some commonly useful properties are defined in the following table. When possible, specializations should reuse these definitions. Specializations should also document the allowable and mandatory properties that are supported. See Job definition for more information.

```
interface JobSupervisor : Resource {
```

Type Definitions:

/* Type for returning results of Job execution. */

```
typedef Global::NameValueSequence Results;
```

JobSpecification Properties:

Name	*Value Type*	*Description*
“JobType”	string	The kind of Job to run. This is useful when a JobSupervisor can initiate more than one type of Job. String values reserved for this property are: ProductRequestJobType, LotJobType, AreaJobType, ProcessMachineJobType, TransportJobType, PMJobType, ControlStrategyJobType, AlgorithmJobType.
“Priority”	long	Integer value, ranges from 1 to 99, where 1 is the highest priority and 99 is the lowest.
“Deadline”	TimeStamp	The Job is expected to be completed no later than the specified value of the Deadline.

Exceptions:

/* Requested Job was rejected. */

```
exception JobRejectedSignal {
        string errorMessage; };
```

/* Requested Job was not found */

```
exception JobNotFoundSignal {
        string errorMessage;
        string missingJobName; };
```

Published Events:

/* Provide lifecycle event for tracking */

```
const string JobLifecycleSubject =
        "/JobSupervision/JobSupervisor/JobLifecycle";
```

/* The use of “name” here (and in all other events) indicates the string value for the name or identifier of the Job to which the event refers. Since filtering does not support object reference comparisons, the filtering must be on the “name” of the object. */

```
struct JobLifecycleFilters {
        Global::Property name;
        Global::Property lifecycle;
};
```

JobLifecycleFilters Properties:

Name	*Value Type*	*Description*
“Name”	string	The name of the Job.
“Lifecycle”	Global::LifecycleState	New lifecycle state.

```
struct JobLifecycleEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        JobLifecycleFilters eventFilterData;
        Global::Properties eventNews;
        Job aJob; // on Delete, aJob is nil
};
```

Provided Services:

/* Request that work be done according to the referred specification. A Job which represents the work is returned for future reference. The post-condition for this operation is the specified Job successfully created. */

```
Job requestJob (
        in Global::Properties aJobSpecification,
        in JobRequestor aJobRequestor)
        raises (Global::FrameworkErrorSignal,
        JobRejectedSignal);
```

/* Request that work be done according to the Job specification. This operation blocks until the Job completes. Results generated by the Job are returned. The post-condition for this operation is a successful execution of the specified Job. This interface offers a lightweight alternative to ***requestJob*** that does not require that requestors support the JobRequestor interfaces (e.g., informJobStateChange operation). A Job may or may not be created by runJob, but if created, the Job may be accessed with the Job query operations of JobSupervisor. */

```
Results runJob (
        in Global::Properties aJobSpecification)
        raises (Global::FrameworkErrorSignal,
        JobRejectedSignal);
```

/* Ask whether the Job specified by the JobSpecification would be accepted for current or future (queued) processing if a requestJob or runJob message were issued now. */

```
boolean canPerform (in Properties aJobSpecification)
        raises (Global::FrameworkErrorSignal);
```

/* Command to begin the pausing of all Jobs of this JobSupervisor which can be paused (e.g. Jobs that have not reached the Finished state). */

```
void pauseAllJobs ()
        raises (Global::FrameworkErrorSignal);
```

/* Command to “resume” all Jobs of this JobSupervisor which are currently Paused. */

```
void resumeAllJobs ()
        raises (Global::FrameworkErrorSignal);
```

/* This command aborts all the Jobs under the control of the JobSupervisor immediately, without regard to the impact of abruptly halting the Job. This service should be used with great caution. It may result in irrevocable change to factory or material state. */

```
void abortAllJobs ()
        raises (Global::FrameworkErrorSignal);
```

/* This command stops all Jobs under control of the JobSupervisor, as quickly as possible. Stopping Jobs should not result in damage to the factory or material being processed. */

```
void stopAllJobs ()
        raises (Global::FrameworkErrorSignal);
```

/* This service removes a Job which is in the terminated state. If required, persistent information about the Job may be captured in a history entry. Jobs may also be removed based on other archiving rules. */

```
void removeFinishedJob (in Job aJob)
        raises (Global::FrameworkErrorSignal);
```

/* Find a Job by name. A Job is a NamedEntity */

```
Job findJobNamed (in string jobName)
        raises (Global::FrameworkErrorSignal,
        JobNotFoundSignal);
```

/* Find a queued Job by name. */

```
Job findQueuedJobNamed (in string jobName)
        raises (Global::FrameworkErrorSignal,
        JobNotFoundSignal);
```

/* Find an active Job by name. */

```
Job findActiveJobNamed (in string jobName)
        raises (Global::FrameworkErrorSignal,
        JobNotFoundSignal);
```

/* Find a canceled Job by name. */

```
Job findCanceledJobNamed (in string jobName)
        raises (Global::FrameworkErrorSignal,
        JobNotFoundSignal);
```

/* Find a finished Job by name. */

```
Job findFinishedJobNamed (in string jobName)
        raises (Global::FrameworkErrorSignal,
        JobNotFoundSignal);
```

/* Return all the specified Jobs. The JobSequence may be empty. */

```
JobSequence allJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allQueuedJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allCanceledJobs ( )
        raises (Global::FrameworkErrorSignal);
```

```
JobSequence allActiveJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allExecutingJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allPausingJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allPausedJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allStoppingJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allAbortingJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allFinishedJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allStoppedJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allAbortedJobs ( )
        raises (Global::FrameworkErrorSignal);

JobSequence allCompletedJobs ( )
        raises (Global::FrameworkErrorSignal);

}; // JobSupervisor
```

Contracted Services: None.

Dynamic Model: Inherited.

