z306	3	49 ± 0.5 mm (1.929 ± 0.020 in.)	horizontal reference plane	bottom edge of side handling flange
z307	3	52.5 mm (2.067 in.) maximum	horizontal reference plane	top surface of side handling flange
z308	3	25 mm (0.984 in.) maximum	horizontal reference plane	edge of side handling exclusion volume
z310	3, 5	8 mm (0.315 in.) maximum	bottom surface of robotic handling flange	top of robotic handling flange
z312	8	44 mm (1.732 in.) maximum	horizontal reference plane	top of rear retainer exclusion volume
z313	n/a	43 ± 1 mm (1.1693 ± 0.039 in.)	horizontal reference plane	top of reticle backstops

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix is an official part of SEMI E111 and was approved by full letter ballot procedures on August 27, 2001, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 Skewness, warp, rock, and stiffness are implicitly defined in the dimensional tolerances.

A1-2 Features on the RSP150 which enable stacking may be required by end users. It is preferred that these features allowing stacking in only one orientation.

A1-3 Features on the RSP150 which provide visual orientation of the RSP150 top and RSP150 door may be required by end users.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E111, and it is not intended to modify or supercede the official standard. This information was inserted by the North America Physical Interfaces and Carriers Committee to alert the readers to potential changes to this provisional standard.

R1-1 In the event end-effector and pellicle exclusion volumes can be developed which would satisfy all lithography equipment manufacturers and allow for a 126 mm pellicle, then the appropriate changes would be balloted to update the standard.

SEMI E112-0302
PROVISIONAL MECHANICAL SPECIFICATION FOR A 150 mm MULTIPLE RETICLE SMIF POD (MRSP150) USED TO TRANSPORT AND STORE MULTIPLE 6 INCH RETICLES

This specification was technically approved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the North American Physical Interfaces and Carriers Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org January 2002; to be published March 2002. Originally published November 2001.

1 Purpose

1.1 This standard specifies the 150 mm Multiple Reticle SMIF Pod (MRSP150) used to transport and store six 6 inch reticles in an integrated circuit (IC) manufacturing facility.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and inter-changeability at all mechanical interfaces. Most of the requirements given in this specification are in the form of maximum or minimum dimensions with very few required surfaces. Only the physical interfaces for the MRSP150 are specified; no materials requirements or micro-contamination limits are given in this specification.

2.2 The pellicle exclusion volumes of this specification accommodates pellicles which extend the full length of the reticle and up to a maximum pellicle width of 124 mm.

2.3 The MRSP150 has the following components, sub-components, and other features. A "●" symbol indicates components or features which are *required* and a "◊" symbol indicates components or features which are *optional*.

- Top
  - ◊ robotic handling flange
- Interior
  - supports for six 6 inch reticles
  - reticle capture
  - reticle contact surfaces
  - end-effector exclusion volumes
  - 2 safety rail exclusion volumes
  - pellicle exclusion volumes
  - lateral constraints
  - reticle backstop
- Sides
  - ◊ 2 side handling flanges on the sides parallel to the bi-lateral reference plane
  - 2 side handling exclusion volumes
- Bottom
  - door compatible with SMIF as defined in SEMI E19.3
  - pod latch-pin holes
  - 2 conveyor rails on the sides parallel to the bi-lateral reference plane

2.4 This standard is provisional because of the issues detailed in the related information section. Once investigation of issues in the related information section has been completed, this standard should be upgraded from provisional status.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3.1 *SEMI Standards*

SEMI E19.3 — 150 mm Standard Mechanical Interface (SMIF)

SEMI E30.1 — Inspection and Review Specific Equipment Model (ISEM)

SEMI E44 — Guide for Procurement and Acceptance of Minienvironments

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI P5 — Specification for Pellicles

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *150 mm Multiple Reticle SMIF Pod* (MRSP150) — a minienvironment compatible carrier capable of holding six 6 inch reticles in a horizontal orientation during transport and storage and is compatible with a Standard Mechanical Interface (SMIF) per SEMI E19.3.

4.2 *bilateral reference plane* — a vertical plane which bisects the MRSP150 and is perpendicular to both the horizontal and facial reference planes and passes through the center of the 150 mm SMIF as defined in SEMI E19.3.

4.3 *facial reference plane* — a vertical plane which bisects the MRSP150 and is parallel to the front side of the pod (where reticles are removed or inserted) and passes through the center of the 150 mm SMIF as defined in SEMI E19.3.

4.4 *horizontal reference plane* — a horizontal plane coplanar with the top surface of the port door as defined in SEMI E19.3.

4.5 *minienvironment* — a localized environment created by an enclosure to isolate the product from contamination and people (as defined in SEMI E44).

4.6 *nominal reticle center line* — the line that is defined by the intersection of two perpendicular vertical planes each of which bisect the reticle at the mid-point of a side.

4.7 *pellicle* — as defined in SEMI P5.

4.8 *reticle* — as defined in SEMI E30.1.

4.9 *robotic handling flanges* — horizontal projections on the top of the box for lifting and rotating the box (as defined in SEMI E47.1).

4.10 *side handling flanges* — horizontal projections on the sides of the pod (sides parallel to the bilateral reference plane) for lifting, transportation or positioning of the pod.

5 Ordering Information

5.1 *Intended Use* — This standard is intended to specify reticle carriers over a reasonable lifetime of use, not just those in new condition. For this reason, the purchaser should specify a time period and the number and type of uses to which the carriers will be put. It is under these conditions that the carriers must remain in compliance with the requirements listed in Section 6.

5.2 *Reticle Thickness* — The purchaser needs to specify the reticle thickness to be accommodated in the MRSP150.

5.3 *Optional Features* — The purchaser needs to specify whether optional components (identified in Section 2) are required.

5.4 *Temperature Ranges* — The purchaser needs to specify two sets of temperatures to which the MRSP150s might be exposed. An operating temperature range is the set of environmental temperatures in which the MRSP150s will remain in compliance with the requirements listed in Section 6. A temporary temperature range is the set of environmental temperatures to which the pods can be exposed such that when the MRSP150s return to the operating temperature range, the MRSP150s will be in compliance with the requirements listed in Section 6. Limits on exposure times to elevated temperatures should be specified.

5.5 *Electrostatic Dissipation* — The end user may require a continuous path to ground from the reticle to the carrier registration and handling features. The purchaser needs to specify whether electrostatic dissipation is required.

5.6 *Contamination Requirements* — The purchaser needs to specify their contamination requirements.

6 Requirements

6.1 *Symmetry* — Most of the dimensions of the MRSP150 are determined with respect to the three orthogonal reference planes defined in this document: the facial reference plane, the horizontal reference plane and the bilateral reference plane. All dimensions are symmetric about the bilateral reference plane.

6.2 *Door* — The pod door, and its frame on the bottom of the pod, must be compatible with a port which conforms to SEMI E19.3.

6.3 *Numbering* — The reticles are numbered in increasing order from bottom to top (so the bottom reticle is reticle number 1, to the top reticle which is reticle number 6).

6.4 *Positioning* — The nominal reticle seating planes are defined by z291 through z296 as shown in Figure 4 and Table 1. The entire bottom surface of a reticle must lie within the z276 dimension of its nominal seating plane shown in Figure 6 and Table 1.

6.5 *Reticle Contact Surfaces* — The reticle contact surfaces are the only 4 locations where the RSP150 may contact the pellicle side of the reticle. These surfaces are shown in Figures 8 and 9 with dimensions given in Table 1. The contact surfaces are defined by x245, x246, y233, y234 and y235.

6.6 *Reticle Capture* — When the carrier is closed, a bisecting plane through the reticle, parallel to the bilateral reference plane must be within x114 of the bilateral reference plane of the load port when the reticle is seated in the carrier. A bisecting plane through the reticle, parallel to the facial reference plane must be within y228 of the facial reference plane of the load port when the reticle is seated in the carrier.

6.7 *Exclusion Volumes* — The interior of the MRSP150 must never intrude into the pellicle exclusion volume, and must not intrude into the end-effector exclusion volumes, lift clearance exclusion volumes or safety rail exclusion volumes when the carrier is open.

6.7.1 *End-Effector Exclusion Volumes* — Volumes in an opened pod which must be free for the end-effector to enter and handle the reticle as defined by x238, x239, x240, y227, y232, y237, y238, z297, z299, z302 (first reticle) and z300 (second through sixth reticle). No obstructions should exist in the end-effector exclusion volumes which extend in the y direction (normal to the facial reference plane.) Table 1 defines the dimensions for the end-effector exclusion volumes shown in Figures 4, 6, 7 and 8.

6.7.2 *Pellicle Exclusion Volume* — Volume in the pod below the reticle which must remain free from intrusion to accommodate the pellicle mounted on the reticle. No obstructions should exist in the pellicle exclusion volume as defined by x119, z290 (first reticle) and the previous reticle lift clearance exclusion volume (second through sixth reticle) which extends in the y direction (normal to the facial reference plane). The pellicle exclusion volume is defined in Table 1 and shown in Figure 4.

6.7.3 *Reticle Lift Clearance Exclusion Volumes* — Volumes in an opened pod which must be free to allow the end-effector to lift and handle the reticles, as defined by x243, z298 and z311 (sixth reticle) as shown in Table 1 and Figures 4 and 6. No obstructions should exist in the reticle lift clearance exclusion volumes which extend in the y direction (normal to the facial reference plane.)

6.7.4 *Safety Rail Exclusion Volumes* — Volumes in an opened pod which must remain free from intrusion to accommodate safety rails which may be used on end-effectors to protect the edge of the reticle during handling. No obstructions should exist in the safety rail exclusion volumes which extend in the y direction (normal to the facial reference plane) as defined by x241 and z301 in Table 1 and shown in Figure 4.

6.7.5 *Rear Retainer Volume* — Volume in an opened pod in which any reticle rear retainer must exist. The volume is defined by x242 and y226 as shown in Figure 7 and Table 1.

NOTE 2: This volume is never to be accessed by an end-effector.

6.7.6 *Reticle Backstops* — The interior of the RSP150 shall have reticle backstops which may be used by end-effectors to position the reticle when being removed from the RSP150.

NOTE 3: These are the minimum required backstops, the backstops may be larger than this minimum specification, occupying any part of the rear retainer volume. The dimensions are defined by x249, x250, y239 and z314 as shown in Table 1 and in Figure 7.

6.8 *External Dimensions* — Figures 1, 2, 3, 5 and 10 show, respectively, the external top view, a detail, the rear view, the robotic handling flange and the conveyor rails of the MRSP150. Table 1 defines the external dimensions of the MRSP150.

6.9 *Internal Dimensions* — Figures 4, 6 and 7 show internal dimensions of the MRSP150. Table 1 defines the internal dimensions of the MRSP150.

6.10 *Robotic Handling Flange* — On the top of the pod is an optional robotic handling flange for automated manipulation of the MRSP150. Figures 1, 3 and 5 show dimensions for the robotic handling flange. Table 1 defines the dimensions for the robotic handling flange.

6.11 *Recess* — Surface on the top of the pod defined by dimensions x100, y106 and z281. Figures 1 and 3 show dimension for the recess. The recess provides clearance for use of robotic handling flange.

NOTE 4: The raised surface around the recess is not required.

6.12 *Side Handling Flanges* — On the sides of the pod parallel to the bilateral reference plane are optional handling flanges for automated manipulation of the MRSP150. Figures 1, 2 and 3 show dimensions for the side handling flanges. Table 1 defines the dimensions for the side handling flanges. No obstructions may exist in the side handling exclusion volumes which extend in the y direction (normal to the facial reference plane) as defined by x236 and z286.

6.13 *Conveyor Rails* — Surfaces on the bottom of the RSP150 used to transport the RSP on conveyors. The rails consist of smooth portions of the bottom periphery, parallel with each other, on two opposite sides, and extending at least y236 from the facial reference plane (optionally the full length) on those sides. Surfaces on these portions of the bottom periphery should be uninterrupted (ie. no notches in the surface along the bottom or the side). No other feature of the carrier may extend below the plane defined by the surfaces of the conveyor rails. The conveyor rail surfaces are bounded by x247, x248 and y236 as shown in Figure 10. Table 1 defines the dimensions for the conveyor rails.

6.14 *Inner and Outer Radii* — All required concave features may have a radius of up to *r*65 to allow cleaning and to prevent contaminant build-up. All required convex features may also have a radius of up to *r*66 to prevent small contact patches with large stresses that might cause wear and particles.

NOTE 5: These limits on the radius of all required features are specified as a maximum (not a minimum) to ensure that the required features are not rounded off too much. The lower bound on the radius is up to the carrier supplier.

NOTE 6: This radius applies to every required feature unless another radius is called out specifically. Here a required feature is an area on the surface of the carrier specified by a dimension (or intersections of dimensions) that has a tolerance and not just a maximum or minimum (such as the edges of the robotic handling flange).

z310	3, 5	8 mm (0.315 in.) maximum	bottom surface of robotic handling flange	top of robotic handling flange
z311	4	12.7 mm (0.500 in.) maximum	nominal reticle seating plane	edge of lift clearance exclusion volume
z314	n/a	133 mm (5.236 in.) minimum	horizontal reference plane	top of reticle backstops

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix is an official part of SEMI E112 and was approved by full letter ballot procedures on August 27, 2001, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 Edge contact only with the photomask is preferred when handling, transporting or storing.

A1-2 Skewness, warp, rock, and stiffness are implicitly defined in the dimensional tolerances.

A1-3 Features on the MRSP150 which enable stacking may be required by end users. It is preferred that these features allow stacking in only one orientation.

A1-4 Features on the MRSP150 which provide visual orientation of the MRSP150 top and MRSP150 door may be required by end users.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E112, and it is not intended to modify or supercede the official standard. This information was inserted by the North America Physical Interfaces and Carriers Committee to alert the readers to potential changes to this provisional standard.

R1-1 In the event end-effector and pellicle exclusion volumes can be developed which would satisfy all lithography equipment manufacturers and allow for a 126 mm pellicle, then the appropriate changes would be balloted to update the standard.

SEMI E113-1101
SPECIFICATION FOR SEMICONDUCTOR PROCESSING EQUIPMENT RF POWER DELIVERY SYSTEMS

This specification was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 Process plasmas are used throughout the semiconductor industry for the etching and deposition of thin films. The majority of the process chambers use RF power to produce and sustain the plasmas. Because the reliability and repeatability of the plasma directly impacts wafer-processing results, RF power delivery systems are a key element of semiconductor manufacturing technology. The accurate and reproducible performance of the entire RF power generation system, including the RF influenced parameters of the plasma, must be within commonly accepted tolerances.

1.2 Design criteria for RF reliability and repeatability demand standardized testing and evaluation of the performance of the RF power delivery systems and control instrumentation on a chamber. Not only must the subsystems (i.e., the generator, cable assemblies, matching network, chuck/coil) be characterized, but the performance of the integrated system must also be characterized over the intended operating range.

1.3 It is the intent of this standard to provide RF power delivery specifications for semiconductor processing equipment that leads to improved system and subsystem performance. It outlines performance criteria as well as required documentation that must be supplied with the system or subsystem components. The goal of the document is to provide the specifications needed to produce a well-characterized RF power delivery system, where stability, repeatability, and important electrical parameters such as delivered power, current/voltage, and the impedance of the system can be determined within the operating space.

2 Scope

2.1 This document specifies the minimum performance criteria for RF equipment used in the semiconductor industry. It does not address specific test methods or procedures for performance verification.

2.2 The primary focus for this specification is semiconductor processing equipment including, but not limited to, the following tool types:

- Dry etch equipment, and
- Film deposition equipment (CVD and PVD).

2.3 This specification applies to semiconductor processing equipment RF power delivery systems whose power is directly used to produce and sustain the plasma.

2.4 This standard does not address any safety or performance issues related to RF emissions or electrical codes (e.g., Underwriter's Laboratory, Inc. (UL), the National Electrical Code (NEC®), Federal Communications Commission (FCC)). It is the responsibility of the users of this standard to conform to the appropriate local codes and regulations as applied to this type of equipment, some of which are covered by referenced documents.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard is meant to address RF systems that primarily operate in the frequency range of 0.2–100 MHz. It does not address higher frequency RF systems or microwave systems.

3.2 This standard is intended to be a performance specification and is not intended to address design issues related to safety, which are covered elsewhere in the SEMI Standards.

3.3 This standard is not meant to address pulsed-power RF systems.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E10 — Specification for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E78 — Electrostatic Compatibility - Guide to Assess and Control Electrostatic Discharge (ESD) and Electrostatic Attraction (ESA) for Equipment

4.2 *IEEE*[1]

IEEE-STD-383 — IEEE Standard for Type Test of Class 1E Electrical Cables, Field Splices, and Connections for Nuclear Power Generating Stations

4.3 *MIL-SPEC*[2]

MIL-C-17G — General Specification for Cables, Radio Frequency, Flexible and Semirigid

MIL-PRF-39012D — General Specification for Connectors, Coaxial, Radio Frequency

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CVD* — Chemical Vapor Deposition

5.1.2 *PVD* — Physical Vapor Deposition

5.1.3 *VSWR* — Voltage Standing Wave Ratio

5.2 *Definitions*

5.2.1 *cable assembly* — the section of cable (transmission line), including the connectors, used to connect various parts of the RF power delivery system.

5.2.2 *electrical length* — the length of the cable assembly at the operating frequency expressed in terms of degrees, where one wavelength at the nominal operating frequency is equal to 360°.

5.2.3 *matching network* — the device used to transform the impedance of the load (chamber/chuck) to match the impedance of the generator/cable assembly, which is typically 50 ohms.

5.2.4 *matching network load impedance* — the impedance of the load to which the matching network is matched.

5.2.5 *power efficiency* — the power efficiency of a matching network is defined as the power exiting the network (output power) divided by the power entering the network (input power).

5.2.6 *harmonic frequency* — the harmonic frequencies are defined as integer multiples of the fundamental frequency. For example, the second harmonic of 13.56 MHz is 27.12 MHz.

5.2.7 *RF applicator/interface* — the part of the chamber where the RF system is terminated. This interface can either be a chuck (driven electrode) or the coil/antenna part of a plasma source.

5.2.8 *load Q* — the quality factor, Q, of the load is defined here as the magnitude of the reactive part of the load divided by the real part of the load. For example, a load impedance of 2 – j20 ohms would have a load Q of 10.

5.2.9 *matched load* — a matched load impedance is defined as typically having a magnitude of 50 ± 3.3 ohms at a phase angle of up to ± 3.8°. In other words, the load is considered matched if the reflection coefficient is no greater than 0.032 at any phase angle.

5.2.10 *tuning element position* — the position of the tuning element is defined as the output voltage or output encoder value that corresponds to the position of a variable tuning element in a Matching Network. For example, the voltage from a rotary potentiometer on the rotating shaft of a variable capacitor (the "Tuning Element") would be referred to as the capacitor's "Position". In this example, the position/voltage corresponds to a certain shaft location or position.

5.2.11 *tap point* — for some systems, partial tuning of the matching network is achieved by switching in a combination of fixed tuning elements, such as different values of capacitors. The tap point is defined as the position of the switch(es) that connect or disconnect tuning elements in the matching network circuit.

5.2.12 *RF system* — the RF system is defined as the combination of the generator, matching network, chamber interface, and the associated connecting cable assemblies that are specific to a particular tool/chamber.

5.2.13 $MTBF_p$ — mean (productive) time between failures; the average time the equipment performed its intended function between failures; productive time divided by the number of failures during that time. Only productive time is included in this calculation.

6 Ordering Information

6.1 Semiconductor manufacturers may use this standard when procuring processing equipment to specify RF power delivery system performance and documentation. The equipment suppliers may also use this document to specify the RF system components and subassemblies.

6.2 Orders for equipment in accordance with this standard shall include:

6.2.1 This specification number and date of issue.

6.2.2 Any certification showing passage of qualification tests required to be provided (optional).

1 Institute of Electrical and Electronics Engineers, IEEE Operations Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, New Jersey 08855-1331, USA. Telephone: 732.981.0060; Fax: 732.981.1721 website: www.ieee.org

2 Available from Naval Publication and Forms Center, 5801 Tabor Avenue, Philadelphia PA 19120 U.S.A website: www.dodssp.daps.mil/products.htm.

6.2.3 Any test results required to be included in reports to be provided (optional).

7 Requirements

7.1 Semiconductor processing equipment shall be designed and built with a reliable RF power delivery system. The requirements defined in this specification address the integrated RF system as well as the following RF power delivery system components: the RF cable assemblies, the matching network, the generator, and the RF applicator/interface, as well as specific components of these assemblies or systems.

7.2 The mean (productive) time between failures ($MTBF_p$), as outlined in SEMI E10, of the generator, matching network, and the RF power delivery system as a whole shall be provided by the supplier, as well as the test method used to determine $MTBF_p$.

7.3 *RF Cable Assemblies (Transmission Lines)*

7.3.1 Many RF power delivery systems use RF cable assemblies to transfer power from the generator to the input of the matching network and, in some cases, from the output of the matching network to the process chamber (e.g., the chuck assembly). All cable assemblies shall adhere to industry standards for cables and connectors (e.g., MIL-C-17G, MIL-PRF-39012D, IEEE-STD-383) in terms of rated power/voltage/ current, allowed bending radius, expected variation in characteristic impedance, and attenuation at the expected operating frequency(s) for the specific cable type (e.g., RG-217, RG-218) per the cable manufacturer's specifications.

7.3.2 The length of the cable assemblies used to connect portions of the RF power delivery system shall be specified in terms of electrical length at the nominal operating frequency, in addition to the nominal physical length. The electrical length shall be given in terms of degrees of phase shift. Variations in the dielectric properties (e.g., phase velocity, characteristic impedance) of the cable assemblies can cause the electrical length to differ between assemblies.

7.3.3 The electrical length of cables used between the matching network and the chamber (if any) shall be specified to within 0.25° of the standard electrical length value at the operating frequency for fixed frequency systems or at the midpoint frequency for variable frequency systems, for frequencies less than or equal to 13.56 MHz. For frequencies above 13.56 MHz, the length should be specified to a value (in degrees) equal to the frequency in MHz multiplied by 0.018 (e.g., the specification for 60 MHz would be $60 \times 0.018 = 1.1°$). For example, at 13.56 MHz, the physical length of typical cable (RG-217) corresponding to 0.25° of phase shift (0.5° of reflection coefficient phase shift) would be approximately 1 cm. This specification would result in impedance variations seen by the matching network of less than approximately 1 percent between processing chambers.

7.3.4 The length of cables used between the matching network and the generator shall be specified to within 1.0° of the standard electrical length value at the operating frequency for fixed frequency systems or at the midpoint frequency for variable frequency systems, for frequencies less than or equal to 13.56 MHz. For frequencies above 13.56 MHz, the length shall be specified to a value (in degrees) equal to the frequency in MHz multiplied by 0.074 (e.g., the specification for 60 MHz would be $60 \times 0.074 = 4.44°$). For example, at 13.56 MHz, the physical length of typical cable (RG-217) corresponding to 1.0° of phase shift (2.0° of reflection coefficient phase shift) would be approximately 4 cm. This specification would minimize the impedance transformation at the harmonic frequencies (10° of phase shift at the 10^{th} harmonic frequency).

7.3.5 The expected power dissipation in the cable assembly(s) supplied with the system shall be provided as a function of the operating frequency(s) of the system. The amount of power transmitted through the cable assembly shall be given in terms of dB (decibels) and percentage. The relationship between dB and percentage is given as:

$$\text{Percentage} = 100 \times 10^{(dB/10)}.$$

For example, approximately 94.8% (–0.232 dB of loss) of the power at 13.56 MHz will be transmitted through a cable assembly made from RG-217 cable with a physical length of 15.24 meters (electrical length of 375.74°). In other words, 5.2% of the power is dissipated in the cable assembly at 13.56 MHz.

7.4 *Matching Networks*

7.4.1 Matching networks transform the impedance of the plasma load to match the impedance of the generator, which is nominally 50 ohms. The transformation is achieved by the use of various reactive components, such as capacitors and inductors, that "tune" the matching network by transforming the impedance at the output of the network to the input of the matching network. For a given frequency, there is a fixed relationship between the impedance at the input of the matching network and the impedance at the output of the matching network (the load impedance). In other words, the impedance to which the matching network is matched (the load impedance) can be determined if the transform properties of the network are known for a given frequency. Typically, there are two methods of impedance transformation. The first method uses a fixed frequency (e.g., 13.56 MHz) and variable tuning elements, while the second method uses a variable frequency and fixed tuning elements. Specifications for both methods are given below.

7.4.2 For those systems that use fixed frequency operation, matching networks typically have two variable tuning elements, which are usually variable capacitors and/or inductors. These variable tuning elements typically have an output voltage or encoder value that corresponds to a certain value of the element (i.e., an output voltage will correspond to a specific value of capacitance or inductance in the matching network). The value of the output voltage or encoder value is referred to as the tuning element position. To obtain information on the operation and performance of the matching network, the tuning element positions must be provided as outputs.

7.4.3 For those systems that use variable frequency operation, matching networks typically have fixed tuning elements (no variation) or tap points between fixed tuning elements, and the frequency is varied to obtain the best matched condition. In some cases, the tap points are also varied for matching. To obtain information on the operation and performance of these types of networks, the operating frequency and the input impedance (or reflection coefficient magnitude and phase angle) shall be provided. For those systems that have variable tap points, the tap point position shall also be provided as an output.

7.4.4 For matching networks run at a fixed frequency with variable tuning elements, the load impedance shall be provided as a function of the tuning element positions. In addition, the efficiency of the matching network shall be provided as a function of the tuning element positions. The information shall be provided in tabular form. The increment of the tuning element positions shall be in steps equal to or less than 10% of the full range. For example, a voltage increment of 1 volt or less shall be used in the case where the full range of the tuning element position is 10 volts. A plot providing an example of the real part of the load transformed to 50 ohms by the matching network as a function of tuning element position indicator is shown in Figure 1 and a plot of the reactive part of the load impedance is shown in Figure 2. A plot of the power efficiency is shown in Figure 3. An example of data to be provided in tabular form is shown in Table 1. The required uncertainty of the magnitude of the impedance is $\pm$ 1.5%, the required uncertainty in the phase angle of the impedance is $\pm$ 0.35°, and the required uncertainty of the power efficiency is $\pm$ 2.0%. For example, a load impedance of 2.0 – j20 ohms would have an uncertainty in the real part of $\pm$ 0.15 ohms and an uncertainty in the reactive part of $\pm$ 0.32 ohms.

7.4.5 For matching networks run at a variable frequency with fixed tuning elements and/or tap points, the efficiency and load impedance as a function of its output parameters (frequency, input impedance, and tap point value (if any)) shall be provided. The information shall be provided in tabular form. The increment of the output parameters shall be in steps equal to or less than 10% of the full range. For example, if the operating frequency parameter is given as an output voltage, a voltage increment of 1 volt or less shall be used in the case where the full range of the output parameter is 10 volts. The required uncertainty of the magnitude of the impedance is $\pm$ 1.5%, the required uncertainty in the phase angle of the impedance is $\pm$ 0.35°, and the required uncertainty of the power efficiency is $\pm$ 2.0%.

7.4.6 The tuning element positions/values for each matching network (of the same type/model) shall be adjusted to provide consistent efficiency and matching network input impedance when the matching network is connected to a fixed load impedance. The load impedance used shall be one that is typically encountered by the matching network during processing and/or shall be an impedance that is near the mid-range of the tuning space (e.g., 2 – j20 ohms). A simple way to ensure network-to-network consistency is to adjust the tuning element positions/values to have consistent values between matching networks when connected to a common/fixed load impedance. The variation in tuning element positions between matching networks shall be less than 1% of full scale for a common fixed load impedance and shall be less than 2% of full scale over 80% of the operating range. For example, if the fixed load impedance is chosen such that the tuning element positions on matching network A are both 5 volts (for a 10 volt range), the tuning element positions for matching network B shall be within 0.1 volts of 5.0 volts.

7.4.7 The maximum power that the system can safely sustain during nominal, steady state processing conditions shall be provided as a function of the positions of the tuning elements (i.e., the plasma load conditions). The operating specifications of the components used in the matching network shall be provided (voltage and current capability), and peak values of voltage and current shall not exceed 80% of the rated voltage and current at the operating frequency for these components over the operating range of the matching network. This specification does not pertain to transient (e.g., plasma strike) conditions.

7.4.8 The maximum power the system can safely sustain without plasma (pre-ignition conditions) shall be provided to the end user, as well as the maximum time limit allowed at the peak power.

7.4.9 To reduce variation between matching networks, the frequency response of the matching network at the harmonic frequencies shall be repeatable between networks up to the 5th harmonic frequency (inclusive). Over the expected operating range of the network, the reflection coefficient measured at the output of the matching network, when the input of the network is terminated with both an open and a short circuit, shall vary less than 5% in magnitude and phase at the harmonic frequencies. Comparisons between networks shall be made at three operating points, which include a nominal operating point (e.g., at the midpoint of the tuning range), a point within 10% of the maximum of the tuning range, and a point within 10% of the minimum operating range. Unless specifically designed to, power dissipation in the network of greater than 10% (reflection coefficient of 0.95) at the harmonic frequencies shall be avoided.

7.4.10 The matching network shall be able to reach a stable tuning solution for any given available preset condition (tuning element position/frequency) in less than 3 seconds when the network is operated into a test load that is in the middle of the network's tuning range. Measurements of the time to tune shall be taken with the preset conditions (tuning elements positions/ frequency) varied in increments equal to 20% or less of full scale. The input power level during this bench test shall be in the range of 20% to 100% of the nominal power rating of the matching network.

7.4.11 There shall be only one tuning solution over the entire tuning range of the matching network. In other words, multiple tuning points for the same loading conditions shall be avoided.

7.5 *Generators*

7.5.1 To maintain consistent process conditions, the generators providing RF power to establish and sustain process plasmas and provide required wafer bias conditions must deliver power to load that can vary in time and value. In general, testing the generator output when driving a 50-ohm load is not sufficient to determine proper operation. In the semiconductor process environment, the generator may be exposed to power from the match/plasma system at the harmonics of the generator output frequency and needs to provide stable output power when operating into typical processing conditions.

7.5.2 The generator shall maintain consistent output impedance at each of the harmonic frequencies. The value of the reflection coefficient measured at the output of the generator shall be consistent at each frequency to within ± 5% in both magnitude and phase up to at least the 10^{th} harmonic frequency (i.e., up to $10 \times$ fundamental frequency) over the lifetime of the generator. This specification should not be interpreted as meaning that the reflection coefficient shall be the same value for all the harmonic frequencies, but the reflection coefficient shall maintain its particular value at each particular harmonic frequency to within 5% over time.

7.5.3 Generators shall deliver power to a nominal 50 ohm fixed load within ± 2.0% of true power from 10% to 100% of the maximum rated output power.

7.5.4 Generators shall provide consistent power delivery with a variation of less than ± 1.0% of the requested power level (over time and during steady state wafer processing conditions) when operated into a matched load.

7.5.5 Generators shall deliver power with a power variation of less than ± 1.5% when operated into a load impedance with a reflection coefficient of at least 0.33 at any phase angle (VSWR of at least 2.0) from 10% to 100% of the maximum rated output power. For example, a 25-ohm resistive load with various lengths of transmission line between the load and the generator can be used to produce the required phase shift variation. An example plot of forward power output vs reflection coefficient phase angle is shown in Figure 4.

7.5.6 The output power spectrum of a generator shall have harmonic content of –40 dB or less when operated into a load impedance with a reflection coefficient of at least 0.33 at any phase angle (VSWR of at least 2.0) from 10% to 100% of the maximum rated output power.

7.5.7 The generator output circuit shall be provided with high VSWR protection.

7.5.8 The transient response of the generator operating into a nominal 50-ohm load shall be provided as a function of the change in set point. Data for set point changes from zero power to full power and back to zero power as well as set point changes in increments of 33% of full scale shall be provided. For example, data for a 1 kW generator would include changes from 0 W to 1000 W, 1000 W to 0 W, 0 W to 333 W, 333 W to 667 W, 667 W to 1000 W, 1000 W to 667 W, 667 W to 333 W, 333 W to 0 W.

7.5.9 The ramp rate for power changes shall be provided in terms of W/second over the power range of the generator.

7.6 *RF Applicator/Interface*

7.6.1 The RF applicator/interface (the driven electrode or the coil/antenna) shall be designed, built, and maintained to provide a high degree of process repeatability. The RF impedance that the applicator/interface presents to the matching network must have minimal variation in order to maintain consistent process conditions. A minimum requirement for consistent operation is for the capacitance between the interface and ground and the inductance (for coil/antenna systems) to vary less that 1.5% through maintenance cycles, during operation and over the expected lifetime of the applicator/interface.

7.6.2 The frequency response of the RF applicator/interface (chuck assembly or coil/antenna) shall be measured to determine the resonance frequency of the assembly up to 10 times the fundamental frequency. If possible, the frequency response should be measured at the operating temperature of the assembly. The increment of the frequency step shall be no greater than 4% of the fundamental frequency (e.g., for 13.56 MHz, incremental frequency step = 0.54 MHz). The data shall be presented in tabular form in terms of the reflection coefficient magnitude and phase angle. An example of tabular data is given in Table 2 and a graphical example is shown in Figures 5 and 6.

7.6.3 For wafer chuck assemblies, the DC leakage current shall be measured to determine the deterioration of the dielectric coating over time. Increased leakage current will flow if the water that cools the chuck has a low resistivity or if the anodization or other dielectric coating has deteriorated.

7.6.4 The RF plasma environment within the tool is a charged environment that alters the charge level on the product being processed. The RF power delivery system, in conjunction with the chamber hardware, shall be compatible with the user-specified sensitivity level(s) per SEMI E78.

7.7 *Tuning and Matching Control Circuits*

7.7.1 Automated matching networks require sensing circuits to determine how to drive their tuning elements in order to reach a matched condition. The performance of these control circuits and the error signals they generate are critical to the proper function of the matching network. For those networks that are designed to match to a nominal 50 ohm input impedance, the matching network input impedance magnitude shall be 50 ± 3.3 ohms with a phase angle of ± 3.8° when the automatic matching algorithm has driven the matching network to achieve a matched condition.

7.7.2 The sensing circuits in a generator and an automated matching network shall ensure that the control signals are insensitive to power in the harmonics of the drive frequency. For example, additional filtration (low pass or band pass filters) can be added to the sensing circuit to achieve this goal.

7.8 *RF System Tests*

7.8.1 The output power spectrum of a generator shall have a harmonic frequency content of −40 dB or less when operated into a matched system (matching network plus test load) that contains a load impedance with a Q of at least 10. In other words, the magnitude of reactive part of the load must be at least ten times greater than the real part of the load (e.g., 2 – j20 ohms). The cable assembly used during testing shall nominally be the specific type to be used between the output of the generator and the input of the matching network.

7.8.2 To reduce variation between matching networks on those systems that have multiple RF frequencies (i.e., one frequency for the source and another frequency for the bias), the frequency response of the matching network at the other operating frequencies and at the harmonics of the other frequencies shall be repeatable between networks (of the same type/model) up to the 5th harmonic frequency (inclusive). Over the expected operating range of the network, the reflection coefficient measured at the output of the matching network, when the input of the network is terminated with both an open and a short circuit, shall vary less than five percent in magnitude and phase at the harmonic frequencies. Comparisons between networks shall be made at three operating points, which include a nominal operating point (e.g., at the midpoint of the tuning range), a point within 10% of the maximum of the tuning range, and a point within 10% of the minimum operating range. Unless specifically designed to, power dissipation in the network greater than 10% (reflection coefficient of 0.95) at the harmonic frequencies shall be avoided.

7.8.3 On those systems that have multiple RF frequencies (i.e., one frequency for the source and another frequency for the bias), the sensing circuits in an automated matching network and the rf generators shall ensure that the control signals are insensitive to power in the other system frequencies and the harmonics of all the system frequencies.

7.8.4 The supplier shall provide system verification hardware (i.e., test fixtures/interfaces) for system verification after assembly and delivery. Nominally, this hardware shall be in the form of a nominal coaxial connector interface (e.g., type "N" connector) for ease of measurement. Example fixtures would include those for interfacing with the RF applicator/interface (i.e., chuck assembly or coil input) and the output of the matching network. The supplier shall provide recommended test methods and/or procedures for system verification.

SEMI E114-0302[E]
TEST METHOD FOR RF CABLE ASSEMBLIES USED IN SEMICONDUCTOR PROCESSING EQUIPMENT RF POWER DELIVERY SYSTEMS

This test method was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on March 20, 2002. Initially available at www.semi.org June 2002; to be published July 2002.

[E] This document was editorially modified in May 2002. A change was made to Section 1.1.

1 Purpose

1.1 The purpose of this document is to define a test method used to determine the electrical length, power losses, and characteristic impedance variation of RF cable assemblies used in RF power delivery systems for semiconductor processing equipment.

2 Scope

2.1 This document specifies the testing procedures and test equipment required for the following:

- Determining the electrical length of RF cable assemblies at the nominal operating frequency in terms of degrees of phase shift.
- Determining the power dissipation (loss) in the RF cable assembly at the nominal operating frequency.
- Verifying the characteristic impedance of the RF cable assembly.

2.2 The primary focus for this specification is semiconductor processing equipment including, but not limited to, the following tool types:

- Dry etch equipment,
- Film deposition equipment (CVD and PVD).

2.3 This standard does not address any safety or performance issues related to RF emissions or electrical codes (e.g., Underwriter's Laboratory, Inc. (UL), the National Electrical Code (NEC®), Federal Communications Commission (FCC)). It is the responsibility of the users of this standard to conform to the appropriate local codes and regulations as applied to this type of equipment, some of which are covered by referenced documents.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard is meant to address RF Cable Assemblies used in RF systems that primarily operate in the frequency range of 0.2–100 MHz. It does not address higher frequency RF systems or microwave systems.

3.2 This standard assumes that the cable assemblies to be tested have a nominal characteristic impedance of 50 ohms. This standard can be used with cable assemblies with a different characteristic impedance if the appropriate standard termination loads are used.

3.3 International, national, and local codes, regulations and laws should be consulted to ensure that the equipment and procedures meet regulatory requirements in each location.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CVD* — Chemical Vapor Deposition

5.1.2 *PVD* — Physical Vapor Deposition

5.1.3 *VSWR* — Voltage Standing Wave Ratio

5.2 *Definitions of Terms*

5.2.1 *cable assembly* — the section of cable (transmission line), including the connectors, used to connect various parts of the RF power delivery system.

5.2.2 *device under test (DUT)* — the cable assembly intended to be tested.

5.2.3 *electrical length* — the length of the cable assembly at the operating frequency expressed in terms of degrees, where one wavelength at the nominal operating frequency is equal to 360 degrees.

5.2.4 *half wave resonant frequency* — the frequency of the cable assembly where the electrical length of the assembly is equal to one half (0.5) of a wavelength. For example, the half wave resonant frequency of a cable assembly with an electrical length of 2 meters would be 74.95 MHz ((c/2-meters)/2).

5.2.5 *harmonic frequency* — the harmonic frequencies are defined as integer multiples of the fundamental frequency. For example, the second harmonic of 13.56 MHz is 27.12 MHz.

5.2.6 *quarter wavelength* — the length equal to one quarter of the wavelength at a given frequency, where the wavelength is equal to the speed of light divided by the frequency.

5.2.7 *S-parameters* — the scattering matrix used to describe a network. The reflection coefficient is the S11 parameter and the transmission coefficient is the S21 parameter.

5.2.8 *speed of light (c)* — the speed of light in free-space is assumed to be 2.9979×10^8 meters/second.

5.2.9 *velocity of propagation (VP)* — the velocity of propagation, *VP*, is defined as the ratio of the speed of an electrical signal down a length of cable divided by the speed in free space. It is the reciprocal of the square root of the relative dielectric constant of the dielectric material between the inner and outer conductor of a coaxial assembly. For example, the *VP* for cable type RG-217 is nominally 0.66.

6 Test Apparatus

6.1 *RF Vector Network Analyzer* — The network analyzer is used to measure the electrical length and can also be used to determine the attenuation (power losses). The network analyzer requires vector capability so that both the magnitude and phase of the reflection coefficient and transmission coefficient can be measured as a function of frequency. The frequency range shall include the operating frequency and the quarter-wave resonant frequency of the RF cable assembly.

6.2 *Time Domain Reflectometer (TDR)* — The TDR is used to measure and verify the characteristic impedance as a function of distance along the transmission line.

6.3 *RF Adapters and Terminations* — Various adapters may be necessary to convert between different types of coaxial connectors (e.g., type N to type HN adapters, etc.). All adapters used shall have the same nominal characteristic impedance as the cable assembly to be tested (DUT), which is typically 50 ohms. For some measurements, additional coaxial cable assemblies may be necessary. These cable assemblies, which should not be confused with the DUT cable assembly, shall be of the same nominal characteristic impedance as the DUT cable assembly. Standard terminations will also be used, such as shorts, opens, and precision 50-ohm loads.

7 Safety Precautions

7.1 Work should be conducted in accordance with local safety requirements and test device manufacturer recommended safety procedures. The tests described in this document involve using low output power test instrumentation (typically less than 10 milli-Watt).

7.2 The area immediately surrounding the Test Setup should be keep free and clear of unnecessary equipment and materials. Some of the cable assemblies to be tested may be long and can be trip and lift/weight hazards.

8 Test Setup for Electrical Length Test

8.1 The Test Setup for the electrical length test consists of the Network Analyzer, the cable assembly to be tested (DUT), the appropriate adapter (if any) to connect the DUT to the network analyzer, and the appropriate adapter (if any) to connect a coaxial short circuit termination to the output of the DUT. A schematic of the Test Setup is shown in Figure 1. Care should be taken to ensure that the cable assemblies to be tested do not exceed the vendor specified bending radius, which is typically 5 times the outer diameter of the cable.

8.2 Prior to making any measurements, the Network Analyzer shall be turned on and allowed to warm up before the testing is to take place. This time allows for electronics to come to a stable operating condition for the measurements.

9 Test Procedure for Determining Electrical Length

9.1 Two test procedures can be used to determine the electrical length of a cable assembly. One method measures it directly at the operating frequency and the other measures the half-wave resonant frequency to determine the electrical length. Each method has advantages, depending on the length of the cable assembly. Prior to choosing a method, the equivalent free-space length of the DUT shall be estimated in units of distance (i.e., meters). This length can be estimated by dividing the physical length of the DUT by the velocity of propagation for the particular type of cable. For example, a DUT made from RG-217 cable with a physical length of 20 meters and a velocity of propagation of 0.66 would have an equivalent free-space length of 30.303 meters (20/0.66 = 30.303). A flow chart showing the steps for choosing which test method to use is shown in Figure 2.

9.2 The equivalent free-space length of the DUT shall be compared with the wavelength of the nominal operating frequency. Test Method 1 (Section 9.3) shall be used if the equivalent free-space length is less than a quarter wavelength of the nominal operating frequency. Test Method 2 shall be used if it is equal to or greater than a quarter wavelength of the nominal operating frequency. For example, if the estimated free-space length is 3 meters and the nominal operating frequency is 13.56 MHz (quarter wavelength = $0.25 \times c/13.56 \times 10^6$ = 5.527 meters), then Test Method 1 is recommended. If the estimated free-space length is 25 meters, then Test Method 2 is recommended.

9.3 *Test Method 1 for Determining Electrical Length*

9.3.1 This test method measures the phase angle of the reflection coefficient at the nominal operating frequency of the DUT when the DUT is terminated by a short circuit.

9.3.2 Calibrate the Network Analyzer at the desired operating frequency (e.g., 13.56 MHz). If adapters are to be used to connect the DUT to the Network Analyzer and/or to the short circuit termination, then the calibration shall be made with the adapters in place. The Network Analyzer shall be calibrated for measuring the reflection coefficient at test Port 1 (see Figure 1) using the calibration kit provided with the Network Analyzer. This measurement is equivalent to measuring the S11 S-parameter. The calibration shall be performed at fixed frequency (continuous-wave operation) using the lowest bandwidth possible (typically 10 Hz).

9.3.3 After calibration, the cable assembly to be tested (DUT) shall be attached to Port 1 on the Network Analyzer. The other end of the DUT shall be terminated with a short circuit. After all connections have been visually inspected to ensure proper contact and the Network Analyzer measurement has stabilized, the value of the reflection coefficient phase angle shall be recorded.

9.3.4 If the indicated phase angle of the reflection coefficient is positive, then the electrical length of the DUT is equal to one half of the value of the difference between 180 and the measured phase angle. For example, if the measure reflection coefficient phase angle is 120 degrees, then the electrical length is 30 degrees ((180-120)/2).

9.3.5 If the indicated phase angle of the reflection coefficient is negative, then the electrical length of the DUT is greater than a quarter wavelength. For this case, the electrical length is equal to one half of the absolute value of the measured value of the reflection coefficient phase angle plus 90. For example, if the measure reflection coefficient phase angle is -10 degrees, then the electrical length is 95 degrees (90 + 10/2).

9.4 *Test Method 2 for Determining Electrical Length*

9.4.1 This test method determines the electrical length of the cable assembly DUT by measuring the half wave resonant frequency when the DUT is terminated by a short circuit. For this measurement, the frequency of the network analyzer is swept. The frequency range of the sweep is determined from the estimated free-space length of the DUT.

9.4.2 Estimate the half wave resonant frequency of the DUT. This frequency is equal to one half of the ratio of the speed of light divided by the estimated free space length determined in Section 9.2. For example, if the estimated free space length of the DUT is 25 meters, then the estimated half wave resonant frequency is 5.996 MHz ($0.5 \times c/25$).

9.4.3 Calibrate the Network Analyzer. If adapters are to be used to connect the DUT to the Network Analyzer and/or to the short circuit termination, then the calibration shall be made with the adapters in place. The center frequency of the frequency sweep shall be at the estimated half wave resonant frequency calculated in Section 9.4.2, and the frequency span of the sweep shall be no greater than 10% of the estimated frequency. For example, if the estimated half wave resonant frequency is 6.0 MHz, then the frequency span shall be no greater than 0.6 MHz. The Network Analyzer shall be calibrated for measuring the reflection coefficient at test Port 1 (see Figure 1) using the calibration kit provided with the Network Analyzer. This measurement is equivalent to measuring the S11 S-parameter. The calibration shall be performed using the lowest bandwidth possible (typically 10 Hz).

9.4.4 After calibration, the cable assembly to be tested (DUT) shall be attached to Port 1 on the Network Analyzer. The other end of the DUT shall be terminated with a short circuit. After all connections have been visually inspected to ensure proper contact and the Network Analyzer measurement has stabilized, the value of the reflection coefficient phase angle can be examined.

9.4.5 The indicated frequency where the reflection coefficient phase angle is ± 180 degrees shall be recorded. The electrical length of the DUT at the desired nominal operating frequency (for example, 13.56 MHz) is equal to 180 degrees multiplied by the ratio of the nominal operating frequency divided by the measured frequency where the phase angle of the DUT is equal to ± 180 degrees. For example, if the measured frequency where the reflection coefficient is ± 180 degrees is 6.1 MHz, then the electrical length of the DUT at 13.56 MHz is 400.13 degrees (180 × 13.56 / 6.1).

10 Test Setup for Power Dissipation (Loss) Test

10.1 The Test Setup for the power dissipation (loss) test consists of the Network Analyzer, the cable assembly to be tested (DUT), an additional short test cable (for transmission calibration), the appropriate adapter (if any) to connect the DUT input to the network analyzer, and the appropriate adapter (if any) to connect the DUT output to the network analyzer. A schematic of the Test Setup is shown in Figure 3.

11 Test Procedure for Determining Power Dissipation

11.1 The test procedure for determining power dissipation in cable assemblies will also use a Network Analyzer. In this case, both Ports of the Network Analyzer will be used. The transmission coefficient will be measured (also called the S21 S-parameter).

11.2 Calibrate the Network Analyzer at the desired operating frequency (for example, 13.56 MHz). If adapters are to be used to connect the DUT to the Network Analyzer and/or to the short circuit termination, then the calibration shall be made with the adapters in place, along with the additional section of test cable needed for the calibration. The Network Analyzer shall be calibrated for measuring the transmission coefficient, S21 (see Figure 3). The calibration shall be performed at fixed frequency (continuous-wave operation) using the lowest bandwidth possible (typically 10 Hz).

11.3 Connect the cable assembly DUT between the two test Ports on the Network Analyzer (including the additional test cable used for calibration). After visually inspecting the connections to ensure proper contact and the Network Analyzer measurement has stabilized, the value of the transmission coefficient (S21) shall be recorded.

11.4 The recorded number shall be expressed in terms of dB (decibels) and percentage of power transferred in the DUT. The conversion between dB and percentage is expressed as:

$$\textit{Power Transfer}\ \% = 100 \times 10^{(\text{loss in dB}/10)}$$

For example, if the transmission coefficient is measured to be –0.4 dB, then the power transfer percentage would be 91.2%. In other words, 8.8% of the power is lost in the DUT.

12 Test Setup for Characteristic Impedance Variation Measurement

12.1 The Test Setup for the Characteristic Impedance variation measurement consists of a Time Domain Reflectometer (TDR), the cable assembly to be tested (DUT), the appropriate adapter (if any) to connect the DUT input to the TDR, and a standard 50-ohm load termination (see Figure 4).

12.2 Prior to making any measurements, the TDR shall be turned on and allowed to warm up. This time allows for electronics to come to a stable operating condition for the measurements.

13 Test Procedure for Determining Characteristic Impedance

13.1 Connect a standard 50-ohm load termination to the input of the TDR and measure the impedance. This measurement determines the normalization factor for the measured impedances. All reported measurements shall be scaled by this factor by multiplying subsequent measurements by the ratio of 50 divided by the impedance value measured with the 50-ohm standard load.

13.2 Prior to measuring the DUT, the nominal velocity of propagation of the cable shall be entered into the TDR. For example, the velocity of propagation is 0.66 for cable type RG-217.

13.3 Connect one end of the DUT to the TDR and terminate the other end of the DUT with a short circuit. Measure the characteristic impedance as a function of distance along the DUT by moving the measurement distance indicator of the TDR. Record the minimum and maximum impedance measured over the length of the cable assembly. The measurement shall be made throughout the length of the DUT, including the connectors, up to the short circuit termination.

13.4 At the short circuit termination, the measurement shall be made up to the point where the falling edge of the impedance is equal to 90 percent of the nominal impedance. For example, if the nominal impedance is 50 ohms, then the measurement can stop at the point where the measured value at the short circuit termination is equal to 45 ohms ($0.9 \times 50 = 45$). An example plot showing the measurement termination point is shown in Figure 5.

NOTE 1: The termination point can be verified by disconnecting the short circuit termination and observing that the impedance increases rapidly due to the open circuit.

14 Reporting Test Results

14.1 Report the type of Network Analyzer and the details of the Network Analyzer parameters used for the tests, including the bandwidth, the number of data points, the test frequency, and the frequency span (if any). An example data sheet is shown in Table 1.

14.2 Report the type of Time Domain Reflectometer used for the test.

14.3 Report the length of the cable assembly in terms of degrees at the nominal operating frequency.

14.4 Report the power dissipation in terms of dB (decibels) and percentage of power transfer.

14.5 Report the variation in characteristic impedance in terms of the minimum and maximum after the values have been scaled according to the reference 50-ohm load.

TEST METHOD FOR DETERMINING THE LOAD IMPEDANCE AND EFFICIENCY OF MATCHING NETWORKS USED IN SEMICONDUCTOR PROCESSING EQUIPMENT RF POWER DELIVERY SYSTEMS

This test method was technically approved by the Global Metrics Committee and is the direct responsibility of the North American Metrics Committee. Current edition approved by the North American Regional Standards Committee on March 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Previously published March 2002.

^E This document was editorially modified in May 2002 to correct an errata. A change was made in Section 1.1.

1 Purpose

1.1 The purpose of this document is to define a test method used to determine the load impedance and efficiency of matching networks used in RF power delivery systems for semiconductor processing equipment.

2 Scope

2.1 This document specifies the testing procedures and test equipment required for determining the load impedance and power efficiency of a matching network based on the positions of the tuning elements in the matching network.

2.2 The primary focus for this specification is semiconductor processing equipment including, but not limited to, the following tool types:

- Dry etch equipment,
- Film deposition equipment (CVD and PVD).

2.3 This standard does not address any safety or performance issues related to RF emissions or electrical codes (e.g., Underwriter's Laboratory, Inc. (UL), the National Electrical Code (NEC®), Federal Communications Commission (FCC)). It is the responsibility of the users of this standard to conform to the appropriate local codes and regulations as applied to this type of equipment, some of which are covered by referenced documents.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard addresses RF Matching Networks used in RF systems that primarily operate in the frequency range of 0.2–100 MHz. It does not address higher frequency RF systems or microwave systems.

3.2 This standard is meant for analyzing matching networks that are designed to operate at fixed frequency with a 50-ohm input impedance.

3.3 International, national, and local codes, regulations and laws should be consulted to ensure that the equipment and procedures meet regulatory requirements in each location.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E113 — Specification for Semiconductor Processing Equipment RF Power Delivery Systems

4.2 *IEEE Standards*[1]

IEEE-STD-383 — IEEE Standard for Type Test of Class 1E Electrical Cables, Field Splices, and Connections for Nuclear Power Generating Stations

4.3 *Military Standards*[2]

MIL-PRF-39012D — General Specification for Connectors, Coaxial, Radio Frequency

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CVD* — Chemical Vapor Deposition

5.1.2 *PVD* — Physical Vapor Deposition

5.1.3 *VSWR* — Voltage Standing Wave Ratio

5.2 *Definitions of Terms*

5.2.1 *complex conjugate load impedance* — the complex conjugate load impedance has the same real part of the load impedance and the negative of the reactive part of the load impedance. For example, the

1 Institute of Electrical and Electronics Engineers, IEEE Operations Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, New Jersey 08855-1331, USA. Telephone: 732.981.0060; Fax: 732.981.1721

2 Available through the Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120-5099, USA. Telephone: 215.697.3321

complex conjugate of a load impedance of 2.0 – j20 ohms would be 2.0 + j20 ohms.

5.2.2 *device under test (DUT)* — the matching network to be tested.

5.2.3 *harmonic frequency* — the harmonic frequencies are defined as integer multiples of the fundamental frequency. For example, the second harmonic of 13.56 MHz is 27.12 MHz.

5.2.4 *"L" type matching network* — this type of network consists of a tuning element that is connected to ground, which is often a variable capacitor, and another tuning element that is in series with the output connection. The series section of the "L" matching network typically consists of an inductor and a capacitor, one of which is variable.

5.2.5 *load and tune position* — for some matching networks, the tuning elements are referred to as the *Load Position* and the *Tune Position*. This terminology is common for "L" type matching networks, which have a tuning element that is connected to ground and another tuning element that is in series with the output connection. The *Load Position* corresponds to the tuning element that is grounded and is associated with matching to the real part of the load impedance. The *Tune Position* corresponds to the tuning element that is in series with the output and is associated with matching to the reactive part of the load impedance.

5.2.6 *load impedance* — the load impedance is the impedance to which a matching network is matched.

5.2.7 *load impedance simulator* — the Load Impedance Simulator is a device that presents a load impedance to which a matching network can match. Details of a typical Load Simulator can be found in the Related Information section of this test method.

5.2.8 *matched input impedance* — a matched load impedance is defined as typically having a magnitude of 50 ± 3.3 ohms at a phase angle of up to ± 3.8 degrees. In other words, the load is considered matched if the reflection coefficient is no greater than 0.032 at any phase angle.

5.2.9 *matching network* — the device used to transform the impedance of the load (chamber/chuck) to match the impedance of the generator/cable assembly, which is typically 50 ohms.

5.2.10 *power efficiency* — the ratio of the power exiting the matching network divided by the power entering the matching network.

5.2.11 *S-parameters* — the scattering matrix used to describe a network. The reflection coefficient is the S11 parameter and the transmission coefficient is the S21 parameter.

5.2.12 *tuning element position* — the position of the tuning element is defined as the output voltage or output encoder value that corresponds to the position of a variable tuning element in a Matching Network. For example, the voltage from a rotary potentiometer on the rotating shaft of a variable capacitor (the "Tuning Element") would be referred to as the capacitor's "Position". In this example, the position/voltage corresponds to a certain shaft location or position.

6 Test Apparatus

6.1 *RF Vector Network Analyzer* — The Network Analyzer is used to measure the load impedance and efficiency of the matching network. The Network Analyzer requires vector capability so that both the magnitude of phase of the reflection coefficient and transmission coefficient can be measured at the operating frequency. The Network Analyzer shall have an up-to-date calibration per the manufacturer.

6.2 *Coaxial Output Adapter* — An adapter to convert the output connection of the matching network to a standard coaxial interface is required for some of the tests.

6.3 *RF Adapters and Terminations* — Various adapters may be necessary to convert between different types of coaxial connectors (e.g., type N to type HN adapters, etc.). All adapters used shall have the same nominal characteristic impedance as the system, which is typically 50 ohms. For some measurements, additional coaxial cable assemblies are used. These cable assemblies shall also be of the same nominal characteristic impedance as the system. Standard terminations are also used, such as shorts, opens, and precision 50-ohm loads.

6.4 *RF Load Impedance Simulator* — A device that can be attached to the output of the DUT to act as a load for the DUT is required for some of the measurements. The load simulator shall have an impedance range to match a minimum of 80% of the tuning space of the matching network to be tested.

7 Safety Precautions

7.1 Work should be conducted in accordance with local safety requirements and test device manufacturer recommended safety procedures. The tests described in this document involve using low output power test instrumentation (typically less than 10 milli-Watt).

7.2 The area immediately surrounding the Test Setup shall be keep free and clear of unnecessary equipment and materials.

8 Test Setup for Determining Load Impedance and Efficiency

8.1 Two test methods are described for analyzing matching networks. The first method for determining the load impedance and efficiency measures the complex conjugate of the load impedance and then corrects for the matching network losses to determine the load impedance and efficiency. A schematic of the Test Setup is shown in Figure 1. The method uses a Network Analyzer to measure the reflection coefficient, which is related to the load impedance, and the transmission coefficient, which is related to the efficiency. The Test Setup for this approach consists of the Network Analyzer, the matching network to be tested (DUT), coaxial test cables, and the appropriate adapters (if any) to connect the DUT to the Network Analyzer.

8.2 The second method for determining the load impedance and efficiency uses a Load Impedance Simulator attached to the output of the matching network. A schematic of the Test Setup is shown in Figure 2. The Test Setup for this approach consists of the Network Analyzer, the matching network to be tested (DUT), the load simulator, coaxial test cables, the appropriate adapter (if any) to connect the DUT to the Network Analyzer, and the appropriate adapter to connect the load simulator to the DUT.

8.3 Prior to making any measurements, the Network Analyzer shall be turned on and allowed to warm up before the testing is to take place. This time will allow for electronics to come to a stable operating condition for the measurements.

9 Test Procedure for Determining Load Impedance and Efficiency

9.1 Two test procedures can be used to determine the load impedance and efficiency of the matching network. The first method is designed for "L" type matching networks, where the losses are dominated by the loss resistance of the inductor that is in series with the load impedance. For the case where there are finite losses in the shunt capacitor, the capacitor losses can be lumped in with the inductor losses without introducing significant error (usually less than 0.5% for typical values of < 0.1 ohms). Lumping the total losses into an overall series loss will also cause a slight shift in the reactive part of the impedance, but the magnitude of the shift is on the same order as the impedance measurement uncertainty and can be ignored.

9.2 The second method is designed for other matching network types and uses a load simulator to determine the load impedance and efficiency.

9.3 *Test Method 1 for Determining Matching Network Load Impedance and Efficiency*

9.3.1 This test method shall be used for "L" type matching networks of the type shown schematically in Figure 1, where the losses in the network are dominated by the loss resistance of the inductor, RLOSS. The efficiency for this type of matching network is given as

$$Eff = \frac{RLOAD}{RLOAD + RLOSS} \quad (1)$$

where *RLOAD* refers to the real part of the load impedance and *RLOSS* refers to the losses of the matching network.

9.3.2 For this type of network, the real part of the complex conjugate impedance, Re(*Zout**), contains the real part of the load impedance plus twice the loss resistance, *RLOSS*.

$$\mathrm{Re}(Zout^*) = RLOAD + 2RLOSS \quad (2)$$

9.3.3 The load impedance, therefore, is equal to the complex conjugate impedance less twice the loss resistance (along with the sign change of the reactive part of the conjugate impedance). For example, if the conjugate impedance is measured as 3 + j20 and RLOSS is determined to be 0.5 ohms, then the load impedance is 2 – j20 ohms.

9.3.4 The efficiency of the matching network and the loss resistance, *RLOSS*, can be determined by measuring both the transmission coefficient, S21, and the reflection coefficient, S11, in the Test Setup shown in Figure 1. Note that the reflection coefficient measurement, S11, is equivalent to measuring the complex conjugate impedance. If the matching network is considered as a test load with an impedance equal to the complex conjugate impedance, then the loss resistance is found by measuring the efficiency of the test load. This efficiency, *Effm*, can be expressed as

$$Effm = \frac{\mathrm{Re}(Zout^*) - RLOSS}{\mathrm{Re}(Zout^*)} \quad (3)$$

where Re(*Zout**) is the real part of the complex conjugate load impedance, *Zout**. The measured efficiency, *Effm*, can be determined from the S21 and S11 measurements (as shown later in this section). Thus, the measurements of Re(*Zout**) and *Effm* can be used to determine *RLOSS* as

$$RLOSS = \mathrm{Re}(Zout^*) \times (1 - Effm) \quad (4)$$

and the load impedance and power efficiency of the matching network can then be determined from

$$Effc = \frac{\mathrm{Re}(Zout^*) - 2RLOSS}{\mathrm{Re}(Zout^*) - RLOSS} \quad (5)$$

$$RLOAD = \mathrm{Re}(Zout^*) - 2\,RLOSS \qquad (6)$$

$$XLOAD = -\,\mathrm{Im}(Zout^*) \qquad (7)$$

where *Effc* is the calculated power efficiency based on the measurement of Re(*Zout**) and *Effm*, *RLOAD* is the real part of the load impedance, and *XLOAD* is the imaginary part of the load impedance.

9.3.5 Calibrate the Network Analyzer at the desired operating frequency (e.g., 13.56 MHz). The Network Analyzer shall be calibrated for measuring the reflection coefficient at test Port 1 and for measuring the transmission coefficient at test Port 2 (see Figure 1) using the calibration kit provided with the Network Analyzer. This measurement requires measuring the S11 and S21 S-parameters and requires a full 2-port calibration. The calibration shall be performed at fixed frequency (continuous-wave operation) using the lowest bandwidth possible (typically 10 Hz). The calibration for each port shall include the additional test cables and any additional adapters.

9.3.6 After calibration of the Network Analyzer, the cable connected to Port 1 of the Network Analyzer shall be connected to the output of the DUT. The cable connected to Port 2 of the Network Analyzer shall be connected to the input of the DUT.

9.3.7 The tuning elements shall be moved to their minimum positions before the measurement is initiated. After all connections are visually inspected for proper contact and the Network Analyzer has stabilized, the value of the complex conjugate impedance (*Zout**), the magnitude of the reflection coefficient (S11), and the magnitude of the transmission coefficient (S21) shall be recorded.

9.3.8 The efficiency when the DUT is viewed as a test load, *Effm*, is determined from both the reflection and transmission coefficients. The efficiency can be calculated by taking the ratio of the output power divided by the input power. The output power is simply $(S21)^2$ and the input power is $(1\text{-}(S11)^2)$.

$$Effm = \frac{(S21)^2}{1-(S11)^2}$$

Typically, the reflection and transmission coefficients are expressed in terms of dB (decibels). The conversion between dB and efficiency is expressed as

$$Effm = \frac{10^{(\mathrm{S21\,in\,dB}/10)}}{1-10^{(\mathrm{S11\,in\,dB}/10)}}$$

For example, if the transmission coefficient is measured to be –10.2 dB and the reflection coefficient is measured to be –0.61 dB, then *Effm* would be 0.7288. The efficiency based on this measurement can then be used to calculate *RLOSS*, *Effc*, *RLOAD*, and *XLOAD* by using the equations previously shown. All of these calculated numbers using equations 3–6 shall be recorded, as well as the positions of the tuning elements of the matching network.

9.3.9 For the next measurement, Tune Position shall remain fixed, and the Load Position shall be increased by an increment equal to no more than 10% of the full-scale range of the tuning element position. For example, if the range of the tuning element is 10 volts, then the tuning element should be moved in increments of no greater than 1 volt. A smaller increment shall be used for the case where the incremental change in Load Position results in an incremental impedance change of more than 20% of the total impedance variation measured by the full-scale variation of the Load Position. For example, if the real part of the load impedance varies 15 ohms over the 10 volt variation of the Load Position, then a smaller Load Position increment shall be used if the real load impedance varies by more than 3 ohms between increments (0.2 × 15 = 0.3). After the tuning elements have been moved to their new values, the previous measurement steps shall be repeated.

9.3.10 After the Load Position has been varied over its entire range, the Tune Position shall be increased by an increment equal to no more than 10% of the full-scale range of the tuning element position. The Load Position shall be moved back to its minimum position and the above steps shall be repeated until the entire tuning range of the matching network is measured.

9.3.11 The data shall be recorded and then presented in both graphical and tabular forms. An example of a typical impedance range graph is shown in Figure 3 for the real load impedance and in Figure 4 for the reactive load impedance. An example of a typical efficiency plot is shown in Figure 5. An example of data presented in tabular form is shown in Table I.

9.4 *Test Method 2 for Determining Matching Network Load Impedance and Efficiency*

9.4.1 This test method shall be used for matching networks that are not necessarily dominated by a series loss resistance as in an ideal "L" type network. This method uses a Load Simulator(s) attached to the DUT and assumes that the DUT has two tuning elements. The Load Simulator(s) shall have a tuning range that will cover no less than 80% of the tuning range of the matching network. Details of a typical Load Simulator can be found in the Related Information section of this Test Method. The test method outlined here assumes that the Load Simulator(s) contains variable tuning elements with position indicators to allow the load impedance to vary. An example of a load simulator would be a matching network used in reverse, where the output of the DUT would attach to the output of another matching network.

9.4.2 Calibrate the Network Analyzer at the desired operating frequency (e.g., 13.56 MHz). The Network Analyzer shall be calibrated for measuring the reflection coefficient at test Port 1 and for measuring the transmission coefficient at test Port 2 (see Figure 1) using the calibration kit provided with the Network Analyzer. This measurement requires measuring the S11 and S21 S-parameters and requires a full 2-port calibration. The calibration shall be performed at fixed frequency (continuous-wave operation) using the lowest bandwidth possible (typically 10 Hz). The calibration for each port shall include the additional test cables and any additional adapters.

9.4.3 After calibration of the Network Analyzer, the test cable connected to Port 1 of the Network Analyzer shall be connected to the input of the matching network to be tested (DUT). The Load Simulator shall be connected to the output of the DUT. The cable connected to Port 2 of the Network Analyzer shall be connected to the output of the Load Simulator.

9.4.4 The tuning elements shall be moved to their minimum positions (or the positions that can match to lowest tuning point of the Load Simulator(s)) before the measurement is initiated. The variable elements in the Load Simulator shall be adjusted until the input impedance of the matching network is matched (i.e., input impedance = 50 ohms). After all connections are visually inspected for proper contact and the Network Analyzer has stabilized, the value of the input impedance and the magnitude of the transmission coefficient (S21) shall be recorded. In addition, the positions of the tuning elements of the DUT and the Load Simulator shall be recorded.

9.4.5 The load impedance of the DUT corresponds to the input impedance of the Load Simulator. At this point in the process, the Load Simulator can be disconnected and its input impedance can be measured. Alternatively, the input impedance can be measured later by moving the Load Simulator tuning element values to the positions recorded in Section 9.4.4.

9.4.6 The efficiency of the Test Setup, which includes the DUT and the Load Simulator, is determined from the transmission coefficient. Typically, the transmission coefficient is expressed in terms of dB (decibels). The conversion between dB and percentage is expressed as:

$$Efficiency(\%) = 100 \times 10^{(\text{loss in dB}/10)}$$

For example, if the transmission coefficient is measured to be –3 dB, then the power transfer efficiency would be 50.1%. In other words, 49.9% of the power is lost in the Test Setup.

9.4.7 The efficiency of the DUT is determined by dividing the efficiency of the Test Setup by the efficiency of the Load Simulator. For example, if the efficiency of the Test Setup is 70% and the efficiency of the Load Simulator is 90%, then the efficiency of the DUT is 77.8% (0.7/0.9). The efficiency of the Load Simulator is typically determined separately (see Related Information Section at the end of this Test Method).

9.4.8 For the next measurement, one tuning element (element 1) shall remain fixed, and the other tuning element (element 2) shall be increased by an increment equal to no more than 10% of the full scale range of the tuning element position. For example, if the range of the tuning element is 10 volts, then the tuning element shall be moved in increments of no greater than 1 volt. A smaller increment shall be used for the case where the incremental change in tuning element position results in an incremental impedance change of more than 20% of the total impedance variation measured by the full-scale variation of the tuning element. For example, if the real part of the load impedance varies 15 ohms over the 10 volt variation of the tuning element, then a smaller tuning element increment shall be used if the real load impedance varies by more than 3 ohms between increments ($0.2 \times 15 = 0.3$). After the tuning elements have been moved to their new values, the previous measurement steps shall be repeated.

9.4.9 After the tuning element (element 2) has been varied over its entire range, the other tuning element (element 1) shall be increased by an increment equal to no more than 10% of its full-scale range. Tuning element 2 shall be moved back to its minimum position and the above steps shall be repeated until the entire tuning range of the matching network is measured.

9.4.10 The data shall be recorded and then presented in both graphical and tabular forms. An example of a typical impedance range graph is shown in Figure 3 for the real load impedance and in Figure 4 for the reactive load impedance. An example of a typical efficiency plot is shown in Figure 5. An example of data presented in tabular form is shown in Table 1.

10 Reporting Test Results

10.1 Report the type of Network Analyzer and the details of the Network Analyzer parameters used for the tests, including the bandwidth, the number of data points, and the test frequency. Also report which Test Method was used.

10.2 Report the matching network load impedance and efficiency as a function of tuning element positions. The data shall be presented in both graphical and tabular forms.

NOTE 1: For this example, the full-scale voltage for both the Tune and Load Positions is 10 V (i.e., Tune = 3.0 V corresponds to 30% of full scale). This example only shows data for a fixed Tune position of 3.0 volts. Data is also required at a Tune position of 0.0 V, 1.0 V, etc.

RELATED INFORMATION 1
LOAD SIMULATORS

NOTE: This related information is not an official part of SEMI E115 and was derived RF Diagnostic Task Force in North America. This related information was approved for publication by full letter ballot on November 27, 2001.

R1-1 Types of Load Simulators

R1-1.1 Load Simulators are used to present a known load impedance to a matching network. One example of a Load Simulator would be a matching network used in reverse. This section will describe a Load Simulator that can be used with typical matching networks that operate at 13.56 MHz with capacitive load impedances. These applications include those networks used in parallel-plate capacitively coupled plasmas and also those networks used in wafer bias applications, where the plasma is mostly sustained by another power source, such as an inductively coupled plasma or a microwave ECR (electron cyclotron resonance) plasma.

R1-1.2 The typical impedance that is seen by the matching network depends on the geometry of the applicator (its capacitance to ground), the type of plasma (gases), the operating pressure, and the density of the plasma. Typical impedances seen by the matching networks operating at 13.56 MHz in capacitive-loading applications have a real part in the range of 0.5 to 10 ohms and a reactive part in the range of –10 to –50 ohms. If a transmission line is used between the output of the matching network and the applicator, the impedance will get transformed. The amount of transformation will depend on the length of the transmission line, but in general the effect will be to decrease the real part of the impedance and to decrease the reactive part of the load (make it less negative). If the transmission line is long enough, the impedance seen by the matching network may even look inductive instead of capacitive because of the impedance transformation.

R1-2 Load Simulator Design

R1-2.1 A typical design for a Load Simulator operated at 13.56 MHz uses two capacitors and a 50-ohm load. A schematic is shown in Figure R1-1. The Load Simulator consists of a series capacitor, C2, and a shunt capacitor, C1. The C1 capacitor is in parallel with a 50-ohm load. The 50-ohm load can be an input port to a Network Analyzer or a high-power 50-ohm load that can be used with high-power testing.

R1-2.2 A picture of a Load Simulator of this type of design is shown in Figure R1-2. Two vacuum variable capacitors are used, with a copper strap connecting them. The capacitors shown in the figure are variable from 8 to 1000 pF. Additional fixed capacitors can be easily added to the circuit to expand the operating range. The strap connecting the capacitors adds roughly 100 nH of inductance to the series part of the circuit for this example.

R1-2.3 The impedance range for this type of Load Simulator is fairly broad. A plot of the real part of the input impedance as a function of the value of the C1 shunt capacitor is shown in Figure R1-3. The real part of the load varies from close to 50 ohms to around 1.2 ohms at a C1 capacitance of 1500 pF. A plot of the reactive part of the input impedance is shown in Figure R1-4. The reactance can be varied as a function of both the C1 and C2 capacitances. A reactance range of –5 to –100 ohms is easily achieved for a C2 capacitance variation of 1500 pF to 100 pF.

R1-3 Measurement of Load Simulator Impedance and Efficiency

R1-3.1 The impedance and the efficiency of the Load Simulator can be measured in much the same way as a matching network. The test setup is shown in Figure R-5. A special fixture may be required to adapt the input connection of the Load Simulator to a coaxial connector.

R1-3.2 Calibrate the Network Analyzer at the desired operating frequency (e.g., 13.56 MHz). The Network Analyzer shall be calibrated for measuring the reflection coefficient at test Port 1 and for measuring the transmission coefficient at test Port 2 (see Figure R-1) using the calibration kit provided with the Network Analyzer. This measurement requires measuring the S11 and S21 S-parameters and requires a full 2-port calibration. The calibration shall be performed at fixed frequency (continuous-wave operation) using the lowest bandwidth possible (typically 10 Hz). The calibration for each port shall include the additional test cables and any additional adapters.

R1-3.3 After calibration of the Network Analyzer, the cable connected to Port 1 of the Network Analyzer shall be connected to the input of the Load Simulator. The cable connected to Port 2 of the Network Analyzer shall be connected to the output of the Load Simulator.

R1-3.4 The tuning elements (variable capacitors) shall be moved to their minimum positions before the measurement is initiated. After all connections are visually inspected for proper contact and the Network Analyzer has stabilized, the value of the input impedance, the magnitude of the reflection coefficient (S11), and the magnitude of the transmission coefficient (S21) shall be recorded. In addition, the positions of the tuning elements of the Load Simulator shall be recorded.

R1-3.5 The efficiency of the Load Simulator is determined from both the reflection and transmission coefficients. The efficiency can be calculated by taking the ratio of the output power divided by the input power. The output power is simply $(S21)^2$ and the input power is $(1-(S11)^2)$.

$$Load\ Simulator\ Efficiency = \frac{(S21)^2}{1-(S11)^2}$$

Typically, the reflection and transmission coefficients are expressed in terms of dB (decibels). The conversion between dB and efficiency is expressed as

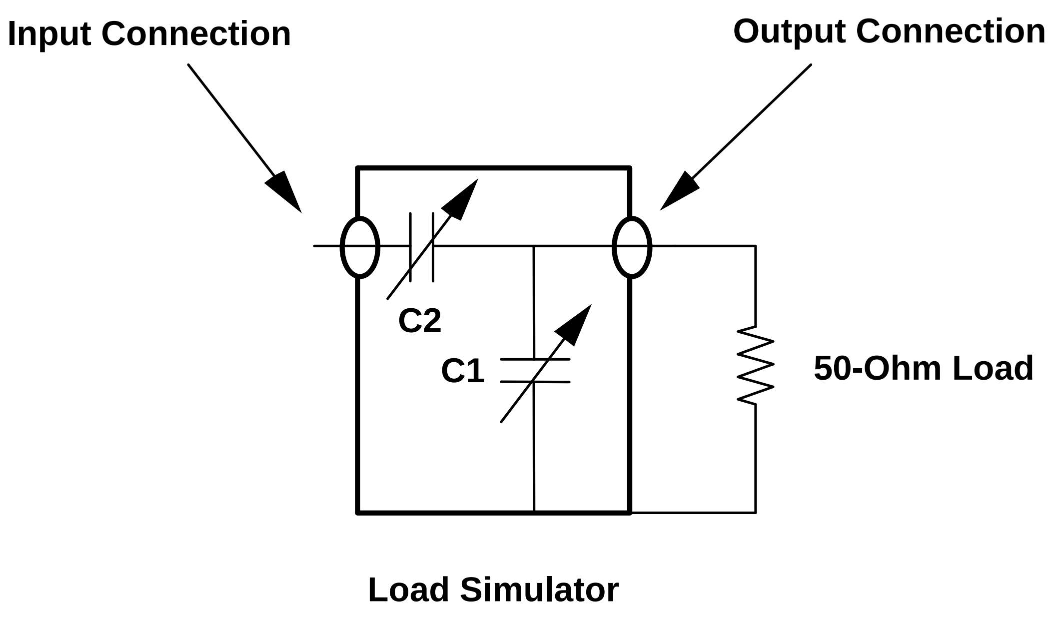
$$Load\ Simulator\ Efficiency = \frac{10^{(\mathrm{S21\,in\,dB}/10)}}{1-10^{(\mathrm{S11\,in\,dB}/10)}}$$

$$Power\ Transfer\ \% = 100 \times \frac{10^{(\mathrm{S21\,in\,dB}/10)}}{1-10^{(\mathrm{S11\,in\,dB}/10)}}$$

For example, if the transmission coefficient is measured to be –10 dB and the reflection coefficient is measured to be –0.5 dB, then the power transfer efficiency would be 91.95%. In other words, 8.05% of the power is lost in the Load Simulator.

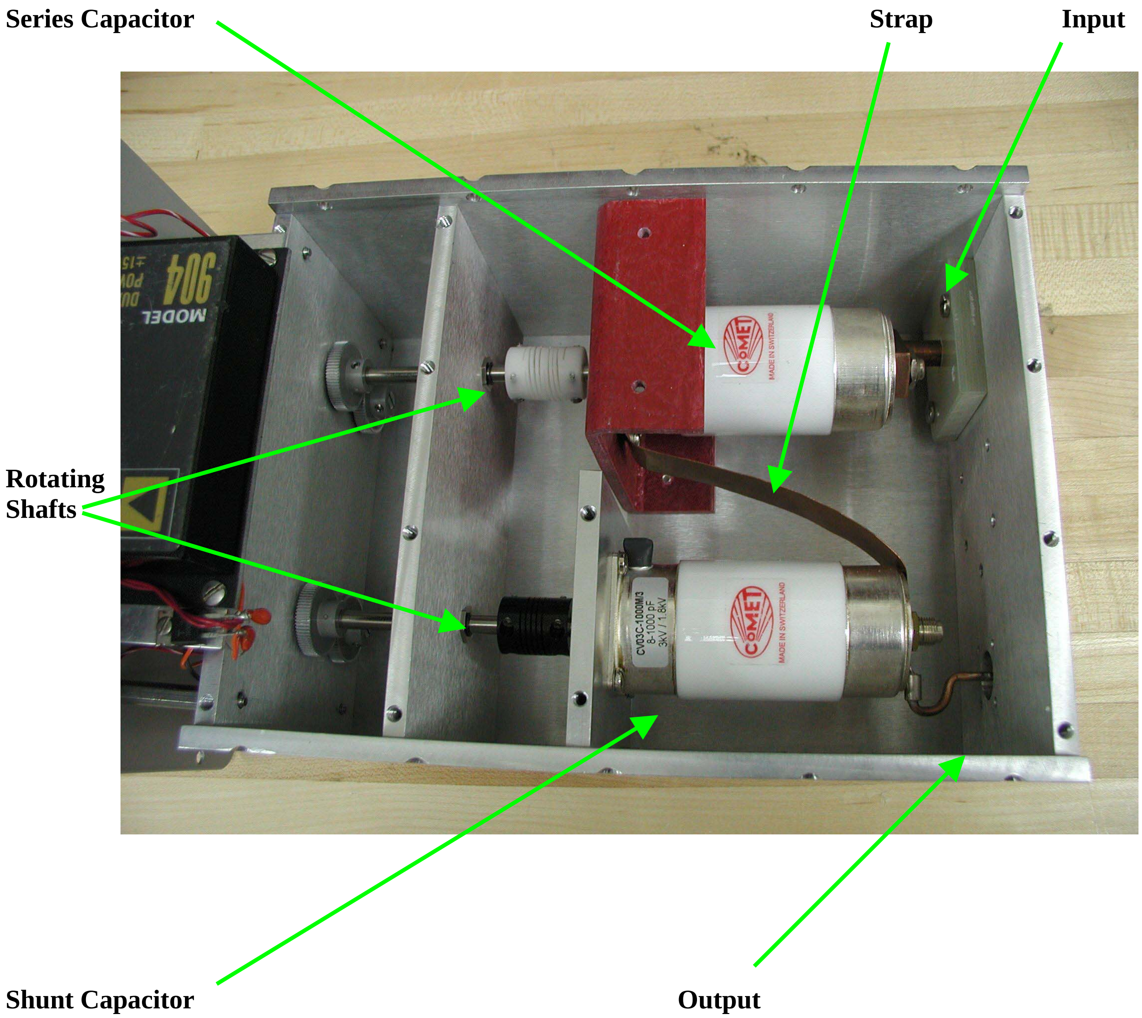
R1-3.6 For the next measurement, one tuning element shall remain fixed (C2), and the other tuning element (C1) shall be increased by an increment equal to no more than 10% of the full scale range of the tuning element position. After the tuning elements have been moved to their new values, steps 3.4 and 3.5 shall be repeated. This process shall be repeated until the tuning element (C1) has covered its entire range.

R1-3.7 After the tuning element (C1) has been varied over its entire range, the other tuning element (C2) shall be increased by an increment equal to no more than 10% of its full-scale range. The C1 tuning element shall then be moved back to its minimum position and the above steps (R1.3.4–R1.3.6) shall be repeated until the entire tuning range of the matching network is measured.



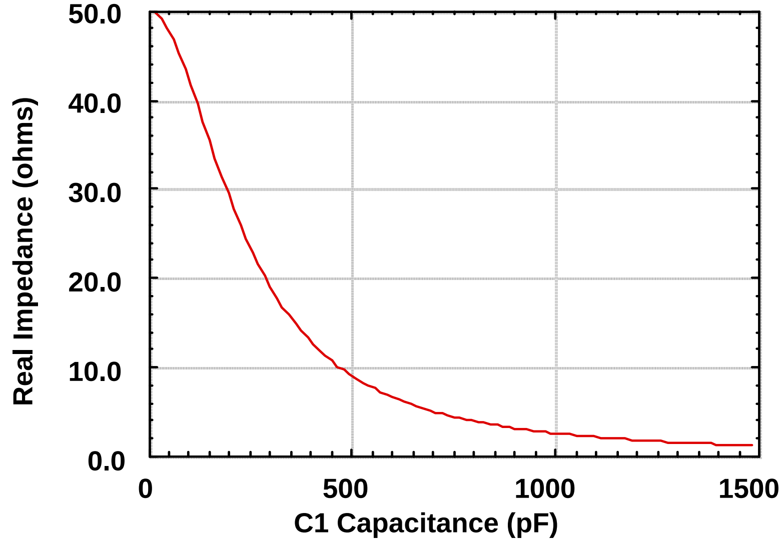
NOTE 1: The input connection is attached to a series variable capacitor, C2. The shunt variable capacitor, C1, is in parallel with a 50-ohm load.