6.6.3 *Job Interface*

Module: AbstractIF

Interface: Job

Inherited Interface: OwnedEntity

Description: The Job interface represents a unit of work requested of an associated JobSupervisor and performed (or facilitated) by a factory entity. A Job generally results in some change of the overall factory state. How the entities that supply the Job and JobSupervisor interfaces actually perform the work (or delegation of work) is an implementation decision. A Job is expected (but not required) to take a non-zero time to perform and have a non-zero chance of refusal or failure. A Job may encapsulate a decomposition into a sequence of jobs/tasks/activities which are delegated to lower level job supervisors. The Job exists during the execution timeframe. The more persistent record of the Job should be maintained in a history entry.

```
interface Job : OwnedEntity {
```

Exceptions:

Published Events:

/* Any time the Job's state changes. */

```
const string JobStateChangedSubject =
        "/JobSupervision/Job/StateChanged";
```

/* This enumerated type identifies the states of Jobs. It is used in event notifications of state changes. */

```
enum JobState {
        JobUndefined,
        JobCreated,
        JobQueued,
        JobActive,
        JobExecuting,
        JobNotPaused,
        JobPausing,
        JobPaused,
        JobNotStopping,
        JobStopping,
        JobNotAborting,
        JobAborting,
        JobFinished,
        JobCanceled,
        JobCompleted,
        JobStopped,
        JobAborted };

struct JobStateChangedFilters {
        Global::Property name;
        Global::Property previousState;
        Global::Property newState;
};
```

JobStateChangedFilters Properties:

Name	*Value Type*	*Description*
"Name"	string	The name of the Job.
"PreviousState"	string	Previous state preceding the most recent change.
"NewState"	RegistrationState	New state following the most recent change.

```
struct JobStateChangedEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        JobStateChangedFilters eventFilterData;
        Global::Properties eventNews;
        Job aJob;
};
```

/* If the Job cannot be completed by the specified deadline, a JobDeadlineCannotBeMetEvent should be sent as early as possible, not necessarily after the deadline has passed. */

```
const string JobDeadlineCannotBeMetSubject =
        "/JobSupervision/Job/DeadlineCannotBeMet";

struct JobDeadlineCannotBeMetFilters {
        Global::Property name;
        Global::Property deadline;
};
```

JobDeadlineCannotBeMetFilters Properties:

Name	*Value Type*	*Description*
"Name"	string	The name of the Job.
"Deadline"	Global::TimeStamp	Value of the Deadline that cannot be met.

```
struct JobDeadlineCannotBeMetEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        JobDeadlineCannotBeMetFilters eventFilterData;
        Global::Properties eventNews;
        Job aJob;
};
```

/* This event is posted when a Job's deadline date has changed. */

```
const string JobDeadlineChangedSubject =
        "/JobSupervision/Job/DeadlineChanged";

struct JobDeadlineChangedFilters {
        Global::Property name;
        Global::Property previousDeadline;
        Global::Property newDeadline;
};
```

JobDeadlineChangedFilters Properties:

Name	*Value Type*	*Description*
"Name"	string	The name of the Job.
"PreviousDeadline"	Global::TimeStamp	Previous Deadline.
"NewDeadline"	Global::TimeStamp	New Deadline.

```
struct JobDeadlineChangedEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        JobDeadlineChangedFilters eventFilterData;
        Global::Properties eventNews;
        Job aJob;
};
```

Exceptions: None.

Provided Services:

/* Ask the Job for its JobRequestor. */

```
JobRequestor getJobRequestor ()
        raises (Global::FrameworkErrorSignal);
```

/* Get a named Job property from its Job Specification. */

```

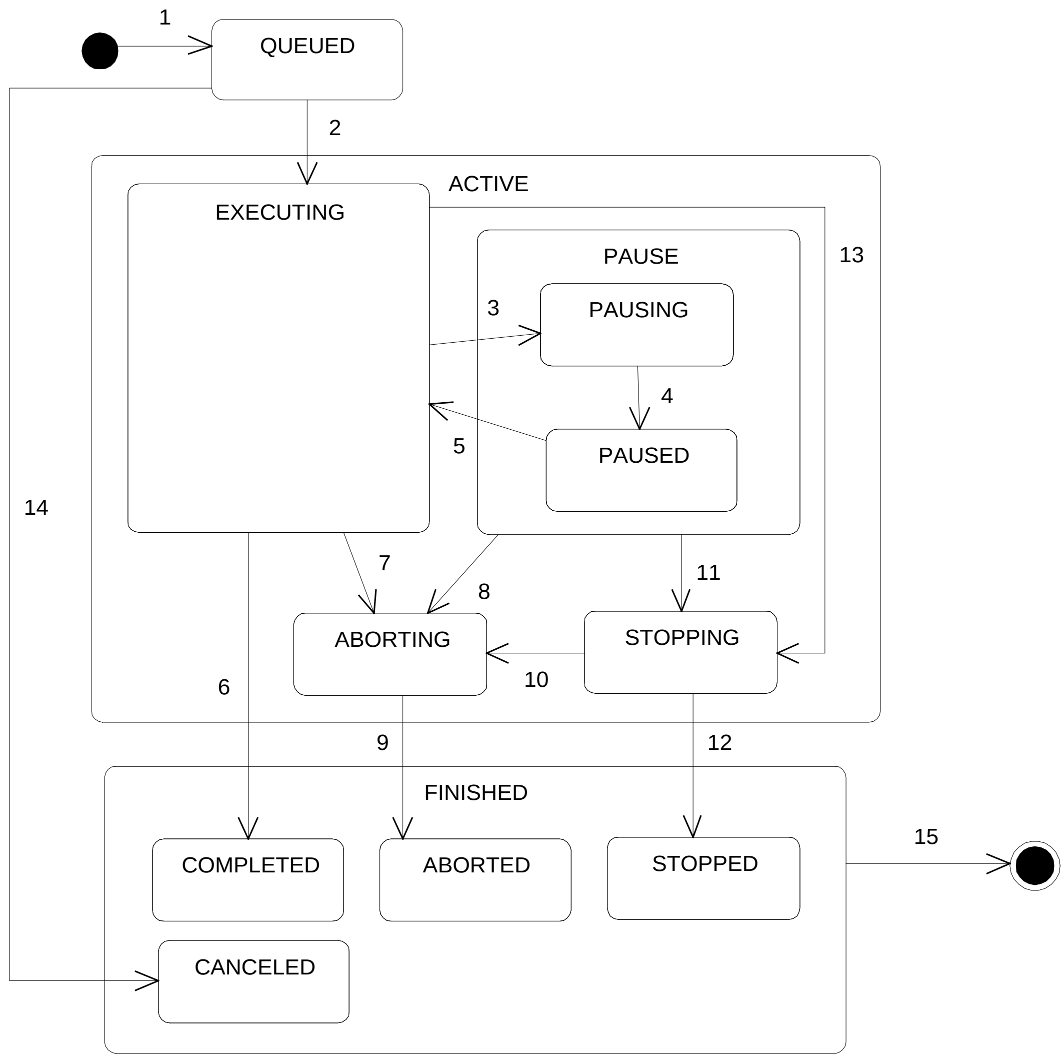

Figure 5
Job Dynamic Model

6.6.3.1 For implementations (e.g., Job derivatives), the Executing state is expected to be extended by partitioning it into at least two "orthogonal" states. One would hold the Pause states. The other would contain the implementation behavior of Executing.

Object State Tables:

Table 3 Job State Definitions and Query Table

State	*Definition*	*Query for State via*
ABORTED	In this state the Job has aborted execution. This is a substate of Finished.	boolean isAborted(); sent to an instance of Job; returns TRUE JobSequence allFinishedJobs (); sent to instance of JobSupervisor will provide some indication.
ABORTING	ABORTING represents an immediate termination of the Job and activities not completed before the aborting will be terminated. After ABORTING, execution is not intended to continue.	boolean isAborting(); sent to an instance of Job; returns TRUE
ACTIVE	This is a parent state representing that the Job is ACTIVE for the JobSupervisor; i.e., the current status of the Job is tracked by the JobSupervisor when the Job is in the ACTIVE state.	boolean isActive(); sent to an instance of Job; returns TRUE. JobSequence allActiveJobs (); or Job findActiveJobNamed (in string jobName); sent to instance of JobSupervisor.
CANCELED	In this state the Job has been removed from the Queue and will never become Active. This is a substate of Finished.	boolean isCanceled(); sent to an instance of Job; returns TRUE
COMPLETED	This state represents that the Job has successfully completed execution. This is a substate of Finished.	boolean isCompleted(); sent to an instance of Job; returns TRUE. Job findCompletedJobNamed (in string jobName); sent to instance of JobSupervisor JobSequence allFinishedJobs (); sent to instance of JobSupervisor will provide some indication.
EXECUTING	This state represents that the Job is EXECUTING. Specializations of Job will normally develop substates representing the specialized Job execution behavior.	boolean isExecuting(); sent to an instance of Job; returns TRUE.
PAUSE	Parent state of PAUSING, PAUSED	None.
PAUSED	In this state the Job has paused execution.	boolean isPaused(); sent to an instance of Job; returns TRUE.
PAUSING	In this state the Job is being paused by the executor of the Job. Execution is intended to continue.	boolean isPausing(); sent to an instance of Job; returns TRUE.
QUEUED	In this state the Job is waiting to become active.	boolean isQueued(); sent to an instance of Job; returns TRUE. JobSequence allQueuedJobs (); or Job findQueuedJobNamed (in string jobName); sent to instance of JobSupervisor.
STOPPED	In this state the Job has stopped execution. This is a substate of Finished.	boolean isStopped(); sent to an instance of Job; returns TRUE. JobSequence allFinishedManagedJobs (); sent to instance of JobSupervisor will provide some indication.
STOPPING	In this state the Job is being stopped. Execution is not intended to continue. STOPPING represents an ordered termination of the Job Activities. Job Activities not completed before stopping may or may not be performed, depending on the implementation.	boolean isStopping(); sent to an instance of Job; returns TRUE.
FINISHED	This is a parent state representing that the Job has finished execution, through either successful execution, abort, or stop. This is the superstate of Completed, Aborted, Stopped, and Canceled.	boolean isFinished(); sent to an instance of Job; returns TRUE. JobSequence allFinishedJobs (); sent to instance of JobSupervisor.

Table 4 Job State Transitions

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	Non Existent	Job creation.	QUEUED	JobStateChanged Event published by the instance of Job	None.
2	QUEUED	Internal to component.	EXECUTING	JobStateChanged Event published by the instance of Job	Job has started.
3	EXECUTING	void makePaused ( ); sent to the Job; or void PauseAllJobs ( ); sent to an instance of JobSupervisor.	PAUSING	JobStateChanged Event published by the instance of Job	Job has been told to pause.
4	PAUSING	Internal to component	PAUSED	JobStateChanged Event published by the instance of Job	Job has completed PAUSING activities. Wait for resume.
5	PAUSED	void makeExecuting ( ); sent to the Job or void resumeAllJobs (); sent to an instance of JobSupervisor.	EXECUTING	JobStateChanged Event published by the instance of Job	Restart EXECUTING from the point PAUSED at.
6	EXECUTING	Internal to component	COMPLETED	Execution of the Job was successful or completed normally.	None.
7	EXECUTING	void makeAborted ( ); sent the Job or void abortAllJobs ( ); sent to the JobSupervisor.	ABORTING	Execution of the Job stops immediately. Product or Job will be unfinished.	None.
8	PAUSE	void makeAborted ( ); sent the Job or void abortAllJobs ( ); sent to the JobSupervisor.	ABORTING	Active Job is aborted immediately.	None.
9	ABORTING	Internal to component	ABORTED	JobStateChanged Event published by the instance of Job	Job has completed aborting activities.
10	STOPPING	void makeAborted ( ); sent the Job or void abortAllJobs ( ); sent to the JobSupervisor.	ABORTING	JobStateChanged Event published by the instance of Job	None.
11	PAUSE	void makeStopped( ); sent to the Job or void stopAllJobs( ); sent to the JobSupervisor.	STOPPING	JobStateChanged Event published by the instance of Job	None.
12	STOPPING	Internal to component	STOPPED	JobStateChanged Event published by the instance of Job	Job has completed stopping activities.
13	EXECUTING	void makeStopped( ); sent to the Job or void stopAllJobs( ); sent to the JobSupervisor.	STOPPING	JobStateChanged Event published by the instance of Job	None.
14	QUEUED	void makeCanceled( ); sent to the Job.	CANCELED	JobStateChanged Event published by the instance of Job	Job has been canceled before starting execution. It cannot be restarted.
15	FINISHED	void removeFinished-Job (in Job aJob); sent to an instance of JobSupervisor.	Non Existent	JobStateChanged Event published by the instance of Job	Job has been removed from the finished queue.

6.6.4 *JobRequestor Interface*

Module: AbstractIF

Interface: JobRequestor

Inherited Interface: Implementation Dependent

Description: In order to request work of a JobSupervisor using the requestJob operation, a component must implement the JobRequestor interface. This is a companion interface to JobSupervisor. The JobRequestor may also subscribe to the state change events of the Job, if more detail is required.