Figure R1-1
Schematic of a Load Simulator



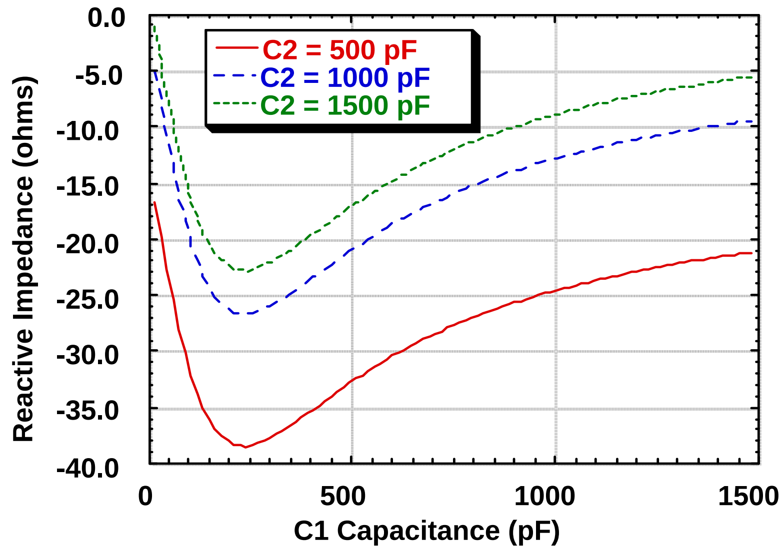
NOTE 1: Picture of a Load Simulator showing the variable capacitors. The capacitors are connected together by a strap that has an inductance of around 100 nH. The values of the capacitors are varied by rotating their shafts. The ends of the shafts are connected to a dial indicator to measure their positions.

Figure R1-2
Picture of a Load Simulator Showing the Variable Capacitors



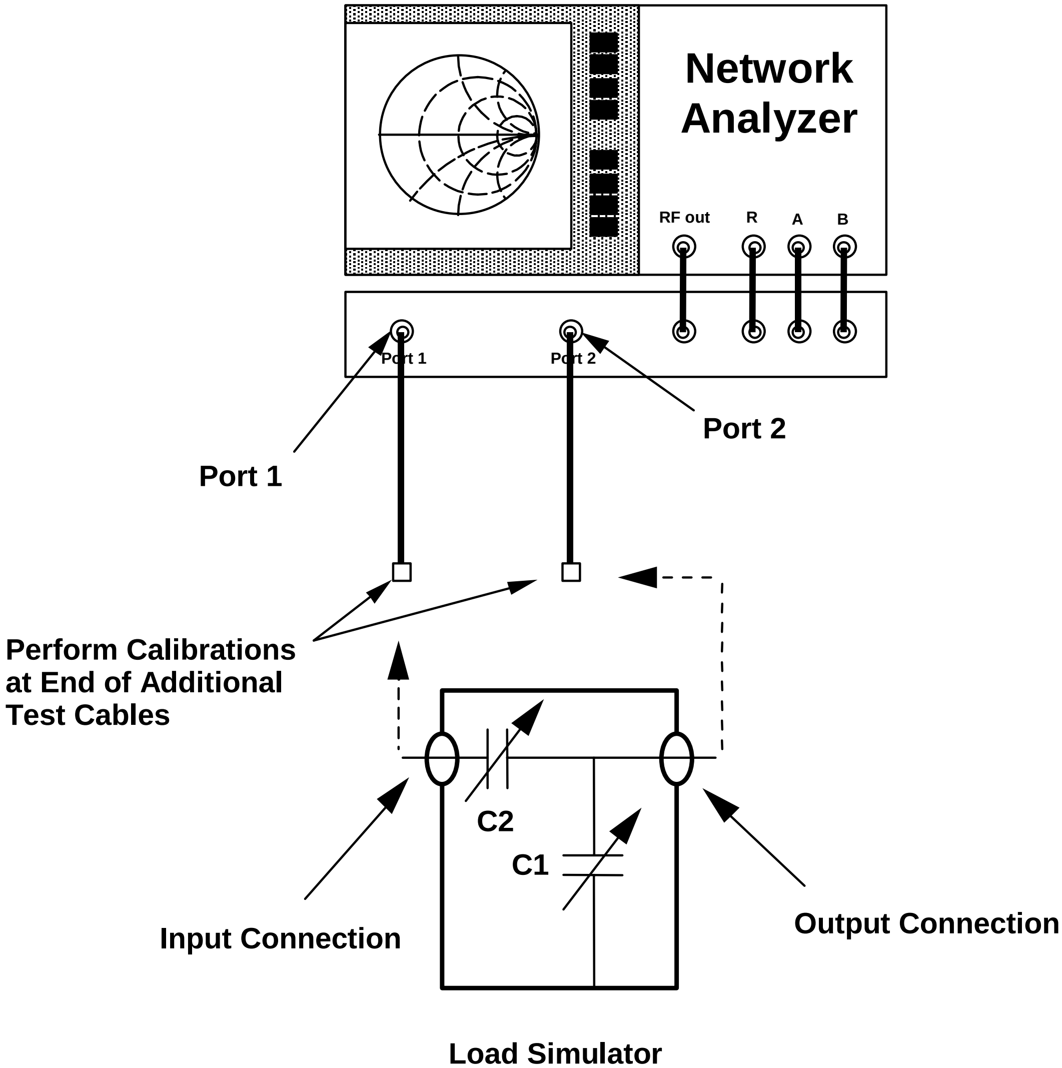
NOTE 1: The real impedance varies from 1.2 ohms to close to 50 ohms.

Figure R1-3
Example Plot of the Real Part of the Load Impedance as a Function of the C1 Shunt Capacitor in the Load Simulator



NOTE 1: The C2 capacitance is at the indicated fixed value for each set of data. For this example, the reactive impedance varies from around –40 ohms to –5 ohms. Decreasing C2 to 100 pF reduces the reactance to less than –100 ohms.

Figure R1-4
Example Plot of the Reactive Part of the Load Impedance as a Function of the C1 Shunt Capacitance in the Load Simulator



NOTE 1: Both the Port 1 and Port 2 outputs need to be used for the measurement. Additional test cables are needed for the transmission calibration between the two ports. The input connection of the Load Simulator attaches to Port 1 of the Network Analyzer. The output connection of Load Simulator attaches to Port 2 of the Network Analyzer.

SEMI INTERNATIONAL STANDARDS

EQUIPMENT AUTOMATION SOFTWARE

Semiconductor Equipment and Materials International

SEMI E4-0699
SEMI EQUIPMENT COMMUNICATIONS STANDARD 1 MESSAGE TRANSFER (SECS-I)

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on February 28, 1999. Initially available at www.semi.org May 1999; to be published June 1999. Originally published in 1980; previously published January 1999.

1 Introduction

1.1 *Revision History* — This is the first major revision since the original release of SECS-I in 1980. Very little of the original intent of SECS-I has been altered, although there are a few significant additions. The changes are summarized in Appendix 1. This specification has been developed in cooperation with the Japan Electronic Industry Development Association Committee 12 on Equipment Communications.

1.2 *Scope* — The SECS-I standard defines a communication interface suitable for the exchange of messages between semiconductor processing equipment and a host. Semiconductor processing equipment includes equipment intended for wafer manufacturing, wafer processing, process measuring, assembly and packaging. A host is a computer or network of computers which exchange information with the equipment to accomplish manufacturing. This standard includes the description of the physical connector, signal levels, data rate and logical protocols required to exchange messages between the host and equipment over a serial point-to-point data path. This standard does not define the data contained within a message. The meaning of messages must be determined through some message content standard such as SEMI Equipment Communications Standard E5 (SECS-II).

1.3 *Intent* — This standard provides a means for independent manufacturers to produce equipment and/or hosts which can be connected without requiring specific knowledge of each other.

1.3.1 *Layered Protocol* — The SECS-I protocol can be thought of as a layered protocol used for point-to-point communication. The levels within SECS-I are the physical link, block transfer protocol, and message protocol. (See Related Information R1-1.1.)

1.3.2 *Speed* — It is not the intent of this standard to meet the communication needs of all possible applications. For example, the speed of RS-232 may be insufficient to meet the needs of transferring mass amounts of data or programs in a short period of time, such as might be required by high speed functional test applications.

1.3.3 *Network Support* — The method by which blocks of data are routed to a piece of equipment or find their way back to the proper host application is not specified by SECS-I. In a network, the roles of host and equipment might be assumed by any party in the network. In this situation, one end of the communications link must assume the role of the equipment and the other the role of the host.

1.4 *Applicable Documents*

1.4.1 *Electronics Industries Association Standards*[1]

1.4.5 *SEMI Specifications*

SEMI E5 — SEMI Equipment Communications Standard 2 — Message Content (SECS-II)

SEMI E6 — SEMI Facilities Interface Specification Format

1.5 *Overview of SECS-I* — The SECS-I standard defines point-to-point communication of data utilizing a subset of the international standard known in the U.S.A. as EIA RS-232-C and in Japan as JIS C 6361 for the connector and voltage levels. The actual transmission consists of 8-bit bytes sent serially with one start and one stop bit. The communication is bidirectional and asynchronous, but flows in one direction at a time. The direction is established by special characters and a handshake, after which the data itself is sent. Data is sent in blocks of 254 bytes or less. Each block consists of a 10-byte header followed by data. A message is a complete unit of communication in one direction and consists of 1 to 32,767 blocks. Each block header contains information for identifying the block as part of a specific message. Messages are paired by a request and its reply which together are called a transaction.

1.6 *Structure of Document* — This document is divided into sections which correspond to major aspects of the standard. The sections outline requirements as well as implications of the requirements. The standard may be implemented in a variety of ways, depending upon the computer environment where it is placed. Implementation is not part of the standard. Information which may be useful for implementation is included in the form of Related Information.

2 Terminology

2.1 The following brief definitions refer to sections providing further information.

2.1.1 *ACK* — "Correct Reception" handshake code. (See Section 5.2.)

2.1.2 *application software* — the software performing the specific task of the equipment or the host.

2.1.3 *block* — header plus up to 244 bytes of data. (See Sections 1.5, 6.7.)

2.1.4 *block length* — the number of bytes sent in the block transfer protocol. (See Section 5.6.)

2.1.5 *block number* — a 15-bit field in the header for numbering blocks in a message. (See Sections 6.7.)

2.1.6 *character* — a byte sent on the SECS-I serial line. (See Section 4.1.)

2.1.7 *checksum* — a 16-bit number used to detect transmission errors. (See Section 5.7.)

2.1.8 *communication failure* — a failure in the communication link resulting from a failed send. (See Section 5.4.)

2.1.9 *device ID* — a 15-bit field in the header used to identify the equipment. (See Section 6.3.)

2.1.10 *E-bit* — a bit in the header identifying the last block of a message. (See Section 6.6.)

2.1.11 *ENQ* — "Request to Send" handshake code. (See Section 5.2.)

2.1.12 *EOT* — "Ready to Receive" handshake code. (See Section 5.2.)

2.1.13 *equipment* — the intelligent system which communicates with a host.

2.1.14 *expected block* — the block of a message which is expected by the message protocol. (See Section 7.4.4.)

2.1.15 *header* — a 10-byte data element used by the message and transaction protocols. (See Section 6.)

2.1.16 *host* — the intelligent system which communicates with the equipment.

2.1.17 *length byte* — the character used to establish the block length during transmission. (See Section 5.6.)

2.1.18 *line control* — a portion of the block transfer protocol. (See Section 5.8.2.)

2.1.19 *master* — the block transfer designation for the equipment. (See Section 5.5.)

2.1.20 *message* — a complete unit of communication. (See Section 7.)

2.1.21 *message ID* — a 15-bit field in the header used in the process of message identification. (See Sections 6.5, 7.3.1.)

2.1.22 *multi-block message* — a message sent in more than one block. (See Sections 6.7, 7.2.2.)

2.1.23 *NAK* — "lncorrect Reception" handshake code. (See Section 5.2.)

2.1.24 *open message* — a multi-block message for which not all of the blocks have been received. (See Section 7.4.4.)

2.1.25 *open transaction* — a transaction in progress. (See Section 7.3.)

2.1.26 *primary message* — a message with an odd numbered message ID. Also the first message of a transaction. (See Section 6.5.)

2.1.27 *primary/secondary attribute* — the least significant bit of the lower message ID which indicates whether a block belongs to a primary or secondary message.

2.1.28 *R-bit* — a bit in the header signifying the direction of the message. (See Section 6.2.)

2.1.29 *receiver* — the end of the SECS-I link receiving a message. (See Section 5.8.4.)

2.1.30 *reply* — the particular secondary message corresponding to a primary message. (See Section 7.3.)

2.1.31 *reply linking* — the process of forming a transaction out of a primary and a secondary message. (See Section 7.3.1.)

2.1.32 *retry count* — the number of unsuccessful attempts to send a block in the block transfer protocol. (See Section 5.4.)

2.1.33 *RTY* — the retry limit or the number of times the block transfer protocol will attempt to retry sending a block before declaring a failed send. (See Section 5.4.)

2.1.34 *secondary message* — a message with an even numbered message ID. Also the second message of a transaction. (See Section 6.5.2.)

2.1.35 *sender* — the end of the SECS-I link sending message. (See Section 5.8.3.)

2.1.36 *slave* — the block transfer designation for the host (See Section 5.5.)

2.1.37 *system bytes* — a 4-byte field in the header used for message identification. (See Section 6.8.)

2.1.38 *T1* — receive inter-character timeout in the block transfer protocol. (See Section 5.3.1.)

2.1.39 *T2* — protocol timeout in the block transfer protocol. (See Section 5.3.2.)

2.1.40 *T3* — reply timeout in the message protocol. (See Sections 5, 7.3.2)

2.1.41 *T4* — inter-block timeout in the message protocol. (See Section 7.4.3.)

2.1.42 *transaction* — a primary message and its associated secondary message, if any. (See Section 7.3.)

2.1.43 *W-bit* — a bit in the header signifying that a reply is expected. (See Section 6.4.)

3 Coupling

3.1 Coupling refers to the physical interface at the equipment. The host will provide compatible signals at this point. No restrictions are implied for any interface other than for equipment covered by this standard.

3.2 *Electrical Interface* — The connection will include a serial interface according to EIA Standard RS-232-C for interface Type E, full duplex communication, modified by the deletions, additions and exceptions described in this section.

3.2.1 *Connector* — Either the 9-pin or 25-pin connector described in the EIA RS232 may be used. In the case of the 25-pin connector a female connector will be mounted on the equipment and a male connector will be mounted on the cable from the host. In the case of the 9-pin connector the male connector will be mounted on the equipment and a female connector will be mounted on the cable. The connector on the equipment will have female 4-40 threaded jack screw locks.

NOTE: Suitable 25-pin connectors known as Type "D" are similar to Amphenol MIN RAC 17 series with jack screw locks. Suitable 9-pin connector is also Type "D" with jackscrew locks. It is the type commonly implemented on desktop and notebook PCs.

3.2.2 *Signal Pins* — Pins on the connector have functions as defined in Table 1. Pins 1, 2, 3, and 7 of the 25-pin connector or pins 3, 2, and 5 of the 9-pin connector are required for all equipment complying with SECS-I. When using a 25-pin connector, the two power supply pins, 18 and 25, are optional as indicated. Any other pins, if used, shall comply with the RS-232-C standard.

Table 1 Signal Connections

25-Pin	*9-Pin*	*RS-232-C Circuit*	*Circuit Description*
1	--	AA	Shield
2	3	BA	Data from Equipment
3	2	BB	Data to Equipment
7	5	AB	Signal Ground
18	--	--	+12 to +15 volts (opt for the 25-pin connector)
25	--	--	-12 to -15 volts (opt for the 25-pin connector)

3.2.3 *Logic Levels* — For the signal pins 2 and 3, the logic 1 level will be a voltage less than -3 volts and the logic 0 level will be a voltage greater than +3 volts. Voltages will never exceed ± 25 volts. These values correspond to those specified by the RS-232-C standard.

3.2.4 *Power Supplies* — When using a 25-pin connector, pins 18 and 25 are optional power supplies for driving external isolation circuits. When provided, both shall be present and must be able to supply at least 50 mA. (See Related Information R1-2 for example use.)

3.3 *Data Rate* — The supported data rates on signal pins shall be 9600, 4800, 2400, 1200, and 300 baud. The same data rate shall apply for data sent to and from the equipment. The data rate shall be controlled to better than 0.5%. (See RS-269-B and RS-334.) Optional rates of 19,200 and 150 baud may be supplied if desired.

3.4 *Physical Medium* — The connection with the host may involve any medium that provides the required RS-232-C quality, signal levels and data rate at the equipment connector. The quality of signal should be such that the effective bit error rate is less than 1×10^{-6}. This rate can be achieved easily with hardwired systems. The distance limits specified in RS-232-C apply only to systems using the wiring technique described in RS-232-C. Since any method may be used in SECS-I as long as RS-232-C signals are supplied at the connector, the distance and isolation is dependent upon the design of the physical medium which is external to the SECS-I standard. (See Related Information R1-2.)

4 Character Structure

4.1 *Characters* — Data will be transmitted or received in a serial bit stream of 10 bits per character at one of the specified data rates. The standard character has one start bit (0), 8 data bits and one stop bit (1). All bit transmissions are of the same duration. The 8 data bits are numbered from 1 to 8 in the order sent (see Figure 1). The timing between characters is asynchronous with respect to the data rate. The 8 data bits may be any arbitrary code. The eight data bits will hereafter be referred to as a byte.

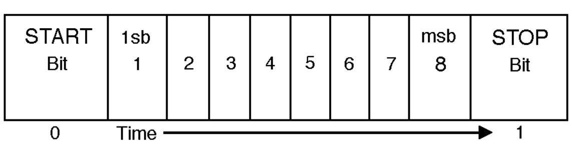

Figure 1

Character Structure

4.2 *Weighted Codes* — For bytes having weighted codes, bit one is the least significant and bit eight is the most significant. The most common weighted code is binary.

4.3 *Non-Weighted Codes* — For codes without numeric value such as ASCII, the bit numbers will be used as the entry into a standard code table for interpretation of the code. SECS-I performs no parity or other verification of the contents of individual bytes.

5 Block Transfer Protocol

5.1 The procedure used by the serial line to establish the direction of communication and provide the environment for passing message blocks is called the block transfer protocol. Most of the protocol is accomplished with a handshake of single bytes. When both ends of the line try to send at the same time, a condition known as line contention exists. The protocol resolves contention by forcing one end of the line, designated as the slave (always the host), to postpone its transmission and enter the receive mode. Retransmission of blocks is used to correct communication errors. The block transfer protocol is shown in flow chart form in Figure 2, and described below. Additional information is also contained in Related Information R1-3 and R1-4.

5.2 *Handshake Bytes* — The four standard handshake codes used in the block transfer protocol are shown in Table 2. The three letter names, ENQ, EOT, ACK, and NAK correspond to the ASCII code having the same pattern.

Table 2 Handshake Codes

Name	*Codeb8 b7.........b1*	*Function*
ENQ	00000101	Request to Send
EOT	00000100	Ready to Receive
ACK	00000110	Correct Reception
NAK	00010101	Incorrect Reception

5.3 *Timeout Parameters* — Timeouts are used to detect communications failures. A timeout occurs when the measured time between two events exceeds a predetermined limit. Generally, the length of time that must pass before it can be assumed that an error has occurred depends upon the particular systems involved. The time required in one situation might be excessively long in another. Thus, the timeout values must be "tuned" to meet the application. In the block transfer protocol, there are two situations requiring timeout values. The two timeout values are called parameters T1 and T2.

5.3.1 *Inter-Character Timeout, T1* — The inter-character timeout, T1, limits the time between receipt of characters within a block after the length byte has been received and until the receipt of the second checksum byte.

5.3.2 *Protocol Timeout, T2* — The protocol timeout, T2, limits the time between sending ENQ and receiving EOT, sending EOT and receiving the length byte, and sending the second checksum byte and receiving any character.

5.4 *Retry Limit, RTY* — The retry limit, RTY, is the maximum number of times the Block Transfer Protocol will attempt to retry sending a block before declaring a failed send. (See Section 5.8.2.)

5.5 *Master/Slave* — The master/slave parameter is used in the resolution of contention (see Section 5.8.2). The host is designated as the slave. The equipment is desig-nated as the master. This convention is based upon the assumption that the equipment is less able to store messages than the host.

5.6 *Block Lengths* — The unsigned integer value of the first byte sent after receipt of EOT is the length of the block being sent. The length includes all the bytes sent after the length byte, excluding the 2 bytes of the checksum. The maximum block length allowed by SECS-I is 254 bytes, and the minimum is 10 bytes.

5.7 *Checksum* — The checksum is calculated as the numeric sum of the unsigned binary values of all the bytes after the length byte and before the checksum in a single block. The checksum is sent as 16 bits in two bytes following the last byte of the block data. The high order eight bits of the checksum will be sent first, followed by the low order eight bits. The checksum is used by the receiver to check for transmission errors. The receiver performs the same checksum calculation on the received header and data.

5.8 *Algorithm* — The operation of the block transfer protocol is best understood by following the logic flow in Figure 2. This flow chart depicts the operation of the five states of the protocol - Receive, Idle, Send Line Control, and Completion. The flow chart shown in Figure 2 is not meant to imply that a particular implementation is required under this standard. However, any SECS-I block transfer protocol implementation must include all the logic described in Figure 2. The same algorithm is executed on each end of the SECS-I communications link.

5.8.1 *Idle State* — Both ends of the communications link are assumed to start in the Idle state. There are two primary activities of the protocol signified by the two exits from the Idle state. These are:

A. SEND — a message block is to be sent.

B. RECEIVE — the other end of the communications link has a message block to send

5.8.2 *Line Control* — The line control section establishes the transmission direction, resolves contention, and handles retries. When an ENQ is received in the Idle state, the Line Control responds with an EOT if the Block Transfer Protocol is ready to receive. The Block Transfer Protocol then goes to the Receive state. If a message block is to be sent, then an ENQ is sent. If an EOT is received in response to the ENQ within the time limit T2, the Block Transfer Protocol goes to the Send state.

5.8.2.1 If the slave receives an ENQ in response to the ENQ, contention has occurred. The slave postpones the send of its block until it receives a block from the master. The slave prepares to receive the incoming block and sends an EOT. When the block transfer protocol returns to the Idle state, the postponed block Send may be sent as if it were a new send request. After a master sends an ENQ, it can ignore all characters except an EOT. After a slave sends at ENQ, it can ignore all characters except an ENQ or EOT.

5.8.2.2 When the time between sending ENQ and receiving EOT exceeds T2, or the time between sending the second checksum byte and receiving any character exceeds T2, or a non-ACK character is received within time T2 after sending the second checksum byte, the Line Control will increment the retry count ("tries" in the flowchart). If the retry count does not exceed the value of the RTY parameter, then the Block Transfer Protocol will retry sending the block beginning with ENQ. If the retry count does exceed the value of the RTY parameter, then a failed send has occurred.

5.8.3 *Send* — Once a send state is established, the first byte sent is the length, N, of the data in the block. After N more bytes have been sent, the two bytes of the checksum are sent. The sender computes the checksum based on the data in the block and the block header, but not the length byte. When the sender receives the ACK before time T2, the block is deemed properly sent. However, if the sender receives a non-ACK character before time T2, or no character within time T2, it returns to the line control state for a possible retry. In the Send state, characters received prior to sending the last checksum byte can be ignored.

5.8.4 *Receive* — Once a receive state is established, the first byte received is the length byte, N. The receiver counts and saves the following N + 2 bytes. The last two bytes are the checksum. The receiver compares the two checksum bytes against its own computation of the checksum. In a good block, the computed and received checksum are the same.

5.8.5 *Receive Completion* — After a block is correctly received, an ACK character is sent and the message protocol is notified that a block has been received. If T2 is exceeded while waiting for the length character, or Tl is exceeded between characters being received, then an NAK is sent. If the length byte is invalid or if the received checksum does not agree with the computed checksum, the receiver continues to listen for characters to ensure that the sender is finished sending. This is detected when the inter-character time exceeds T1, at which point the receive is aborted and a NAK is sent. In any case when an NAK is sent, the receiver may discard any data it has received for the block. The receiver returns immediately to the Idle state after sending an ACK or NAK.

5.8.6 *Send Completion* — After the second checksum byte is sent, if an ACK is received within time T2, the message protocol is notified that the send was successful. If a failed send occurs, the message protocol is informed of the failure. Application-level software must take the possibility of a send failure into account.

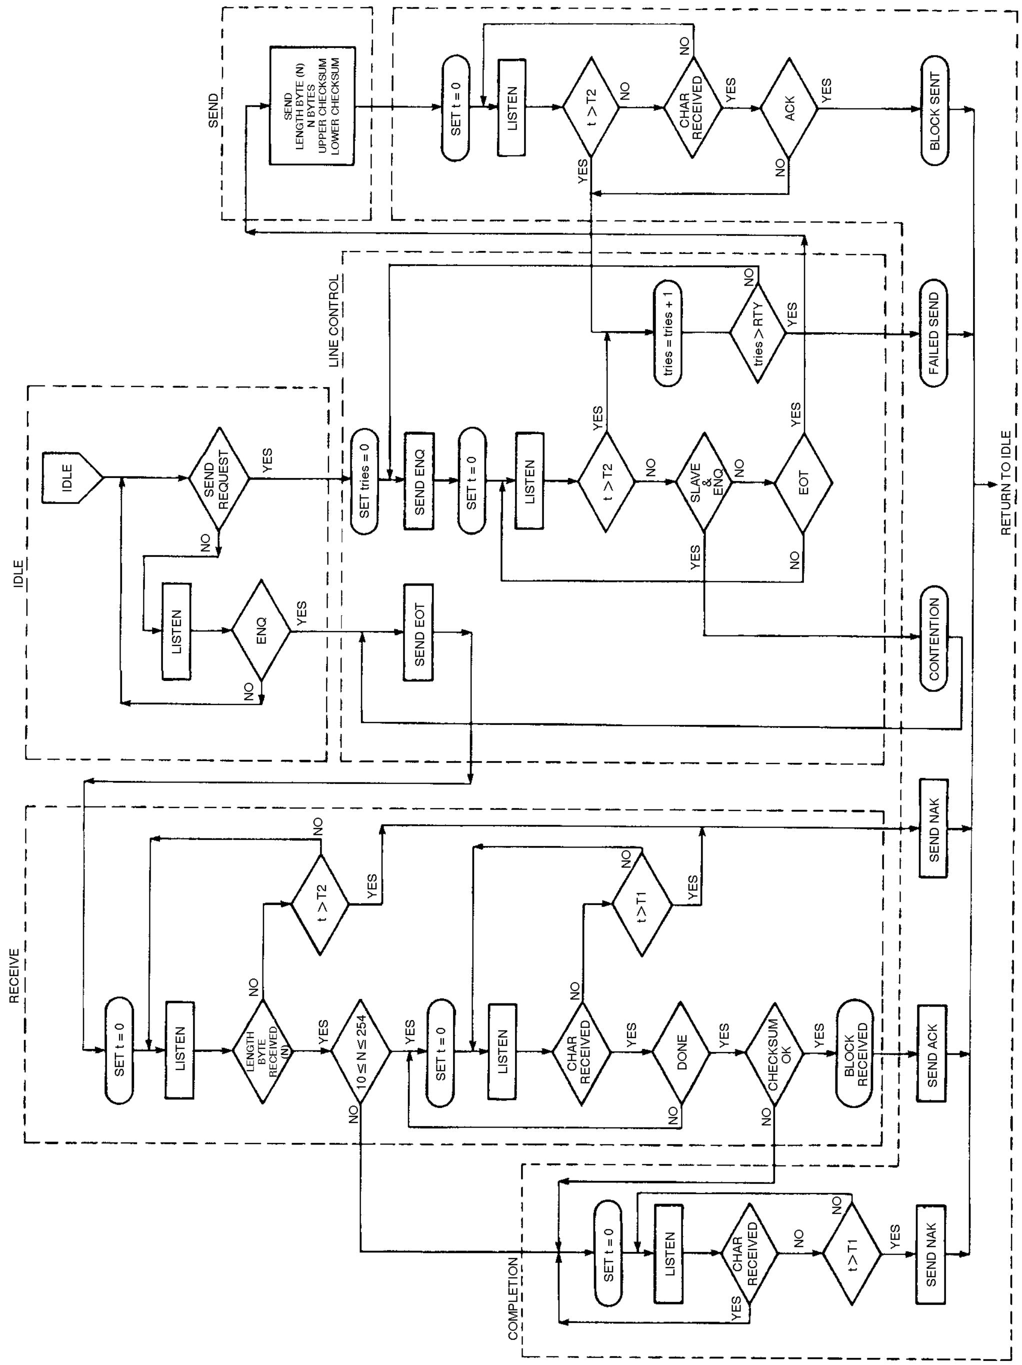

Figure 2

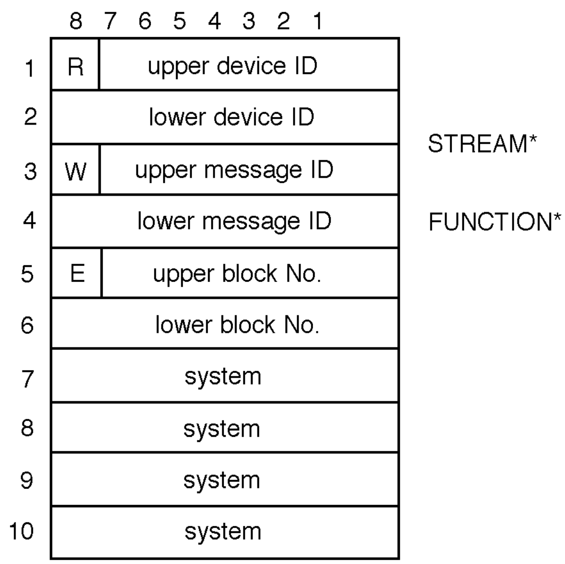
Block Transfer Protocol

6 Header Structure

6.1 The operation of all communications functions above the block transfer protocol is linked to information contained in a 10-byte data element called the header. The header is always the first 10 bytes of every block sent by the block transfer protocol. The information in the header is also used by the message protocol (see Section 7). The fixed format of the header is described in this section. The general header structure is shown in Figure 3.

NOTE: The header also contains information required by SECS-II.

6.2 *Reverse Bit (R-Bit)* — The reverse bit (R-bit) signifies the direction of a message. The R-bit is set to 0 for messages to the equipment and set to 1 for messages to the host. The R-bit is included in the header so that the direction of the message is contained in every block.



*Defined in SECS-II and included here for reference only.
(UPPER MEANS MOST SIGNIFICANT, LOWER MEANS LEAST SIGNIFICANT)

Figure 3

Block Header Structure

Table 3 Influence of the R-BIT

R-Bit	*Device ID*	*Message Direction*
0	Destination	Host to Equipment
1	Source	Equipment to Host

6.3 *Device ID* — The device ID defines the source or destination of the message depending upon the value of the R-bit as shown in Table 3. Device identification is a property of the equipment and must be settable according to Section 8. The host can view the device ID as a logical identifier connected with a physical device within the equipment. The host has no device ID.

6.4 *Wait Bit (W-Bit)* — The wait bit (W-bit) is used to indicate that the sender of a primary message expects a reply. A value of one in the W-bit means that a reply is expected. A value of zero in the W-bit means that no reply is expected. The W-bit must be set to zero in all secondary messages. For multi-block messages, the sender must ensure that the W-bit is the same in every block of the message.

6.5 *Message ID* — The message ID identifies the format and content of the message being sent (the particular message is one of many possible for the device in question). The exact message content is equipment-dependent. The upper message ID is the most significant portion of the ID.

6.5.1 *Primary Message* — A primary message is defined as any odd numbered message. An odd numbered message will have bit 1 of the lower message ID set to 1.

6.5.2 *Secondary Message* — A secondary message is defined as any even numbered message. An even-numbered message will have bit 1 of the lower message ID set to 0.

NOTE: In SECS-II, byte three of the header (excluding the W-bit) is known as the stream, and byte four of the header is known as the function. See SECS-II for more information.

6.6 *End Bit (E-Bit)* — The end bit (E-bit) is used to determine if a block is the last block of a message. A value of one in the E-bit means that the block is the last block. A value of zero means that more blocks are to follow.

6.7 *Block Number* — A message sent as more than one block is called a multi-block message. The first block is given a block number of one, and the block number is incremented by one for each subsequent block until the entire message is sent. The blocks of a multi-block message are sent in order. In a single-block message, the block number must have a value of zero or one. The maximum block number is 32,767. The upper block number is the most significant portion of the block number. (See also 7.2.)

6.8 *System Bytes* — The system bytes in the header of each message for a given device ID must satisfy the following requirements. (For a further discussion of system bytes, see Related Information R1-5.)

6.8.1 *Distinction* — The system bytes of a primary message must be distinct from those of all currently open transactions initiated from the same end of the communications link. They must also be distinct from those of the most recently completed transaction. (See Section 7.3.) They must also be distinct from any system bytes of blocks that were not successfully sent since the last successful block send.

6.8.2 *Reply Message* — The system bytes of the reply message are required to be the same as the system bytes of the corresponding primary message.

6.8.3 *Multi-Block Messages* — The system bytes of all blocks of a multi-block message must be the same.

7 Message Protocol

7.1 A message is a complete unit of communication in one direction. The message protocol uses the services of the block transfer protocol to send and receive messages. The message consists of the message data together with the following information from the header — R-bit, device ID, W-bit, message ID, and system bytes.

7.2 *Message Send* — When a message is ready to be sent, the message send protocol performs the functions described below. A block send failure terminates the message protocol action on that message.

7.2.1 *Message Length* — The maximum data length in a single block of a message is 244 bytes. The maximum number of blocks that can be sent in a multi-block message is 32,767, and so the maximum data length allowed in one message is 244 × 32,767 bytes.

7.2.2 *Message Blocking* — Message blocking is the division of the message data into blocks to be sent to the Block Transfer Protocol. For best performance, it is recommended, but not required, that the sender fill all blocks of a multi-block message, except possibly the last block, with the maximum 254 bytes. The receiver of a multi-block message should be able to accept any block size from 11 to 254 bytes, and should not require consecutive blocks necessarily to be the same size.

7.2.2.1 Certain older implementations may impose application-specific requirements on block sizes for certain incoming messages. Beginning with the 1988 revision of the standard, new applications may not impose application-specific requirements on incoming block sizes. Applications implemented before 1988 may impose such requirements.

NOTE: In SECS-II, certain messages are defined as single-block messages and must be sent as a single block in SECS-I.

7.2.3 *Header* — The message protocol must establish the header in each block of the message according to the requirements of Section 6.

7.2.4 *Interleaving Messages* — This standard allows, but does not require, the support of more than one concurrent open transaction. This standard allows, but does not require, the support of interleaving the blocks of different multi-block messages. (See documentation requirements in 9.)

7.3 *Transactions* — A transaction is a primary message and an optional corresponding secondary message is called the reply. A transaction is opened when a primary message is ready to be sent. A transaction is closed when the last block of a primary message requesting no reply has been sent, or when the last block of the reply has been received.

7.3.1 *Reply Linking* — When a reply is expected for a primary message, the message protocol starts the reply timer for the transaction after the last block of the message is successfully sent. When a primary message is sent for which a reply is requested, an expected block is established for the message receive algorithm. (See Section 7.4.) The expected block will have the complement of the R-bit, will have the same device ID, will be the first block of a secondary message, and will have the same system bytes as those of the given primary message.

NOTE: In SECS-II, the reply will have the same upper message ID (stream), and the lower message ID (function) will either be one greater than that of the corresponding primary message, or it will be zero.

7.3.2 *Reply Timeout, T3* — The reply timeout, T3, is a limit on the length of time that the message protocol is willing to wait after the last block of a primary message has been sent and before the arrival of the first block of the reply. If the first block of the reply does not arrive within the T3 limit, the expected block is removed from the list of expected blocks, and the transaction is aborted. A timer, called the reply timer, is used to measure the time between the last block of the primary message and the first block of its reply. Each open transaction for which a reply is expected requires a separate reply timer.

7.4 *Message Receive* — Each block successfully received by the block transfer protocol is passed to the message protocol. It is the task of the message protocol to identify the blocks and assemble them into the proper message.

7.4.1 *Routing Error* — When a piece of equipment receives a block of data which has a device ID in the block header which does not match its own device ID and it has no other knowledge of this device ID, it can assume that the block was sent in error.

7.4.2 *Duplicate Block Detection* — A duplicate block is a block which is exactly the same as the previous block received by the Block Transfer Protocol. This may occur when the receiver has sent an ACK but, for some reason, the ACK did not arrive in time at the sender, causing a send retry. A duplicate block is detected by the SECS-I message protocol by comparing the full 10-byte header of a block currently received by the block transfer protocol with the header of the last block accepted as non-duplicate by the message protocol. If the headers are identical, the new block is a duplicate and should be discarded. If the headers are different, the new block is a non-duplicate. The header of the non-duplicate block saved for comparison with the next block passed on by the block transfer protocol, and the block containing the header is further processed by the message receive algorithm.

NOTE: Some implementations which follow the 1980 version of SECS-I may not provide the unique headers required for duplicate block detection. An option for disabling the duplicate block detection is required to be compatible with these systems.

7.4.3 *Inter-Block Timeout T4* — The time interval between the successful receipt of a block in a multiblock message, and the successful receipt of the subsequent block of the same message, is limited to time T4. If this time is exceeded, the message is cancelled and the transaction is aborted. A time called the inter-block timer is used to measure the time between block arrivals in the message protocol. There must be one inter-block timer for each open multi-block message currently being received by the protocol. As each successive block of a message is received, the corresponding inter-block timer is reset.

7.4.4 *Algorithm* — When a block arrives at the message protocol, a combination of all the bytes in the header is used to determine what to do with the block. The operation of the message receive algorithm is to be understood by following the logic flow in Figure 4. The flow chart shown in Figure 4 and the description of the algorithm below are not meant to imply that particular implementation is required under this standard. However, any SECS-I message protocol implementation must include all the logic shown in Figure 4 on page 11.

7.4.4.1 The description of the message protocol uses the concepts of an expected block. When a (properly routed and non-duplicate) block is received by the message protocol, the first determination is whether the block is one of the expected blocks or not. In order to determine if a block is one of the expected blocks, the header information is compared with the header information in a list of expected blocks.

7.4.4.2 If the block is not one of the expected blocks, it must be the first block of a primary message, otherwise the block has been sent in error and can be discarded. If the block is the first block of a primary message, and it is not the last block of the message (E-bit = 0), an inter-block timer for the given message is established and set, and the expected block for the given message is set to have the same R-bit, device ID, system bytes, W-bit, message ID, and a block number one greater than that of the block just received.

7.4.4.3 If the block is one of the expected blocks, then it is either the first block of a reply message or it is part of an open message.

7.4.4.4 If the block is the first block of a reply message, the reply timer for the given message is cancelled. For the first block of a reply message, the expected block will have block number one (or possibly zero if the reply is a single block message) and will be a secondary message, but the full message ID is undetermined. (See Section 7.3.1.)

7.4.4.5 If the block is the last block of the given message (E-bit = 1), the message is complete. If the message is a primary message for which a reply is requested (W-bit = 1), the system bytes are saved for sending with the reply message. (See Section 7.2.3.)

7.4.4.6 If the block is not the last block of the message (E-bit = 0), then the inter-block timer for the given message is reset, and the (next) expected block for the given message is set to have the same R-bit, device ID, system bytes, W-bit, message ID, and a block number one greater than that of the block just received.

8 Parameter Setting

8.1 The eight protocol parameters are listed in Table 4. The selection of baud rate should be based on system performance. The value of the device ID is determined by the particular system requirements and is generally unique within one factory. The values of the next five parameters are determined by the performance characteristics of the host system and the baud rate of the communication channel. The first seven parameters must be adjustable by the user. All parameters must be stored in such a manner that the settings will be retained if the power fails or if the system software is reloaded. The range and resolution of protocol parameters must be at least as shown in Table 4. The M/S parameter is set to master in the equipment and to slave in the host.

Table 4 Protocol Parameters

Symbol	*Parameter Name*	*Typical Function*	*Typical Value*	*Range*	*Resolution*
BAUD	Baud Rate	Sets serial line speed	9600	300 - 9600	see Section 3.3
DEVID	Device ID	Identifier assigned to the equipment	—	0 - 32767	1
T1	Inter-Character Timeout	Detects an interruption between characters	0.5 sec.	0.1-10 sec.	0.1 sec.
T2	Protocol Timeout	Detects a lack of protocol response	10 sec.	0.2-25 sec.	0.2 sec.
T3	Reply Timeout	Detects a lack of reply message	45 sec.	1-120 sec.	1 sec.
T4	Inter-Block Timeout	Detects an interruption in a multi-block message	45 sec.	1-120 sec.	1 sec.
RTY	Retry Limit	The maximum number of send retries allowed	3	0 - 31	1
M/S	Master Slave	Contention resolution	—	—	—

9 Documentation

9.1 For equipment or host to comply with SECS-I, a document is required containing the following information. (See also SEMI E6, Facilities Interface Specifications Guideline and Format.)

1. Method for setting all the parameters in Table 4.
2. Range allowed and resolution for each parameter in Table 4.
3. Compatibility with duplicate block detection and the method for enabling and disabling the same if present (see Section 7.4.2).
4. Maximum expected inter-character, protocol, reply, and inter-block delays generated under normal operating conditions.
5. Whether multi-block messages are supported as a receiver.
6. Whether multi-block messages are used as a sender.
7. Whether there is a limit to the size of a message received and, if so, what the limit is.
8. Maximum expected size of a message being sent.
9. Whether message interleaving is supported as a receiver.
10. Whether message interleaving is used as a sender.
11. Number of device ID's supported on the port.
12. Maximum number of supported concurrent open transactions.

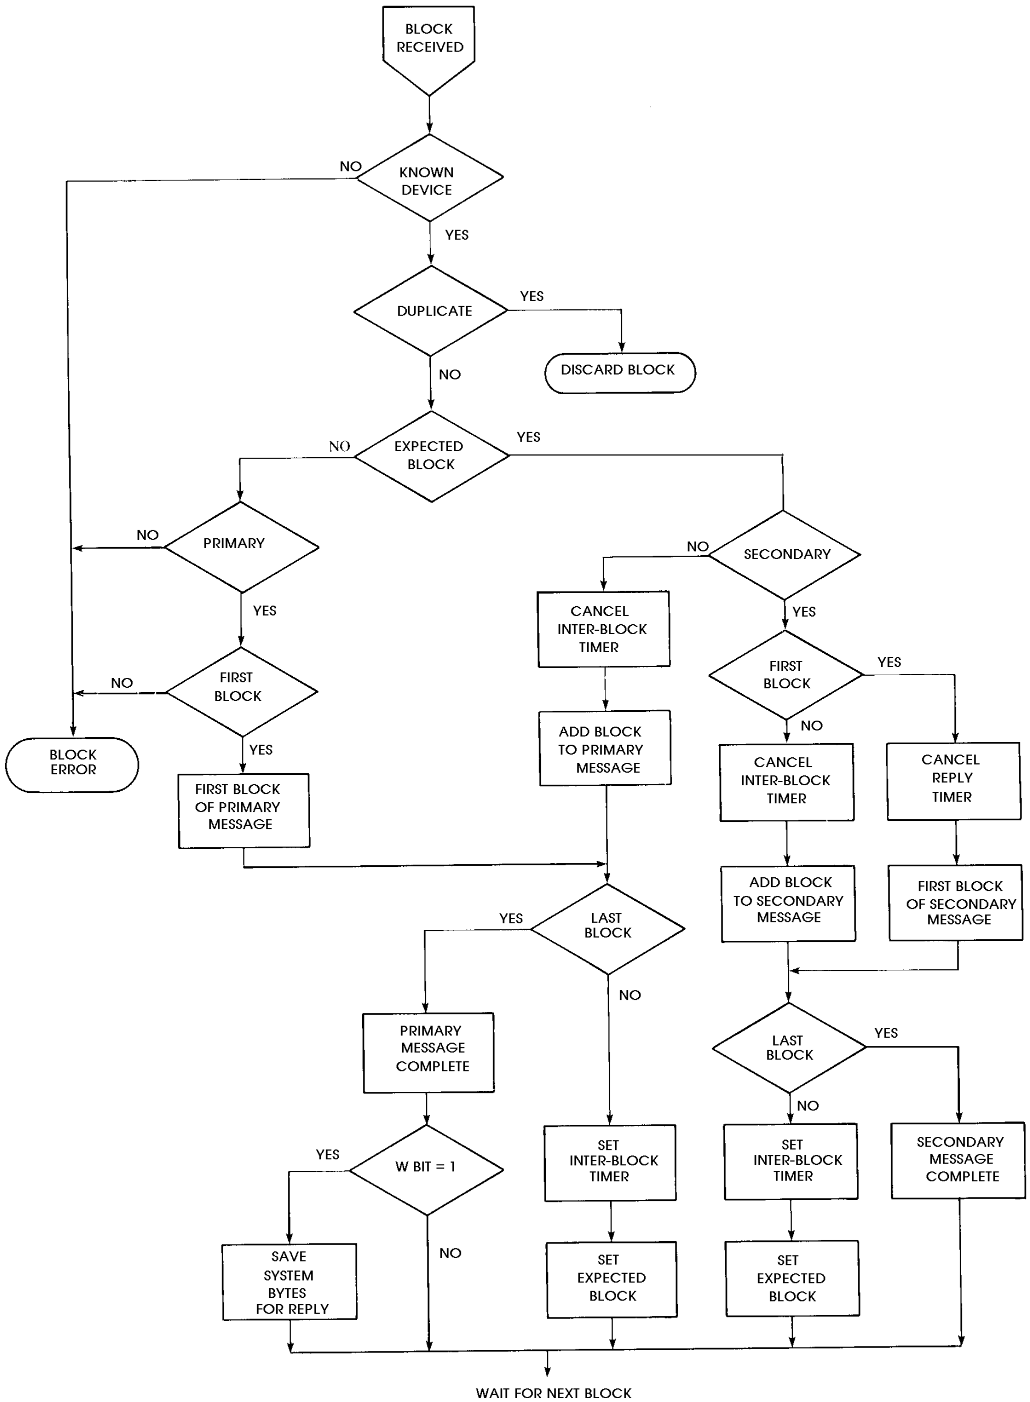


Figure 4

Message Receive Algorithm

APPENDIX 1

A1-1 Differences from SECS-I 1980

This appendix describes the major differences between this version of the standard and the version originally adopted in 1980.

A1-1.1 *Signal Connections* — The required voltage levels for pins 18 and 25 on the 25 pin "D" connector are now optional.

A1-1.2 *Data Rate* — The 150 baud data rate has been made optional.

A1-1.3 *Timeout Parameters* — The T4 timeout, which limits the inter-block arrival time of multi-block messages, has been added. Use of the T3 timeout has been clarified.

A1-1.4 *Time Before Length Byte* — The protocol time with limit T2 is now used while waiting for the length byte after sending an EOT.

A1-1.5 *Block Send Acknowledgment* — Any character other than an ACK received after sending the second checksum byte is treated as an NAK.

A1-1.6 *Illegal Block Lengths and Bad Checksums* — An NAK code is sent for an illegal block length or for a bad checksum, but only after waiting for the sender to stop sending by forcing an inter-character (T1) timeout.

A1-1.7 *Block Number* — The wording describing the block number has been clarified to say that the value, zero, is allowed only for single block messages.

A1-1.8 *System Bytes* — The handling of the system bytes for secondary messages sent by a host is now the same as for the equipment. Also, specific functional requirements have been added for the content of the system bytes field.

A1-1.9 *Duplicate Blocks* — A mechanism for the detection of duplicate blocks has been added.

A1-1.10 *Messages* — The discussion of message assembly from blocks has been clarified and expanded.

A1-1.11 *Transactions* — The discussion of transaction handling and reply linking has been moved from SECS-II and expanded.

A1-1.12 *Appendix* — Parts of the Appendix have been moved to a new section called Related Information to distinguish the content from the standard itself. The general node transaction flow chart has been moved from the Appendix in SECS-II to the Related Information in SECS-I.

A1-1.13 *Titles* — The title of SECS-I has been changed from "Data Link" to "Message Transfer." This phrase more accurately covers the content of the standard and avoids confusion with other uses of the term "data link." The title of the "Data Link" section of SECS-I has been changed to "Block Transfer." The "Data Link Control" portion of the Block Transfer Protocol has been retitled "Line Control."

A1-1.14 *W-Bit* — The W-bit is now required to be set consistently in all blocks.

A1-1.15 *Documentation* — A section has been added on the documentation required for compliance with the standard.

RELATED INFORMATION

NOTICE — The material contained in this Related Information is not an official part of SEMI E4 (SECS-I) and is not intended to modify or supercede the official standard. Rather, this information describes possible methods for implementing the protocol described by the standard and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

R1-1 Miscellaneous Notes on SECS-I

R1-1.1 *Layered Protocol (see Section 1.3.1)* — The lnternational Standards Organization (ISO) has published a model for Open Systems lnterconnection (OSI). The SECS-I protocol both predates the ISO/OSI model and is not a true "open system" and, therefore, does not correspond exactly to the ISO/OSI model. The SECS-I protocol is a communications interface rather than a network protocol. However, the SECS-I levels can be roughly compared to layers 1 through part of layer 5 of the ISO/OSI model. ISO/OSI layer 1, the physical link layer, corresponds to the SECS-I physical link. ISO/OSI layer 2, the data link layer, corresponds to the SECS-I block transfer protocol. lSO/OSI layer 3, the network layer, is a function of the host and is not defined in SECS-I beyond the provision for a bi-directional flow (see Section 6.2). Similarly, network management is assumed to be the responsbility of the host. ISO/OSI layer 4, the transport layer, is covered by the SECS-I block transfer protocol, duplicate block detection, and the message protocol. ISO/OSI layer 5, the session layer, is partially covered by the SECS-I message protocol.

R1-1.2 *Single Timer for T1 and T2 (see Section 5.3)* — A single timer can be used for both the inter-character timer and the protocol timer, since both are the time between receiving successive characters and both limits are never in effect at the same time.

R1-1.3 *Stalling (see Section 5.8.2)* — The line control portion of the block transfer protocol has the ability to delay the acceptance of a data block by not responding with an EOT immediately after receiving an ENQ. Such an action by the receiver is called "Stalling." If the delay exceeds the sender's T2 value, the sender will send another ENQ. This can be continued depending upon the sender's setting of T2 and RTY. Such a delay should be an occasional convenience to accommodate random short delays in the receiver's ability to accept a new block and should not be counted upon routinely to make up for poor response. In particular, the block transfer protocol should probably have at least two buffers available for storing incoming blocks. This allows one block to be inspected by the message protocol while the next block is being received, thus allowing a reasonably continuous reception of data. If both buffers are full and the message protocol is slow in freeing the buffer for the block transfer protocol, then the block transfer protocol will start stalling the sender. If the sender is stalled long enough, it will declare a send error, which is probably the correct thing to do. The sender cannot distinguish between a reluctance to receive and failure in the communications. In either situation, since no block gets through in a predetermined time limit, the communications link is effectively broken. Arbitrarily long delays are not acceptable in SECS-I.

R1-1.4 *Determining the Cause of an NAK (see Section 5.8.5)* —The block transfer protocol does not include a way for a sender to determine the cause of an NAK. If such information is useful for application purposes, it must be collected at the receiving end.

R1-1.5 *Master Sending a Long Message (see Section 5.8)* —When the master is sending a long message, the slave may be unable to send a block, which may result in timeouts. It is good practice for the master to introduce enough delay between blocks so that the slave has a chance to send a block every few seconds.

R1-1.6 *Device Identification (see Section 6.3)* — Although the 15 bits of the device ID can identify 32,767 different devices, the host may find it more convenient to use the upper seven bits to identify the type of device such as a spinner or diffusion furnace, and to use the lower eight bits to identify the specific device of that type.

R1-1.7 *Sending Multiple Open Messages (see Section 7.2.4)* —The message protocol algorithms defined in the standard are capable of inter-leaving the blocks of any number of open multi-block messages. Since the receiving protocol is sensitive to the time between blocks of each message being received, it is proper procedure for the sending algorithm to alternate between messages when sending blocks from interleaved multi-block messages.

R1-1.8 *Single Timer for T3 and T4 (see Sections 7.3.2 and 7.4.3)* — For a given transaction, a single timer can be used for both the inter-block timer and the reply timer, since both are the time between receiving successive blocks of a message, and both limits are never in effect at the same time.

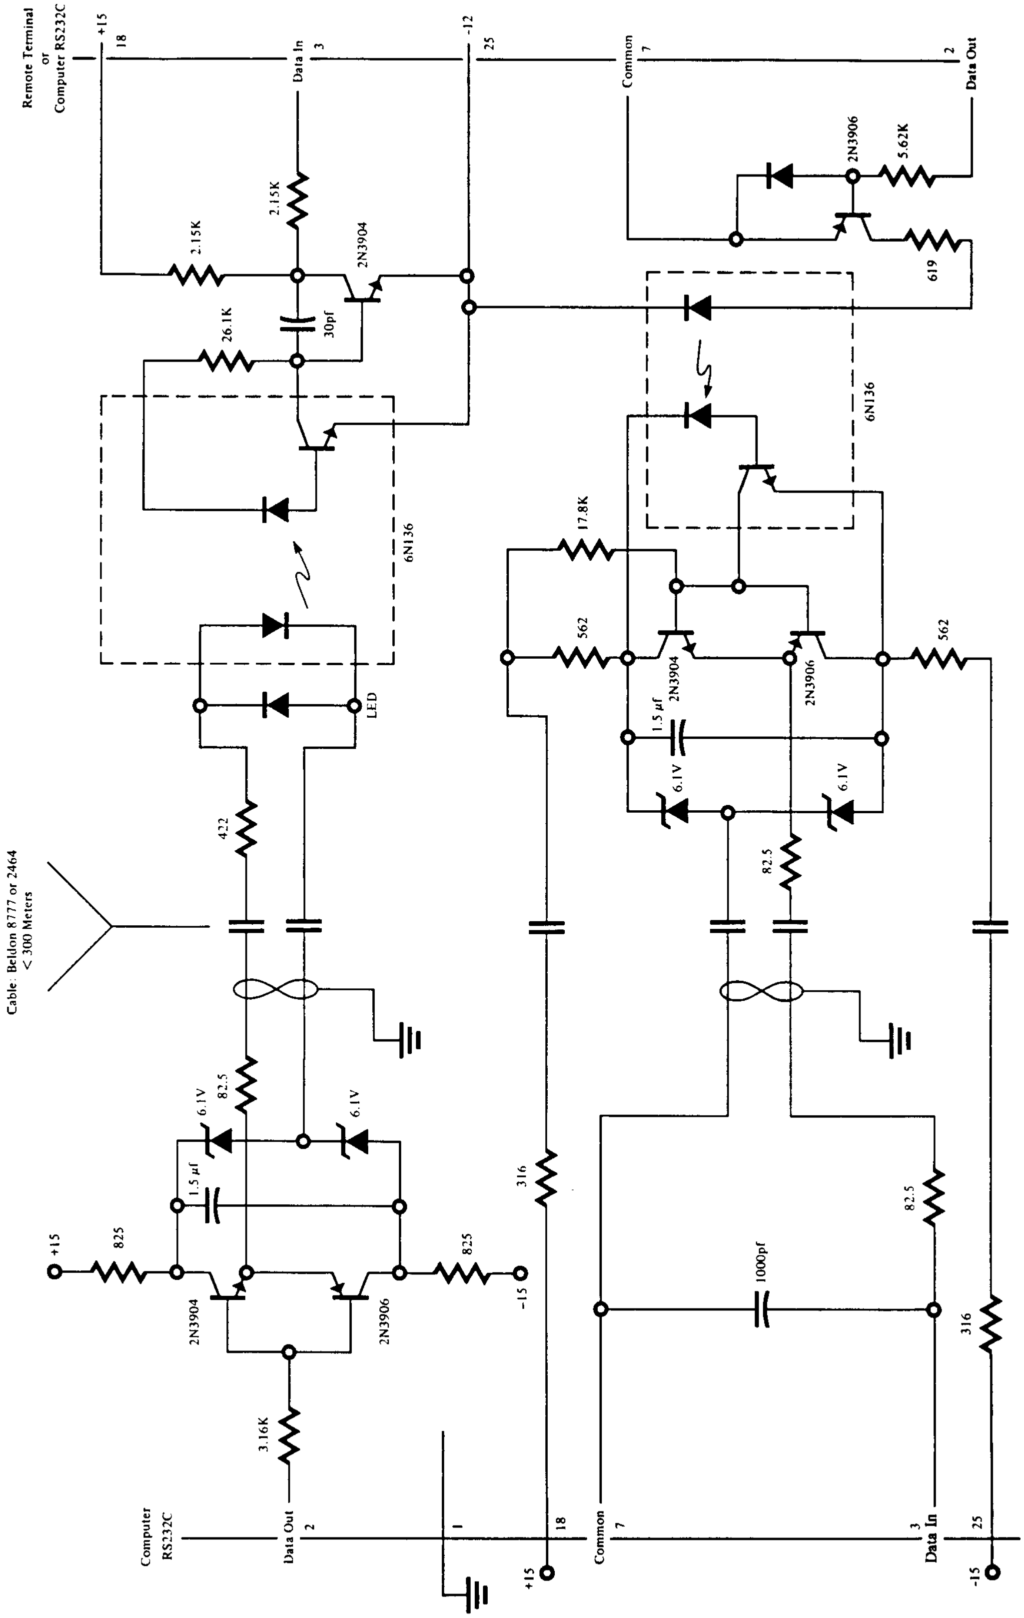

Figure R1-1

RS-232 Isolation Example

R1-2 Isolation

R1-2.1 As mentioned in Section 3.4, the standard RS-232-C line does not provide isolation between the grounds of remote equipment and a central computer. It is often desirable to provide isolation to minimize communications errors and to protect equipment. The following example is provided here to illustrate how such an isolation might be provided between two devices using RS-232-C, while at the same time providing the capability to drive longer lines. This description is provided for information only and is not part of the standard.

R1-2.2 Figure R1-1 illustrates a possible circuit for isolation which provides line isolation and line driving capability. The two wires used to provide power to the remote isolator are required since any local power supply would have the same isolation problems as the data wires. The power wires also eliminate extra supplies at every terminal or remote device. There are many other possible circuits. This example has been used successfully and works quite well at 9600 baud for lines less than 300 meters and illustrates the use of the voltages on pins 18 and 25 as mentioned in 3.2.4.

R1-3 Examples of Block Transfer Protocol

R1-3.1 Figures R1-2 and R1-3 illustrate some simple message interactions between the host and the equipment. Figure R1-2 shows the handshake sequence possible to acquire the status of the equipment. Fig-ure R1-3 shows the sequence of events when both the host and the equipment try to send at the same time.

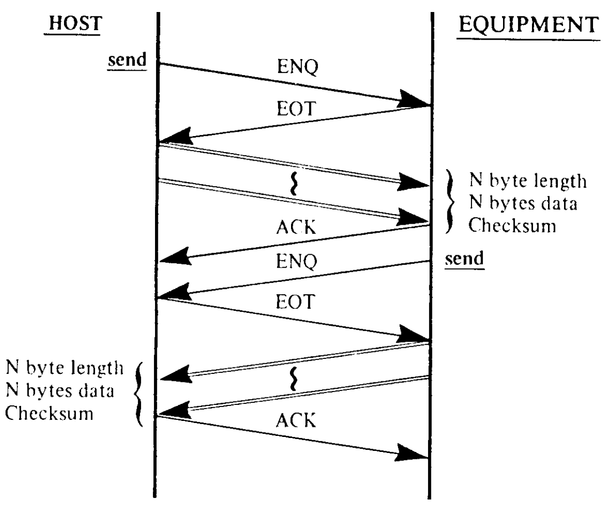

Figure R1-2

Ask for Status

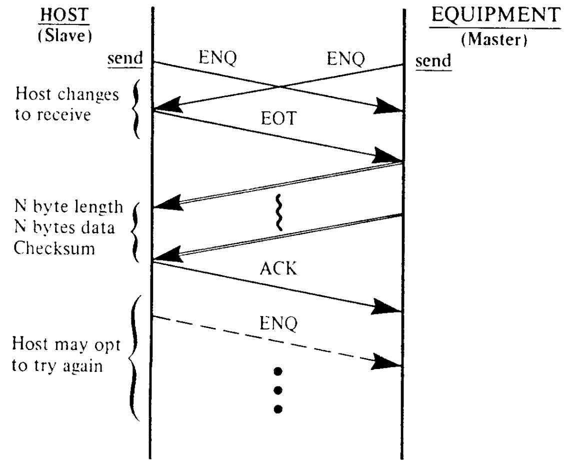

Figure R1-3

Contention Resolution

R1-4 Use of Buffers in the Block Transfer Protocol

R1-4.1 In the flow chart of the Block Transfer Protocol (Figure 2), the flow chart entry "LISTEN" implies that characters are recognized after entering the given state and not before. If the particular implementation uses buffers and stores all of the characters received before the "LISTEN" state is achieved, care must be taken in the proper handling of the data in the buffer to avoid problems due to "timing windows" between sending and receiving.

R1-4.2 If the buffer is cleared before sending the last character prior to the "LISTEN" (last checksum byte in sending a message, ENQ or EOT in line control), there is still a time, albeit small, where spurious characters could be received into the buffer.

R1-4.2.1 In addition, during the sending of the message, a delay between the checksum bytes while the buffer is cleared may cause an inter-character timeout by the receiver. If the buffer is cleared after the last character sent before the "LISTEN," there is a possibility that the desired character will be cleared from the buffer.

R1-4.3 One solution is to look at the buffer after entering the "LISTEN" state and examine the last character in the buffer, if any are there. This works while listening for an EOT after sending an ENQ. In the case where the sender is listening for an ACK after sending the second checksum byte, it is possible that the receiver also has a block to send, and follows the

ACK immediately with an ENQ. In this case the last character in the buffer might be an ENQ, and so the last two characters should be examined. If an ACK precedes the ENQ, then it should be assumed that the block was sent successfully, and the ENQ should be saved for establishing line control (i.e., send an EOT, or an ENQ if there is contention).

R1-4.4 The handling of the buffer when listening for the length byte is not improved by this suggestion. The buffer should be cleared after the ENQ is received and before the EOT is sent. Spurious characters received before the length byte will cause a send failure.

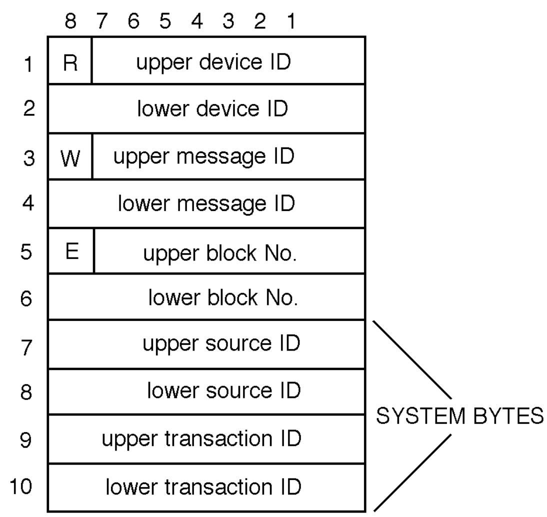

Figure R1-4

Possible Bock Header Structure

R1-5 System Bytes

R1-5.1 This section presents a sample scheme for generating and managing the system bytes field of the block header. There are many possible implementations which meet the requirements of SECS-I. This section describes one of those implementations.

R1-5.2 *Source ID and Transaction ID* — The system bytes are divided into two parts, a source ID and a transaction ID, as shown in Figure R1-4.

R1-5.3 Distinct source IDs are assigned to each application level originator of primary messages in a host or equipment. This allows a secondary message to be routed to the source of the corresponding primary message of the transaction. The transaction ID is an integer that is incremented for each primary message sent by the SECS-I interface. It is the same for all blocks of a multi-block message.

R1-5.4 *Actions* — When a SECS-II message is passed to the SECS-I protocol, the least significant bit of the lower message ID is examined to determine whether the message is primary (bit 1 = 1) or secondary (bit 1 = 0) message. If the message is primary, transaction ID is generated and placed in the transaction ID portion of the system bytes. One method for generating the transaction ID is to start with a value of 0 upon initialization, and increment by 1 for each new transaction, starting with 1 (not 0) when the largest transaction ID value has been used. At the same time, the application sender's source ID is placed in the source ID portion of the system bytes. If the message is secondary, the system bytes are the same as those of the corresponding primary message. It is assumed that the application generating the reply can identify the reply to the message protocol, which has saved the system bytes from the primary message.

R1-5.5 *Block Send Failures (see Sections 5.8.2 and 6.8.1)* — Since it is a requirement that the system bytes be distinct from those used in blocks that were not successfully sent since the last successful block send, the use of two bytes for the transaction ID would effectively satisfy the requirement by allowing for up to 65,536 consecutive block send failures.

R1-6 Using SECS in a Network

R1-6.1 The SECS standard can be used to control the flow of data within a network of computers. A network is an interconnection of computers or intelligent controllers communicating with one another over communications lines. Each intelligent entity is a node of the network. Each node may have a number of connections to other members of the network.

R1-6.2 One connection of equipment and computers is in the form of a tree network with the processing equipment at the ends of branches as shown in Figure R1-5. Intermediate Nodes A and B service like pieces of equipment; i.e., all the furnaces to Node A, all masking to Node B, and so on, for more nodes.

R1-6.3 Node A monitors the three stations 1A, 2A, and 3A. Node A handles most of the normal requirements of coordinating 1A, 2A, and 3A. Node A receives instructions from Node C regarding the behavior desired from 1A, 2A, and 3A. A CRT or operator interface connected to Node A is shared by 1A, 2A, and 3A. Any node can direct messages up or down the tree. A message such as an alarm can be sent from 1A to Node A and from Node A to Node C which might be considered the host of the network. Node A might be part of a system supplied by a company which has its own communications scheme for devices tied to Node A. As long as the company provides one connection to Node A which is consistent with this standard, then

Node A and its attached equipment can be connected to the host, Node C, and collectively be called one node.

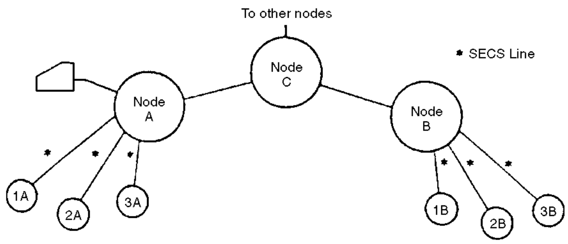

Figure R1-5

Tree Network

R1-6.4 This tree structure can be extended even further as shown in Figure R1-6 to include multiple manufacturing plants at remote sites. However, the primary intent of this standard is to address the communication between processing equipment and a host. At higher levels of the tree, the message is combined with more system level messages and more computer file manipulations. At these levels, the communications may require more complex or higher speed standards. Thus, the SECS line is intended to be used within one integrated circuit manufacturing area rather that between general purpose computer centers, although its only limitations for such a use would be speed.

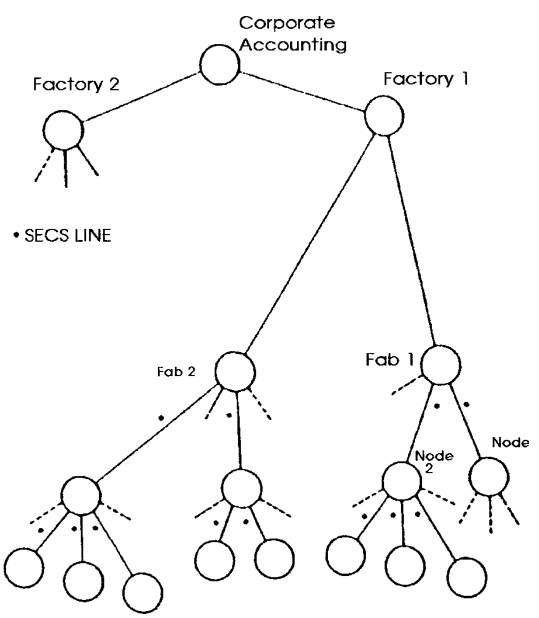

Figure R1-6

Extended Tree Network for a Large Organization

R1-6.5 The tree network is characterized by the fact that there is only one possible path between any two nodes in the network. This feature makes handling messages in the tree network relatively easy when compared to networks where more than one communication path exists between nodes. In these latter networks, the nodes must make some judgment about which path to take, perhaps based on the conditions of the lines or on the destination of the message.

R1-6.6 The device ID and the R (Reply) bit play an important role in directing messages in the network. Each node of the three maintains a table of the device below it. From the device code, it knows on which branch to send the data. When a message is going from the central node toward the device, the R-bit is set to 0. When a message is being sent from the device up the tree, the R-bit is set to 1. When a node sees the R-bit set to 1, the message must take the one communication direction that goes up the tree structure. Thus, the R-bit serves to direct messages up the tree or down the tree, depending on its value. At any given node, this behavior may be explained in Figure R1-7.

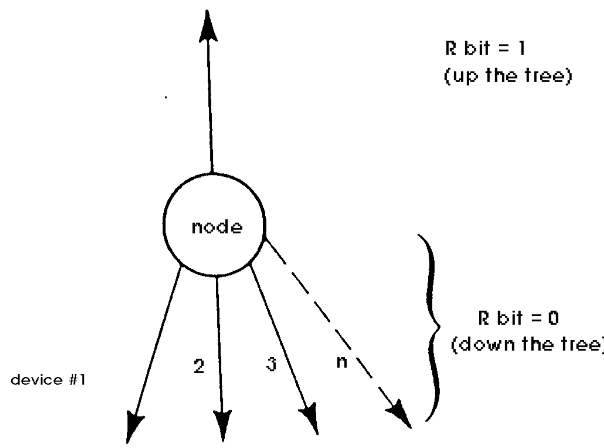

Figure R1-7

Message Handling at a Node by Using the R-Bit

R1-7 The General Node Transaction Protocol

R1-7.1 The transaction protocol has three primary functions. First, it coordinates the receiving of messages that arrive in multiple blocks. Second, it provides a mechanism for matching primary and secondary messages. Third, it does error detection on incomplete messages whether they are due to a break during multiple blocks or a lack of reply messages. The third function is vital to the maintenance of a working system, as can be seen from the following discussion. Once a transaction is begun with the first block of a primary message, the receiving machine will have some memory allocated to buffering or pointing to interpreting modules. If the transaction remains incomplete for some reasonable length of time, it may be assumed that an error has occurred and the receiving machine should release any memory it may be holding for the transaction. If memory were to remain allocated to incomplete transactions, conceivably the receiving machine could run out of available memory and would be unable to function properly. For this reason, the error detection of incomplete transactions is an essential part of the message transaction protocol in SECS-I.

R1-7.2 The message transaction protocol is based on a system of timers called transaction timers. These timers are maintained in software and are associated with a given transaction. Once a transaction is begun, there will exist a timer on the time interval between all blocks of the transaction independent of the direction of the message. The machine that expects to receive a block has the burden of timing and error detection. Timers are required in any machine that (1) makes a request and expects to receive data back; (2) must receive multiple block requests; or (3) sends data and expects an acknowledgement. A machine may require several transaction timers if it can conduct multiple transactions at one time on one port or has multiple ports. A message timer will exist for each link involved in the transaction. This allows the error detection to identify the particular link which has failed.

R1-7.3 A general algorithm can be constructed to handle an arbitrary number of SECS ports. Such an algorithm is presented in the form of a flow chart in Figure R1-8. There is one such algorithm for each device ID. The algorithm handles all SECS data blocks that enter, leave or pass the device ID. A new block causes the procedure to be executed starting from the point marked "block in" and continues until the point marked "block out." The block of data will then be directed to the proper destination.

R1-7.4 This algorithm makes use of a stored version of the message header for each transaction being handled. The stored header may be visualized as shown in Figure R1-9. The stored header has two system areas and an associated transaction timer. The two system areas are required to keep the incoming and the outgoing system areas independent in coding, yet related in meaning. The two system areas are referred to by the state of the R-bit in the message block header. One area is related to R = 0 and the other R = l. When a prime message is received that requires a reply, the system bytes from the block are stored in the system area corresponding to the opposite state of the R bit on the message. When the reply is sent, the system bytes are used from the store system bytes corresponding to the same R-bit as the reply. The system area corresponding to the same R-bit as the message is called OUTSYS while the system area corresponding to the opposite R-bit is called INSYS.

R1-7.5 When a block is presented to this algorithm, the first task is to determine if the block is part of an ongoing transaction, the first block of a new transaction, or some other unknown block. This test is accomplished by comparing the header of the block with the stored headers. If a match is not found, then a check is made to see if the block is the first of a primary message. If this is true, then a new header is added to the stored header list. If the primary message is only one block long and requires no reply, then no stored header is created. When a match is found, the algorithm modifies the stored header so that it will look like the next block of the transaction to be expected. On all blocks requiring a stored header, except the last, a transaction timer is set to a timeout value prior to sending the block to its destination. The last part of the algorithm directs the block to its destination or detects an error in the destination.

R1-7.6 Error recovery is an important part of the algorithm to ensure that the system will remain operational in spite of bad data blocks. For any block that does not pass the tests described in the algorithm, the header of the message is saved and sent in the host direction on a Stream 9 error message. This information can be useful in tracking down the source of the error. Another type of error occurs when one of the transaction timers times out. Such an error message means that the transaction has been interrupted. An error message is formed which sends the stored header in the host direction on Stream 9. The stored header and the timer are then released. This procedure aids in keeping software cleared and ready in case of difficulties in the network.

SEMI E5-0702
SEMI EQUIPMENT COMMUNICATIONS STANDARD 2 MESSAGE CONTENT (SECS-II)

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current changes approved by the North American Regional Standards Committee on. Initially available at www.semi.org June 2002; to be published July 2002. Originally published in 1982; previously published March 2002.

NOTICE: The user's attention is called to the possibility that some implementations of this standard, particularly those related to the use of Stream 4, may involve the use of inventions covered by U.S. patents 4,884,674 and 5,216,613, and by other patents issued or pending, held by Texas Instruments Incorporated. By publication of this standard, SEMI takes no position respecting either the applicability or the validity of these or other patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

1 Introduction

1.1 *Intent* — The SEMI Equipment Communications Standard Part 2 (SECS-II) defines the details of the interpretation of messages exchanged between intelligent equipment and a host. This specification has been developed in cooperation with the Japan Electronic Industry Development Association Committee 12 on Equipment Communications.

1.1.1 It is the intent of this standard to be fully compatible with SEMI Equipment Communications Standard E4 (SECS-I). It is also the intent to allow for compatibility with alternative message transfer protocols. The details of the message transfer protocol requirements are contained in Section 3.

1.1.2 It is the intent of this standard to define messages to such a level of detail that some consistent host software may be constructed with only minimal knowledge of individual equipment. The equipment, in turn, may be constructed with only minimal knowledge of the host.

1.1.3 The messages defined in the standard support the most typical activities required for IC manufacturing. The standard also provides for the definition of equipment-specific messages to support those activities not covered by the standard messages. While certain activities can be handled by common software in the host, it is expected that equipment-specific host software may be required to support the full capabilities of the equipment.

1.2 *Overview* — SECS-II gives form and meaning to messages exchanged between equipment and host using a message transfer protocol, such as SECS-I.

1.2.1 SECS-II defines the method of conveying information between equipment and host in the form of messages. These messages are organized into categories of activities, called streams, which contain specific messages, called functions. A request for information and the corresponding data transmission is an example of such an activity.

1.2.2 SECS-II defines the structure of messages into entities called items and lists of items. This structure allows for a self-describing data format to guarantee proper interpretation of the message.

1.2.3 The interchange of messages is governed by a set of rules for handling messages called the transaction protocol. The transaction protocol places some minimum requirements on any SECS-II implementation.

1.3 *Application* — SECS-II applies to equipment and hosts used in the manufacturing of semiconductor devices. Examples of the activities supported by the standard are: transfer of control programs, material movement information, measurement data, summarized test data, and alarms.

1.3.1 The minimum compliance to this standard involves meeting the few constraints outlined in Section 5. It is expected that a given piece of equipment will require only a subset of the functions described in this standard. The number of functions and the selection of functions will depend upon the equipment capabilities and requirements. For each piece of equipment, the exact format for each function provided must be documented according to the form outlined in Section 7.

1.3.2 It is assumed that the equipment will define the messages used in a particular implementation of SECS-II. It is assumed the host will support equipment implementation.

1.4 *Applicable Documents*

1.4.1 *ANSI*[1]

X3.4-1977 — Code for Information Interchange (ASCII)

1.4.2 *IEEE*[2]

754 — Standard for Binary Floating Point Arithmetic

1.4.3 *SEMI Standards*[3]

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transfer (SECS-I)

SEMI E6 — Facilities Interface Specifications Guideline and Format

1.4.4 The Japan Electronic Industry Development Association (JEIDA) has requested that the SECS-II standard incorporate support for the JIS-8 codes for data exchange. This code would allow support for katakana characters in Japanese implementations of SECS-II.

JIS 8-bit Coded Character Set (JIS-6226) for information Interchange, Japanese Industrial Standards.

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

1.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2 Selected Definitions

2.1 The following brief definitions refer to sections providing further information.

2.1.1 *block* — a physical division of a message used by the message transfer protocol (see Section 3.3).

2.1.2 *conversation* — a sequence of related messages (see Section 5.4).

2.1.3 *conversation timeout* — an indication that a conversation has not completed properly (see Section 5.4.1).

2.1.4 *device ID* — a number between 0 and 32767 used in identifying the particular piece of equipment communicating with a host (see Section 3.4.1).

2.1.5 *equipment* — the intelligent system which communicates with a host.

2.1.6 *function* — a specific message for a specific activity within a stream (see Section 4.2).

2.1.7 *host* — the intelligent system which communicates with the equipment.

2.1.8 *interpreter* — the system that interprets a primary message and generates a reply when requested (see Section 3.2).

2.1.9 *item* — a data element within a message (see Section 6.2).

2.1.10 *item format* — a code used to identify the data type of an item (see Section 6.2).

2.1.11 *list* — a group of items (see Section 6.3).

2.1.12 *message* — a complete unit of communication (see Section 3.2).

2.1.13 *message header* — information about the message passed by the message transfer protocol (see Section 3.4).

2.1.14 *multi-block message* — a message sent in more than one block by the message transfer protocol (see Section 3.3.2).

2.1.15 *originator* — the creator of a primary message (see Section 3.2).

2.1.16 *packet* — a physical division of a message used by the message transfer protocol (see Section 3.3).

2.1.17 *primary message* — an odd numbered message. Also, the first message of a transaction (see Sections 3.2 and 4.2).

2.1.18 *reply* — the particular secondary message corresponding to a primary message (see Sections 3.2 and 4.2).

2.1.19 *secondary message* — an even-numbered message. Also the second message of a transaction (see Sections 3.2 and 4.2).

2.1.20 *single-block message* — a message sent in one block by the message transfer protocol (see Section 3.3.1).

2.1.21 *stream* — a category of messages (see Section 4.1).

2.1.22 *transaction* — a primary message and its associated secondary message, if any (see Section 5.2).

2.1.23 *transaction timeout* — an indication from the message transfer protocol that a transaction has not completed properly (see Section 3.5).

3 The Message Transfer Protocol

3.1 *Intent* — SECS-II is fully compatible with the message transfer protocol defined by SECS-I. It is the

1 ANSI, 1430 Broadway, New York, NY 10018

2 IEEE Service Center, 445 Hoe Lane, Piscataway, NJ 08854

3 SEMI, 805 E. Middlefield Road, Mountain View, CA 94043

intent of this standard to allow for compatibility with alternative message transfer protocols. The purpose of this section is to define the requirements of the interaction between an application using SECS-II and the message transfer protocol. The methods used to implement these requirements are not covered as a part of this standard. The terms used in this standard are those used by SECS-I. Equivalent terms may be different for other message transfer protocols.

3.2 *Messages* — The message transfer protocol is used to send messages between equipment and host. The message transfer protocol must be capable of sending a primary message, indicating whether a reply is requested; and, if a reply is requested, it must be capable of associating the corresponding secondary message or reply message with the original primary message. The term originator will refer to the creator of the original primary message. The term interpreter will refer to the entity that interprets the primary message at its destination and generates a reply when requested.

3.3 *Blocking Requirements* — The message transfer protocol must support the following SECS-II message blocking requirements.

3.3.1 *Single-Block Messages* — SECS-II requires that certain messages be sent in a single block or single packet by the message transfer protocol. Those messages defined in this standard as single-block SECS-II messages must be sent in a single-block or packet. The method used by the application software to tell the message transfer protocol that a particular message must be sent as a single block is not covered as part of this standard. For compatibility with SECS-I, the maximum length allowed for a single-block SECS-II message is 244 bytes. The minimum requirement for the message transfer protocol is to be able to send single-block SECS-II messages.

3.3.2 *Multi-Block Messages* — For compatibility with SECS-I, SECS-II messages that are longer than 244 bytes are referred to as multi-block messages. Also, certain SECS-II messages are allowed to be multi-block messages even if they otherwise meet the single-block length requirements. Certain older implementations may impose application-specific requirements on block sizes for certain incoming messages. Beginning with the 1988 revision of the standard, new applications may not impose application-specific requirements on incoming block sizes. Applications implemented before 1988 may impose such requirements.

3.4 *Message Header* — The message transfer protocol must provide the following information, called the message header, with every message. Only the content of the message header is defined by this standard. The exact format of the message header passed between the application and the message transfer protocol is not covered as part of this standard.

NOTE 2: In SECS-I, this information is contained in the 10-byte header of each block of a message.

3.4.1 *Device ID* — The message transfer protocol must be capable of identifying the device ID (0-32767) which indicates the source or destination of a message.

3.4.2 *Stream and Function* — The message transfer protocol must be capable of identifying to SECS-II a minimum15-bit message identification code. In SECS-II, messages are identified by a stream code (0-127, 7 bits) and a function code (0-255, 8 bits). Each combination of stream and function represents a distinct message identification.

3.4.3 *Reply Requested* — The message transfer protocol must be capable of identifying whether a reply is requested to a primary message.

3.5 *Transaction Timeout* — It is presumed that the message transfer protocol will notify SECS-II in the event of failure to receive an expected reply message within a specified transaction timeout period.

NOTE 3: In SECS-I, a transaction timeout occurs if either the reply timeout (T3) is exceeded before the first block of a reply message is received or if the inter-block timeout (T4) is exceeded before an expected block of a multi-block message is received.

3.6 *Multiple Open Transactions* — This standard allows, but does not require, the support of more than one concurrent open transaction.

4 Streams and Functions

4.1 *Streams* — A stream is a category of messages intended to support similar or related activities.

4.2 *Functions* — A function is a specific message for a specific activity within a stream. All the functions used in SECS-II will follow a numbering convention corresponding to primary and secondary message pairs. All primary messages will be given an odd- numbered function code. The reply message function code is determined by adding one to the primary message function code. The even-numbered function following a primary message which requests no reply is reserved and is not to be used. Function code 0 is reserved in all streams for aborting transactions as described in Section 7.4.

4.3 *Stream and Function Allocation* — Some of the stream and function code combinations are reserved for this standard, while others are available for user definition. The stream and function codes reserved for this standard are as follows:

In Stream 0, Functions 0-255.

In Streams 1-63, Functions 0-63.

In Streams 64-127, Function 0.

The stream and function codes available for user definition are as follows:

In Streams 1-63, Functions 64-255.

In Streams 64-127, Functions 1-255.

4.3.1 The stream and function code assignment can also be represented by the diagram shown in Figure 1.

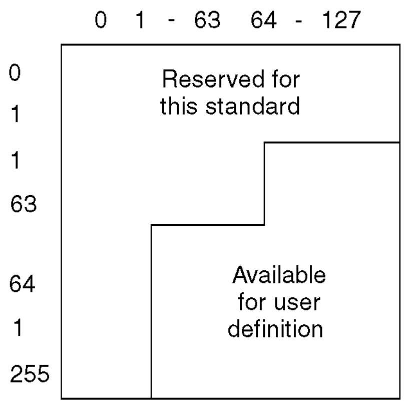

Figure 1
Stream and Function Allocation

4.3.2 The reserved codes assigned by this standard are listed in Section 7. It is recognized that there will be user needs beyond the specific definitions given in this standard. In these situations, the streams and functions reserved for user definition should be used subject to the guidelines for minimum compliance outlined in Section 5.

5 Transaction and Conversation Protocols

5.1 *Intent* — For an implementation to be in compliance with SECS-II, it must meet the minimum transaction requirements outlined in this section. The conversation protocols serve to further define the use and interaction between transactions.

5.2 *Transaction Definition* — A transaction forms the basis for all information exchanges in SECS-II. A transaction consists of either a primary message for which no reply is requested, or a primary message which requests a reply together with its corresponding secondary message. Secondary messages cannot request a reply.

5.3 *Transaction Level Requirements* — The following are the requirements to comply with the SECS-II protocol at the transaction level:

1. Respond to S1F1 with S1F2 as described in Section 7.5.
2. For any received message that cannot be processed by the equipment, send the appropriate error message on Stream 9. As described in Section 7.13, S9-F1, F3, F5, F7, or F11 are possible.
3. Format any other supported messages according to Section 7.
4. Upon detection of a transaction timeout at the equipment, send S9F9 to the host.
5. Upon receipt of function 0 as a reply to a primary message, terminate the related transaction. No error message should be sent to the host by the equipment.

5.4 *Conversation Protocols* — A conversation is a series of one or more related transactions used to complete a specific task. A conversation should include all transactions necessary to accomplish the task and leave both the originator and interpreter free of resource commitments at its conclusion.

5.4.1 *Conversation Timeout* — A conversation timeout is used to indicate that a conversation has not completed properly. A conversation timeout is application-dependent, and the methods used for detecting conversation timeouts are not covered as part of this standard. A conversation timeout will terminate further action on the conversation, and will allow for the clearing of any committed resources. Upon detection of a conversation timeout at the equipment, S9F13 should be sent to the host.

5.4.2 *Types of Conversations* — There are seven types of conversations which characterize all information exchanges in SECS-II:

1. A primary message with no reply is the simplest conversation. This message must be a single-block SECS-II message. The originator must assume that the interpreter responds to the message. This conversation is used where the originator can do nothing if the message is rejected.
2. If the interpreter has data that the originator wants, the data are requested with a primary message and the data returned to the originator as a reply message. It is assumed that the originator requesting the data is prepared to receive the amount of data returned. This is the request/data conversation.
3. If the originator wishes to send data in a single-block SECS-II message to the interpreter, then the originator sends the data and expects an acknowledgment from the interpreter. This is the send/acknowledge conversation.

4. If the originator has a multi-block SECS-II message to send for a particular exchange, then the originator must receive permission from the interpreter prior to sending the data. The first transaction requests permission to send, and the interpreter either grants or denies permission. If permission is granted, the originator sends the data and the interpreter replies appropriately. This is the inquire/grant/send/acknowledge conversation. Between the inquire and the send, the interpreter may commit some resources in preparation for the data. Consequently, a conversation timeout may be set by the interpreter at a time dependent upon the application, at which time the interpreter will free its resources and send an S9,F13 error message to the originator. Note that under the definition of S9,F13 in this standard, only the equipment should generate an error message to the host under these conditions.
5. There is a conversation related to the transfer of unformatted data sets between equipment and host. This conversation is described in detail in Stream 13. (See Section 7.17)
6. There is a conversation related to the handling of material between equipment. This conversation is described in detail in Stream 4. (See Section 7.8)
7. The originator may request information from the interpreter which requires some time to obtain (e.g., operator input is required). The first transaction requests the information and the interpreter responds in one of three ways: 1) the information is returned, 2) the interpreter indicates that the information cannot or will not be obtained, or 3) the interpreter indicates that the information will be obtained and returned in a subsequent transaction, as specified for this conversation. For case number 3, the interpreter will initiate the subsequent transaction when the information is available.

Case 3 is the request/acknowledge/send/acknowledge transaction.

The originator of the request/acknowledge/send/acknowledge conversation may commit some resources in anticipation of the send/acknowledge transaction. Consequently, a conversation timeout may be set by the originator at a time dependent on the application. On timeout, the originator will free its resources and restart the conversation with the ‘request' , or send an S9,F13 error message. Note that under the definition of S9,F13 in this standard, only the equipment should generate an error message to the host under these conditions.

5.4.3 The key words, request, data, send, acknowledge, inquire, and grant are used in the function names as an aid to understanding the relationship between the messages and the conversation. Single message transactions do not use these words.

6 Data Structures

6.1 *Intent* — All information transmitted according to this standard will be formatted using two data structures, items and lists. These data structures define the logical divisions of the message, as distinct from the physical divisions of the message transfer protocol. They are intended to provide a self-describing internal structure to messages passed between equipment and host.

6.2 *Item* — An item is an information packet which has a length and format defined by the first 2, 3, or 4 bytes of the item. These first bytes are called the item header (IH). The item header consists of the format byte and the length byte(s) as shown in Figure 2. Bits one and two of the item header tell how many of the following bytes refer to the length of the item. This feature allows for long items without requiring the byte overhead for shorter items. The item length refers to the number of bytes following the item header, called the item body (IB), which is the actual data of the item. The item length refers only to the item body not including the item header, so the actual number of bytes in the message for one item is the item length plus 2, 3, or 4 bytes for the item header. All bytes in the item body are in the format specified in the format byte.

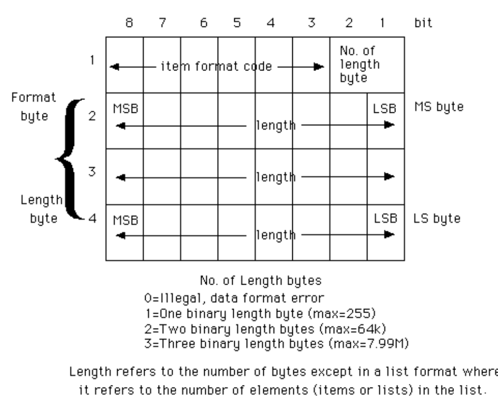

Figure 2
Item and List Header

6.2.1 A zero-length in the format byte is illegal and produces an error. A zero-length in the item length bytes has a special meaning as defined in the detailed message definitions.

6.2.2 Bits 3 through 8 of the format byte of the item header define the format of the data which follows. Of the 64 possible formats, 15 are defined as shown in Table 1. Format code 0 is called a list and is defined in

E5 6.3. Format code 22 (octal) is called a localized string and is defined in SEMI E5 Section 6.4. The remaining 14 item formats define unspecified binary, code 10 (octal); Boolean, code 11 (octal); ASCII character strings, code 20 (octal); JIS-8 character strings, code 21 (octal) signed integer, codes 30, 31, 32, 34 (octal); floating point, codes 40, 44 (octal); and unsigned integer, codes 50, 51, 52, 54 (octal). These formats are used for groups of data which have the same representation in order to save repeated item headers. Signed integers will be two' s complement values. Floating point numbers will conform to the IEEE standard 754. Boolean values will be byte quantities, with zero being equivalent to false, and non-zero being equivalent to true.

6.3 *List* — A list is an ordered set of elements, where an element can be either an item (6.2) or a list. The list header (LH) has the same form as an item header with format type 0. However, the length bytes refer to the number of elements in the list rather than to the number of bytes. The list structure allows grouping items of related information which may have different formats into a useful structure.

6.3.1 A zero-length in the format byte is illegal and produces an error. A zero-length in the list length bytes has a special meaning, which is defined in the detailed message definitions.

Format Code		*Meaning*
Binary		*The data after the heading*
Bit 876543	*Octal*	*has the following form*
000000	00	LIST (length in elements)
001000	10	Binary
001001	11	Boolean
010000	20	ASCII[1]
010001	21	JIS-8
010010	22	2-byte character[2, 4]
011000	30	8-byte integer (signed)[2]
011001	31	1-byte integer (signed)
011010	32	2-byte integer (signed)[2]
011100	34	4-byte integer (signed)[2]
100000	40	8-byte floating point[3]
100100	44	4-byte floating point[3]
101000	50	8-byte integer (unsigned)[2]
101001	51	1-byte integer (unsigned)
101010	52	2-byte integer (unsigned)[2]
101100	54	4-byte integer (unsigned)[2]

[1]Non-printing characters are equipment-specific.

[2]Most significant byte sent first.

[3]IEEE 754. The byte containing the sign bit is sent first.

[4]The code for Multi-byte character must be specified in the data in the first 2 bytes of the TEXT item.

NOTE: Changes in integer format codes may conflict with earlier implementations.

6.4 *Localized Character String Items* — A localized character string is an item which is used for representing a string of multi-byte character. Because there are many different encoding schemes and the information could be in any one of a number of languages, these characteristics must also be included in the item. Thus for localized character strings which use item format code 22 (octal), there is an additional localized string header (LSH) .

This localized string header follows the item header and precedes the string. The localized string header is part of the item data, thus the length of the header (2 bytes) is included in the length in the item header. The length of the localized string itself is the number of bytes that it occupies, regardless of the number of characters that represents the string. The localized string header followed by the string together comprise the localized string item. For example, a 2 byte localized string (which may represent a single character), because of the 2 byte length of the localized string header, will have a 4 byte length in the item header.

The LSH is a 16 bit number which specifies the encoding method used for the string. Defined values for the encoding are as follows:

Encoding Code (Decimal)	*Encoding Scheme*	*Notes*
0	none	reserved
1	ISO 10646 UCS-2	Unicode 2.0
2	UTF-8	Transformation of ISO 10646 UCS-2
3	ISO 646-1991	ASCII, 7-bit
4	ISO 8859-1	ISO Latin-1, Western Europe
5	ISO 8859-11 (proposed)	Thai
6	TIS 620	Thai (will be supported by ISO 8859-11)
7	IS 13194 (1991)	ISCII
8	Shift JIS	
9	Japanese EUC-JP	
10	Korean EUC-KR	
11	Simplified Chinese GB	
12	Simplified Chinese EUC-CN	
13	Traditional Chinese Big5	
14	Traditional Chinese EUC-TW	

Encoding Codes from 15 to 32767 are reserved for future expansion. Encoding codes from 32768 to 65535 are available for custom purposes.

6.5 *Example Data Structures* — The data structures for different types of items are illustrated in the following examples:

a. An item contains one binary code 10101010.

```
bit
87654321

00100001    Item, binary, 1 length byte
00000001    1 byte long
10101010    data byte
```

b. An item contains three ASCII characters ABC.

```
01000001    Item ASCII, 1 length byte
00000011    Three bytes long
01000001    ASCII A
01000010    ASCII B
01000011    ASCII C
```

c. An item contains three binary numbers in 2-byte signed integer form.

```
01101001 Item, 2-byte integers
00000110 6 bytes total (6/2=3 integers)
   xxxxxxxx    MSByte number x
   xxxxxxxx    LSByte number x
   yyyyyyyy    MSByte number y
   yyyyyyyy    LSByte number y
   zzzzzzzz    MSByte number z
   zzzzzzzz    LSByte number z
```

d. An item contains one 4-byte IEEE floating point number.

```
10010001    Item, 4-byte floating point
00000100    4 bytes (4/4=1 number)
ffffffff
ffffffff    Floating point number
ffffffff    in IEEE 754
ffffffff
```

e. A message is sent from device 66 telling the host that the temperature at point T1 has exceeded a preset process limit. The message ID is stream 5, function 1, and the data consists of a list of three items. The first item is a code for the alarm set and the alarm category code. The second item is the equipment-specific alarm number for this alarm (e.g., 17). The third item is a string of text giving a brief description of the alarm (e.g., " T1 HIGH.") No reply is requested. The complete message including the header is as follows:

```
10000000    R=1 (to the host)
01000010    Device Code=66
00000101    Stream 5, W=0
00000001    Function 1
10000000    E=1
00000001    Block 1
00000000
00000000    System bytes=0
00000000
00000000
00000001    List
00000011    3 Elements
00100001    Binary Item next byte length
00000001    1 byte long
00000100    Alarm set, category 4
01100101    Item, 1-byte integer, next byte length
00000001    1 byte long
00010001    Alarm 17
01000001    Item, ASCII, next byte length
00000111    7 characters
01010100    ASCII T
00110001    ASCII 1
00100000    ASCII space
01001000    ASCII H
01001001    ASCII I
01000111    ASCII G
01001000    ASCII H
```

The entire message contains 17 bytes of data, 1-byte length (not shown), 10 bytes of header, and 2 bytes checksum (not shown) for a total of 30 bytes. At 9600 baud transmission, the message would be sent in 31 milliseconds.

6.6 *Data Item Dictionary* — This section defines the data items used in the standard SECS-II messages described in Section 7, Message Detail.

Name: A unique mnemonic name for this data item. This name is used in message definitions.

Format: The allowable item format codes which can be used for this standard data item. Item format codes are shown in octal, as described in Table 1, Item Format Codes. The notation " 3()" indicates any of the signed integer formats (30, 31, 32, 34). The notation " 4()" indicates any of the floating point formats (40, 44). The notation " 5()" indicates any of the unsigned integer formats (50, 51, 52, 54). The notation " 0" indicates that a list with user-defined structure may be used. Where more than one format is shown, a given implementation can use any of the formats specified.

Description: A description of the data item, with the meanings of specific values.

Where Used: The standard messages in which this data item appears.

ABS Format: 10

Any binary string

Where Used: S2F25, F26

ACCESSMODE Format: 51

Load Port Access Mode. Possible values are:

```
0 = Manual
1 = Auto
```

Where Used: S3F27

ACDS Format: 32, 52

After Command Codes

```
Vector of all command codes which defined command must succeed within the
same block.
```

Where Used: S7F22

ACKA Format: 11

Indicates success of a request:

```
TRUE is successful else FALSE
```

Where Used: S5F14, F15, F18; S16F2, F4, F6, F12, F14, F16, F18, F24, F26, F28, F30; S17F4, F8, F14

ACKC3 Format: 10

Acknowledge code, 1 byte

```
0   =   Accepted
>0  =   Error, not accepted
1-63 Reserved
```

Where Used; S3F6, F8, F10

ACKC5 Format: 10

Acknowledge code, 1 byte

```
0   =   Accepted
>0  =   Error, not accepted
1-63 Reserved
```

Where Used; S5F2, F4

ACKC6 Format: 10

Acknowledge code, 1 byte

```
0   =   Accepted
>0  =   Error, not accepted
1-63 Reserved
```

Where Used; S6F2, F4, F10, F12, F14

ACKC7 Format: 10

Acknowledge code, 1 byte

```
0   =   Accepted
1   =   Permission not granted
2   =   Length error
3   =   Matrix overflow
4   =   PPID not found
5   =   Mode unsupported
>5  =   Other error
6-63 Reserved
```

Where Used: S7F4, F12, F14, F16, F18, F24, F32

ACKC7A Format: 31, 51

Acknowledge Code, 1 byte

```
0   =   Accepted
1   =   MDLN is inconsistent
2   =   SOFTREV is inconsistent
3   =   Invalid CCODE
4   =   Invalid PPARM value
5   =   Other error (described by ERRW7)
6-63 Reserved
```

Where Used: S7F27

ACKC10 Format: 10

Acknowledge Code, 1 byte

```
0   =   Accepted for display
1   =   Message will not be displayed
2   =   Terminal not available
3-63 Reserved
```

Where Used: S10F2, F4, F6, F10

ACKC13 Format: 10

Return code for secondary messages 1 byte.

```
0   =   O.K.
1   =   ERROR: Try Later
2   =   ERROR: Unknown Data Set name
3   =   ERROR: Illegal Checkpoint value
4   =   ERROR: Too many open Data Sets
5   =   ERROR: Data set open too many times
6   =   ERROR: No open Data Set
7   =   ERROR: Cannot continue
8   =   ERROR: End of Data
9   =   ERROR: Handle in Use
>10 =   ERROR: Pending Transaction
11-127 Reserved
```

Where Used: S13F2, F4, F6, F8

AGENT Format: 20

Where Used: S15F11, 12, 21, 22, 25

ALCD Format: 10

Alarm code byte

```
bit 8 = 1 means alarm set
bit 8 = 0 means alarm cleared
bit 7-1 is alarm category
0   =   Not used
1   =   Personal safety
2   =   Equipment safety
3   =   Parameter control warning
4   =   Parameter control error
5   =   Irrecoverable error
6   =   Equipment status warning
7   =   Attention flags
8   =   Data integrity
>8  =   Other categories
9-63 Reserved
```

Where Used: S5F1, F6

ALED Format: 10

Alarm enable/disable code, 1 byte

```
bit 8 = 1 means enable alarm
bit 8 = 0 means disable alarm
```

Where Used: S5F3

ALID Format: 3(), 5()

Alarm identification

Where Used: S5F1, F3, F5, F6

ALTX Format: 20

Alarm text limited to 40 characters

Where Used: S5F1, F6

ATTRDATA Format: 0, 10, 20, 3(), 4(), 5(), 11

Contains a specific attribute value for a specific object.

Where Used: S1F20; S3F17, F18; S13F14, F16; S14F1, F2, F3, F4, F9, F10, F11, F12, F13, F14, F15, F16, F17, F18; S18F2, F3

ATTRID Format: 20, 5()

Identifier for an attribute for a specific type of object.

Where Used: S1F19; S3F17, F18; S13F14, F16; S14F1, F2, F3, F4, F8, F9, F10, F11, F12, F13, F14, F15, F16, F17, F18; S18F1, F3

ATTRRELN Format: 51

The relationship that a specified qualifying value has to the value of an attribute of an object instance (the value of interest):

```
0  =  The qualifying value is equal to the value of interest,
1  =  The qualifying value is not equal to the value of interest,
2  =  The qualifying value is less than the value of interest,
3  =  The qualifying value is less than or equal to the value of interest,
4  =  The qualifying value is greater than the value of interest,
5  =  The qualifying value is greater than or equal to the value of
      interest,
6  =  The qualifying value is present (contained in the set of) the value
      of interest,
7  =  The qualifying value is absent (not contained in the set of) the
      value of interest,
>7 =  Reserved.
```

Where Used: S14F1

BCDS Format: 32, 52

Before Command Codes

Vector of all command codes which defined command must precede within the same block.

Where Used: S7F22

BCEQU Format: 20, 51

Bin code equivalents

Array of all codes that are to be processed. Must be the same format as BINLT and NULBC. Zero length indicates all codes be sent.

Where Used: S12F3, F4

BINLT Format: 20, 51

The Bin List

Is an array of bin values. Format must be the same as used in NULBC and BCEQU.

Where Used: S12F7, F9, F11, F14, F16, F18

BLKDEF Format: 31, 51

Block Definition

```
Blocks define the range for before/after code checking (specified by BCDS,
IBCDS, NBCDS, ACDS, IACDS, and NACDS). BLKDEF specifies whether the command
being defined starts a block (+1), terminates a block (-1), or is within the
body of a block (0). All other values are invalid. The outermost block of
a process program is implicit, and is bounded by the first and last command
of the process program. Before/after checks for a particular command are per-
formed with all other commands in the same block and at the same nesting
level. For the purpose of before/after checking, a set of commands making up
a block is considered to be a single body command of its containing block.
This command has the before/after restrictions of the start block command
which begins the block.
```

Where Used: S7F22

BPD Format: 10

Boot program Data

Where Used: S8F2

BYTMAX Format: 3(), 5()

Byte Maximum

```
Maximum length of process program. A value of zero indicates no limit.
Negative values are invalid.
```

Where Used: S7F22

CAACK Format: 51

Carrier Action Acknowledge Code. One byte.

```
0    =   Acknowledge, command has been performed.
1    =   Invalid command
2    =   Can not perform now
3    =   Invalid data or argument
4    =   Acknowledge, request will be performed with completion signaled later
         by an event.
5    =   Rejected.  Invalid state.
6    =   Command performed with errors.
7-63     reserved.
```

Where Used: S3F18, F20, F22, F24, F26, F30, F32

CARRIERACTION Format: 20

Specifies the action requested for a carrier.

Where Used: S3F17

CARRIERID Format: 20

The identifier of a carrier.

Where Used: S3F17

CARRIERSPEC Format: 20

The object specifier for a carrier. Conforms to OBJSPEC.

Where Used: F29, F31

CATTRDATA Format: 0, 10, 20, 3(), 4(), 5(), 11

The value of a carrier attribute.

Where Used: S3F17

CATTRID Format: 20

The name of a carrier attribute.

Where Used: S3F17

CCODE Format: 32, 52

Command Code

```
Each command code corresponds to a unique process operation the machine
is capable of performing.
```

Where Used: S7F22, F23, F26, F31

CEED Format: 11

Collection event or trace enable/disable code, 1 byte

```
FALSE = Disable
TRUE = Enable
```

Where Used: S2F37; S17F5

CEID Format: 20, 3(), 5()

Collected event ID

Where Used: S2F35, F37; S6F3, F8, F9, F11, F13, F15, F17; S17F5, F9, F10, F11, F12

CEPACK Format: 0, 51

Command Enhanced Parameter Acknowledge. If a specific value of CPNAME is defined to have a CEPVAL that is a LIST, then CEPACK shall have the same structure as the corresponding list format of CEPVAL as used in S2,F49. Otherwise CEPACK will be a 1 byte integer. Enumerated:

```
0    =   No error
1    =   Parameter name (CPNAME) does not exist
2    =   Illegal value specified for CEPVAL
3    =   Illegal format specified for CEPVAL
4    =   Parameter name (CPNAME) not valid as used
5-63 Reserved
```

Where Used: S2F50

CEPVAL Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Command Enhanced Parameter Value. A specific application of CEPVAL shall always be identified with a specific value of CPNAME. A CEPVAL has the following forms: a single (non-list) value (e.g., CPVAL), a list of single items of identical format and type, or a list of items of the form.

```
L,2
  1. CPNAME
  2. CEPVAL
```

Where Used: S2F49

CKPNT Format: 54

Checkpoint as defined by the sending system

Where Used: S13F3, F6

CMDA Format: 31, 51

Command acknowledge code

```
0    =   Completed or done
1    =   Command does not exist
2    =   Cannot perform now
>2   =   Other equipment-specific error
3-63 Reserved
```

Where Used: S2F22, F28

CMDMAX Format: 3(), 5()

Command Maximum

```
Maximum number of commands to be allowed in a process program. A value of
zero indicates no limit. Negative values are invalid.
```

Where Used: S7F22

CNAME Format: 20

Command Name = 16 characters

```
Text string unique among other CNAMEs in PCD which describes the processing
done by the equipment for the corresponding CCODE.
```

Where Used: S7F22

COLCT Format: 5()

Column count in die increments

Where Used: S12F1, F4

COLHDR Format: 20

Text description of contents of TBLELT. 1 - 20 characters

Where Used: S13F13, F16

COMMACK Format: 10

Establish Communications Acknowledge Code, 1 byte

```
0   =   Accepted
1   =   Denied, Try Again
2-63 Reserved
```

Where Used: S1F14

CPACK Format: 10

Command Parameter Acknowledge Code, 1 byte

```
1   =   Parameter Name (CPNAME) does not exist
2   =   Illegal Value specified for CPVAL
3   =   Illegal Format specified for CPVAL
>3  =   Other equipment-specific error
4-63 Reserved
```

Where Used: S2F42

CPNAME Format: 20, 3(), 5()

Command Parameter Name

Where Used: S2F41, F42, F49, F50; S4F21, F29; S16F5, F27

CPVAL Format: 10, 11, 20, 21, 3(), 5()

Command Parameter Value

Where Used: S2F41, F49; S4F21, F29; S16F5, F27; S18F13

CSAACK Format: 10

Equipment Acknowledgement code, 1 byte

```
0   =   Everything correct
1   =   Busy
2   =   Invalid SPID
3   =   Invalid data
>3  =   Equipment-specific error
4-63 Reserved
```

Where Used: S2F8

CTLJOBCMD Format: 51

Control Job command codes are assigned as follows:

```
1 – CJStart
2 – CJPause
3 – CJResume
4 – CJCancel
5 – CJDeselect
6 – CJStop
7 – CJAbort
8 – CJHOQ
```

Where used: S16F27

CTLJOBID Format: 20

Identifier for Control Job. Conforms to OBJID.

Where used: S16F27

DATA Format: 20

A vector or string of unformatted data.

Where Used: S3F29, F31; S18F6,F7

DATAACK Format: 10

Acknowledge code for data.

```
0   =   Acknowledge
1   =   Unknown DATAID
2   =   At least parameter is invalid
3–63 Reserved
```

Where used: S14F22

DATAID Format: 20, 3(), 5()

Data ID

Where Used: S2F33, F35, F39, F45, F49; S3F15, F17; S4F19, F25; S6F3, F5, F7, F8, F9, F11, F13, F16, F18, F27; S13F11, F13, F15; S14F19, F21, F23; S15F27, F29, F33, F35, F37, F39, F41, F43, F45, F47; S16F1, F3, F5, F11, F13; S17F1, F5, F9

DATALENGTH Format: 3(), 5()

Total bytes to be sent

Where Used: S2F39; S3F15, F29, F31; S4F25; S6F5; S13F11; S14F23; S16F1, F11; S18F5, F7

DATASEG Format: 20

Used to identify the data requested.

Where Used: S3F29, F31; S18F5,F7

DATASRC Format: 20

Object type for Data Source Objects

Where Used: S14F1, F3, F6, F7, F8; S17F1

DATLC Format: 51

Data location

```
Location of invalid data, represented in bytes, measured from the start of
the message in question, excluding all header bytes.
```

Where Used: S12F19

DRACK Format: 10

Define Report Acknowledge Code, 1 byte

```
0   =   Accept
1   =   Denied. Insufficient space
2   =   Denied. Invalid format
3   =   Denied. At least one RPTID already defined
4   =   Denied. At least VID does not exist
>4  =   Other errors
5-63 Reserved
```

Where Used: S2F34

DSID Format: 20, 3(), 5()

Data set ID

Where Used: S6F3, F8, F9

DSNAME Format: 20

The name of the Data Set

```
The minimum length is zero. The maximum is 50 characters.
```

Where Used: S13F1, F2, F3, F4

DSPER Format: 20

Data sample period. DSPER has two allowable formats

```
Format 1: hhmmss, 6 bytes
Format 2: hhmmsscc, 8 bytes

Where “hh” is hours, “mm” is minutes, “ss” is seconds’ and “cc” is
centiseconds.

Equipment shall either (1) support only Format 1, or (2) support both Format
1 and Format 2. Equipment shall document which formats it accepts.

Equipment which supports Format 2 need not necessarily support a minimum
DSPER of 1 centisecond, nor a trace resolution of 1 centisecond, but
equipment suppliers shall document its trace performance limits.
```

Where Used: S2F23

DUTMS Format: 20

Die Units of Measure

```
Use units description per SEMI E5 Section 9.
```

Where Used: S12F1, F4

DVNAME Format: 3(), 20, 5()

Data value name

Where Used: S6F3, F8

DVVAL Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Data value

Where Used: S6F3, F8, F9

EAC Format: 10

Equipment acknowledge code, 1 byte

```
0   =   Acknowledge
1   =   Denied. At least one constant does not exist
2   =   Denied. Busy
3   =   Denied. At least one constant out of range
>3  =   Other equipment-specific error
4-63 Reserved
```

Where Used: S2F16

ECDEF Format: 10, 11, 20, 21, 3(), 4(), 5()

Equipment constant default value

Where Used: S2F30

ECID Format: 3(), 20, 5()

Equipment Constant ID

Where Used: S2F13, F15, F29, F30

ECMAX Format: 10, 11, 20, 21, 3(), 4(), 5()

Equipment constant maximum value

Where Used: S2F30

ECMIN Format: 10, 11, 20, 21, 3(), 4(), 5()

Equipment constant minimum value

Where Used: S2F30

ECNAME Format: 20

Equipment constant name

Where Used: S2F30

ECV Format: 10, 11, 20, 21, 3(), 4(), 5()

Equipment Constant Value

Where Used: S2F14, F15

EDID Format: 10, 20, 3(), 5()

Expected data Identification

```
Three possible responses.
      MEXP     EDID    EDID
      S02F03, <SPID>   A[6]
      S03Fl3, <PTN>    B[1]
      S07F03, <PPID>   A[80], B[80]
```

Where Used: S9F13

EMID Format: 10, 20

Equivalent material ID (16 bytes maximum)

Where Used: S3F9

EPD Format: 10

Executive program data

Where Used: S8F4

EQNAME Format: 20

A unique ASCII equipment identifier assigned by the factory to the equipment. Limited to a maximum of 80 characters.

Where Used: S4F29

ERACK Format: 10

Enable/Disable Event Report

Acknowledge Code, 1 byte

```
0   =   Accepted
1   =   Denied. At least one CEID does not exist
>1  =   Other Errors
2-63 Reserved
```

Where Used: S2F38

ERRCODE Format: 5()

Code identifying an error

```
 0  =  No error
 1  =  Unknown object in Object Specifier
 2  =  Unknown target object type
 3  =  Unknown object instance
 4  =  Unknown attribute name
 5  =  Read-only attribute - access denied
 6  =  Unknown object type
 7  =  Invalid attribute value
 8  =  Syntax error
 9  =  Verification error
10  =  Validation error
11  =  Object identifier in use
12  =  Parameters improperly specified
13  =  Insufficient parameters specified
14  =  Unsupported option requested
15  =  Busy
16  =  Not available for processing
17  =  Command not valid for current state
18  =  No material altered
19  =  Material partially processed
20  =  All material processed
21  =  Recipe specification related error
22  =  Failed during processing
23  =  Failed while not processing
24  =  Failed due to lack of material
25  =  Job aborted
26  =  Job stopped
27  =  Job cancelled
28  =  Cannot change selected recipe
29  =  Unknown event
30  =  Duplicate report ID
31  =  Unknown data report
32  =  Data report not linked
33  =  Unknown trace report
34  =  Duplicate trace ID
35  =  Too many data reports
36  =  Sample period out of range
37  =  Group size to large
38  =  Recovery action currently invalid
39  =  Busy with another recovery currently unable to perform the recovery
40  =  No active recovery action
41  =  Exception recovery failed
42  =  Exception recovery aborted
43  =  Invalid table element
44  =  Unknown table element
45  =  Cannot delete predefined
46  =  Invalid token
47  =  Invalid parameter
48-63 Reserved
```

Where Used: S1F20; S3F16, F30, F32; S4F20, F22, F23, F33, F35; S5F14, F15, F18; S13F14, F16; S14F2, F4, F6, F8, F10, F12, F14, F16, F18, F26, F28; S15F28, F18, F20, F22, F24, F26, F30, F32, F34, F36, F38, F40, F42, F44, F48; S16F12, F14, F16, F18, F24, F26, F28; S17F2, F4, F6, F8, F10, F12, F14

ERRTEXT Format: 20

Text string describing the error noted in the corresponding ERRCODE. Limited to 80 characters maximum.

Where Used: S1F20; S3F16, F18, F20, F22, F24, F26, F30, F32; S4F20, F22, F23, F33, F35; S5F14, F15, F18; S13F14, F16; S14F2, F4, F6, F8, F10, F12, F14, F16, F18, F26, F28; S15F28, F30, F32, F34, F36, F38, F40, F42, F44, F48; S16F12, F14, F16, F18, F24, F26, F28; S17F4, F8, F14

ERRW7 Format: 20

Text string describing error found in process program.

Where Used: S7F27

EVNTSRC Format: 20

Object type for Event Source Objects

Where Used: S17F5, F9, F10, F11, F12

EXID Format: 20

Unique identifier for the exception. Maximum length of 20 characters.

Where Used: S5F9, F11, F13, F14, F15, F17, F18

EXMESSAGE Format: 20

Text which describes the nature of the exception.

Where Used: S5F9, F11

EXRECVRA Format: 20

Text which specifies a recovery action for an exception. Maximum length of 40 bytes.

Where Used: S5F9, F13

EXTYPE Format: 20

Text which identifies the type of an exception. It is usually a single word of text.

```
"ALARM"
"ERROR"
```

Where Used: S5F9, F11; S14F1, F2, F8

FCNID Format: 51

Function Identification

Where Used: S2F43, F44

FFROT Format: 52

Film Frame Rotation

In degrees from the bottom CW. (Bottom equals zero degrees.) Zero length indicates not used.

Where Used: S12F1, F3

FILDAT Format: 10, 20

Data from the Data Set

The maximum length is the RECLEN from Open Data Set Data.

Where Used: S13F6

FNLOC Format: 52

Flat/Notch Location

In degrees from the bottom CW. (Bottom equals zero degrees.) Zero length indicates not used.

Where Used: S12F1, F3, F4

FRMLEN Format: 3(), 5()

Formatted Process Program Length

If greater than zero, indicates PPID is available as a formatted process program and its length in bytes. If zero, the PPID is not available as a formatted program. Negative values are invalid.

Where Used: S7F34

GRANT Format: 10

Grant code, 1 byte

```
0   =   Permission Granted
1   =   Busy, Try Again
2   =   No Space Available
3   =   Duplicate DATAID
>3  =   Equipment Specific Error Code
4-63 Reserved
```

Where Used: S2F2, F40; S3F16; S4F26; S13F12; S14F24; S16F2, F12

GRANT6 Format: 10

Permission to send, 1 byte

```
0   =   Permission granted
1   =   Busy, try again
2   =   Not interested
>2  =   Other errors
3-63 Reserved
```

Where Used: S6F6

GRNT1 Format: 10

Grant code, 1 byte

```
0   =   Positive response, transfer ok
1   =   Busy, try again
2   =   No space
3   =   Map too large
4   =   Duplicate ID
5   =   Material ID not found
6   =   Unknown map format
>6  =   Error
7-63 Reserved
```

Where Used: S12F6

HANDLE Format: 3(), 5()

Logical unit or channel

Where Used: S13F3, F4, F5, F6, F7, F8

HCACK Format: 10

Host Command Parameter Acknowledge Code, 1 byte

```
0   =   Acknowledge, command has been performed
1   =   Command does not exist
2   =   Cannot perform now
3   =   At least one parameter is invalid
4   =   Acknowledge, command will be performed with completion signaled later
        by an event
5   =   Rejected, Already in Desired Condition
6   =   No such object exists
7-63 Reserved
```

Where Used: S2F42, F50

HOACK Format: 11

Conveys whether the corresponding handoff activity succeeded (=True) or failed (=False)

Where Used: S4F31, F33

HOCANCELACK Format: 51

Tells whether the cancel ready message was accepted or rejected

```
0   =   Cancel Ready Accepted
1   =   Atomic Transfer Unknown
2   =   Cancel Ready Rejected - Handoff Begun
```

Where Used: S4F13

HOCMDNAME Format: 20

Identifier for the handoff command to be executed

Where Used: S4F31

HOHALTACK Format: 51

Tells whether the halt command was accepted or rejected

```
0   =   Halt Accepted
1   =   Atomic Transfer Unknown
2-63 Reserved
```

Where Used: S4F41

IACDS Format: 32, 52

Immediately After Command Codes

```
Vector of all command codes which defined command must immediately succeed
within the same block.
```

Where Used: S7F22

IBCDS Format: 32, 52

Immediately Before Command Codes

```
Vector of all command codes which defined command must immediately precede
within the same block.
```

Where Used: S7F22

IDTYP Format: 10

Id type

```
0   =   Wafer ID
1   =   Wafer Cassette ID
2   =   Film Frame ID
>2  =   Error
3-63 Reserved
```

Where Used: S12F1, F3, F4, F5, F7, F9, F11, F13, F14, F15, F16, F17, F18

INPTN Format:10, 51

A specialized version of PTN indicating the InputPort.

Where Used: S3F35

LENGTH Format: 3(), 5()

Length of the service program or process program in bytes

Where Used: S2F1; S7F1, F29

LIMITACK Format: 10

Acknowledgment code for variable limit attribute set, 1 byte

```
1   =   LIMITID does not exist
2   =   UPPERDB > LIMITMAX
3   =   LOWERDB < LIMITMIN
4   =   UPPERDB < LOWERDB
5   =   Illegal format specified for UPPERDB or LOWERDB
6   =   ASCII value cannot be translated to numeric
7   =   Duplicate limit definition for this variable
>7  =   Other equipment-specific error
8-63 Reserved
```

Where Used: S2F46

LIMITID Format: 10

The identifier of a specific limit in the set of limits (as defined by UPPERDB and LOWERDB) for a variable to which the corresponding limit attributes refer, 1 byte.

Where Used: S2F45, F46, F48

LIMITMAX Format: 11, 20, 3(), 4(), 5()

The maximum allowed value for the limit values of a specific variable. The equipment manufacturer should specify this value, which would typically coincide with the maximum value of the variable being monitored. The format must match that of the referenced variable.

Where Used: S2F48

LIMITMIN Format: 11, 20, 3(), 4(), 5()

The minimum allowed value for the limit values of a specific variable. The equipment manufacturer should specify this value, which would typically coincide with the minimum value of the variable being monitored. The format must match that of the referenced variable.

Where Used: S2F48

LINKID Format: 54

Used to link a completion message with a request that an operation be performed. LINKID is set to the value of RMOPID in the initial request except for the last completion message to be sent, where it is set to zero.

Where Used: S6F25; S14F20, F21; S15F22, F30

LLIM Format: 3(), 4(), 5()

Lower limit for numeric value

Where Used: S7F22

LOC Format: 10

Machine material location code, 1 byte

Where Used: S2F27; S3F2

LOCID Format: 20

The logical identifier of a material location.

Where used: S3F29, F31

LOWERDB Format: 11, 20, 3(), 4(), 5()

A variable limit attribute which defines the lower boundary of the deadband of a limit. The value applies to a single limit (LIMITID) for a specified VID. Thus, UPPERDB and LOWERDB as a pair define a limit.

Where Used: S2F45, F48

LRACK Format: 10

Link Report Acknowledge Code, 1 byte

```
0   =   Accepted
1   =   Denied. Insufficient space
2   =   Denied. Invalid format
3   =   Denied. At least one CEID link already defined
4   =   Denied. At least one CEID does not exist
5   =   Denied. At least one RPTID does not exist
>5  =   Other errors
6-63 Reserved
```

Where Used: S2F36

LVACK Format: 10

Variable limit definition acknowledge code, 1 byte. Defines the error with the limit attributes for the referenceVID.

```
1   =   Variable does not exist
2   =   Variable has no limits capability
3   =   Variable repeated in message
4   =   Limit value error as described in LIMITACK
5-63 Reserved
```

Where Used: S2F46

MAPER Format: 10

Map Error

```
0   =   ID not found
1   =   Invalid Data
2   =   Format Error
>2  =   Invalid error
3-63 Reserved
```

Where Used: S12F19

MAPFT Format: 10

Map data format type

```
0   =   Row format
1   =   Array format
2   =   Coordinate format
>2  =   Error
3-63 Reserved
```

Where Used: S12F3, F5

MCINDEX Format: 5()

Identifier used to link a handoff command message with its eventual completion message. Corresponding messages carry the same value for this data item.

Where Used: S4F31, F33

MDACK Format: 10

Map data acknowledge

```
0   =   Map received
1   =   Format error
2   =   No ID match
3   =   Abort/discard map
>3  =   Error
4-63 Reserved
```

Where Used: S12F8, F10, F12

MDLN Format: 20

Equipment Model Type, 6 bytes max

```
Same data as returned by S1,F2
```

Where Used: S1F2, F13, F14; S7F22, F23, F26, F31

MEXP Format: 20

Message expected in the form SxxFyy where x is stream and y is function.

Where Used: S9F13

MF Format: 10, 20

Material format code 1 byte by Format 10

```
 Items with format 10 will be encoded as follows:
 1   =   Quantities in wafers
 2   =   Quantities in cassette
 3   =   Quantities in die or chips
 4   =   Quantities in boats
 5   =   Quantities in ingots
 6   =   Quantities in leadframes
 7   =   Quantities in lots
 8   =   Quantities in magazines
 9   =   Quantities in packages
10   =   Quantities in plates
11   =   Quantities in tubes
12   =   Quantities in waterframes
13   =   Quantities in carriers
14   =   Quantities in substrates
15-63 Reserved
Items with format 20 will be a unit identifier for one of the special SECS
generic units, as specified in Section 9
```

Where Used: S3F2, F4, F5, F7 S16F11, F13, F15

MHEAD Format: 10

SECS message block header associated with message block in error

Where Used: S9F1, F3, F5, F7, F11

MID Format: 10, 20

Material ID

```
80 Characters maximum
```

Where Used: S2F27; S3F2, F4, F7, F9, F12, F13; S4F1, F3, F5, F7, F9, F11, F13, F15, F17; S7F7, F8, F10, F11, F13, F35, F36; S12F1, F3, F4, F5, F7, F9, F11, F13, F14, F15, F16, F17, F18; S16F11, F13, F15; S18F10, F11

MIDAC Format: 10

Material ID Acknowledge Code, 1 byte

```
0   =   Accepted
1   =   Invalid port number
2   =   Material is not present at identified port
>2  =   Error
3-63 Reserved
```

Where Used: S3F14

MIDRA Format: 10

Material ID Acknowledge Code, 1 byte

```
0   =   Acknowledge, MID follows
1   =   Acknowledge, will not send MID
2   =   Acknowledge, will send MID later in S3F13
3-63 Reserved
```

Where Used: S3F12

MLCL Format: 5()

Message length

```
Defined by message size in (bytes)
```

Where Used: S12F4, F5

MMODE Format: 10

Matrix mode select, 1 byte

```
1 = Host source mode
    Use S7F7 and F8 to define the process program to be used.
2 = Local source mode
    Use the matrix defined by S7F9, F10, F11 and F13 to define the process
    program to be used. The equipment will initialize to local source mode at
    power up. The equipment will default to local source mode from host
    source mode in the event of loss of communication with the host.
3 = Host immediate mode
    Use the current process program for all material unless changed by S7F1-
    F4. The timing of the mode change is equipment-specific
```

Where Used: S7F15

NACDS Format: 32, 52

Not After Command Codes

```
Vector of all command codes which defined command may not succeed within the
same block.
```

Where Used: S7F22

NBCDS Format: 32, 52

Not Before Command Codes

```
Vector of all command codes which defined command may not precede within the
same block.
```

Where Used: S7F22

NULBC Format: 20, 51

Null bin code value

```
This value is the bin code value that is used for no die at a location.
(For X/Y coordinate format the ASCII value is a value with "n" length. For
other map formats, ASCII is a single byte per bin with "n" length per item;
thus, the total number of bins is the length, i.e., length "n"=10 for ASCII
format is 10 single byte bin codes.) The format used must be the same as the
one used for BINLT and BCEQU. Zero length indicates not used.
```

Where Used: S12F1, F3, F4

OBJACK Format: 51

Acknowledge code:

```
0   =   Successful completion of requested data
1   =   Error
>1 Reserved
```

Where Used: S14F2, F4, F6, F8, F10, F12, F14, F16, F18, F26, F28

OBJCMD Format: 51

Specifies an action to be performed by an object:

```
0   =   Reserved
1   =   Attach to requestor
2   =   Detach from requestor (requires authorization token)
3   =   Reattach to requestor
4   =   Set attributes (requires authorization token)
>4 Reserved
```

OBJID Format: 20, 5()

Identifier for an object

Where Used: S1F19; S14F1, F2, F3, F4

OBJSPEC Format: 20

A text string that has an internal format and that is used to point to a specific object instance. The string is formed out of a sequence of formatted substrings, each specifying an object’s type and identifier. The substring format has the following four fields:

```
object type, colon character “:”, object identifier, greater-than symbol “>”
```

where the colon character “:” is used to terminate an object type and the “greater than” symbol “>” is used to terminate an identifier field. The object type field may be omitted where it may be otherwise determined. The final “>” is optional.

Where Used: S2F49; S13F11, F13, F15; S14F1, F3, F5, F7, F9, F10, F11, F13, F15, F16, F17, F19, F25, F27; S15F43, F47

OBJTOKEN Format: 54

Token used for authorization.

Where Used: S14F14, F15; S15F37, F39, F41, F43

OBJTYPE Format: 20, 5()

Identifier for a group or class of objects. All objects of the same type must have the same set of attributes available.

Where Used: S1F19; S14F1, F3, F6, F7, F8, F25, F26, F27

OFLACK Format: 10

Acknowledge code for OFF-LINE request.

```
0   =   OFF-LINE Acknowledge
1-63 Reserved
```

Where Used: S1F16

ONLACK Format: 10

Acknowledge code for ON-LINE request.

```
0   =   ON-LINE Accepted
1   =   ON-LINE Not Allowed
2   =   Equipment Already ON-LINE
3-63 Reserved
```

Where Used: S1F18

OPID Format: 5()

Operation ID. A unique integer generated by the requestor of an operation, used where multiple completion confirmations may occur.

Where Used: S6F25; S14F19, F21; S15F21, F29, F30, F37, F41, F44, F46

ORLOC Format: 10

Origin Location

```
implicit value of (0,0)
0   =   Center die of wafer
(Determined by:

row or column count +1
            2

            truncated)
1   =   Upper right
2   =   Upper left
3   =   Lower left
4   =   Lower right
>4  =   Error
5-63 Reserved
Zero length indicates not available
```

Where Used: S12F1, F3, F4

OUTPTN Format: 10, 51

A specialized version of PTN indicating the OutPutPort

Where Used: S3F35

PARAMNAME Format: 20

The name of a parameter in a request.

Where Used: S3F21,F23

PARAMVAL Format: 1, 10, 11, 20, 3(), 4(), 5()

The value of the parameter named in PARAMNAME. Values that are lists are restricted to lists of single items of the same format type.

Where Used: S3F21,F23

PDFLT Format: 11, 20, 3(), 4(), 5()

Parameter Default Value

```
Specifies default value and data type of parameter. If no defaults are
provided, item data length will be zero. For numeric or Boolean data,
the default item may be a multi-varied vector if the parameter itself
can be a vector.
If RQPAR is false:
Position of data in a default item is significant. When obtaining a
default value to be used in the Nth position of a vector parameter, the
value is obtained from the Nth position of the default item. If the
default item has L entries, no default value will be provided for the
L+1,...,PMAX parameter entries.
If RQPAR is true:
The length of the default vector (L) specifies the minimum number of
entries which must be entered for the parameter. If > PMAX, only PMAX
entries are required.
```

Where Used: S7F22

PFCD Format: 10

Predefined form code, 1 byte

Where Used: S6F9

PGRPACTION Format: 20

The action to be performed on a port group.

Where Used: S3F23

PMAX Format: 3(), 5()

Parameter Count Maximum

```
Maximum amount of data to be accepted by the host for this parameter. When a
conflict arises between value of PMAX and length of PDFLT, PMAX takes
precedence.
For numeric and Boolean parameters:
   PMAX < 0 invalid
   PMAX = 0 specifies there is no upper bound
   PMAX = 1 specified a single value is expected
   PMAX > 1 specifies a vector of values is expected with a maximum of PMAX
        entries
For string parameters:
   PMAX < 0 invalid
   PMAX = 0 specifies there is no upper bound
   PMAX > 0 maximum length of parameter string
```

Where Used: S7F22

PNAME Format: 20

Parameter Name ≤ 16 characters

```
Text string identifying the parameter value expected by its parent process
command.
```

Where Used: S7F22

PORTACTION Format: 20

The action to be performed on a port.

Where Used: S3F25

PORTGRPNAME Format: 20

The identifier of a group of ports.

Where Used: S3F21,F23

PPARM Format: 11, 20, 3(), 4(), 5()

Process Parameter

```
Numeric or Boolean SECS data item, single or multiple value, or text string
which provides information required to complete the process command to
which the parameter refers.
```

Where Used: S7F23, F26, F31

PPBODY Format: 10, 20, 3(), 5()

Process program body

```
The process program describes to the equipment, in its own language, the
actions to be taken in processing the material it receives.
```

Where Used: S7F3, F6, F36

PPGNT Format: 10

Process program grant status, 1 byte

```
0   =   OK
1   =   Already have
2   =   No space
3   =   Invalid PPID
4   =   Busy, try later
5   =   Will not accept
>5  =   Other error
6-63 Reserved
```

Where Used: S7F2, F30

PPID Format: 10, 20

Process program ID.

```
Limited to a maximum of 80 bytes.
The format used in the PPID will be host-dependent. For internal use of the
equipment, the PPID can be treated as a unique binary pattern. If the local
equipment is not prepared to display the transmitted code, the display
should be in hexadecimal form.
```

Where Used: S2F27; S7F1, F3, F5, F6, F8, F10, F11, F13, F17, F20, F23, F25, F26, F27, F31, F33, F34, F36; S9F13

PRAXI Format: 10

Process axis.

```
0   =   Rows (X-axis), top, increasing
1   =   Rows (X-axis), top, decreasing
2   =   Rows (X-axis), bottom, increasing
3   =   Rows (X-axis), bottom, decreasing
4   =   Columns (Y-axis), left, increasing
5   =   Columns (Y-axis), left, decreasing
6   =   Columns (Y-axis), right, increasing
7   =   Columns (Y-axis), right, decreasing
>7  =   Error
8-63 Reserved
```

Where Used: S12F1, F3

PRCMDNAME Format: 20

Commands sent to a process job:

“START”
“STOP”
“PAUSE”
“RESUME”
“ABORT”
“CANCEL”

Where Used: S16F5

PRDCT Format: 5()

Process Die Count

```
Number of die to be processed or number of die which have been processed.
(Zero length indicates not used.)
```

Where Used: S12F1, F4

PREVENTID Format: 5()

Processing related event identification:

```
1 = Waiting for material
2 = Job state change
```

Where Used: S16F9

PRJOBID Format: 20

Text string which uniquely identifies a process job.

Where Used: S16F4, F5, F6, F7, F9, F11, F12, F13, F14, F15, F16, F17, F20, F23, F25

PRJOBMILESTONE Format: 5()

Notification of Processing status shall have one of the following values:

```
1 = Job Setup
2 = Job Processing
3 = Job Processing Complete
4 = Job Complete
5 = Job Waiting for Start
```

Where Used: S16F7

PRJOBSPACE Format: 52

The number of process jobs that can be created.

Where used: S16F22

PRMTRLORDER Format: 51

Defines the order by which material in the process jobs material list will be processed. Possible values are assigned as follows:

```
1 – ARRIVAL – process whichever material first arrives
2 – OPTIMIZE – process in an order that maximizes throughput
3 – LIST – follow the order in the list
```

Where used: S16F29

PRPAUSEEVENT Format: 00

The list of event identifiers, which may be sent as an attribute value to a process job. When a process job encounters one of these events it will pause, until it receives the PRJobCommand RESUME.

Where used: S16F11, F13, F15

PRPROCESSSTART Format: 11

Indicates that the process resource start processing immediately when ready:

```
TRUE – Automatic Start
FALSE – Manual Start
```

Where used: S16F11, S16F13, S16F15, S16F25

PRRECIPEMETHOD Format: 51

Indicates the recipe specification type, whether tuning is applied and which method is used.:

```
1 – Recipe only
2 – Recipe with variable tuning
```

Where used: S16F11, S16F13, S16F15

PRSTATE Format: 51

Enumerated value, 1 byte

Where used: S16,F20

PTN Format: 10, 51

Material Port number, 1 byte

Where Used: S3F17, F21, F25; S4F1, F3, F5, F7, F9, F11, F13, F15, F17; S16F13, F17, F21

QUA Format: 10

Quantity in format, 1 byte

Where Used: S3F2, F4, F5, F7

RAC Format: 31, 51

Reset acknowledge, 1 byte

```
0   =   Reset to be done
1   =   Reset denied
>1  =   Other errors
2-63 Reserved
```

Where Used: S2F20

RCMD Format: 20, 31, 51

Remote command code or string

Where Used: S2F21, F41, F49

RCPATTRDATA Format: 0, 10, 11, 20, 3(), 4(), 5()

The contents (value) of a recipe attribute.

Where Used: S6F25; S15F13, F15, F18, F27, F28, F30, F32

RCPATTRID Format: 20

The name (identifier) of a non-identifier recipe attribute.

Where Used: S6F25; S15F13, F15, F18, F27, F28, F30, F32

RCPBODY Format: 10, 20, 3(), 5()

Recipe body

Where Used: S15F13, F15, F18, F27, F32

RCPCLASS Format: 20

Recipe class

Where Used: S15F11

RCPCMD Format: 51

Indicates an action to be performed on a recipe

```
 5   =   Delete
 8   =   Unprotect
 9   =   Protect
10   =   Verify
11   =   Link
12   =   Unlink
13   =   Certify
14   =   De-certify
15   =   Download
16   =   Upload
0-4, 6-7, 17-63 Reserved
```

Where Used: S15F21, F22

RCPDEL Format: 51

```
0   =   Delete
1   =   Deselect
>1 Reserved
```

Where Used: S15F35

RCPDESCLTH Format: 5()

The length in bytes of a recipe section.

Where Used: S15F24

RCPDESCNM Format: 20

Identifies a type of descriptor of a recipe: “ASDesc”, “BodyDesc”, “GenDesc”.

Where Used: S15F24

RCPDESCTIME Format: 20

The timestamp of a recipe section, in the format “YYYYMMDDhhmmsscc”.

Where Used: S15F24

RCPID Format: 20

Recipe identifier. Formatted text conforming to the requirements of OBJSPEC.

Where Used: S15F21, F23, F28, F29, F30, F33, F35, F37, F41, F44

RCPNAME Format: 20

Recipe name

Where Used: S15F11

RCPNEWID Format: 20

The new recipe identifier assigned as the result of a copy or rename operation.

Where Used: S15F19, F41, F44

RCPOWCODE Format: 11

Indicates whether any pre-existing recipe is to be overwritten (=TRUE) or not (=FALSE) on download.

Where Used: S15F27

RCPPARNM Format: 20

The name of a recipe variable parameter. Maximum length of 40 characters.

Where Used: S15F25, F33; S16F3, F11, F13, F15, F23

RCPPARRULE Format: 20

The restrictions applied to a recipe variable parameter setting. Maximum length of 80 characters.

Where Used: S15F25

RCPPARVAL Format: 10, 11, 20, 3(), 4(), 5()

The initial setting assigned to a recipe variable parameter. Text form restricted to maximum of 80 characters.

Where Used: S15F25, F33; S16F3, F11, F13, F15, F23

RCPRENAME Format: 11

Indicates whether a recipe is to be renamed (= TRUE) or copied (= FALSE).

Where Used: S15F19

RCPSECCODE Format: 10

Indicates the sections of a recipe requested for transfer or being transferred:

```
 1   =   Generic attributes only
 3   =   Generic attributes and body
 4   =   All agent-specific datasets (zero or more)
 7   =   Generic attributes, body, and all agent-specific datasets
 8   =   Single agent-specific dataset (zero or one)
11   =   Generic attributes, body, and single agent-specific datasets
All other values reserved
```

Where Used: S15F15, F16, F17

RCPSECNM Format: 20

Recipe section name: “Generic”, “Body”, or “ASDS”.

Where Used: S15F15, F18

RCPSPEC Format: 20

Recipe specifier. The object specifier of a recipe.

Where Used: S15F1, F9, F13, F15, F17, F19, F27, F28, F31, F32, F45; S16F11, F13, F15, F23

RCPSTAT Format: 51

The status of a managed recipe

```
0   =   Does not exist
8   =   Unprotected
9   =   Protected
```

Where Used: S15F10

RCPUPDT Format: 11

Indicates if an existing recipe is to be updated (= True) or a new recipe is to be created (= False).

Where Used: S15F13

RCPVERS Format: 20

Recipe version

Where Used: S15F10, F12

READLN Format: 3(), 5()

Maximum length to read

Where Used: S13F5

RECLEN Format: 3(), 5()

Maximum length of a Discrete record

Where Used: S13F4

REFP Format: 3()

Reference Point

Where Used: S12F1, F4

REPGSZ Format: 20, 3(), 5()

Reporting group size

Where Used: S2F23; S17F5

RESC Format: 31, 51

Resolution code for numeric data

```
1 = Absolute. Value may be specified to nearest increment of RESV
2 = Significant Digits. Value may be specified with no more significant
    digits than RESV allows
```

Where Used: S7F22

RESPEC Format: 20

Object specifier for the recipe executor

Where Used: S15F29, F33, F35

RESV Format: 3(), 4(), 5()

Resolution value for numeric data

```
If RESC=1, then RESV contains smallest increment allowed for parameter
```

Where Used: S7F22

RETICLEID Format: 20

The object identifier for a reticle. Conforms to OBJSPEC

Where Used: S3F35

RETPLACEINSTR Format: 51

Instructions to indicate which pod slots will have reticles placed. Possible values for ReticlePlacementInstruction are

```
0 = PLACE
1 = PASS BY
```

Where Used: S3F35

RETREMOVEINSTR Format: 51

Instructions to indicate which pod slots will have reticles removed

```
0 = REMOVE
1 = PASS BY
```

Where Used: S3F35

RIC Format: 31, 51

Reset code, 1 byte

```
0   =   Not used
1   =   Power up reset
>1 Other reset conditions
2-63 Reserved
```

Where Used: S2F19

RMACK Format: 51

Conveys whether a requested action was successfully completed, denied, completed with errors, or will be completed with notification to the requestor.

```
0   =   Successful completion
1   =   Cannot perform action
2   =   Completed with errors
3   =   Action will be completed and notification sent
4   =   No request for this action exists
```

Where Used: S15F4, F6, F8, F10, F12, F14, F16, F18, F20, F22, F24, F25, F26, F28, F30, F32, F34, F36, F38, F40, F42, F44, F48

RMCHGSTAT Format: 5()

Indicates the change that occurred for an object.

```
 0   =   No change
 1   =   Created
 2   =   Updated
 3   =   Stored (new)
 4   =   Replaced
 5   =   Deleted
 6   =   Copied (new object)
 7   =   Renamed
 8   =   Unprotected
 9   =   Protected
10   =   Verified
11   =   Linked
12   =   Unlinked
13   =   Certified
14   =   De-certified
15   =   Selected
16   =   Deselected
```

Where Used: S15F25

RMCHGTYPE Format: 5()

Indicates the type of change for a recipe.

```
 0   =   No change
 1   =   Create
 2   =   Update
 5   =   Delete
 6   =   Copy (new object)
 7   =   Rename
 8   =   Unprotect
 9   =   Product
10   =   Verify
11   =   Link
12   =   Unlink
13   =   Certify
14   =   De-certify
15   =   Change generic attribute
16   =   Change agent-specific attribute
17   =   Change both generic and agent-specific attributes
```

Where Used: S15F37, F41, F44, F46, F47, F48

RMDATASIZE Format: 5()

The maximum total length, in bytes, of a multi-block message, used by the receiver to determine if the anticipated message exceeds the receiver's capacity.

Where Used: S15F1

RMGRNT Format: 10

Grant code, used to grant or deny a request. 1 byte.

```
0   =   Permission granted
1   =   Cannot accept now, try again
2   =   No space
3   =   Request is on hold
4-64 Reserved
```

Where Used: S15F2, F37, F46

RMNEWNS Format: 20

New name (identifier) assigned to a recipe namespace

Where Used: S15F5

RMNSCMD Format: 51

Action to be performed on a recipe namespace

```
1   =   Created
5   =   Deleted
0, 2-4, 6-63 Reserved
```

Where Used: S15F3

RMNSSPEC Format: 20

The object specifier of a recipe namespace.

Where Used: S15F3, F5, F7, F11, F21, F23, F25, F47

RMRECSPEC Format: 20

The object specifier of a distributed recipe namespace recorder.

Where Used: S15F39, F41, F43

RMREQUESTOR Format: 11

Set to TRUE if initiator of change request was an attached segment. Set to FALSE otherwise.

Where Used: S15F41, F44, F46

RMSEGSPEC Format: 20

The object specifier of a distributed recipe namespace segment.

Where Used: S15F37, F39, F41, F44, F46, F47

RMSPACE Format: 5()

The amount of storage available for at least one recipe in a recipe namespace, in bytes.

Where Used: S15F8

ROWCT Format: 5()

Row count in die increments

Where Used: S12F1, F4

RPMACK Format: 51

Reticle Pod management service acknowledge code. One byte

```
0 = Acknowledge, service has been performed
1 = Service does not exist
2 = Can not perform now
3 = At least parameter does not exist
4 = Acknowledge, service will be performed with completion notified with
with parameters for response
5 = Service is not completed or prohibited
6 = No such object exists
7-63 reserved
```

RPMDESTLOC Format: 20

The LocationID towards which a reticle must be moved. Conforms to OBJID.

Where Used: S14F19

RPMSOURLOC

The LocationID of the location from which to pick-up a reticle for moving it to another location. Conforms to OBJID.

Where Used: S14F19

RPSEL Format: 51

Reference Point Select

```
Number of reference point from 0-n.
```

Where Used: S12F1, F4

RPTID Format: 20, 3(), 5()

Report ID

Where Used: S2F33, F35; S6F11, F13, F16, F11, F19, F21, F22; S17F1, F2, F3, F4, F5, F9, F11, F12

RPTOC Format: 11

A Trace Object attribute for a flag which, if set TRUE, causes only variables which have changed during the sample period to be included in a report.

Where Used: S14F1, F2, F3, F4; S17F5

RQCMD Format: 11

Required Command

```
True = Command must be specified
False = Command is optional
```

Where Used: S7F22

RQPAR Format: 11

Required Parameter

```
True = Parameter must be specified
False = Parameter is optional
```

Where Used: S7F22

RRACK Format: 10

Request to Receive Acknowledge code, 1 byte

```
0   =   Acknowledge, OK (note that 'OK' differs from 'ready')
1   =   Invalid port number
2   =   Requested material is not at identified port
3   =   Busy. Try again
4   =   Sender does not have permission to perform this operation
5-63 Reserved
```

Where Used: S4F18

RSACK Format: 10

Ready to Send Acknowledge code, 1 byte

```
0   =   Acknowledge, OK (note that 'OK' differs from 'ready')
1   =   Invalid port number
2   =   Port is already occupied
3   =   Busy, unable to move material at this time. Try again
4   =   Receiver does not have permission to perform this operation
5-63 Reserved
```

Where Used: S4F2

RSDA Format: 10

Request Spool Data Acknowledge

```
0   =   OK
1   =   Denied, busy try later
2   =   Denied, spooled data does not exist
3-63 Reserved
```

Where Used: S6F24

RSDC Format: 51

Request Spool Data Code

```
0   =   Transmit Spooled Messages
1   =   Purge Spooled Messages
2-63 Reserved
```

Where Used: S6F23

RSINF Format: 3()

Starting location for row or column. This item consists of 3 values (x,y, direction). If direction value is negative, it equals decreasing direction. If the value is positive, it equals increasing direction. Direction must be a non-zero value.

Where Used: S12F7, F14

RSPACK Format: 10

Reset Spooling Acknowledge

```
0   =   Acknowledge, spooling setup accepted
1   =   Spooling setup rejected
2-63 Reserved
```

Where Used: S2F44

RTYPE Format: 3(), 5()

Type of record

```
0   =   Stream
1   =   Discrete
2-63 Reserved
```

Where Used: S13F4

SDACK Format: 10

Map set-up data acknowledge

```
0   =   Received data
>1  =   Error
1-63 Reserved
```

Where Used: S12F2

SDBIN Format: 10

Send bin information flag

```
0   =   Sent bin information
1   =   Don't send bin information
>1  =   Error
2-63 Reserved
```

Where Used: S12F17

SEQNUM Format: 3(), 5()

Command Number

```
Value which identifies a unique process program command by its position in
the list of commands relative to the first. For the first command of the
process program, SEQNUM is l.
```

Where Used: S7F27

SFCD Format: 10

Status form code, 1 byte

Where Used: S1F5

SHEAD Format: 10

Stored header related to the transaction timer

Where Used: S9F9

SLOTID Format: 51

Used to reference material by slot (a position that holds material/substrates) in a carrier. This item may be implemented as an array in some messages.

Where used: S16F11, F13, F15

SMPLN Format: 3(), 5()

Sample number

Where Used: S6F1

SOFTREV Format: 20

Software revision code 6 bytes maximum

Where Used: S1F2, F13, F14; S7F22, F23, F26, F31

SPAACK Format: 10

Equipment acknowledgement code, 1 byte

```
0   = Everything correct
1   = Invalid data
>1  = Equipment-specific error
2-63 Reserved
```

Where Used: S2F4

SPD Format: 10

Service program data

Where Used: S2F3, F6

SPID Format: 20

Service program ID, 6 characters

Where Used: S2F1, F5, F7, F9, F12; S9F13

SPNAME Format: 20

Service parameter name defined in specific standard. If service parameter is defined as an object attribute, this is completely the same as ATTRID except format restrictions above.

Where used: S14F19, F20, F21, F28

SPR Format: Device Dependent

Service program results

```
Device dependent
```

Where Used: S2F10

SPVAL Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Service parameter value, corresponding to SPNAME. If service parameter is defined as an object attribute, this is completely the same as ATTRDATA except format restrictions for the attribute.

Where used: S14F19, F20, F21

SSACK Format: 20

Indicates the success or failure of a requested action. Two characters.

Where Used: S18F2, F4, F6, F8, F10, F12, F14

SSCMD Format: 20

Indicates an action to be performed by the subsystem.

Where Used: S18F13

STATUS Format: 20

Provides status information for a subsystem component. Used in the data item STATUSLIST.

Where Used: See STATUSLIST.

STATUSLIST Format: 0

A list of STATUS data sent in a fixed order. STATUSLIST has the following form:

```
L,s
  1. <STATUS_1>
  .
  s. <STATUS_s>
```

Where used: S18F4, F8, F10, F12, F14

STEMP Format: 20

```
String template. ASCII text string acceptable to equipment as a parameter
value. A data string matches a template string if the data string is at
least as long as the template and each character of the data string matches
the corresponding character of the template. A null list indicates all
user data is acceptable to the machine.
```

Where Used: S7F22

STIME Format: 20

Sample time, 12 or 16 bytes

```
If 12 bytes the format is YYMMDDhhmmss
YY=Year                   00 to 99
MM=Month                  01 to 12
DD=Day                    01 to 31
hh=Hour                   00 to 23
mm=Minute                 00 to 59
ss=Second                 00 to 59
If 16 bytes the format is YYYYMMDDhhmmsscc
YYYY=Year                 0000 to 9999
MM=Month                  01 to 12
DD=Day                    01 to 31
hh=Hour                   00 to 23
mm=Minute                 00 to 59
ss=Second                 00 to 59
cc=Centisecond            00 to 99
```

NOTE 4: The 16-byte format is currently optional. After January 1, 1998, the 16-byte format shall be required on new and updated implementations. Support for the 12-byte format shall be supported as a configurable option using the equipment constant TimeFormat. This is a format requirement only and does not imply either precision or accuracy.

Where Used: S6F1

STRACK Format: 10

Spool Stream Acknowledge

```
1   =   Spooling not allowed for stream (i.e., Stream 1)
2   =   Stream unknown
3   =   Unknown function specified for this stream
4   =   Secondary function specified for this stream
```

Where Used: S2F44

STRID Format: 51

Stream Identification

Where Used: S2F43, F44

STRP Format: 3()

Starting position in die coordinate position. Must be in (X,Y) order.

Where Used: S12F9, F16

SV Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Status variable value

Where Used: S1F4; S6F1

SVCACK Format: 10

Service acceptance acknowledge code, 1 byte.

```
0   =   Acknowledge, service has been performed
1   =   Service does not exist
2   =   Cannot perform now
3   =   At least parameter is invalid
4   =   Acknowledge, service will be performed with completion notified later
        with parameters for response
5   =   Service is not completed or prohibited
6   =   No such object exists
7-63 Reserved
```

Where used: S14F20

SVCNAME Format: 20

Service name provided on specified object asking by the host.

Where used: S14F19, F26, F27, F28

SVID Format: 20, 3(), 5()

Status variable ID

```
Status variables may include any parameter that can be sampled in time such
as temperature or quantity of a consumable.
```

Where Used: S1F3, F11, F12; S2F23

SVNAME Format: 20

Status Variable Name

Where Used: S1F12

TARGETID Format: 20

Description. Identifies where a request for action or data is to be applied. If text, conforms to OBJSPEC.

Where Used: S18F1, F3, F5, F7, F9, F11, F13

TARGETSPEC Format: 20

Object specifier of target object

Where Used: S14F17; S15F43

TBLACK Format: 51

Indicates success or failure

```
0   =   Success
1   =   Failure
```

Where Used: S13F14, F16

TBLCMD Format: 51

Provides information about the table or parts of the table being transferred or requested. Enumerated:

```
0   =   Complete Table
1   =   New rows (add)
2   =   New columns (append)
3   =   Replace existing rows
4   =   Replace existing columns
```

Where Used: S13F13, F15

TBLELT Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Table element. The first table element in a row is used to identify the row.

Where Used: S13F13, F15, F16

TBLID Format: 20

Table identifier. Text conforming to the requirements of OBJSPEC.

Where Used: S13F13, F15, F16

TBLTYP Format: 20

A reserved text string to denote the format and application of the table. Text conforming to the requirements of OBJSPEC.

Where Used: S13F13, F15, F16

TEXT Format: 10, 20, 22, 3(), 5()

A single line of characters

Where Used: S10F1, F3, F5, F9

TIAACK Format: 10

Equipment acknowledgement code, 1 byte

```
0   =   Everything correct
1   =   Too many SVIDs
2   =   No more traces allowed
3   =   Invalid period
>3  =   Equipment-specified error
4-63 Reserved
```

Where Used: S2F24

TIACK Format: 10

Time Acknowledge Code, 1 byte

```
0   =   OK
1   =   Error, not done
2-63 Reserved
```

Where Used: S2F32

TID Format: 10

Terminal number, 1 byte

```
0   =   Single or main terminal
>0  =   Additional terminals at the same equipment
```

Where Used: S10F1, F3, F5, F7

TIME Format: 20

Time of day, 12 or 16 bytes

```
If 12 bytes the format is YYMMDDhhmmss
YY=Year                   00 to 99
MM=Month                  01 to 12
DD=Day                    01 to 31
hh=Hour                   00 to 23
mm=Minute                 0000 to 9999
ss=Second                 00 to 59
If 16 bytes the format is YYYYMMDDhhmmsscc
YYYY=Year                 0000 to 9999
MM=Month                  01 to 12
DD=Day                    01 to 31
hh=Hour                   00 to 23
mm=Minute                 00 to 59
ss=Second                 00 to 59
cc=Centisecond            00 to 99
```

NOTE 5: The 16-byte format is currently optional. After January 1, 1998, the 16-byte format shall be required on new and updated implementations. Support for the 12-byte format shall be supported as a configurable option using the equipment constant TimeFormat. This is a format requirement only and does not imply either precision or accuracy.

Where Used: S2F18, F31

TIMESTAMP Format: 20

A text string indicating the time of an event, which encodes time in the following format:

```
YYYYMMDDhhmmsscc
YYYY = year               0000 to 9999
MM = month                01 to 12
DD = day                  01 to 31
hh = hour                 00 to 23
mm = minute               00 to 59
ss = second               00 to 59
cc = centisecond          00 to 99
```

Where Used: S5F9, F11, F15; S15F41, F44; S16F5, F7, F9

TOTSMP Format: 20, 3(), 5()

Total samples to be made

Where Used: S2F23; S17F5

TRACK Format: 11

Tells whether the related transfer activity was successful (=True) or unsuccessful (=False).

Where Used: S4F20, F22, F23

TRATOMICID Format: 5()

Equipment assigned identifier for an atomic transfer

Where Used: S4F20

TRAUTOD Format: 11

A Trace Object attribute for a control flag which, if set TRUE, causes the Trace Object to delete itself when it has completed a report.

Where Used: S14F1, F2, F3, F4; S17F5

TRAUTOSTART Format: 11

For each atomic transfer, this data item tells the equipment if it should automatically start the handoff when ready (=TRUE) or await the host's "StartHandoff" command (=FALSE) following setup. This data item only affects the primary transfer partner.

Where Used: S4F19

TRCMDNAME Format: 20

Identifier of the transfer job-related command to be executed. Possible values:

"CANCEL"
"PAUSE"
"RESUME"
"ABORT"
"STOP"
"STARTHANDOFF" (requires a TRATOMICID as a parameter)

Where Used: S4F21

TRDIR Format: 51

Direction of handoff.

```
1   =   Send material
2   =   Receive material
0, 3-63 Reserved
```

Where Used: S4F19, F29

TRID Format: 20, 3(), 5()

Trace request ID

Where Used: S2F23; S6F1, F27, F28; S17F5, F6, F7, F8, F13, F14

TRJOBID Format: 10

Equipment assigned identifier for the transfer job.

Where Used: S4F20, F21

TRJOBMS Format: 51

Milestone for a transfer job (e.g., started or complete).

```
1   =   Transfer Job Started
2   =   Transfer Job Complete
0, 3-63 Reserved
```

Where Used: S4F23

TRJOBNAME Format: 20

Host assigned identifier for the transfer job. Limited to a maximum of 80 characters.

Where Used: S4F19, F23

TRLINK Format: 5()

Common identifier for the atomic transfer used by the transfer partners to confirm that they are working on the same host-defined task.

Where Used: S4F19, F29, F31, F33, F39

TRLOCATION Format: 5()

Identifier of the material location involved with the transfer. For one transfer partner, this will represent the designated source location for the material to be sent. For the other transfer partner, it will represent the designated destination location for the material to be received.

Where Used: S4F19, F29

TROBJNAME Format: 20

Identifier for the material (transfer object) to be transferred

Where Used: S4F19, F23, F29

TROBJTYPE Format: 5()

Type of object to be transferred

Where Used: S4F19, F29

TRPORT Format: 5()

Identifier of the equipment port to be used for the handoff

Where Used: S4F19, F29

TRPTNR Format: 20

Name of the equipment which will serve as the other transfer partner for this atomic transfer. This corresponds to EQNAME.

Where Used: S4F19, F29

TRPTPORT Format: 5()

Identifier of the transfer partner's port to be used for the transfer.

Where Used: S4F19, F29

TRRCP Format: 20

Name of the transfer recipe for this handoff. Limited to a maximum of 80 characters.

Where Used: S4F19

TRROLE Format: 51

Tells whether the equipment is to be the primary or secondary transfer partner.

```
1   =   Primary Transfer Partner
2   =   Secondary Transfer Partner
```

Where Used: S4F19, F29

TRSPER Format: 4()

A Trace Object attribute which holds the value for sampling interval time.

Where Used: S14F1, F2, F3, F4; S17F5

TRTYPE Format: 51

Tells whether the equipment is to be an active or passive participant in the transfer.

```
1   =   Active
2   =   Passive
```

Where Used: S4F19, F23, F29

TSIP Format: 10

Transfer status of input port, 1 byte

```
1   =   Idle state
2   =   Prep state
3   =   Track on state
4   =   Stuck in Receiver state
5-63 Reserved
```

Where Used: S1F10

TSOP Format: 10

Transfer status of output port, 1 byte

```
1   =   Idle state
2   =   Prep state
3   =   Track on state
4   =   Stuck in Sender state
5   =   Completion state
6-63 Reserved
```

Where Used: S1F10

TTC Format: 3(), 5()

Time to completion

Where Used: S3F4

ULIM Format: 3(), 4(), 5()

Upper limit for numeric value

Where Used: S7F22

UNFLEN Format: 3(), 5()

Unformatted Process Program Length

If greater than zero, indicates PPID is available as an unformatted process program and its length in bytes. If zero, the PPID is not available as an unformatted process program. Negative values are invalid.

Where Used: S7F34

UNITS Format: 20

Units Identifier

As allowed by SEMI E5 Section 9

Where Used: S1F12; S2F30, F48; S7F22

UPPERDB Format: 11, 20, 3(), 4(), 5()

A variable limit attribute which defines the upper boundary of the deadband of a limit. The value applies to a single limit (LIMITID) for a specified VID. Thus, UPPERDB and LOWERDB as a pair define a limit.

Where Used: S2F45, F48

V Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Variable data

Where Used: S6F11, F13, F16, F20, F22

VID Format: 20, 3(), 5()

Variable ID

Where Used: S2F33, F45, F46, F47, F48; S6F13, F18, F22; S17F1

VLAACK Format: 10

Variable Limit Attribute Acknowledge Code, 1 byte

```
0   =   Acknowledge, command will be performed
1   =   Limit attribute definition error
2   =   Cannot perform now
>2  =   Other equipment-specific error
3-63 Reserved
```

Where Used: S2F46

XDIES Format: 4(), 5()

X-axis die size (index)

Where Used: S12F1, F4

XYPOS Format: 3()

X and Y Coordinate Position. Must be in (X,Y) order

Where Used: S12F11, F18

YDIES Format: 4(), 5()

Y-axis die size (index)

Where Used: S12F1, F4

6.7 *Variable Item Dictionary* — This section defines variable data items which are available to the Host for data collection purposes.

Name: A unique mnemonic name for this variable data item. This name is provided for reference only.

Class: The data type classification (SV, ECV, or DVVAL) of the item. Status values (SV' s) always contain valid information, while data values (DVVAL' s) may only be valid upon the occurrence of a particular event. All equipment constants (ECV' s) are settable by the Host.

Format: The allowable item format codes which can be used for this variable data item. ...as in Data Item Dictionary...

Description: A description of the variable data item, with the meanings of specific values. Also, specify validity for item of class DVVAL.

AlarmID Format: 3(), 5()

Class: DVVAL

This variable is valid only upon the setting or clearing of an alarm condition and contains the current alarm identification (ALID), regardless of whether that alarm is enabled for reporting.

AlarmsEnabled Format: 0

Class: SV

Contains the list of alarms (ALIDs) enabled for reporting (via Stream 5).

Structure: L,n n= # of alarms enabled

```
1.<ALID1>
.
.
n.<ALIDn>
```

AlarmsSet Format: 0

Class: SV

Contents of this variable is a list of alarms (ALIDs) currently in the UNSAFE (alarm set) state, regardless of whether the alarms are enabled for reporting.

Structure: L,n n= # of alarms set

1.<$ALID_1$>
.
.
n.<$ALID_n$>

ARAMSAccumReset Format: 20

Class: SV

The timestamp of when the set of accumulators EngTime, InterruptionCtr, PrdTime, NSTime, SbyTime, SDTime, and UDTime were reset to zero. Uses format defined for CLOCK.

ARAMSInfo Format: 20

Class: SV

Text field set by the equipment to provide additional information concerning an ARAMS state change.

ARAMSState Format: 20

Class: SV

The ARAMS code corresponding to the current state/substate. Four characters.

ARAMSText Format: 20

Class: SV

Text describing the ARAMSState. 3-80 characters.

ARAMSTimeStamp Format: 20

Class: SV

The timestamp of the last ARAM state change. This is a format requirement only and does not imply precision or accuracy. Uses format defined for CLOCK.

CLOCK Format: 20

Class: SV

The value of the equipment' s internal clock. This is a format requirement only and does not imply precision or accuracy.

```
Format: YYYYMMDDhhmmsscc
YYYY = Year              0000 to 9999
MM = Month               01 to 12
DD = Day                 01 to 31
hh = Hour                00 to 23
mm = Minute              00 to 59
ss = Second              00 to 59
cc = centisecond         00 to 99
```

ControlState Format: 10, 51

Class: SV

This status variable contains the code which identifies the current control state of the equipment. When reported related to a control state transition, its value should represent the state current after the transition.

```
1   =   OFF-LINE/EQUIPMENT OFF-LINE
2   =   OFF-LINE/ATTEMPT ON-LINE
3   =   OFF-LINE/HOST OFF-LINE
4   =   ON-LINE/LOCAL
5   =   ON-LINE/REMOTE
6-63 Reserved
```

CycleCtr Format: 5()

Class: SV

The number of machine cycles during the lifetime of the equipment. Non-resettable.

DowntimeAlarm Format: 3(), 5()

Class: SV

Identifier of the last alarm or exception triggering an equipment-initiated transition to UNSCHEDULED DOWNTIME from the PRODUCTIVE or STANDBY states.

DowntimeAlarmText Format: 20

Class: SV

Text associated with DowntimeAlarm. 0-80 characters.

DowntimeData Format: 20

Class: SV

Equipment defined data associated with transitions to, or within, the SCHEDULED or UNSCHEDULED DOWNTIME states. For example, this may be used to carry fault information, the component serial number of a repaired component, or comments entered at the equipment's control panel. 0-256 characters.

EngTime Format: 5()

Class: ECV

Accumulation of time in ENGINEERING reported in minutes.

EqpModel Format: 20

Class: SV

Text string describing the equipment model. 1-80 characters.

EqpName Format: 20

Class: ECV

Text string containing a user-assigned name for equipment. 1-80 characters. Information in the data item EQNAME is a subset of EqpName.

EqpSerialNum Format: 20

Class: SV

Text string describing the product serial number assigned by the manufacturer. 1-80 characters. Information in the data item MDLN is a subset of EqpSerialNum.

EstablishCommunicationsTimeout Format: 52

Class: ECV

The length of time, in seconds, of the interval between attempts to send S1F13 when establishing communications.

EventsEnabled Format: 0

Class: SV

Contains the list of events (CEIDs) enabled for reporting (via Stream 6).

Structure: L,n n= # of events enabled

```
1.<CEID1>
.
.
n.<CEIDn>
```

EventLimit Format: 0, 10, 11, 20, 21, 3(), 4(), 5()

Class: DVVAL

Used with the Limits Monitoring capability, it contains the LIMITID of the limit reached or crossed by LimitVariable. Since multiple zone transitions for a variable may occur simultaneously (e.g., due to identical limit definitions or a slow data sampling rate), EventLimit has been defined to allow for a list of LIMITIDs.

InterruptionCtr Format: 5()

Class: ECV

The number of transitions to UNSCHEDULED DOWNTIME from PRODUCTIVE.

LastPowerdown Format: 20

Class: SV

Timestamp estimate of when the last powerdown or reset occurred. Uses format defined for Clock.

LimitVariable Format: 5()

Class: DVVAL

This variable contains the VID for the variable whose value changed monitoring zones.

MaxSpoolTransmit Format: 54

Class: ECV

The maximum number of messages which the equipment will transmit from the spool in response to an S6,F23 " Transmit Spooled Messages" request. If MaxSpoolTransmit is set to zero, no limit is placed on the messages sent from the spool. Multi-block inquire/grant messages are not counted in this total.

NSTime Format: 5()

Class: ECV

Accumulation of time in NON-SCHEDULED TIME, reported in minutes.

OperatorCommand Format: 5()

Class: DVVAL

This data variable is valid in the event the operator issues a command to the equipment. The codes for this variable are equipment-dependent.

OverWriteSpool Format: 11

Class: ECV

This Equipment Constant is used to indicate to the equipment either to overwrite data in the spool area or to stop spooling whenever the spool area limits are exceeded.

```
= TRUE to overwrite spooled data
= FALSE to stop spooling when limits exceeded
```

PowerdownTime Format: 20

Class: SV

This timestamp is periodically updated based on an interval set by the user. It is used to determine the approximate time that the equipment went down in the event of a power loss. Uses format defined for CLOCK.

PowerupState Format: 20

Class: SV

Specifies the powerup ARAMS state when powerdown occurs during manufacturing time. Single text digit: " 2" = STANDBY, " 5" = UNSCHEDULED DOWNTIME.

PPChangeName Format: 10, 20

Class: DVVAL

The PPID which was affected upon the event of the creation, editing, or deletion of a Process Program local to the equipment. If the PPID Data Item is also defined and implemented for the equipment, then the values for PPChangeName are subject to the same format restrictions defined for the PPID Data Item.