```
interface JobRequestor {
```

Exceptions: None.

Published Events: None.

Provided Services:

/* The Job has transitioned to a new state. Required for transition to Executing from Queued and for any transition to a Finished sub-state. This operation is in addition to the required JobStateChangedEvent notifications. */

```
void informJobStateChange (
        in Job aJob,
        in Job::JobState previousState,
        in Job::JobState newState)
        raises (Global::FrameworkErrorSignal);

}; // JobRequestor
```

Contracted Services: None.

Dynamic Model: None.

Scenario:

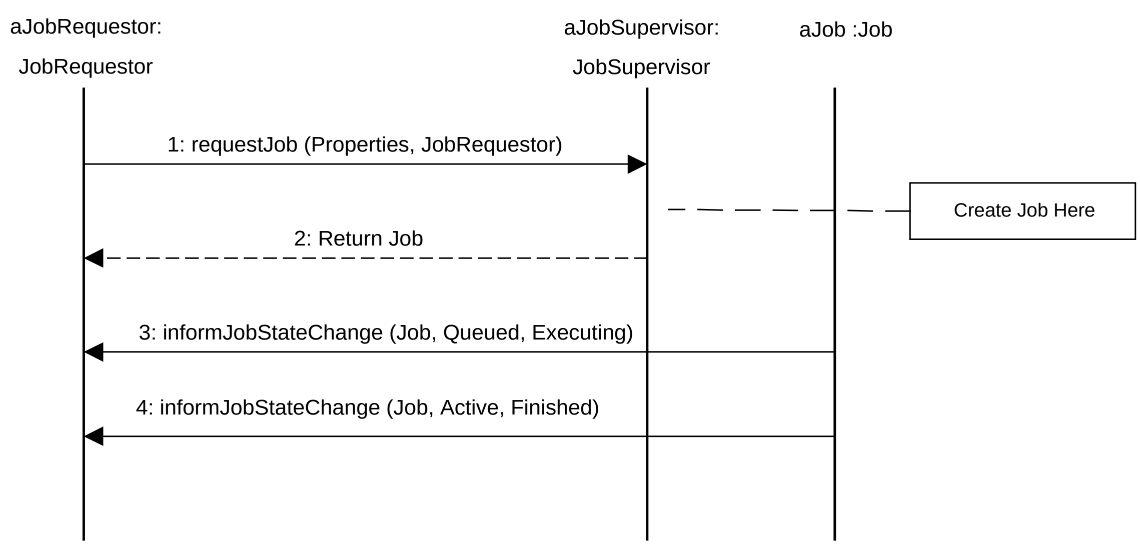

Figure 6
Job Supervision Scenario

6.6.4.1 Figure 6 shows the most basic of scenarios for Job Supervision interactions. It proceeds in this fashion:

6.6.4.1.1 The JobRequestor populates a JobSpecification then requests a Job according to that specification.

6.6.4.1.2 In response to the Job request, the JobSupervisor facilitates the creation of a Job to represent the task. A handle to the Job is returned to the JobRequestor (assuming the Job request is accepted).

6.6.4.1.3 The Job Supervision component (e.g. in the form of the Job) informs the JobRequestor when the Job begins.

6.6.4.1.4 The Job Supervision component (e.g. in the form of the Job) informs the JobRequestor when the Job has completed (assuming successful completion). It also issues events for each state change (not shown in the scenario diagram).

6.7 *Factory Component*

6.7.1 The Factory interfaces provide configuration services to specify the existence and connectivity of factory resources that constitute a factory. This includes area configuration and the registration of CIM system components, and the ability to dynamically configure a factory to enforce business policy.

6.7.1.1 These interfaces are included here to satisfy dependencies and meet needs of other CIM Framework Components. These interfaces will be moved to the Factory Operations Component in a subsequent revision ballot.

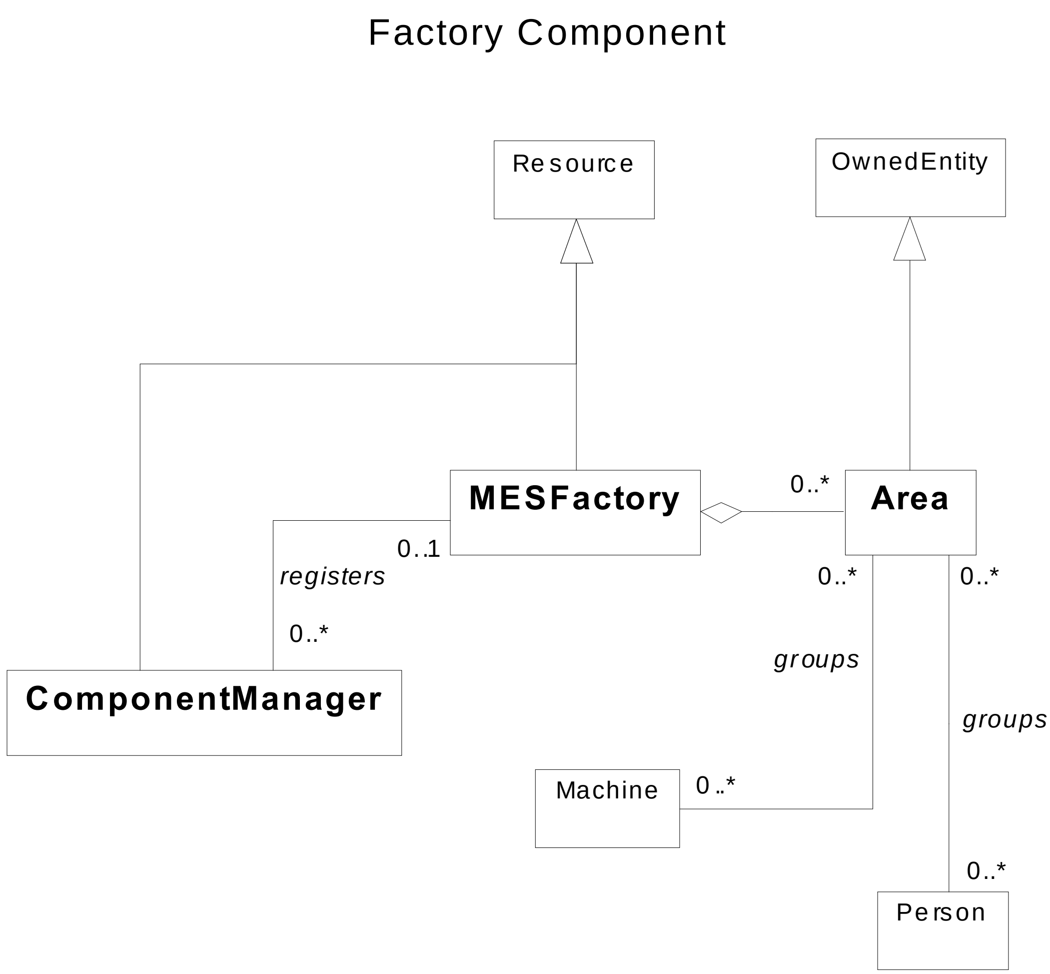

Figure 7
Factory Component Information Model

6.7.2 *Factory Declarations*

6.7.2.1 The following declarations are used by the interfaces of the Factory Component.