PPChangeStatus Format: 51

Class: DVVAL

The action taken on the Process Program named in PPChangeName. This variable is valid upon the event of the creation, editing, or deletion of a Process Program local to the equipment.

```
1   =   Credited
2   =   Edited
3   =   Deleted
4-63 Reserved
```

PPError Format: 20

Class: SV or DVVAL

Contains information about a failure to verify a text process program.

PPExecName Format: 0, 10, 20

Class: SV

The PPID(s) of the currently selected Process Program(s). The selection of a new Process Program updates this variable. If multiple Process Programs can be selected, then this variable is a list of PPIDs. If the PPID Data Item is also defined and implemented for the equipment, then the values for PPExecName are subject to the same format restrictions defined for the PPID Data Item.

PPFormat Format: 51

Class: SV

Indicates the type or types of process programs and recipes that are supported.

```
1   =   Unformatted process programs
2   =   Formatted process programs
3   =   Both unformatted and formatted process programs
4   =   Execution Recipes
>4 Reserved
```

PrdRecovery Format: 11

Class: ECV

A boolean value that enables (TRUE) or disables (FALSE) the equipment-initiated return to PRODUCTIVE from UNSCHEDULED DOWNTIME.

PrdState Format: 20

Class: SV

Default ARAMS Substate Code for automated transitions to PRODUCTIVE.

PrdTime Format: 5()

Class: ECV

Accumulation of time in PRODUCTIVE, reported in minutes.

PrevARAMSState Format: 20

Class: SV

The ARAMS code corresponding to the previous state/substate. Four characters.

PreviousProcessState Format: 51

Class: SV

The previous processing state of the equipment, before the most recent process state change.

```
0-63 Reserved
```

ProcessState Format: 51

Class: SV

The current processing state of the equipment.

```
0-63 Reserved
```

RcpChangeName Format: 20

Class: DVVAL

The identifier of the recipe affected upon the event of the creation, editing, or deletion of a recipe.

RcpChangeStatus Format: 51

Class: DVVAL

The type of change that occurred for the recipe indicated in RcpChangeName

```
0   =   No change
1   =   Created
2   =   Updated (modified)
3   =   Stored (new)
4   =   Replaced
5   =   Deleted
6   =   Copied
7   =   Renamed
8,9 Reserved
>10 Reserved
```

RcpExecName Format: 0, 20

Class: SV

The identifier, or a list of identifiers, of currently selected recipes. A zero-length item or list indicates no recipes are currently selected.

SbyRecovery Format: 11

Class: ECV

A boolean value that enables (TRUE) or disables (FALSE) the equipment-initiated return to STANDBY from UNSCHEDULED DOWNTIME.

SbyTime Format: 5()

Class: ECV

Accumulation of time in STANDBY, reported in minutes.

SDTime Format: 5()

Class: ECV

Accumulation of time in SCHEDULED DOWNTIME, reported in minutes.

SpoolCountActual Format: 5()

Class: SV

Used to keep a count of the messages actually contained in the equipment' s spool area. Multi-block inquire/grant messages are not spooled and not included in this count.

SpoolCountTotal Format: 5()

Class: SV

Used to keep a count of the total number of primary messages directed to the spool, regardless of whether placed or retained in the spool. Multi-block inquire/grant messages are not spooled and not included in this count.

SpoolFullTime Format: 20

Class: SV

Contains the timestamp from the time the spool last became full. If the spool was not filled during the last spooling period, this will contain a time value prior to the current SpoolStartTime. Uses the same format as the CLOCK variable data item.

SpoolStartTime Format: 20

Class: SV

Contains the timestamp from the time spooling last became active. Uses the same format as the CLOCK variable data item.

SymptomID Format: 5()

Class: SV

A numeric code representing the symptom that initiated the user-initiated state change. A value of zero indicates " no symptom" .

SymptomText Format: 20

Class: SV

Text describing the SymptomID. 0-80 characters.

TimeFormat Format: 5()

Class: ECV

NOTE 6: The setting of this ECV controls whether the equipment shall send the Data Items STIME and TIME in 12 or 16-byte format.

```
0   =   12-byte format
1   =   16-byte format
>1 Reserved
```

TransitionType Format: 10

Class: DVVAL

Used with the Limits Monitoring capability, it defines the direction of the zone transition which has occurred.

```
0   =   Transition from lower to upper zone.
1   =   Transition from upper to lower zone.
```

TRATID Format: 5()

Class: DVVAL

Contains the TRATOMICID of the atomic transfer referenced by the event.

TRJOBIDENT Format: 5()

Class: DVVAL

Contains the TRJOBID for the transfer job referenced by the event.

TRJOBNM Format: 20

Class: DVVAL

Contains the TRJOBNAME for the transfer job referenced by the event.

TRLNK Format: 5()

Class: DVVAL

Contains the TRLNK value for the atomic transfer referenced by the event.

UDTime Format: 5()

Class: ECV

Accumulation of time in UNSCHEDULED DOWNTIME, reported in minutes.

6.8 *Object Dictionary* — This section defines the public attributes of objects which are available through SECS-II messages.

The attributes of an object are defined in a table for each object in the following form:

Agent Attribute Definition

Attribute Name	*Definition*	*Access*	*Format*	*Value*
"ObjType"	Agent object type.	RO	20	"Agent"
"ObjID"	The agent's name, assigned by an *authorized user*.	RO	20	

Agent-Specific Dataset Object Attribute Definition

Attribute Name	*Definition*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"MRcpASDS"
"ObjID"	The object's identifier. Contains the value in AgentSpec Agent.	RO	20	

"AgentSpec_Agent"	The name of the *executing agent* to which the other attributes in the *dataset* apply. *Mandatory*.	RO	20	
"AgentSpec_AttrLength"	The length of the *agent-specific* attributes, in bytes. *Mandatory*.	RO	54	
"AgentSpec_ChgTime"	Timestamp of when an *agent-specific* attribute was last changed. *Mandatory*.	RO	20	
"AgentSpec_Comments"	Comments specific to the *agent* entered by the author.	RW	20	Maximum length is 80 characters.
"AgentSpec_LinkParam"	A list of *variable parameter definitions* modified from the list in LinkParam. Valid only for a *linked main* recipe. *Parameter name* and form may not be changed.	RO	00	List of structures composed of parameter name, value, and restrictions.
"Certified"	The certification level for the specific *agent*, assigned by an *authorized user*. Reset when AgentSpec LinkParam is modified. Required for *certification* support.	RW	52	
"AgentSpec_UD_"	Non-standard attribute defined by the supplier or user. Asterisk indicates the part of the attribute name that is provided in this definition. Must be preserved exactly except by the defining entity.	RO	10, 11 20, 3() 4(), 5()	Text form is limited to 80 characters.

Collection Event Object

Attribute Name	*Description*	*Access*	*Format*	*Related Data Items*	*Value*
"ObjType"	Collection Event Object type	RO	20	-	"COLLEVENT"
"ObjID"	Collection Event Identifiers	RO	20	CEID	-
"Enabled"	Boolean true means reporting is enabled for a specific CEID.	RW	11	CEED	-
"EventSource"	Object specifier for object which generates the event for a specific CEID.	RO	20	EVNTSRC	-
"DataReportList"	List of Report Identifiers linked to a specific CEID.	RO	20	-	(list of) RPTID

Data Report Object

Attribute Name	*Description*	*Access*	*Format*	*Related Data Items*	*Value*
"ObjType"	Data Report Object Type	RO	20	-	"DATARPT"
"ObjID"	Object identifier for a data report	RO	20	RPTID	-
"DataSource"	Source for the variable data, not writable for predefined provider reports	RO	20	DATASRC	-
"AttrList"	Returns the attribute (or variable) names that this report is requesting from the Data source.	RW	*	-	(list of) VID

Data Source Object

Attribute Name	*Description*	*Access*	*Format*	*Related Data Items*	*Value*
"ObjType"	Data Source Object Type	RO	20	-	"DataSource"
"ObjID"	Identifier of a specific Data Source Object	RO	20	DATASRC	-
"AttrList"	Name of attributes for a specific Data Source Object	RO	*	-	(list of) VID

Distributed Recipe Namespace Attribute Definition

Attribute Name	*Description*	*Access*	*Format*	*Value*

"ObjType"	The object type.	RO	20	"RNSD"
"ObjID"	Text.	RO	20	
"LockedRecipes"	A list of *identifiers* of all recipes with existing *change request records.*	RO	20	
"Recorder"	The *recorder specifier* of the attached *distributed recipe namespace recorder*.	RO	20	
"Segments"	A list of *specifiers* of the *distributed recipe namespace segments* attached to the *namespace.*	RO	20	

Distributed Recipe Namespace Manager Attribute Definition

Attribute Name	*Description*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"RNS_MgrD"
"ObjID"	The *manager's* name.	RO	20	

Distributed Recipe Namespace Recorder Attribute Definition

Attribute Name	*Description*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"RNSDRecorder"
"ObjID"	Text.	RO	20	
"LockedRecipes"	List of *identifiers* of recipes with existing *change request records.*	RO	00	
"Namespace"	Identifies the *namespace* to which the recorder is attached. May be set by the manager.	RO	20	
"NamespaceManager"	Identifies the *distributed recipe namespace manager*. May be set by the manager.	RO	20	
"Segments"	List of *specifiers* of currently attached segments.	RO	00	

Distributed Recipe Namespace Segment Attribute Definition

Attribute Name	*Description*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"RNSDSegment"
"ObjID"	The object name (identifier).	RO	20	
"Namespace"	The name (ObjID) of the *namespace* to which the *segment* belongs. May be set by the manager.	RO	20	
"NamespaceManager"	Identifies the *distributed recipe namespace manager*. May be set by the manager.	RO	20	
"RecipeReadOnlyLevel"	Used to track the corresponding attribute of the *namespace* to which the *segment* belongs. May be set by the manager.	RO	52	

Exception Attributes

Attribute Name	*Description*	*Access*	*Format*	*Related Data Items*	*Value*
"ObjType"	The object type	RO	20	-	"EXCEPTION"
"ObjID"	The identifier of a specific Exception	RO	20	EXID	-
"EXType"	Identifies the type of exception	RO	20	-	Select from set: "ALARM" "ERROR"
"EXMessage"	Text message describing the abnormal situation monitored.	RO	20	-	Max. length of 80 characters
"EXEnabled"	Indicates that reporting to the decision authority on the exception condition is enabled.	RW	11	-	Boolean; TRUE is enabled.
"EXRecoveryAction"	List of possible recovery actions (EXRecovery).	RO	20	-	list of text
"EXState"	Current state of an Exception Object. The Exception Object state is usually defined as a combination of substates and concurrent states.	RO	20	-	Composed from the set: "CLEARED" "SET" "NOTPOSTED" "POSTED" "NOTRECOVERING" "RECOVERING" "ABORTINGRECOVERY"

Execution Recipe Attribute Definition

Attribute Name	*Definition*	*Acc.*	*Rqmt*	*Form*	*Default Value*
Identification Attributes					
"ObjType"	The object type.	RO	Y	Text: "ERcp"	"ERcp"
"ObjID"	An identifier derived from Namespace, Class, Name, and Version.	RO	Y	Formatted text.	-
"Namespace"	The name of the *originating namespace*.	RO	Y	Text.	-
"Name"	A logical name assigned by the user when the recipe is *created*.	RO	Y	Text.	-
"Class"	The recipe's class (e.g., "/PROCESS/" OR "/PROCESS/LOADER/").	RO	Y	Formatted text: "CLASS/CLASS/.. /CLASS/"	-
"Version"	The version of the recipe.	RO	Y	Text.	-
Mandatory Attributes					
"ExecAttrLength"	The *length attribute* for the attributes of the *execution recipe*. Calculated when the recipe is *downloaded* and whenever an attribute changes. *Mandatory*.	RO	Y	Unsigned integer	-
"ExecChgTime"	The *timestamp* of a change to the attributes of the *execution recipe*. *Mandatory*.	RO	Y	Formatted text, *timestamp* format	-
"AttrLength"	Preserved. *Mandatory*.	RO	Y	Unsigned integer	-
"AttrChgTime"	Preserved. *Mandatory*.	RO	Y	Timestamp format	-
"EditTime"	Preserved unless recipe is modified. *Timestamp* of when the *body* was *created* or modified. *Mandatory*.	RO	Y	Formatted text *Timestamp* format	-

Attribute Name	*Definition*	*Acc.*	*Rqmt*	*Form*	*Default Value*
"BodyLength"	Preserved unless recipe is modified. Length of the recipe's body, in bytes. *Mandatory*.	RO	Y	Unsigned integer	-
"BodyFormat"	Indicates the form and format of the recipe's *body*.	RO	Y	Enumerated unsigned integer: 0 = *source*, 1 = *object*, > 1 reserved.	0
"Verified"	Indicates whether the recipe's body is syntactically correct.	RO	Y	Boolean.	FALSE
"Linked"	Indicates whether the recipe is *linked*.	RO	Y	Boolean.	FALSE
"ChangedBody"	Set to TRUE if the recipe body has changed without a subsequent upload to the originating namespace. Note: this attribute is never updated to a namespace. Required only if recipe can be changed or created.	RO	Y	Boolean.	FALSE
"ExecChgCtl"	Preserved. Specifies change control requirements for recipe.	RO	Y	Binary. Bitwise: 1 - may change 2 - change notification required 4 - recipe may be selected after change, 8 - most recent parameter settings shall be saved. Any combination of these four bits is allowed.	0
Optional Attributes					
"AgentSpec_ Comments"	Copied from the original *agent-specific* attribute when downloaded. Set by the user.	RO	N	Text. Maximum length is 80 characters.	-
"ApprovalLevel"	Indicates the level of approval assigned by an *authorized* user.	RO	N	Unsigned integer	0
"Certified"	Preserved from the *agent-specific* attribute as downloaded. May be used as control for production-worthy recipes.	RO	N	Unsigned integer	0
"Comments"	User comments. Preserved from the *generic* attribute as downloaded.	RO	N	Text. Maximum length is 80 characters.	-
"EditedBy"	Preserved unless recipe is modified. The name of the person or *executing agent* who last modified the recipe.	RO	N	Text. Maximum length is 40 characters.	-
"EstRunTime"	The nominal or estimated execution (run) time of the recipe, in seconds. Used for scheduling purposes. Preserved from the *generic* attribute as downloaded.	RO	N	Unsigned integer	0
"ExecLinkParam"	Preserved unless last value is changed (Section 6.7.4). Contains the list of *parameter definitions* including any *agent-specific* modifications. Required for *variable parameter* support.	RO	N	Structure composed of parameter name, initial value, and restrictions.	NULL
"LinkList"	Preserved. A complete list of recipe *specifiers* for a *linked recipe set*. Required for multi-part recipe support.	RO	N	List of formatted text.	NULL

Attribute Name	*Definition*	*Acc.*	*Rqmt*	*Form*	*Default Value*
"SrcRcpID"	For a derived *object form* recipe, contains the recipe *identifier* of the original *source form* recipe. Required only for *derived object form* recipes.	RO	N	Formatted text.	NULL
"VerificationID"	Identification code used by the *verifier* of the recipe. May be used to determine out-of-date formats that need to be *re-verified*.	RO	N	Text. Maximum length is 40 characters.	NULL
Non-Standard Attributes					
AgentSpec_UD_*	Preserved from the original *agent-specific* attributed as downloaded.	RO	N	Defined by supplier or user. Text limited to 80 characters.	-
UD_*	Non-standard attribute defined by supplier or *user*. Asterisk indicates the part of the attribute name that is provided in this definition. Shall be preserved exactly except by the entity that defined it.	RO	N	Varies with definition. Text form is limited to 80 characters.	-

Managed Recipe Attribute Definition

Attribute Name	*Description*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"MRcp"
"ObjID"	An identifier derived from Class, Name, and Version. No part of a recipe's identifier shall be changed except through *renaming*.	RO	20	
(other)	Description of the information contained.	RO or RW	Varies with definition.	Varies with definition.
"Name"	A logical name assigned by the user when the recipe is *created* or *renamed*.	RO	20	
"Class"	The recipe's class (e.g., "/PROCESS/" or "/PROCESS/LOADER/").	RO	20	Formatted text: "CLASS/CLASS/../CLASS/"
"Version"	The version of the recipe.	RO	20	
"AttrLength"	The total length of the *generic* attributes, in bytes. *Mandatory*.	RO	5()	
"AttrChgTime"	Timestamp of the last change to a *generic* attribute. *Mandatory*.	RO	20	
"BodyLength"	Length of the recipe's body, in bytes. *Mandatory*.	RO	5()	
"EditTime"	Timestamp of when the *body* was *created* or last *updated*. *Mandatory*.	RO	20	*Timestamp* format: "YYYYMMDDhhmmsscc"
"BodyFormat"	Indicates the form and format of the recipe's *body*. *Default* is zero.	RO	52	0 = source, 1 = object, >1 reserved.
"Verified"	Indicates whether the recipe's body is syntactically correct. Reset when the recipe is *created* or *updated*. Default is FALSE.	RO	11	
"Linked"	Indicates whether the recipe is linked. Reset when the recipe is *originated*, *verified*, or *unlinked*. Default is FALSE.	RO	11	
"ApprovalLevel"	Indicates the level of approval assigned by an *authorized user*. *Default* is zero. Reset when the recipe is *originated* or *linked*. For a *linked* recipe, may not be higher than any of its *subrecipes*.	RW	52	

Attribute Name	*Description*	*Access*	*Format*	*Value*
"Comments"	User comments.	RW	20	Maximum length is 80 characters.
"EditedBy"	The name of the person who last edited the recipe.	RO	20	Maximum length is 40 characters.
"EstRunTime"	The nominal or estimated execution (run) time of the recipe, in seconds. Reset when the recipe, is *created* or *updated*. Set when the recipe is *verified*. May be recalculated to total time for a *main* recipe when *linked*. Used for scheduling purposes. Algorithm for calculation shall be documented. Default is 0.	RW	54	
"ExecChgCtrl"	Specifies change control requirements for recipe. Default is 0. Combinations of bits are used to indicate multiple permissions.	RW	10	Binary. Bitwise (MSB = 8): 1 - the recipe body may be changed 2 - change notification required 4 - recipe may be selected after change, 8 - most recent parameter settings shall be saved. Any combination of these four bits is allowed
"ExtRef"	A list of all recipe *specifiers* as referenced within the recipe. Explicit *versions* not required. Reset when the recipe is *created*, *updated*, and *verified*.	RO	00	List of items of format 20.
"LinkList"	A complete list of recipe *specifiers* found in the ExtRef attribute of a *main* recipe and all of its *subrecipe*s, with duplicates removed and all *versions* explicitly determined. Set for the *main* recipe when linked. Reset when the recipe is *originated* or *verified*. Required for multi-part recipe support.	RO	00	List of items of format 20.
"LinkParam"	A list of all variable parameter definitions contained in the Parameters attribute of a *main* recipe and all of its *subrecipes*, with duplicates removed. Reset when the recipe is *created*, *updated*, or *verifie*d. Set when the recipe is *linked*. Required for *variable parameter* support.	RO	00	List of parameter definition structures composed of parameter name, initial value, and restrictions.
"Parameters"	A list of variable parameter definitions contained in the recipe. Reset when the recipe is *created*, *updated*, and *verified*. Set when the recipe is *verified*. Required only for *variable parameter* support.	RO	00	List of parameter definition structures composed of parameter name, initial value, and restrictions.
"SrcRecID"	*Identifier* of the *source form* recipe from which a *derived object form* recipe is derived. Value determined by the *verifier* of the recipe. Required only for support of *derived object form* recipes.	RO	20	
"VerificationID"	Identification code set by the *verifier* of the recipe. May be used to determine out-of-date formats that need to be *re-verified*.	RO	20	Maximum length is 40 characters.
"UD_"	Non-standard attribute defined by supplier or *user*. Asterisk indicates the part of the attribute name that is provided in this definition. Shall be preserved exactly except by the entity that defined it.	RO	10, 11, 20, 3(), 4(), 5()	Text form is limited to a maximum of 80 characters.

Process Job Attributes

Attribute Name	*Description*	*Access*	*Format*	*Related Data Item*	*Value*
"ObjType"	Name of the Object Type	RO	20	-	"PROCESSJOB"
"ObjID"	Identifier of a Process Job	RO	20	PRJOBID	-
"PRMt1Type"	Type of material being processed	RO	20	-	allowed values: "css" "wfr"
"PRMt1NameList"	Process Material Name, identifies material being processed by a job, which could be more than one item.	RO	20	-	(list of) Text
"RecID"	Object Specifier of Recipe used by a Process Job, see SEMI E39 and SEMI E42	RO	20	-	-
"PRRecipeMethod"	Indicates any special handling for a Process Job's Recipe	RO	20	-	allowed values: "STANDARD" "USETUNING"
"PRJobState"	Indicates the current state of a Process Job. The state of a job may be a combination of sub-states and concurrent states.	RO	20	-	Composed from the set: "WAITINGFOR JOB" "JOBQUEUED" "JOB CANCELLED" "JOBACTIVE" "SETUP" "WAITINGFORSTART" "PROCESSING" "NOTPAUSED" "PAUSING" "PAUSED" "NOTSTOPPING" "STOPPING" "NOTABORTING" "ABORTING" "PROCESSCOMPLETE" "JOBCOMPLETE"
"PRProcessStart"	Processing should start automatically after Job is defined when this Boolean is set TRUE	RO	11	-	Boolean

Recipe Executor Attribute Definition

Attribute Name	*Description*	*Access*	*Rqmt*	*Form*
"ObjType"	The object type	RO	Y	Text = "RcpExec"
"ObjID"	Text	RO	Y	Text
"DefaultNamespace"	The name of an *executing agent's name-space* used for all hardware-dependent and other *agent-specific* recipes.	RW	Y	Text
"ProdApprove"	The minimum value of a recipe's *approval level* accepted during productive and standby states. Required for SEMI E10 support only.	RW	N	Unsigned integer
"ProdCertify"	The minimum value of a recipe's *certification level* accepted during productive and standby states. Required for SEMI E10 support only.	RW	N	Unsigned integer
"RunCycleUnit"	The process unit on which the calculation of the estimated value of the recipe *generic attribute* EstRunTime is based.	RO	N	Case-sensitive formatted text composed of a unit of measure and an optional numeric suffix. Compliant with SEMI E5, Section 9.
"RecipeSelectID"	A list of recipe *identifiers* for the currently selected	RO	Y	List of formatted text.

	recipes.			
"RecipeSelect-Parameters"	A list of all *parameter definitions* in effect for the ith recipe *identifier* in RecipeSelectID. The maximum value for i is determined by the equipment supplier as the maximum number of recipes which may be *selected* at the same time. Required if variable parameters are supported.	RO	N	List of structures composed of parameter name, parameter value, parameter restriction.

Recipe Namespace Attribute Definition

Attribute Name	*Definition*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"RNS"
"ObjID"	The *name* of the *namespace*.	RO	20	A name of "Default" is prohibited.
"RecipeReadOnlyLevel"	The level of *approval* at which recipes are *read-only*.	RW	52	
"Members"	The *names* of *agents* capable of *verifying* and *executing* the recipes in the *namespace*.	RW	00	List of items of format 20.

Recipe Namespace Manager Attribute Definition

Attribute Name	*Definition*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"RNS_Mgr"
"ObjID"	The *manager's* name.	RO	20	
"NamespaceName"	The *name* of the *namespace* managed.	RO	20	

Table Attribute Definition

Attribute Name	*Definition*	*Access*	*Format*	*Value*
"ObjType"	The object type.	RO	20	"Table"
"ObjID"	The object's identifier.	RO	20	1-80 characters.
"NumCols"	Number of columns.	RO	5()	Non-zero.
"NumRows"	Number of rows.	RO	5()	Non-zero.
"TableLength"	Total number of bytes required to store the table elements, exclusive of any formatting required for storage.	RO	5()	Non-zero.

Trace Object

Attribute Name	*Description*	*Access*	*Format*	*Related Data Items*	*Value*
"ObjType"	Trace Report Object type	RO	20	-	"TRACE"
"ObjID"	Identifier of a specific Trace Report	RO	20	TRID	-
"Enabled"	Boolean true means the specific Trace Report is enabled.	RW	*	CEED	-
"ReportID"	List or report linked to this Trace Report	RO	20	-	(list of) RPTID
"SamplePeriod"	Time between report samples given in floating point seconds.	RW	4 ()	TRSPER	-
"TotalSamples"	The maximum number of samples that this Trace Report will perform.	RW	*	TOTSMP	-
"GroupSize"	Number of trace reports to be grouped before a report is sent.	RW	*	REPGSZ	-
"StartEventID"	Identifier of the event which starts trace reporting.	RW	20	CEID	-

“StartEvtSrcSpec”	Source for the start event	RW	20	EVNTSRC	-
“StopEventID”	Identifier of the event which stops trace reporting.	RW	20	CEID	-
“StopEvtSrcSpec”	Source for the stop event	RW	20	EVNTSRC	-
“AutoDelete”	Boolean true means this report is deleted when reporting is complete.	RW	11	TRAUTOD	-
“ReportChangeOnly”	Boolean, if true, then trace reports are sent only if at least one of the reported variables changes.	RW	11	RPTOC	-

attribute name — A reserved text string, of at most 40 characters, that is unique for that object.

description — A description of the attribute.

access — Indicates whether the attribute may be set through messages. Access is either read-only (RO) or read-write (RW).

format — Indicates the type of data (format code).

timestamp format — Text form indicating date and time in the format “YYYYMMDDhhmmsscc”.

related data items — Indicates an explicit relationship with a corresponding data item.

value — Specifies any restrictions on the possible values. Examples of restrictions include exclusion of zero for format 5(), a maximum length for text, a format imposed on text, an order imposed on a list, or an enumerated set of valid values.

Requirements:

- The attributes “ObjType” and “ObjID” are required for all object definitions and shall use format 20.
- The attribute “ObjType” shall be assigned a fixed value for each object.
- The value of “ObjID” may not be changed by using SetAttr (S14F3).

The value of “ObJType” may be used for messages using the data item OBJTYPE. The value of the attribute “ObjID” may be used for messages using the data item OBJID.

The name of a public attribute may be used for messages using the data item ATTRID. The value of a public attribute may be used for messages using the data item ATTRDATA.

Variable data items defined in Section 6.7 may be regarded as attributes of the object type “Equipment”, where SVs and DVVALs are RO and ECVs are RW.

6.9 With the use of Harel[4] state diagrams to describe the behavior of objects, an object’s state must be describable as a combination of a set of sub-states and concurrent states. The rules for describing the state of an object are: (1) use the comma (',') to deliminate concurrent states, (2) use the foreslash ('/') to delimit super-state and sub-state, (3) to deliver the set of lowest level concurrent states, and (4) optionally omit super-state names when there are no ambiguities in the names of the lowest level states.

Please refer to Figure 1 in order to follow the discussions for the notations. In Harel notation, 'pump' and 'vacuum' are concurrent states. The text to specify this relation in a response to a request for state is 'pump, vacuum'. The comma can be read as meaning 'and'. 'on' and 'off' are sub-states of 'pump'. 'vent', 'rough', and 'Hi-V' are sub-states of 'vacuum'. The sub-state syntax is 'state/sub-state' where the '/' can be read as 'in sub-state'. So using the example in Figure 1, if the pump is off and the vacuum is vented, then the text message which conveys this is ‘pump/off, vacuum/vent’. This message can be shortened to ‘off,vent’ because there is no ambiguity in doing so.

4 Harel D. “Statecharts: A Visual Formalism for Complex Systems”, Science of Computer Programming, 8, 1987, pp. 231-274. Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elvesier.nl/homepage/browse.htt

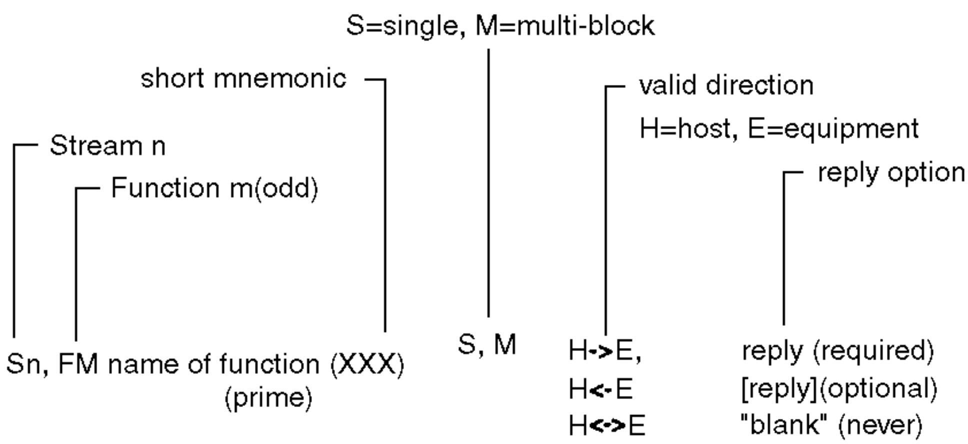
State Chart Example

7 Message Detail

7.1 *Intent* — This section defines a number of specific functions in different streams which can be used as a basis for communication between host and equipment. The functions are defined in the form of transaction message pairs according to the transaction level requirements specified in Section 5.

7.2 The functions are described in a standard form which involves specification of the number, name, single or multiple block, direction of communication, nature of reply required, description, variable definition, and the detailed structure of the message in terms of lists and items. Double lines separate streams, and single lines separate transactions to aid readability.

7.2.1 The abbreviations used in each transaction are as follows:



Description: A description of the action generated by the function.

Structure:
Detailed structure showing lists and defined items. Lists are denoted by a capital L followed by the length separated by a comma. The individual elements in the list are numbered on separate lines. Nested lists are indented to emphasize the structure. The detailed form of the items is given in the define section at the beginning of the transaction. The symbols "<" and ">" are used to enclose each item in the structure data and imply that there is an item header. A detailed description of each data item as well as a list of the allowable data formats can be found in the Data Item Dictionary.

Exception:
Special cases in the structure that have a different meaning.

Sn,Fm+ 1 Name of function (secondary) (same structure as above except never with reply)

7.3 *Message Usage* — This section discusses message features and where they may be used.

7.3.1 *Zero Length Items and Lists* — Certain message definitions may use zero length data items and zero length lists as a technique to convey specific information to the receiver of the message. For commands (i.e., “Do Something”) and requests (i.e., “Return Some Data”), it may be used to mean “Use default values for the data item(s) which were not included”. The default may be a specific value or a value chosen by the equipment.

7.3.1.1 For messages reporting data (either responses to requests or asynchronous reports), the technique may be used to indicate that the desired information is not available or not applicable. In some cases, the fact that data is unavailable may indicate success or failure of a command.

7.3.1.2 Certain message definitions may define a zero length data item or a zero length list to mean “the information is not supplied.” The receiving party should react to this lack of information as it deems appropriate.

7.3.2 *Compliance to Message Definitions* — Any given standard SECS-II message shall comply to the format shown in the Message Definition for that Stream and Function. Specifically:

1. The message shall contain all Lists and Data Items shown as required in the Message Definition.
2. The message shall not contain any Lists or Data Items not shown in the Message Definition, unless the Message Definition specifically allows this.
3. The message shall not contain any List Item or Data Item with zero length unless the Message Definition specifically defines a meaning for such a zero length item.

7.4 *Stream 0 and Function 0* — Stream 0 is always defined as not used since a 0 is the most likely error. No functions are defined in stream 0.

7.4.1 Function 0 exists in all streams and has the same special meaning in each stream. A function 0 message closes a transaction, so that the originator will not have to wait for a transaction timeout to proceed. Function 0 is sent in lieu of the expected secondary message when the interpreter cannot, because of a transmission error or some other reason, respond with the expected reply. It is not a requirement that the interpreter send function 0 to close a transaction.

7.5 *Stream 1 Equipment Status* — This stream provides a means for exchanging information about the status of the equipment, including its current mode, depletion of various consumable items, and the status of transfer operations.

S1,F0 Abort Transaction (S1F0) S,H<->E

Description: Used in lieu of an expected reply to abort a transaction. Function 0 is defined in every stream and has the same meaning in every stream.

Structure: Header only

S1,F1 Are You There Request (R) S,H<->E,reply

Description: Establishes if the equipment is on-line. A function 0 response to this message means the communication is inoperative. In the equipment, a function 0 is equivalent to a timeout on the receive timer after issuing S1,F1 to the host.

Structure: Header only

S1,F2 On Line Data (D) S,H<->E

Description: Data signifying that the equipment is alive.

Structure: L,2
1. <MDLN>
2. <SOFTREV>

Exception: The host sends a zero-length list to the equipment.

S1,F3 Selected Equipment Status Request (SSR) S,H->E,reply

Description: A request to the equipment to report selected values of its status.

Structure: The following structure is approved for all item formats and should be used by all new implementations:

L,n
1. <$SVID_1$>
.
.
n. <$SVID_n$>

The following structure is included for compatibility with previous implementations and may only be used for items of format 3() and 5():

<$SVID_1$,...,$SVID_n$>

Exception: A zero-length list (structure 1) or item (structure 2) means report all SVIDs.

S1,F4 Selected Equipment Status Data (SSD) M,H<-E

Description: The equipment reports the value of each SVID requested in the order requested. The host remembers the names of values requested.

Structure: L,n
1. <SV_1>
.
.
n. <SV_n>

Exceptions: A zero-length list item for SV_i means that $SVID_i$ does not exist.

S1,F5 Formatted Status Request (FSR) — S,H->E,reply

Description: A request for the equipment to report the status according to a pre-defined fixed format.

Structure: <SFCD>

S1,F6 Formatted Status Data (FSD) — M,H<-E

Description: The equipment reports the value of status variables according to the SFCD.

Structure: Depends upon the structure specified by the status form.

Exception: A zero-length item means that no report can be made.

S1,F7 Fixed Form Request (FFR) — S,H->E,reply

Description: A request for the form used in S1,F6.

Structure: <SFCD>

S1,F8 Fixed Form Data (FFD) — M,H<-E

Description: The form is returned with the name of each value and the data format item having a zero length as a two-element list in the place of each single item to be returned in S1,F6.

Structure: Depends upon the form being specified.

Exception: A zero-length item means the form is unavailable.

S1,F9 Material Transfer Status Request (TSR) — S,H->E,reply

Description: A request to report the status of all material ports to the host.

Structure: Header only

S1,F10 Material Transfer Status Data (TSD) — M,H<-E

Description: The equipment reports to the host the transfer status of all material ports.

Structure: L,2

1. <$TSIP_1$,...,$TSIP_n$>
2. <$TSOP_1$,...,$TSOP_n$>

Exception: A zero-length item means there are no such ports. A zero-length list means there are no ports.

S1,F11 Status Variable Namelist Request (SVNR) S,H->E,reply

Description: A request to the equipment to identify certain status variables.

Structure: L,n
1. <SVID$_1$>
.
.
n. <SVID$_n$>

Exception: A zero length means report all SVIDs.

S1,F12 Status Variable Namelist Reply (SVNRR) M,H<-E

Description: The equipment reports to the host the name and units of the requested SVs.

Structure: L,n
- 1. L,3
  - 1. <SVID$_1$>
  - 2. <SVNAME$_1$>
  - 3. <UNITS$_1$>
- 2. L,3
- .
- .
- n. L,3
  - 1. <SVID$_n$>
  - 2. <SVNAME$_n$>
  - 3. <UNITS$_n$>

Exceptions: Zero-length ASCII items for both SVNAME$_i$ and UNITS$_i$ indicates that the SVID does not exist.

S1,F13 Establish Communications Request (CR) S,H<->E,reply

Description: The purpose of this message is to provide a formal means of initializing communications at a logical application level both on power-up and following a break in communications. It should be the following any period where host and Equipment SECS applications are unable to communicate. An attempt to send an Establish Communications Request (S1,F13) should be repeated at programmable intervals until an Establish Communications Acknowledge(S1,F14) is received within the transaction timeout period with an acknowledgement code accepting the establishment.

Structure: L,2
1. <MDLN>
2. <SOFTREV>

Exception: The host sends a zero-length list to the equipment.

S1,F14 Establish Communications Request Acknowledge (CRA) S,H<->E

Description: Accept or deny Establish Communications Request (S1,F13). MDLN and SOFTREV are on-line data and are valid only if COMMACK = 0.

Structure:
```
L,2
  1. <COMMACK>
  2. L,2
       1. <MDLN>
       2. <SOFTREV>
```

Exception: The host sends a zero-length list for item 2 to the equipment.

S1,F15 Request OFF-LINE (ROFL) S,H->E,reply

Description: The host requests that the equipment transition to the OFF-LINE state.

Structure: Header only

S1,F16 OFF-LINE Acknowledge (OFLA) S,H<-E

Description: Acknowledge or error

Structure: <OFLACK>.

S1,F17 Request ON-LINE (RONL) S,H->E,reply

Description: The host requests that the equipment transition to the ON-LINE state.

Structure: Header only

S1,F18 ON-LINE Acknowledge (ONLA) S,H<-E

Description: Acknowledge or error

Structure: <ONLACK>.

Macro Level Messages

S1,F19 Get Attribute (GA) S,H<—>E,reply[5]

Description: Request for attribute data relating to the specified object or entity within the equipment.

Structure: L,3
  1.<OBJTYPE>
  2.L,m [m=number of objects for which attributes requested]
    1.<$OBJID_1$>
    .
    .
    m.<$OBJID_m$>
  3.L,n [n=number of attributes requested for each object]
    1.<$ATTRID_1$>
    .
    .
    n.<$ATTRID_n$>

Exception: A zero-length list (m=0) is a request for attributes of all objects of the specified type.
A zero-length list (n=0) is a request for all attributes of the object(s)to be returned in a predefined order.

5 Material Movement Management used only the Host to Equipment direction for this message. However, both directions are included for future compatibility with Recipe Management and other future services.

S1,F20 Attribute Data (AD) M,H<—>E

Description: This message is used to transfer the requested set of object attributes. The order of requested objects and attributes is retained from the primary message.

Structure:

```
L,2
  1. L,m        [m=number of objects for which data is sent]
       1.L,n      [n= number of attributes returned for OBJID1]
           1.<ATTRDATA1>
           .
           .
           n.<ATTRDATAn>
       .
       .
       m.L,n      [n= number of attributes returned for OBJIDm]
           1.<ATTRDATA1>
           .
           .
           n.<ATTRDATAn>
  2. L,p        [p=# errors reported]
       1.L,2
           1.<ERRCODE1>
           2.<ERRTEXT1>
           .
           .
       p.L,2
           1.<ERRCODEp>
           2.<ERRTEXTp>
```

Exception: If m=0, it indicates that the specified OBJTYPE is unknown.
If any n=0, it indicates that the corresponding object was not found.
If any ATTRDATA item is reported as a zero-length item, it indicates that the specified attribute does not exist.
If no errors were found, p=0.

7.6 *Stream 2 Equipment Control and Diagnostics* — Messages which deal with control of the equipment from the host. This includes all remote operations and equipment self-diagnostics and calibration but specifically excludes the control operations which are associated with material transfer (see Stream 4), loading of executive and boot programs (Stream 8), and all file and operating system calls (Streams 10, 13). See also continuations in Stream 17.

S2,F0 Abort Transaction (S2F0) S,H<->E

Description: Same form as S1,F0

S2,F1 Service Program Load Inquire (SPI) S,H<->E,reply

Description: Either the host or equipment wants to send the specified program.

Structure:

```
L,2
  1. <SPID>
  2. <LENGTH>
```

S2,F2 Service Program Load Grant (SPG) S,H<->E

Description: Provides permission to load

Structure: <GRANT>

S2,F3 Service Program Send (SPS) M,H<->E, reply

Description: The data associated with the S2,F1 inquire is sent. If S2,F3 is multi-block, it must be preceded by the S2,F1/S2,F2 Inquire/Grant transaction.

Structure: <SPD>

S2,F4 Service Program Send Acknowledge (SPA) S,H<->E

Description: Acknowledge or error

Structure: <SPAACK>

S2,F5 Service Program Load Request (SPR) S,H<->E,reply

Description: A service program is requested.

Structure: <SPID>

S2,F6 Service Program Load Data (SPD) M,H<->E

Description: A service program is sent.

Structure: <SPD>

Exception: A zero-length item means that the requested program cannot be returned.

S2,F7 Service Program Run Send (CSS) S,H->E,reply

Description: Start the requested program

Structure: <SPID>

S2,F8 Service Program Run Acknowledge (CSA) S,H<-E

Description: Acknowledge or error

Structure: <CSAACK>

S2,F9 Service Program Results Request (SRR) S,H->E,reply

Description: Ask for results of service program

Structure: <SPID>

S2,F10 Service Program Results Data (SRD) — M,H<-E

Description: Get the results back

Structure: <SPR>

Exception: A zero-length item means SPR does not exist.

S2,F11 Service Program Directory Request (SDR) — S,H<->E,reply

Description: There may be more than one service program.

Structure: Header only

S2,F12 Service Program Directory Data (SDD) — S,H<->E

Description: A list of service program names.

Structure:

L,n
  1. <SPID$_1$>
  .
  .
  n. <SPID$_n$>

Exception: If n = 0, there are no service programs.

S2,F13 Equipment Constant Request (ECR) — S,H->E,reply

Description: Constants such as for calibration, servo gain, alarm limits, data collection mode, and other values that are changed infrequently can be obtained using this message.

Structure: The following structure is approved for all item formats and should be used by all new implementations:

L,n
  1. <ECID$_1$>
  .
  .
  n. <ECID$_n$>

The following structure is included for compatibility with previous implementations and may only be used for items of format 3() and 5():

<ECID$_1$, . . . , ECID$_n$>

Exception: A zero-length list (structure1) or item (structure2) means report all ECV's according to a predefined order.

S2,F14 Equipment Constant Data (ECD) M,H<-E

Description: Data Response to S2,F13 in the order requested.

Structure: L,n
1. <ECV$_1$>
2. <ECV$_2$>
.
.
n. <ECV$_n$>

Exceptions: A zero-length list item for ECV$_i$ means that ECID$_i$ does not exist. The list format for this data item is not allowed, except in this case.

S2,F15 New Equipment Constant Send (ECS) S,H->E,reply

Description: Change one or more equipment constants.

Structure: L,n
1. L,2
    1. <ECID$_1$>
    2. <ECV$_1$>
2. L,2
.
.
n. L,2
    1. <ECID$_n$>
    2. <ECV$_n$>

S2,F16 New Equipment Constant Acknowledge (ECA) S,H<-E

Description: Acknowledge or error If EAC contains a non-zero error code, the equipment should not change any of the ECIDs specified in S2F15.

Structure: <EAC>

S2,F17 Date and Time Request (DTR) S,H<->E,reply

Description: Useful to check equipment time base or for equipment to synchronize with the host time base.

Structure: Header only

S2,F18 Date and Time Data (DTD) S,H<->E

Description: Actual time data

Structure: <TIME>

Exception: A zero-length item means no time exists.

S2,F19 Reset/Initialize Send (RIS) S,H->E,reply

Description: Causes equipment to reach one of several predetermined initialized conditions.

Structure: <RIC>

S2,F20 Reset Acknowledge (RIA) S,H<-E

Description: Acknowledge or error

Structure: <RAC>

S2,F21 Remote Command Send (RCS) S,H->E,[reply]

Description: Similar to pressing buttons on the front panel or causes some equipment activity to commence or to cease.

Structure: <RCMD>

S2,F22 Remote Command Acknowledge (RCA) S,H<-E

Description: Acknowledge or error

Structure: <CMDA>

S2,F23 Trace Initialize Send (TIS) M,H->E,reply

Description: Status variables exist at all times. This function provides a way to sample a subset of those status variables as a function of time. The trace data is returned on S6,F1 and is related to the original request by the TRID Multiple trace requests may be made to that equipment allowing it. If equipment receives S2,F23 with the same TRID as a trace function that is currently in progress, the equipment should terminate the old trace and then initiate the new trace. A trace function currently in progress may be terminated by S2,F23 with TRID of that trace and TOTSMP=0.

If S2,F23 is multi-block, it must be preceded by the S2,F39/S2,F40 Inquire/Grant transaction. Some equipment may support only single-Block S6,F1, and may refuse a S2,F23 message which would cause a multi-block S6,F1.

Each equipment shall document its trace performance limits. The Host Computer shall not send an S2,F23 which exceeds the equipment's performance limits, or the equipment may operate incorrectly.

Structure: The following structure is approved for all item formats and should be used by all new implementations:

```
L,5
  1. <TRID>
  2. <DSPER>
  3. <TOTSMP>
  4. <REPGSZ>
  5. L,n
       1. <SVID1>
       .
       .
       n. <SVIDn>
```

The following structure is included for compatibility with previous implementations and may only be used for items whose SVID is format 3() and 5():

```
L,5
  1. <TRID>
  2. <DSPER>
  3. <TOTSMP>
  4. <REPGSZ>
  5. <SVID1, . . . , SVIDn>
```

S2,F24 Trace Initialize Acknowledge (TIA) S,H<-E

Description: Acknowledge or error

Structure: <TIAACK>

S2,F25 Loopback Diagnostic Request (LDR) S,H<->E,reply

Description: A diagnostic message for checkout of protocol and communication circuits. The binary string sent is echoed back.

Structure: <ABS>

S2,F26 Loopback Diagnostic Data (LDD) S,H<->E

Description: The echoed binary string

Structure: <ABS>

S2,F27 Initiate Processing Request (IPR) S,H->E,reply

Description: Host requests equipment to initiate processing of the identified material at the specified location in the machine using the specified process program.

Structure:
```
L,3
  1. <LOC>
  2. <PPID>
  3. L,n
       1. <MID1>
       .
       .
       n. <MIDn>
```

Exception: A zero-length PPID indicates no process program is being specified and the equipment is to take whatever action is appropriate for it to determine the proper program to use. A zero-length MID list indicates no MID is to be associated with the material to be processed.

S2,F28 Initiate Processing Acknowledge (IPA) S,H<-E

Description: Response by equipment to Initiate Processing Request. Returned status indicates whether or not the request was honored by the equipment.

Structure: <CMDA>

S2,F29 Equipment Constant Namelist Request (ECNR) S,H->E,reply

Description: This function allows the host to retrieve basic information about what equipment constants are available in the equipment.

Structure:
```
L,n
  1. <ECID1>
  .
  .
  n. <ECIDn>
```

Exception: A zero-length list means send information for all ECIDs.

S2,F30 Equipment Constant Namelist (ECN) M,H<-E

Description: Data Response

Structure: L,n (number of equipment constants)

```
1. L,6
      1. <ECID_1>
      2. <ECNAME_1>
      3. <ECMIN_1>
      4. <ECMAX_1>
      5. <ECDEF_1>
      6. <UNITS_1>
2. L,6
.
.
n. L,6
      1. <ECID_n>
      2. <ECNAME_n>
      3. <ECMIN_n>
      4. <ECMAX_n>
      5. <ECDEF_n>
      6. <UNITS_n>
```

Exceptions: Zero-length ASCII items for $ECNAME_i$, $ECMIN_i$, $ECMAX_i$, $ECDEF_i$, and $UNITS_i$ indicates that the ECID does not exist.

S2,F31 Date and Time Set Request (DTS) S,H->E,reply

Description: Useful to synchronize the equipment time with the host time base.

Structure: <TIME>

S2,F32 Date and Time Set Acknowledge (DTA) S,H<-E

Description: Acknowledge the receipt of time and date.

Structure: <TIACK>

S2,F33 Define Report (DR) M,H->E,reply

Description: The purpose of this message is for the host to define a group of reports for the equipment.

The type of report to be transmitted is designated by a Boolean "Equipment Constant." An "Equipment Constant Value" of "False" means that an "Event Report"(S6,F11) will be sent, and a value of "True" means that an "Annotated Event Report"(S6,F13) will be sent.
If S2,F33 is Multi-block, it must be preceded by the S2,F39/S2,F40 Inquire/Grant transaction.

Structure:

```
L,2
  1. <DATAID>
  2. L,a                                    # reports
       1. L,2                                 report 1
            1. <RPTID1>
            2. L,b                      #VIDs this report
                 1. <VID1>
                 .
                 .
                 b.<VIDb>
       a. L,2                                 report a
            1. <RPTIDa>
            2. L,c                      #VIDs this report
                 1. <VID1>
                 .
                 .
                 c. <VIDc>
```

Exceptions:
1. A list of zero-length following <DATAID> deletes all report definitions and associated links. See S2,F35 (Link Event/Report).
2. A list of zero-length following <RPTID> deletes report type RPTID. All CEID links to this RPTID are also deleted.

S2,F34 Define Report Acknowledge (DRA) S,H<-E

Description: Acknowledge or error If an error condition is detected the entire message is rejected (i.e., partial changes are not allowed).

Structure: <DRACK>

S2,F35 Link Event Report (LER) M,H->E,reply

Description: The purpose of this message is for the host to link n reports to an event (CEID). These linked event reports will default to 'disabled' upon linking. That is, the occurrence of an event would not cause the report to be sent until enabled. See S2,F37 for enabling reports.

If S2,F35 is Multi-block, it must be preceded by the S2,F39/S2,F40 Inquire/Grant transaction.

Structure:

```
L,2
  1. <DATAID>
  2. L,a                                         # events
       1. L,2                                      event 1
            1. <CEID1>
            2. L,b
                 1. <RPTID1>
                 .
                 .
                 b. <RPTIDb>
       .
       .
       a. L,2                                      event a
            1. <CEIDa>                    # RPTIDS this event
            2.L,c
                1.<RPTID1>
                .
                .
                c. <RPTIDc>
```

Exception: A list of zero length following CEID deletes all report links to that event.

S2,F36 Link Event Report Acknowledge (LERA) S,H<-E

Description: Acknowledge or error If an error condition is detected the entire message is rejected (i.e., partial changes are not allowed).

Structure: <LRACK>

S2,F37 Enable/Disable Event Report (EDER) S,H- >E,reply

Description: The purpose of this message is for the host to enable or disable reporting for a group of events (CEIDs).

Structure:

```
L,2
  1. <CEED>                                        enable/disable
  2. L,n   #CEIDs
       1. <CEID1>
       .
       .
       n. <CEIDn>
```

Exception: A list of zero length following <CEED> means all CEIDs.

S2,F38 Enable/Disable Event Report Acknowledge (EERA) — S,H<-E

Description: Acknowledge or error If an error condition is detected the entire message is rejected, i.e., partial changes are not allowed.

Structure: <ERACK>

S2,F39 Multi-block Inquire (DMBI) — S,H->E,reply

Description: If a S2,F23 S2,F33, S2,F35, S2,F45, or S2,F49 message is more than one block, this transaction must precede the message.

Structure: L,2
- 1. <DATAID>
- 2. <DATALENGTH>

S2,F40 Multi-block Grant (DMBG) — S,H<-E

Description: Grant permission to send multi-block message.

Structure: <GRANT>

S2,F41 Host Command Send (HCS) — S,H->E,reply

Description: The Host requests the Equipment perform the specified remote command with the associated parameters.

Structure: L,2
- 1. <RCMD>
- 2. L,n # of parameters
  - 1. L,2
    - 1. <CPNAME$_1$> parameter 1 name
    - 2. <CPVAL$_1$> parameter 1 value
  - .
  - .
  - n. L,2
    - 1. <CPNAME$_n$>parameter n name
    - 2. <CPVAL$_n$>parameter n value

S2,F42 Host Command Acknowledge (HCA) S,H<-E

```
Description:   Acknowledge Host command or error. If command is not accepted due to
               one or more invalid parameters (i.e., HCACK=3), then a list of
               invalid parameters will be returned containing the parameter name and
               reason for being invalid.

Structure:     L,2
                 1. <HCACK>
                 2. L,n # of parameters
                    1. L,2
                         1. <CPNAME1> parameter 1 name
                         2. <CPACK1> parameter 1 reason
                    .
                    .
                    n. L,2
                         1. <CPNAMEn>parameter n name
                         2. <CPACKn>parameter n reason

Exception:     If there are no invalid parameters, then a list of zero length will
               be sent for item 2.
```

S2,F43 Reset Spooling Streams and Functions (RSSF) S,H->E,reply

```
Description:   This message allows the host to select specific streams and functions
               to be spooled whenever spooling is active.

Structure:     L,m
                 1. L,2
                      1.<STRID1>
                      2. L,n
                           1. <FCNID1>
                           .
                           .
                           n. <FCNIDn>
                      .
                      .
                      m. L,2
                           1. <STRIDm>
                           2. L,n
                              1. <FCNID1>
                              .
                              .
                              . <FCNIDn>

Exceptions:    1. A zero-length list, m=0, turns off spooling for all streams and
                  functions.
               2. A zero-length list, n=0, turns on spooling for all functions for
                  the associated stream.

Notes:         1. Turning off spooling for all functions for a specific stream is
                  achieved by omitting reference to the stream from this message.
               2. Spooling for Stream 1 is not allowed.
               3. Equipment must allow host to spool all primary messages for a
                  stream (except Stream 1).
               4. A defined list of functions for a stream in this message will
                  replace any previously selected functions.
```

S2,F44 Reset Spooling Acknowledge (RSA) M,H<-E

Description: Acknowledge or error

Structure: L,2

1. <RSPACK> (accept or reject)
2. L,m (m = number of streams with errors)
    1. L,3
        1. <$STRID_1$>
        2. <$STRACK_1$> (error in stream)
        3. L,n (n = number of functions in error)
            1. <$FCNID_1$>
            .
            .
            n. <$FCNID_n$>

    .
    .
    m. L,3
        1. <$STRID_m$>
        2. <$STRACK_m$> (error in stream)
        3. L,n (n = number of functions in error)
            1. <$FCNID_1$>
            .
            .
            n. <$FCNID_n$>

Exceptions:

1. If RSPACK=0, a zero-length list, m=0, is given, indicating no streams or functions in error.
2. A zero-length list, n=0, indicates no functions in error for specified stream.

S2,F45 Define Variable Limit Attributes (DVLA) M,H->E,reply

```
Structure:    L,2
              1. <DATAID>
              2. L,m (m=# of variables in this definition)
                   1. L,2
                        1. <VID_1>
                        2. L,n (n=# of limits being defined/changed for VID_1)
                             1. L,2
                                  1. <LIMITID_1>
                                  2. L,p (p={0,2})
                                       1. <UPPERDB_1>
                                       2. <LOWERDB_1>
                                       .
                                       .
                                       n. L,2
                                            1. <LIMITID_n>
                                            2. L,p (p={0,2})
                                                 1. <UPPERDB_n>
                                                 2. <LOWERDB_n>
              .
              .
              m.L,2
                  1. <VID_m>
                  2. L,n (n=# of limits being defined/changed for VID_m)
                       1. L,2
                            1. <LIMITID_1>
                            2. L,p (p={0,2})
                                 1. <UPPERDB_1>
                                 2. <LOWERDB_1>
                            .
                            .
                            n. L,2
                                 1. <LIMITID_n>
                                 2. L,p (p={0,2})
                                      1. <UPPERDB_n>
                                      2. <LOWERDB_n>

Exceptions:   1. A zero-length list, m=0, sets all limit values for all monitored
                 VIDs to "undefined."
              2. A zero-length list, n=0, sets all limits values for that VID to
                 "undefined."
              3. A zero-length list, p=0, sets that limit to "undefined."
```

S2,F46 Variable Limit Attribute Acknowledge (VLAA) M,H<-E

Description: Acknowledge definition of variable limit attributes or report error. If DVLA is not accepted due to one or more invalid parameters (e.g., LIMITACK=3), then a list of invalid parameters is returned containing the variable limit attribute and reason for rejection. If an error condition is detected, the entire message is rejected (i.e., partial changes are not allowed).

Structure:

```
L,2
  1. <VLAACK>
  2. L,m                           (m=number of invalid parameters)
       1. L,3
            1. <VID_1>             (VID with error)
            2.<LVACK_p>            (reason)
            3.L,n {n=0,2}
                1. <LIMITID_1>     (1st limit in error for VID_p)
                2. <LIMITACK_1>    (reason)
       .
       .
       m. L,3
            1. <VID_m>             (VID with error)
            2. <LVACK_m>           (reason)
            3. L,n {n=0,2}
                 1. <LIMITID_1>    (1st limit in error for VID_x)
                 2. <LIMITACK_1>   (reason)
```

Exceptions:

1. A zero-length list, m=0 indicates no invalid variable limit attributes.
2. A zero-length list, n=0 indicates no invalid limit values for that VID.

S2,F47 Variable Limit Attribute Request (VLAR) S,H->E,reply

Description: This message allows the host to query the equipment for current variable limit attribute definitions.

Structure:

```
L,m                                (m=# of VIDs this request)
  1. <VID_1>
  .
  .
  m. <VID_m>
```

Exception: A zero-length list, m=0, requests a list of all VID values that can have variable limit attributes.

S2,F48 Variable Limit Attributes Send (VLAS) M,H<-E

Description: Equipment sends values of requested variable limit attribute definitions in the order requested.

Structure:

```
L,m                               (m=# of VIDs this request)
  1.L,2
      1. <VID1>
      2. L,p {p=0,4}
           1. <UNITS1>
           2. <LIMITMIN1>
           3. <LIMITMAX1>
           4. L,n                 (n=# of limits defined for this VID)
                1. L,3
                     1. <LIMITID1>
                     2. <UPPERDB1>
                     3. <LOWERDB1>
                .
                .
                n. L,3
                     1.<LIMITIDn>
                     2.<UPPERDBn>
                     3.<LOWERDBn>
  .
  .
  m.L,2
      1.<VIDm>
      2. L,p {p=0,4}
           1.<UNITSm>
           2.<LIMITMINm>
           3.<LIMITMAXm>
           4. L,n                 (n=# of limits defined for this VID)
                1. L,3
                     1.<LIMITID1>
                     2.<UPPERDB1>
                     3.<LOWERDB1>
                .
                .
                n. L,3
                     1.<LIMITIDn>
                     2.<UPPERDBn>
                     3.<LOWERDBn>
```

Exceptions:

1. A zero-length list, p=0, indicates that limits are not supported for the VID.
2. A zero-length list, n=0, means no limits are currently defined for the specified variable.

S2,F49 Enhanced Remote Command — M,H->E

Description: The host requests an object to perform the specified remote command with its associated parameters. If multi-block, it shall be preceded by the S2,F39/S2,F40 Multi-Block Inquire/Grant transaction.

Structure:

```
L,4
  1. <DATAID>
  2. <OBJSPEC>
  3. <RCMD>
  4. L,m # of parameter groups
       1. L,2
            1. <CPNAME1> command parameter 1 name
            2. <CEPVAL1> command-enhanced parameter 1 value
       2. L,2
            1. <CPNAME2> command parameter 2 name
            2. <CEPVAL2> command-enhanced parameter 2 value
       .
       .
       .
       .
       m. L,2
            1. <CPNAMEm> command parameter m name
            2. <CEPVALm> command enhanced parameter m value
```

If a specific value of CPNAME is defined to have a CEPVAL defined as a LIST, it shall always be a LIST. If the CEPVAL that is associated to that specific value of CPNAME is defined to be anything other than LIST, it will result in a format error.

Exception: A zero length list, m = 0, indicates that no parameter groups are sent with the command. OBJSPEC can be a null length item.

Notes: 1. If CEPVAL is a LIST, the items that make up that list shall take on one of the following forms: (1) a list of items with an identical format, (2) a LIST of CPNAME, CEPVAL pairs, as illustrated below.

```
A) L,2
     1. <CPNAMEa>
     2. L,m
          1. <CPVALa1>
          2. <CPVALa2>
          .
          .
          .
          .
          .
          .
          m. <CPVALam>
```

```
B) L,2
     1. <CPNAMEb>
     2. L,n
          1. L,2
               1. <CPNAMEb1>
               2. <CEPVALb1>
          .
          .
          n. L,2
               1. <CPNAMEbn>
               2. <CEPVALbn>
```

S2,F50 Enhanced Remote Command Acknowledge M,H<-E

Description: The equipment acknowledges Enhanced Remote Command or reports any error(s). If the command is not accepted due to one or more invalid parameters, (i.e. HCACK = 3), then a list of invalid parameters will be returned containing the parameter name and reason for being invalid.

Structure: L,2
- 1. <HCACK>
- 2. L,n # of parameter groups
  - 1. L,2
    - 1. <CPNAME$_1$>
    - 2. <CEPACK$_1$>
  - .
  - .
  - n. L,2
    - 1. <CPNAME$_n$>
    - 2. <CEPACK$_n$>

7.7 *Stream 3 Materials Status* — The functions of the material status stream are used to communicate information and actions related to material, including carriers and material-in-process, time-to-completion information, and extraordinary material occurrences.

S3,F0 Abort Transaction (S3F0) S,H<->E

Description: Same form as S1,F0.

S3,F1 Material Status Request (MSR) S,H->E,reply

Description: Host requests the device to send the status of all material in process.

Structure: Header only

S3,F2 Material Status Data (MSD) M,H<-E

Description: Material-in-process information is sent from the equipment to the host. There are m locations.

Structure: L,2
- 1. <MF>
- 2. L,m
  - 1. L,3
    - 1. <LOC$_1$>
    - 2. <QUA$_1$>
    - 3. <MID$_1$>
  - 2. L,3
  - .
  - .
  - m. L,3
    - 1. <LOC$_m$>
    - 2. <QUA$_m$>
    - 3. <MID$_m$>

Exception: A zero-length list returned means no such data exists.

S3,F3 Time to Completion Request (TCR) S,H->E,reply

```
Description:   Host requests the equipment to send the time-to-completion of
               operations on all material in possession.

Structure:     Header only
```

S3,F4 Time to Completion Data (TCD) M,H<-E

```
Description:   Time-to-completion information is sent by the equipment to the host.

Structure:     L,2
                 1. <MF>
                 2. L,m
                      1. L,3
                           1. <TTC1>
                           2. <QUA1>
                           3. <MID1>
                      2. L,3
                      .
                      .
                      m. L,3
                           1. <TTCm>
                           2. <QUAm>
                           3. <MIDm>

Exception:     A zero-length list header returned means no such data exists.
```

S3,F5 Material Found Send (MFS) S,H<-E,[reply]

```
Description:   The equipment advises the host that unsolicited material has appeared
               at one of its sensors.

Structure:     L,2
                 1. <MF>
                 2. <QUA>
```

S3,F6 Material Found Acknowledge (MFA) S,H->E

```
Description:   Acknowledge or error

Structure:     <ACKC3>
```

S3,F7 Material Lost Send (MLS) S,H<-E,[reply]

```
Description:   The equipment advises the host that material has disappeared from its
               sensors.

Structure:     L,3
                 1. <MF>
                 2. <QUA>
                 3. <MID>
```

S3,F8 Material Lost Acknowledge (MLA) S,H->E

```
Description:   Acknowledge or error

Structure:     <ACKC3>
```

S3,F9 Material ID Equate Send (IES) — S,H<-E,reply

Description: Provide an alternative name to be used as equivalent to the original material ID.

Structure: L,2
1. <MID>
2. <EMID>

S3,F10 Material ID Equate Acknowledge (IEA) — S,H->E

Description: Acknowledge or error

Structure: <ACKC3>

S3,F11 Material ID Request (MIDR) — S,H<-E,reply

Description: The equipment requests the Material ID of the material at the specified port.

Structure: <PTN>

S3,F12 Material ID Request Acknowledge (MIRA) — S,H->E

Description: The host acknowledges the request for the Material ID. If the use of a request/acknowledge/send/acknowledge conversation is required, it indicated by the acknowledge code MIDRA=2. In this case, the send/ acknowledge transaction is S3,F13, S3,Fl4. A timeout when electing S3,F13 is indicated by S9,F13 or a restart of the conversation, with S3,F11.

Structure: L,3
1. <PTN>
2. <MIDRA>
3. <MID>

Note: For all cases except MIDRA=0 (accepted, <MID> follows), the <MID> will be ignored by the receiver of message S3,F12. When MIDRA=0, a zero-length MID indicates that no MID is available.

S3,F13 Material ID Send (MIS) — S,H->E,reply

Description: The host sends the Material ID of the material at the specified port.

Structure: L,2
1. <PTN>
2. <MID>

Note: A zero-length MID indicates that no MID is available.

S3,F14 Material ID Acknowledge (MIA) — S,H<-E

Description: Acknowledge or error

Structure: <MIDAC>

S3,F15 Materials Multi-Block Inquire (MMBI) — S,H->E,reply

Description: This message requests permission to send a multi-block message based upon a maximum length of the total message. It must be sent prior to sending any multi-block primary message in Stream 3.

Structure: L,2
1. <DATAID>
2. <DATALENGTH>

S3,F16 Materials Multi-Block Grant (MMBG) — S,H< - E

Description: This message grants or denies permission to send a multi-block primary message in Stream 3.

Structure: <GRANT>

S3,F17 Carrier Action Request — M,H->E,reply

Description: This message requests an action to be performed for a specified carrier. If multi-block, this message must be preceded by the S3,F11/F12 transaction.

Structure: L,5
1. <DATAID>
2. <CARRIERACTION>
3. <CARRIERID>
4. <PTN>
5. L,n — n = number of carrier attributes
   1. L,2
      1. <CATTRID$_1$>
      2. <CATTRDATA$_1$>
   .
   .
   n. L,2
      1. <CATTRID$_n$>
      2. <CATTRDATA$_n$>

Exception: If n = 0, then no carrier attributes are included. If CARRIERID is not a zero-length item, then PTN may be omitted (a zero-length item). ATTRID and ATTRDATA may be substituted for CATTRID and CATTRDATA Respectively.

S3,F18 Carrier Action Acknowledge — S,H<-E

Description: This message acknowledges the carrier action request.

Structure:
L,2
  1. <CAACK>
  2. L,n
     1. L,2
        1. <ERRCODE$_1$>
        2. <ERRTEXT$_1$>
     .
     .
     n. L,2
        1. <ERRCODE$_n$>
        2. <ERRTEXT$_n$>

Exception: If n = 0, no errors exist.

S3,F19 Cancel All Carrier Out Request — S,H->E, reply

Description: This message is used to cancel all pending carrier out requests.

Structure: Header only.

S3,F20 Cancel All Carrier Out Acknowledge — S,H<-E

Description: This message acknowledges the Cancel Carrier Out request.

Structure:
L,2
  1. <CAACK>
  2. L,n
     1. L,2
        1. <ERRCODE$_1$>
        2. <ERRTEXT$_1$>
     .
     .
     n. L,2
        1. <ERRCODE$_n$>
        2. <ERRTEXT$_n$>

Exception: If n = 0, no errors exist.

S3,F21 Port Group Definition — S,H->E, reply

Description: This message defines the port in a port group and provides the initial port access.

Structure:
L,3
  1. <PORTGRPNAME>
  2. <PORTACCESS>
  3. L,n
     1. <PTN$_1$>

```

S3,F27 Change Access S,H->E, reply

Description: The Host requests the Equipment to change the Access Mode for the specified Load Ports. ACCESSMODE specifies the desired Access Mode. PTN specifies a desired Load Port Number.

```
Structure:    L,2
                 1. <ACCESSMODE>
                 2. L,n
                       1. <PTN1>
                       .
                       .
                       n. <PTNn>
```

Exceptions: If n=0, then the command applies to all Load Ports on the equipment. If any specified port is already in the specified Access Mode, then the Equipment shall accept the command, and toggle all loadports to specified mode. If the Equipment is unable to change one or more of specified Port(s) to the specified Access Mode, then the Equipment shall accept the command (with appropriate response acknowledgement), and shall change only the Access Mode of those Port(s) allowed by the equipment, supplying the host with an indication that not all ports were successfully changed.

S3,F28 Change Access Acknowledge S,H<-E

```
Structure:    L, 2
                 1. <CAACK>
                 2. L, n
                       1. L, 3
                             1. <PTN1>
                             2. <ERRCODE1>

                       .
                       .
                       n. L, 3
                             1. <PTNn>
                             2. <ERRCODEn>
                             3. <ERRTEXTn>
```

Exceptions: If the command is successful, CAACK = 0, and n=0.
If the command was successful for some ports, CAACK = 6, and n>0.

S3,F29 Carrier Tag Read Request — S,H->E, reply

Description: The host requests the equipment to read data from the carrier tag of a carrier. The carrier must be identified either by its location identifier or its carrier identifier, or both. DATASEG may be used to indicate a specific section of data to be read. DATALENGTH is used to limit the amount of data for that section.

Structure:

```
L, 4
   1. <LOCID>
   2. <CARRIERSPEC>
   3. <DATASEG>
   4. <DATALENGTH>
```

Exceptions: Either LOCID and CARRIERSPEC can omitted (zero length item), but not both. If DATASEG and DATALENGTH are both omitted (are zero length items) then all data is requested. If DATALENGTH only is omitted, then all data within the indicated section is requested.

S3,F30 Carrier Tag Read Data (CTRD) — S,H<-E

Description: This message is used to return requested information from the carrier tag of the carrier indicated in the request and to acknowledge the results of the request.

Structure:

```
L, 2
   1. <DATA>
   2. <L, 2>
          1. <CAACK>
          2. L, s
                1. L, 2
                      1. <ERRCODE_1>
                      2. <ERRTEXT_1>
                .
                .
                s. L, 2
                      1. <ERRCODE_s>
                      2. <ERRTEXT_s>
```

Exceptions: If the carrier identifier or the carrier location originally specified is unknown, then DATA is zero length. If CAACK is non-zero, then DATA is zero length.

S3,F31 Carrier Tag Write Data Request (CTWDR) S,H->E, reply

Description: The host requests the equipment to write data to a carrier tag. The carrier must be indicated either by its location identifier or its carrier identifier, or both. DATASEG may be used to indicate a specific section of data to be written or overwritten. DATALENGTH may be used to indicate the length of the data to be written.

```
Structure:    L, 5
                 1. <LOCID>
                 2. <CARRIERSPEC>
                 3. <DATASEG>
                 4. <DATALENGTH>
                 5. <DATA>
```

Exceptions: Either LOCID and CARRIERSPEC can be omitted (zero length item), but not both. If DATASEG and DATALENGTH are both omitted (are zero length items) then all data is to be overwritten. If only DATALENGTH is omitted, then all data within the indicated section is to be written.

S3,F32 Carrier Tag Write Data Acknowledge (CTWDA) S,H<-E

Description: This message acknowledges the success or failure of writing data to the carrier tag requested.

```
Structure:    L, 2
                 1. <CAACK>
                 2. L, s
                       1. L, 2

7.8 *Stream 4 Material Control* — The material control stream contains the original material control protocol and the newer protocol which supports SEMI E32.

7.8.1 *Original Material Control Protocol* — The functions in the material control stream are used to effect the automatic transfer of material between equipment. A simple handshake is achieved which provides for a variety of error conditions which gracefully terminate the handshake. Separate messages advise the host of errors and completed material transfers.

7.8.1.1 Since the handshake and host messages are separate, the handshake may be achieved transparently through the host or by direct connection between equipment. The host completes the handshake by relaying messages between the equipment. Only a single port is required on the equipment, and the equipment has a simple message handling requirement. When a direct connection is desired, at least three ports are required, the receiving equipment must look like the host with respect to the sending equipment, and message handling in the equipment is significantly more complicated than in the host-only connection. Nevertheless, the direct connection may still be chosen in an attempt to provide operation without a host. Since the host is reasonably transparent in the material handshake, a simple explanation of the handshake may be achieved by just considering the exchange of messages between the sender, the equipment wanting to get rid of material, and the receiver (the equipment able to accept the material).

7.8.1.2 Figure S4.1 shows six possible handshake situations between the sender and the receiver. There are two normal handshakes. Figure S4.1(a) shows the normal three-message exchange when material is passed between equipment. The host is informed of a complete transfer of material. Figure S4.1(b) shows an alternative message exchange where the sender changes its mind and decides not to send the material. Figures S4.1(c) and (d) show two situations where the material gets stuck during the transfer. In each situation an error message is issued to the host from the equipment where the material is stuck. The other equipment terminates normally. When material is stuck, manual intervention is required to move the material towards the equipment which indicates the stuck condition. The manual intervention has two possible outcomes. One, the material can be moved to a position where the handshake can resume or, two, the material is broken or lost from the transfer. Lost material causes a lost material error message to be sent to the host prior to resuming the operation. The specific details of recovering front stuck material are equipment-dependent. The stuck material condition is determined by the amount of time the material transfer mechanism is turned on. The sender claims stuck material if the material is not clear of its sensor before a time t1. The receiver claims stuck material if the material is not received before time t2. Figures S4.1(e) and (f) show the possible error conditions in the unlikely event that for some reason a handshake message is lost. Figure S4.1(e) shows that time t3 is the longest that the sender will wait for material received message. Times t2 and t3 set an upper limit on the amount of time either material transport mechanism will operate.

7.8.1.3 Figure S4.2 summarizes the interaction of the timers, handshake messages, and the error messages in the form of a flow chart. It also identifies specific states for the sender and the receiver. These states are referred to in the messages.

The ranges of timer values are as follows:

tl — time to leave sender

tl+ 10<= t2<= 60sec.---time to receive

t2+ 10<= t3<= 70sec.---time to complete send

Default values, tl= 10 sec., t2= 60 sec., t3= 70 sec.

NOTE 7: t1, t2, t3 defined for Stream 4 are not to be confused with timeouts T1, T2, T3, and T4 defined in SEMI E4 (SECS-I).

```

S4,F4 Not Used

S4,F5 Handshake Complete (HCN) S,H<->E

```
Description:   Receiver advises sender that the handshake is complete. The sender
               may now stop its transfer mechanism.

Structure:     L,2
                 1. <PTN>
                 2. <MID>
```

S4,F6 Not Used

S4,F7 Not Ready to Send (ABN) S,H<->E

```
Description:   Sender advises receiver that no material is being sent. The receiver
               may now stop its transfer mechanism.

Structure:     L,2
                 1. <PTN>
                 2. <MID>
```

S4,F8 Not Used

S4,F9 Stuck in Sender (SSN) S,H<-E

Description: An error from the sender to the host. The time between the receipt of Material (SMN) and the material leaving the sender's sensor exceeds the sender's t1 timeout. The sender goes to a hold state until the disposition of the stuck material is determined.

Structure: L,2
1. <PTN>
2. <MID>

S4,F10 Not Used

S4,F11 Stuck in Receiver (SRN) S,H<-E

Description: An error from the receiver to the host. The time between Send Material (SMN) and detection of the material at the receiver exceeds the receiver's t2 timeout. The receiver goes to a hold state until the disposition of material is determined.

Structure: L,2
1. <PTN>
2. <MID>

S4,F12 Not Used

S4,F13 Send Incomplete Timeout (SIN) S,H<-E

Description: An error from the sender to the host. The time between the receipt of the Send Material (SMN) and the receipt of Handshake-Complete (HCN) exceeds the sender's t3 timeout. There has been an error in the handshake and the transfer mechanism is turned off.

Structure: L,2
1. <PTN>
2. <MID>

S4,F14 Not Used

S4,F15 Material Received (MRN) S,H<-E

Description: A message from the receiver to the host. Material has been transferred to the receiver.

Structure: L,2
1. <PTN>
2. <MID>

S4,F16 Not Used

S4,F17 Request to Receive (RTR) S,H<->E,reply

Description: Receiver requests the sender initiate a conversation to send the specified material to the specified port.

Structure: L,2
1. <PTN>
2. <MID>

Exceptions: A zero-length MID means equipment doesn't know MID.

S4,F18 Request to Receive Acknowledge (RRA) S,H<->E

Description: Acknowledge or error

Structure: <RRACK>

7.8.2 *Support for Material Movement Management Services* — The following messages were defined to support SEMI E32.

7.8.2.1 *Macro Level Messages* — The following messages support the host supervised macro level of material movement as defined in SEMI E32. Stream 1 Macro Level Messages can be found in Section 7.5: S1F19, Get Attribute (GA); S1F20, Attribute Data (AD).

S4,F19 Transfer Job Create (TJ) M,H—>E,reply

Description: The host requests that the equipment undertake one or more discrete (or atomic) transfers to achieve a host defined objective. The host provides the transfer specifications for each atomic transfer. Atomic transfers on separate ports on the equipment are allowed to execute in parallel. Atomic transfers for a port must be executed sequentially or in some cases concurrently. Both equipment transfer partners for each atomic transfer must receive appropriate Transfer Job Request messages in order to execute a transfer. If S4,F20 is multi-block, it must be preceded by the S4,F25/S4,F26 Inquire/Grant transaction.

Structure:

      2.<ERRTEXT$_n$>

Exception: If the command is accepted, n=0.

S4,F23 Transfer Job Alert (TJA) — S,H<—E,[reply]

Description: Equipment informs the host that a transfer job milestone has been reached (e.g., job started or job complete). If complete, all equipment resources originally reserved for the transfer have been released.

Structure: L,4
  1.<TRJOBID>
  2.<TRJOBNAME>
  3.<TRJOBMS>
  4. L,2
    1.<TRACK> [success or failure]
    2. L,n [n=# errors reported]
      1. L,2
        1.<ERRCODE$_1$>
        2.<ERRTEXT$_1$>
      .
      .
      n. L,2
        1.<ERRCODE$_n$>
        2.<ERRTEXT$_n$>

Exception: If the transfer job is completed successfully, n=0.

S4,F24 Transfer Alert Acknowledge (TLA) — S,H—>E

Description: Acknowledge receipt of the S4,F23 message.

Structure: Header Only

S4,F25 Multi-block Inquire (MB14) S,H—>E,reply

```
Description:   If a Stream 4 host-initiated message is more than a single block in
               length, this transaction must precede the message.

Structure:     L,2
                 1.<DATAID>
                 2.<DATALENGTH>
```

S4,F26 Multi-block Grant (MBG4) S,H<—E

```
Description:   Grant (or deny) permission to send multi-block message.

Structure:     <GRANT>
```

7.8.2.2 *Micro Level Messages* — The following messages support the equipment-to-equipment micro level handoff of material as defined in SEMI E32.

7.8.2.2.1 The messages which support the micro level are passed directly between the equipment. For the purpose of the communication link, one of the equipment must be designated the host and the other the equipment. The choice is up to the implementer. Equipment which are configurable to act as either host or equipment are suggested for ease of installation.

7.8.2.2.2 The two equipment involved in a micro level transfer assume different roles. One equipment is designated the " Primary Transfer Partner," and the other is the " Secondary Transfer Partner" (see SEMI E32 for more definition). While some consistency of roles is expected, this designation is fluid and may change from one transfer to the next. The Primary Transfer Partner has more responsibility and thus initiates messages which the Secondary does not.

7.8.2.2.3 The selection of " Host" and " Equipment" for the communication link is not related to the fluid relationship of Primary and Secondary Transfer Partner. However, it is the designation of Primary or Secondary which determines the originator of certain messages. It is for this reason that the designation P = Primary and S = Secondary Transfer Partner.

Micro Level Messages

S4,F27 Handoff Ready (HR) S,P<—>S

```
Description:   Each transfer partner informs the other when they are ready to
               perform a specified atomic transfer. The TRLINK values from the two
               partners must match. The values contained in the atomic transfer
               specification pertain to the sender of the message (except where
               specified).

Structure:     L,2
                 1.<EQNAME>
                 2.L,11               [Specification for atomic xfr]
                      1.<TRLINK>      [Atomic transfer identifier]
                      2.<TRPORT>      [Port to be used for transfer]
                      3.<TROBJNAME>   [Transfer object identifier]
                      4.<TROBJTYPE>   [Object type-what form the material is in]
                      5.<TRROLE>      [Role in transfer-primary/secondary]
                      7.<TRPTNR>      [Identifier of transfer partner]
                      8.<TRPTPORT>    [Partner's Port to be Used]
                      9.<TRDIR>       [Transfer direction-send or receive]
                     10.<TRTYPE>      [Active or Passive]
                     11.<TRLOCATION>  [Location to send/receive mtl]
```

S4,F28 Not Used

S4,F29 Handoff Command (HC) S,P—>S

```
Description:   Command issued by the primary to the secondary transfer partner to
               achieve some physical action.

Structure:     L,4
                 1.<TRLINK>            [Atomic Transfer identifier]
                 2.<MCINDEX>           [Identified this specific Micro Cmd request]
                 3.<HOCMDNAME>         [Requested Micro Cmd]
                 4.L,n                 [n=number of parameters]
                     1.L,2
                         1.<CPNAME1>  [Micro Cmd parameter name]
                         2.<CPVAL1>   [Micro Cmd parameter value]
                     .
                     .
                     n.L,2
                         1.<CPNAMEn>
                         2.<CPVALn>

Exception:     n=0 if no parameters are used.
```

S4,F30 Not Used

S4,F31 Handoff Command Complete (HCC) S,P<—S

```
Description:   Completion status of the micro command. This is sent from the
               secondary to the primary transfer partner when the command is
               completed or terminated.

Structure:     L,3
                 1.<TRLINK>             [Atomic Transfer identifier]
                 2.<MCINDEX>            [Links to specific micro command (S4,F31)]
                 3.L,2
                     1.<HOACK>          [success or failure]
                     2.L,n              [n=# errors reported]
                         1.L,2
                             1.<ERRCODE1>

S4,F34 Not Used

S4,F35 Handoff Cancel Ready (HCR) P<—>S

Description: Sent by either transfer partner to cancel a previous Handoff Ready message. This message is valid only before the handoff has begun.

Structure: <TRLINK>

S4,F36 Not Used

S4,F37 Handoff Cancel Ready Acknowledge (HCA) P<—>S

Description: Sent by the receiver of the Handoff Cancel Ready message to accept or deny the cancel. The cancel request is denied if the handoff process has begun.

Structure:

L,2
  1.<TRLINK>
  2.<HOCANCELACK>

S4,F38 Not Used

S4,F39 Handoff Halt (HH) P<—>S

Description: Sent by either transfer partner to cause all transfer related activity of the other to cease immediately. It is used when the equipment or material is at risk of damage.

Structure: <TRLINK>

S4,F40 Not Used

S4,F41 Handoff Halt Acknowledge (HHA) P<—>S

Description: Sent to equipment's transfer partner following completion of halt activities resulting from a previously received S4,F39.

```
Structure:    L,2
                1.<TRLINK>
                2.<HOHALTACK>
```

S4,F42 Not Used

7.9 *Stream 5 Exception Handling* — This stream contains messages regarding binary and analog equipment exceptions. Exceptions are classified into two categories: errors and alarms. Messages S5,F1 through S5,F8 of this section provide basic alarm messages. The messages S5,F9 through S5,F18 provide extended capabilities for Exception Handling. When using messages F1 - F8, alarms may be divided into categories as follows:

1. *personal safety* — Condition may be dangerous to people.
2. *equipment safety* — Condition may harm equipment.
3. *parameter control warning* — Parameter variation outside of preset limits — may harm product.
4. *parameter control error* — Parameter variation outside of reasonable control limits — may indicate an equipment malfunction.
5. *irrecoverable error* — Intervention required before normal use of equipment can resume.
6. *equipment status warning* — An unexpected condition has occurred, but operation can continue.
7. *attention flags* — A signal from a process program indicating that a particular step has been reached.
8. *data integrity* — A condition which may cause loss of data; usually related to Stream 6.

7.9.1 For messages F1 through F8, it will be the equipment' s responsibility to categorize the alarm. Some alarm conditions may cause more than one type of alarm to be issued. For example, a parameter control error on over temperature may also trip a protective device that makes the alarm irrecoverable without some intervention.

S5,F0 Abort Transaction (S5F0) S,H<->E

Description: Same form as S1,F0.