```
interface ComponentManager;

interface Area;

typedef sequence <ComponentManager> ComponentManagerSequence;

typedef sequence <Area> AreaSequence;

exception AreaNotFoundSignal {Area requestedArea;};

exception AreaDuplicateSignal { };

exception AreaNotAssignedSignal { };

exception AreaRemovalFailedSignal { };
```

6.7.3 *MESFactory Interface*

Module:	FactoryOperations
Interface:	MESFactory
Inherited Interface:	AbstractIF::Resource
Description:	The MESFactory interface represents one particular factory. This instance is a composite object referring to the objects that represent factory resources, particularly CIM system components. The factory instance provides overall startup and shutdown capability.

```
interface MESFactory : AbstractIF::Resource {
```

Exceptions: None.

Published Events:

/* MES Factory state change event definition. */

```
const string MESFactoryStateChangedSubject = "/Factory/MESFactory/StateChanged";
```

/* This enumerated type identifies the states of the MES Factory. It is used in event notifications of state changes. */

```
enum MESFactoryState {
        FactoryUndefined,
        FactoryStartingUp,
        FactoryOperating,
        FactoryGoingToStandby,
        FactoryStandby,
        FactoryShuttingDownImmediately,
        FactoryShuttingDownNormally,
        FactoryOff };

struct MESFactoryStateChangedFilters {
        Global::Property name;
        Global::Property previousState;
        Global::Property newState;
};
```

MESFactoryStateChangedFilters Properties:

Name	*Value Type*	*Description*
"MESFactoryName"	string	The name of the MES Factory.
"PreviousState"	MESFactoryState	Previous state preceding the most recent change.
"NewState"	MESFactoryState	New state following the most recent change.

```
struct MESFactoryStateChangedEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        MESFactoryStateChangedFilters eventFilterData;
        Global::Properties eventNews;
        MESFactory aMESFactory;
};
```

/* Registration of Component Manager has changed */

```
const string ComponentManagerRegistrationChangedSubject =
"/Factory/MESFctory/ComponentManagerRegistrationChanged";
```

/* This enumerated type identifies the states of Component Manager registration. It is used in event notifications of state changes. */

```
enum RegistrationState {
        RegistrationUndefined,
        Registered,
        NotRegistered };

struct RegistrationChangedFilters {
        Global::Property MESFactoryName;
        Global::Property componentManagerName;
        Global::Property newState;
};
```

RegistrationChangedFilters Properties:

Name	*Value Type*	*Description*
"MESFactoryName"	string	The name of the MES Factory.
"ComponentManagerName"	string	The name of the Component Manager.
"NewState"	RegistrationState	New state following the most recent change.

```
struct ComponentManagerRegistrationChangedEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        RegistrationChangedFilters eventFilterData;
        Global::Properties eventNews;
        MESFactory aMESFactory;
        ComponentManager aComponentManager;
};
```

Provided Services:

        raises (Global::FrameworkErrorSignal);

boolean isStandby ( )
        raises (Global::FrameworkErrorSignal);

}; // MESFactory
```

Contracted Services: None.

Dynamic Model:

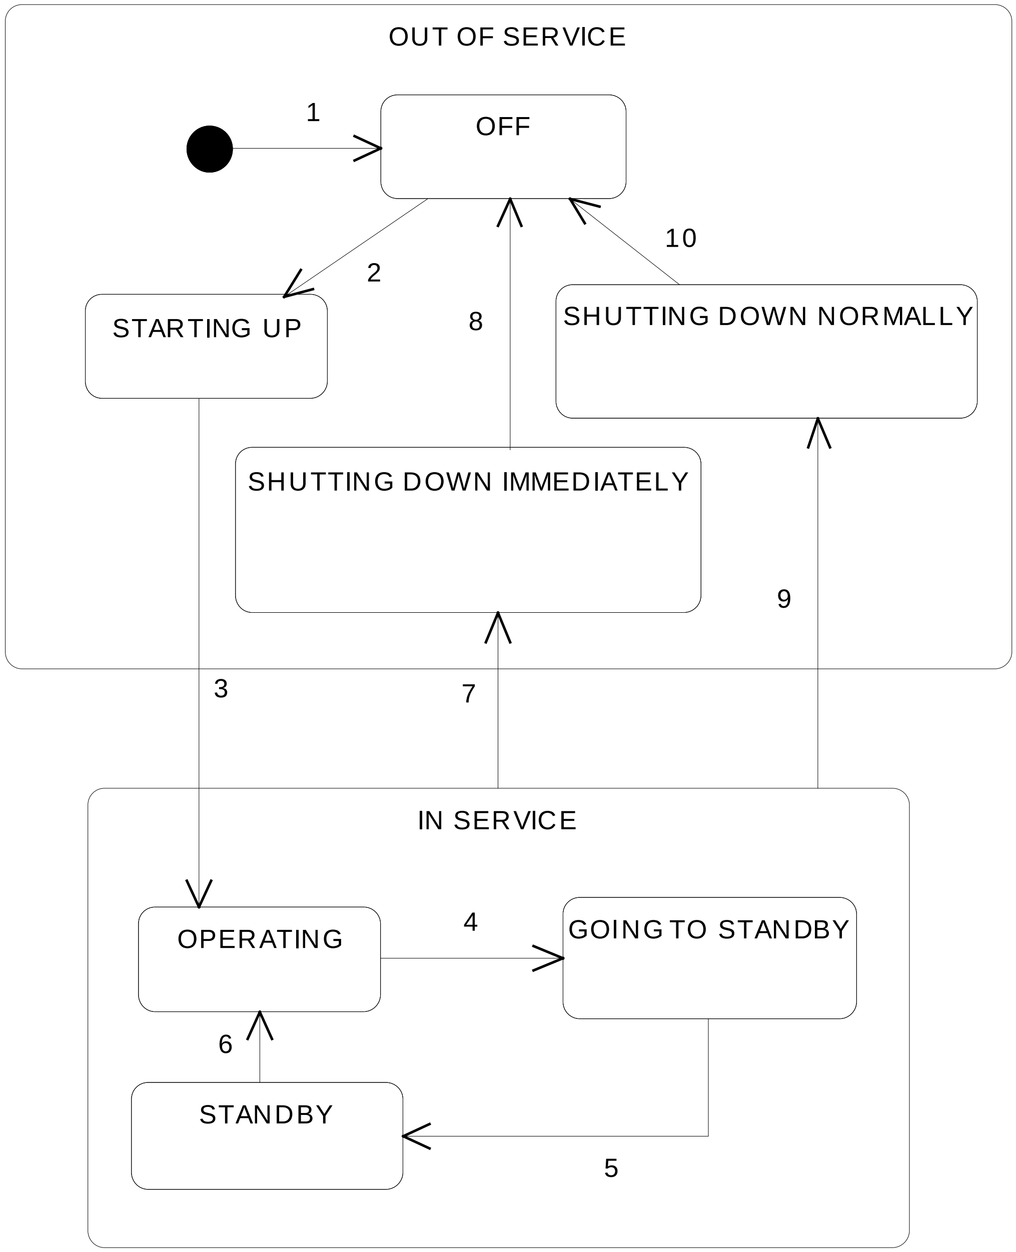

Figure 8
MESFactory Dynamic Model

Table 5 MESFactory State Definitions and Query Table

State	*Definition*	*Query for State via*
OUT OF SERVICE	A superstate, inherited from Resource, encompassing the next four substate definitions.	boolean isOutOfService ( ); sent to the instance of MESFactory returns FALSE.
OFF	In this state the MESFactory has a building, machines and other resources. No CIM activities should be allowed. ComponentManagers should not be registered yet.	boolean isOff ( ); sent to the instance of MESFactory returns TRUE.
STARTING UP	In this state the MESFactory has requested startup sequences for all resources.	boolean isStartingUp ( ); sent to the instance of MESFactory returns TRUE.
SHUTTING DOWN NORMALY	In this state MESFactory resources and material are brought to a safe state in preparation for terminating in an orderly fashion.	boolean isShuttingDownNormaly ( ); sent to the instance of MESFactory returns TRUE.
SHUTTING DOWN IMMEDIATELY	In this state the MESFactory is shutting down without regard for the safe state of material or potential product and data loss. All processes are terminated immediately.	boolean isShuttingDownImmediately ( ); sent to the instance of MESFactory returns TRUE.
IN SERVICE	A superstate, inherited from Resource, encompassing the next three substate definitions.	boolean isInService ( ); sent to the instance of MESFactory returns TRUE.
OPERATING	In this state the MESFactory is able to process product. Applications are prepared to support factory operations to process product.	boolean isOperating ( ); sent to the instance of MESFactory returns TRUE.
GOING TO STANDBY	In this state the MESFactory is performing sequences to make the transition to STANDBY. It brings all product and equipment to a safe stopping place.	boolean isGoingToStandby ( ); sent to the instance of MESFactory returns TRUE.
STANDBY	STANDBY means nearly available for immediate use. In this state the MESFactory is idle and available; applications are able to respond to a subset of selected messages.	boolean isStandby ( ); sent to the instance of MESFactory returns TRUE.

Table 6 MESFactory State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	non-existent	No CIM Framework trigger necessary	OFF	Building(s), machines and other resources are added after this transition.	The MESFactory object instance is unique in the Framework. It is the only object that must be created by the implementation.
2	OFF	void makeStartingUp ( ); sent to the instance of MESFactory.	STARTING UP		Startup sequence performed, including delegated messages to component managers. Resource inherited interface also defines startup.
3	STARTING UP	void makeOperating ( ); sent to the instance of MESFactory.	OPERATING	MESFactory is operating event published by the instance of MESFactory.	Relevant registered components inform the factory when they have completed startup prior to startup being complete.

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
4	OPERATING	void makeStandby ( ); sent to the instance of MESFactory.	GOING TO STANDBY		MESFactory is requested to go to STANDBY state.
5	GOING TO STANDBY	completion of Standby transition by MESFactory.	STANDBY	MESFactory is in STANDBY state event published by the instance of MESFactory.	All component managers, machines and material are idle and in a safe state.
6	STANDBY	void makeOperating ( ); sent to MESFactory	OPERATING	void startup ( ); sent to an instance of Component-Manager.	Since standby means nearly available for immediate use, this startup transition should be minimal.
7	IN SERVICE	void makeShuttingDown Immediately ( ); sent to the instance of MESFactory.	SHUTTING DOWN IMMEDI-ATELY	void shutdownImmediate ( ); sent to all instances of registered Component Managers.	As an action, messages delegated to component managers. The Resource inherited interface also implements shutdownImmediate
8	SHUTTING DOWN IMMEDI-ATELY	void makeOff (); sent to the instance of MESFactory.	OFF	void informComponent ManagerIsStopped (in ComponentManager aComponentManager); sent to the instance of MESFactory by the Component Managers. MESFactory is off event published by the instance of MESFactory.	The MESFactory polls the ComponentManagers and Resources for completion of shutdown before the MESFactory state transitions to OFF.
9	IN SERVICE	void makeShuttingDown Normally ( ); sent to the instance of MESFactory.	SHUTTING DOWN	void shutdown Normal ( ); sent to all instances of registered Component-Managers.	As an action, messages delegated to component managers.
10	SHUTTING DOWN NORMALLY	void makeOff ( ); sent to the instance of MESFactory.	OFF	void informComponent ManagerIsStopped (in ComponentManager aComponentManager); sent to the instance of MESFactory by the Component Managers. MESFactory is off event published by the instance of MESFactory.	The MESFactory polls the ComponentManagers and Resources for completion of shutdown before the MESFactory state transitions to OFF.

6.7.4 *Area Interface*

Module:	FactoryOperations
Interface:	Area
Inherited Interface:	OwnedEntity
Description:	Area is the interface corresponding to a physical or logical grouping of factory resources (the complement of machines and/or personnel assigned to it). Area may represent a singular entity or it may represent a collection of other Areas. For example, an Area may represent an entire facility for maintenance purposes, or an Area may represent a processing area such as a “bay” which is comprised of “zones.”