S5,F1 Alarm Report Send (ARS) S,H<-E,[reply]

Description: This message reports a change in or presence of an alarm condition. One message will be issued when the alarm is set and one message will be issued when the alarm is cleared. Irrecoverable errors and attention flags may not have a corresponding clear message.

```
Structure:    L,3
                1. <ALCD>
                2. <ALID>
                3. <ALTX>
```

S5,F2 Alarm Report Acknowledge (ARA) S,H->E

Description: Acknowledge or error

Structure: <ACKC5>

S5,F3 Enable/Disable Alarm Send (EAS) S,H->E,[reply]

Description: This message will change the state of the enable bit in the equipment. The enable bit determines if the alarm will be sent to the host. Alarms which are not controllable in this way are unaffected by this message.

Structure: L,2
  1. <ALED>
  2. <ALID>

Exception: A zero-length item for ALID means all alarms.

S5,F4 Enable/Disable Alarm Acknowledge (EAA) S,H<-E

Description: Acknowledge or error

Structure: <ACKC5>

S5,F5 List Alarms Request (LAR) S,H->E,reply

Description: This message requests the equipment to send binary and analog alarm information to the host.

Structure: <$ALID_1$, . . . ,$ALID_n$>

Exception: A zero-length item means send all possible alarms regardless of the state of ALED.

S5,F6 List Alarm Data (LAD) M,H<-E

Description: This message contains the alarm data known to the equipment. There are “m” alarms in the list.

Structure: L,m
  1. L,3
      1. <$ALCD_1$>
      2. <$ALID_1$>
      3. <$ALTX_1$>
  2. L,3
  .
  .
  m. L,3
      1. <$ALCD_m$>
      2. <$ALID_m$>
      3. <$ALTX_m$>

Exception: If m=0, no response can be made. A zero-length item returned for $ALCD_i$ or $ALTX_i$ means that value does not exist.

S5,F7 List Enabled Alarm Request (LEAR) S,H->E,reply

Description: List alarms which are enabled.

Structure: Header only

S5,F8 List Enabled Alarm Data (LEAD) M,H<-E

Description: This message is similar to S5,F6 except that it lists only alarms which are enabled.

Structure: Same as S5,F6

S5,F9 Exception Post Notify (EXPN) S,H<-E,[reply]

Description: This message provides the means to inform a host system that an exception condition is 'set'. Optionally, recovery actions for the exception may be sent.

Structure:

```
L,5
  1. <TIMESTAMP>
  2. <EXID>
  3. <EXTYPE>
  4. <EXMESSAGE>
  5. L,n
       1. <EXRECVRA1>
       .
       .
       .
       n. <EXRECVRAn>
```

Exception: A zero-length list (n = 0) shall be sent when there are no possible recovery actions.

Exception: This is a single block message. The text in each of the EXRECVRA data items may need to be restricted in length to meet the single block requirement.

S5,F10 Exception Post Confirm (EXPC) S,H->E

Description: Host confirms receipt of S5,F9 message from the equipment.

Structure: Header only

S5,F11 Exception Clear Notify (EXCN) S,H <-E,[reply]

Description: This message provides the means to inform a host system that an exception/alarm condition is no longer active (set).

Structure:

```
L,4
  1. <TIMESTAMP>
  2. <EXID>
  3. <EXTYPE>
  4. <EXMESSAGE>
```

Exception: EXMESSAGE can be used to provide the reason that the exception cleared.

S5,F12 Exception Clear Confirm (EXCC) S,H->E

Description: Host confirms receipt of S5,F11 message from the equipment.

Structure: Header only

S5,F13 Exception Recover Request (EXRR) S,H->E,reply

Description: Request that the entity which is experiencing an error execute a recovery action.

Structure:
```
L,2
  1. <EXID>
  2. <EXRECVRA>
```

S5,F14 Exception Recover Acknowledge (EXRA) S,H<-E

Description: The entity indicates a response to the recovery request.

Structure:
```
L,2
  1. <EXID>
  2. L,2
       1. <ACKA>
       2. L,m (m = {0,2})
            1. <ERRCODE>
            2. <ERRTEXT>
```

Exception: The list m can be zero length, if the recovery request was accepted.

S5,F15 Exception Recovery Complete Notify (EXRCN) S,H<-E,[reply]

Description: Allows the service provider to inform the controller/host that the recovery operation completed on a specific exception and an error code if the recovery terminated abnormally.

Structure:
```
L,3
  1. <TIMESTAMP>
  2. <EXID>
  3. L,2
       1. <ACKA>
       2. L,m (m = {0,2})
            1. <ERRCODE>
            2. <ERRTEXT>
```

Exception: This list m can be of zero length if the recovery was successful.

S5,F16 Exception Recovery Complete Confirm (EXRCC) S,H->E

Description: Host confirms receipt of S5,F15 message from the equipment.

Structure: Header only

S5,F17 Exception Recovery Abort Request (EXRAR) S,H->E,reply

Description: Stop the recovery procedure on a specific exception.

Structure: 1. <EXID>

S5,F18 Exception Recovery Abort Acknowledge (EXRAA) S,H<-E

```
Description:   Indicate the success of the request for Recovery Abort.

Structure:     L,2
                 1. <EXID>
                 2. L,2
                      1. <ACKA>
                      2. L,m (m = {0,2})
                           1. <ERRCODE>
                           2. <ERRTEXT>

Exception:     The list m can be of zero length if the abort was successful.
```

7.10 *Stream 6 Data Collection* — This stream is intended to cover the needs of in-process measurements and equipment monitoring.

S6,F0 Abort Transaction (S6F0) S,H<->E

```
Description:   Same form as S1,F0.
```

S6,F1 Trace Data Send (TDS) M,H<-E,[reply]

```
Description:   This function sends samples to the host according to the trace setup
               done by S2,F23. Trace is a time-driven form of equipment status.

               Even if S6,F1 is multi-block, it is not preceded by an Inquire/Grant
               transaction, because the Host S2,F23 is an implicit grant. Some
               equipment may support only single-block S6,F1, and may refuse an
               S2,F23 (Trace Initiate Send) message which would cause a multi-block
               S6,F1.

Structure:     L,4
                 1. <TRID>
                 2. <SMPLN>
                 3. <STIME>
                 4. L,n
                      1. <SV1>
                      2. <SV2>
                      .
                      .
                      n. <SVn>

Exception:     A zero-length STIME means no value is given and that the time is to
               be derived from SMPLN along with knowledge of the request.
```

S6,F2 Trace Data Acknowledge (TDA) S,H->E

```
Description:   Acknowledge or error

Structure:     <ACKC6>
```

S6,F3 Discrete Variable Data Send (DVS) — M,H<-E,[reply]

Description: Any data report which is initiated by an event, such as the completion of a measurement, rather than passage of time is called a discrete variable. Some equipment may have several possible events on which to send the data. S2,F15 is used to select the desired reporting events. Reports requiring only one block of data may report directly to the host with this message. If S6,F3 is multi-block, it must be preceded by the S6,F5/S6,F6 Inquire/Grant transaction.

Structure: L,3
1.<DATAID>
2.<CEID>
3. L,n
 1. L,2
  1. <DSID$_1$>
  2. L,m
   1. L,2

 n. L,2
  1. <DSID$_n$>
  2. etc.

S6,F4 Discrete Variable Data Acknowledge (DVA) — S,H->E

Description: Acknowledge or error

Structure: <ACKC6>

S6,F5 Multi-block Data Send Inquire (MBI) — S,H<-E,reply

Description: If the discrete data report S6F3, F9, F11, F13 can involve more than one block, this transaction must precede the transmission.

Structure: L,2
1. <DATAID>
2. <DATALENGTH>

S6,F6 Multi-block Grant (MBG) — S,H->E

Description: Grant permission to send

Structure: <GRANT6>

S6,F7 Data Transfer Request (DDR) S,H->E,reply

Description: The host may initiate a data transfer of specified data stored in the equipment with this function.

Structure: <DATAID>

S6,F8 Data Transfer Data (DDD) M,H<-E

Description: Equipment sends data to the host.

Structure: Similar to the structure of S6,F3

Exception: A zero-length item returned means the requested data cannot be sent.

S6,F9 Formatted Variable Send (FVS) M,H<-E,[reply]

Description: The same function as S6,F3 except that the DVNAMEs are supplied from a predefined form that is known to the host. Thus, the data are more compact. If S6,F9 is multi-block, it must be preceded by the S6,F5/S6, F6 Inquire/Grant transaction.

Structure:

```
L,4
  1.<PFCD>
  2.<DATAID>
  3.<CEID>
  4. L,n
       1. L,2
            1. <DSID1_1>
            2. L,m
                 1. <DVVAL_1>
                 .
                 .
                 m. <DVVAL_m>
       2. L,2
       .
       .
       n. L,2
            1. <DSID_n>
            2. etc.
```

S6,F10 Formatted Variable Acknowledge (FVA) S,H->E

Description: Acknowledge or error

Structure: <ACKC6>

S6,F11 Event Report Send (ERS) M,H<-E, reply

Description: The purpose of this message is for the equipment to send a defined, linked, and enabled group of reports to the host upon the occurrence of an event (CEID).

If S6,F11 is Multi-block, it must be preceded by the S6,F5/S6,F6 Inquire/Grant transaction.

Structure:

```
L,3
  1.<DATAID>
  2.<CEID>
  3.L,a
      1. L,2
           1. <RPTID1>
           2. L,b
                1.<V1>
                .
                .
                b.<Vb>
           .
           .
      a.L,2                   report a
          1. <RPTIDa>
          2. L,c#Vs           this report
               1. <V1>
               .
               .
               c.<Vc>
```

Exceptions: If there are no reports linked to the event a 'null' report is assumed. A zero-length list for # of reports means there are no reports linked to the given CEID.

S6,F12 Event Report Acknowledge (ERA) S,H->E

Description: Acknowledge or error

Structure: <ACKC6>

S6,F13 Annotated Event Report Send (AERS) M,H<-E,reply

Description: This message is the same as S6F11 with the exception that VID's are sent with data.

If S6,F13 is Multi-block, it must be preceded by the S6,F5/S6,F6 Inquire/Grant transaction.

Structure:

```
L,3
  1.<DATAID>
  2.<CEID>
  3. L,a
       1. L,2
            1. <RPTID1>
            2. L,b
                 1. L,2
                      1.<VID1>
                 .
                 .
                 b. L,2
                      1.<VIDb>
                      b.<Vb>
       .
       .
       a. L,2
            1. <RPTIDa>
            2. L,c
                 1. L,2
                      1.<VID1>
                      2.<V1>
                     .
                     .
                      c. L,2
                           1.<VIDc>
                           2.<Vc>
```

Exception: If there are no reports linked to the event a 'null' report is assumed. A zero-length list for # of reports means there are no reports linked to the given CEID.

S6,F14 Annotated Event Report Acknowledge (AERA) S,H->E

Description: Acknowledge or error

Structure: <ACKC6>

S6,F15 Event Report Request (ERR) S,H->E, reply

Description: The purpose of this message is for the host to demand a given report group from the equipment.

Structure: <CEID>

S6,F16 Event Report Data (ERD) M,H<-E

Description: Equipment sends reports linked to given CEID to host.

Structure: Identical to structure of S6,F11.

Exceptions: A zero-length item means there are no reports linked to the given CEID.

S6,F17 Annotated Event Report Request (AERR) S,H->E,reply

Description: Same as S6,F15, but requests annotated reports.

Structure: <CEID>

S6,F18 Annotated Event Report Data (AERD) M,H<-E

Description: Equipment sends annotated reports linked to given CEID.

Structure: Same as S6,F13.

Exceptions: A zero-length item means there are no reports linked to the given CEID.

S6,F19 Individual Report Request (IRR) S,H->E,reply

Description: The purpose of this message is for the host to request a defined report from the equipment.

Structure: <RPTID>

S6,F20 Individual Report Data (IRD) M,H<-E

Description: Equipment sends variable data defined for the given RPTID to the host.

Structure: L,n # of variable data items
  1. <V_1>
  .
  .
  n. <V_n>

Exceptions: A zero length list means RPTID is not defined.

S6,F21 Annotated Individual Report Request (AIRR) S,H->E,reply

Description: The purpose of this message is for the host to request an annotated defined report from the equipment.

Structure: <RPTID>

S6,F22 Annotated Individual Report Data (AIRD) M,H<-E

Description: Equipment sends annotated variable data defined for the given RPTID to the host.

Structure: L,n # of variable data items
  1.L,2
    1. <VID_1>
    2. <V_1>
  .
  .
  n. L,2
    1. <VID_n>
    2. <V_n>

Exceptions: A zero-length list for # of variable data items means RPTID is not defined.

S6,F23 Request Spooled Data (RSD) S,H->E,reply

Description: The purpose of this message is for the host to request transmission or deletion of the messages currently spooled by the equipment.

Structure: <RSDC>

S6,F24 Request Spooled Data Acknowledgement Send (RSDAS) S,H<-E

Description: The purpose of this message is to acknowledge the receipt of the Request Spooled Data (S6,F23) and to respond with an appropriate acknowledge code.

Structure: <RSDA>

S6,F25 Notification Report Send — M, H<->E,[reply]

Description: This message is used for change notifications or confirmation reports. A change notification is a report of an internal action and is not associated with a prior action requested by the host.

A confirmation report is always associated with an earlier request for action. A confirmation report is sent to the initial requestor of a delayed action at the time the action is completed. A delayed action is an action that is any action not performed before the response to the initial request is sent. OPID contains the value of OPID in the initial request. LINKID is set to a non-zero value if and only if additional completion reports with the same OPID will be sent. If S6,F25 is multiblock, it must be preceded by the S6,F5/S6,F6 Inquire Grant transaction.

Structure: L,7

- 1. <DATAID>
- 2. <OPID>
- 3. <LINKID>
- 4. <RCPSPEC>
- 5. <RMCHGSTAT>
- 6. L,m
  - 1. L,2
    - 1. <RCPATTRID$_1$>
    - 2. <RCPATTRDATA$_1$>
  - .
  - .
  - m. L,2
    - 1. <RCPATTRID$_m$>
    - 2. <RCPATTRDATA$_m$>
- 7. L,2
  - 1. <RMACK>
  - 2. L,p
    - 1. L,2
      - 1. <ERRCODE$_1$>
      - 2. <ERRTEXT$_1$>
    - .
    - .
    - p. L,2
      - 1. <ERRCODE$_p$>
      - 2. <ERRTEXT$_p$>

Exception: OPID and LINKID are zero-length items when and only when S6,F25 is sent as a change notification rather than as a confirmation report. p = 0 if and only if RMACK indicates no errors.

S6,F26 Notification Report Send Acknowledge — S, H<->E

Description: This message is used to acknowledge the confirmation report. It is defined for completeness and as an aid to the user in identifying problems.

Structure: <ACKC6>

Exception: None

S6,F27 Trace Report Send (TRS) — M,H <-E,[reply]

Description: The equipment sends a completed Trace Report to the host.

Structure:

```
L,3
  1. <DATAID>
  2. <TRID>
  3. L,n          (n cannot exceed group size specified by S2F53)
       1. L,p      (p is the number of reports for each trace sample)
            1. L,2
                 1. <RPTID1>
                 2. L,m (number of items in this data report)
                      1. <V1>
                      .
                      .
                      m. <Vm>
                         .
                         .
                         p. L,2
                               1. <RPTIDp>
                               2. L,m
                                     1. <V1>
                                     .
                                     .
                                     m. <Vm>
                         .
                         .
       n. L,p      (p is the number of reports for each trace sample)
            1. L,2
                 1. <RPTID1>
                 2. L,m (number of items in this data report)
                      1. <V1>
                      .
                      .
                      m. <Vm>
            .
            .
            p. L,2
                 1. <RPTIDp>
                 2. L,m
                      1. <V1>
                      .
                      .
                      m. <Vm>
```

Exception: The lists of variables associated with a unique RPTID are also unique. This structure illustrates the form of the message, so in general, V_1 for $RPTID_a$ and V_1 for $RPTID_b$ do not reference the same variable.

S6,F28 Trace Report Send Acknowledge — S,H ->E

Description: The host Acknowledges receipt of the Trace Report.

Structure: <TRID>

S6,F29 Trace Report Request (TRR) S,H->E

Description: Request that the data reports assigned to the trace report be sampled and returned to the host.

Structure: <TRID>

S6,F30 Trace Report Data (TRD) M,H<-E

Description: Message containing the requested data reports associated with the TRID of trace data report definition.

Structure:
L,3
  1. <TRID>
  2. L,n (n = number data reports defined for this TRID)
    1. L,2
      1. <RPTID$_1$>
      2. L,m (m = number of items in this RPTID)
        1. <V$_1$>
        .
        m. <V$_m$>
    .
    .
    n. L,2
      1. <RPTID$_n$>
      2. L,m (m = number of items in this RPTID)
        1. <V$_1$>
        .
        m. <V$_m$>
      3. <ERRCODE>

Exception: If TRID is unknown, a zero-length list (n = 0) shall be sent. Item 3 (ERRCODE) shall be set to zero length when there is no error.

7.11 *Stream 7 Process Program Management* — The functions in this stream are used to manage and transfer process programs. Process programs are the equipment-specific descriptions that determine the procedure to be conducted on the material by a single piece of equipment. Methods are provided to transfer programs as well as establish the link between the process program and the material to be processed with that program.

S7,F0 Abort Transaction (S7F0) S,H<->E

Description: Same form as S1,F0

S7,F1 Process Program Load Inquire (PPI) S,H<->E,reply

Description: This message is used to initiate the transfer of a process program or to select from stored programs. The message may be used to initiate the transfer of an unformatted process program (S7,F3/S7,F4) or a formatted process program (S7,F23/S7,F24),(S7,F31/S7,F32).

Structure:
L,2
  1. <PPID>
  2. <LENGTH>

S7,F2 Process Program Load Grant (PPG) S,H<->E

```
Description:    This message gives permission for the process program to be loaded.

Structure:      <PPGNT>
```

S7,F3 Process Program Send (PPS) M,H<->E,reply

```
Description:    The program is sent. If S7,F3 is multi-block, it must be preceded by
                the S7,F1/S7,F2 Inquire/Grant transaction.

Structure:      L,2
                  1. <PPID>
                  2. <PPBODY>
```

S7,F4 Process Program Acknowledge (PPA) S,H<->E

```
Description:   Acknowledge or error

Structure:     <ACKC7>
```

S7,F5 Process Program Request (PPR) S,H<->E,reply

```
Description:   This message is used to request the transfer of a process program.

Structure:     <PPID>
```

S7,F6 Process Program Data (PPD) M,H<->E

```
Description:   This message is used to transfer a process program.

Structure:     L,2
                 1. <PPID>
                 2. <PPBODY>

Exception:     A zero-length list means request denied.
```

NOTE 8: The equipment-to-host transfer of the process program, denoted by the R bit in the header (R=1), provides the mechanism for the host computer to receive process programs created on the equipment. This allows use of the equipment without having process program generation capabilities on the host.

S7,F7 Process Program ID Request (PIR) S,H<-E,reply

```
Description:   This message is used to request the PPID for use on the material
               identified.

Structure:     <MID>
```

S7,F8 Process Program ID Data (PID) S,H->E

```
Description:   This message is used to transmit a single matrix entry in response to
               S7,F7.

Structure:     L,2
                 1. <PPID>
                 2. <MID>

Exception:     A zero-length list returned means no such MID or other error.
```

S7,F9 M/P M Request (MMR) S,H<->E,reply

```
Description:   This message is used to request the transmission of the material/
               process matrix. If the message is from the host, the response will be
               the current matrix in the equipment. If the message is from the
               equipment, the response will be a new matrix to initialize the
               equipment.

Structure:     Header only
```

NOTE 9: M/PM defines the Material/Process Matrix. The Material/Process Matrix is a table which links the material to the process program to be used in processing the material.

S7,F10 M/P M Data (MMD) M,H<->E

Description: In the response to S7,F9, the equipment will transmit the current matrix it contains. The matrix will be the sum of all matrix updates transmitted since initialization less the completed material whose linkages have been deleted. Programs with no pending material will be deleted from the matrix but not from the equipment program directory.

Structure: L,n number of process programs

1. L,2
   1. <PPID$_1$>
   2. L,a (number of MID for this PPID)
      1. <MID$_1$>
      .
      .
      a. <MID$_a$>
2. L,2
.
.
n. L,2
   1. <PPID$_n$>
   2. L,b
      1. <MID$_1$>
      .
      .
      b. <MID$_b$>

Exception: a=0 indicates that this PPID will be used for all material processed. The last default transmitted will be the one used; all other entries will be deleted from the active matrix. A zero-length list returned means no such matrix.

Function 10 Example 2 process programs (1 and 3 MID, respectively)

L,2
  L,2
    1. <PPID$_1$>
    2. L,1
       1. <MID$_a$>
  L,2
    1. <PPID$_2$>
    2. L,3
       1. <MID$_b$>
       2. <MID$_c$>
       3. <MID$_d$>

S7,F11 M/P M Update Send(UMS) — S,H->E,[reply]

Description: This message is used by the host to add to the M/PM in the equipment.

Structure:

```
L,n (number of process programs)
  1. L,2
       1. <PPID1>
       2. L,a (number of MID's using PPID1)
            1. <MID1>
            .
            .
            a. <MIDa>
  2. L,2
  .
  .
   n. L,2
        1. <PPIDn>
        2. L,b
             1. <MID1>
             .
             .
             b. <MIDb>
```

Exception: If a=0, then the preceding PPID is to be used for all material processed. All other entries will be deleted from the active matrix.

S7,F12 M/P M Update Acknowledge (UMA) — S,H<-E

Description: Acknowledge or error

Structure: <ACKC7>

S7,F13 Delete M/P M Entry Send (DES) — S,H->E,[reply]

Description: This message is used to delete program to material linkages in the M/PM of the equipment.

Structure:

```
L,n (number of process programs)
  1. L,2
       1. <PPID1>
       L,a (number of MID's using PPID)
         1. <MID1>
         .
         .
         a. <MIDa>
  2. L,2
  .
  .
  n. L,2
       1. <PPIDn>
       2. L,b
            1. <MID1>
            .
            .
            b. <MIDb>
```

Exception: A delete consisting of a zero-length means delete all entries and generate a S7,F9 request to initialize matrix.

S7,F14 Delete M/P M Entry Acknowledge (DEA) S,H<-E

Description: Acknowledge or error

Structure: <ACKC7>

S7,F15 Matrix Mode Select Send (MMS) S,H->E,reply

Description: This message is used by the host to change the method of process program selection in the equipment which might not support all modes.

Structure: <MMODE>

S7,F16 Matrix Mode Select Acknowledge (MMA) S,H<-E

Description: Acknowledge or error

Structure: <ACKC7>

NOTE 10: The matrix structure allows the program linkages to be established for each MID or the multi-MID production plans for an extended period of time. The host system makes the choice of operating mode. By continuous updates to the equipment matrix, automatic system backup is achieved.

S7,F17 Delete Process Program Send (DPS) S,H->E,reply

Description: This message is used by the host to request the equipment to delete process programs from equipment storage.

Structure: L,n (Number of process programs to be deleted)

1. <PPID$_1$>
.
.
n. <PPID$_n$>

Exception: If n=0, then delete all.

S7,F18 Delete Process Program Acknowledge (DPA) S,H<-E

Description: Acknowledge or error

Structure: <ACKC7>

S7,F19 Current EPPD Request (RER) S,H->E,reply

Description: This message is used to request the transmission of the current equipment process program directory (EPPD). This is a list of all the PPIDs of the process programs stored in the equipment.

Structure: Header only

S7,F20 Current EPPD Data (RED) — M,H<-E

Description: This message is used to transmit the current EPPD.

Structure:

```
 L,n (number of process programs in the directory)
   1. <PPID1>
   .
   .
   n. <PPIDn>
```

S7,F21 Equipment Process Capabilities Request (PCR) — S,H->E,reply

Description: This message is used to request the Equipment Process Capabilities Data(PCD).

Structure: Header only

S7,F22 Equipment Process Capabilities Data (PCD) — M,H<-E

Description: This equipment message provides the information necessary for the host to create and partially verify the contents of a new process program or display the object of a process program previously generated by a host or equipment. The PCD defines the process program content acceptable to the originating equipment.

Structure:

```
L,5
  1. <MDLN>
  2. <SOFTREV>
  3. <CMDMAX>
  4. <BYTMAX>
  5. L,c (c=Number of Possible Commands)
       1. L,11
             1. <CCODE>
             2. <CNAME>
             3. <RQCMD>
             4. <BLKDEF>
             5. <BCDS>
             6. <IBCDS>
             7. <NBCDS>
             8. <ACDS>
             9. <IACDS>
            10. <NACDS>
            11. L,p (p=Number of Parameters)
       1. (parameter specification)
          (see below)
       .
       .
       p. (parameter specification)
       2. L,11
       .
       .
       c. L,11
```

Parameter specifications depend on the data type of each parameter. The structure of each of the possible three groups is as follows:

Numeric Data	*String Data*	*Boolean Data*
L,9	L,5	L,4
1. <PNAME>	1. <PNAME>	1. <PNAME>
2. <RQPAR>	2. <RQPAR>	2. <RQPAR>
3. <PDFLT>	3. <PDFLT>	3. <PDFLT>
4. <PMAX>	4. <PMAX>	4. <PMAX>
5. <LLIM>	5. L,s	
6. <ULIM>	1. <$STEMP_1$>	
7. <UNITS>	.	
8. <RESC>	.	
9. <RESV>	s. <$STEMP_s$>	

S7,F23 Formatted Process Program Send (FPS) M,H<->E,reply

Description: This message allows movement of formatted process programs between a piece of equipment and its host system. The values of MDLN and SOFTREV are obtained from the PCD used to generate the process program. If S7,F23 is multi-block, it must be preceded by the S7F1/F2 Inquire/Grant transaction.

Structure:

```
L,4
  1. <PPID>
  2. <MDLN>
  3. <SOFTREV>
  4. L,c (c=Number of Process Commands)
       1. L,2
            1. <CCODE>
            2. L,p (p=Number of Parameters)
                 1. <PPARM1>
                 .
                 .
                 p. <PPARMp>
       2. L,2
       .
       .
       c. L,2
```

S7,F24 Formatted Process Program Acknowledge (FPA) S,H<->E

Description: Acknowledges reception of a formatted process program at its destination and whether the process program was accepted by the interpreter. A returned status of "accepted" by the interpreter means only that the message is understood. The validity of the contents of the process program is determined through a separate transaction (S7,F27/S7,F28).

Structure: <ACKC7>

S7,F25 Formatted Process Program Request (FPR) — S,H<->E,reply

Description: This message is used by either equipment or host to request a particular process program from the other.

Structure: <PPID>

S7,F26 Formatted Process Program Data (FPD) — M,H<->E

Description: This message transfers a process program in response to a request for the PPID. The values of MDLN and SOFTREV are obtained from the PCD used to generate the process program.

Structure:

```
L,4
  1. <PPID>
  2. <MDLN>
  3. <SOFTREV>
  4. L,c (c=Number of Process Commands)
       1. L,2
            1. <CCODE>
            2. L,p (p=Number of Parameters)
                 1. <PPARM1>
                 .
                 .
                 p. <PPARMp>
       2. L,2
       .
       .
       c. L,2
```

Exception: A zero length list indicates the request was denied.

S7,F27 Process Program Verification Send (PVS) — S,H<-E,reply

Description: This message indicates to the host that a process program has been received and checked by the equipment. The result of the check is specified by the list of errors. An empty error list (list of zero-length) or a one-element list with ACKC7A having a value of zero (0) indicates no errors were found in the process program. The equipment may report as many errors as it seems appropriate. The equipment is responsible for sending a single copy of this message to the host after any reception of a formatted process program (S7,F23 or S7,F26 or S7,F31). If S7,F27 is multi-block, it must be preceded by the S7,F29/S7,F30 Inquire/Grant Transaction.

Structure:

```
L,2
  1. <PPID>
  2. L,n (n=number of errors being reported)
       1. L,3
            1. <ACKC7A>
            2. <SEQNUM>
            3. <ERRW7>
       2. L,3
       .
       .
       n. L,3
```

S7,F28 Process Program Verification Acknowledge (PVA) S,H->E

Description: Reply by host to equipment acknowledging reception of Process Program Verification Send (PVS).

Structure: Header only

S7,F29 Process Program Verification Inquire (PVI) S,H<-E,reply

Description: This message allows a piece of equipment to ask a host for permission to send a multi-block PVS.

Structure: <LENGTH>

S7,F30 Process Program Verification Grant (PVG) S,H->E

Description: Reply by host to equipment providing response to Process Program Verification Inquire (PVI).

Structure: <PPGNT>

S7,F31 Verification Request Send (VRS) M,H->E,reply

Description: This message requests the interpreting equipment to check the contents of the provided process program and inform the host whether or not the process program is acceptable for processing at the machine. The values of MDLN and SOFTREV are obtained from the PCD used to generate the process program. If S7,F31 is multi-block, it must be preceded by the S7,F1/S7,F2 Inquire/Grant transaction.

Structure:
```
L,4
  1. <PPID>
  2. <MDLN>
  3. <SOFTREV>
  4. L,c (c=Number of Process Commands)
       1. L,2
            1. <CCODE>
            2. L,p (p=Number of Parameters)
                 1. <PPARM1>
                 .
                 .
                 p. <PPARMp>
       2. L,2
       .
       .
       c. L,2
```

S7,F32 Verification Request Acknowledge (VRA) S,H<-E

Description: Acknowledges reception of a formatted process program verification request at its destination and whether the process program was accepted by the equipment. A returned status of accepted by the interpreter means only that the message is understood. The validity of the contents of the process program is specified through a separate transaction (S7,F27/S7,F28).

Structure: <ACKC7>

S7,F33 Process Program Available Request (PAR) S,H<->E,reply

Description: This message requests the interpreting host or equipment to check its process program library and tell the requester if the PPID will be supplied if requested.

Structure: <PPID>

S7,F34 Process Program Availability Data (PAD) S,H<->E

Description: This message allows originator to tell requester whether it can provide the specified process program and whether it can provide it formatted, unformatted, or both.

Structure: L,3
1. <PPID>
2. <UNFLEN>
3. <FRMLEN>

S7,F35 Process Program for MID Request (PPMR) S,H<->E,reply

Description: This message is used to request the transfer of the process program to be used for the material identified.

Structure: <MID>

S7,F36 Process Program for MID Data (PPMD) M,H<->E

Description: This message is used to transfer the process program for the material identified.

Structure: L,3
1. <MID>
2. <PPID>
3. <PPBODY>

Exception: A zero-length list returned means no such MID or other error.

7.12 *Stream 8 Control Program Transfer* — The purpose of this stream is to provide the method for transmitting the programs used in the equipment to perform the control function or to execute the transmitted process program.

S8,F0 Abort Transaction (S8F0) S,H<->E

Description: Same form as S1,F0.

S8,F1 Boot Program Request (BPR) S,H<->E,reply

Description: This message is used to request the transmission of the boot program. It is assumed that there is only one boot program associated with any given equipment.

Structure: Header only

S8,F2 Boot Program Data (BPD) M,H<->E

Description: The boot program is required by some systems as a precursor to loading an operating system or executive program.

Structure: <BPD>

Exception: A zero-length item means no boot.

S8,F3 Executive Program Request (EPR) S,H<->E,reply

Description: This message is used to request the executive program. It is assumed that there is only one executive program associated with any given equipment.

Structure: Header only

S8,F4 Executive Program Data (EPD) M,H<->E

Description: The executive program is the master control program of the equipment. The executive may contain all the program required or it may contain the information required to request the rest of the program it needs on Stream 13.

Structure: <EPD>

7.13 *Stream 9 System Errors* — This stream provides a method of informing the host that a message block has been received which cannot be handled or that a timeout on a transaction (receive) timer has occurred. The messages indicate either a Message Fault or a Communications Fault has occurred but do not indicate a Communications Failure has occurred.

7.13.1 *Communications Failure* — A Communications Failure occurs in a SECS-I environment when, and only when, the RTY limit is exceeded.

NOTE 11: In the event of a Communications Failure, no Stream 9 message is sent.

7.13.2 *Communications Fault* — A Communications Fault occurs when the equipment does not receive an expected message (when a transaction timer or a conversation timer has expired).

7.13.3 *Message Fault* — A Message Fault occurs when the equipment receives a message which it cannot process because of a fault that arises from the content, context, or length of the message.

S9,F0 Abort Transaction (S9F0) S,H<->E

Description: Same form as S1,F0.

S9,F1 Unrecognized Device ID (UDN) S,H<-E

Description: The device ID in the message block header did not correspond to any known device ID in the node detecting the error.

Structure: <MHEAD>

S9,F2 Not used

S9,F3 Unrecognized Stream Type (USN) S,H<-E

Description: The equipment does not recognize the stream type in the message block header.

Structure: <MHEAD>

S9,F4 Not Used

S9,F5 Unrecognized Function Type (UFN) S,H<-E

Description: This message indicates that the function in the message ID is not recognized by the receiver.

Structure: <MHEAD>

S9,F6 Not Used

S9,F7 Illegal Data (IDN) S,H<-E

Description: This message indicates that the stream and function were recognized, but the associated data format could not be interpreted.

Structure: <MHEAD>

S9,F8 Not Used

S9,F9 Transaction Timer Timeout (TTN) S,H<-E

Description: This message indicates that a transaction (receive) timer has timed out and that the corresponding transaction has been aborted. It is up to the host to respond to this error in an appropriate manner to keep the system operational.

Structure: <SHEAD>

S9,F10 Not Used

S9,F11 Data Too Long (DLN) S,H<-E

Description: This message to the host indicates that the equipment has been sent more data than it can handle.

Structure: <MHEAD>

S9,F12 Not Used

S9,F13 Conversation Timeout (CTN) S,H<-E

```
Description:   Data were expected but none were received within a reasonable length
               of time. Resources have been cleared.

Structure:     L,2
                 1. <MEXP>
                 2. <EDID>
```

S9,F14 Not Used

7.14 *Stream 10 Terminal Services* — The functions of this stream is to pass textual messages between operator terminals attached to processing and/or testing equipment and the host. The equipment makes no attempt to interpret the text of the message, but merely passes it from terminal keyboard to the host or from the host to the display of the terminal. Management of human response times to information displayed on terminals is the responsibility of the host.

S10,F0 Abort Transaction (S10F0) S,H<->E

```
Description:   Same form as S1,F0.
```

S10,F1 Terminal Request (TRN) S,H<-E,[reply]

```
Description:   A terminal text message to the host.

Structure:     L,2
                 1. <TID>
                 2. <TEXT>
```

S10,F2 Terminal Request Acknowledge (TRA) S,H->E

```
Description:   Acknowledge or error

Structure:     <ACKC10>
```

S10,F3 Terminal Display, Single (VTN) S,H->E, [reply]

```
Description:   Data to be displayed.

Structure:     L,2
                 1. <TID>
                 2. <TEXT>
```

S10,F4 Terminal Display, Single Acknowledge (VTA) S,H<-E

```
Description:   Acknowledge or error

Structure:     <ACKC10>
```

S10,F5 Terminal Display, Multi-Block (VTN) M,H->E,[reply]

Description: Data to be displayed on the equipment's terminal.

Structure: L,2
1. <TID>
2. L,N
1. <TEXT$_1$>
.
.
n.<TEXT$_n$>

S10,F6 Terminal Display, Multi-block Acknowledge (VMA) S,H<-E

Description: Acknowledge or error

Structure: <ACKC10>

S10,F7 Multi-block Not Allowed (MNN) S,H<-E

Description: An error message from a terminal that cannot handle a multi-block message from S10,F5.

Structure: <TID>

S10,F8 Not Used

S10,F9 Broadcast (BCN) S,H->E,[reply]

Description: This function is generally the same as S10,F3 except that specific TID in each equipment need not be specified. Instead, the text is directed to each terminal in the equipment when the function is received. This function assumes that this feature exists on all equipment, otherwise repeated S10,F3 messages should be used.

Structure: <TEXT>

S10,F10 Broadcast Acknowledge (BCA) S,H<-E

Description: Acknowledge or error

Structure: <ACKC10>

7.15 Stream 11 has been deleted and will not appear again in this publication.

It is the consensus of the Communications Committee that Stream 11 is obsolete. Its use is discouraged, and it has been removed from the 1989 edition of the standard. The reasons for removal are three-fold:

1. The purpose of this stream, as it was originally envisioned, is perceived to be of little use and can best be accomplished by other means beyond the scope of this standard;
2. The functions in this stream have many technical problems that severely limit their use;
3. There is a noticeable lack of implementations of this standard that utilize Stream11 in its originally intended form.

NOTE 12: Applications that need to transfer unformatted data between the host and equipment should use the facilities of Stream 13.

7.16 *Stream 12 Wafer Mapping* — Messages which deal with coordinate positions and data associated with those positions. This includes functions such as wafer mapping with coordinates of die on a wafer and the associated binning information.

7.16.1 *Structure* — Functions 1 through 20 address the variations required by semiconductor equipment manufacturers in transmitting wafer maps to and from the process equipment (wafer probe through die attach). The functions include three basic formats. The three formats developed are:

1. Row/column format where a coordinate row starting position is given with die count in the row and starting direction. The respective binning information follows for each die.
2. Array format is structured such that a matrix array captures all or part of a wafer with the associated binning information.
3. Coordinate format provides an X/Y location and bin code for die on the wafer.

7.16.2 *Definitions and Descriptions* — The following information is required to perform map association to the physical wafer as it relates to the archival use and transmission of wafer maps.

1. Flat/Notch Location
2. Frame Rotation
3. Row Count
4. Column Count
5. Die Units of Measure
6. Die Size
7. Process Die Count
8. Reference Points
9. Bin Code Equivalents
10. Process Axis
11. Null Bin Code Value
12. ID Type

7.16.2.1 *Flat/Notch Location* — The position in degrees that the flat or notch are oriented during processing relative to a " normal" position of zero degrees. See Figure S12.1.

7.16.2.2 *Frame Rotation* — The orientation of a film frame relative to a " normal" position of zero degrees. See Figure S12.2.

7.16.2.3 *Row/Column Count* — The row and column counts are the total number of rows and columns, respectively, on a wafer which must be correlated directly with the wafer map. These numbers will always be greater than zero.

7.16.2.4 *Die Sizes* — The die size is given in standard units as specified by the die unit of measure item DUTMS, and will also be greater than zero. The value of the die size is determined by measuring the distance from a point on one die to the same point on the next die, often referred to as an index. This is depicted in the lower portion of Figure 7, Section B in the General Rules Section.

7.16.2.5 *Process Die Count* — The process die count item is used by equipment that is being map driven to make determinations about how much material to prepare. For example, a die attach will epoxy lead frames in advance of the attach process. By knowing the total number of die to be processed within a wafer map, the equipment can stop epoxying lead frames equivalent to the last die to be attached. This item is also used by the equipment to tell the host how many total die it processed for that map. For example, a die attach would use PRDCT to report the total die actually attached from a particular wafer.

7.16.2.6 *Reference Points* — Reference points provide a means of relating a map to the physical wafer. The total number of these points, and the method for assigning and detecting them, is the responsibility of the equipment. This standard only provides a means for transmitting them.

7.16.2.7 *Origin* — The origin is in one of five locations which is specified by the equipment when generating a wafer map. The origin is on an array structure having dimensional values equal to those specified by the row and column count. The origin then lies on one of the four corners of that array or in a center location determined by the following formula:

$$\left(\frac{row \sim or \sim column + 1}{2}\right) truncated$$

7.16.2.7.1 It is implicit in determining the center location that the upper-left-hand corner of the area, in the normal position, be counted as the first row and column position. An equipment requesting a map provides the origin location that it wants the map to be based on before transmission. If the equipment does not provide an origin, the host must provide a default value. An equipment transmitting a map must provide the origin with the map setup data.

7.16.2.8 *Bin Code Equivalents* — Bin code equivalents is a list of bin codes that the receiving equipment will process. (i.e., if a map contains codes 1 through 10 and the good die are bins 1 and 2, then bin code equivalent list could indicate 1 and 2 if only the good die categories were needed. These are the only bin codes to which an equivalent will drive for its respective process function.) In the case of X/Y coordinate format, the locations transmitted will be only those with the bin codes stated in the Bin Code Equivalent list, unless the length byte is set to zero, in which all of the bin codes in the map will be transmitted.

7.16.2.9 *Process Axis* — The process axis is the axis, either rows or columns, increasing or decreasing, and the side of the map, (top, bottom, left, or right, respectively) that the map data will originate from. This is based on the coordinate system as described under the General Rules section of this document.

7.16.2.10 *ID Type* — ID type indicates the appropriate material ID type (i.e., wafer, cassette, or film frame).

7.16.3 *General Rules*

7.16.3.1 *Map Data Size* — Stream 12 provides for the transmission of a complete map regardless of size. Equipment requiring segmented maps for transmission or reception will not be able to use the Stream 12 functions to handle the complete conversation.

7.16.3.2 *Orientation Conventions* — The orientation of a wafer presented for processing will differ from equipment to equipment. Stream 12 specifies conventions for expressing wafer orientation so that a map can be translated from one geometric representation to another.

7.16.3.2.1 The bottom of the wafer is the notch or the line of the major flat. The orientation of a wafer is measured in positive degrees clockwise (CW) from the " normal" position. The " normal" position is where the bottom of the wafer is closest to you when the wafer is lying horizontally in front of you with the die side facing up. The " normal" position has an orientation of zero degrees. See Figure S12.1 for graphic representation of wafer orientations.

7.16.3.2.2 The bottom of a film frame is also the notch or the line of notches. Its orientation and " normal" position are measured in the same manner as for wafers. See Figure S12.2 for examples of bottoms of film frames.

7.16.3.2.3 The orientation of an unmounted wafer presented for processing is given by the parameter FNLOC, Flat/Notch LOCation.

7.16.3.2.4 The ultimate orientation of a wafer presented for processing after it has been mounted on a film frame is the cumulative rotation of the wafer from the " normal" position on the film frame and the rotation of film frame as it is presented to the equipment. This is determined by the sum of the parameters FNLOC and FFROT, Film Frame ROTation. It is possible for an application to represent the ultimate orientation of a wafer in one of these parameters only and pass the other parameter as zero length.

7.16.3.2.5 Figure 6 shows wafers oriented at 270 degrees with respect to the bottoms of a metal and round film frame. If one of these film frames were presented to an equipment rotated 90 degrees clockwise (CW), (bottom facing the left edge of the page), the ultimate orientation of the wafer would be zero degrees.

7.16.3.2.6 In the case where either FNLOC or FFROT are unknown or irrelevant information, a zero-length data item is transmitted, and the item will be ignored by the application. One of the items must exist.

7.16.3.3 *Coordinate Axis System* — The coordinate axis orientation is shown in Figure S12.3, Section A. The assumption is that the " X" or " column" coordinates increase to the right of the " Y-axis" and the " Y" or " row" coordinates increaseabove the " X-axis." In describing the physical wafer it is also given that the coordinate axis orientation never rotates. The wafer moves or rotates within the coordinate axis system. The origin within the array describing the wafer' s coordinate system must be in one of five locations on that array (the center, upper-left, lower-left, upper-right, or lower-right corner of the array).

7.16.3.3.1 Figures S12.4 and S12.5 summarize the conversation protocol in the form of a flow chart. Since a single transmit inquire/grant can be used for one of three message function pairs, the application is required to examine MAPFT, is received as part of the map setup data to determine the appropriate function to follow. If the appropriate function is not transmitted, the conversation is aborted and the error is reported using the appropriate error reporting stream and function.

S12,F0 Abort Transaction (S12F0) S,H<->E

Description: Same form as S1F0.

S12,F1 Map Set-up Data Send (MSDS) S,H<-E,reply

Description: Used to send all of the map set-up data common to all formats and required to link the data map with the physical wafer.

7.17 *Stream 13 Data Set Transfers* — This stream provides protocols to transfer data sets between systems. It is not intended to provide a general file access mechanism.

7.17.1 *Data Set Characteristics* — The data set may reside on the host or the equipment.

The term *data set* is used in a very general sense. A data set may represent a file, a data structure in memory, a collection of sensor values, or high density wafer profile data. The protocols define only the way data is sent from one system to another and do not define how the data set is stored by either the host or equipment.

The *sending* system is defined to be the system that has the data set. The *receiving* system is defined to be the system to which the data set is being transferred. The host or the equipment may assume either role.

7.17.2 *Unformatted Data Set Protocol* — The protocol for transferring unformatted data sets has the following characteristics:

1. Information about the record structure of the data set may be available.
2. ASCII records are transferred without the record terminating “noise” characters used by some operating systems.
3. Data sets do not need to be transferred in a single message.
4. No arbitrary limits are imposed on the length of one message. The maximum amount of data sent in each message is determined by both the sending and receiving systems, so there can be no data overruns.
5. There is a method of restarting a transfer in the event of an interruption.

7.17.2.1 *Data Set Name* — An ASCII string (format 20) which performs a function similar to the Message ID (Stream and Function) of the SECS-I protocol. This is a logical name which has meaning to both the equipment and the host. Neither the equipment nor the host is required to use the *Data Set Name* for the same information in any other context. For example, maintenance data may be stored in the equipment in the file "WIDGET.DAT" and in the host as records in a database, but the *Data Set Name* may be "S11,F2".

7.17.2.2 *Records* — The Record Type determines the way the data set is divided into messages for transfer to the receiving system. There are two types of records: Discrete and Stream.

1. A data set with *Discrete* records has a traditional record structure, such as ASCII text. *RecordLength* is the length of the longest record. Zero-length records are allowed. Each record from the data set is sent as a single item in a message.

2. If *Record Type* is *Stream,* then the data set has no internal structure which can be communicated with this protocol.

These kind of data set might be, for example, a dump of main memory, SECS-II structured data, or data which has implicit record boundaries. RecordLength has no meaning for this kind of data set. Items containing data from the data set have no relationship to the structure of the data set.

7.17.2.3 *Transactions* — The basic data transfer is performed by the OPEN, READ, and CLOSE transactions. There is no explicit write transaction. A write is performed indirectly using the SEND transaction. A RESET transaction is provided to allow a graceful recovery after a crash. This protocol describes the transactions over the communications channel only. No assumption is made about the implementation of the transactions. For example, the OPEN transaction on a data set which is stored on a disk file does not necessarily cause the sending system to open the file.

7.17.2.3.1 The OPEN, READ, and CLOSE transactions are initiated by the receiving system. The SEND transaction is initiated by the sending system. The RESET transaction is initiated by either system. The usual transaction timer operates between the primary and secondary messages of each transaction. The time between transactions, especially between READ transactions, is application-specific so no additional timer is defined.

7.17.2.3.2 Internally, the protocol uses a *Handle* to keep track of multiple open data sets, and a *Checkpoint* which aids in error recovery. A value called *ReadLength* is used to negotiate the amount of data sent at one time.

7.17.2.4 *Handle* — Between the sending and receiving systems, more than one data set may be open at a time, or one data set may be opened many times. The Handle is a short name used to keep track of the state of a particular data set and instance of OPEN between the sending and receiving systems (see Figure S13.1). This *Handle* may be thought of as a name for a single application level connection from the sending to the receiving system. Its value is assigned in the primary message of the OPEN transaction.

7.17.2.4.1 The value used for the *Handle* must not be used in another OPEN by the receiving system to the same sending system until it is used in a CLOSE to that sending system, or the RESET transaction is sent by either system. For example, assume a host system opens a data set on equipment 255 using *Handle 1*. The host may not issue another OPEN to equipment 255 using *Handle 1* until it closes 1 on 255. However, the host may use *Handle 1* to open a data set on another piece of equipment, and equipment 255 may use *Handle 1* to open a data set on the host.

7.17.2.4.2 The number of data sets which may be open at one time and the number of times one data set may be opened is not specified by this standard. Error codes are defined for situations where the limits are exceeded. It must be possible to have one outstanding transaction (i.e., a primary message for which there has not been a reply) for each open *Handle*. If the sending system receives a primary message for a Handle which already has an outstanding transaction, then the error code for Pending Transaction is returned in the secondary message (see Figure 10).

7.17.2.5 *Checkpoint* — The response to each READ transaction contains the data and a new Checkpoint value. The *Checkpoint* is defined by and has meaning only for the sending system. Its purpose is to allow a data transfer to be restarted from the point of the last complete message after some communication interruption. The exact nature of the *Checkpoint* is not specified. It could be the byte index in the data set, a record counter (for Discrete records), or some other system-dependent value.

NOTE 13: Checkpoint and the SECS-II transaction timer define a performance requirement for the sending system. The sending system must be able to get data from any checkpoint location within a data set between the receipt of the OPEN primary message and the time for reply to the first READ.

7.17.2.5.1 The value of *Checkpoint* must conform to several rules:

1. The Checkpoint value is exactly four bytes long.

2. The beginning of the data set has Checkpoint value with all bits reset.

3. A Checkpoint with all bits set is illegal.

4. A Checkpoint supplied by the sending system which does not have all bits set is usable in an OPEN

transaction to restart a data transfer without any lost data or duplicated data.

7.17.2.5.2 The receiving system defines the initial *Checkpoint* in the primary message of the OPEN transaction. The sending system returns the next *Checkpoint* in the response to each READ.

7.17.2.6 *Read Length* — The *Read Length* must be supplied by the receiving system with each READ transaction. It specifies the maximum number of data bytes which that system is prepared to process at one time. The sending system may supply less if it has limited resources. The sending system may supply more if *ReadLength* is zero, or is smaller than *RecordLength*.

7.17.2.7 *Reading a Data Set* — The basic data transfer is initiated with the OPEN transaction and completed with the CLOSE transaction. Information is sent from the sending to the receiving systems by a series of READ transactions.

7.17.2.8 *OPEN Transaction* — The receiving system sends a primary message containing the *DataSet Name* of the desired data set, the *Handle* to be used, and the *Checkpoint* of the initial READ transaction. The response from the sending system is a secondary message with a return code and the *RecordType* and *RecordLength* of the data set. If the return code is one of the error codes, then no data set was opened and the values of *RecordType* and *RecordLength* are undefined. If the *RecordType* is *Stream*, then the value of *RecordLength* is undefined. Notice that the undefined items will still appear in the secondary message.

7.17.2.8.1 The return code in the secondary message is one of the following:

OK.

ERROR: Unknown Data Set ID.

ERROR: Try later (i.e., the data set is in use).

ERROR: Too many open data sets.

ERROR: Data set open too many times.

ERROR: Handle in use.

ERROR: Pending Transaction.

7.17.2.9 *The READ Transaction* — The receiving system sends a primary message which contains the *Handle*, and the *ReadLength*. The sending system responds with a secondary message which has a return code, the next Checkpoint, and zero or more items with data. At least one data item must be supplied unless there is an error. The return codes are:

OK.

ERROR: End of Data.

ERROR: No open Data Set (i.e., incorrect Handle).

ERROR: Cannot continue (i.e., a disk read error on the sending system).

ERROR: Pending Transaction.

7.17.2.9.1 Any READ transaction which follows a READ which returned an error, except "Pending Transaction," will generate the same error. The value of *Checkpoint* must be illegal (i.e., all bits must be set) when the "End of Data," "No open Data Set," or "Pending Transaction" error is returned. The value of *Checkpoint* error must be a value from which recovery may be attempted without duplicating data when the "Cannot continue" error is returned. Recovery may be attempted by issuing a CLOSE, followed by an OPEN with the last value of *Checkpoint*, and then another READ.

7.17.2.9.2 Each secondary message for the READ transaction must contain a whole number of *Discrete* records. A record may be sent as an ASCII or a binary item. *Stream* data sets are broken into pieces by the READ transaction without regard to internal structure. Each piece would be sent as a single binary item. The number of items which contain data depends on the *RecordType, Record Length,* and *Read Length*. The algorithm is designed so that the maximum length of the secondary message is deterministic. It gives the receiving system the ability to control the amount of resources (such as SECS-I buffers) which it must allocate. The sending system may send less data than the maximum if it has limited resources. The performance (i.e., the packing of records into a message of some maximum size) should be very good for the case where records are all nearly the maximum length. This is assumed to be the usual case. The efficiency in pathological cases (e.g., many short records) will not be good, but the algorithm is robust enough to accommodate this without exceeding the maximum message size.

NOTE 14: If the *RecordType* is *Stream,* then there is exactly one item with a binary format whose length is not more than *ReadLength*. If the *RecordType* is *Discrete,* then the maximum number of items, MaxItems, is calculated by the formula:

$$\mathrm{MaxItems} = \max\left(1, \mathrm{int}\left(\frac{\mathrm{ReadLength}}{\mathrm{RecordLength}}\right)\right)$$

7.17.2.9.3 The size of the secondary message may be less because of limited resources in the sending system.

7.17.2.9.4 For data sets with *Discrete* records, the format of each item is either ASCII (format 20) or binary (format 10). There is no requirement that all records be in the same format, but mixed record formats are not encouraged. Items with ASCII format should have only data characters. Characters which the sending system uses for control information (e.g., newline for a record terminator) should not appear. If an application finds it necessary to include these characters, then format 10, or Stream should be used.

7.17.2.10 *CLOSE Transaction* — This transaction terminates a data transfer and frees the *Handle* for future use. The primary message is sent by the receiving system and contains only the *Handle.* The sending system responds with a secondary message which has a return code.

7.17.2.10.1 The return code is one of the following:

OK.

ERROR: No open Data Set (i.e., incorrect *Handle*).

ERROR: Pending Transaction.

7.17.2.11 *Sending a Data Set* — Writing a data set is performed by requesting that the receiving system read it. The sending system initiates the SEND transaction to request that a data set be read. The receiving system is expected to perform the OPEN, READ, and CLOSE transactions to transfer the data set if it accepts the request. The time between the secondary message of the SEND and the primary message of the OPEN depends on the application.

7.17.2.12 *The SEND Transaction* — The primary message sent from the sending system to the receiving system contains the *Data Set Name*.

7.17.2.12.1 The secondary message contains the *Data Set Name* and a return code which is one of the following:

OK.

ERROR: Unknown Data Set Name.

ERROR: Try later (i.e., the system is busy).

7.17.2.13 *Error Recovery* — The receiving system may crash while a data set is open but no READ transaction is pending. The sending system will not be able to tell that this has happened because there is no timeout value defined between READ transactions. When the receiving system is restarted it may have forgotten which data sets were open. States in the two systems are now inconsistent.

7.17.2.14 *RESET Transaction* — The RESET transaction offers a way to resynchronize the two systems. When one system issues the primary message of the RESET transaction, it is informing the other system that any data sets which may have been open are to be closed. This applies to all data sets open between both systems. It is not necessary to issue CLOSE transactions for each individual data set because the RESET transaction is a global close.

7.17.2.15 Any equipment which uses Stream 13 must issue the RESET transaction as part of its initialization or bootstrap procedure. A host system must issue a RESET to equipment which uses Stream 13 during the initialization for that equipment.

7.17.2.16 *SECS-II Protocol Definition* — Figure 10 shows the state diagram for the sending system while a data set is being transferred. Each circle shows a possible state of the sending system. The names of these states are for reference only. They are not meant to suggest an implementation. The arrows show transitions due to SECS-II messages received or sent by the sending system.

7.17.2.16.1 In the initial state (Idle) handle X is not open. The states marked with an asterisk are those in which a transaction is outstanding. If the sending system receives any primary message from the receiving system with handle X during the time it is in these states, then the secondary message for that transaction will contain the " Pending Transaction" error code, but the original transaction for handle X will not be affected. Some states, especially the error states, may take zero time in some implementations. In these cases, the " Pending Transaction" error code would not be returned from those states.

7.17.3 *Formatted Data Sets* — Formatted data sets are data sets transferred in a standard format. Stream 13 provides a method for transferring data sets in a table format. A table has both attributes and content. The attributes of the table provide information about the data set as a whole, such as the date and time that it was last modified, its size, etc. The content of the table consists of column headers and rows. A row is an ordered list of table elements. A column refers to all table elements at a specific position within all rows, where each column is identified by a corresponding text string as a column header. The table elements in the 1st column position are used as an identifier for the row.

S13,F0 Abort Transaction (S13F0) S,H<->E

Description: Same form as S1,F0

S13,F1 Send Data Set Send (DSSS) S,H<->E,reply

Description: Sent by the sending system to request that the other system read a dataset.

Structure: L,1
1. <DSNAME>

S13,F2 Send Data Set Acknowledge (DSSA) S,H<->E

Description: Sent by the receiving system in response to Send Data Set Send.

1. <DSNAME>
2. <ACKC13>

Exceptions: The possible ACKC13 codes for this message are:

0=O.K.
1=ERROR:Try later.
2=ERROR:Unknown Data Set Name.

S13,F3 Open Data Set Request (DSOR) S,H<->E,reply

Description: Sent by the receiving system to open a data set for reading.

Structure: L,3
1. <HANDLE>
2. <DSNAME>
3. <CKPNT>

S13,F4 Open Data Set Data (DSOD) S,H<->E

Description: Sent by the sending system in response to Open Data Set Request.

Structure: L,5
1. <HANDLE>
2. <DSNAME>
3. <ACKC13>
4. <RTYPE>
5. <RECLEN>

Exceptions: The possible ACKC13 codes for this message are:

0=O.K.
1=ERROR:Try later.
2=ERROR:Unknown Data Set Name.
3=ERROR:Illegal Checkpoint value.
4=ERROR:Too many open Data Sets.
5=ERROR:Data set open too many times.
9=ERROR:Handle in Use.
10=ERROR:Pending Transaction.

S13,F5 Read Data Set Request (DSRR) S,H<->E,reply

Description: Sent by the receiving system to read data from an open data set.

Structure: L,2
1. <HANDLE>
2. <READLN>

S13,F6 Read Data Set Data (DSRD) M,H<->E

Description: Sent by the sending system in response to Read Data Set Request.

Structure: L,4
1. <HANDLE>
2. <ACKC13>
3. <CKPNT>
4. L,n
   1. <FILDAT>
   .
   .
   n. <FILDAT>

Exceptions: The possible item formats, number of items (n), and length of each FILDAT item (|th) are given by the following table. MaxItems is defined in Section 7.17.10.2.

RTYPE	0 (Stream)	1 (Discrete)
Item Format	10 (binary)	10 (binary) or 20 (ASCII)
Maximum n	1	MaxItems
Maximum n	1 (ACKC13=0) 0(any error)	1 (ACKC13=0) 0(any error)
Maximum |th	READLN	RECLEN
Maximum |th	0	0

The possible ACKC13 codes for this message are:
0 = O.K.
6 = ERROR: No open Data Set
7 = ERROR: Cannot Continue
8 = ERROR: End of Data
10= ERROR: Pending Transaction

S13,F7 Close Data Set Send (DSCS) S,H<->E,reply

Description: Sent by the receiving system to close an open data set.

Structure: L,1
1. <HANDLE>

S13,F8 Close Data Set Acknowledge (DSCA) S,H<->E

```
Description:   Sent by the sending system in response to Close Data Set Send (DSCS).

Structure:     L,2
                 1. <HANDLE>
                 2. <ACKC13>

The possible ACKC13 codes for this message are:
               0 = O.K.
               6 = ERROR:No open Data Set.
               10= ERROR:Pending Transaction.
```

S13,F9 Reset Data Set Send (DSRS) S,H<->E,reply

```
Description:   Sent by either system to close all open data sets.

Structure:     Header only
```

S13,F10 Reset Data Set Acknowledge (DSRA) S,H<->E

```
Description:   Sent in response to Reset Data Set Send.

Structure:     Header only
```

S13,F11 Data Set Object Multi-Block Inquire (DSOMGI) S,H<->E,reply

```
Description:   This message requests permission to send a multi-block data set. If
               the receiving system does not grant permission in the reply, the
               multi-block data set may not be sent. OBJSPEC is used to identify the
               data set object type and identifier and may include a destination.
               DATALENGTH represents the total message length, not the length of the
               data set.

Structure:     L,3
                 1. <DATAID>
                 2. <OBJSPEC>
                 3. <DATALENGTH>
```

S13,F12 Data Set Object Multi-Block Grant (DSOMBG) S,H<->E

```
Description:   This message grants or denies permission to send a multi-block data
               set.

Structure:     <GRANT>
```

S13,F13 Table Data Send (TDS) M,H<->E,reply

Description: This message allows the host and the equipment to exchange predefined datasets in a tabular format. The first element of every row is used to reference that row for all other elements. If S13,F13 is Multi-block, it must be preceded by the S13,F11/S13,F12 Inquire/Grant transaction.

Structure:

       c. <COLHDR_c>          cth column element description
  8. L,r                      # of row definitions
       1. L,c_1               # of entries per definition
            1. <TBLELT_11>    1st table element, 1st row
            .
            m. <TBLELT_1c1>   mth table element, 1st row
       .
       r. L,c_r               rth row definition
            1. <TBLELT_r1>    1st table element, rth row
           .
            m. <TBLELT_rcr>   mth table element, rth row
```

Exception: If OBJSPEC is a zero-length item, then the owner of the table is the receiver of the message. If r is zero, any existing table definition of the given type and id is to be deleted. Otherwise, c_1 may not be zero, and the value of c_1 shall be less than or equal to the value of c.

S13,F14 Table Data Acknowledge (TDA) — S,H<->E

Description: This message is used to acknowledge the receipt of a table and to indicate any errors.

Structure:

L,2
1. <TBLACK>
2. L,p
   1. L,2
      1. <ERRCODE$_1$>
      2. <ERRTEXT$_1$>

   .

   .

   P. L,2
      1. <ERRCODE$_p$>
      2. <ERRTEXT$_p$>

Exception: p = 0 if and only if TBLACK indicates no errors.

S13,F15 Table Data Request (TDR) — M,H<->E,reply

Description: This message allows the host or the equipment to request part or all of a specific table. Either specific columns or specific rows may be requested, but not both at the same time. If S13,F15 is Multi-block, it must be preceded by the S13,F11/S13,F12 Inquire/Grant transaction.

Structure:

L,7
1. <DATAID>
2. <OBJSPEC>
3. <TBLTYP>
4. <TBLID>
5. <TBLCMD>
6. L,p — # of column definitions
   1. <COLHDR$_1$> — 1st column element description

   .

   p. <COLHDR$_p$> — pth column element description
7. L,q
   1. <TBLELT$_1$> — 1st row identifier

   .

   .

   q. <TBLELT$_q$>

Exception: If OBJSPEC is a zero-length item, then the owner of the table is the receiver of the message. Either p or q, or both, must be zero. If p = 0 and q = 0, all rows are requested; otherwise, only the specified columns, or the rows referenced by TBLELT, are requested.

S13,F16 Table Data (TD) M,H<->E

Description: This message is used to return data from the requested table.

Structure:

```
L,6
  1. <TBLTYP>
  2. <TBLID>
  3. L,n                     # of table attributes
       1. L,2

       1. <COLHDR_1>         1st column element description
       .
       c. <COLHDR_c>         cth column element description
  5. L,r                     # of row definitions
       1. L,c_1              # of entries per definition
            1. <TBLELT_11>   1st table element, 1st row
            .
            m. <TBLELT_1c1>  last table element, 1st row
       .
       r. L,c_r              rth row definition
            1. <TBLELT_r1>   1st table element, rth row
            .
            m. <TBLELT_rcr>  mth table element, rth row
  6. L,2
       1. <TBLACK>
       2. L,p
            1. L,2
                 1. <ERRCODE_11>
                 2. <ERRTEXT_12>
            .
            P. L,2
                 1. <ERRCODE_p1>
                 2. <ERRTEXT_p2>
```

Exceptions: p = 0 if, and only if, TBLACK indicates no errors. The length c_{11} of a table row may not exceed the value of c.

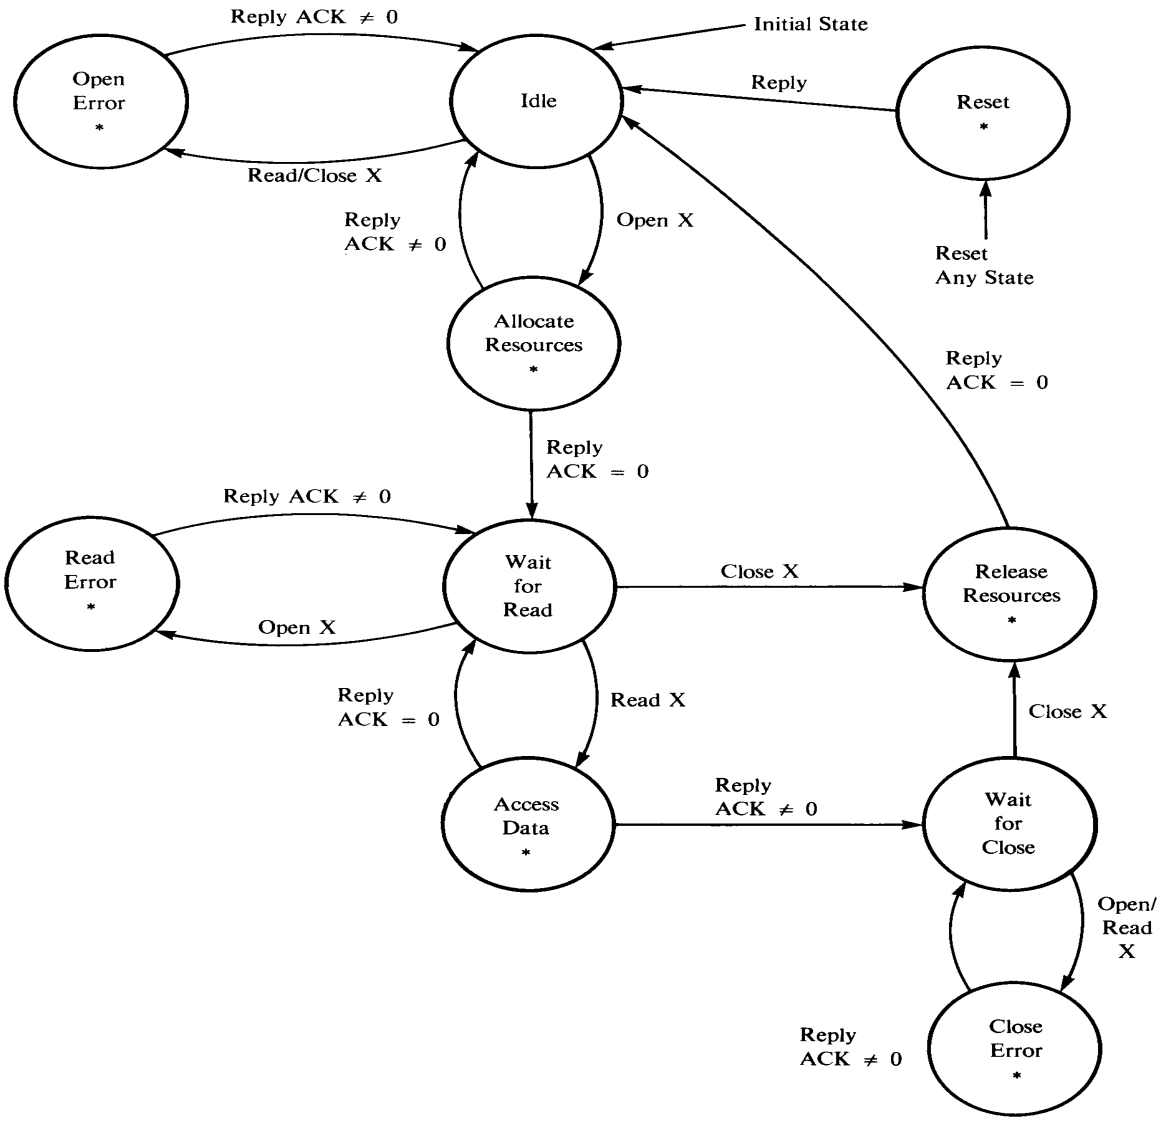

Figure S13.1
The Sending System's State Diagram During a Data Set Transfer
An Asterisk (*) marks the states where a primary message which uses handle X would result in a secondary message with the error code for "Pending Transaction."

7.18 *Stream 14 Object Services* — The functions in this stream are used for generic functions concerning objects, including obtaining information about objects and setting values for an object.

S14,F0 Abort Transaction (S14F0) S,H<->E

Description: Same form as S1,F0.

S14,F1 GetAttr Request (GAR) S,H<->E,reply

Description: This message is used to request a set of specified attributes for one or more objects. It consists of an "object specifier" for the owner of the target objects (the objects of interest), the target object type, a list of identifiers of the target objects, a filter (a list of qualifying relationships) that limits the target objects of interest to those that meet all of the qualifications in and the specific attributes whose values are requested.

The object specifier provides a specification of the owner of the target object(s). It contains a sequence of hierarchical object relationships. Each element of the object specifier identifies a specific object instance that is the superior of the following object instance in the sequence. The last object instance in the sequence is in a hierarchical relationship to the target objects.

The target object type designates the type of the target object, and the list of object identifiers indicates the specific instance of that type that are of interest. The target type may be omitted only if object identifiers are unique across all object types and the list of identifiers is not empty.

The object filter is an optional list of qualifications, each of which provides a condition to be applied to the object instances of interest. Each qualification objects of interest are those that meet all of the specified qualifications.

The attribute relationship quantifier is a logical binary relationship $ATTRRELN_i$ that the specified qualifying value $ATTRDATA_i$ has to the corresponding attribute of each instance of the desired object type(s). The objects that are to be qualified with this filter have an attribute value V_i such that the statement "$ATTRDATA_i$ $ATTRRELN_i$ V_i" is TRUE. If $ATTRRELN_i$ is omitted, the relationship of equality is intended.

For ASCII attribute values $ATTRDATA_i$, the characters for question mark "?" and asterisk "*" are used as "wild characters" to provide filtering for certain object types. The character "?" may be used in any attribute or key attribute value with an ASCII format to represent "any single character" and may be repeated. The asterisk character "*" may be similarly used to represent a variable-length string, including a null string. The string "*x" represents a string of any length that ends in "x", the string "x*" represents any string that begins with "x", and the string "*" represents any string of any non-zero length. The comparison for text characters is case insensitive.

Equipment is not required to support wild characters in particular, or attribute filters in general.

Structure: L,5

                 2. <ERRTEXTp>
```

Exception: If OBJSPEC is a zero-length item, no objects matched the specified filter.
If p = 0, no errors were detected.

S14,F9 Create Object Request (COR) M,H<->E,reply

Description: This message is used to request an object owner to create an object instance. OBJSPEC specifies the object owner.

Structure:
```
L,3
  1. <OBJSPEC>
  2. <OBJTYPE>
  3. L,a                a = # attributes requested
       1. L,2
            1. <ATTRID1>
            2. <ATTRDATA1>
       .
       .
       a. L,2
            1. <ATTRIDa>
            2. <ATTRDATAa>
```

Exception: If OBJSPEC is a null-length item, no object specifier is provided. If a = 0, no specific attribute settings are requested for the new object.

S14,F10 Create Object Acknowledge (CAO) M,H<->E

Description: This message is used to acknowledge the success or failure of creating the new object specified. If successful, OBJSPEC is the object specifier of the new object. The list of attributes returned is dependent upon the type of object specified.

Structure:
```
L,3
  1. <OBJSPEC>
  2. L,b                b = number of attributes returned
       1. L,2
            1. <ATTRID1>
            2. <ATTRDATA1>
       .
       .
       b. L,2

            2. <ATTRDATAb>
  3. L,2
       1. <OBJACK>
       2. L,p           p = number of errors reported
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            p. L,2
                 1. <ERRCODEp>
                 2. <ERRTEXTp>
```

Exception: If OBJSPEC is a null-length item, no object was created. If b = 0, no attributes of the new object are returned. If p = 0, no errors were detected.

S14,F11 Delete Object Request — S,H<->E,reply

Description: This message is used to request that the object specified in OBJSPEC be deleted. The list of attribute settings depends upon the type of object to be deleted.

Structure:

```
L,2
  1. <OBJSPEC>
  2. L,a                n = # attribute settings
       1. L,2
            1. <ATTRID_1>
            2. <ATTRDATA_1>
       .
       .
       a. L,2
            1. <ATTRID_a>
            2. <ATTRDATA_a>
```

Exception: If n = 0, no attribute settings are provided.

S14,F12 Delete Object Acknowledge (DOA) — M,H<->E

Description: This message is used to acknowledge the success or failure of deleting the object specified. The list of attributes returned is dependent upon the type of object to be deleted.

Structure:

```
L,2
  1. L,b                n = number of attributes returned
       1. L,2
            1. <ATTRID_1>
            2. <ATTRDATA_1>
       .
       .
       b. L,2
            1. <ATTRID_b>
            2. <ATTRDATA_b>
  2. L,2
       1. <OBJACK>
       2. L,p           p = number of errors reported
            1. L,2
                 1. <ERRCODE_1>
                 2. <ERRTEXT_1>
            .
            .
            p. L,2
                 1. <ERRCODE_p>
                 2. <ERRTEXT_p>
```

Exception: If n = 0, no attribute values are returned. If p = 0, no errors were detected.

S14,F13 Object Attach Request (OAR) M,H<->E,reply

Description: This message is sent by a supervisor to request the object specified in OBJSPEC to attach or reattach itself to the requestor.

Structure:

L,2
1. <OBJSPEC>
2. L,a — a = # attribute settings
   1. L,2
      1. <ATTRID$_1$>
      2. <ATTRDATA$_1$>

      .
      .

   a. L,2
      1. <ATTRID$_a$>
      2. <ATTRDATA$_a$>

Exception: If a = 0, no attribute settings are provided.

S14,F14 Object Attach Acknowledge (OAA) M,H<->E

Description: This message is used to acknowledge the success or failure of the requested attachment. If successful, a non-zero token shall be returned for the supervisor’s use in subsequent communications with the attached object.

Structure:

L,3

         .

      p. L,2
         1. <ERRCODE$_p$>
         2. <ERRTEXT$_p$>

Exception: OBJTOKEN is zero if and only if p is non-zero. If b = 0, no attribute values are returned. If p = 0, no errors were detected.

S14,F15 Attached Object Action Request (AOAR) M,H<->E,reply

Description: This message is used by a supervisor (only) to request an attached object to perform an action.

Structure:
```
L,4
  1. <OBJSPEC>
  2. <OBJCMD>
  3. <OBJTOKEN>
  4. L,a                a = # attribute settings
       1. L,2
            1. <ATTRID_1>
            2. <ATTRDATA_1>
       .
       .
       a. L,2
            1. <ATTRID_a>
            2. <ATTRDATA_a>
```

Exception: If a = 0, no attribute settings are provided.

S14,F16 Attached Object Action Acknowledge (AOAA) M,H<->E

Description: This message is used to acknowledge the success or failure of an action requested by a supervisor.

Structure:
```
L,2
  1. L,b                b = number of attributes
       1. L,2
            1. <ATTRID_1>
            2. <ATTRDATA_1>
       .
       .
       b. L,2
            1. <ATTRID_b>
            2. <ATTRDATA_b>
  2. L,2
       1. <OBJACK>
       2. L,p           p = number of errors reported
            1. L,2
                 1. <ERRCODE_1>
                 2. <ERRTEXT_1>
            .
            .
            p. L,2
                 1. <ERRCODE_p>
                 2. <ERRTEXT_p>
```

Exception: If p = 0, no errors were detected.

S14,F17 Supervised Object Action Request (SOAR) S,H<->E,reply

Description: This message is used to request a supervisor to have a supervised attached object perform an action. OBJSPEC specifies the supervisor, and TARGETSPEC specifies the attached object.

Structure:
```
L,4
  1. <OBJSPEC>
  2. <OBJCMD>
  3. <TARGETSPEC>
  4. L,a                a = number of attribute settings
       1. L,2
            1. <ATTRID_1>
            2. <ATTRDATA_1>
       .
       .
       a. L,2
            1. <ATTRID_a>
            2. <ATTRDATA_a>
```

Exception: If a = 0, no attribute settings are provided.

S14,F18 Supervised Object Action Acknowledge (SOAA) M,H<->E

Description: This message is used to acknowledge the success or failure of an action requested of a supervisor.

Structure:
```
L,2
  1. L,b               b = number of attributes
       1. L,2
            1. <ATTRID_1>
            2. <ATTRDATA_1>
       .
       .
       b. L,2
            1. <ATTRID_b>
            2. <ATTRDATA_b>
  2. L,2
       1. <OBJACK>
       2. L,p          p = number of errors reported
            1. L,2
                 1. <ERRCODE_1>
                 2. <ERRTEXT_1>
            .
            .
            p. L,2
                 1. <ERRCODE_p>
                 2. <ERRTEXT_p>
```

Exception: If b = 0, no attributes are returned. If p = 0, no errors were detected.

S14,F19 Generic Service Request (GSR) M,H->E, Reply

Description: The host requests an object to perform the specified service with its associated parameters. If multi-block, it shall be preceded by the S14F23/F24 Multi-Block Inquire/Grant transaction. DATAID is given uniquely to each message. OPID is uniquely specified to identify delayed completion information for time consuming service. OPID could be zero if and only if the service cannot take a long time.

Structure: L,5

1. <DATAID>
2. <OPID>
3. <OBJSPEC>
4. <SVCNAME>
5. L,m # of parameter groups
    1. L,2
        1. <SPNAME$_1$> service parameter 1 name
        2. <SPVAL$_1$> service parameter 1 value
    2. L,2
        1. <SPNAME$_2$> service parameter 2 name
        2. <SPVAL$_2$> service parameter 2 value

    .

    .

    m. L,2
        1. <SPNAME$_m$> service parameter m name
        2. <SPVAL$_m$> service parameter m value

If a specific value of SPNAME is defined to have a SPVAL defined as a LIST, it shall always be a LIST. If the SPVAL that is associated to that specific value of SPNAME is defined to be anything other than LIST, it will result in a format error.

Exception: A zero length list, m = 0, indicates that no parameter groups are sent with the service request. OBJSPEC can be a null length item if no object provide the services is defined in the standards which are referred to and it is assumed that “Equipment” is delegated and handled as if it is an object.

Notes:

1. If some service parameters are attributes of the specified object, service parameter name-value pair, that is SPNAME and SPVAL, is actually attribute id-data pair, that is ATTRID and ATTRDATA. An example of parameter part in the message format could be interpreted as below.

    L,m
    1. L,2
        1. <SPNAME$_1$>
        2. <SPVAL$_1$>
    2. L,2

    .

    .

    .

    k. L,2
        1. <ATTRID$_k$>
        2. <ATTRDATA$_k$>

    .

    m. …

2. If SPVAL is a LIST, the items that make up that list shall take on

one of the following forms: (1) a list of items with an identical format, (2) a LIST of SPNAME, SPVAL pairs, as illustrated below. When SPVAL is actually ATTRDATA, even if it is a LIST, it or its parts are not required to expand into lower level items if their names have not been formally named in the corresponding SEMI standard.

```
A)            L,2
                1. <SPNAME_a>
                2. L,m
                     1. <SPVAL_a1>
                     2. <SPVAL_a2>
                     :
                     :
                     m. <SPVAL_am>
B)            L,2
                1. <SPNAME_b>

                           1. <SPNANE_bn>
                           2. <SPVAL_bn>
```

S14,F20 Generic Service Acknowledge (GSA) M,H<-E

Description: The equipment acknowledges requested service or reports any error(s). If the service is accepted and completed at once, (i.e. SVCACK =0), then required parameter for response are listed with in this message. If the service is accepted but it takes relatively longer time to do due to some physical reason, (i.e. SVCACK = 4), then response of the service will be replied later with parameters when it is completed successfully or faultily. Criteria of the time whether it is delayed response or not depends on implementation. LINKID is set to a non-zero value if and only if additional completion reports will be sent.

```
Structure:    L,3
                1. <SVCACK>
                2. <LINKID>
                3. L,n                       # of parameter groups
                     1. L,2
                          1. <SPNAME_1>      service parameter 1 name
                          2. <SPVAL_1>       service parameter 1 value
                     2. L,2
                          1. <SPNAME_2>      service parameter 2 name
                          2. <SPVAL_2>       service parameter 2 value
                     :
                     :
                     n. L,2
                          1. <SPNAME_n>      service parameter n name
                          2. <SPVAL_n>       service parameter n value
```

S14,F21 Generic Service Completion Information (GSCI) M,H<-E, Reply

Description: The equipment notifies the original service requestor when requested service on an object is completed, either successfully or unsuccessfully. The equipment may send required information using reply parameters. If the service was accepted and completed at once, the information was carried with the acknowledge message, that is secondary message of requesting one, and this message is not provided.

OPID contains the value of OPID in the initial request, i.e. S14F19. LINKID is set to a non-zero value if and only if additional completion reports with the same OPID will be sent. If multi-block, it shall be preceded by the S14F23/F24 Multi-Block Inquire/Grant transaction.

Structure:
```
L,4
  1. <DATAID>
  2. <OPID>
  3. <LINKID>
  4. L,n                          # of parameter groups
       1. L,2

```

7.19 *Stream 15 Recipe Management* — The functions in this stream are used requesting information and operations concerning recipes, recipe namespaces, and recipe executors. A recipe is an object that is transferred in sections, where a section consists of either recipe attributes, agent-specific dataset attributes, or the body of the recipe. An attribute is information concerning the recipe body, the recipe as a whole, or the application of the recipe. An attribute consists of an attribute name/attribute value pair.

```
Description:   This message is used to confirm whether the requested action was
               completed successfully or to provide error information otherwise.

Structure:     L,2
                 1. <RMACK>
                 2. L,p
                      1. L,2
                           1. <ERRCODE1>
                           2. <ERRTEXT1>
                      .
                      .
                      p. L,2
                           1. <ERRCODEp>
                           2. <ERRTEXTp>

Exception:     p = 0 if and only if RMACK indicates no errors.
```

S15,F5 Recipe Namespace Rename Request S,H<->E, reply

Description: A request is made for a recipe namespace to be renamed.

Structure:
```
L,2
  1. <RMNSSPEC>
  2. <RMNEWNS>
```

S15,F6 Recipe Namespace Rename Acknowledge M,H<->E

Description: This message is used to acknowledge or deny a request to rename a recipe namespace.

Structure:
```
L,2
  1. <RMACK>
  2. L,p
       1. L,2
            1. <ERRCODE_1>
            2. <ERRTEXT_1>
       .
       .
       p. L,2
            1. <ERRCODE_p>
            2. <ERRTEXT_p>
```

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F7 Recipe Space Request S,H<->E, reply

Description: This message requests the amount of recipe storage available in the storage of a recipe namespace or recipe executor, as indicated by its object specifier OBJSPEC.

Structure: <OBJSPEC>

Exception: None.

S15,F8 Recipe Space Data M,H<->E

Description: This message contains the amount of storage available for recipes.

Structure:
```
L,2
  1. <RMSPACE>
  2. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE_1>
                 2. <ERRTEXT_1>
            .
            .
            p. L,2
                 1. <ERRCODE_p>
                 2. <ERRTEXT_p>
```

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F9 Recipe Status Request S,H<->E, reply

Description: This message is used to request the status of a recipe and the next available numeric version for that recipe class and name.

Structure: <RCPSPEC>

Exception: None.

S15,F10 Recipe Status Data M,H<->E

Description: This message contains the protected status of the recipe and the next available version number for that recipe class and name.

Structure:
```
L,3
  1. <RCPSTAT>
  2. <RCPVERS>
  3. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            p. L,2
                 1. <ERRCODEp>
                 2. <ERRTEXTp>
```

Exception: RCPVERS is a zero-length item if and only if the recipe does not exist. p = 0 if and only if RMACK indicates no errors.

S15,F11 Recipe Version Request S,H<->E, reply

Description: This message is used to request the best version of a recipe for the specified agent.

Structure:
```
L,4
  1. <RMNSSPEC>
  2. <RCPCLASS>
  3. <RCPNAME>
  4. <AGENT>
```

Exception: If item 2 is zero length, the recipe class PROCESS is indicated. If item 4 is a zero-length item, no agent is specified.