The association between an Area and its composite Areas may be hierarchical or there may simply be a collection of peer Areas without any explicit or implicit relationship.

Area may or may not be an optional construct, depending on such issues as security.

```
interface Area {
```

Exceptions: None.

Published Events:

/* Area configuration changed event definition. */

```
const string AreaConfigurationChangedSubject =
"/Factory/Area/AreaConfigurationChanged";
```

/* This enumerated type identifies the types of configuration changes for Areas. It is used in event notifications of state changes. */

```
enum AreaChangeType {
        MachinesChanged,
        PersonsChanged,
        SubAreaChanged };

struct AreaConfigurationChangedFilters {
        Global::Property name;
        Global::Property changeType;
};
```

AreaConfigurationChangedFilters Properties:

Name	*Value Type*	*Description*
"Name"	string	The name of the Area.
"ChangeType"	AreaChangeType	The type of change to the Area.

```
struct AreaConfigurationChangedEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        AreaConfigurationChangedFilters eventFilterData;
        Global::Properties eventNews;
        Area anArea;
};
```

Provided Services:

/* Answer the Area to which this Area is associated. If no membership has been established, nil is returned. */

```
Area getSuperArea ( )
        raises (Global::FrameworkErrorSignal);
```

/* Get the unique identifier for the Area. */

```
string getAreaIdentifier ( )
        raises (Global::FrameworkErrorSignal);
```

/* Adds a machine to the receiver. Returns the machine added. */

```
EquipmentTracking::Machine addMachine (in EquipmentTracking::Machine aMachine)
        raises (Global::FrameworkErrorSignal,
        EquipmentTracking::MachineDuplicateSignal);
```

/* Create an association between an Area and the Area to which it belongs. The service will add the Area indicated by the argument to the receiver's set of subareas. The service will also update the superarea for the argument. The service returns the argument. */

```
Area addSubArea (in Area anArea)
        raises (Global::FrameworkErrorSignal,
        AreaDuplicateSignal);
```

/* Adds a person to the receiver. Returns the person added. */

```
Labor::Person addPerson (in Labor::Person aPerson)
        raises (Global::FrameworkErrorSignal,
        Labor::PersonDuplicateSignal);
```

/* Remove the association between an Area and the Area to which it belongs. The service will remove the Area indicated by the argument from the receiver's set of subareas. The service will also nullify membership (ownership) for the argument. */

```
void removeSubArea (in Area anArea)
        raises (Global::FrameworkErrorSignal,
        AreaNotAssignedSignal,
        AreaRemovalFailedSignal);
```

/* Removes a machine from the receiver. */

```
void removeMachine (in EquipmentTracking::Machine aMachine)
        raises (Global::FrameworkErrorSignal,
        EquipmentTracking::MachineNotAssignedSignal,
        EquipmentTracking::MachineRemovalFailedSignal);
```

/* Removes a person from the receiver. */

```
void removePerson (in Labor::Person aPerson)
        raises (Global::FrameworkErrorSignal,
        Labor::PersonNotAssignedSignal,
        Labor::PersonRemovalFailedSignal);
```

/* Set the unique identifier for the Area. */

```
void setAreaIdentifier (in string identifier)
        raises (Global::FrameworkErrorSignal,
        Global::DuplicateIdentifierSignal);
```

/* Returns the set of subareas associated with this Area, that is, the Areas "contained" within this higher-level Area. If no membership has been established, an empty set is returned. */

```
AreaSequence allSubAreas ( )
        raises (Global::FrameworkErrorSignal);
```

/* Returns the receiver's set of process machines. */

```
EquipmentTracking::MachineSequence allMachines ( )
        raises (Global::FrameworkErrorSignal);
```

/* Returns the receiver's set of persons */

```
Labor::PersonSequence allPersons ( )
        raises (Global::FrameworkErrorSignal);
```

```
}; // Area
```

Contracted Services: None.

Dynamic Model: None.

6.7.5 *Component Manager Interface*

Module: FactoryOperations

Interface: ComponentManager

Inherited Interface: Resource

Description: The ComponentManager is an abstract interface that supports the registration and control (enabling/disabling) of a component's interface and for managing the resources in its domain.

Exceptions: None.

Published Events:

```
interface ComponentManager : Resource {
```

/* Component Manager state has changed */

```
const string ComponentManagerStateChangedSubject =
"/Factory/ComponentManager/ComponentManagerStateChanged";
```

/* This enumerated type identifies the states of Component Managers. It is used in event notifications of state changes. */

```
enum ComponentManagerState {
        ComponentManagerUndefined,
        ComponentManagerStopped,
        ComponentManagerStartingUp,
        ComponentManagerShuttingDown };

struct ComponentManagerStateChangedFilters {
        Global::Property name;
        Global::Property previousState;
        Global::Property newState;
};
```

ComponentManagerStateChangedFilters Properties:

Name	*Value Type*	*Description*
"Name"	string	The name of the ComponentManager.
"PreviousState"	ComponentManagerState	Previous state prior to the most recent transition.
"NewState"	ComponentManagerState	New state following the most recent transition.

```
struct ComponentManagerStateChangedEvent {
        string eventSubject;
        Global::TimeStamp eventTimeStamp;
        ComponentManagerStateChangedFilters eventFilterData;
        Global::Properties eventNews;
        ComponentManager aComponentManager;
};
```

Provided Services:

/* This operation causes the component to do its portion of the registration interchange with the factory indicated by the argument. */

```
void makeRegistered (in MESFactory aFactory)
        raises (Global::FrameworkErrorSignal,
        Global::InvalidStateTransitionSignal);
```

/* This operation causes the component to remove its registration from the factory. */

```
void makeNotRegistered (in MESFactory aFactory)
        raises (Global::FrameworkErrorSignal,
        Global::InvalidStateTransitionSignal);
```

/* This operation causes a registered component to perform its startup sequence. Each manager gets itself to the point where it is capable of interacting with other components. When it is ready to support all services defined in the interface, the component manager tells the factory that component startup is complete. */

```
void makeStartingUp ( )
        raises (Global::FrameworkErrorSignal,
        Global::InvalidStateTransitionSignal);
```

/* This operation causes the component to perform its shutdown sequence and then enter the state STOPPED. During shutting down activities, time is allotted to bringing the resources of a component to a safe stopping condition. The component manager tells the factory that component shutdown is complete. */

```
void makeShuttingDown ( )
        raises (Global::FrameworkErrorSignal,
        Global::InvalidStateTransitionSignal);
```

/* This operation causes the component to go into the state STOPPED without regard to data loss or the stopping condition of resources or material. There is no communication with the factory. */

```
void makeStopped ( )
        raises (Global::FrameworkErrorSignal,
        Global::InvalidStateTransitionSignal);
```

/* This operation causes a registered component to go into the state IN SERVICE from the state STOPPED. */

```
void makeInService ( )
        raises (Global::FrameworkErrorSignal,
        Global::InvalidStateTransitionSignal);
```

/* Answer whether the status of the component is that indicated. */

```

}; // ComponentManager
```

Contracted Services: None.

Dynamic Model:

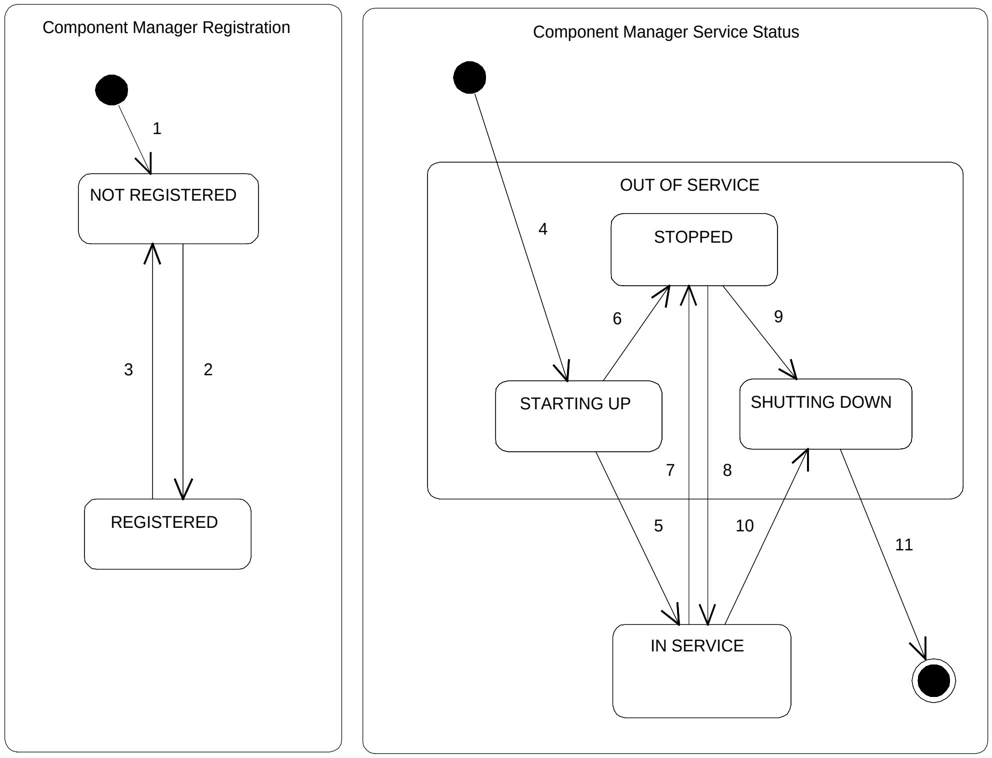

Figure 9
Component Manager Dynamic Model

Table 7 ComponentManager State Definitions and Query Table

State	*Definition*	*Query for State via*
NOT REGISTERED	Component is not registered with a factory and is not connected to the system.	boolean isNotRegistered ( ); sent to the instance of ComponentManager returns TRUE.
REGISTERED	Component is registered with a factory and is connected to the system.	boolean isRegistered ( ); sent to the instance of ComponentManager returns TRUE.
STOPPED	Component is not able to provide services.	boolean isStopped ( ); sent to the instance of ComponentManager returns TRUE.
STARTING UP	Component is performing a startup sequence.	boolean isStartingUp ( ); sent to the instance of ComponentManager returns TRUE.
IN SERVICE	Component is capable of interacting with other components.	boolean isInService ( ); sent to the instance of ComponentManager returns TRUE.
SHUTTING DOWN	Component is performing shutdown sequence.	boolean isShuttingDown ( ); sent to the instance of ComponentManager returns TRUE.
OUT OF SERVICE	Component is not able to provide services.	None.

Table 8 ComponentManager State Transitions

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	Non Existent	No CIM Framework trigger necessary.	NOT REGISTERED	Instance creation is done by the specialization.	ComponentManager is an abstract inherited interface designed to provide common behavior for specializations.
2	NOT REGISTERED	makeRegistered() sent to the instance of ComponentManager.	REGISTERED	Component manager registers with a Factory instance via Trader.	None.
3	REGISTERED	makeNotRegistered() sent to the instance of ComponentManager.	NOT REGISTERED	Component manager removes registration from the Factory via Trader.	None.
4	Unknown	makeStartingUp() sent to the instance of ComponentManager.	STARTING UP	Component manager is requested to startup.	Implementation can use startup() or makeStartingUp() services.
5	STARTING UP	Internal to component.	IN SERVICE	Report to Factory that Component is able to provide services, via events.	Component manager has finished its startup sequence.
6	STARTING UP	Internal to component.	STOPPED	None.	Component Manager could not complete startup procedure and is stopped for further corrective action.
7	IN SERVICE	makeStopped() sent to the instance of Component Manager.	STOPPED	Component will also go out of service.	ComponentManager is stopped and it may be resumed as needed.
8	STOPPED	makeInService() sent to the instance of Component Manager.	IN SERVICE	Component Manager has resumed operations and is in service for execution.	None.
9	STOPPED	makeShuttingDown() sent to the instance of ComponentManager.	SHUTTING DOWN	As an action it reports to the Factory that resources and material are brought to a safe state.	The component manager receives “shutdown normal” message.
10	IN SERVICE	makeShuttingDown() sent to the instance of ComponentManager.	SHUTTING DOWN	As an action it reports to the Factory that resources and material are brought to a safe state.	The component manager receives “shutdown normal” message.
11	SHUTTING DOWN	makeNotRegistered() sent to the instance of Component Manager.	Non Existent	The Component Manager is unregistered.	None.

APPENDIX 1
FULL IDL SPECIFICATION

NOTE: The material in this appendix is an official part of SEMI E97 and was approved by full letter ballot procedures on October 21 and December 15, 1999 by the North American Regional Standards Committee.