S15,F12 Recipe Version Data M,H<->E

```
Description:   This message contains the recommended version.

Structure:     L,3
                 1. <AGENT>
                 2. <RCPVERS>
                 3. L,2
                      1. <RMACK>
                      2. L,p
                           1. L,2
                                1. <ERRCODE1>
                                2. <ERRTEXT1>
                           .
                           .
                           p. L,2
                                1. <ERRCODEp>
                                2. <ERRTEXTp>

Exception:     If AGENT is a zero-length item in the request, it shall also be a
               zero-length item in the reply. If it is not zero-length in the
               request, and it is of zero-length in the reply, then no qualifying
               recipe was found specific to that equipment. p = 0 if and only if
               RMACK indicates no errors.
```

S15,F13 Recipe Create Request M,H<->E, reply

```
Description:   This message is used to create or modify a recipe body. If multi-
               block, it shall be preceded by the S15,F1/F2 inquire/grant
               transaction.

Structure:     L,5
                 1. <DATAID>
                 2. <RCPUPDT>
                 3. <RCPSPEC>
                 4. L,m
                      1. L,2
                           1. <RCPATTRID1>
                           2. <RCPATTRDATA1>
                      .
                      .
                      m. L,2
                           1. <RCPATTRIDm>
                           2. <RCPATTRDATAm>
                 5. <RCPBODY>

Exception:     RCPBODY may be of zero length.
```

S15,F14 Recipe Create Acknowledge M,H<->E

Description: This message is used to acknowledge that a recipe has been created or updated with the body sent in the request.

Structure:
```
L,2
  1. <RMACK>
  2. L,2
       1. L,2
            1. <ERRCODE1>
            2. <ERRTEXT1>
       .
       .
       p. L,2
            1. <ERRCODEp>
            2. <ERRTEXTp>
```

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F15 Recipe Store Request M,H<->E, reply

Description: This message is used to send a recipe, or one or more recipe sections, to a recipe namespace. If multi-block, it shall be preceded by the S15,F1/F2 inquire/grant transaction.

Structure:

```
L,4
  1. <DATAID>
  2. <RCPSPEC>
  3. <RCPSECCODE>
  4. L,q                (q = 1,2,3)
       1. L,r           (r = 0 or 2)
            1. <RCPSECNM>
            2. L,g      (g = # generic attributes)
                 1. L,2
                      1. <RCPATTRID1>
                      2. <RCPATTRDATA1>
                 .
                 .
                 g. L,2
                      1. <RCPATTRIDg>
                      2. <RCPATTRDATAg>
       2. <RCPBODY>
       3. L,m           (m = # agent-specific datasets)
            1. L,2
                 1. <RCPSECNM1>
                 2. L,a
                      1. L,2
                           1. <RCPATTRID11>
                           2. <RCPATTRDATA11>
                      .
                      .
                      a. L,2
                           1. <RCPATTRID1a>
                           2. <RCPATTRDATA1a>
            .
            .
            m. L,2
                 1. <RCPSECNMm>
                 2. L,b
                      1. L,2
                           1. <RCPATTRIDm1>
                           2. <RCPATTRDATAm1>
                      .
                      .
                      b. L,2
                           1. <RCPATTRIDmb>
                           2. <RCPATTRDATAmb>
```

Exception: RCPBODY is a zero-length item when the body is omitted. If g = 0, no generic attributes are transferred and RCPBODY shall be a zero-length item. If m = 0, no agent-specific datasets are transferred.

S15,F16 Recipe Store Acknowledge M,H<->E

Description: This message is used to acknowledge that the specified recipe has been stored as requested or to indicate the error(s).

Structure:

```
L,2
  1. <RECPSECCODE>
  2. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            p. L,2
                 1. <ERRCODEp>
                 2. <ERRTEXTp>
```

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F17 Recipe Retrieve Request S,H<->E, reply

Description: This message is used to get a recipe, or one or more recipe sections, from a recipe namespace.

Structure:

```
L,2
  1. <RCPSPEC>
  2. <RCPSECCODE>
```

Exception: None.

S15,F18 Recipe Retrieve Data M,H<->E

Description: This message is used to acknowledge that the specified recipe, or recipe sections, have been set as requested, or to indicate the error(s).

Structure:

```
L,2
  1. L,q                (q = 1,2,3)
       1. L,r           (r = 0 or 2)

            2. L,2
                 1. <RMACK>
                 2. L,p
                      1. L,2
                           1. <ERROCODE_1>
                           2. <ERRTEXT_1>
                      .
                      .
                      p. L,2
                           1. <ERRCODE_p>
                           2. <ERRTEXT_p>
```

Exception: If r = 0, no generic attributes are transferred and RCPBODY shall be a zero-length item. If m = 0, no agent-specific datasets are transferred. p = 0 if and only if RMACK indicates no errors.

S15,F19 Recipe Rename Request — S,H<->E, reply

Description: This message is used to request that a recipe be copied to, or renamed to, a recipe with a new identifier.

Structure: L,3
1. <RCPSPEC>
2. <RCPRENAME>
3. <RCPNEWID>

Exception: None.

S15,F20 Recipe Rename Acknowledge — M,H<->E

Description: This message acknowledges the request to copy or rename a recipe and indicates whether the action was successfully performed or errors that occurred.

Structure: L,2
1. <RMACK>
2. L,p
    1. L,2
        1. <ERRCODE$_1$>
        2. <ERRTEXT$_1$>

    .
    .

    p. L,2
        1. <ERRCODE$_p$>
        2. <ERRTEXT$_p$>

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F21 Recipe Action Request — M,H<->E, reply

Description: This message is used to acknowledge the request to perform an action on one or more recipes within a namespace.

Structure: L,6
1. <DATAID>
2. <RCPCMD>
3. <RMNSSPEC>
4. <OPID>
5. <AGENT>
6. L,n
    1. <RCPID$_1$>

    .
    .

    n. <RCPID$_n$>

Exception: AGENT may be a zero-length item except for requests for certify, de-certify, download, and upload.

S15,F22 Recipe Action Acknowledge M,H<->E

Description: This message is used to acknowledge the request to originate a new recipe.

Structure:
```
L,4
  1. <AGENT>
  2. <LINKID>
  3. <RCPCMD>
  4. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            p. L,2
                 1. <ERRCODEp>
                 2. <ERRTEXTp>
```

Exception: LINKID is zero if and only if all requested actions have been completed. p = 0 if and only if RMACK indicates no errors.

S15,F23 Recipe Descriptor Request M,H<->E, reply

Description: This message is used to request the descriptors of a list of the specified recipes. If multi-block, it must be preceded by the S15,F1/F2 inquire/grant transaction. OBJSPEC is the object specifier of either a recipe namespace of a recipe executor.

Structure:
```
L,3
  1. <DATAID>
  2. <OBJSPEC>
  3. L,n
       1. <RCPID1>
       .
       .
       n. <RCPIDn>
```

Exception: None.

S15,F24 Recipe Descriptor Data M,H<->E

Description: This message returns the requested descriptors in the same order as requested.

Structure:

```
L,2
  1. L,n                (n = number of recipes from request)
       1. L,a           (descriptors for recipe #1)
            1. L,r      (r = 0 or 3) (1st component descriptor)
                 1. <RCPDESCNM_11>
                 2. <RCPDESCTIME_11>
                 3. <RCPDESCLTH_11>
            .
            .
            a. L,r      (r = 0 or 3)
                 1. <RCPDESCNM_1a>
                 2. <RCPDESCTIME_1a>
                 3. <RCPDESCLTH_1a>
       .
       .
       n. L,b           (descriptors for recipe #n)
            1. L,r      (r = 0 or 3) (1st component descriptor)
                 1. <RCPDESCNM_n1>
                 2. <RCPDESCTIME_n1>
                 3. <RCPDESCLTH_n1>
            .
            .
            b. L,r      (r = 0 or 3)
                 1. <RCPDESCNM_nb>
                 2. <RCPDESCTIME_nb>
                 3. <RCPDESCLTH_nb>
  2. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE_1>
                 2. <ERRTEXT_1>
            .
            .
            p. L,2
                 1. <ERRCODE_p>
                 2. <ERRTEXT_p>
```

Exception: A zero-length recipe descriptor (r = 0) means that the specified recipe does not exist (could not be located). p = 0 if and only if RMACK indicates no errors.

S15,F25 Recipe Parameter Update Request M,H<->E, reply

```
Description:   This message is used to update the variable parameter definitions
               for a specific agent. If multi-block, it must be preceded by the
               S15,F1/F2 inquire/grant transaction.

Structure:     L,4
                 1. <DATAID>

S15,F27 Recipe Download Request — M,H->E,reply

Description: This message is used to send a recipe to a recipe executor. If multi-block, it shall be preceded by the S15,F1/S15,F2 inquire/grant transaction.

Structure:

```
L,5
  1. <DATAID>
  2. <RCPOWCODE>
  3. <RCPSPEC>
  4. L,m
       1. L,2
            1. <RCPATTRID1>
            2. <RCPATTRDATA1>
       .
       .
       m. L,2
            1. <RCPATTRIDm>
            2. <RCPATTRDATAm>
  5. <RCPBODY>
```

Exception: None.

S15,F28 Recipe Download Acknowledge — M,H<-E

Description: This message is used to acknowledge that a recipe has been received by the recipe executor. If the recipe was successfully verified, the results are returned to the sender. RCPID contains the identifier of a derived object form recipe if created during verification.

Structure:

```
L,3
  1. <RCPID>
  2. L,n (n = # of attributes)
       1. L,2
            1. <RCPATTRID1>
            2. <RCPATTRDATA1>
           .
           .
       n. L,2
            1. <RCPATTRIDn>
            2. <RCPATTRDATAn>
  3. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            p. L,2
                 1. <ERRCODEp>
                 2. <ERRTEXTp>
```

Exception: If item is a zero length item, no derived object form recipe was originated. n = 0 if and only if the recipe was not verified or failed verification. p = 0 if and only if RMACK indicates no errors.

Description: This message is used to request verification of one or more recipes by a recipe executor. If multi-block, it shall be preceded by the S15F1, F2 inquire/grant transaction. The operation identifier OPID, used where multiple verification requests may be outstanding, may be zero if no further verifications will be requested before all current verification requests are completed by the recipe executor. Otherwise, OPID is generated to be unique for the requestor. RESPEC is the object specifier for the recipe executor.

Structure:

```
L,4
  1. <DATAID>
  2. <OPID>
  3. <RESPEC>
  4. L,m
       1. <RCPID1>
       .
       .
       m. <RCPIDm>
```

Exception: If RESPEC is a zero length item, the target is the recipient of the message.

S15,F30 Recipe Verify Acknowledge M,H<-E

Description: This message is used to acknowledge the request to verify one or more recipes. If a single recipe verification was requested and the recipe was successfully verified, the results are returned to the sender in this message, and RCPID contains the identifier of a derived object form recipe if created during verification. If multiple recipe verifications were requested, then LINKID shall be non-zero.

Structure:
```
L,5
  1. <OPID>
  2. <LINKID>
  3. <RCPID>
  4. L,n (n = # attributes)
       1. L,2
            1. <RCPATTRID1>
            2. <RCPATTRDATA1>
       .
       .
       n. L,2
            1. <RCPATTRIDn>
            2. <RCPATTRDATAn>
  5. L,2
       1. <RMACK>
       2. L,p
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            p. L,2
                 1. <ERRCODEp>
                 2. <ERRTEXTp>
```

Exception: LINKID is zero if and only if a single recipe verification was requested and has been completed. If item 3 is zero length item, no derived object form recipe was originated. n = 0 if and only if the recipe was not verified or failed verification. p = 0 if and only if RMACK indicates no errors.

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F33 Recipe Select Request — M,H->E,reply

Description: This message is used to request the selection of one or more execution recipes. If multi-block, it shall be preceded by the S15,F1/S15,F2 inquire/grant transaction.

Structure:

```
L,3
1. <DATAID>
2. <RESPEC>
3. L,r            (r = # selections)
   1. L,2
      1. <RCPID_1> (1st recipe selection)
      2. L,p      (p = # parameter settings for 1st recipe)
         1. L,2
            1. <RCPPARNM_11>
            2. <RCPPARVAL_11>
         .
         .
        p. L,2
            1. <RCPPARNM_1p>
            2. <RCPPARVAL_1p>
   .
   .
   r. L,2
      1. <RCPID_r> (rth recipe selection)
      2. L,s      (s = # parameter settings for rth recipe)
         1. L,2
            1. <RCPPARNM_r1>
            2. <RCPPARVAL_r1>
         .
         .
         s. L,2
            1. <RCPPARNM_rs>
            2. <RCPPARVAL_rs>
```

Exception: If the list of parameter settings for a recipe selection is of zero length, then no parameter settings are specified for the corresponding recipe.

S15,F34 Recipe Select Acknowledge — M,H<-E

Description: This message is used to acknowledge the request for recipe selection.

Structure:

```
L,2
  1. <RMACK>
  2. L,p
       1. L,2
            1. <ERRCODE_1>
            2. <ERRTEXT_1>
       .
       .
       p. L,2
            1. <ERRCODE_p>
            2. <ERRTEXT_p>
```

Exception: p = 0 if and only if RMACK indicates no errors.

S15,F35 Recipe Delete Request M,H->E,reply

Description: This message is used to request that one or more recipes be deleted or deselected. If multi-block, it shall be preceded by the S15,F1/ S15,F2 inquire/grant transaction.

Structure: L,4
  1. <DATAID>
  2. <RESPEC>
  3. <RCPDEL>
  4. L,n (n = # recipes deselected)
     1. <RCPID$_1$>
     .
     .
     n. <RCPID$_n$>

Exception: If n = 0 and recipes are to be deselected (RCPDEL = 1), then all currently-selected recipes are indicated.

S15,F36 Recipe Delete Acknowledge M,H<-E

Description: This message is used to acknowledge the request that recipes be deleted or deselected.

Structure: L,2
  1. <RMACK>
  2. L,p
     1. L,2

        2. <ERRTEXT$_p$>

Exception: p = 0 if and only if RMACK indicates no errors.

7.20 *Steam 16 Processing Management* — This stream provides protocol for a set of messages that enable the control of material processing at equipment and equipment resources. Control is implemented by supporting two job types; the control job and the process job. A process job is a single unit of work that ensures that the appropriate processing is applied to a particular material by a processing resource. The Process Job provides a widely applicable supervisory control capability for automated processing of material in equipment, irrespective of the particular process being used. The Process Job creates a transient link between the three elements of the manufacturing process; the first is the material to be processed. The second is the equipment on which the process will occur. The third is the process specification, a Process Recipe. When a Process Job has completed, it ceases to exist; its Process Job ID is no longer valid. The control job is used to group a set of related process jobs. The group is logically related from the host's viewpoint. For instance; if a carrier contains multiple lots, then the process jobs for each lot (in the carrier) could be included in the control job specification. Control jobs also provide mechanisms for specifying the destination for processed material.

S16,F0 Abort Transaction (S16F0) S,H<->E

Description: Same form as S1F0.

S16,F1 Multi-block Process Job Data Inquire (PRJI) S,H->E,reply

Description: If any of Processing Management messages are larger than one block, then this transaction must precede that message.

Structure: L,2
1. <DATAID>
2. <DATALENGTH>

S16,F2 Multi-block Process Job Data Grant (PRJG) S,H<-E

Description: Message to indicate if permission is granted to transmit a multi-block Job Data message.

Structure: <GRANT>

S16,F3 Process Job Create Request (PRJCR) M,H->E,reply

Description: The purpose of this message is to request material to be processed on a Process Module.

Structure: L,5

- 1. <DATAID>
- 2. <MF>
- 3. L,n
  - 1. <MID$_1$>
  - .
  - .
  - n. <MID$_n$>
- 4. L,3
  - 1. <PRRECIPEMETHOD>
  - 2. <RCPSPEC>
  - 3. L,m (m = {c,2})
    - 1. L,2
      - 1. <RCPPARNM$_1$>
      - 2. <RCPPARVAL$_1$>
    - .
    - .
    - .
    - m. L,2
      - 1. <RCPPARNM$_m$>
      - 2. <RCPPARVAL$_m$>
- 5. <PRPROCESSSTART>

Exception: For the m length list m = 0 may be allowed value depending on the value of PRRECIPEMETHOD.

S16,F4 Process Job Create Acknowledge (PRJCA) S,H<-E

Description: Acknowledge or report error in the creation of a Process Job.

Structure: L,2

- 1. <PRJOBID>
- 2. L,2
  - 1. <ACKA>
  - 2. L,n
    - 1. L,2
      - 1. <ERRCODE$_1$>
      - 2. <ERRTEXT$_1$>
    - .
    - .
    - .
    - n. L,2
      - 1. <ERRCODE$_n$>
      - 2. <ERRTEXT$_n$>

Exception: This list may be zero length, generally the case when ACKA indicates success. When ACKA indicates a create failure, the equipment may supply one or more ERRCODE’s.

S16,F5 Process Job Command Request (PRJCMDR) M,H->E,reply

```
Description:   Send a job control command to a processing job.

Structure:     L,4
                 1. <DATAID>
                 2. <PRJOBID>
                 3. <PRCMDNAME>
                 4. L,n
                      1. L,2
                           1. <CPNAME1>
                           2. <CPVAL1>
                      .
                      .
                      .
                      n. L,2
                           1. <CPNAMEn>
                           2. <CPVALn>

Exception:      The CPNAME, CPVAL pairs are command parameter identifiers and
                values; n = 0 is valid for some commands (PRCMDNAME).
```

S16,F6 Process Job Command Acknowledge (PRJCMDA) S,H<-E

```
Description:   The processing service sends its confirmation for receipt of a
               command request.

Structure:      L,2
                  1. <PRJOBID>
                  2. L,2
                       1. <ACKA>
                       2. L,n          (n = {0,n})
                            1. L,2
                                 1. <ERRCODE1>
                                 2. <ERRTEXT1>
                            .
                            .
                            .
                            n. L,2
                                 1. <ERRCODEn>
                                 2. <ERRTEXTn>

Exception:     This list n may be zero length.
```

S16,F7 Process Job Alert Notify (PRJA) S,H<-E,[reply]

Description: The processing service may notify the controlling entity of important events. The Process Job Milestones only assume small number of different values. However, the conditions under which a process job meets one of these milestones may vary. For instance, a Job may reach Job Complete because the Process was Aborted. By using item 4, the status of the Alert (PRJOBMILESTONE) can be indicated. See the list of Error Codes for Processing in Data Item Dictionary.

Structure: L,4
  1. <TIMESTAMP>
  2. <PRJOBID>
  3. <PRJOBMILESTONE>
  4. L,2
      1. <ACKA>
      2. L,n (n = {0,n})
          1. L,2
              1. <ERRCODE$_1$>
              2. <ERRTEXT$_1$>
          .
          .
          .
          n. L,2
              1. <ERRCODE$_n$>
              2. <ERRTEXT$_n$>

Exception: The list n may be zero length.

S16,F8 Process Job Alert Confirm (PRJAC) S,H->E

Description: Host confirms receipt of Process Job Alert message from the equipment.

Structure: Header only

S16,F9 Process Job Event Notify (PRJE) S,H<-E,[reply]

Description: Send Processing Job related event to the controlling entity.

Structure: L,4
  1. <PREVENTID>
  2. <TIMESTAMP>
  3. <PRJOBID>
  4. L,n
      1. L,2
          1. <VID$_1$>
          2. <V$_1$>
      .
      .
      .
      n. L,2
          1. <VID$_n$>
          2. <V$_n$>

Exception: The VID, V pairs are variable data identifiers and values; exceptions n = 0 is valid for some events (PREVENTID).

S16,F10 Process Job Event Confirm (PRJEC) — S,H->E

Description: Host confirms receipt of S16,F9 message to equipment.

Structure: Header only.

S16,F11 PRJobCreateEnh — M,H->E,reply

Description: Request equipment to create a Process Job with the given PRJOBID. If multi-block, this message must be preceded by the S16,F1/F2 transaction.

Structure:

```
L,7
  1. <DATAID>
  2. <PRJOBID>
  3. <MF>
  4a. L,n                  [MF = carrier, n = # of carriers]
        1. L,2

                      2. <SLOTID2>
                      .
                      j. <SLOTIDj>
            .
            .
            n. L,2
                 1. <CARRIERIDn>
                 2. L,j   [j = # of slots, may be implemented
                               as an array]
                      1. <SLOTID1>
                      2. <SLOTID2>
                      .
                      j. <SLOTIDj>
      3b. L,n              [MF = substrate, n = # of MID]
            1. <MID1>
            .
            n. <MIDn>
      4. L,3
           1. <PRRECIPEMETHODp>
           2. <RCPSPECp>
           3. L,m          [m = # recipe parameters]
                1. L,2
                     1. <RCPPARNM1>
                     2. <RCPPARVAL1>
                .
                m. L,2
                     1. <RCPPARNMm>
                     2. <RCPPARVALm>
      5. <PRPROCESSSTARTp>
      6. <PRPAUSEEVENTp>
```

Exception: The list for specifying material (item 3a and 3b) is empty (L,0 instead of L,n), when no material is specified for the process job. The form of data item 3(a or b) depends on the value in MF.

S16,F16 PRJobMultiCreate Acknowledge S,H<-E

Description: This message acknowledges the request and reports any errors in the creation of a process job. ERRTEXT contains the identifier of process jobs that were not created.

Structure:
```
L,2
  1. L,m                          [m = # jobs created]
       1. <PRJOBID_1>
       .
       m. <PRJOBID_m>
  2. L,2
       1. <ACKA>
       2. L,n
            1. L,2
                 1. <ERRCODE_1>
                 2. <ERRTEXT_1>
            .
            .
            n. L,2
                 1. <ERRCODE_n>
                 2. <ERRTEXT_n>
```

Exception: If n = 0, no errors exist.

S16,F17 PRJobDequeue S,H->E,reply

Description: Used to remove process jobs from the equipment for jobs that have not begun processing.

Structure:
```
L,m                               [m = # jobs to remove]
  1. <PRJOBID_1>
  .
  m. <PRJOBID_m>
```

Exception: If m = 0, then de-queue all.

S16,F18 PRJobDequeue Acknowledge — S,H<-E

Description: Acknowledge the request to de-queue and report any errors. ERRTEXT will contain the identifier of any jobs that were not de-queued.

Structure:

```
L,2
  1. L,m                            [m = # jobs removed]
       1. <PRJOBID1>
       .
       m. <PRJOBIDm>
  2. L,2
       1. <ACKA>
       2. L,n
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            n. L,2
                 1. <ERRCODEn>
                 2. <ERRTEXTn>
```

Exception: If n = 0, no errors exist.

S16,F19 PRGetAllJobs — S,H->E

Description: Requests the equipment to return a list of process jobs which have not completed. They may be running or waiting to run.

Structure: header only

S16,F20 PRGetAllJobs Send — S,H<-E

Description: Returns the requested list of process jobs.

Structure:

```
L,m                                 [m = # jobs in the list]
  1. L,2
       1. <PRJOBID1>
       2. <PRSTATE1>
  .
  m. L,2
       1. <PRJOBIDm>
       2. <PRSTATEm>
```

Exception: If m = 0, then no process jobs are running or waiting to run.

S16,F21 PRGetSpace — S,H->E

Description: Requests the equipment to return the number of process jobs it has space to create.

Structure: header only

S16,F22 PRGetSpace Send — S,H<-E

Description: Sends the host the number of process jobs which can be created.

Structure: <PRJOBSPACE>

S16,F23 PRJobSetRecipeVariable — S,H->E

Description: Reset the value of recipe variable parameters for a specific process job.

Structure:

L,2
  1. <PRJOBID>
  2. L,m [m = # recipe variables]
    1. L,2
      1. <$RCPPARNM_1$>
      2. <$RCPPARVAL_1$>
    .
    .
    m. L,2
      1. <$RCPPARNM_m$>
      2. <$RCPPARVAL_m$>

S16,F24 PRJobSetRecipeVariable Acknowledge — S,H<-E

Description: Indicate the status of the request to set recipe variables. ERRTEXT will contain the RCPPARNM value for parameters that could not be reset.

Structure:

L,2
  1. <ACKA>
  2. L,n
    1. L,2
      1. <$ERRCODE_1$>
      2. <$ERRTEXT_1$>
    .
    .
    n. L,2
      1. <$ERRCODE_n$>
      2. <$ERRTEXT_n$>

Exception: If n = 0, no errors exist.

S16,F25 PRJobSetStartMethod — S,H->E

Description: Used to request to change the start method (USERSTART or AUTO) for one or more process jobs.

Structure:

L,2
  1. L,m [m = # of jobs]
    1. <$PRJOBID_1$>
    .
    .
    m. <$PRJOBID_m$>
  2. <PRPROCESSSTART>

S16,F26 PRJobSetStartMethod Acknowledge — S,H<-E

Description: Acknowledges request to set job start method and indicates any errors. ERRTEXT will contain the identifiers of any process jobs that did not accept the new process start method.

Structure:

```
L,2
  1. L,m                        [m = # of jobs]
       1. <PRJOBID1>
       .
       m. <PRJOBIDm>
  L,2
       1. <ACKA>
       2. L,n
            1. L,2
                 1. <ERRCODE1>
                 2. <ERRTEXT1>
            .
            .
            n. L,2
                 1. <ERRCODEn>
                 2. <ERRTEXTn>
```

S16,F27 Control Job Command Request — S,H->E

Description: Send a control job command to a control job.

Structure:

```
L,3
  1. <CTLJOBID>
  2. <CTLJOBCMD>
  3. L,2
       1. <CPNAME>
       2. <CPVAL>
```

Exception: 3. L,2 IS L,0 for commands that do not need parameters.

S16,F28 Control Job Command Acknowledge — S,H<-E

Description: Indicates success or failure of command request to a control job. If applicable ERRTEXT shall contain information on specific command parameter names or values that caused the error.

Structure:

```
L,2
  1. <ACKA>
  2. L,2
       1. <ERRCODE>
       2. <ERRTEXT>
```

Exception: 2. L,2 IS L,0 if no errors.

S16,F29 PRSetMtrlOrder (PRJSMO) — S,H -> E,reply

Description: This message requests the equipment’s Processing Management Service to use a specific strategy for the order in which materials are processed.

Structure:

```
<PRMTRLORDER>
```

S16,F30 PRSetMtrlOrder Acknowledge (PRJSMOA) S,H <- E

Description: This message acknowledges the request for change to the material process strategy by reporting back the value requested, if correct.

Structure: <ACKA>

7.21 *Stream 17 Equipment Control and Diagnostics* — This stream is a continuation of Stream 2.

S17,F0 Abort Transaction (S17F0) S,H<->E

Description: Same form as S1F0.

S17,F1 Data Report Create Request (DRC) M,H->E,reply

Description: Create a Data Report definition. This function allows the referencing of a Data Source for the items (variables or attributes) specified in the data report.

Structure:
```
L,4
  1. <DATAID>
  2. <RPTID>
  3. <DATASRC>
  4. L,n
       1. <VID1>
       2. <VID2>
       .
       .
       .
       n. <VIDn>
```

Exception: DATAID is a zero length item when the request can be sent in a single block. If RPTID is a zero length item, then the equipment shall return a value in RPTID by which the host can then reference the report efinition. If RPTID has a value, then the equipment shall retain this value by which the host can then reference the report definition.

S17,F2 Data Report Create Acknowledge (DRCA) S,H<-E

Description: Equipment confirms creation of a Data Report and returns RPTID.

Structure:
```
L,2
  1. <RPTID>
  2. <ERRCODE>
```

Exception: If ERRCODE is a zero length item, then no error occurred.

S17,F3 Data Report Delete Request (DRD) S,H->E,reply

Description: Delete one or more data reports. This shall cause those reports to be unlinked from any Event Reports to which they were linked. This shall cause the report to be excluded from any Trace Reports for in which it had originally been included.

Structure: L,n

1. <$RPTID_1$>
2. <$RPTID_2$>

.
.
.

n. <$RPTID_n$>

Exception: If this message is sent with a zero length list, then all reports shall be deleted.

S17,F4 Data Report Delete Acknowledge (DRDA) S,H<-E

Description: Equipment confirms or indicates any errors on the request to delete Data Reports. All Data Reports which could be deleted shall be listed in the response and the associated error code shall be included in the list.

Structure: L,2

1. <ACKA>
2. L,m
    1. L,3
        1. <$RPTID_1$>
        2. <$ERRCODE_1$>
        3. <$ERRTEXT_1$>

    .
    .

    m. L,3
        1. <$RPTID_m$>
        2. <$ERRCODE_m$>
        3. <$ERRTEXT_m$>

Exception: If ACKA is TRUE, then no errors were encountered, meaning all report requests were completed successfully and a zero-length list (m = 0) shall be sent.

Exception: If some reports could not be deleted, then their RPTID’s shall be given in a space separated list in ERRTEXT.

S17,F5 Trace Create Request (TRC) M,H->E,reply

```
Description:   Establish a Trace Report definition.

Structure:     L,6
                 1. <DATAID>
                 2. <TRID>
                 3. <CEED>
                 4. L,n
                      1. <RPTID1>
                      2. <RPTID2>
                      .
                      .
                      n. <RPTIDn>
                 5. <TRSPER>
                 6. L,m                (m = {0,8})
                      1. <TOTSMP>
                      2. <REPGSZ>
                      3. <EVNTSRC>     (Defines source for start Event)
                      4. <CEID>        (Defines ID of the start Event)
                      5. <EVNTSRC>     (Defines source for stop Event)
                      6. <CEID>        (Defines ID of the stop Event)
                      7. <TRAUTOD>
                      8. <RPTOC>

Exception:     The list m can be zero-length, or it can contain all eight data
               items.  Since specifying values for each item is optional, each of
               the eight items can be zero-length.  If the item is zero-length, the
               format of the item shall be the same format used in other instances
               of the S17,F5 message where the value is not zero-length.
```

S17,F6 Trace Create Acknowledge (TRCA) S,H<-E

```
Description:   Equipment confirms creation of an Event Report and returns a TRID.

Structure:      L,2
                  1. <TRID>
                  2. <ERRCODE>

Exception:     If ERRCODE is a zero length item, then no error occurred.
```

S17,F7 Trace Delete Request (TRD) S,H->E,reply

```
Description:   The host requests to delete one or more Trace Reports.

Structure:     L,n
                 1. <TRID1>
                 2. <TRID2>
                 .
                 .
                 n. <TRIDn>
```

S17,F8 Trace Delete Acknowledge (TRDA) — S,H<-E

Description: This message is required to inform the host when a Trace Report could not be deleted. This message does not need to be sent to confirm the successful deletion of a Trace Report. If the report is sent for a successfully deleted Trace Report, then the ERRCODE item length shall be set to zero.

Structure:

L,2
  1. <ACKA>
  2. L,m
    1. L,3
      1. <TRID$_1$>
      2. <ERRCODE$_1$>
      3. <ERRTEXT$_1$>
    .
    .
    m. L,3
      1. <TRID$_m$>
      2. <ERRCODE$_m$>
      3. <ERRTEXT$_m$>

Exception: If ACKA is TRUE, then no errors were encountered, meaning all report requests were completed successfully and a zero-length list (m = 0) shall be sent.

Exception: If some reports could not be deleted, then their TRID’s shall be provided in a space separated list in ERRTEXT.

S17,F9 Collection Event Link Request (CELR) — M,H->E,reply

Description: Establish a Collection Event Report definition with respect to a specific Event Source.

Structure:

L,4
  1. <DATAID>
  2. <EVNTSRC>
  3. <CEID>
  4. L,n (n is the number of Reports to be linked)
    1. <RPTID$_1$>
    2. <RPTID$_2$>
    .
    .
    n. <RPTID$_n$>

S17,F10 Collection Event Link Acknowledge (CELA) — S,H<-E

Description: Indicate the success or failure of a Collection Event Link Request.

Structure:

L,3
  1. <EVNTSRC>
  2. <CEID>
  3. <ERRCODE>

Exception: Item 3 should be set to zero length to indicate success.

S17,F11 Collection Event Unlink Request (CEUR) S,H->E,reply

Description: Request to unlink a specific Data Report from a Collection Event Report.

Structure: L,3
1. <EVNTSRC>
2. <CEID>
3. <RPTID>

Exception: Item one can be zero length, in which case the default event source is assumed.

S17,F12 Collection Event Unlink Acknowledge (CEUA) S,H<-E

Description: Indicates success or failure of a requested Unlink.

Structure: L,4
1. <EVNTSRC>
2. <CEID>
3. <RPTID>
4. <ERRCODE>

Exception: Item one can be zero length to indicate the default event source. Item 4 is set to zero length if the primary request was successful.

S17,F13 Trace Reset Request (TRR) S,H->E,reply

Description: The Host requests the equipment to clear the data and reset the specified trace reports. If n = 0, then all defined Trace Objects will be reset.

Structure: L,n
1. <$TRID_1$>
2. <$TRID_2$>
.
.
n. <$TRID_n$>

S17,F14 Trace Report Reset Acknowledge (TRRA) S,H<-E

Description: This list in item 1 contains the identifiers of all the Trace Objects which were reset. If all Trace Objects are successfully reset, then ACKA shall be set to TRUE.

Structure: L,2
1. <ACKA>
2. L,m
   1. L,3
      1. <TRID$_1$>
      2. <ERRCODE$_1$>
      3. <ERRTEXT$_1$>
   .
   .
   m. L,3
      1. <TRID$_m$>
      2. <ERRCODE$_m$>
      3. <ERRTEXT$_m$>

Exception: If ACKA is TRUE, then no errors were encountered, meaning all report requests were completed successfully and a zero-length list (m = 0) shall be sent.

Exception: If some reports could not be reset, then their TRID's shall be given in a space separated list in ERRTEXT.

7.22 *Stream 18 Subsystem Control and Data* — Messages exchanged between component subsystems and higher level controllers. Compared to similar messages exchanged between equipment and host, subsystem messages are less complex.

S18,F1 Read Attribute Request (RAR) S,H->E,reply

Description: This message requests the current values of specified attributes of the subsystem component indicated in TARGETID.

Structure: L,2
1. <TARGETID>
2. L,n   n = # attribute identifiers
   1. <ATTRID$_1$>
   .
   n. <ATTRID$_n$>

Exceptions: If n = 0, then all attributes of the target component are requested.

S18,F2 Read Attribute Data (RAD) S,H<-E

Description: This message returns the current values of requested attributes and the current status of the requested component indicated in TARGETID. Attributes are returned in the order requested.

Structure:
```
L,3
  1. <TARGETID>
  2. <SSACK>
  3. L,n
       1. <ATTRDATA1>
       .
       n. <ATTRDATAn>
```

Exceptions: Both n = 0 and s = 0 if the target component is unknown.

S18,F3 Write Attribute Request (WAR) S,H->E,reply

Description: This message requests the subsystem to set the value of read/write attributes of the component specified in TARGETID.

Structure:
```
L,2
  1. <TARGETID>
  2. L,n
       1. L,2
            1. <ATTRID1>
            2. <ATTRDATA1>
       .
       n. L,2
            1. <ATTRIDn>
            2. <ATTRDATAn>
```

S18,F4 Write Attribute Acknowledge (WAA) S,H<-E

Description: This message acknowledges the success of failure of the request to write attribute data to the subsystem indicated in TARGETID.

Structure:
```
L, 3
   1. <TARGETID>
   2. <SSACK>
   3. <STATUSLIST>
```

Exceptions: s = 0 if the target component is unknown.

S18,F5 Read Request (RR) S,H->E,reply

Description: The host requests the subsystem indicated in TARGETID to read information. DATASEG may be used to indicate a specific section of data to be read. DATALENGTH is used to limit the amount of data for that section.

Structure: L,3
1. <TARGETID>
2. <DATASEG>
3. <DATALENGTH>

Exceptions: If DATASEG and DATALENGTH are both omitted (are zero length items) then all data is requested. If DATALENGTH only is omitted, then all data within the indicated section is requested.

S18,F6 Read Data (RD) S,H<-E

Description: This message is used to return requested information from the subsystem indicated in TARGETID or to acknowledge the results of the request.

Structure: L,3
1. <TARGETID>
2. <SSACK>
3. <DATA>

Exceptions: If TARGETID is unknown, then DATA is zero length.

S18,F7 Write Data Request (WDR) S,H->E,reply

Description: This message requests to write data to the subsystem component indicated in TARGETID. DATASEG may be used to indicate a specific section of data to be written or overwritten.

Structure: L,4
1. <TARGETID>
2. <DATASEG>
3. <DATALENGTH>
4. <DATA>

Exceptions: If DATASEG and DATALENGTH are both omitted (are zero length items) then all data is to be overwritten. If only DATALENGTH is omitted or if DATALENGTH has a value of zero, then all data within the indicated section is to be written.

S18,F8 Write Data Acknowledge (WDA) S,H<-E

Description: This message acknowledges the success or failure of writing data to the subsystem indicated in TARGETID.

Structure: L,3
1. <TARGETID>
2. <SSACK>
3. <STATUSLIST>

Exceptions: s = 0 if and only if TARGETID is unknown.

S18,F9 Read ID Request (RIR) S,H->E,reply

Description: This message is used to request the subsystem indicated by TARGETID to read an identifier.

Structure: <TARGETID>

Exceptions: None.

S18,F10 Read ID Data (RID) S,H<-E

Description: This message returns a requested material identifier MID as read by the subsystem indicated in TARGETID.

Structure: L,4
1. <TARGETID>
2. <SSACK>
3. <MID>
4. <STATUSLIST>

Exceptions: s = 0 if and only if TARGETID is unknown.

S18,F11 Write ID Request (WIR) S,H->E,reply

Description: This message is used to request the subsystem indicated by TARGETID to write an identifier.

Structure: L,2
1. <TARGETID>
2. <MID>

Exceptions: None.

S18,F12 Write ID Acknowledge (WIA) S,H<-E

Description: This message acknowledges the success or failure of the subsystem specified in TARGETID in writing the ID.

Structure: L,3
1. <TARGETID>
2. <SSACK>
3. <STATUSLIST>

Exceptions: s = 0 if and only if TARGETID is unknown.

S18,F13 Subsystem Command Request (SCR) S,H->E,reply

Description: This message is used to request the subsystem indicated in TARGETID to perform a specific action.

Structure: L,3
1. <TARGETID>
2. <SSCMD>
3. L,n
   1. <$CPVAL_1$>
   .
   n. <$CPVAL_n$>

Exceptions: If n = 0, no parameters are provided.

S18,F14 Subsystem Command Acknowledge (SCA) S,H<-E

Description: This message reports the results from the subsystem specified in TARGETID for the requested action.

Structure: L,3
1. <TARGETID>
2. <SSACK>
3. <STATUSLIST>

Exceptions: s = 0 if and only if TARGETID is unknown.

8 Message Documentation

8.1 *Intent* — Equipment makers using SECS-II messages must communicate the equipment-specific details of each message to the host designer in order for the host to properly adapt to the equipment. The details are communicated in a document which will follow a standard form in order to convey most clearly the information required. The following form is presented here to act as a guide for organizing the equipment-specific details.

8.2 *Standard Form SECS-II Document* — The standard form will contain three clearly labeled parts as follows.

Part I — General Information

Part II — Message Summary

Part III — Message Detail

8.2.1 Part I will contain general information on the following:

Manufacturer and product number

General description of equipment function

Intended function of interface

Software revision code

Changes from previous versions

8.2.2 Part II will contain two lists of all messages understood and all messages sent by the equipment in terms of their stream and function codes. The first list will have pairs of columns: the first for the message received and understood and the second for the message sent in response. The second list will also have two columns: the first for the message sent and the second for the response understood. The message will be identified using the format " SxxFyy," where xx is the stream number and yy is the function number. Each transaction will be on a separate line. A " -" will indicate that one of a pair is not included. All messages not listed on the received side are implied to cause an error message to the host. All messages not listed on the sent side are assumed never to be sent from the equipment. Since some messages can be sent in two directions, the same message pair may appear in each list with the sent and received orders interchanged. A transaction listed in the standard as being allowed in two directions does not have to be implemented in both directions. This list will indicate which directions are implemented.

8.2.3 Part III will contain the details for every message listed in Part II. Messages that appear on both the sent and received sides must be detailed separately. The details shall include the following information on the data in each message:

1. For each fixed item, all the values or strings either understood or possible to send are listed along with their meaning to the equipment.
2. For each variable item, the restriction on or possible range of value or length of string.
3. Any other special interpretation of the message.

8.2.4 Each message so detailed must be clearly labeled with its stream and function code.

9 Units of Measure

9.1 *Intent* — Certain SECS-II transactions require specification of units of measure for data items passed between equipment and host. The concept of units of measure has been included as part of the SECS-II standard to enhance the ability of the host system to prompt its human operators for proper information when generating process programs, and also to facilitate automated handling of process programs by host systems and automated handling of data reported to a host by equipment.

9.2 *Units Symbols* — Under SECS-II, a units symbol is a text string of unspecified length which specifies the physical significance of a numeric value. Units of measure symbols under SECS-II may be either a SECS-II recognized unit identifier, a SECS-II unit identifier with prefix and/or suffix symbols, or an arithmetic expression of SECS-II identifiers.

9.2.1 A SECS-II units identifier is a text string which may be the full name, an abbreviation of the full name, or a special character which is unique for a specific unit of weight or measure. Identifier strings may consist of upper or lower case alphabetic characters and numerals or special characters of the ASCII character set. The first character of an identifier may not be a numeral. The case of alphabetic characters is significant (e.g., G and g, the units symbols for Gauss and gram, respectively).

9.2.2 A unit identifier may be nationally or internationally recognized, may be unique to the semiconductor industry, or, due to the special requirements of SECS-II, may be unique to this standard. Section 9.4 lists all units identifiers recognized by SECS-II. For each identifier defined in Section 9.4, six pieces of information are provided. They are:

1. Unit — Full name of the unit of measure in question.
2. Unit Identifier — SECS-II-recognized identifier for the unit.
3. Prefix Allowed — Specifies whether or not the unit identifier may be combined with a prefix symbol to generate a unit identifier which is a decimal multiple or submultiple of the base unit. Metric (or SI) units are usually capable of accepting a prefix symbol while English units may not.
4. Suffix Allowed — Specifies whether or not the unit identifier may be concatenated with a numeric suffix which provides additional information to the meaning of the associated unit symbol. The numeric suffix is composed of the ASCII digits 0 through 9 and represents a decimal value. This meaning of the numeric value is symbol-dependent and must be specified in the description section of the unit symbol' s definition.
5. Equivalence — In those cases where a unit can be expressed as an arithmetic expression (of simpler units), this column will contain the expression of simpler units. For those units which are non-standard to either of the standard systems of units of measure (English or SI), this column will contain an expression which relates the non-standard unit to the equivalent unit of the standard units system. In either case, the expression provided in this column may be substituted for the corresponding SECS-II units identifier whenever required.
6. Description — Additional information as may be required to uniquely define the unit of measure in question.

9.2.3 Any SECS-II identifier which Section 9.4 indicates as being capable of taking on a prefix symbol may be appended to one of the prefix symbols shown in Table 2, forming a new unit which is a decimal multiple or submultiple of the base unit. A prefix symbol may not be used alone. It must appear concatenated to one of the identifiers in Section 9.4. Finally, only one prefix symbol may appear before any identifier. A units symbol such as " mus" (micromillisecond) is not allowed. The proper symbol is " ns" (nanosecond).

Prefix Name	*Multiplicative Factor*	*Prefix Symbol*
exa	10^ 18	E
peta	10^ 15	P
Tera	10^ 12	T
giga	10^ 9	G
mega	10^ 6	M
kilo	10^ 3	k
hecto	10^ 2	h
deka (deca)	10^ 1	da
deci	10^ -1	d
centi	10^ -2	c
milli	10^ -3	m
micro	10^ -6	u
nano	10^ -9	n
pico	10^ -12	p
femto	10^ -15	f
atto	10^ -18	a

9.2.4 Any SECS-II identifier which Section 9.4 indicates as being capable of taking on a suffix value may have a numeric string appended to it. This decimal value allows the user to identify one of a family of symbol names with only the generic symbol name of the family being defined in Section 9.4. The meaning of a numeric suffix is dependent on the particular symbol with which it is being used and must be defined in the description section of the symbol definition.

9.2.5 Arithmetic expressions of units of measure identifiers are recognized by SECS-II as units symbols if they are formed by the following rules:

1. All units identifiers in the expression are SECS-II units identifiers defined in Section 9.4 or SECS-II prefixed units identifiers as defined above.
2. Exponentiation is denoted by a circumflex (^) between the identifier to be operated on and the exponent. Exponents may be positive or negative values. A negative value is denoted by a unary minus sign (-) between the circumflex and exponent. For positive values, the exponent will immediately follow the circumflex (A^ 2 or A^ -2).
3. Multiplication of units identifiers is expressed by an asterisk (*) positioned between the factors to be multiplied (A*B).
4. Division of units identifiers is expressed by a slash (/) positioned between the dividend and divisor. Division may also be expressed as the product of the dividend and the divisor with a negative exponent (A/B or A*B^ -1).
5. Parentheses may be used to specify the order in which the arithmetic operations will be performed.
6. Within expressions or sub-expressions where parentheses do not specify the order of operations, exponentiation will be carried out first, followed by left-to-right evaluation of all multiplication and division that is (A*B^ -2*30*C^ 2) is equivalent to (((A/(B^ 2))*30)*(C^ 2)).

9.3 *Compliance* — For the units of measure information to have any value and to be in compliance with SECS-II, equipment and host system manufacturers must ensure that only units symbols allowed by SECS-II are used by their systems. In those instances where SECS-II does not provide a units symbol required for a particular application, the manufacturer requiring the new symbol may submit a proposal to the SEMI Communications Subcommittee requesting the enhancement. A proposal must include all the information provided by each entry of Section 9.4 as described above.

9.3.1 A proposal must undergo the full approval cycle as prescribed by SECS-II for amending a standard (acceptance by committee, balloting, etc.). As a result, the proposal should be submitted as soon as possible, so that sufficient time is available to complete the standard amendment process and to notify all interested parties of the change before the product requiring the new symbol becomes available for use in a manufacturing facility.

9.4 *SECS-II Units of Measure Identifiers* — All units of measure symbols recognized by SECS-II are defined in this section or are compound symbols based on the identifiers defined here and formed by the rules specified in Section 9.2. Portions of the information provided below have been obtained from ANSI/IEEE 260-1978, ANSI X3.5-1976, ISO 2955-1974(E), Webster' s New World Collegiate Dictionary (copyright 1977), and the CRC Handbook of Chemistry and Physics (52nd edition for 1971-1972).

Unit — Non-dimensional quantities (pure numbers)
Unit Identifier — null string   Prefix Allowed — No
Equivalence — None   Suffix Allowed — No
Description — For all quantities which have no associated unit of measure, a zero length (null) text string is the appropriate 'identifier' to use when units of measure information is required.

Unit — ampere   Prefix Allowed — Yes
Unit Identifier — A   Suffix Allowed — No
Equivalence — None
Description — SI unit of electric current.

Unit — ampere (turn)   Prefix Allowed — Yes
Unit Identifier — AT   Suffix Allowed — No
Equivalence — None
Description — SI unit of magnetomotive force.

Unit — angstrom
Unit Identifier — Ang   Prefix Allowed — Yes
Equivalence — m*10^ -10   Suffix Allowed — No
Description — Unit of length used when measuring wavelength of light.

Unit — atmosphere, standard
Unit Identifier — atm   Prefix Allowed — No
Equivalence — 101325*Pa   Suffix Allowed — No
Description — A unit of pressure.

Unit — atmosphere, technical
Unit Identifier — at   Prefix Allowed — No
Equivalence — kgf/cm^ 2   Suffix Allowed — No
Description — A unit of pressure.

Unit — atomic mass unit (unified)
Unit Identifier — u   Prefix Allowed — No
Equivalence — 1.660531*10^ -27*kg   Suffix Allowed — No
Description — One twelfth the mass of an atom of carbon 12 nuclide.

Unit — bar
Unit Identifier — bar   Prefix Allowed — Yes
Equivalence — 100*kPa   Suffix Allowed — No
Description — CGS unit of pressure.

Unit — barn
Unit Identifier — barn   Prefix Allowed — Yes
Equivalence — 10^ -28*m^ 2   Suffix Allowed — No
Description — Unit for measuring capture cross sections of elements.

Unit — barrel (petroleum)
Unit Identifier — bbl   Prefix Allowed — No
Equivalence — 42*gal or 158.99*1   Suffix Allowed — No
Description — A unit of volume.

Unit — baud
Unit Identifier — Bd Prefix Allowed — Yes
Equivalence — bit/s Suffix Allowed — No
Description — Telecommunications measure of data transfer rate equivalent to one bit of information transferred per second.

Unit — bel
Unit Identifier — B Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — The logarithm of the ratio of two power signals.

Unit — Becquerel
Unit Identifier — Bq Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — SI unit of activity of a radionuclide.

Unit — bit
Unit Identifier — bit Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — A unit of computer information equivalent to the choice between two alternatives (as yes or no, on or off).

Unit — boat
Unit Identifier — boat Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a holder of wafers or packages with discrete positions. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — British thermal unit
Unit Identifier — Btu Prefix Allowed — No
Equivalence — 1054.35*J Suffix Allowed — No
Description — The quantity of heat required to raise the temperature of one pound of water one degree Fahrenheit at or near 39.2˚F.

Unit — byte
Unit Identifier — byte Prefix Allowed — Yes
Equivalence — 8*bit Suffix Allowed — No
Description — Unit of storage for computer memory.

Unit — calorie (International Table)
Unit Identifier — callIT Prefix Allowed — Yes
Equivalence — 4.1868*J Suffix Allowed — No
Description — Defined by the 1929 International Stream Table Conference to be 1/860 international joules or l/859.858 joules.

Unit — calorie (thermochemical)
Unit Identifier — cal Prefix Allowed — Yes
Equivalence — 4.l840*J Suffix Allowed — No
Description — Unit of energy defined by the NBS to be 4.184 joules. Also, called the gram calorie.

Unit — candela
Unit Identifier — cd Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — SI unit of luminous intensity.

Unit — candle
Unit Identifier — cd Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — Alternate name for candela.

Unit — carrier
Unit Identifier — carrier Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a holder for substrates, wafers or wafer frames. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — cassette
Unit Identifier — css Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a holder for wafers or wafer frames. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — Coulomb
Unit Identifier — C Prefix Allowed — Yes
Equivalence — A*s Suffix Allowed — No
Description — SI unit of electric charge.

Unit — curie
Unit Identifier — Ci Prefix Allowed — No
Equivalence — 3.7*l0^ l0*Bq Suffix Allowed — No
Description — A unit of activity of radionuclide.

Unit — cycle
Unit Identifier — c Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — Unit equivalent to one complete performance of a periodic process.

Unit — darcy
Unit Identifier — D Prefix Allowed — No
Equivalence — cP*(cm/s)(cm/atm) or 0.986923*um^ 2 Suffix Allowed — No
Description — Unit of permeability of a porous medium. By traditional definition, a permeability of one darcy will permit a flow of 1 cm^ 3/s of fluid of 1 cP viscosity through an area of 1 cm^ 2 under a pressure gradient of 1 atm/cm.

Unit — day (mean solar)
Unit Identifier — d Prefix Allowed — No
Equivalence — 24*h Suffix Allowed — No
Description — The period required for the Earth to complete one rotation about its axis.

Unit — degree (plane angle)
Unit Identifier — deg Prefix Allowed — No
Equivalence — pi/180*rad Suffix Allowed — No
Description — One three hundred sixtieth part of the circumference of a circle.

Unit — degree Celsius
Unit Identifier — degC Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Unit of temperature where 0˚C corresponds to the freezing point of water and l00˚C corresponds to the boiling point at standard atmospheric conditions.

Unit — degree Fahrenheit
Unit Identifier — degF Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Unit of temperature where 32˚F corresponds to the freezing point of water and 212˚F corresponds to the boiling point at standard atmospheric conditions.

Unit — degree Kelvin
Unit Identifier — K Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — SI unit of temperature.

Unit — die
Unit Identifier — die Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Special SECS generic unit corresponding to an individual integrated circuit both on a wafer and after wafer separation. Also referred to as a bar or chip.

Unit — dyne
Unit Identifier — dyn Prefix Allowed — Yes
Equivalence — 10^ -5*N Suffix Allowed — No
Description — Unit of force in the cgs system. One dyne is the force required to provide a one grain mass with an acceleration of 1 cm/s^ 2.

Unit — electronvolt
Unit Identifier — eV Prefix Allowed — Yes
Equivalence — l.60209*10^ -19*J Suffix Allowed — No
Description — Energy acquired by a small particle carrying a unit electronic charge when it falls through a potential difference of one volt.

Unit — erg
Unit Identifier — erg Prefix Allowed — Yes
Equivalence — l0^ -7*J Suffix Allowed — No
Description — Unit of work or energy in the cgs system. One erg is equal to the work done or energy expended to exert a force of one dyne through a distance of 1 cm.

Unit — farad
Unit Identifier — F Prefix Allowed — Yes
Equivalence — A*s/V Suffix Allowed — No
Description — SI unit of capacitance.

Unit — foot
Unit Identifier — ft Prefix Allowed — No
Equivalence — 12*in Suffix Allowed — No
Description — English unit of length.

Unit — footcandle
Unit Identifier — Fc Prefix Allowed — No
Equivalence — lm/ft^ 2 Suffix Allowed — No
Description — Unit of illuminance. Also called lumen per square foot.

Unit — footlambert
Unit Identifier — FL Prefix Allowed — No
Equivalence — (1/pi)*cd/ft^ 2 Suffix Allowed — No
Description — A unit of luminance. One lumen per square foot leaves a surface whose luminance is one footlambert in all directions within a hemisphere.

Unit — gal
Unit Identifier — Gal Prefix Allowed — Yes
Equivalence — cm/s^ 2 Suffix Allowed — No
Description — A unit of acceleration used especially for values of gravity.

Unit — gallon (US)
Unit Identifier — gal Prefix Allowed — No
Equivalence — 23l*in^ 3 or 4*qt or 3.7854*1 Suffix Allowed — No
Description — United States version of English system unit of volume.

Unit — gallon (UK)
Unit Identifier — galUK Prefix Allowed — No
Equivalence — 4.546l*l Suffix Allowed — No
Description — United Kingdom version of English system unit of volume.

Unit — gauss
Unit Identifier — G Prefix Allowed — Yes
Equivalence — Mx/cm^ 2 Suffix Allowed — No
Description — Electromagnetic CGS unit of magnetic flux density.

Unit — gilbert
Unit Identifier — Gb Prefix Allowed — Yes
Equivalence — l0/(4*pi)*AT Suffix Allowed — No
Description — Electromagnetic CGS unit of magnetomotive force.

Unit — grain
Unit Identifier — gr Prefix Allowed — No
Equivalence — .0022857l43*oz Suffix Allowed — No
Description — English unit of weight.

Unit — gram
Unit Identifier — g Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — One thousandth of the SI unit of mass.

Unit — gram-force
Unit Identifier — gf Prefix Allowed — Yes
Equivalence — 9.80665*N*10^ -3 Suffix Allowed — No
Description — The weight of a gram mass when subjected to the mean gravitational attraction of the Earth.

Unit — gray
Unit Identifier — Gy   Prefix Allowed — Yes
Equivalence — Unknown   Suffix Allowed — No
Description — SI unit of absorbed dose in the field of radiation dosimetry.

Unit — henry
Unit Identifier — H   Prefix Allowed — Yes
Equivalence — V*s/A   Suffix Allowed — No
Description — SI unit of inductance.

Unit — hertz
Unit Identifier — Hz   Prefix Allowed — Yes
Equivalence — c/s   Suffix Allowed — No
Description — SI unit of frequency.

Unit — horsepower (electric)
Unit Identifier — hp   Prefix Allowed — No
Equivalence — 746*W   Suffix Allowed — No
Description — Archaic unit of power.

Unit — hour
Unit Identifier — h   Prefix Allowed — No
Equivalence — 60*min   Suffix Allowed — No
Description — Derived unit of time.

Unit — inch
Unit Identifier — in   Prefix Allowed — No
Equivalence — 2.54*cm   Suffix Allowed — No
Description — English unit of length.

Unit — conventional inch of mercury
Unit Identifier — inHg   Prefix Allowed — No
Equivalence — 3386.4*Pa   Suffix Allowed — No
Description — Unit equivalent to the pressure required to balance a one inch high column of mercury in a manometer at 32˚F.

Unit — conventional inch of water
Unit Identifier — inH_2O Prefix Allowed — No
Equivalence — 249.09*Pa   Suffix Allowed — No
Description — Unit equivalent to the pressure required to balance a one inch high column of water in a manometer at 4˚C.

Unit — ingot
Unit Identifier — ing   Prefix Allowed — No
Equivalence — None   Suffix Allowed — No
Description — Special SECS generic unit corresponding to the entity of semiconductor manufacture from which wafers are made.

Unit — ion
Unit Identifier — ion   Prefix Allowed — No
Equivalence — None   Suffix Allowed — No
Description — SECS II unique symbol equivalent to an atom that carries an electric charge as a result of losing or gaining electrons.

Unit — joule
Unit Identifier — J Prefix Allowed — Yes
Equivalence — N*m Suffix Allowed — No
Description — SI unit of energy, work, and quantity of heat.

Unit — kelvin
Unit Identifier — K Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — SI unit of temperature. Also referred to as degree Kelvin.

Unit — kilopound force
Unit Identifier — klbf Prefix Allowed — No
Equivalence — l000*lbf Suffix Allowed — No
Description — A multiple of the English unit of force or weight.

Unit — knot
Unit Identifier — kn Prefix Allowed — No
Equivalence — nmi/h Suffix Allowed — No
Description — Unit of velocity expressed in nautical miles per hour.

Unit — lambert
Unit Identifier — L Prefix allowed — Yes
Equivalence — (l/pi)*cd/cm^ 2 Suffix allowed — No
Description — CGS unit of luminance. One lumen per square centimeter leaves a surface whose luminance is one lambert in all directions within a hemisphere.

Unit — leadframe
Unit Identifier — ldfr Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a structure for leads which is removed after packaging. The structure may be fixed length or a reel. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — liter
Unit Identifier — l Prefix Allowed — Yes
Equivalence — 10^ -3*m^ 3 Suffix Allowed — No
Description — A metric unit of volume.

Unit — lot
Unit Identifier — lot Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Special SECS generic unit corresponding to a grouping of material which is undergoing the same processing operations. The amount of material represented by " 1 lot" is situation-dependent.

Unit — lumen
Unit Identifier — lm Prefix Allowed — Yes
Equivalence — cd*sr Suffix Allowed — No
Description — SI unit of luminous flux.

Unit — lux
Unit Identifier — lx Prefix Allowed — Yes
Equivalence — lm/m^ 2 Suffix Allowed — No
Description — SI unit of illuminance.

Unit — magazine
Unit Identifier — mgz Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special, SECS generic unit corresponding to a holder of fixed length leadframes. The unit capacity is specified by the symbols suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — maxwell
Unit Identifier — Mx Prefix Allowed — Yes
Equivalence — 10^ -8*Wb Suffix Allowed — No
Description — Electromagnetic CGS unit of magnetic flux.

Unit — meter
Unit Identifier — m Prefix Allowed — Yes
Equivalence — None Suffix Allowed — No
Description — SI unit of length.

Unit — metric ton
Unit Identifier — t Prefix Allowed — No
Equivalence — 10^ 3*kgf Suffix Allowed — No
Description — Unit of weight of force.

Unit — mho
Unit Identifier — mho Prefix Allowed — Yes
Equivalence — S Suffix Allowed — No
Description — Previous name for the SI unit siemens.

Unit — micron
Unit Identifier — um Prefix Allowed — No
Equivalence — l0^ -6*m Suffix Allowed — No
Description — Alternate name for a micrometer.

Unit — conventional micron of mercury
Unit Identifier — umHg Prefix Allowed — No
Equivalence — 133.32*Pa*10^ -3 Suffix Allowed — No
Description — Unit of pressure.

Unit — mil
Unit Identifier — mil Prefix Allowed — No
Equivalence — 10^ -3*in Suffix Allowed — No
Description — English unit of length.

Unit — mile
Unit Identifier — mi Prefix Allowed — No
Equivalence — 5280*ft Suffix Allowed — No
Description — English unit of length.

Unit — conventional millimeter of mercury
Unit Identifier — mmHg Prefix Allowed — No
Equivalence — 133.322*Pa Suffix Allowed — No
Description — Unit of pressure.

Unit — millimicron
Unit Identifier — nm Prefix Allowed — No
Equivalence — 10^ -9*m Suffix Allowed — No
Description — Alternate name for nanometer.

Unit — minute (plane angle)
Unit Identifier — mins Prefix Allowed — No
Equivalence — deg/60 Suffix Allowed — No
Description — One sixtieth of a degree (plane angle).

Unit — minute(time)
Unit Identifier — min Prefix Allowed — No
Equivalence — 60*s Suffix Allowed — No
Description — Unit of time.

Unit — mole
Unit Identifier — mol Prefix Allowed — No
Equivalence — 6.02252*l0^ 23 Suffix Allowed — No
Description — SI unit of number of entities within a substance.

Unit — month
Unit Identifier — mo Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Unit of time.

Unit — nautical mile
Unit Identifier — nmi Prefix Allowed — No
Equivalence — 1852*m Suffix Allowed — No
Description — English unit of measurement.

Unit — neper
Unit Identifier — Np Prefix Allowed — Yes
Equivalence — 0.1l51*dB Suffix Allowed — No
Description — Unit for expressing ratios of power levels.

Unit — newton
Unit Identifier — N Prefix Allowed — Yes
Equivalence — kg*m/s^ 2 Suffix Allowed — No
Description — SI unit of force.

Unit — nit
Unit Identifier — nt Prefix Allowed — Yes
Equivalence — cd/m^ 2 Suffix Allowed — No
Description — Alternate name for the SI unit of luminance, candela per square meter.

Unit — oersted
Unit Identifier — Oe Prefix Allowed — Yes
Equivalence — 79.577472*A/m Suffix Allowed — No
Description — Electromagnetic CGS unit of magnetic field strength.

Unit — ohm
Unit Identifier — ohm Prefix Allowed — Yes
Equivalence — V/A Suffix Allowed — No
Description — SI unit of resistance.

Unit — ounce (avoirdupois)
Unit Identifier — oz Prefix Allowed — No
Equivalence — lbf/16 Suffix Allowed — No
Description — English unit of weight.

Unit — package
Unit Identifier — pkg Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Special SECS generic unit corresponding to an individual entity both as a place for the die to reside and as a completed unit.

Unit — pascal
Unit Identifier — Pa Prefix Allowed — Yes
Equivalence — N/m^ 2 Suffix Allowed — No
Description — SI unit of pressure or stress.

Unit — percent
Unit Identifier — % Prefix Allowed — No
Equivalence — 1/100 Suffix Allowed — No
Description — Ratio of parts per hundred.

Unit — phot
Unit Identifier — ph Prefix Allowed — Yes
Equivalence — lm/cm^ 2 Suffix Allowed — No
Description — CGS unit of illuminance.

Unit — pH
Unit Identifier — pH Prefix Allowed — No
Equivalence — 1 Suffix Allowed — No
Description — Normalized measure of acidity or alkalinity.

Unit — pint (UK)
Unit Identifier — ptUK Prefix Allowed — No
Equivalence — 0.56826*1 Suffix Allowed — No
Description — United Kingdom version of English unit of capacity.

Unit — pint (US dry)
Unit Identifier — ptUS Prefix Allowed — No
Equivalence — 0.55061*1 Suffix Allowed — No
Description — United States version of English unit of dry capacity.

Unit — pint (US liquid)
Unit Identifier — pt Prefix Allowed — No
Equivalence — 0.47318*1 Suffix Allowed — No
Description — United States version of English unit of liquid capacity.

Unit — plate
Unit Identifier — plt Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a temporary fixture used to hold die during assembly operations. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — poise
Unit Identifier — P Prefix Allowed — Yes
Equivalence — 36*N*s/m^ 2, or 36*kg/(m*s) Suffix Allowed — No
Description — A CGS unit of viscosity equal to the viscosity of a fluid that would require a shearing force of one dyne to move a square centimeter area of either of two parallel layers of fluid one centimeter apart with a velocity of one centimeter per second relative to the other layer, with the space between the layers being filled with fluid.

Unit — pound
Unit Identifier — lb Prefix Allowed — No
Equivalence — 0.0310810*slug Suffix Allowed — No
Description — English unit of mass.

Unit — pound-force
Unit Identifier — lbf Prefix Allowed — No
Equivalence — 4.4482217*N Suffix Allowed — No
Description — English unit of force or weight.

Unit — poundal
Unit Identifier — pdl Prefix Allowed — No
Equivalence — 0.0310810*lbf Suffix Allowed — No
Description — Force required to accelerate a one pound mass at one ft/s^ 2.

Unit — parts per million
Unit Identifier — ppm Prefix Allowed — No
Equivalence — 1/I0^ 6 Suffix Allowed — No
Description — Ratio of parts per million.

Unit — quart (UK)
Unit Identifier — qtUK Prefix Allowed — No
Equivalence — 1.1365*1 Suffix Allowed — No
Description — United Kingdom version of an English unit of capacity.

Unit — quart (US dry)
Unit Identifier — qtUS Prefix Allowed — No
Equivalence — 1.1012*1 Suffix Allowed — No
Description — United States version of an English unit of dry capacity.

Unit — quart (US liquid)
Unit Identifier — qt Prefix Allowed — No
Equivalence — 0.94635*1 Suffix Allowed — No
Description — United States version of an English unit of liquid capacity.

Unit — rad
Unit Identifier — rd Prefix Allowed — Yes
Equivalence — 10^ -2*Gy Suffix Allowed — No
Description — A unit of absorbed dose in the field of radiation dosimetry.

Unit — radian
Unit Identifier — rad | Prefix Allowed — Yes
Equivalence — None | Suffix Allowed — No
Description — SI unit of plane angle.

Unit — rem
Unit Identifier — rem | Prefix Allowed — Yes
Equivalence — 10^ -2*Sv | Suffix Allowed — No
Description — A unit of dose equivalent in the field of radiation dosimetry.

Unit — revolution
Unit Identifier — r | Prefix Allowed — No
Equivalence — c | Suffix Allowed — No
Description — One complete cycle of a rotating body.

Unit — roentgen
Unit Identifier — R | Prefix Allowed — No
Equivalence — Unknown | Suffix Allowed — No
Description — A unit of exposure in the field of radiation dosimetry.

Unit — second (plane angle)
Unit Identifier — sec | Prefix Allowed — No
Equivalence — mins/60 | Suffix Allowed — No
Description — One sixtieth of a minute of a degree.

Unit — second (time)
Unit Identifier — s | Prefix Allowed — Yes
Equivalence — None | Suffix Allowed — No
Description — SI unit of time.

Unit — siemens
Unit Identifier — S | Prefix Allowed — Yes
Equivalence — 1/ohm | Suffix Allowed — No
Description — SI unit of conductance.

Unit — sievert
Unit Identifier — Sv | Prefix Allowed — Yes
Equivalence — Unknown | Suffix Allowed — No
Description — SI unit of dose equivalent in the field of radiation dosimetry.

Unit — slug
Unit Identifier — slug | Prefix Allowed — No
Equivalence — 145939*kg | Suffix Allowed — No
Description — English unit of mass.

Unit — standard cubic centimeter per minute
Unit Identifier — sccm | Prefix Allowed — No
Equivalence — cc/min | Suffix Allowed — No
Description — A unit of flow equivalent to one cubic centimeter of a gas at standard temperature and pressure flowing past a point in one minute.

Unit — standard liter per minute
Unit Identifier — slpm Prefix Allowed — No
Equivalence — 1/min Suffix Allowed — No
Description — A unit of flow equivalent to one liter of a gas at standard temperature and pressure flowing past a point in one minute.

Unit — steradian
Unit Identifier — Sr Prefix Allowed — Yes
Equivalence — Unknown Suffix Allowed — No
Description — SI unit of solid angle.

Unit — stilb
Unit Identifier — sb Prefix Allowed — Yes
Equivalence — cd/cm^ 2 Suffix Allowed — No
Description — A CGS unit of luminance.

Unit — stokes
Unit Identifier — St Prefix Allowed — Yes
Equivalence — P*cm^ 3/g Suffix Allowed — No
Description — A CGS unit of kinematic viscosity.

Unit — substrate
Unit Identifier — substrate Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Special SECS generic unit corresponding to the entity of material being operated on, processed or fabricated.

Unit — tesla
Unit Identifier — T Prefix Allowed — Yes
Equivalence — N/(A*m) or Wb/m^ 2 Suffix Allowed — No
Description — SI unit of magnetic flux density (magnetic induction).

Unit — therm
Unit Identifier — thm Prefix Allowed — No
Equivalence — 10^ 5*Btu Suffix Allowed — No
Description — An English unit of energy.

Unit — ton (short)
Unit Identifier — ton Prefix Allowed — No
Equivalence — 2000*lbf Suffix Allowed — No
Description — English unit of weight.

Unit — torr
Unit Identifier — torr Prefix Allowed — Yes
Equivalence — mmHg Suffix Allowed — No
Description — Pressure unit. Alternative name for millimeters of mercury.

Unit — tube
Unit Identifier — tube Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a holder of packages arranged in a flow. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — var
Unit Identifier — var Prefix Allowed — Yes
Equivalence — Unknown Suffix Allowed — No
Description — SI unit for reactive power.

Unit — volt
Unit Identifier — V Prefix Allowed — Yes
Equivalence — W/A Suffix Allowed — No
Description — SI unit of voltage.

Unit — wafer
Unit Identifier — wfr Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Special SECS generic unit corresponding to the entity of material on which semiconductor devices are fabricated.

Unit — waferframe
Unit Identifier — wffr Prefix Allowed — No
Equivalence — None Suffix Allowed — Yes
Description — Special SECS generic unit corresponding to a temporary fixture for wafers. The unit capacity is specified by the symbol's suffix, if provided. Otherwise, the capacity is situation-dependent.

Unit — watt
Unit Identifier — W Prefix Allowed — Yes
Equivalence — J/s Suffix Allowed — No
Description — SI unit of power.

Unit — watthour
Unit Identifier — Wh Prefix Allowed — Yes
Equivalence — 3600*J Suffix Allowed — No
Description — Unit of energy.

Unit — weber
Unit Identifier — Wb Prefix Allowed — Yes
Equivalence — V*s Suffix Allowed — No
Description — SI unit of magnetic flux.

Unit — year
Unit Identifier — yr Prefix Allowed — No
Equivalence — None Suffix Allowed — No
Description — Unit of time.

APPLICATION NOTES

NOTICE: The material contained in these Application Notes is not an official part of SEMI E5 (SECS-II) and is not intended to modify or supersede the official standard. Rather, these notes describe possible methods for implementing the protocol described by the standard and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

A1 The General Node Transaction Protocol

A1.1 This application note has been moved to follow SEMI E4 (SECS-I) as Application Note A7.

A2 Some Suggested Message Usage

A2.1 The number of messages implemented and the choice of messages are greatly influenced by the actual function of the equipment. To illustrate which messages might be appropriate, the following suggestions are offered for a variety of different types of equipment capabilities. It is assumed that the minimum message sets S1,F1; F2 and S9,F1; F3; F5; F7 are always implemented.

A2.2 For equipment which makes nondestructive in-process measurements using a fixed measurement procedure, it may be necessary only to implement S6, F9 to send the data according to a fixed format upon measurement. Optional remote control can be added with S2,F21 to start a measurement.

A2.3 If the equipment has a variety of measurement routines, it might be desirable to respond to S1,F5 with S1,F6, which would give the host a brief report of the test being made. The test can be thought of as a process program. Accordingly, S7,F1 and S7,F2 could be used for the host to select the program. The same messages in conjunction with S7,F3 and S7,F4 could load a new test procedure. S7,F19 could be used by the host to find out what tests were available.

A2.4 Some equipment which automatically processes wafers in a batch might make more extensive use of S1,F5 or S1,F3 and might include some error reporting on S5,F1. More sophisticated equipment may include some trace features with S2,F23 and S6,F1 or some control loop tuning by S2,F15.

A2.5 Equipment using in-line wafer movement could utilize Stream 4, S1,F9, and Stream 3 to keep track of wafers.

A2.6 Stream 7,F9 through F19 can be used to manage a local backup of process programs should the host fail for a short while.

A2.7 Microprocessor equipment can benefit from features such as provided by Stream 8 and S2,F1 through F12 which allow managing and servicing the software routines.

A2.8 Equipment, including a CRT, might elect to make it available to the host by including Stream 10 messages.

A2.9 Some equipment, such as functional testers, might have sufficient need to undertake remote file usage such as provided in Stream 13.

A2.10 These brief suggestions serve to illustrate that the final choice of the messages included in a given equipment depends upon its function. The messages can be viewed as interface features in the same way that other parts of the equipment are viewed as processing features or wafer handling features.

A3 Notes on SECS-II Data Transfers

A3.1 *Introduction*

A3.1.1 There are two primary ways to send and ask for data in SECS-II. One of these is to use the trace feature and the other is to use the event reporting method. The purpose of this note is to describe the intended operation of the messages described in the existing standard. Discussion of completeness or need for other reporting methods is left for task force and committee work.

A3.2 *Trace Data Collection and Reporting*

A3.2.1 This method of collecting data is intended for engineering and developmental use rather than routine data collection for production. The features included allow the collection of relatively large amounts of real time data over a finite amount of time. The data is generated at regular time intervals as determined by a timing generator in the equipment. The function of the host is to set up the trace and then to subsequently store the data as it is received from the equipment. It is assumed that some host resident applications will exist to analyze the data either as it is received or at some later time.

A3.2.2 The trace feature will only exist in equipment which implements it.

A3.2.3 The host sets up the trace with the S2,F23-24 transaction. At this time, the host assigns several important parameters. TRID is the trace request ID and is used later when the equipment sends back the data. Every trace data reply includes the TRID corresponding to the request that set up the trace. Several traces can theoretically be done at the same time if the equipment allows it and the TRID keeps the data for each trace distinct from other trace data. DSPER is the data sample period and is used to indicate how often the specified parameters should be sampled (that is, have their values saved). TOTSMP is the total number of samples to be made. Since TOTSMP is finite and the number of parameters is specified in this transaction, the host can reserve adequate file space for the reported data if required. The REPGSZ is the reporting group size and corresponds to the number of time samples that should be combined into one message prior to transmission. Thus, if it is desired to sample one or two parameters every second but only send those samples to the host once a minute, the reporting group size would be 60. Having the reporting group size parameter allows the host to have some control over how often it may be interrupted to handle the trace data. However, as presently defined in the standard, the trace data is reported as a single block message (S6,F1), which restricts both the number of status variables or the number of samples which can be combined into one message. The equipment may be able to accommodate this in several ways, to be described shortly.

The last element in the trace initialize request is a list of status variable IDs. The trace command only allows tracing variables that have been declared and are known to the equipment as status variables. It is assumed that the equipment will report the variable values in the same order as specified in the trace request. This will allow the host to identify the values returned.

A3.2.4 The trace data send message, S6,F1-2, sends the trace data as a single block message to minimize the overhead in reporting data. The TRID is the first item and identifies the request that asked for the data. The next item is SMPLN, the sample number of the last sample in this message, should more than one sample be combined. The next item is STIME which is the time of the last sample in this message. These three items are followed by the list of values. If five (5) values were requested with a reporting group size of 5, then 25 values would be in this list, each group of 5 in the same order as requested and in the time order sampled. Some flexibility is allowed in how the equipment chooses to report the data to the host when the reporting group size exceeds one block of data. The equipment can send the data when it has a complete block or it can reject the request when it is set up.

A3.3 *Event Driven Data Reporting*

A3.3.1 The second major type of data reporting is initiated by some event in the equipment. Data reporting is often desired after some event such as the completion of a measurement, the completion of a lot, the completion of a wafer, the occurrence of a special event command in the recipe, or some other action which is determined by the equipment. The two aspects involved in event driven data reporting are the control of which events cause data to be sent to the host and the formatting of the data sent to the host.

A3.3.2 It is assumed that a set of events has been established for a particular piece of equipment and that each event can produce a report of some sort. It is further assumed that a set of equipment constants exist in the machine such that they have control over the optional reporting of the events. For example, a boolean constant may exist for each possible reporting event, and when the host sets the constant to a logical 1, the corresponding event will cause a report to be sent to the host, when the host sets the constant to logical 0, the event will not send a report. S2,F15-16 in the equipment constant send transaction can be used to control the event reporting.

A3.3.3 When an event causes data to be sent to the host, there are several possible conversations, depending upon the length of the data and the complexity of the formatting. S6,F3-4 is the basic data transaction, which has a very general format. The parameters provide for an overall name, DATAID, for the type of data; a collection event identification, CEID, should there be more than one event that could generate the same type of data; and a list of data sets. This structure allows reporting such data as the measurements taken on each of the wafers in a lot. The measurements on each wafer make up one data set, and the list of data sets is the whole lot. The collection event would be the lot completion, and the data ID might be film thickness measurements. Other types of organizations are possible, depending upon the type of data being sent. The same type of data might be produced by a different CEID, such as the forced termination of the lot. This collection ID would indicate that the data is incomplete for the lot. Within each data set, each data value is reported as a pair of items, one item being the name of the value and the other being the value.

A3.3.4 Since many simple measuring devices have only a very few types of data sets, an alternative data format is provided in S6,F9-10, which has the same form as S6,F3-4 but does not require the value name in the data set. Instead, the order of the values is fixed format for the particular DSID in that particular equipment.

A3.3.5 When either of the above data messages is long enough to require multiple blocks, it must be preceded by S6,F5-6 to gain permission to send a multiple block message.

A3.3.6 The last data control transaction is S6,F7-8, which is initiated by the host and causes a specified DATAID to be sent to the host. The implementation of this function is highly equipment-dependent. In essence, it is equivalent to the host causing an event that triggers the sending of the data. Since the equipment may be generating the data, the actual data sent depend upon the equipment implementation. The equipment can respond with a zero length item if no data can be sent.

A3.4 *Event Reporting*

A3.4.1 The third major type of data reporting is similar to that described in A3.3 above, with the following enhancements:

a. Contents of data reports are not limited to DVVALs, but may include SVs or even ECVs.

b. Contents of data reports are user programmable.

A3.4.2 It is assumed that the equipment vendor supplies a list of all " events" identified within a particular piece of equipment. A Collection Event Identifier (CEID) must be specified for each of these events. It is further assumed that the vendor supplies a list of all available variables within the machine. This includes Status Variables (SVs) and their identifiers (SVIDs), Equipment constants (ECVs) and their identifiers (ECIDs), and Data Values (DVVALs) and their identifiers(DVNAMEs). Each of the identifiers must be unique. The term VID (Variable Identifier) encompasses all SVIDs, ECIDs, and DVNAMEs. Likewise, the term V (Variable Data) encompasses all SVs, ECVs, and DVVALs.

A3.4.3 Note that a Variable (V) may be a list (format code 0). This provides for referencing a group of related data values with one identifier. Consider the following:

```
VID1=1 zone 1 temperature ID  Format 32
V1    zone 1 temperature value Format 52
.
.
VIDn=n zone n temperature ID  Format 32
Vn    zone n temperature value Format 52
VIDx=x all temperatures ID    Format 32
Vx  L,n                       Format 0
      1. L,2
           1. <VID1>
           2. <V1>
      .
      .
      n. L,2
           1. <VIDn>
           2. <Vn>
```

Any V in a list may also be a list (for nesting).

A3.4.4 In a typical initialization sequence, the host would define all the desired programmable data reports with S2,F33/S2,F34 (Define Report) transactions. Then S2,F35/S2,F36 (Link Report/Event) transactions would be used to define which reports are to be made by the equipment upon specific events (CEIDs). An individual report may be linked to more than one event. At this point the host may request reports with the S6,F15/S6,F16 (Report Request) transactions to obtain initial report data and/or to verify reports as defined and linked. Finally, the desired reports would be enabled by the host with S2,F37/S2,F38 (Enable/Disable Event Report) transactions.

A3.4.5 There are two methods for the equipment to send event reports to the host. S6,F13 includes the Variable Identifier (VID) with each Variable Data item (V). S6,F11 is a shorter form, without the identifiers; some users prefer this form to reduce message size.

A3.4.6 When any message is long enough to require multiple blocks, it must be preceded by an inquire/grant transaction.The DATAID parameter is used only to link the inquire/grant transaction with a multiblock message. This linkage is to alleviate problems in the case of interleaved messages. A unique value for DATAID must be used for each Inquire/Grant/Send/Acknowledge conversation (similar to the use of SYSBYTES in SECS-I). The DATAID parameter should not be used for any other purpose.

A4 Process Programs

A4.1 *Introduction*

A4.1.1 Two forms of process programs are supported by SECS-II: unformatted and formatted. The contents of an unformatted process program conform to no set standard. The format of the program is defined by the vendor of the equipment and probably bears no similarity to the format used by other vendors for their equipment. Because special programming would be required at the host to understand the equipment' s unique data format, the process program is most likely generated at the machine and the host is only used as a data repository, saving the foreign data for later retransmission to the equipment. S7,F3 and S7,F6 are the SECS-II messages used to move unformatted process programs between host and equipment.

A4.1.2 Unformatted process programs were the original accepted means for moving processing instructions between host and equipment under SECS-II. However, the inability of a host to generate process programs for its subordinate machines was quickly recognized as a severe problem. As a result, the formatted process program and its associated transactions were added. Five transactions are provided under SECS-II for handling formatted process programs: S7,F23-24, S7,F25-26 allow movement of process programs between host and equipment; S7,F21-22 originates at a machine and provides a host with the information it needs to generate a process program for that machine; S7,F27-28 allows the equipment to tell the host whether or not the contents of the formatted process program received from the host are valid; and S7,F31-32 provides the host with the ability to ask the equipment to check the validity of a process program without actually downloading the program into the machine for production use.

A4.2 *Normal Sequence of Operations*

A4.2.1 Formatted process programs may be generated at a host or machine. The actions taken to generate one in a machine are left to the equipment manufacturer. If the process program is created at a host, a sequence of operations is assumed.

1. Once the host' s process program generator has been invoked and has been told for which machine a process program is to be created, the host editor must obtain a copy of the process capabilities data for that machine. The information may already be available on the host or it may be obtained directly from the machine. In either case, the information originates at the equipment and is obtained using S7,F21-22. (See Section A4.4 for additional information.)

2. With the machine' s process capabilities in its possession, the process program editor may proceed with creating the desired process program. At the conclusion of the editing session, the new machine process program will either be saved at the host or sent directly to the machine for storage and/or use.At this point, the process program is known to satisfy a number of constraints, but it is not necessarily completely acceptable to the machine due to interrelationships of the process program data which are too complex to be described in the machine process capabilities data. The host at any time may verify that a process program is truly valid by sending the process program to the machine and asking it to check the process program and tell the host whether or not the process program is, in fact, correct. If not correct, the equipment is expected to provide information on what data in the process program is unacceptable. This action is accomplished through S7,F31-32. This transaction is equivalent to S7,F23-24, with one important exception, the machine is not to do anything with the process program received under S7,F31 except acknowledge that it got the message (S7,F32) and, as soon as it is able, respond with S7,F27, which provides the host with information on the validity of the process program. In this way, a new version of a process program already held by a machine may be checked for validity without affecting the operation of the machine (i.e., a newer version of a particular process program may be checked while an older version is simultaneously being used by the equipment for material processing).

3. At some point, a host resident process program will be required by the equipment for material processing. Transfer of a program may be accomplished in either of two ways. First, the host may initiate transfer by transmitting S7,F23. In this case, immediately upon reception of the message, the equipment is required to respond with S7,F24, which tells the host that the process program arrived and whether or not the process program is accepted for further processing by the equipment. The second means is for the equipment to initiate the transfer by asking for a process program using S7,F25. In this case, the host will send the process program to the equipment or tell the equipment it is unable to satisfy the request. S7,F23 may also be used by a piece of equipment to transfer a process program to its host for archiving. In this case, the host will respond with S7,F24 and an appropriate completion code. Likewise, a host may request a process program transfer from its machine using S7,F25. The machine will respond with S7,F26, which will contain the process program or an error indication.

4. Following reception by the equipment of the process program, it is the machine' s responsibility to check the contents of the process program for validity and respond to the host with a S7,F27 message formatted with the appropriate information about the just received process program. To complete the process program exchange transaction, the host will acknowledge the S7,F27 message with S7,F28. What is done with the process program once accepted and checked for validity is dependent on the state of the process equipment.

A4.3 *Equipment Process Capabilities Data*

A4.3.1 The underlying assumption of SECS-II formatted process programs is that processing instructions for equipment can be expressed as sequences of commands with parameters. Commands are integer codes which tell the machine what to do. The parameters of each command are numeric (integer or floating point) values, Boolean values, or text strings which specify how to carry out the particular command. This provides a very flexible structure for building process programs but does not provide the specific information (code values, types and number of parameters, legal parameter values, etc.) required by a host system to generate a process program for a particular piece of equipment. Under SECS-II, this information is provided to a host via the machine' s Equipment Process Capabilities Data or PCD.

A4.3.2 A PCD provides three levels of information global data pertaining to the entire process program; definition of each possible command understood by the machine; and definition of each command parameter. Global process program definition data consist of MDLN, SOFTREV,CMDMAX, BYTMAX, and the list of command descriptors.

A4.3.3 MDLN and SOFTREV provide the same data to the host as the equipment' s response to the S1,F1 host interrogative, " Are youthere? " They are included in the PCD to provide a means of distinguishing between PCDs for different machines and revisions of PCDs for the same piece of equipment. Also, when a process program is generated, the MDLN/SOFTREV values of the PCD are provided in the process program to allow the machine an unambiguous method of determining if the process program was generated from a PCD it understands.

A4.3.4 BYTMAX and CMDMAX are two integer values which allow the equipment to limit the size of the process program which will be generated. BYTMAX specifies the maximum number of bytes a process program may occupy. CMDMAX specifies the maximum number of commands which may appear in the process program. Either value may be zero, which indicates that no maximum limit is being imposed by the equipment.

A4.3.5 The PCD command list identifies (in no particular order) each of the unique operations its associated machine is capable of performing. These operations may correspond to processing operations of the equipment (bake, spin), initialization of equipment components (set beamline controls), definition of data values referenced by later commands (define bond coordinates or inspection points), or even " pseudo-operations," which allow conditional execution of the process program (go to X; if temperature out of range, then go to y; repeat ramping until speed 200; etc.).

A4.3.6 Each command in the PCDlist has a number of data values associated with it which provide the host with the command' s personality. These are CCODE, CNAME, RQCMD, BLKDEF, BCDS, IBCDS, NBCDS, ACDS, IACDS, NACDS, and the commands parameter list.

A4.3.7 CCODE defines the unique numeric code which the equipment recognizes as representing the command being defined. CNAME is a text string which hopefully describes the function of the command. The string must be unique for each command since humans generating process programs at the host will use them, and the host process program generator will translate the CNAME to the corresponding CCODE.

A4.3.8 RQCMD. This Boolean value allows equipment to specify whether or not a command must appear at least once within their process program. If true, the command must be used. If RQCMD is set false, the command may or may not be used in the process program at the discretion of the person creating the process program.

A4.3.9 In addition to the information the PCD provides on allowed data content within a process program, it also can provide information to the host on possible interdependencies between the commands. Specifically, through the PCD the host can know such things as: command code A must appear before command code B; command code A must come after command code D; command code A must immediately precede command code X; command code A must not come before command code E; command code A must not come after command code F; and/or command code A must immediately come after command code T. Each of the PCD entries, BCDS (before codes), ACDS (after codes), IBCDS (immediately before codes), IACDS (immediately after codes), NBCDS (not before codes), and NACDS (not after codes), is a SECS item which may contain one or more command codes. Each particular item defines the relation to be satisfied. The elements of the item identify the command codes which are to satisfy the relation with the command being defined. A zero length item indicates that no restrictions apply for that type of checking. For example, if the values of the various fields take on the values shown in Figure A4-1, the host process program editor will assure that the TEST command (code 10) will occur before commands with codes 5, 6, and 8; that it will come after commands with codes 100 and 2; that TEST will not appear after the command with code 20; and that each occurrence of command code 3 will have a TEST command immediately before it, subject to the block checking limitations described elsewhere.

CNAME = TEST

CCODE = 10

BCDS = 5,6,8

IBCDS = 3

NBCDS = none

ACDS = 100.2

IACDS = none

NACDS = 20

Figure A4-1

A4.3.10 Associated with before/after checking is the concept of a block which allows setting of limits on before/after checking. A block consists of a start block command, a block terminator command and possibly body commands, commands which are included between the start and terminator commands. There are no specific command codes for start, or terminator commands in SECS-II formatted process programs. Instead, being a start block, terminator block, or body command is merely an attribute of each command defined in the PCD. The field BLKDEF defines this attribute for each command. A positive one indicates the command starts a new block. Zero indicates that the command is a body command and neither starts nor terminates a block. A value of negative one indicates that the command is a terminator command.

A4.3.11 Before/after checking for a particular command is performed only with other commands within the same block. To be within the same block, a command must have the same nesting level as the command of interest or the command must be a contained block.

The example data in Figure A4-2 shows six grouping of commands for before/after checking: (A,B' ,N), (B,C,D' ,G' ,M), (D,E,F), (G,H' ,L), (H,I' ,K), (I,J). A letter followed by an apostrophe (`) indicates a block which has been collapsed to a command and has the before/after attributes of its start block command. Note that body and terminator commands occur in only one grouping, while block start commands occur in two. Also, note that the outermost block is assumed to begin with the first command of the process program and to end with the last command.

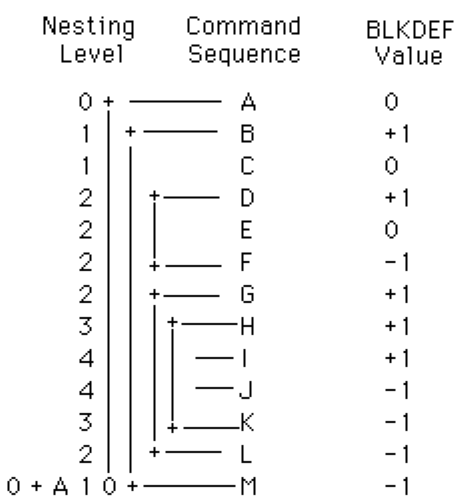

Figure A4-2

A4.3.12 Each command' s parameter list defines the parameters required by the equipment to carry out each particular command. The order in which each parameter descriptor appears in the PCD parameter list also defines the order in which parameters will appear in a process program command parameter list. Each parameter is one of three possible types: numeric, text, or Boolean.

A4.3.13 Regardless of parameter type, the first four elements of any parameter descriptor list are the same. The first field, PNAME, specifies the text string which names the parameter. This data will be displayed by a host when prompting a human for the parameter data. The second field, RQPAR, specifies if the value must be specified at the time the process program is generated (true) or if specifying the data is optional (false). The third field, PDFLT, identifies the type of data to be accepted for this parameter as well as providing default values to include in the process program if the RQPAR is false and no data is input for the parameter when the process program is generated. PDFLT will have zero length if no default value is provided.

A4.3.14 The final field, PMAX, specifies the maximum length of the parameter data placed in a process program. For numeric and Boolean data, it specifies the maximum number of data entries in the SECS-II item. For a string parameter, it specifies the maximum number of characters acceptable to the machine. In either case, negative values are invalid and a value of zero indicates there is no length restriction.

A4.3.15 For numeric and Boolean parameters which are multi-valued items, usage of PDFLT becomes a bit more complex. In these cases, PDFLT may also be a vector of values. When default values are to be included in a process program, the entry of the default vector in the same ordinal position as the parameter entry requiring the default is used. If the parameter is allowed to have N entries but only M defaults are provided, the last N-M parameter entries will have no defaults.

A4.3.16 If the numeric or Boolean vector parameter is required to be entered, PDFLT will contain no default data values, but dummy values must be provided so that the length of the item specifies the minimum number of entries the equipment expects to receive for the parameter. If this minimum number of entries exceeds the maximum number of entries allowed for the parameter (PMAX), then only PMAX entries will be provided in the process program.

A4.3.17 Numeric parameters may be any of the SECS recognized floating point or integer data types. PDFLT identifies the particular type. ULIM and LLIM will be of the same data type and specify the range of legal values for the parameter (LLIM≤ x ≤ULIM).UNITS is a character string formed according to E5, Section 9, which specifies the expected units of measure of the numeric value. RESC specifies whether the resolution of the data item to be entered is to be in terms of a fundamental increment or significant digits. In the case of the former, RESV will be of the same type as the expected parameter and will specify the base increment. In the case of the latter, RESV will be an integer and will specify the number of significant digits to accept for the parameter.

A4.3.18 In addition to the standard fields described above, string parameter descriptors have one unique field. This field provides a set of template strings. A text parameter will be assumed valid by a host process program generator if it matches one of the template strings. A match occurs if the input string is at least as long as the corresponding template and each position of the template and data strings match. A null string specified as a template will result in a match with any data string. A null data string will match only a null template string. A null template list indicates all strings are acceptable to the equipment.

A4.4 *Equipment Capabilities Descriptor Availability*

A4.4.1 Ideally, each piece of equipment should be able to respond to a host PCD request at any time. However, inasmuch as an equipment' s PCD may be rather large and the equipment may have limited storage capacity, constant availability may be impossible. In these cases, some compromise will have to be made such as making it available only at machine initialization or when idle. In extremely severe cases, an equipment manufacturer may have to provide the PCD data with the rest of the machine documentation, requiring his customer to manually enter the data into his host system.

A4.4.2 In light of this difficulty, host systems should maintain copies of PCD' s for each piece of equipment under its control and not expect to be able to obtain the PCD from the machine whenever it is required. Doing so, in fact, will permit more flexible process program development in the host, allowing creation of process programs even when equipment is not online and encourage the use of formatted process programs by equipment manufacturers.

A5 Suggested Baseline SECS Equipment Implementation

A5.1 *Purpose and Scope*

A5.1.1 This document provides a recommendation prepared by the Rigid Disk Subcommittee for generating a baseline implementation of the SECS (SEMI Equipment Communication Standard) standards on production process and test equipment. This document is not a tutorial to aid in understanding SECS but rather serves as an introduction to the requirements of SECS, and a brief guide to the selection of SECS messages for equipment. Actual system requirements of many implementations are beyond the scope of this document. The full standards, SEMI Equipment Communications Standard I (SECS-I), SEMI E4 and SEMI Equipment Communications Standard II (SECS-II), SEMI E5 should be consulted by all users.

A5.2 *Introduction*

A5.2.1 The SECS standards are an existing and developed set of communication standards currently used by the semiconductor and other industries to support automated production. The standards provide a means for communicating information and control between production equipment and a " host" computer. This transfer of information and control can be used to provide production tracking and location of WIP (Work-In-Process), scheduling of WIP and control of material transfer at the equipment. The process measurements and records can be used to provide process engineers with a database for statistical process control. SECS messages are appropriate to a wide variety of applications, including measurement, processing, and material transport equipment.

A5.3 *SECS-I Standard*

A5.3.1 SECS-I defines the lower protocol layers of a point-to-point interface between equipment and a host computer system. The standard requires a simple, well understood physical interface, RS-232. The SECS-I protocol allows the equipment control over the protocol: the equipment is the master of the link and can initiate the transfer of a message to the host. Likewise, the equipment can regulate the receipt of a message by its response to a handshake to receive the message. Thus, the interface takes place at the convenience of the equipment, and equipment with very limited computer resources can still support the standard.

A5.4 *SECS-II Standard*

A5.4.1 SECS-II defines the higher layer in the protocol, including message content, structure, and data types and their formats. SECS-II defines messages in sets with related functions called Streams. The actual content of the messages are specific to an application, but it is possible for a properly designed host software system to unpack a message and present the data in a meaningful way with no prior definition as to the content. Equipment need only implement those messages appropriate to meet its system requirements; thus, very simple equipment will require implementation of few messages.

A5.4.2 Application Note A2 contains some suggestions for message utilization, including some information on minimum message sets. It is the intent of this report to expand in a somewhat different direction, to identify those messages which typically constitute a sufficient set given a selected equipment function.

A5.4.3 To select a message set, the requirements for the equipment must be identified. This requirement, in turn, determines a message set. Identified below are a number of types of equipment requirements and a baseline set of messages supporting those requirements. The message sets identified are baseline recommendations. Actual equipment implementations may need more messages than those specified here to satisfy all system requirements. The published standards should be consulted for all applications. Issues such as handling of multi-block messages, optional replies, and others are described in detail in the SEMI specifications and are not a topic of this baseline recommendation.

A5.4.4 The implementation for a specific equipment type begins by specifying which tasks that equipment is required to perform from the following list, and then studying the expanded descriptions for those tasks chosen in the SECS-II implementation section.

Typical Tasks for Measurement and Process:

1. Measurement or Action Reports
2. Equipment Alarm Reports
3. Remote Request for Equipment Condition or State
4. Operator Interface to the Host
5. Remote Access to Process Programs
6. Remote Commands

Typical Tasks for Material Control and Transport:

1. Material Status Information
2. Material Transport Control

Additional Tasks for Special Situations:

1. File Transfer

A5.5 *Baseline SECS Implementation Recommendations: SECS-I*

A5.5.1 The baseline SECS-I requirement for equipment is to fully implement the SECS-I protocol as defined in SEMI E4. This requirement applies to all SECS compatible equipment independent of the equipment' s function. The flow chart (Figure 2 of SEMI E4) illustrates the block transfer protocol of SECS-I. The body of the SECS-I standard describes protocol timeouts and other requirements that are essential components of the specification.

A5.6 *Baseline SECS Implementation Recommendations: SECS-II*

A5.6.1 The SECS-II implementation begins with a choice or selection of messages for the equipment. In order for equipment to meet the baseline requirements for a viable SECS-II interface, the equipment must be capable of generating a certain set of messages and recognizing another set. The messages required for either set will depend on tasks of equipment and on system requirements for production and process control by the host. Equipment must accept S1,F1 and send S1,F2. Note that implementation in the reverse direction is optional. In order to ensure a viable data communication link, certain messages are required:

Messages for All Equipment — Required by SECS-II

a. Messages Generated by the Equipment

    S1,F2:On Line Data

    S9,F1: Unrecognized Device ID

    S9,F3: Unrecognized Stream Type

    S9,F5: Unrecognized Function Type

    S9,F7: Illegal Data

b. Messages Recognized by the Equipment

    S1,F1: Are You There Request

A5.6.2 In addition to those messages which are required, the following are strongly recommended. These messages are used for diagnostic purposes:

Messages for All Equipment — Strongly Recommended

A. Messages Generated by the Equipment

    1. S2,F25: String Diagnostic Request

B. Messages Recognized by the Equipment

    1. S2,F26: String Diagnostic Data

A5.6.3 Note that messages are identified by a " stream" number and a " function" number. All primary messages have an odd-numbered function, and the corresponding reply is the next consecutive even-numbered function. Thus, many messages are paired. For example, the Stream 1, Function 1 (S1,F1) message generated by either host of equipment has the reply of Stream 1, Function 2 (S1,F2).

A5.6.4 *Reports of Measurements or Process Actions —* The simplest task for measurement and process equipment is to report their measurements or actions to the host. This report could also include equipment setup parameters and sample identification. The ability to accurately transfer this data from equipment to a factory host is of prime importance in automating production. Depending on the equipment requirements, the function can be far greater.

A5.6.4.1 *Measurements or Action Reports* — Given an equipment requirement to relay data to a host computer, the equipment must handle one or both of the following messages as defined by SEMI E5.

S6,F3: Discrete Variable Send

S6,F9: Formatted Variable Send

A5.6.4.2 *Equipment Alarm Reports* — These messages are unsolicited by the host, they transmit information warning of conditions threatening personal safety, equipment safety, or out of limit equipment parameters which may cause harm to the product or indicate equipment malfunction:

S5,F1: Alarm Report Send

A5.6.4.3 *Remote Request for Equipment Condition or State* — This is the method where the host requests data from the equipment.

Messages Transmitted to the Equipment:

S6,F7: Data Transfer Request

Messages Transmitted by the Equipment in Reply:

S6,F8: Data Transfer Data

A5.6.4.4 *Operator Interface to the Host* — Many equipment systems will have an interactive operator's console; some will have computer terminals used for this purpose. SECS-II has a message type to transfer text from host to the equipment console. There are also messages through which equipment operators may transmit text from their console, directly to the host. This text may include desired information which is not accessible by the equipment computer directly.

Message Transmitted by the Equipment:

S10,F1: Terminal Request

Message Recognized by the Equipment:

S10,F3: Terminal Display, Single

A5.6.4.5 *Remote Access to Process Programs* — SECS-II defines a means for storing or retrieving equipment process programs. This function allows upload and download of such programs through the SECS interface. By this means, programs for equipment may be archived in the host computer system. Either the host or the equipment may request the transfer of a Process Program from the other. To do this:

The Requestor transmits:

S7,F5: Process Program Request

The Sender of the Process Program replies:

S7,F6: Process Program Data

In addition, either host or equipment may initiate sending the Process Program. In this case:

The sender transmits:

S7,F1: Process Program Load Inquire,

Receiver replies with:

S7,F2: Process Program Load Grant,

Sender transmits:

S7,F3: Process Program Send,

The receiver answers:

S7,F4: Process Program Acknowledge.

A5.6.4.6 *Remote Commands* — The host can initiate a command to the equipment in a manner similar to an operator pressing a button.

The host transmits:

S2,F21: Remote Command Send,

The equipment replies:

S2,F22: Remote Command Acknowledge.

Execution of the remote command may cause the equipment to transmit a message to the host at a time greater than the reply time required for the S2,F22 message. If this type of reply is desired, the S6,F3: Discrete Variable Data Send may be used to transfer data to the host.

A5.6.5 *Typical Tasks for Material Control and Transport*

A5.6.5.1 *Material Status Information* — The host may query the equipment for material-in-process information. The information is transmitted only as a answer to a host request.

The equipment recognizes:

S3,F1: Material Status Request.

The equipment transmits:

S3,F2: Material Status Data.

A5.6.5.2 *Material Transport Control* — The SECS-II protocol includes the means to affect automated transfer of material from one SECS-compatible device to another. Baseline compatibility requires the equipment to perform a simple material transfer process, an actual implementation may require means for graceful error recovery as well. This recommendation does not include messages to handle error conditions.

Receiving Material:

Equipment Recognizes S4,F1:

Ready to Send Material

Equipment Transmits:

S4,F3: Send Material,

S4,F5: Handshake

Sending Material:

Equipment Transmits:

S4,F1: Ready to Send Material

Equipment Recognizes:

S4,F3: Send Material,

S4,F5: Handshake Complete

Equipment Recognizes:

S4,F2: RTS Acknowledge

A5.7 *Conclusion* — The baseline requirements for equipment using the SECS standards includes all of SECS-I and a limited selection of messages from SECS-II. The choice of SECS-II messages, and data contained therein, is dictated by the equipment and system requirements. The benefits in using the standards are many, including support for growth in equipment function, and standardization needed for effective automation. The results include automated process monitoring and all of the associated benefits.

SEMI E30-1000
GENERIC MODEL FOR COMMUNICATIONS AND CONTROL OF MANUFACTURING EQUIPMENT (GEM)

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on July 14 and August 28, 2000. Initially available at www.semi.org August 2000; to be published October 2000. Originally published in 1992; previously published June 2000.

CONTENTS

SEMI E30-1000
GENERIC MODEL FOR COMMUNICATIONS AND CONTROL OF MANUFACTURING EQUIPMENT (GEM)

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on July 14 and August 28, 2000. Initially available at www.semi.org August 2000; to be published October 2000. Originally published in 1992; previously published June 2000.

1 Introduction

1.1 *Revision History* — This is the first release of the GEM standard.

1.2 *Scope* — The scope of the GEM standard is limited to defining the behavior of semiconductor equipment as viewed through a communications link. The SEMI E5 (SECS-II) standard provides the definition of messages and related data items exchanged between host and equipment. The GEM standard defines which SECS-II messages should be used, in what situations, and what the resulting activity should be. Figure 1.1 illustrates the relationship of GEM, SECS-II and other communications alternatives.

The GEM standard does NOT attempt to define the behavior of the host computer in the communications link. The host computer may initiate any GEM message scenario at any time and the equipment shall respond as described in the GEM standard. When a GEM message scenario is initiated by either the host or equipment, the equipment shall behave in the manner described in the GEM standard when the host uses the appropriate GEM messages.

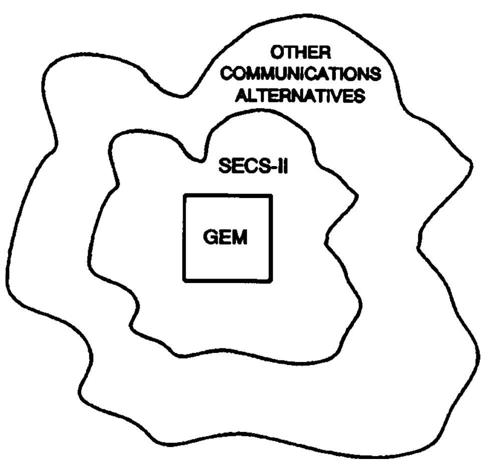

Figure 1.1
GEM Scope

The capabilities described in this standard are specifically designed to be independent of lower-level communications protocols and connection schemes (e.g., SECS-I, SMS, point-to-point, connection-oriented or connectionless). Use of those types of standards is not required or precluded by this standard.

This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.3 *Intent* — GEM defines a standard implementation of SECS-II for all semiconductor manufacturing equipment. The GEM standard defines a common set of equipment behavior and communications capabilities that provide the functionality and flexibility to support the manufacturing automation programs of semiconductor device manufacturers. Equipment suppliers may provide additional SECS-II functionality not included in GEM as long as the additional functionality does not conflict with any of the behavior or capabilities defined in GEM. Such additions may include SECS-II messages, collection events, alarms, remote command codes, processing states, variable data items (data values, status values or equipment constants), or other functionality that is unique to a class (etchers, steppers, etc.) or specific instance of equipment.

GEM is intended to produce economic benefits for both device manufacturers and equipment suppliers. Equipment suppliers benefit from the ability to develop and market a single SECS-II interface that satisfies most customers. Device manufacturers benefit from the increased functionality and standardization of the SECS-II interface across all manufacturing equipment. This standardization reduces the cost of software development for both equipment suppliers and device manufacturers. By reducing costs and increasing functionality, device manufacturers can automate semiconductor factories more quickly and effectively. The flexibility provided by the GEM standard also enables device manufacturers to implement unique automation solutions within a common industry framework.

The GEM standard is intended to specify the following:

— A model of the behavior to be exhibited by semiconductor manufacturing equipment in a SECS-II communication environment,

— A description of information and control functions needed in a semiconductor manufacturing environment,

— A definition of the basic SECS-II communications capabilities of semiconductor manufacturing equipment,

— A single consistent means of accomplishing an action when SECS-II provides multiple possible methods, and

— Standard message dialogues necessary to achieve useful communications capabilities.

The GEM standard contains two types of requirements:

— fundamental GEM requirements and

— requirements of additional GEM capabilities.

The fundamental GEM requirements form the foundation of the GEM standard. The additional GEM capabilities provide functionality required for some types of factory automation or functionality applicable to specific types of equipment. A detailed list of the fundamental GEM requirements and additional GEM capabilities can be found in Chapter 8, GEM Compliance. Figure 1.2 illustrates the components of the GEM standard.

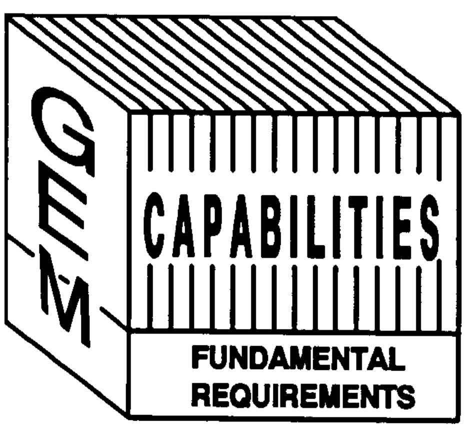

Figure 1.2
GEM Components

Equipment suppliers should work with their customers to determine which additional GEM capabilities should be implemented for a specific type of equipment. Because the capabilities defined in the GEM standard were specifically developed to meet the factory automation requirements of semiconductor manufacturers, it is anticipated that most device manufacturers will require most of the GEM capabilities that apply to a particular type of equipment. Some device manufacturers may not require all the GEM capabilities due to differences in their factory automation strategies.

1.4 *Overview* — The GEM standard is divided into sections as described below.

Section 1 — Introduction

This section provides the revision history, scope and intent of the GEM standard. It also provides an overview of the structure of the document and a list of related documents.

Section 2 — Definitions

This section provides definitions of terms used throughout the document.

Section 3 — State Models

This section describes the conventions used throughout this document to depict state models. It also describes the basic state models that apply to all semiconductor manufacturing equipment and that pertain to more than a single capability. State models describe the behavior of the equipment from a host perspective.

Section 4 — Capabilities and Scenarios

This section provides a detailed description of the communications capabilities defined for semiconductor manufacturing equipment. The description of each capability includes the purpose, definitions, requirements, and scenarios that shall be supported.

Section 5 — Data Definitions

This section provides a reference to the Data Item Dictionary and Variable Item Dictionary found in SEMI Standard E5. The first subsection shows those data items from SECS-II which have been restricted in their use (i.e., allowed formats). The second subsection lists variable data items that are available to the host for data collection and shows any restrictions on their SECS-II definitions.

Section 6 — Collection Events

This section provides a list of required collection events and their associated data.

Section 7 — SECS Message Subset

This section provides a composite list of the SECS-II messages required to implement all capabilities defined in the GEM standard.

Section 8 — GEM Compliance

This section describes the fundamental GEM requirements and additional GEM capabilities and provides references to other sections of the standard where detailed requirements are located. This section also defines standard terminology and documentation that can be used by equipment suppliers and device manufacturers to describe compliance with this standard.

Section A — Application Notes

These sections provide additional explanatory information and examples.

Section A.1 — Factory Operational Script

This section provides an overview of how the required SECS capabilities may be used in the context of a typical factory operation sequence. This section is organized according to the sequence in which actions are typically performed.

Section A.2 — Equipment Front Panel

This section provides guidance in implementing the required front panel buttons, indicators, and switches as defined in this document. A summary of the front panel requirements is provided.

Section A.3 — Examples of Equipment Alarms

This section provides examples of alarms related to various equipment configurations.

Section A.4 — Trace Data Collection Example

This section provides an example of trace initialization by the host and the periodic trace data messages that might be sent by the equipment.

Section A.5 — Harel Notation

This section explains David Harel's "Statechart" notation that is used throughout this document to depict state models.

Section A.6 — Example Control Model Application

This section provides one example of a host's interaction with an equipment's control model.

Section A.7 — Examples of Limits Monitoring

This section contains four limits monitoring examples to help clarify the use of limits and to illustrate typical applications.

1.5 *Applicable Documents*

1.5.1 *SEMI Standards* — The following SEMI standards are related to the GEM standard. The specific portions of these standards referenced by GEM constitute provisions of the GEM standard.

SEMI E4 — SEMI Equipment Communications Standard 1 — Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 — Message Content (SECS-II)

SEMI E13 — Standard for SEMI Equipment Communication Standard Message Service (SMS)

SEMI E23 — Specification for Cassette Transfer Parallel I/O Interface

1.5.2 *Other References*

Harel, D., "Statecharts: A Visual Formalism for Complex Systems," Science of Computer Programming 8 (1987) 231-274[1].

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

2 Definitions

2.1 *alarm* — An alarm is related to any abnormal situation on the equipment that may endanger people, equipment, or material being processed. Such abnormal situations are defined by the equipment manufacturer based on physical safety limitations. Equipment activities potentially impacted by the presence of an alarm shall be inhibited.

2.1.1 Note that exceeding control limits associated with process tolerance does not constitute an alarm nor do normal equipment events such as the start or completion of processing.

2.2 *capabilities* — Capabilities are operations performed by semiconductor manufacturing equipment. These operations are initiated through the communications interface using sequences of SECS-II messages (or scenarios). An example of a capability is the setting and clearing of alarms.

2.3 *collection event* — A collection event is an event (or grouping of related events) on the equipment that is considered to be significant to the host.

2.4 *communication failure* — A communication failure is said to occur when an established communications link is broken. Such failures are

1 Elsevier Science, P.O. Box 945, New York, NY 10159-0945, http://www.elvesier.nl/homepage/browse.htt

protocol specific. Refer to the appropriate protocol standard (e.g., SEMI E4 or SEMI E37) for a protocol-specific definition of communication failure.

2.5 *communication fault* — A communication fault occurs when the equipment does not receive an expected message, or when either a transaction timer or a conversation timer expires.

2.6 *control* — To control is to exercise directing influence.

2.7 *equipment model* — An equipment model is a definition based on capabilities, scenarios, and SECS-II messages that manufacturing equipment should perform to support an automated manufacturing environment. (See also Generic Equipment Model.)

2.8 *event* — An event is a detectable occurrence significant to the equipment.

2.9 *GEM compliance* — The term "GEM Compliance" is defined with respect to individual GEM capabilities to indicate adherence to the GEM standard for a specific capability. Section 8 includes more detail on GEM Compliance.

2.10 *Generic Equipment Model* — The Generic Equipment Model is used as a reference model for any type of equipment. It contains functionality that can apply to most equipment, but does not address unique requirements of specific equipment.

2.11 *host* — The SEMI E4 and E5 standards define Host as "the intelligent system that communicates with the equipment."

2.12 *message fault* — A message fault occurs when the equipment receives a message that it cannot process because of a defect in the message.

2.13 *operational script* — An operational script is a collection of scenarios arranged in a sequence typical of actual factory operations. Example sequences are system initialization powerup, machine setup, and processing.

2.14 *operator* — A human who operates the equipment to perform its intended function (e.g., processing). The operator typically interacts with the equipment via the equipment supplied operator console.

2.15 *process unit* — A process unit refers to the material that is typically processed as a unit via single run command, process program, etc. Common process units are wafers, cassettes, magazines, and boats.

2.16 *processing cycle* — A processing cycle is a sequence wherein all of the material contained in a typical process unit is processed. This is often used as a measure of action or time.

2.17 *scenario* — A scenario is a group of SECS-II messages arranged in a sequence to perform a capability. Other information may also be included in a scenario for clarity.

2.18 *SECS-I* — SEMI Equipment Communications Standard 1 (SEMI E4). This standard specifies a method for a message transfer protocol with electrical signal levels based upon EIA RS232-C.

2.19 *SECS-II* — SEMI Equipment Communications Standard 2 (SEMI E5). This standard specifies a group of messages and the respective syntax and semantics for those messages relating to semiconductor manufacturing equipment control.

2.20 *SMS* — SECS Message Service. An alternative to SECS-I to be used when sending SECS-II formatted messages over a network.

2.21 *state model* — A State Model is a collection of states and state transitions that combine to describe the behavior of a system. This model includes definition of the conditions that delineate a state, the actions/reactions possible within a state, the events that trigger transitions to other states, and the process of transitioning between states.

2.22 *system default* — Refers to state(s) in the equipment behavioral model that are expected to be active at the end of system initialization. It also refers to the value(s) that specified equipment variables are expected to contain at the end of system initialization.

2.23 *system initialization* — The process that an equipment performs at power-up, system activation, and/or system reset. This process is expected to prepare the equipment to operate properly and according to the equipment behavioral models.

2.24 *user* — A human or humans who represent the factory and enforce the factory operation model. A user is considered to be responsible for many setup and configuration activities that cause the equipment to best conform to factory operations practices.

3 State Models

The following sections contain state models for semiconductor manufacturing equipment. These state models describe the behavior of the equipment from a host perspective in a compact and easy to understand format. State models for different equipment will be identical in some areas (e.g., communications), but may vary in other areas (e.g., processing). It is desirable to divide the equipment into parallel components that can be modeled separately and then combined. An example of a component overview of an equipment is provided as Figure 3.0.

Equipment manufacturers must document the operational behavior of their equipment using state model methodology. State models are discussed in Sections 3.1 and A.5 and in a referenced article. Documentation of a state model shall include the following three elements:

— A *state diagram* showing the possible states of the system or components of a system and all of the possible transitions from one state to another. The states and transitions must each be labeled. Use of the Harel notation (see A.5) is recommended.

— A *transition table* listing each transition, the beginning and end states, what stimulus triggers the transition, and any actions taken as a result of the transition.

— A *definition of each state* specifying system behavior when that state is active.

Examples of the above elements are provided in Section A.5.

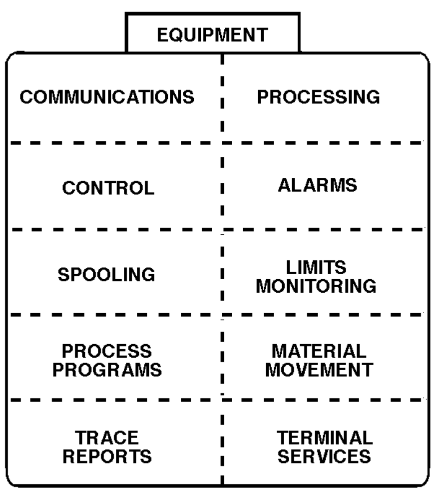

Figure 3.0
Example Equipment Component Overview

The benefits of providing state models are:

1. State machine models are a useful specification tool,
2. A host system can anticipate machine behavior based upon the state model,
3. End-users and equipment programmers have a common description of machine behavior from which to work,
4. "Legal" operations can be defined pertaining to any machine state,
5. External event notifications can be related to internal state transitions,
6. External commands can be related to state transitions,
7. State model components describing different aspects of machine control can be related to one another (example: processing state model with material transport state model; processing state model with internal machine safety systems).

3.1 *State Model Methodology* — To document the expected functionality of the various capabilities described in this document, the "Statechart" notation developed by David Harel has been adopted. An article by Harel is listed in Section 1.5 and should be considered "must" reading for a full understanding of the notation. The convention used in this and following sections is to describe the dynamic functionality of a capability with three items: a textual description of each state or substate defined, a table that describes the possible transitions from one state to another, and a graphical figure that uses the symbols defined by Harel to illustrate the relationships of the states and transitions. The combination of these items define the state model for a system or component. A summary of the Harel notation and a more detailed description of the text, table, and figure used to define behavior with this methodology is contained in the Application Note A.5.

The basic unit of a state model is the state. A state is a static set of conditions. If the conditions are met, the state is current. These conditions might involve sensor readings, switch positions, time of day, etc. Also part of a state definition is a description of reactions to specific stimuli (e.g., if message Sx,Fy is received, generate reply message Sx,Fy + 1). Stimuli may be quite varied but for semiconductor equipment would include received SECS messages, expired timers, operator input at an equipment terminal, and changes in sensor readings.

To help clarify the interpretation of this document and the state models described herein, it is useful to distinguish between a state and an event and the relationship of one to the other. An event is dynamic rather than static. It represents a change in conditions, or more specifically, the awareness of such a change. An event might involve a sensor reading exceeding a limit, a switch changing position, or a time limit exceeded.

A change to a new active state (state transition) must always be prompted by a change in conditions, and thus an event. In addition, a state transition may itself be termed an event. In fact, there are many events that may occur on an equipment, so it is important to classify events based on whether they can be detected and whether they are of interest. In this document, the term event has been more narrowly defined as a detectable occurrence that is significant to the equipment.

A further narrowing of the definition of event is represented by the term "collection event," which is an event (or group of related events) on the equipment that is considered significant to the host. It is these events that (if enabled) are reported to the host. By this definition, the list of collection events for an equipment would typically be only a subset of total events. The state models in this document are intended to be limited to the level of detail in which the host is interested. Thus, all state transitions defined in this standard, unless otherwise specified, shall correspond to collection events.

3.2 *Communications State Model* — The Communications State Model defines the behavior of the equipment in relation to the existence or absence of a communications link with the host. Section 4.1 expands on this section by defining the Establish Communications capability. This model pertains to a logical connection between equipment and host rather than a physical connection.

3.2.1 *Terminology* — The terms communication failure, connection transaction failure, and communication link are defined for use within this document only and should not be confused with the same or similar terms used elsewhere.

- See SEMI E4 (SECS-I) or SEMI E37 (HSMS) for a protocol specific definitions of communications failure.
- A connection transaction failure occurs when attempting to establish communications and is caused by
  - — a communication failure,
  - — the failure to receive an S1,F14 reply within a reply timeout limit, or
  - — receipt of S1,F14 that has been improperly formatted or with COMMACK[2] not set to 0.
- A reply timeout period begins after the successful transmission of a complete primary message for which a reply is expected. (See SEMI E4 (SECS-I) or SEMI E37 (HSMS) for a protocol-specific definition of reply timeout.)
- A communication link is established following the first successful completion of any one S1,F13/F14 transaction with an acknowledgement of "accept". The establishment of this link is logical rather than physical.
- Implementations may have mechanisms which allow outgoing messages to be stored temporarily prior to being sent. The noun queue is used to cover such stored messages. They are queued when placed within the queue and are dequeued by removing them from this storage.
- Send includes "queue to send" or "begin the process of attempting to send" a message. It does not imply the successful completion of sending a message.
- The host may attempt to establish communications with equipment at any time due to the initialization of the host or by independent detection of a communications failure by the host. Thus, the host may initiate an S1,F13/F14 transaction at any time.

3.2.2 *CommDelay Timer* — The CommDelay timer represents an internal timer used to measure the interval between attempts to send S1,F13. The length of this interval is equal to the value in the EstablishCommunicationsTimeout. The CommDelay timer is not directly visible to the host.

EstablishCommunicationsTimeout is the user-configurable equipment constant that defines the delay, in seconds, between attempts to send S1,F13. This value is used to initialize the CommDelay timer.

The CommDelay timer is initialized to begin timing. The CommDelay timer is initialized only when the state WAIT DELAY is entered.

The CommDelay timer is expired when it "times out," and the time remaining in the interval between attempts to send is zero. When the timer expires during the state WAIT DELAY, it triggers a new attempt to send S1,F13 and the transition to the state WAIT CRA[3] .

3.2.3 *Conventions*

- The attempt to send S1,F13 is made only upon transit into the state WAIT CRA. The CommDelay Timer should be set to "expired" at this time.

2 Establish Communications Acknowledge Code, defined in Section 4.1. See the SEMI E5 Standard for further definition of this Data Item.

3 CRA is the mnemonic defined for Establish Communications Request Acknowledge (S1,F14).

- The CommDelay timer is initialized only upon transit into the state WAIT DELAY. A next attempt to send S1,F13 shall occur only upon a transit to the state WAIT CRA.

3.2.4 *Communication States* — There are two major states of SECS communication, DISABLED and ENABLED. The system default state must be user-configurable at the equipment (e.g., via a jumper setting or non-volatile memory variable).

Once system initialization has been achieved, the operator shall be able to change the communication state selection at any time via equipment terminal functions or momentary switch. A two-position type switch must not be used due to possible conflict with the system default.

The ENABLED state has two substates, NOT COMMUNICATING and COMMUNICATING, described below. The equipment must inform the operator of the current communication state via continuous display at the equipment, including the NOT COMMUNICATING and COMMUNICATING sub-states.

In the event of a connection transaction failure, a user-configurable equipment constant EstablishCommunicationsTimeout is used to establish the interval between attempts to send an S1,F13 (Establish Communications Request) while in the NOT COMMUNICATING substate.

Figure 3.2.1 shows the relationship between the superstates and substates of the Communications State Model. A description of the events triggering state transitions and the actions taken is given in Table 3.2.

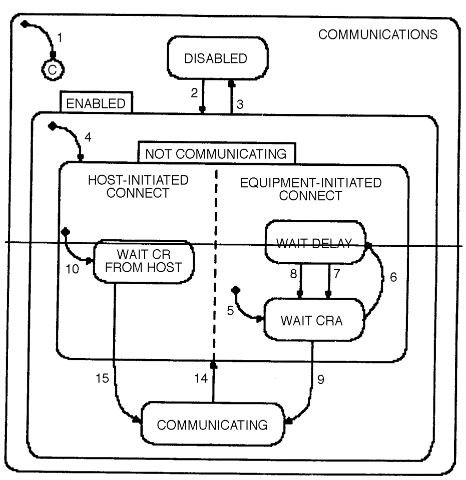

Figure 3.2.1
Communications State Diagram

The states of the Communications State Model are defined as follows:

DISABLED

In this state SECS-II communication with a host computer is non-existent. If the operator switches from ENABLED to DISABLED, all SECS-II communications must cease immediately. Any messages queued to send shall be discarded, and all further action on any open transactions and conversations shall be terminated.[4] Handling of messages currently being transmitted is an issue for lower level message transfer protocols and is not addressed in this standard.

The DISABLED state is a possible system default.

ENABLED

ENABLED has two substates, COMMUNICATING and NOT COMMUNICATING. Whenever communications are enabled, either during system initialization or through operator selection, the substate of NOT COMMUNICATING is active until communications are formally established. Lower-level protocols (such as SECS-I) are assumed to be functioning normally in that they are capable of supporting the communication of SECS-II syntax.

The ENABLED state is a possible system default.

ENABLED/NOT COMMUNICATING

No messages other than S1,F13, S1,F14, and S9,Fx shall be sent while this substate is active. The equipment shall discard any messages received from the host other than S1,F13 or S1,F14 (Establish Communications Acknowledge). It shall also periodically attempt to establish communication with a host computer by issuing an S1,F13 until communications are successfully established. However, only one equipment-initiated S1,F13 transaction may be open at any time.

The NOT COMMUNICATING state has two AND substates, HOST-INITIATED CONNECT and EQUIPMENT-INITIATED CONNECT, both of which are active whenever the equipment is NOT COMMUNICATING. These two substates clarify the behavior of the equipment in the event that both

4 Refer to SEMI E5, Section 5, for definitions of SECS-II transaction and conversation protocols.

the equipment and the host attempt to establish communications during the same period of time[5] .

NOT COMMUNICATING/EQUIPMENT-INITIATED CONNECT

This state has two substates, WAIT CRA and WAIT DELAY. Upon any entry to the NOT COMMUNICATING state, whenever EQUIPMENT-INITIATED CONNECT first becomes active, a transition to WAIT CRA occurs, the CommDelay timer is set to “expired,” and an immediate attempt to send S1,F13 is made.

NOT COMMUNICATING/EQUIPMENT-INITIATED CONNECT/WAIT CRA

An Establish Communications Request has been sent. The equipment waits for the host to acknowledge the request.

NOT COMMUNICATING/EQUIPMENT-INITIATED CONNECT/WAIT DELAY

A connection transaction failure has occurred. The CommDelay timer has been initialized. The equipment waits for the timer to expire.

NOT COMMUNICATING/HOST-INITIATED CONNECT

This state describes the behavior of the equipment in response to a host-initiated S1,F13 while NOT COMMUNICATING is active.

NOT COMMUNICATING/HOST-INITIATED CONNECT/WAIT CR FROM HOST

The equipment waits for an S1,F13 from the host. If an S1,F13 is received, the equipment attempts to send an S1,F14 with COMMACK = 0.

ENABLED/COMMUNICATING

Communications have been established. The equipment may receive any message from the host, including S1,F13. When the equipment is COMMUNICATING, SECS communications with a host computer must be maintained. This state remains active until communications are disabled or a communication failure occurs. If the equipment receives S1,F13 from the host while in the COMMUNICATING substate, it should respond with S1,F14 with COMMACK set to zero. If the equipment receives S1,F14 from a previously sent S1,F13, no action is required.

In the event of communication failure, the equipment shall return to the NOT COMMUNICATING substate and attempt to re-establish communications with the host.

It is possible that the equipment may be waiting for an S1,F14 from the host in EQUIPMENT-INITIATED CONNECT/WAIT CRA at the time an S1,F13 is received from the host in HOST-INITIATED CONNECT/WAIT CR FROM HOST. When this situation occurs, both equipment and host have an open S1,F13/S1,F14 transaction. Since communications are successfully established on the successful completion of any S1,F13/S1,F14 transaction, either of these two transactions may be the first to complete successfully and to cause the transition from NOT COMMUNICATING state to COMMUNICATING. In this event, the other transaction shall remain open regardless of the transition to COMMUNICATING until it is closed in a normal manner.

If the equipment has not yet sent[6] an S1,F14 to a previously received S1,F13 at the time when COMMUNICATING becomes active, the S1,F14 response shall be sent in a normal manner. A failure to send the S1,F14 is then treated as any other communication failure.

If the equipment-initiated S1,F13/S1,F14 is still open when the transition to COMMUNICATING occurs, subsequent failure to receive a reply from the host is considered a communication fault by equipment. An S9,F9 should be sent when a transaction timer timeout occurs[7]. (See Section 4.9 for definitions of communication faults and message faults, as well as detail on Stream 9 Error Messages.)

3.2.5 *State Transitions* — Table 3.2 contains a full description of the state transitions depicted in Figure 3.2.1.

When the operator switches from the DISABLED state to the ENABLED state, no collection event shall occur, since no messages can be sent until communications have been established. The process of establishing communications serves to notify the host that communications are ENABLED. No other collection events are defined for the Communications State Model.

5 Note that in the Harel notation, an exit from any AND substate is an exit from the parent state and thus from all other AND substates of that parent substate.

6 This includes transmissions that may have started but not yet successfully completed at the time that the transition to COMMUNICATING occurs.

7 The existence of a transaction timer is not a requirement in some protocols, such as SMS (SEMI E13).

Table 3.2 Communications State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	(Entry to COMMUNICA-TIONS)	System initialization.	System Default	None.	The system default may be set to DISABLED or ENABLED.
2	DISABLED	Operator switches from DISABLED to ENABLED.	ENABLED	None.	SECS-II communications are enabled.
3	ENABLED	Operator switches from ENABLED to DISABLED.	DISABLED	None.	SECS-II communications are prohibited.
4	(Entry to ENABLED)	Any entry to ENABLED state.	NOT COMMUNICATING	None.	May enter from system initialization to ENABLED or through operator switch to ENABLED.
5	(Entry to EQUIPMENT-INITIATED CONNECT)	(Any entry to NOT COMMUNICA-TING)	WAIT CRA	Initialize communications. Set CommDelay timer “expired.” Send S1,F13.	Begin the attempt to establish communications.
6	WAIT CRA	Connection transaction failure.	WAIT DELAY	Initialize CommDelay timer. Dequeue all messages queued to send.	If appropriate, dequeued messages shall be placed in spool buffer in the order generated. Wait for timer to expire.
7	WAIT DELAY	CommDelay timer expired.	WAIT CRA	Send S1,F13	Wait for S1,F14. May receive S1,F13 from Host.
8	WAIT DELAY	Received a message other than S1,F13.	WAIT CRA	Discard message. No reply. Set CommDelay timer “expired”. Send S1,F13.	Indicates opportunity to establish communications.
9	WAIT CRA	Received expected S1,F14 with COMMACK = 0.	COMMUNICATING	None.	Communications are established.
10	(Entry to HOST-INITIATED CONNECT)	(Any entry to NOT COMMUNICA-TING)	WAIT CR FROM HOST	None.	Wait for S1,F13 from Host.
14	COMMUNICATING	Communication failure. (See SEMI E4 or SEMI E37 for a protocol-specific definition of communication failure.)	NOT COMMUNICATING	Dequeue all messages queued to send.	Dequeued messages may be placed in spool buffer as appropriate.
15	WAIT CR FROM HOST	Received S1,F13.	COMMUNICATING	Send S1,F14 with COMMACK = 0.	Communications are established.

3.3 *Control State Model* — The CONTROL state model defines the level of cooperation between the host and equipment. It also specifies how the operator may interact at the different levels of host control. While the COMMUNICATIONS state model addresses the ability for the host and equipment to exchange messages, the CONTROL model addresses the equipment's responsibility to act upon messages that it receives.

The CONTROL model provides the host with three basic levels of control. In the highest level (REMOTE), the host may control the equipment to the full extent possible. The middle level (LOCAL) allows the host full access to information, but places some limits on how the host can affect equipment operation. In the lowest level (OFF-LINE), the equipment allows no host control[8] and only very limited information.[9]

The control model and communications model (when implemented) do not interact directly. That is, no action or state of one model directly causes a change in behavior of the other. It is true, however, that when the communication state is NOT COMMUNICATING then most message transaction are not functional. When messages cannot be transmitted, the control capabilities and all other GEM capabilities are affected.

Refer to Figure 3.3 as the CONTROL substates and state transitions are defined.

OFF-LINE

When the OFF-LINE state is active, operation of the equipment is performed by the operator at the operator console. While the equipment is OFF-LINE, message transfer is possible. However the use of messaging for any automation purpose is severely restricted. While the OFF-LINE state is active, the equipment will only respond to those messages used for the establishment of communications or a host request to activate the ON-LINE state.

While OFF-LINE, the equipment will respond with an Sx,F0 to any primary message from the host other than S1,F13 or S1,F17. It will process and respond to S1,F13 and S1,F17. S1,F17 is used by the host to request the equipment to transition to the ON-LINE state. The equipment will accept this request and send a positive response only when the HOST OFF-LINE state is active (see transition 11 definition below).

8 The host may establish communications. This does not affect equipment operation and for that reason is not termed a control operation.

9 The host may determine the equipment identification via the S1F13/F14 transaction.

While the OFF-LINE state is active, the equipment shall attempt to send no primary message other than S1,F13,[10] S9,Fx,[11] and S1,F1 (see ATTEMPT ON-LINE substate). If the equipment receives a reply message from the host other than S1,F14 or S1,F2, this message is discarded.

No messages enter the spool when the system is OFF-LINE. Spooling may be active when the Communications State of NOT COMMUNICATING is active. This might occur during OFF-LINE, but since the equipment will not attempt to send messages except as mentioned in the previous paragraph[12], no messages will enter the spool.

OFF-LINE has three substates: EQUIPMENT OFF-LINE, ATTEMPT ON-LINE, and HOST OFF-LINE.

OFF-LINE/EQUIPMENT OFF-LINE

While this state is active, the system maintains the OFF-LINE state. It awaits operator instructions to attempt to go ON-LINE.

OFF-LINE/ATTEMPT ON-LINE

While the ATTEMPT ON-LINE state is active, the equipment has responded to an operator instruction to attempt to go to the ON-LINE state. Upon activating this state, the equipment attempts to send an S1,F1 to the host.

Note that when this state is active, the system does not respond to operator actuation of either the ON-LINE or the OFF-LINE switch.

10 Sending of S1,F13 is based upon the COMMUNICATIONS state model.

11 S9,Fx messages may be issued only in response to the messages to which the equipment will normally respond while OFF-LINE (i.e. S1,F13 and S1,F17).

12 The equipment may send S1,F1 or S1,F13, but since Stream 1 messages are not eligible for spooling, they will not enter the spool either.

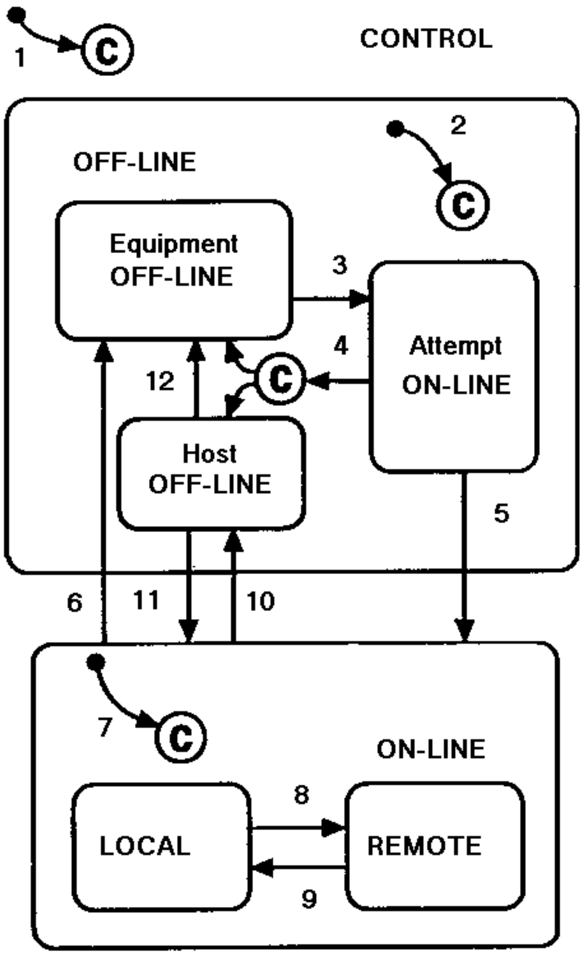

Figure 3.3
CONTROL State Model

OFF-LINE/HOST OFF-LINE

While the HOST OFF-LINE state is active, the operator's intent is that the equipment be ON-LINE. However, the host has not agreed. Entry to this state may be due to a failed attempt to go ON-LINE or to the host's request that the equipment go OFF-LINE from ON-LINE (see the transition table for more detail). While this state is active, the equipment shall positively respond to any host's request to go ON-LINE (S1,F17). Such a request shall be denied when the HOST OFF-LINE state is not active.

ON-LINE

While the ON-LINE state is active, SECS-II messages may be exchanged and acted upon. Capabilities that may be available to the host should be similar to those available from the operator console wherever practical.

The use of Sx,F0 messages is not required while the ON-LINE state is active. Their use is discouraged in this case. The only allowed use is to close open transactions in conjunction with message faults.

ON-LINE/LOCAL

Operation of the equipment is implemented by direct action of an operator. All operation commands shall be available for input at the local operator console of the equipment.

The host shall have the following capabilities and restrictions when the LOCAL state is active:

— The host shall be prohibited from the use of remote commands that cause physical movement or which initiate processing. During processing, the host shall be prohibited from the use of any remote command that affects that process.

— During processing, the host shall be prohibited from modifying any equipment constants that affect that process. Other equipment constants shall be changeable during processing. The host shall be able to modify all available equipment constants when no processing is in progress.

— The host shall be capable of initiating the upload and download of recipes to/from the recipe storage area on the equipment. The host shall be capable of selecting recipes for execution so long as this action does not affect any currently executing recipe.

— The host shall be able to configure automatic data reporting capabilities including alarms, event reporting, and trace data reporting. The host shall receive all such reports at the appropriate times.

— The host shall be able to inquire for data from the equipment, including status data, equipment constants, event reports, process program directories, and alarms.

— The equipment shall be able to perform Terminal Services as defined in GEM.

The host shall be allowed any other capabilities that were not specifically restricted in the above items as long as the LOCAL state is active.

NOTE 2: Capabilities mentioned above which are not implemented on a specific equipment may be ignored in this context.

ON-LINE/REMOTE

For equipment which supports the GEM capability of remote control (see Section 4.4), while the REMOTE state is active, the host shall have access, through the communications interface, to the necessary commands to operate the equipment through the full process cycle in an automated manner. The equipment does not restrict any host capabilities when REMOTE is active. The degree of control executed by the host may vary from factory to factory. In some cases, the operator maybe required to interact during remotely controlled processes. This interaction may involve set-up operations, operator assist situations, and others. This state is intended to be flexible enough to accommodate these different situations.

To support the different factory automation policies and procedures, it shall be possible to configure the equipment to restrict the operator in specific non-emergency procedures. These restrictions shall be configurable so that the equipment may be set up to allow the operator to perform necessary functions without contention with the host. The categories for configuration shall include (but are not limited to):

— change equipment constants (process-related),

— change equipment constants (non-process-related),

— initiate process program download,

— select process program,

— start process program,

— pause/resume process program,

— operator assist,

— material movement to/from equipment,

— equipment-specific commands (on a command-by-command basis if needed).

NOTE 3: Capabilities mentioned above which are not implemented on a specific equipment may be ignored in this context.

No capabilities that are available to the operator when the LOCAL state is active should be unconditionally restricted when the REMOTE state is active. The supplier may provide for configurable restriction of operator capabilities not included in the list above if desired. No configurability is necessary for any operator functions not available to the host.

The control functions must be shared to some degree between the host and the local operator. At the very least, the operator must have the capability to change the CONTROL state, actuate an Emergency Stop, and interrupt processing (e.g., STOP, ABORT, or PAUSE). All of these capabilities except Emergency Stop may be access-limited.[13]

The host software should be designed to be compatible with the capabilities allotted to the operator.

13 Definition of the method of limiting operator access (password, key, etc.) to a capability is not within the scope of this document.

Table 3.3 CONTROL State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comments*
1	(Undefined)	Entry into CONTROL state (system initialization).	CONTROL (Substate conditional on configuration).	None	Equipment may be configured to default to ON-LINE or OFF-LINE . (See NOTE 1.)
2	(Undefined)	Entry into OFF-LINE state.	OFF-LINE (Substate conditional on configuration.)	None	Equipment may be configured to default to any substate of OFF-LINE.
3	EQUIPMENT OFF-LINE	Operator actuates ON-LINE switch.	ATTEMPT ON-LINE	None	Note that an S1,F1 is sent whenever ATTEMPT ON-LINE is activated.
4	ATTEMPT ON-LINE	S1,F0.	New state conditional on configuration.	None	This may be due to a communication failure (See NOTE 2), reply timeout, or receipt of S1,F0. Configuration may be set to EQUIPMENT OFF-LINE or HOST OFF-LINE.
5	ATTEMPT ON-LINE	Equipment receives expected S1,F2 message from the host.	ON-LINE	None	Host is notified of transition to ON-LINE at transition 7.
6	ON-LINE	Operator actuates OFF-LINE switch.	EQUIPMENT OFF-LINE	None	"Equipment OFF-LINE" event occurs. (See NOTE 3.) Event reply will be discarded while OFF-LINE is active.
7	(Undefined)	Entry to ON-LINE state.	ON-LINE (Substate conditional on REMOTE/LOCAL switch setting.)	None	"Control State LOCAL" or "Control State REMOTE" event occurs. Event reported based on actual ON-LINE substate activated.
8	LOCAL	Operator sets front panel switch to REMOTE.	REMOTE	None	"Control State REMOTE" event occurs.
9	REMOTE	Operator sets front panel switch to LOCAL.	LOCAL	None	"Control State LOCAL" event occurs.
10	ON-LINE	Equipment accepts "Set OFF-LINE" message from host (S1,F15).	HOST OFF-LINE	None	"Equipment OFF-LINE" event occurs.
11	HOST OFF-LINE	Equipment accepts host request to go ON-LINE (S1,F17).	ON-LINE	None	Host is notified to transition to ON-LINE at transition 7.
12	HOST OFF-LINE	Operator actuates OFF-LINE switch.	EQUIPMENT OFF-LINE	None	"Equipment OFF-LINE" event occurs.

NOTE 1: The configuration mentioned for transitions 1 and 2 should be a single setting. This would provide the user with a choice of entering the EQUIPMENT OFF-LINE, ATTEMPT ON-LINE, HOST OFF-LINE, or ON-LINE states.

NOTE 2: Communication failures are protocol specific. Refer to the appropriate protocol standard (e.g., SEMI E4 or SEMI E37) for a protocol-specific definition of communication failure.

NOTE 3: Any host initiated transaction open at the equipment must be completed. This may happen either by sending the appropriate reply to the host prior to sending the event message or by sending an Sx,F0 message following the event message (i.e., after the transaction).

3.4 *Equipment Processing States* — The behavior of the equipment in the performance of its intended function must be documented. This processing state model is highly dependent on the equipment process, technology, and style. However, there are expected to be common aspects to these models.

The Processing State Diagram, Figure 3.4, is provided as an example of an implementation model. This model demonstrates the expected nature of the processing state model documentation. There is no requirement that these specific states be implemented.

The equipment must generate collection events for each processing state transition, as well as provide status variables (ProcessState, PreviousProcessState) whose values are the current processing state and the previous processing state.

In referring to the Processing State Diagram, note that the initialization state INIT is not an actual processing state. It is shown here simply to indicate that the IDLE processing state is entered upon completion of equipment system initialization. On the following pages detailed descriptions are provided for the equipment processing states and state transitions (numbered) as shown in the diagram.

3.4.1 *Description of Equipment Processing States*

IDLE

In this state the equipment is awaiting instructions.

PROCESSING ACTIVE

This state is the parent of all substates where the context of process program execution exists.

PROCESS

This state is the parent of those substates that refer to the active preparation and execution of a process program.

SETUP

In this state all external conditions necessary for process execution are satisfied, such as ensuring material is present at the equipment, input/output ports are in the proper state, parameters such as temperature and pressure values are within limits, etc. If all setup operations are already complete, then this becomes a fall through state and a transition to the next state takes place.

READY

In this state the equipment is ready for process execution and is awaiting a START command from the operator or the host.

EXECUTING

Executing is the state in which the equipment is executing a process program automatically and can continue to do so without external intervention.

PAUSE

In this state processing is suspended and the equipment is awaiting a command.

Each state transition is defined in the following table. Note that all transitions in this table should be considered collection events.

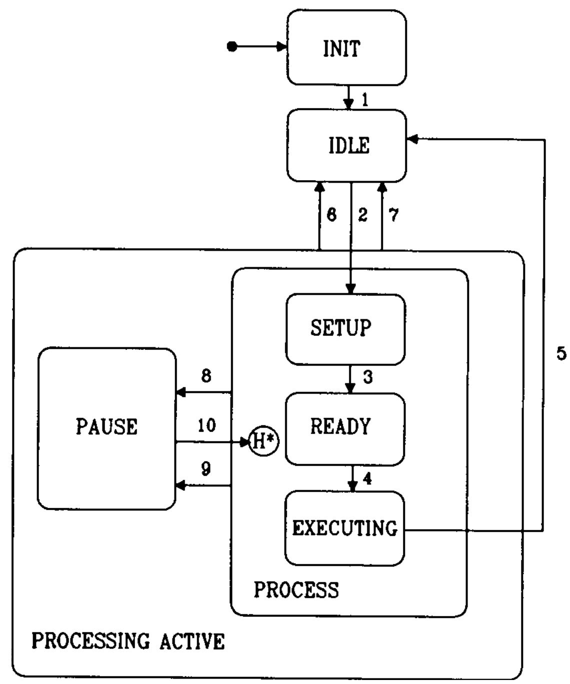

Figure 3.4
Processing State Diagram

Table 3.4 Processing State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comments*
1	INIT	Equipment initialization complete.	IDLE	None	None
2	IDLE	Commit has been made to set up.	SETUP	None	None
3	SETUP	All setup activity has completed and the equipment is ready to receive a START command.	READY	This activity is equipment-specific.	None
4	READY	Equipment has received a START command from the host or operator console.	EXECUTING	This activity is equipment-specific.	None
5	EXECUTING	The processing task has been completed.	IDLE	None	None
6	PROCESSING ACTIVE	Equipment has received a STOP command from host or operator console.	IDLE	None	None
7	PROCESSING ACTIVE	Equipment has received an ABORT command from host or operator console.	IDLE	This activity is equipment-specific.	None
8	PROCESS	The equipment decides to PAUSE due to a condition such as alarm.	PAUSE	This activity is equipment-specific.	For this type of problem, an operator assist is usually required.
9	PROCESS	Equipment has received a PAUSE command from host or operator console.	PAUSE	This activity is equipment-specific.	None
10	PAUSE	Equipment has received a RESUME command from host or operator console.	Previous PROCESS substate	This activity is equipment-specific.	None

4 Equipment Capabilities and Scenarios

This section describes the details of the capabilities required by GEM and provides scenarios for their use. Capabilities are operations performed by semiconductor manufacturing equipment. These operations are initiated through the communications interface using SECS-II messages. A scenario is a group of SECS-II messages arranged in a sequence to perform a capability. Other information may be included with the scenario for clarity. For each capability, the reader is provided with a statement of purpose, pertinent definitions, a detailed description, requirements, and scenarios.

The following capabilities are discussed:

Establish Communications

Event Notification

Dynamic Event Report Configuration

Variable Data Collection

Trace Data Collection

Limits Monitoring

Status Data Collection

On-line Identification

Alarm Management

Remote Control

Equipment Constants

Process Program Management

Material Movement

Equipment Terminal Services

Error Messages

Clock

Spooling

Control

4.1 *Establish Communications* — The Establish Communications capability provides a means of formally establishing communications following system initialization or any loss of communications between communicating partners, and thus of notifying the communication partner that a period of non-communication has occurred.

4.1.1 *Purpose* — Communications between host and equipment are formally established through use of the Establish Communications Request/Establish Communications Acknowledge transaction.

The use of S1,F1/F2 for this purpose is ambiguous since the transaction can be used for other purposes and may occur at any time.

The S1,F13/F14 transaction, used in conjunction with the Communications State Model, provides a means for equipment to notify the host, or the host to notify the equipment, that there has been a period of inability to communicate. The successful completion of this transaction also signals a possible need for synchronization activities between host and equipment.

4.1.2 *Definitions*

COMMACK — Acknowledge code returned in the Establish Communications Acknowledge message. See the SEMI E5 Standard for a full definition of this data item.

EstablishCommunicationsTimeout — An equipment constant used to initialize the interval between attempts to re-send an Establish Communications Request. This value specifies the number of seconds for the interval. See the SEMI E5 Standard for a full definition of this variable data item.

4.1.3 *Description* — There are potential problems when one side of the communications link fails and the other side does not detect it. From the point of view of the host, a loss of communications has many possible causes. In some cases, host-controlled settings on the equipment may need to be reset. In other cases, the equipment may have continued an automatic processing sequence during the period of no communication and may have changed states. The definition of a formal protocol for establishing communications alerts the host to the need to synchronize itself with the equipment's current status.

Equipment shall consider communications as formally established whenever either of the following conditions have been satisfied:[14]

— Communications Request has been sent to the host and an Establish Communications Acknowledge has been received within the transaction timeout period and with an acknowledge code of Accept, or

— Communications Request has been received from the host, and an Establish Communications Acknowledge response has been successfully sent with an acknowledge code of Accept.

When the equipment sends an Establish Communications Request to the host, this notifies the host of the possible need to synchronize itself with the equipment.

When the equipment is attempting to establish communications, an Establish Communications Request shall be sent periodically until communications have been formally established as described above. The interval between attempts must be user-configurable and begins as soon as a connection transaction failure is detected (see Section 3.2).

Attempting to establish communications is not a low-level connectivity issue, but rather a logical application issue used by either party to notify its partner that the host may need to perform synchronization activities with the equipment.

4.1.4 *Requirements*

— Equipment must support the Communication State Model (see Section 3.2).

— Equipment must provide the EstablishCommunicationsTimeout equipment constant described above.

14 Satisfaction of either of these conditions will result in a transition to the COMMUNICATING substrate. See Section 3.2 for further detail.

4.1.5 *Scenarios*

4.1.5.1 *Host Attempts to Establish Communications*

                                                         Timeout
                                                  [ENDIF]
                                                  [END_LOOP]--SEND
                                                  [IF] COMMACK = Accept
                                                  [THEN] Communications state=
                                                         Communicating
                                                         exit_loop--
                                                  [ELSE] Reset timer for delay,
                                                         and delay for interval
                                                         specified in
                                                         EstablishCommunications—
                                                         Timeout
                                                  [ENDIF]
                                                  [END_LOOP]
```

4.1.5.3 *Simultaneous Attempts to Establish Communications* — For equipment that supports interleaving, it is possible that either the host or equipment could send an Establish Communications Request before receiving the request from its partner. As communications are established by the successful acceptance of any one Establish Communications Request, it is immaterial who sends the request first. The roles of host and equipment may be reversed.

Equipment Receives S1,F14 From Host Before Sending S1,F14:

COMMENT	**HOST**	**EQUIPMENT**	**COMMENT**
Communications State = NOT COMMUNICATING			
		<--S1,F13	Establish Communications Request
Establish Communications Request	S1,F13-->		
Reply COMMACK = Accept	S1,F14-->		S1,F14 received from Host and Communications established[15] and Communications state = COMMUNICATING
		<--S1,F14	Reply COMMACK = Accept[16]

Equipment Sends S1,F14 To Host Before Receiving S1,F14:

COMMENT	**HOST**	**EQUIPMENT**	**COMMENT**
Communications State = NOT COMMUNICATING			
		<--S1,F13	Establish Communications Request
Establish Communications Request	S1,F13-->		
		<--S1,F14	Reply COMMACK = Accept[15] Communications established[15] and Communications state = COMMUNICATING
Reply COMMACK = Accept	S1,F14-->		S1,F14 received from Host

4.2 *Data Collection* — Data collection allows the host to monitor equipment activity via event reporting, trace data reporting, limits monitoring, and query of selected status or other variable data.

4.2.1 *Event Data Collection* — Event data collection provides a dynamic and flexible method for the user to tailor the equipment to meet individual needs with respect to data representation and presentation to the host. The event-based approach to data collection provides automatic notification to the host of equipment activities and is useful in monitoring the equipment and in maintaining synchronization with the equipment.

Event data collection may be broken into two logical parts: host notification when an event occurs and dynamic configuration of the data attached to the event notification.

4.2.1.1 *Event Notification* — This section describes the method of notifying the host when equipment collection events occur.

4.2.1.1.1 *Purpose* — This capability provides data to the host at specified points in equipment operation. This asynchronous reporting eliminates the need for the host to poll the equipment for this information. Events on the equipment may trigger activity on the part of the host. Also, knowledge of the occurrence of events related to

15 Communications are establisted at the successful completion of the S1,F13/14 transaction where COMMACK is set to zero.

16 Communications are established on the successful transmission of S1,F14, even if there is an open S1,F13.

the equipment state models allows the host to track the equipment state. An equipment's behavior is related to its current state. Thus, this capability helps the host understand how an equipment will behave and how it will react to host behavior.

4.2.1.1.2 *Definitions*

Collection Event — An event (or grouping of related events) on the equipment that is considered significant to the host.

Collection Event ID (CEID) — A unique identifier of a collection event. See the SEMI E5 Standard for a full definition of this data item.

Event — A detectable occurrence significant to the equipment.

Report — A set of variables predefined by the equipment or defined by the host via S2,F33/F34.

4.2.1.1.3 *Detailed Description* — The equipment supplier must provide a set of predefined collection events. Specific collection events are required by individual capabilities and state models. Examples of collection events include:

— The completion of each action initiated by a host requested command,

— Selected processing and material handling activities,

— Operator action detected by the equipment,

— A state transition,

— The setting or clearing of an alarm condition on the equipment, and

— Exception conditions not considered alarms.

See Section 6 for a list of required collection events.

The reporting of a collection event may be disabled per event by the user to eliminate unwanted messages. An event report message shall be sent to the host upon the occurrence of a particular collection event if the collection event (CEID) has been enabled. Attached to each event message is one or more event reports which contain variable data. Section 4.2.1.2 describes the capability which allows for the dynamic customization of event reports. The values of any data contained in an event report message must be current upon the occurrence of the event. This implies that event reports be built at the time of the event occurrence.

The equipment shall also provide the S6,F15/F16 transaction to allow the host to request the data from a specific event report.

4.2.1.1.4 *Requirements*

— The equipment supplier shall provide documentation of all collection events defined on the equipment and the conditions for each event to occur.

— The equipment supplier shall provide unique CEIDs for each of the various collection events that are available for reporting.

— The equipment supplier shall provide a method for enabling and disabling the reporting of each event. This method shall either be available via the host interface (see Section 4.2.1.2) or the equipment's operator console.

— For each event, the equipment supplier shall provide either

- a default set of report(s) linked to the event which contain data pertinent to that event, or
- the ability for the user to configure the data linked to that event via the equipment's operator console or host interface (see Section 4.2.1.2).

4.2.1.1.5 *Scenarios*

Collection Event Occurs on the Equipment:

```
COMMENT                            HOST    EQUIPMENT                        COMMENT

                                                    [IF] Event Report is Multi-block
                                           <--S6,F5    [THEN] send Multi-block inquire
Multi-block grant                 S6,F6-->
                                                    [ENDIF]
                                           <--S6,F11   Equipment sends Event Report
Host acknowledges Event Report S6,F12-->
```

Host Requests Event Report:

```
COMMENT                           HOST    EQUIPMENT                          COMMENTS

Host requests an event report S6,F15-->
                                         <--S6,F16    Equipment sends event report.
```

4.2.1.2 *Dynamic Event Report Configuration* — This section describes a capability which allows the host to dynamically modify the equipment event reporting setup.

4.2.1.2.1 *Purpose* — This capability is defined to provide the data reporting flexibility required in some manufacturing environments. It allows the host to increase or decrease the data flow according to need. For example, if the performance of an equipment degrades, the data flow from that equipment may be increased to help diagnose the problem.

4.2.1.2.2 *Definitions*

EventsEnabled — A variable data item that consists of a list of currently enabled collection events (CEIDs). See SEMI E5 for a full definition of this variable data item.

Report ID (RPTID) — A unique identifier of a specific report. See SEMI E5 for a full definition of this data item.

Variable Data (V) — A data item containing status (SV), data (DVVAL), or constant (ECV) values. See SEMI E5 for a full definition of this data item.

Variable Data ID (VID) — A unique identifier of a variable data item. The set of VID's is the union of all SVID's, ECID's, and ID's for DVVAL's (DVNAME's). See SEMI E5 for a full definition of this data item.

4.2.1.2.3 *Detailed Description* — The equipment shall support the following event report configuration functionality through the SECS-II interface:

— Host definition/deletion of custom reports,

— Host linking/unlinking of defined reports to specified collection events, and

— Host enabling/disabling the reporting of specified collection events.

NOTE 4: The equipment may also supply alternative means for defining reports and linking reports to events (e.g., via the operator console). Implementation of alternate means is not required.

The equipment can be instructed by the host to enable or disable reporting of collection events on an individual or collective basis. A status value (SV) shall be available that consists of a list of enabled collection events. (See Section 5.2, Variable Item List, EventsEnabled variable.)

Reports may be attached to an event report message (S6,F11). These reports are specifically linked to the desired event and typically contain variable data relating to that event. The reports may be provided by the equipment supplier or created by the user. The user must be able to create reports and link them to events via the SECS-II interface.

The data reported in the event report messages may consist of Status Values (SV's), Equipment Constant Values (ECV's), or Data Values (DVVAL's). Note that data values shall be valid and current on certain events and certain states and might not be current at other times. The implementor shall document when a data value will be current and available for reporting.

4.2.1.2.4 *Requirements*

— The equipment manufacturer must provide documentation of all variable data available from the equipment. This is to include variable name, variable type or class (SV, ECV, DVVAL), units, format codes, possible range of values, and a description of the meaning and use of this variable.

— The equipment manufacturer must provide unique VIDs for the various variable data (V) available for data collection in the equipment. For example, this means that no SV shall have a VID which is the same as the VID of any ECV or DVVAL.

— All variable data must be available for report definition and event data collection. See Section 5.2, Variable Item List, for a list of required variable data.

— All report definitions, report-to-event links, and enable/disable status of event reports must be retained in non-volatile storage.

4.2.1.2.5 *Scenario*

Collection Event Reporting Set-up:

```
COMMENT                                 HOST   EQUIPMENT                        COMMENT

                                                     specified reports when the
                                                     appropriate collection events
                                                     happen
```

4.2.2 *Variable Data Collection*

4.2.2.1 *Purpose* — This capability allows the host to query for the equipment data variables and is useful during initialization and synchronization.

4.2.2.2 *Definitions*

Report ID (RPTID) — A unique identifier of a specific report. See SEMI E5 for a full definition of this data item.

Variable Data (V) — A variable data item containing status, discrete, or constant data. See SEMI E5 for a full definition of this data item.

4.2.2.3 *Detailed Description* — The host may request a report containing data variables from the equipment by specifying the RPTID. It is assumed that the report has been previously defined (e.g., using the Define Report S2,F33 transaction (see Section 4.2.1)). The values of any status variables (SV's) and equipment constants (ECV's) contained within the report must be current. Discrete data values (DVVAL's) are only guaranteed to be valid upon the occurrence of a specific collection event. If DVVAL cannot be specified in equipment due to some restrictions depend on hardware and/or software conditions, the zero length item is reported.

4.2.2.4 *Requirements*

— Variable data items (V's) and associated units of measure must be provided by the equipment manufacturer.

17 Define Report Acknowledge Code, see SEMI E5 for full definition of this Data Item.

4.2.2.5 *Scenario*

Host Requests Report:

```
COMMENT                            HOST   EQUIPMENT                          COMMENT

Host requests data variables
contained in report RPTID     S6,F19-->
                                       <--S6,F20     Equipment responds with a list of
                                                     variable data for the given
                                                     RPTID.
```

4.2.3 *Trace Data Collection*

4.2.3.1 *Purpose* — Trace data collection provides a method of sampling data on a periodic basis. The time-based approach to data collection is useful in tracking trends or repeated applications within a time window, or monitoring of continuous data.

4.2.3.2 *Definitions*

Data Sample Period (DSPER) — The time delay between samples. See SEMI E5 for a full definition of this data item.

Reporting Group Size (REPGSZ) — The number of samples included per trace report transmitted to the host. See SEMI E5 for a full definition of this data item.

Status Variable (SV) — Status data item (included in trace report). See SEMI E5 for a full definition of this data item.

Status Variable ID (SVID) — A unique identifier of a status variable. See SEMI E5 for a full definition of this data item.

Total Samples (TOTSMP) — Number of samples to be taken during a complete trace period. See SEMI E5 for a full definition of this data item.

Trace Request ID (TRID) — An identifier associated with a trace request definition. See SEMI E5 for a full definition of this data item.

4.2.3.3 *Detailed Description* — The equipment shall establish a trace report as instructed by the host (S2,F23). For a trace report (S6,F1), the host shall designate a name for the trace report (TRID), a time interval for data sampling (DSPER), the total number of samples to be taken (TOTSMP), the number of samples per trace report (REPGSZ), and a listing of which data will be sent with the report (SVID's). The number of trace reports sent to the host is determined by total samples divided by reporting group size (TOTSMP/REPGSZ).

The equipment shall sample the specified data (SV's) at the interval designated by the host (DSPER) and shall send a predefined trace report to the host for the specified reporting group size (REPGSZ). The trace report definition shall be automatically deleted from the equipment after the last trace report has been sent.

The host may modify or re-initiate a trace function currently in progress by specifying the same TRID in a trace request definition, at which point the old trace shall be terminated and the new trace shall be initiated, or the host can instruct the equipment to terminate a trace report prior to its completion by specifying TOTSMP = 0 for that TRID, at which point the trace report definition shall be deleted.

A detailed example is included as Application Note A.4.

4.2.3.4 *Requirements*

— The equipment must have a local mechanism (e.g., internal clock) for triggering the periodic sampling and transmission of trace reports to the host.

— A minimum of four (4) concurrent traces shall be supported by the equipment. The same SVID may be collected in multiple traces simultaneously.

— All SVID's available at the equipment shall be supported for trace data collection. The exception to this is any SV that will not fit into a single block.

NOTE 5: SEMI E5 provides for SV's to be of a list format. Since this may in practice be a variable list, there is a potential problem with such an SV supported by the Trace Data Collection capability. This is a problem with the SEMI E5 standard. Care should be exercised in the use of SV's using the list format.

4.2.3.5 *Scenario*

Host Initiates Trace Report:

```
COMMENT                            HOST  EQUIPMENT                      COMMENT

Trace Data initialization
requested                     S2,F23-->
                                      <--S2,F24     Acknowledge, trace initiated
                                                    [DO] TOTSMP REPGSZ times
                                                    [DO] REPGSZ many times: collect
                                                    SVID1,...SVIDn data, delay
                                                    time by DSPER.
                                                    [END_DO]
                                      <--S6,F1      Send SV1,...SVn
Acknowledge receipt            S6,F2-->
                                                    [END_DO]
Optional:
Request trace termination prior to
completion (TOTSMP = 0)       S2,F23-->
                                      <--S2,F24     Acknowledge premature termination
```

4.2.4 *Limits Monitoring* — This capability relates to the monitoring of selected equipment variables and has three primary aspects:

— Defines a standard set of monitoring zones and limits.

— Provides for reporting to the host when selected equipment variables transition between monitoring zones.

— Empowers the host to modify the values of the variable limit attributes for these same selected equipment variables.

4.2.4.1 *Purpose* — The limits monitoring capability provides the host a means of monitoring equipment conditions by a flexible, efficient, and asynchronous method which is consistent across equipment. It eliminates the need for constant polling of equipment by the host for current status values. Further, this capability allows the host to implement changes in the monitoring range as needed. This capability has application to both production operation and diagnostic/testing scenarios, and it also has applicability to statistical process control.

4.2.4.2 *Definitions*

LimitVariable — DVVAL containing the VID of a specific equipment variable for which a zone transition collection event has been generated.

EventLimit — DVVAL containing the LIMITID of the limit crossed by LimitVariable.

TransitionType — DVVAL which defines the direction of the zone transition which has occurred: 0 = transition from lower to upper zone, 1 = transition from upper to lower zone.

Limit — Used in this section to represent the set of variable limit attributes that completely describe a variable monitoring "barrier." The attributes include VID, Units, UPPERDB, LOWERDB, LIMITMAX, and LIMITMIN. In some contexts it may be interpreted more narrowly as the combination of UPPERDB and LOWERDB.

$LIMITID_n$ — Refers to the identifier of a specific limit (as defined by UPPERDB and LOWERDB) among the set of limits for a monitored equipment variable. LIMITIDs are consecutively numbered, beginning at one through the number of limits possible (seven minimum).

Monitoring Zone — A subset of the possible range of values for a variable of interest to the host. A single limit divides the range into two zones. Multiple limits may be combined to divide the range even further.

Zone Transition — The movement of a variable value from one monitoring zone to another. This transition is a collection event and has a corresponding CEID.

Deadband — An overlap of two zones implemented to prevent constant zone transitions by a variable sitting on or near a limit (i.e., "chattering").

UPPERDB — A variable limit attribute that defines the upper boundary of the deadband of a limit.[18] The value applies to a single limit (LIMITID) for a specified VID.

18 The format and units must be the same as the format of the variable being monitored.

Thus, UPPERDB and LOWERDB as a pair define a limit.

LOWERDB — A variable limit attribute that defines the lower boundary of the deadband of a limit.[18] The value applies to a single limit (LIMITID) for a specified VID. Thus, UPPERDB and LOWERDB as a pair define a limit.

UPPER ZONE — The range of values lying above a limit.

LOWERZONE — The range of values lying below a limit.

LIMITMAX — The maximum value for any limits of a specific equipment variable. This value is set by the equipment manufacturer and typically coincides with the maximum value allowed for the monitored variable.

LIMITMIN — The minimum value for any limits of a specific equipment variable.[19] This value is set by the equipment manufacturer and typically coincides with the minimum value allowed for the monitored variable.

Undefined — When used in reference to variable limits, it indicates that monitoring/reporting of zone transitions involving that particular limit are disabled.

4.2.4.3 *Description* — The limits monitoring capability provides the host with a minimum of seven configurable limits or barriers that may be applied to selected equipment status variables (SV's) of the types floating point, integer, and boolean. When one of these barriers is crossed, a collection event is generated to alert the host to a change in monitoring zone or state of the monitored variable. These seven limits may be combined in a variety of ways to match the needs of the host system.[19] An illustration of a combination of five of the limits to provide one type of variable monitoring is shown in Figure 4.2.1.[20] This section describes the key aspects of limits monitoring. Detailed implementation examples of limits monitoring are provided as Application Note A.7.

NOTE 6: While the SEMI E5 standard allows SV's to be lists, such variable lists are not allowed under this capability.

4.2.4.3.1 *Monitoring Limit Characteristics* — A limit is defined by a set of attributes that include the variable (VID) to which the limit corresponds, the units of that variable, the maximum and minimum possible values of the limit (LIMITMAX and LIMITMIN) and the specific borders of the limit (UPPERDB and LOWERDB). See Figure 4.2.2. There is a limitation to the values of UPPERDB and LOWERDB which may be stated as:

LIMITMAX≥UPPERDB≥LOWERDB≥LIMITMIN

A limit divides the possible range of variable values into two parts, the upper zone and the lower zone. At any time, the monitored variable is considered to be in one and only one of these zones. However, as Figure 4.2.2 shows, these two zones have an area of overlap. This is called the deadband.

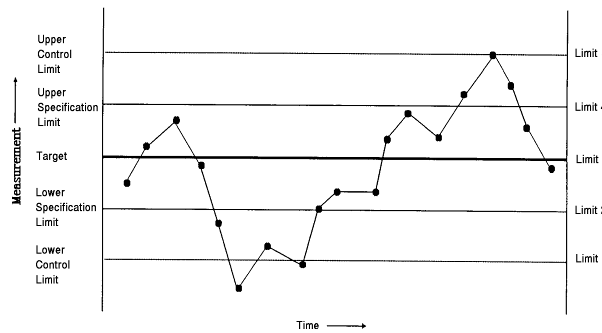

Figure 4.2.1
Limit Combination Illustration: Control Application

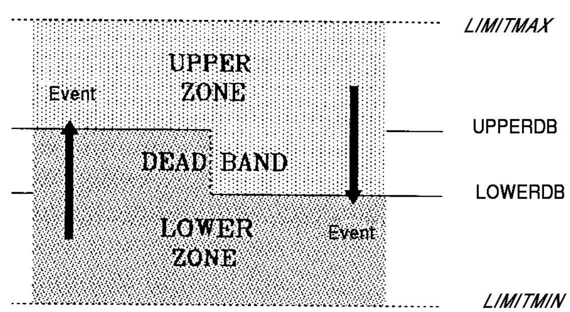

Figure 4.2.2
Elements of One Limit

The deadband is a key concept of limits monitoring, especially for floating point variables. Its purpose is to prevent a phenomenon known as chattering — the repeated changing of zones due to small, rapid fluctuations in variable value while near the zone boundary. In practice, the value of a variable must reach the opposite boundary of the deadband before a zone transition can occur. Thus, if a variable's value reaches the UPPERDB and transitions into the upper zone, it will not return to the lower zone until it falls back to the

19 Note that while at least seven limits per variable are available from the equipment, the host need not use all seven.

20 This illustration shows the reading which might be available to the equipment, not the limit excursions reported to the host. Reporting is covered later in the section.

LOWERDB. The difference between UPPERDB and LOWERDB should always be greater than the typical amplitude of those fluctuations deemed to be insignificant. In some cases, the width of the deadband may set to zero (i.e., UPPERDB = LOWERDB). At first glance, this would seem to make indeterminate the current zone when an integer value sits on the limit. This is not the case, however, when movement of the value is considered. To illustrate, an example is given, assuming that UPPERDB = LOWERDB = 100. The list shows consecutive readings of the variable and the resultant zone:

99 Lower Zone (Initial Reading)

101 Upper Zone (Zone Transition)

100 Lower Zone (Zone Transition)

100 Lower Zone

99 Lower Zone

100 Upper Zone (Zone Transition)

Transition from one zone into another generates a collection event, as might be reported via S6,F11. The host has the option of receiving notification by enabling event reporting for the event. For each variable that has monitoring capability, one CEID is reserved to indicate zone transitions for that variable. To aid in the determination of the nature of a transition event, three DVVAL's have been defined:

LimitVariable — The VID of the monitored variable to which the collection event refers.

EventLimit — Contains the LIMITID of the limit reached or crossed by LimitVariable.

TransitionType — Defines the direction of the zone transition which has occurred: 0 = transition from lower to upper zone, 1 = transition from upper to lower zone.

Sampling frequency is an important element of limits monitoring and should be considered during equipment specification. If changes in variable value are relatively fast compared to sampling frequency, it is possible for some zone transitions to be missed or for multiple zone transitions to occur between readings. Since it is possible for zone transitions to occur "simultaneously" or for limits to be identically defined, the DVVAL EventLimit has been defined to allow for a list of multiple zone transitions of a variable to be reported with a single collection event.

It also should be emphasized that a single CEID is used to report transitions in both directions across a limit. Thus, reporting for one direction but not the other cannot be configured.

The functionality of each limit for each variable can be described with the state model shown in Figure 4.2.3. Below, the three states are described more fully, followed by a table defining the transitions.

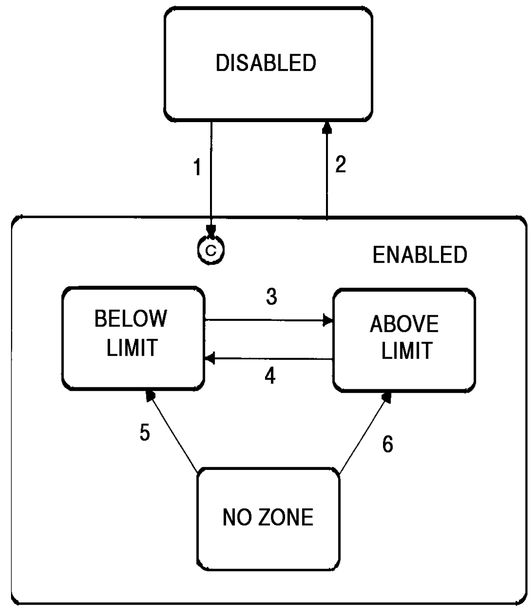

Figure 4.2.3
Limit State Model

ABOVE LIMIT

A variable is considered to be above a limit when its value increases to equal or exceed the upper boundary of the deadband, UPPERDB. The significance attached to this state is a function of the host's usage.

BELOW LIMIT

A variable is considered to be below a limit when its value decreases to equal or fall below the lower boundary of the deadband, LOWERDB. The significance attached to this state is a function of the host's usage.

NO ZONE

In some circumstances it is possible for the variable value to be in neither the upper zone nor the lower zone. This may occur upon definition of a new limit or upon equipment startup when the value of the variable lies in the deadband. In this case, the active state of the limit is considered to be NO ZONE. The limit shall remain in this state until the variable value reaches either boundary of the deadband.

4.2.4.3.2 *Modification of Limit Values* — Values for the monitoring limits on any monitored variable may be modified by the host using the message transaction

S2,F45/F46 (Define Variable Limit Attributes). The equipment must reject any S2,F45 message which contains limit information which conflicts with the following rules:

— LIMITMAX≥UPPERDB≥LOWERDB≥LIMITMIN;

— If either UPPERDB or LOWERDB is defined, both must be defined; if either UPPERDB or LOWERDB is undefined, both must be undefined.

The first rule is defined and graphically depicted in Figure 4.2.2. The second rule refers to the host's ability to turn any limit "on" or "off". While a minimum of seven limits must be available for each monitored variable, it will be common for the host application to require less than seven or even none of the limits be used. The limits not needed can be disabled by leaving the values for UPPERDB and LOWERDB "undefined". Limits may be disabled for a VID or for all monitored VIDs by using zero length lists in the S2,F45 message.

All monitored variables must be one of three types: integer, floating point, or Boolean. This may be accomplished by using the following formats: 11, 20, 3(), 4(), 5().

NOTE 7: The binary format is not allowed. If the ASCII format is used, the equipment shall perform a conversion into one of the numeric types before performing any value comparisons, both for limit validations and zone transitions.

4.2.4.3.3 *Limit Values Request* — The host may request the current limit values for a specified VID using the message transaction S2,F47/F48 (Variable Limit Attribute Request).

4.2.4.4 *Requirements*

— A minimum of seven limits per monitored variable must be available.

— One CEID per monitored variable must be supplied for zone transition reporting.

— All limit definitions must be kept in non-volatile storage.

— The equipment must enforce the limit validation rules defined above.

— The specification and documentation of which variables may be monitored with this capability is the responsibility of the equipment manufacturer based on the specific instance of equipment. This subject also may be addressed by equipment models of classes of semiconductor equipment.

Table 4.2 Limit State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	DISABLED	Limit attributed defined w/ S2,F45.	ENABLED	None	The substate of ENABLED is determined by the current value of the monitored variable.
2	ENABLED	Limit attributes set to undefined w/ S2,F45.	DISABLED	None	None
3	BELOW LIMIT	Variable Increased to be ≥UPPERDB	ABOVE LIMIT	None	Zone Transition.
4	ABOVE LIMIT	Variable decreases to be ≤LOWERDB	BELOW LIMIT	None	Zone Transition.
5	NO ZONE	Variable decreases to be ≤LOWERDB	BELOW LIMIT	None	Zone Transition.
6	NO ZONE	Variable increases to be ≥UPPERDB	ABOVE LIMIT	None	Zone Transition.

4.2.4.5 *Scenarios* — Zone Transition Event occurs in equipment:

```
COMMENTS                          HOST   EQUIPMENT                          COMMENTS

Send enabled event report to host as shown in Section 4.2.1.
```

Host defines Limit Attributes:

```
COMMENTS                          HOST   EQUIPMENT                          COMMENTS

[IF] S2,F45 is Multi-block
[THEN] Send Multi-block inquire S2,F39-->
                                        <--S2,F40    Multi-block grant.
[END IF]
Host defines new variable limit
attributes.                     S2,F45-->
                                        <--S2,F46    Equipment acknowledges host
                                                     request.
```

Host queries equipment for current Limits:

```
COMMENTS                          HOST   EQUIPMENT                          COMMENTS

Host queries equipment          S2,F47-->
for current variable limit
attribute definitions.
                                        <--S2,F48    Equipment returns report
                                                     containing requested variable
                                                     limit attribute values.
```

4.2.5 Status Data Collection

4.2.5.1 *Purpose* — This capability allows the host to query the equipment for selected status information and is useful in synchronizing with equipment status.

4.2.5.2 *Definitions*

Status variable value (SV) — A data item containing the value of a status variable. See SEMI E5 for a full definition of this data item.

Status variable ID (SVID) — A unique identifier of a status variable. See SEMI E5 for a full definition of this data item.

4.2.5.3 *Detailed Description* — The host may query equipment status by specifying the desired SVID's. Upon such a request, the equipment sends the host the value of the selected status variables. The host also may request the description (name and units) of any or all available status variables.

4.2.5.4 *Requirements*

— The equipment manufacturer must provide unique SVID's for the various status variables (SV) available for data collection in the equipment.

— All status data is available for status data collection. See Section 5.2, Variable Item List, for a list of status variables.

— All SV's must contain valid data whenever provided to the host.

4.2.5.5 *Scenario*

Request Equipment Status Report:

COMMENT	HOST	EQUIPMENT	COMMENT
Host requests report of selected status variable values	S1,F3-->		
		<--S1,F4	Equipment responds with the requested status variable data.

Request Equipment Status Variable Name list:

COMMENT	HOST	EQUIPMENT	COMMENT
Host requests equipment to identify selected status variables.	S1,F11-->		
		<--S1,F12	Equipment responds with the requested status variable descriptions.

4.2.6 *On-line Identification*

4.2.6.1 *Purpose* — Implementation of SEMI E5 (a GEM Fundamental Requirement) requires the equipment to accept the S1,F1 from the Host at any time while it is ONLINE and COMMUNICATING, and respond with S1,F2. The On-line Identification capability describes the host-initiated scenario. The equipment-initiated scenario is used for a different purpose and is defined in sections 3.3 and 4.12 describing the GEM "Control Model".

4.2.6.2 *Definitions*

Equipment Model Type (MDLN) — ASCII string containing the equipment model. See SEMI E5 for a full definition of this data item.

Equipment Software Revision Code (SOFTREV) — ASCII string containing the equipment software revision. See SEMI E5 for a full definition of this data item.

4.2.6.3 *Detailed Description* — On-line Identification allows the host to verify the presence and identity of the equipment.

4.2.6.4 *Requirements* — (Host-Initiated) An S1,F2 response from the equipment must provide MDLN and SOFTREV information which reflects the hardware and software configuration of the equipment.

SOFTREV must uniquely identify different releases of equipment software. Any change in equipment software must result in a corresponding change to SOFTREV.

The equipment-initiated S1,F1 is not required except as described in sections 3.3 and 4.12 describing the GEM "Control Model".

4.2.6.5 *Scenario:*

Host Initiated

COMMENT	HOST	EQUIPMENT	COMMENT
Are you there?	S1,F1-->		
		<--S1,F2	Equipment replies with MDLN and SOFTREV.

4.3 *Alarm Management* — The alarm management capability provides for host notification and management of alarm conditions occurring on the equipment.

4.3.1 *Purpose* — Historically, a precise definition of an equipment alarm has been absent. Consequently, differing interpretations have resulted in inconsistent implementations. This is addressed by providing a more rigorous definition (see definition in Section 4.3.2 below) of an alarm.

In addition, it is often important for equipment to report more extensive information to the host than has been available in the S5,F1/F2 (Alarm Report Send/ Acknowledge) transaction. The data required in such cases is very dependent on equipment type, host information requirements, and alarm situation. This issue is addressed by providing event reporting methods that are tied to alarm state changes.

Lastly, the alarm management capability provides mechanisms for:

— Reporting the time of an alarm state change,

— Uploading a list of alarm texts,

— Enabling and disabling the notification of specific alarms, and

— Host query of alarms set and enabled status on the equipment.

4.3.2 *Definitions*

Alarm — An alarm is related to any abnormal situation on the equipment that may endanger people, equipment, or material being processed. Such abnormal situations are defined by the equipment manufacturer based on physical safety limitations. Equipment activities potentially impacted by the presence of an alarm shall be inhibited.

Note that exceeding control limits associated with process tolerance does not constitute an alarm nor do normal equipment events such as the start or completion of processing.

AlarmsEnabled — Status value consisting of a list of the alarm ID's currently enabled for reporting to the host. See SEMI E5 for a full definition of this variable data item.

AlarmsSet — Status value consisting of a list of the alarm ID's currently in the ALARM SET (or unsafe) state. See SEMI E5 for a full definition of this variable data item.

ALCD — Alarm code data item used in the S5,F1 (Alarm Report Send) and S5,F6 (List Alarm Data) messages. This code is divided into two parts, the alarm set/cleared bit and the 7 bit alarm category code. Only the set/cleared bit is used—bit 8 = 1 means alarm set, = 0 means alarm cleared. The alarm category code is not used. See SEMI E5 for a full definition of this data item.

ALID — Alarm identifier. See SEMI E5 for a full definition of this data item.

ALTX — Data item contained in the S5,F1 and S5,F6 messages containing a brief textual description of an alarm. See SEMI E5 for a full definition of this data item.

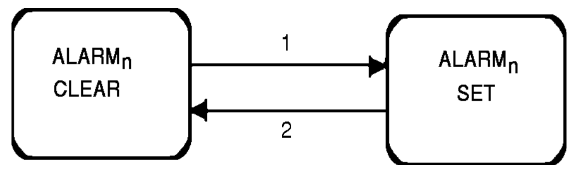

Figure 4.3
State Diagram for Alarm $ALID_n$

4.3.3 *Detailed Description* — Two alarm notification mechanisms are defined to achieve the flexibility necessary for the reporting required by host systems. First, stream 5 alarm reporting enables a brief, yet fixed, method for notification of alarm occurrences using the S5,F1/F2 transaction. Second, to address the host's potential need for more extensive and flexible data reporting, two collection events ("alarm set" and "alarm cleared") are defined for each possible alarm condition on the equipment to allow the use of event data collection mechanisms. In the latter case, reports are sent by the equipment using the Event Report/ Acknowledge transaction (see Section 4.2 on event data collection).

The $alarm_n$ detected and cleared events are derived from the state model for an alarm (see Figure 4.3 and Table 4.3.1). In this model each of n alarms can be in one of two possible states, either ALARM CLEAR or ALARM SET. The transition from the ALARM CLEAR to the ALARM SET state is defined as the collection event "$Alarm_n$ detected" (transition 1). Conversely, the transition from ALARM SET to ALARM CLEAR is defined as the collection event "$Alarm_n$ cleared" (transition 2).

NOTE 8: The alarm capability is intended as an addition to standard safety alarms (e.g., lights, horns). There is no intent to replace direct operator notification of such problems, nor is there the expectation that the host can prevent or directly address such alarms.

Table 4.3.1 Alarm State Transition Table

#	*Current*	*Trigger*	*New State*	*Action*	*Comment*
1	$ALARM_n$ CLEAR	$Alarm_n$ is detected on the equipment.	$ALARM_n$ SET	Initiate local actions (if any) to ensure safety. Update AlarmsSet and $ALCD_n$ values. Generate and issue alarm message if enabled.	Inhibited activities require operator or host intervention prior to resuming.
2	$ALARM_n$ SET	$Alarm_n$ is no longer detected on the equipment.	$ALARM_n$ CLEAR	Update AlarmsSet and $ALCD_n$ values. Generate and issue alarm message if enabled.	Inhibited activities require operator or host intervention prior to resuming.

The equipment manufacturer is responsible for identifying all alarms on their equipment by:

— Applying the above alarm definition,

— Consulting Application Note A.3 for examples of alarms for various equipment configurations,

— Noting that the presence of an alarm typically requires some action or intervention before resuming safe operation of the equipment, and by

— Referring to Table 4.3.2 below which delineates the differences between events and alarms.

Table 4.3.2

EVENT	*ALARM*
Any occurrence detectable by the equipment.	Related to only those occurrences that are abnormal, undesirable, AND endanger people, equipment, or physical material being processed.
Certain events may trigger a state transition(s).	Each alarm has an associated two-state state model: ALARM SET (or unsafe) and ALARM CLEAR (or safe).
Equipment activities are not necessarily inhibited by the occurrence of an event (unless it is associated with an alarm or intentional inhibit).	The presence of an alarm inhibits equipment activities to ensure safe operation until the alarm condition is cleared.
Certain events may occur in an expected sequence.	Alarms may occur at any time.

4.3.3.1 *Enable/Disable Alarms* — Upon request from the host, the equipment shall enable or disable reporting of certain alarms. Enabling or disabling a given alarm shall impact the communication of both the alarm set and clear messages equally (i.e., turn them both on or both off). This is not the case for enabling/disabling of the associated collection events, where the alarm-set and alarm-cleared events can be enabled and disabled separately. The current enable/disable settings must be stored in non-volatile memory. Changes to the enable/disable settings must be reflected in the AlarmsEnabled status value.

NOTE 9: The alarm itself is not being enabled or disabled, but the reporting of the alarm through SECS-II messages is being enabled or disabled.

4.3.3.2 *Send Alarm Report* — Upon detecting a change in the status of a given alarm, an associated alarm state model shall transition to the opposite state. Following initiation of local actions necessary to ensure safety, the equipment must update the AlarmsSet and associated ALCD values and send an alarm message and/or an event message to the host assuming one or both are enabled. Alarm messages must be sent before the corresponding event messages if both are enabled.

NOTE 10: The ALCD is divided into two parts, the alarm set/cleared bit and the 7 bit alarm category code. Only the set/cleared bit is used—bit 8 = 1 means alarm set, = 0 means alarm cleared. The alarm category code is not used.

4.3.3.3 *List Alarm Text* — Upon request from the host, the equipment sends values of alarm text associated with a specified list of alarm ID's using the S5,F5/F6 (List Alarms Request/Data) transaction.

4.3.3.4 *List Currently Set Alarms* — The host may obtain a listing of currently set alarms by employing any data collection method specified by GEM and referencing the variable data item called "AlarmsSet" (e.g., including " AlarmsSet in a report definition). When reported, AlarmsSet must contain a list of all currently set alarms. Each alarm set or clear occurrence must cause a change to the AlarmsSet status value prior to reporting it to the host.

4.3.3.5 *List Currently Enabled Alarms* — The host may obtain a listing of currently enabled alarms by employing any data collection method specified by GEM and referencing the variable data item called "AlarmsEnabled" (e.g., including AlarmsEnabled in a report definition). When reported, AlarmsEnabled must contain a list of all alarm ID's currently enabled for reporting. The equipment must update the value of AlarmsEnabled upon corresponding change(s) to the enable/disable settings.

4.3.4 *Requirements*

— A set of alarms relating to the physical safety limits of operator, equipment, or material being processed must be defined for the equipment by the equipment manufacturer.

— The equipment must maintain all enable/disable states and report definitions for alarms and collection events in non-volatile memory.

— Each alarm defined on the equipment must have a brief description of its meaning, an associated unique alarm identifier (ALID), alarm text (ALTX), an alarm status (ALCD) and two unique collection event identifiers (CEIDs), one for set and one for cleared.

— Enabled alarm reports must be sent prior to corresponding enabled event reports.

4.3.5 *Scenarios*

NOTE 11: Consult event reporting sections of this document for descriptions of enabling, disabling, and sending collection event reports.

Enable/Disable Alarms:

```
COMMENTS                         HOST   EQUIPMENT                          COMMENT

```

4.4 *Remote Control*

4.4.1 *Purpose* — This capability provides the host with a level of control over equipment operations.

4.4.2 *Definitions*

Host Command Parameter (CPNAME/CPVAL/CEPVAL) — A parameter name/value associated with a particular host command (S2,F41/S2,F49). The equipment manufacturer must provide unique names (CPNAMEs) for any supported command parameters. Command parameters are not specified in this document but are left to equipment manufacturers to define. Equipment models of specific classes of semiconductor equipment also may address this issue. Note that if there are no associated parameters a zero-length list is sent. The data item CEPVAL, which can be defined as a list, allows grouping of related parameters within a main parameter. If the CEPVAL is defined as a single (non-list) item, then it is the equivalent of a CPVAL.

The uses of OBJSPEC in the header structure of the S2,F49 Enhanced Remote Command allows the equipment supplier to define a set of unique identifiers for different objects within the equipment such as: equipment sub-systems, sub-system components, processing stations, ports, and exchange stations.

4.4.3 *Description* — The equipment responds to host commands that provide the following functions relative to individual equipment implementations:

— Start processing

— Select a process program or recipe

— Stop processing

— Temporarily suspend processing

— Resume processing

— Abort processing

Additional commands may be implemented by the equipment manufacturer (e.g., vent chamber, clear material, open door).

Remote commands shall be interpreted as “request action be initiated” rather than “do action.” The equipment may then respond via S2,F42/S2,F50 with HCACK = 4 if the command “is going to be performed.” This alleviates any transaction timeouts for commands that may take a long time to perform. The completion of the action initiated by the remote command (i.e., HCACK = 0 or 4) must result in either a state transition or other action that generates a collection event upon normal/abnormal completion.

The format for all remote commands is ASCII, with a maximum length of 20 characters. The character set is restricted to the printable characters (hexadecimal 21 through 7E). Note that spaces are not allowed.

The following remote commands (RCMDs), if implemented on the equipment, shall be supported as described below (see Section 3.4 for a description of Equipment Processing States).

NOTE 12: The terms “current cycle” and “safe break point” used below are to be defined by the supplier or within the models of classes of semiconductor equipment.

START — This command is available to the host when a process program or recipe has been selected and the equipment is in the “ready” processing state. The START command instructs the equipment to initiate processing. Variable parameter settings may be included as name/value command parameters CPNAME/CPVAL/CEPVAL.

PP-SELECT — This command instructs the equipment to make the requested process program(s) available in the execution area. The process programs (PPIDs) are specified via the command parameter list. A status variable (PPExecName) contains the PPID of the process program(s) currently selected.

RCP-SELECT — This command uses the Enhanced Remote Command S2,F49 to instruct the equipment to prepare the requested recipes for execution in the execution area. The recipes and variable parameters are specified via command parameter lists. Each recipe specification may be accompanied by new variable parameter settings, if any, in the command parameter list. A status variable RcpExecName contains the recipe specifiers or identifiers of the recipes currently selected.

STOP — Command to complete the current cycle, stop in a safe condition and return to the “idle” processing state. Stop has the intent of stopping the process. The equipment is not required to support the continuation of processing. Stop leaves material either fully processed or partially processed so that the processing can be later completed. For example, for a single wafer process tool, five wafers have been processed while the remaining wafers remain unprocessed.

PAUSE — Command to suspend processing temporarily at the next safe break point. Pause has the intent of resuming the process at the same point where it was paused. The process may be RESUMED, STOPPED, or ABORTED while in a PAUSED condition. RESUME shall be able to continue the process from the same point where it was paused.

RESUME — Command to resume processing from the point where the process was paused.

ABORT — Command to terminate the current cycle prior to its completion. Abort has the intent of immediately stopping the process and is used because of abnormal conditions. Abort makes no guarantee about the subsequent condition of material. In the above example, the wafers being processed at the time of the abort may not be completely processed. Other AbortLevels > 1 may be defined by the manufacturer or addressed by models of specific classes of semiconductor equipment.

CPNAME = AbortLevel, CPVAL = 1 means terminate current cycle at the next "safe break point," retrieve all material, stop in a safe condition and return to the idle state in the processing state machine.

4.4.4 *Requirements*

— The following Remote Commands, as defined under Descriptions, must be implemented on equipment to satisfy minimum requirements for this capability:

— START

— STOP

— The RCMD value for all commands supported on the equipment must be recognized if sent with all upper-case characters (e.g., "STOP", "START", "PP-SELECT", "PAUSE", etc.). In addition to accepting strings with all upper-case characters, the equipment can optionally accept strings with all lower-case characters or mixed-case strings. The equipment documentation should describe whether or not the optional lower-case or mixed-case strings are supported.

— Stream 2 currently provides for Host Command Send and Enhanced Remote Command. The equipment shall support one or both methods, based on appropriateness.

— The Enhanced Remote Command is used to address size, complexity, or the need to target a specific sub-system within the equipment, (i.e., processing station, port, exchange station, material handler, chamber).

4.4.5 *Scenarios*

4.4.5.1 *Host Command Send Scenario*

```
COMMENTS                          HOST    EQUIPMENT                      COMMENT

Host Command                 Send S2,F41-->
                                          <-- S2,F42   Host Command Acknowledge

                                                       [IF] Command Accepted
                                                       (HCACK = 0 or 4)

                                          <-- S6,F11   [THEN] Event Report-state
                                                       change or other collection
                                                       event occurrence.
Event Report Acknowledge          S6,F12-->
```

4.4.5.2 *Enhanced Remote Command Scenario*

COMMENTS	HOST	EQUIPMENT	COMMENT
Enhanced Remote Command	S2,F49-->		
		<--S2,F50	EnhancedRemote Command Acknowledge
			[IF] Command Accepted (HCACK = 0 or 4)
		<--S6,F11	[THEN] Event Report-state change or other collection event occurrence.
Event Report Acknowledge	S6,F12-->		

4.5 *Equipment Constants*

4.5.1 *Purpose* — This capability provides a method for the host to read and to change the value of selected equipment constants on the equipment.

4.5.2 *Definitions* — None.

4.5.3 *Description* — This capability allows the host to reconfigure equipment constants to support a variety of situations. The following functions are included:

Host Sends Equipment Constants — Allows the host to change the value of one or more equipment constants.

Host Equipment Constant Request — Allows the host to determine the current value of equipment constants.

Host Equipment Constant Namelist Request — Allows the host to retrieve basic information about the equipment constants available at the equipment.

4.5.4 *Requirements*

- Equipment constants must be stored in non-volatile memory.
- The equipment must be in a "safe" condition to accept new constant(s) settings as defined by the equipment manufacturer.
- The equipment must provide a collection event to alert the host whenever an equipment constant is changed by the operator. Information indicating which constant was changed shall be available for the event report.

4.5.5 *Scenarios*

Host Sends Equipment Constants:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends	S2,F15-->		
equipment constants		<-- S2,F16	EAC = 0 equipment sets constants

Host Equipment Constants Request:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host constant request	S2,F13-->		
		<-- S2,F14	Equipment constant data

NOTE: This capability also can be accomplished using S6,F19 & S6,F20. See Section 4.2.

Host Equipment Constant Namelist Request:

```
COMMENTS                          HOST    EQUIPMENT                        COMMENTS

Host constant namelist          S2,F29-->
request                                 <-- S2,F30   Equipment constant namelist
```

Operator Changes Equipment Constant

```

4.6 *Process Program Management* — Process programs and recipes must be managed through interaction between the equipment and the host system.

4.6.1 *Purpose* — Process program management provides a means to transfer process programs or recieps, and to share the management of those process programs or recipes, between the host and equipment.

4.6.2 *Definitions*

PPError — A text data value with information about verification errors of a process program that failed verification. If the equipment provides an event for recipe verification and/or recipe verification failure, then PPError shall be a DVVAL. Otherwise, PPError shall be an SV.

PPFormat — A variable (SV) indicating the type or types of process programs and recipes that are supported.

1 = Unformatted process programs

2 = Formatted process programs

3 = Both unformatted and formatted process programs

4 = Execution recipes

4.6.2.1 *Definitions for Process Programs*

Process Program — A process program is the pre-planned and reusable portion of the set of instructions, settings, and parameters under control of the equipment that determine the processing environment seen by the manufactured object and that may be subject to change between runs or processing cycles.

Process Program Identifier — A text string (PPID) used to identify a process program.

Formatted Process Program — A process program that is presented as an ordered sequence of command codes with their associated parameters as dictated by S7,F23, and S7,F26. Where formatted process programs are supported, equipment must also provide information sufficient to allow a user at the host to create, display, modify, and partially verify their contents (for example, that information provided in S7,F22).

Unformatted Process Program — An unformatted process program is transferred without structure as the single data item PPBODY (refer to SEMI E5 for a complete description of PPBODY).

Process Program Change Event — The collection event associated with the occurrence of the creation, modification, or deletion of a process program by the operator.

PPChangeName — A data value (DVVAL) containing the PPID of the process program affected by the event Process Program Change Event. See SEMI E5 for a full definition of this variable data item.

PPChangeStatus — The action taken on the process program named by PPChangeName. This variable is valid for the collection event Process Program Change Event. See SEMI E5 for a full definition of this variable data item.

PPExecName — The status variable containing the PPID(s) of the currently selected process program(s). See SEMI E5 for a full definition of this variable data item.

PP-SELECT — The remote command used to select one or more process programs for execution. The process programs are specified by PPID via the command parameter list.

Process Program Verification — Verification is syntax checking of a process program. Verification ensures only that a process program is structured correctly. It does not ensure that the program has the correct parameters to run a particular process or product (see Process Program Validation). Equipment supporting unformatted process programs should provide a variable DVVAL PPError that provides information to the user concerning the error or errors when an attempt to verify a process program fails.

NOTE 14: It may not be possible for the equipment to verify unformatted process programs other than to check the size of the program and internal program checksums. Equipment has no standard means of indicating the type of error encountered in an unformatted process program.

Process Program Validation — Validation is type-and-range checking of parameters in a process program, and is performed after verification.

4.6.2.2 *Definitions for Recipes*

Execution recipe — A type of recipe stored by the equipment for purposes of editing, verification, and execution.

For complete definitions of execution recipes and their standard attributes, see SEMI E42, Section 6.

Execution Recipe Change Event — The collection event associated with the occurrence of the modification or deletion of an execution recipe stored by the equipment.

Note 15: A recipe is modified whenever its body is changed.

New Execution Recipe Event — The collection event associated with the creation of a new execution recipe at the equipment.

Object form recipe — A recipe with body in a proprietary format that may be presented without structure.

RcpChangeName — A data value (DVVAL) containing the identifier of the recipe affected by the event Execution Recipe Change Event or New Execution Recipe Event. See the SEMI E5 Standard for a full definition of this variable data item.

RcpChangeStatus — The action taken on the recipe named by RcpChangeName. This variable is valid for the collection event Execution Recipe Change Event or New Execution Recipe Event. See the SEMI E5 Standard for a full definition of this variable data item.

RcpExecName — The status variable containing the specifiers of the currently selected recipe(s). See the SEMI E5 Standard for a full definition of this variable data item.

RCP-SELECT — The remote command used to select one or more recipes for execution. See Section 4.4.3.

Recipe Attribute — Information about the recipe that is transferred with the recipe as a name/value pair. The value may be a single item or a list.

Recipe — A recipe contains both a set of instructions, settings, and parameters that the equipment uses to determine the processing environment (its body or process program) and a set of attributes that provide information about the recipe, such as the date and time the body was last changed.

SEMI E42 defines two types of recipes: *managed recipes* and *execution recipes*. For purposes of GEM, the term *recipe* refers to an *execution recipe* only.

Recipe identifier — A recipe identifier is a formatted text string (RCPID) used to identify the recipe.

Recipe specifier — A formatted text string (RCPSPEC) used in messages to indicate a specific recipe. A recipe specifier includes the recipe identifier. It may also include additional information, such as the name of the specific component of the equipment where the recipe is to be executed (e.g. a process chamber) and the name of a recipe repository on the host.

Recipe Verification — Verification is syntax checking of a recipe's body. Verification ensures that a recipe body is structured correctly and has the correct syntax. It may also provide a check of semantics. It does not ensure that the body has the correct parameters to run a particular process or product (see Recipe Validation).

NOTE 16: Unverified recipes shall be verified upon download.

Recipe Validation — Validation is type-and-range checking of parameters in a recipe, and is performed when the recipe is selected for execution. The recipe may be correct in its syntax and semantics but should fail validation if it can not be executed with the current equipment configuration.

Source form recipe — A recipe with a body that is presented as an ordered sequence of text. A source form recipe may be created and edited off-line to the equipment. Definition of syntax requirements shall be documented, in order to allow proper off-line editing.

Variable Parameters — Variable parameters are recipe parameters that are defined in the body of the recipe and whose run-time values may be set outside of the recipe when the recipe is selected for execution and/or when processing is started. Both the host and the operator may specify new settings as a parameter name/value pair.

Variable Parameter Definition — A variable parameter definition has three parts: the name of the variable parameter, its default setting, and restrictions on the run-time value selected. Variable parameter definitions are stored in the recipe attribute "Parameters".

4.6.3 *Description*

4.6.3.1 *Process Program Description*

Process programs allow the equipment's process, and/or the parameters used by that process, to be set and modified by the engineer to achieve different results. Different process programs maybe required for different products, while often the same process program will be used for all lots of a given product. The engineer must be able to create such programs, to modify current programs, and to delete programs from equipment storage.

For the host to ensure that the proper process programs are in place at the equipment, there must be a means of transferring them from equipment to host and from host to equipment. The host also may need to delete process programs from the equipment's storage to make room for a process program to be downloaded. In addition, the host must be kept informed whenever a local change occurs in the contents or status of a process program.

Both formatted and unformatted process programs may be uploaded and downloaded. This capability provides for both host- and equipment-initiated transfers. The equipment-initiated transfer may be used at the request of the process engineer or operator at the equipment.

If a process program exists with the same PPID as the one given in the SECS-II message, the old process program must be replaced. The PPID in the e process program in non-volatile storage.

4.6.3.2 *Recipe Description*

Specifications in Section 4.6.3.1 apply to recipes as well as process programs, with the following differences:

- A recipe contains a body corresponding to a process program. In addition, it contains attributes defined for execution recipes in SEMI E42, Section 6. Recipe attributes are transferred whenever the recipe is downloaded or uploaded.
- The same SECS-II messages are used for all execution recipes, regardless of the internal structure of the recipe body.
- If an execution recipe already exists with the same identifier as the one given in the SECS-II message, the downloaded recipe shall be rejected (not stored) unless the host has specified a "forced overwrite" in the data item RCPOWCODE.
- A recipe currently being edited shall be protected from inadvertent change or overwriting by a recipe with the same identifier that is downloaded during this time. If the downloaded recipe is accepted (stored), the equipment shall require the operator either to save the edited recipe to a new (unused) identifier or to discard it.
- For the equipment to initiate either an upload or download of a recipe, it shall request the host to initiate an upload or download procedure. In addition, it may be necessary to also specify the name of the repository (recipe namespace) at the host.

4.6.4 *Requirements*

- The equipment manufacturer shall provide a method to create, modify, and delete process programs or recipes. This method shall exist on either the equipment or on a separate computing system.
- A CEID shall be defined for a collection event for the creation, the deletion, or the modification (completion of an editing session) of a process program (Process Program Change Event). For recipes, there are two separate CEIDs and collection events, one for the creation of a new recipe (New Execution Recipe Event) and one when a recipe is changed or deleted (Execution Recipe Change Event). A New Execution Recipe Event shall occur whenever a new recipe identifier is created through download, edit, copy, or rename operations. A Execution Recipe Change Event shall occur whenever the body of an existing recipe is modified.
- The name (identifier) that the engineer or operator uses to refer to the process program or recipe is the same as the identifier used by the host.
- Upon request from the host or operator, the equipment shall perform the following actions with regard to process programs and recipes stored in non-volatile storage: upload, download, delete, and list current equipment process program or recipe directory.
- The equipment shall be able to store in non-volatile memory the number of process programs or recipes sufficient to execute three unique process cycles. For example, if a wire-bonder requires both an "ALIGN" process program and a "BOND" process program for a full process cycle, then it must provide non-volatile storage for at least three pairs of process programs. These stored process programs or recipes may not be modified in any way by the execution process, nor may the execution process be affected by the modification of any process program or recipes in storage, either by downloading or by local editing, while that process program or recipes is being executed.

- The equipment must provide verification and validation of all downloaded process programs and recipes.
- Stream 7 provides for formatted and unformatted process programs, while Stream 15 provides for recipes. The equipment must support at least one of these three methods.
- The equipment supplier shall document any restrictions on the length or test format of PPID. The maximum length allowed by equipment may be less than that allowed by SECS-II.
- Where recipes are supported, the following requirements also apply:
  - The variable PPFormat shall be provided to indicate to the user the messages supported by the equipment.
  - The recipe and its attributes shall comply to the requirements for execution recipes as defined in SEMI E42, Section 6.

4.6.5 *Scenarios for Process Programs*

4.6.5.1 *Process Program Creation, Editing, or Deletion Process Program Created, Edited, or Deleted by Operator*

4.6.6.5 *Recipe Verification*

Host requests equipment to verify a recipe that it has stored:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Recipe Verify Request	S15,F29-->		
			Equipment verifies recipe
		<--S15,F30	Recipe Verify Data

4.7 *Material Movement* — The material movement capability includes the physical transfer of material (WIP, tools, expendable materials, etc.) between equipment, buffers, and storage facilities. The transfer of material can be performed by operators, AGV robots, tracks, or dedicated fixed material handling equipment.

4.7.1 *Purpose* — This capability is limited in implementation, serving to notify the host of the appearance or removal of material at the equipment's ports.

4.7.2 *Definitions*

Port — A point or area on the equipment at which a change in equipment ownership of material may occur.

4.7.3 *Description* — This capability consists of alerting the host whenever material is sent or received from any of the ports on the equipment. Event-specific information, such as port identification and material identification, also may be useful, but definition of these and other related DVVAL's are left to the implementation.

4.7.4 *Requirements* — The equipment must supply two CEIDs, one to report when material is sent from any port and the other to report when material is received at any port.

4.7.5 *Scenarios*

COMMENTS	HOST	EQUIPMENT	COMMENTS
			Material is sent or received at an equipment port.
		<--S6,F11	Send collection event to host.
Host acknowledges.	S6,F12-->		

4.8 *Equipment Terminal Services* — Equipment Terminal Services allows the host to display information on the equipment's display device or the operator of the equipment to send information to the host.

4.8.1 *Purpose* — Equipment Terminal Services allows the factory operators to exchange information with the host from their equipment workstations.

4.8.2 *Definitions* —Message Recognition: a positive action by the equipment operator indicating the operator has viewed the text of a host initiated message.

4.8.3 *Detailed Description* — The equipment must be capable of displaying information passed to it by the host for the operator's attention. The information, or an indication of a message, must remain on the equipment's display until the operator indicates message recognition. Message recognition results in a collection event that informs the host that the operator has actually viewed the information.

The equipment must be capable of passing information to the host that has been entered from the operator's equipment console. This information is intended for host applications and is not processed by the equipment.

The equipment has no responsibility for interpreting any of the data passed to or from the host using this method.

4.8.4 *Requirements*

— Any new Terminal Display message sent by the host shall overwrite an unrecognized message at the same equipment terminal.

— The equipment must provide a display device capable of displaying at least 160 characters to the operator.

— The equipment must provide a mechanism for displaying information sent to it by the host.

— The equipment must provide an indicator to notify the operator when an unrecognized message is present.

— The equipment must provide a mechanism for the operator to indicate message recognition (e.g., push button, terminal function).

— The equipment must provide a means for alpha numeric data entry that can be used by the operator.

— The equipment must support operator entry of at least 160 characters per message.

— The equipment must have a mechanism to send operator-entered messages to the host.

— The equipment must support single-block messages as a minimum. Support of multi-block messages is optional.

— A Terminal Display message received by the equipment with a zero length TEXT data item shall be accepted and replace any previous unrecognized message, but shall not itself be considered an unrecognized message. This provides a method of clearing an unrecognized message and turning off the unrecognized message indicator.

4.8.5 *Scenarios*

Host sends information to an equipment's display device:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends textual information to equipment for display to the operator on terminal x.	S10,F3-->		
		<--S10,F4	Equipment acknowledges request to display text. (Equipment sets unrecognized message indicator.) Operator indicates message recognition. (Equipment clears unrecognized message indicator.)
		<--S6,F11	Message recognition event. (See Section 4.2.1, Event Data Collection, for details.)
Host acknowledges Optional:	S6,F12-->		
		<--S10,F1	Operator responds with text via terminal x.
Host acknowledges receipt of operator text.	S10,F2-->		

Host sends information to an equipment's display device and then overwrites the information before operator recognizes message:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends textual information to equipment for display to the operator on terminal x.	S10,F3-->		
		<--S10,F4	Equipment acknowledges request to display text. (Equipment sets unrecognized message indicator.)
Host sends textual information to equipment for display to the operator on terminal x. This message overwrites the first one sent by the host since it is still unrecognized.	S10,F3-->		
		<--S10,F4	Equipment acknowledges request to display text. (Equipment sets unrecognized message indicator.) Operator indicates message recognition. (Equipment clears unrecognized message indicator.)
		<--S6,F11	Message recognition event. (See Section 4.2.1, Event Data Collection, for details.)
Host acknowledges	S6,F12-->		

Operator sends information to the host:

COMMENTS	HOST	EQUIPMENT	COMMENTS
		<--S10,F1	Operator sends textual information via equipment terminal x.
Host acknowledges receipt of operator initiated message.	S10,F2-->		
Optional: Host responds with information for display to the operator on terminal x.	S10,F3-->		
		<--S10,F4	Equipment acknowledges receipt of request to display text. (Equipment sets unrecognized message indicator.) Operator indicates message recognition.
		<--S6,F11	Message recognition event. (See Event data collection for details.)
Host acknowledges	S6,F12-->		

Host sends a multi-block display message:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Send information	S10,F5-->		
		<--S10,F6	Accepted or denied. [IF] Message from host is multi-block and multi-block is not supported by the equipment, [THEN]
		<--S10,F7	Send Multi-block Not Allowed. [END_IF]

4.9 *Error Messages*

4.9.1 *Purpose* — Error messages provide the host with information describing the reason for a particular message or communication fault detected by the equipment.

4.9.2 *Definitions*

Communication Fault — Refer to Section 2 for the definition.

Message Fault — Refer to Section 2 for the definition.

4.9.3 *Detailed Description* — The equipment must inform the host that it cannot process a message due to an incorrect:

— device ID,

— message stream type,

— message function,

— message format, or

— data format.

The equipment must inform the host if the message has more data than it can handle.

The equipment must inform the host if the equipment's transaction timer expires.

The equipment shall treat the above conditions as application-level errors and shall not take any further action on any message in error.

Error messages are invoked whenever the equipment detects communication or message faults.

4.9.4 *Requirements* — Support of all Stream 9 messages.

4.9.5 *Scenario*

Message Fault Due to Unrecognized Device ID:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends a message.	Sx,Fy-->		
			Equipment detects an unrecognized device ID within the message from the host.
		<--S9,F1	Equipment reports to the host that an "unrecognized device ID" was detected in the received message.

Message Fault Due to Unrecognized Stream Type:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends a message.	Sx,Fy-->		
			Equipment detects an unrecognized stream type within the message from the host.
		<--S9,F3	Equipment reports to the host that an "unrecognized stream type" was detected in the received message.

Message Fault Due to Unrecognized Function Type:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends a message.	Sx,Fy-->		
			Equipment detects an unrecognized function type within the message from the host.
		<--S9,F5	Equipment reports to the host that an "unrecognized function type" was detected in the received message.

Message Fault Due to Illegal Data Format:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends a message.	Sx,Fy-->		
			Equipment detects illegal data format within the message from the host.
		<--S9,F7	Equipment reports to the host that "illegal data format" was detected in the received message.

Communication Fault Due to Transaction Timer Timeout:

COMMENTS	HOST	EQUIPMENT	COMMENTS
			Equipment does not receive an expected reply message from the host and a transaction timer timeout occurs.
		<--S9,F9	Equipment reports to the host that a transaction timer timeout occurred.

Message fault due to data too long:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends a message.	Sx,Fy-->		
			Equipment detects that the message from the host contains more data than it can handle.
		<--S9,F11	Equipment reports to the host that "data too long" was detected in the received message.

Communication Fault Due to Conversation Timeout:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host sends a message.	Sx,Fy-->		
		<--Sx,Fy+1	Equipment sends reply. Equipment is now expecting a specific message from the host as a result of the previous transaction. Equipment has not received the expected message from the host and a conversation timeout occurs.
		<--S9,F13	Equipment reports to the host that a conversation timeout occurred.

4.10 *Clock* — The clock capability enables host management of time-related activities and occurrences associated with the equipment and across multiple pieces of equipment.

4.10.1 *Purpose* — The purpose of the clock capability is to enable time stamping of collection event and alarm reports. Time stamping is useful for resolving relative order of event/alarm occurrences and scheduling of equipment activities by the host.

The ability for the host to instruct the equipment to set an internal clock to a specified time value, and for the equipment to request the current date and time, is needed for effective time management and synchronization between host and equipment.

4.10.2 *Definitions*

Clock — Clock is a status variable containing the current value of time at the equipment. Clock may be included in report definitions and/or queried separately by the host. See SEMI E5 for a full definition of this variable data item and its required formatting.

TIME — TIME is a data item contained in messages used by the host to set time at the equipment and by the equipment or host to request the current time from the other. (See SEMI E5 for a full definition of this data item.)

4.10.3 *Detailed Description* — The clock capability assumes the existence of a relative time reference on the equipment. This time reference is used as a basis for updating the time value of an equipment status variable called "Clock." The time reference must reflect the current time to within a resolution range of seconds to centiseconds (refer to the format for Clock in the SEMI E5 Standard). The purpose of time stamping with centiseconds is to resolve the order in which nearly simultaneous events occur rather than to provide a more precise record of the time of day at which they occurred. Where more than one event occurs within a given period of clock resolution, the centiseconds reported in the time stamps for these events must reflect the actual order in which the events were detected. Equipment with a clock resolution of less than a second should report centiseconds. Otherwise, centiseconds should be assigned to reflect the relative order in which events were detected. Equipment unable to resolve time to less than a second and unable to reflect the relative order in which events were detected may report centiseconds as "00".

The host employs the “Date and Time Set Request” message (S2,F31) to initialize the value of Clock to the value contained in the TIME data item. Similarly, the equipment may employ the “Date and Time Request“ message (S2,F17) to obtain a new initialization time for Clock. As before, the value of TIME returned by the host is used to set Clock. Note, in the event that the precision of TIME is seconds and that for Clock is centiseconds, in both cases the initial value of Clock shall contain “00” for its Centisecond digits upon initialization. Additionally, for any field in TIME that is not supported by the equipment, the local value of this field is equipment dependent. For example, Equipment that cannot resolve time to less than a second might round or ignore centiseconds and always set the Centisecond field to “00”.

4.10.4 *Requirements*

— The resolution and update rate of the internal time reference must be sufficient to distinguish between two nearly simultaneous collection events and/or alarms.

— The equipment supplier shall provide documentation describing the resolution of the internal time reference.

— The equipment supplier shall provide documentation describing how centisecond values are assigned, including the case of unresolvable simultaneous events.

4.10.5 *Scenarios*

Equipment Requests TIME (Optional Scenario):

COMMENTS	HOST	EQUIPMENT	COMMENTS
		<--S2,F17	Equipment requests a time value from the host.
Host responds with a TIME value	S2,F18-->		
			Equipment sets its internal time reference to the value of TIME received from the host.

Host Instructs Equipment to Set Time:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host instructs equipment to set its time.	S2,F31-->		
		<--S2,F32	Equipment sets its internal time reference to the value of TIME received from the host and acknowledges completion.

Host Requests Equipment’s Current Time Value:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host requests equipment time.	S2,F17-->		
		<--S2,F18	Equipment returns its internal time reference value to the host.

4.11 *Spooling* — Spooling is a capability whereby the equipment can queue messages intended for the host during times of communication failure and subsequently deliver these messages when communication is restored. Spooling is limited to primary messages of user-selected streams.

4.11.1 *Purpose* — The purpose of spooling is to provide a method for retaining equipment message data that might otherwise be lost due to communication failure. The motive for producing this functionality is to retain valuable data used to track material and to improve product quality. The spooling capability fills a gap in the SEMI E5 standard. In the past, without a spooling capability, the equipment has typically discarded messages that could not be delivered, or turned messaging off altogether. It is intended that the host initiate the spool unload process immediately following the reestablishment of communications.

4.11.2 *Definitions*

MaxSpoolTransmit — An equipment constant containing the maximum number of messages that the equipment shall transmit from the spool in response to an S6,F23 "Transmit Spooled Messages" request. If MaxSpoolTransmit is set to zero, no limit is placed on the messages sent from the spool. Multi-block inquire/grant messages are not counted in this total.

OverWriteSpool — A boolean equipment constant used to indicate to the equipment whether to overwrite data in the spool area or to discard further messages whenever the spool area limits are exceeded.

Send Queue — Refers to the queue into which equipment generated SECS messages are placed in preparation for transmission to the host.

Spool — The spool is an area of non-volatile storage in which the equipment stores certain messages that cannot be delivered to the host (when the equipment is in the NOT COMMUNICATING substate of COMMUNICATIONS ENABLED). The spool area can be thought of as a sequential "ring" buffer. The term spool is also used to denote the action of placing messages into the spool area.

SpoolCountActual — A status variable used to keep a count of the messages actually stored in the equipment's spool area. Multi-block inquire/grant messages are not spooled and not included in this count.

SpoolCountTotal — A status variable used to keep a count of the total number of primary messages directed to the spool, regardless of whether placed or currently retained in the spool. Multi-block inquire/grant messages are not spooled and not included in this count.

SpoolFullTime — A status variable containing the timestamp when the spool last became full. If the spool was not filled during the last spooling period, this will contain a time value prior to the current SpoolStartTime.

SpoolStartTime — A status variable containing the timestamp from when spooling was last activated.

4.11.3 *Description*

4.11.3.1 *Spooling State Model* — There are two major states of spooling: SPOOL INACTIVE and SPOOL ACTIVE. SPOOL ACTIVE has two components: SPOOL UNLOAD and SPOOL LOAD. These are each broken into substates. A description of all spooling states, substates, and applicable state transitions follows. The POWER OFF and POWER ON parent states are common to all equipment subsystems. They are shown here to illustrate the retention of spooling context during a power down situation.

NOTE 20: Disabling SECS communications does not affect the current spooling state since no messages are generated until communications are subsequently enabled. Spooling is effectively frozen in this case.

POWER OFF

The equipment has lost power for any reason (e.g., power failure, power switch set to off).

POWER ON

The equipment is powered up.

SPOOL INACTIVE

This is the normal operating mode. No spooling occurs. The spool area is empty. Primary SECS-II messages are transmitted normally.

SPOOL ACTIVE

All primary SECS-II messages ready for sending and for which spooling is enabled (see S2,F43) are directed to the spool area. All other primary messages, except Stream 1, are discarded. The equipment shall attempt to send any secondary messages that are generated and discard these messages should the attempt to send fail.

Spool state transitions from SPOOL INACTIVE to SPOOL ACTIVE if the communications state changes from COMMUNICATING to NOT COMMUNICATING (Communication State Transition Table, #14) or from WAIT CRA to WAIT DELAY (Communication STATE Transition Table, #6).

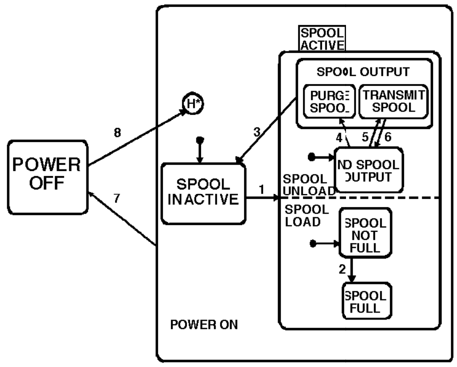

Figure 4.11
Spooling State Diagram

Once communications are established, the host must initiate the spool unload sequence to restore full functionality (see below). Since the equipment will deliver secondary messages, the host may inquire for information or send commands as needed.

The SPOOL ACTIVE state has two AND states: SPOOL LOAD and SPOOL UNLOAD. This means that they operate independently, though sharing data and some state change stimuli. See Section 3.1 for explanation of state model terms and notation.

SPOOL LOAD

The SPOOL LOAD component enters messages into the spool area. It is divided into two substates: SPOOL NOT FULL and SPOOL FULL. SPOOL NOT FULL is the default entry substate of the parent state SPOOL LOAD.

SPOOL NOT FULL

As primary SECS-II messages are directed to the spool area, the equipment shall "write" the SECS-II message to the end of the spool. Status variables SpoolCountTotal and SpoolCountActual shall be incremented each time a message is placed in the spool area.

SPOOL FULL

In this state, all of the allocated spooling area is filled. Choice of the following options shall be controlled by the setting of a Boolean equipment constant called "OverWriteSpool." The first message to be dealt with is that which could not be fit into the spool prior to transition from SPOOL NOT FULL (see transition table below).

OverWriteSpool is True: The equipment deletes as many of the "oldest" records (e.g., SECS-II messages) contained in the spool area necessary to make space for the new message and then adds the message. Status variable SpoolCountTotal shall be incremented whenever a message is submitted to the spool area. Status variable SpoolCountActual shall be manipulated to keep an accurate count of the number of messages contained in the spool area. For example, if it is necessary to delete three messages in the spool area to spool one message, SpoolCountActual would have three subtracted and then one added to the total.

OverWriteSpool is False: Any subsequent primary messages shall be discarded. When such a message is discarded, SpoolCountTotal is incremented.

SPOOL UNLOAD

The SPOOL UNLOAD component of SPOOLACTIVE deals with movement of messages out of the spool. It has an active substate (SPOOL OUTPUT) and a passive substate (NO SPOOL OUTPUT). NO SPOOL OUTPUT is the default entry substate, since the equipment is NOT COMMUNICATING at the time spooling is initiated. When communications between equipment and host are restored, there is an opportunity for the host to recover spooled messages. No action is taken until the host initiates the spool output process via the S6,F23 (Request Spooled Data). The host has the option to either receive the spooled messages (see substate TRANSMIT SPOOL) or discard all messages in the spool (see substate PURGE SPOOL).

NO SPOOL OUTPUT

In this state, no messages are removed from the spool.

SPOOL OUTPUT

The SPOOL OUTPUT state encompasses the removal of messages from the spool. Its substates are TRANS-MIT SPOOL and PURGE SPOOL.

TRANSMIT SPOOL

The host elects to receive all messages contained in the spool area. The equipment is expected to keep track of the oldest record (i.e., message) within the spool area. When communications are re-established with the host and transmission of the spool area is started, the oldest record must be the first record transmitted, then the next oldest record, etc. There is no prioritization of messages to be sent from the spool.

As each spooled message is successfully transmitted to the host, it is removed from the spool area upon successful completion of the transaction. Spool-CountActual is decremented as each message is removed from the spool. The equipment shall transmit messages only from the spool area until all spooled messages have been completely transmitted to the host.

Flow control of the spool transmit process is achieved in two ways. First, only one open transaction on the equipment is allowed during spool unload. Thus, if a message requires a reply, the equipment shall wait for that reply before transmitting the next spooled message. Messages which require no reply may be transmitted sequentially as rapidly as the message transfer mechanism will allow.

The second flow control method is to allow the host to limit the maximum number of messages sent from the spool in response to the S6,F23 request. An equipment constant named MaxSpoolTransmit may be set by the host to achieve this behavior. If MaxSpoolTransmit is set to five, for example, the equipment will send the first five messages from the spool and then transition to the NO SPOOL OUTPUT state, awaiting the next S6,F23 request. There is no event report generated when MaxSpoolTransmit is reached. The host is responsible for determining this situation by a) counting the messages received, b) timing out waiting for the next message, c) inquiring to the equipment for the curent value of the SpoolCountActual status variable, or d) some combination of the above. If MaxSpool-Transmit is set to zero, the spool shall be transmitted completely in response to S6,F23.

Normal spooling continues during the spool transmit process. If the SPOOL LOAD component should transition to SPOOL FULL, it shall not have any effect on the SPOOL UNLOAD component. Once full, the spool cannot make the transition back to SPOOL NOT FULL except via the SPOOL INACTIVE state. Space made available due to the spool unload process shall not be used in this case.

When a multi-block message is to be transmitted from the spool, any required inquire/grant transaction shall be initiated. If the host's response denies permission to send the multi-block message, the equipment shall discard that message and continue with the transmit process. This sequence shall count as one message in the MaxSpoolTransmit count.

There is one area where SPOOL LOAD and SPOOL UNLOAD may interact: When the spool is full and OverWriteSpool is True. During the spool transmit process, spooled messages are being removed and new primary messages are being written to the spool. These new messages are overwriting the oldest messages available, unless the unload process has freed sufficient spool space. There is a possibility that the unload and overwrite processes may compete for control of the same message area. For example, if the spool holds messages ABCDE, with A oldest and E newest, A might be sent to the host, B (and the space from A) overwritten by the new message F, C sent to the host, D and E (and the space from message C) overwritten by G, etc. The loss of continuity may be "disorienting" to the host program receiving the messages. It is expected that the unload process will be fast relative to the generation of new messages, so that this occurrence will be rare.

Should a communication failure occur during the spool transmit process, spooling shall continue as before the transmit process began. However, the spool unload sequence shall terminate (i.e., transition to NO SPOOL OUTPUT will occur — see transition table below).

PURGE SPOOL

The equipment shall discard all messages in the spool and, when the spool is empty, zero SpoolCountActual.

Spooling State Transitions

A table follows detailing all spooling state transitions as presented in the state transition diagram.

Table 4.11 Spooling State Transition

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	SPOOL INACTIVE	Communication state changes from COMMUNICATING to NOT COMMUNICATING or from WAIT CRA to WAIT DELAY and Enable Spool is true.	SPOOL ACTIVE	SpoolCountActual and SpoolCountTotal are initialized to zero. Any open transactions with the host are aborted. SpoolStartTime (SV) is set to current time. Alert the operator that spooling is active.	The default state in each AND substate is entered. The message which could not be sent remains in the send queue and is dealt with in Spool Active state. The collection event Spooling Activated has occurred.
2	SPOOL NOT FULL	Message generate which will not fit into spool area.	SPOOL FULL	SpoolFullTime (SV) is set to current time. Alert the operator that spool is full.	The message which would not fit into the spooling area is dealt with after the transition. No collection event is generated.
3	SPOOL OUTPUT	Spool area emptied.	SPOOL INACTIVE	Spooling process disabled. Alert the operator that spooling has been terminated.	The collection event Spooling Deactivated has occurred. Transition from the AND substate Spool Unload component occurs.
4	NO SPOOL OUTPUT	S6,F23 received w/RSDC = 1.	PURGE SPOOL	No action.	Initiates purging process. No collection event is generated since this is based on host request.
5	NO SPOOL OUTPUT	S6,F23 received w/RSDC = 0.	TRANSMIT SPOOL	No action.	Initiates message transmission from spool. No collection event is generated since this is based on host request.
6	TRANSMIT SPOOL	Communication failure or MaxSpoolTransmit reached.	NO SPOOL OUTPUT	Spool transmission process suspended.	If communications failure, the event Spool Transmit Failure has occurred. No collection event generated for MaxSpoolTransmit reached.
7	POWER ON	Equipment power source discontinued.	POWER OFF	No action.	Spooling context has been maintained in non-volatile storage prior to this transition.
8	POWER OFF	Equipment power source restored.	POWER ON	Spooling context restored from non-volatile memory.	If spooling were active prior to power down, it shall continue. If TRANSMIT SPOOL were active at powerdown, transition #6 is expected to follow since communications state is initially NOT COMMUNICATING.

4.11.3.2 *Enabling Spooling* — The equipment shall provide the host with the ability to enable and disable Spooling for any message (except Stream 1 messages (i.e., S1,F1, S1,F13)) via the S2,F43/F44 transaction. Spooling may be enabled for an entire Stream, for individual messages within a stream, or for any combination of the two. Streams and Functions not referenced in this message are not spooled. Spooling can be totally disabled by sending an S2,F43 with a zero length list for the first item (see S2,F43 definition). In addition, the equipment shall provide an equipment constant, EnableSpooling, to allow setting the enable or disable of spooling. NOTE: When EnableSpooling is false, the SPOOL state cannot transition from SPOOLINACTIVE to SPOOLACTIVE. Changing EnableSpooling does not change the spool state, purge the spool or change streams and functions enabled for spooling. Once the equipment is “SPOOL ACTIVE”, the host must initiate the spool unload sequence to restore full functionality even though "Enable Spooling" has changed to false.

4.11.4 *Requirements* — The following items are required to support the spooling capability:

- At a minimum, the equipment shall reserve for spooling non-volatile storage with sufficient capacity to store all of the primary SECS-II messages that would occur during a normal processing cycle.
- While spooling is enabled, the equipment shall reply to primary messages sent by the host with the appropriate secondary message.
- Secondary messages which cannot be delivered shall be discarded, never spooled.
- All spooling-related status variables and setup information (as per S2,F43) must be stored in non-volatile memory along with any other information required for the potential unloading of the spool area after a power loss.
- Upon powerup, the equipment shall retain all spooling context from the time the equipment was last shutdown or reset. This means that spooling, if previously active, continues upon system powerup.
- The Equipment must reject any message that attempts to set "Spooling" for Stream 1.
- If a multi-block primary message need for the inquire/grant is to be sent during SPOOL ACTIVE, the message should be placed in the spool and the grant resolved during spool transmit.

4.11.5 *Scenarios*

Define the Set of Messages to be Spooled:

This Scenario is used to set up the list of messages that the equipment should spool (or by defining none, to disable spooling).

```
COMMENTS                          HOST   EQUIPMENT                            COMMENTS

Host defines messages to be     S2,F43-->
spooled in case of communications
failure.
                                       <--S2,F44    Equipment acknowledges setup.
```

Define the Maximum Number of Messages to Send in Response to S6,F23:

This Scenario sets the value of the equipment constant MaxSpoolTransmit.

```
COMMENTS                          HOST   EQUIPMENT                            COMMENTS

Host sends value for            S2,F15-->
equipment constant MaxSpoolTransmit.
                                       <--S2,F16    Equipment acknowledges
                                                    equipment constant change.
```

Request or Delete Spooled Data (MaxSpoolTransmit = 0):

This Scenario is used to initiate the transfer of the spooled data from the equipment to the host or to purge the spool.

```
COMMENTS                          HOST    EQUIPMENT                           COMMENTS

                Communications were lost and then re-established.
Host requests data that
includes spool-related
status variables.                 S1,F3-->
                                          <--S1,F4     Send status data.
NOTE: S1,F3 is one of
various methods that
could be used. Request
or delete spooled data.          S6,F23-->
                                          <--S6,F24    Request spooled data
                                                       acknowledgement.
                                                       [IF] RSDC = 0 (Spool data
                                                       requested.)
                                                       [THEN]
                                                       The appropriate Streams and
                                                       Functions are used to transmit
                                                       the spooled data to the host.
                                                       [ELSE_IF] RSDC = 1
                                                       [THEN]
                                                       Spool data discarded.
                                                       [END_IF]
                                          <--S6,F11    Spooling Deactivated event
                                                       report sent.
Acknowledge                      S6,F12-->
```

Request or Delete Spooled Data (MaxSpoolTransmit > 0):

This Scenario shows the affect of MaxSpoolTransmit < SpoolCountActual on the Spool Transmit process. For the purpose of illustration, the value of MaxSpoolTransmit is 5 and the SpoolCountActual is 8 (at the time communications are re-established). No messages are added to the Spool during the transmit process.

```
COMMENTS                          HOST   EQUIPMENT                          COMMENTS

                Communications were lost and then re-established.
Host requests data that
includes spool-related
status variables.                  S1,F3-->
                                         <--S1,F4     Send status data (e.g.
                                                      SpoolCountActual = 8, MaxSpool-
                                                      Transmit = 5).
Host requests spooled data
(RSDC=0).                         S6,F23-->
                                         <--S6,F24    Request spooled data
                                                      acknowledgement.
                                                      The five oldest messages in the
                                                      Spool are transmitted to the
                                                      host. Spooling remains active.
Host recognizes that MaxSpoolTransmit
is reached.
Host requests additional          S6,F23-->
spooled data (RSDC = 0).
                                         <--S6,F24    Request spooled data
                                                      acknowledgement.
                                                      The three remaining messages
                                                      are transmitted from the spool.
                                         <--S6,F11    Spooling Deactivated event
                                                      report sent.
Acknowledge                       S6,F12-->
```

4.12 *Control* — The control-related capabilities allow for configuration and manipulation of the control state model. In this way the host and/or user may modify the equipment's control-related behavior.

4.12.1 *Purpose* — This section complements the CONTROL state model description found in Section 3.3. It defines the requirements for implementation of this model.

4.12.2 *Definitions* — None.

4.12.3 *Description*

4.12.3.1 *Control Configuration* — The control state model has two areas of configuration. The first area is related to default entry states of the state model. Upon system initialization, the system must activate either the ON-LINE or OFF-LINE state. Upon entry to OFF-LINE, the system must in turn activate one of the substates of OFF-LINE (EQUIPMENT OFF-LINE, ATTEMPT ON-LINE, or HOST OFF-LINE). In both these cases, the user shall configure the equipment to make the choices appropriate to that factory. Entry to the ON-LINE state also involves a choice of substates. In this case, the equipment reads the front panel REMOTE/LOCAL switch to determine the appropriate state.

The second area of configuration involves the transition to be made if the ON-LINE attempt should fail. The model may be set to transition to either HOST OFF-LINE or to EQUIPMENT OFF-LINE should the S1,F1 transaction be terminated unsuccessfully. Choosing HOST OFF-LINE allows the host to cause the equipment to transition to ON-LINE when the host becomes ready. This is accomplished via the message S1,F17 (see below).

4.12.3.2 *Changing Control State* — In the control state model, both the operator and the host can affect the control state. The operator retains ultimate authority to set the equipment OFF-LINE by means of an OFF-LINE switch mechanism. The operator also can cause the equipment to attempt to go ON-LINE. Under some circumstances, the host can initiate the transition to ON-LINE.

If the operator requests ON-LINE, the equipment will send an S1,F1 to the host. The host may confirm ON-

LINE with an S1,F2 or deny ON-LINE by sending an S1,F0.[23]

When the equipment is ON-LINE, the host may request that it transition to OFF-LINE. It will transition into the HOST OFF-LINE substate. When the equipment HOST OFF-LINE state is active, the host may request that it transition to ON-LINE. The combination of these two allow the host to cycle the equipment between ON-LINE and OFF-LINE.

Only the operator may change the ON-LINE substate (REMOTE or LOCAL).

4.12.4 *Requirements*

— The equipment shall supply a method for configuring the default CONTROL state to be activated upon system initialization. The choice of states must be among ATTEMPT ON-LINE, EQUIPMENT OFF-LINE, HOST OFF-LINE, and ON-LINE.

— The equipment shall supply a method for configuring which state should be activated when the attempt to go ON-LINE fails. The option is a transition to either the HOST OFF-LINE state or the EQUIPMENT OFF-LINE state.

— The equipment shall supply a momentary switch which will initiate the transition to OFF-LINE and another which will begin the process to go ON-LINE. Discrete position switches shall not be used. These should be designed so that they may not be actuated simultaneously. The switch may be mounted on the front panel or be available via keyboard input at the operator console.

— The equipment shall supply a discrete two-position switch which the operator may use to indicate the desired substate for ON-LINE (i.e., REMOTE or LOCAL). The switch may be mounted on the front panel or be available via keyboard input at the operator console. If implemented in software, this setting shall be retained in non-volatile storage.

— The equipment shall supply an indicator on the front panel which displays the full identification of the current CONTROL state/substate (e.g., OFF-LINE/ATTEMPT ON-LINE). This may be accomplished either with labelled display lights or via the operator console display. It is recommended that this indicator be visible at all times.

— The equipment shall supply a status variable that contains the current state/substate of the CONTROL state model.

— Whenever the ON-LINE/REMOTE state is active and the operator issues a command to the equipment, the equipment shall cause an “operator command issued” event.

23 If there is no host response (i.e. reply timeout), the equipment shall treat it as a denial.

4.12.5 *Scenarios*

4.12.5.1 *Operator-Initiated Scenarios*

Host Accepts ON-LINE:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Operator actuates ON-LINE switch when equipment OFF-LINE state is active.			
		<--S1,F1	Equipment requests ON-LINE.
Host grants ON-LINE.	S1,F2-->		
		<--S6,F11	"Control State LOCAL (or REMOTE)" event.
Acknowledge.	S6,F12-->		

Host Denies ON-LINE:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Operator actuates ON-LINE switch when equipment OFF-LINE state is active.			
		<--S1,F1	Equipment requests ON-LINE.
Host denies ON-LINE.	S1,F0-->		

Operator Sets OFF-LINE:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Operator actuates OFF-LINE switch when equipment ON-LINE state is active.			
		<--S6,F11	"Equipment requests OFF-LINE" event.
Acknowledge.	S6,F12-->		

Operator Sets REMOTE:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Operator sets switch from LOCAL to REMOTE.			
		<--S6,F11	"Control State REMOTE" event.
Acknowledge.	S6,F12-->		

Operator Sets LOCAL:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Operator sets switch from REMOTE to LOCAL.			
		<--S6,F11	"Control State LOCAL" event.
Acknowledge.	S6,F12-->		

4.12.5.2 *Host-Initiated Scenarios*

Host Sets OFF-LINE:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host requests OFF-LINE.	S1,F15-->		
			[IF] Equipment is OFF-LINE
			[THEN]:
		<--S1,F0	Equipment does not process requests.
			[ELSE] Equipment ON-LINE
		<--S1,F16	Equipment acknowledges request and transitions to OFF-LINE.
		<--S6,F11	"Equipment OFF-LINE" event.
Acknowledge	S6,F12-->		
			[END_IF]

Host Sets ON-LINE:

COMMENTS	HOST	EQUIPMENT	COMMENTS
Host requests ON-LINE.	S1,F17-->		
			[IF] Equipment is HOST OFF-LINE state not active.
			[THEN]
		<--S1,F18	Equipment denies request (ONLACK = 1).
			[ELSE] Equipment HOST OFF-LINE state is active.
		<--S1,F18	Equipment acknowledges request (ONLACK != 1).
		<--S6,F11	"Control state LOCAL (or REMOTE)" event. (only if ONLACK = 0)
Acknowledge	S6,F12-->		
			[END_IF]

5 Data Items

The following sections specify which data items and variable data items are required.

Except for the specified format restrictions, all data items and variable data items follow the definitions contained in SEMI E5.

5.1 *Data Item Restrictions* — The following is a subset of the data items used by SECS-II messages specified in this standard. Each data item listed in this section is restricted in its SEMI E5-defined usage. Most are limited to a single format from their standard list of formats. Data items used by SECS-II messages contained in this document, but which have no restrictions are not duplicated here.

NOTE 21: One data item, ALCD, is restricted in other than its format. Take note of this restriction as described below.

NOTE 22: The equipment supplier shall document any restrictions on length or format of CPNAME. Suppliers shall document the behavior of spaces in a CPNAME. The maximum length of CPNAME shall be 40. This change became effective in September 1995.

ACKC7A	Format: 51
ALCD	Only bit 8 (alarm set/cleared) of the binary byte is used. Bits 1–7, denoting alarm category, are not used.
ALID	Format: 5()
CCODE	Format: 52
CEID	Format: 5()
CPNAME	Format: 20
DATAID	Format: 5()
DATALENGTH	Format: 5()
ECID	Format: 5()
LENGTH	Format: 5()
PPID	Format: 20
RCMD	Format: 20
REPGSZ	Format: 5()
RPTID	Format: 5()
SEQNUM	Format: 52
SMPLN	Format: 5()
SVID	Format: 5()
TEXT	Format: 20
TOTSMP	Format: 5()
TRID	Format: 5()
VID	Format: 5()

5.2 *Variable Item List* — The following variable data items from the Variable Item Dictionary in SEMI E5 are required. Format restrictions are noted.

DVVAL's:

AlarmID Format: 5()
EventLimit
LimitVariable
PPChangeName Format: 20
PPChangeStatus
PPError
RcpChangeName
RcpChangeStatus
TransitionType

ECV's:

EstablishCommunicationsTimeout
MaxSpoolTransmit
OverWriteSpool
TimeFormat

SV's:

AlarmsEnabled
AlarmsSet
Clock
ControlState
EventsEnabled
PPError
PPExecName Format: 0,20
PPFormat
PreviousProcessState
ProcessState
RcpExecName
SpoolCountActual
SpoolCountTotal
SpoolFullTime
SpoolStartTime

6 Collection Events

Table 6.1 provides the list of collection events required to support the capabilities addressed within this standard. Also shown are typical variable data that would most likely be included in the associated collection event report and a reference to the event trigger and to the appropriate section of the standard.

This list does not represent all events that might be needed to properly monitor/control equipment. Many events are unique to the specific equipment characteristics. The needed additions are a matter for other standards and for collaboration between equipment supplier and user.

See Section 5.2 for further detail of variable data items.

Table 6.1 GEM-Defined Collection Events

Event Designation	*Typical Variable Data*	*Reference*
Control-Related Events:		Section 3.3
Equipment OFF-LINE	ControlState, Clock	ON-LINE->OFF-LINE
Control State LOCAL	ControlState, Clock	REMOTE->LOCAL or OFF-LINE->LOCAL
Control State REMOTE	ControlState, Clock	LOCAL->REMOTE or OFF-LINE->REMOTE
Operator Command Issued	OperatorCommand	Operator Activity while REMOTE state is active.
Processing-Related Events:	Note: Any transition in the implemented processing state model must have a corresponding collection event.	Section 3.4
Processing Started	Clock, PreviousProcessState	Entry into EXECUTING state.
Processing Completed	Clock, PreviousProcessState	Normal exit of EXECUTING state.
Processing Stopped	Clock, PreviousProcessState	Result of STOP command from host or operator.
Processing State Change	Clock, ProcessState, PreviousProcessState	Any processing state transition.
Alarm Management Events:		Section 4.3
Alarm_nDetected	Clock, AlarmID, AlarmsSet, Associated variable data	ALARM_nCLEAR->ALARM_nSET
Alarm_nCleared	Clock, AlarmID, AlarmsSet	ALARM_nSET->ALARM_nCLEAR
Equipment Constant Events:		Section 4.5
Operator Equipment Constant Change	ECID	Operator activity
Limits Monitoring:		Section 4.2.4
Limit Zone Transition_n (separate CEID per variable)	Clock, LimitVariable, EventLimit, Transition Type	Entry into BELOW LIMIT or ABOVE LIMIT states.
Process Program Management Events:		Section 4.6
Process Program Change	PPChangeName, PPChangeStatus	Operator activity
Process Program(s) Selected	PPExecName	Operator/Host activity
Material Movement Events:		Section 4.7
Material Received	Clock	
Material Removed	Clock	
Spooling Events:		Section 4.11
Spooling Activated	SpoolStartTime	SPOOL INACTIVE->SPOOL ACTIVE
Spooling Deactivated	SpoolCountTotal	SPOOL OUTPUT->SPOOL INACTIVE
Spool Transmit Failure	Clock, SpoolCountActual SpoolCountTotal	TRANSMIT SPOOL->NO SPOOL OUTPUT
Terminal Services Events:		Section 4.8
Message Recognition	Clock	Operator
New Execution Recipe Event	RcpChangeName, RcpChangeStatus	Section 4.6.2.2
Execution Recipe Change Event	RcpChangeName, RcpChangeStatus	Section 4.6.2.2

7 SECS-II Message Subset

This section lists the required set of SECS-II messages as referenced in this document. Definitions for these messages can be found in SEMI E5. All primary messages (for which SEMI E5 defines replies) should have replies available. Replies are required or optional as specified in SEMI E5.

STREAM 1: Equipment Status

S1,F1 Are You There Request (R)	S,H<->E
S1,F2 On-Line Data (D)	S,H<->E
S1,F3 Selected Equipment Status Request (SSR)	S,H->E
S1,F4 Selected Equipment Status Data (SSD)	M,H<-E
S1,F11 Status Variable Namelist Request (SVNR)	S,H->E
S1,F12 Status Variable Namelist Reply (SVNRR)	M,H<-E
S1,F13 Establish Communications Request (CR)	S,H<->E
S1,F14 Establish Communications Request Acknowledge (CRA)	S,H<->E
S1,F15 Request OFF-LINE (ROFL)	S,H->E,reply
S1,F16 OFF-LINE Acknowledge (OFLA)	S,H<-E
S1,F17 Request ON-LINE (RONL)	S,H->E,reply
S1,F18 ON-LINE Acknowledge (ONLA)	S,H<-E

STREAM 2: Equipment Control and Diagnostics

S2,F13 Equipment Constant Request (ECR)	S,H->E
S2,F14 Equipment Constant Data (ECD)	M,H<-E
S2,F15 New Equipment Constant Send (ECS)	S,H->E
S2,F16 New Equipment Constant Acknowledge (ECA)	S,H<-E
S2,F17 Date and Time Request (DTR)	S,H<->E
S2,F18 Date and Time Data (DTD)	S,H<->E
S2,F23 Trace Initialize Send (TIS)	S,H->E
S2,F24 Trace Initialize Acknowledge (TIA)	S,H<-E
S2,F29 Equipment Constant Namelist Request (ECNR)	S,H->E
S2,F30 Equipment Constant Namelist (ECN)	M,H<-E
S2,F31 Date and Time Send (DTS)	S,H->E
S2,F32 Date and Time Acknowledge (DTA)	S,H<-E
S2,F33 Define Report (DR)	M,H->E
S2,F34 Define-Report Acknowledge (DRA)	S,H<-E
S2,F35 Link Event Report (LER)	M,H->E
S2,F36 Link Event Report Acknowledge (LERA)	S,H<-E
S2,F37 Enable/Disable Event Report (EDER)	S,H->E,reply

S2,F38 Enable/Disable Event Report Acknowledge (EDEA)	S,H<-E
S2,F39 Multi-Block Inquire (DMBI)	S,H->E
S2,F40 Multi-Block Grant (DMBG)	S,H<-E
S2,F41 Host Command Send (HCS)	S,H->E
S2,F42 Host Command Acknowledge (HCA)	S,H<-E
S2,F43 Reset Spooling Streams and Functions (RSSF)	S,H->E
S2,F44 Reset Spooling Acknowledge (RSA)	M,H<-E
S2,F45 Define Variable Limit Attributes (DVLA)	M,H->E
S2,F46 Variable Limit Attribute Acknowledge (VLAA)	M,H<-E
S2,F47 Variable Limit Attribute Request (VLAR)	S,H->E
S2,F48 Variable Limit Attributes Send (VLAS)	M,H<-E
S2,F49 Enhanced Remote Command	M,H->E
S2,F50 Enhanced Remote Command Acknowledge	M,H<-E

STREAM 5: Exception (Alarm) Reporting

S5,F1 Alarm Report Send (ARS)	S,H<-E
S5,F2 Alarm Report Acknowledge (ARA)	S,H->E
S5,F3 Enable/Disable Alarm Send (EAS)	S,H->E
S5,F4 Enable/Disable Alarm Acknowledge (EAA)	S,H<-E
S5,F5 List Alarms Request (LAR)	S,H->E
S5,F6 List Alarm Data (LAD)	M,H<-E

STREAM 6: Data Collection

S6,F1 Trace Data Send (TDS)	S,H<-E
S6,F2 Trace Data Acknowledge (TDA)	S,H->E
S6,F5 Multi-block Data Send Inquire (MBI)	S,H<-E
S6,F6 Multi-block Grant (MBG)	S,H->E
S6,F11 Event Report Send (ERS)	M,H<-E
S6,F12 Event Report Acknowledge (ERA)	S,H->E
S6,F15 Event Report Request (ERR)	S,H->E
S6,F16 Event Report Data (ERD)	M,H<-E
S6,F19 Individual Report Request (IRR)	S,H->E
S6,F20 Individual Report Data (IRD)	M,H<-E
S6,F23 Request Spooled Data (RSD)	S,H->E
S6,F24 Request Spooled Data Acknowledgement Send (RSDAS)	S,H<-E

STREAM 7: Process Program Load

S7,F1 Process Program Load Inquire (PPI)	S,H<->E, reply
S7,F2 Process Program Load Grant (PPG)	S,H<->E
S7,F3 Process Program Send (PPS)	M,H<->E
S7,F4 Process Program Acknowledge (PPA)	S,H<->E
S7,F5 Process Program Request (PPR)	S,H<->E
S7,F6 Process Program Data (PPD)	M,H<->E
S7,F17 Delete Process Program Send (DPS)	S,H->E
S7,F18 Delete Process Program Acknowledge (DPA)	S,H<-E
S7,F19 Current EPPD Request (RER)	S,H->E
S7,F20 Current EPPD Data (RED)	M,H<-E
S7,F23 Formatted Process Program Send (FPS)	M,H<->E
S7,F24 Formatted Process Program Acknowledge (FPA)	S,H<->E
S7,F25 Formatted Process Program Request (FPR)	S,H<->E
S7,F26 Formatted Process Program Data (FPD)	M,H<->E
S7,F27 Process Program Verification Send (PVS)	S,H<-E
S7,F28 Process Program Verification Acknowledge (PVA)	S,H->E
S7,F29 Process Program Verification Inquire (PVA)	
S7,F30 Process Program Verification Grant (PVG)	

STREAM 9: System Errors

S9,F1 Unrecognized Device ID (UDN)	S,H<-E
S9,F3 Unrecognized Stream Type (USN)	S,H<-E
S9,F5 Unrecognized Function Type (UFN)	S,H<-E
S9,F7 Illegal Data (IDN)	S,H<-E
S9,F9 Transaction Timer Timeout (TTN)	S,H<-E
S9,F11 Data Too Long (DLN)	S,H<-E
S9,F13 Conversation Timeout (CTN)	S,H<-E

STREAM 10: Terminal Services

S10,F1 Terminal Request (TRN)	S,H<-E
S10,F2 Terminal Request Acknowledge (TRA)	S,H->E
S10,F3 Terminal Display, Single (VTN)	S,H->E
S10,F4 Terminal Display, Single Acknowledge (VTA)	S,H<-E
S10,F5 Terminal Display, Multi-block (VMN)	M,H->E
S10,F6 Terminal Display, Multi-block Acknowledge (VMA)	S,H<-E
S10,F7 Multi-block Not Allowed (MNN)	S,H<-E

STREAM 14: Object Services

S14,F1 GetAttr Request	S,H <-> E
S14,F2 GetAttr Data	M,H <-> E

STREAM 15: Recipe Management

S15,F1 Recipe Management Multi-block Inquire	S,H <-> E
S15,F2 Recipe Management Multi-block Grant	S,H <-> E
S15,F21 Recipe Action Request	M,H <-> E
S15,F22 Recipe Action Acknowledge	M,H <-> E
S15,F27 Recipe Download Request	M,H -> E
S15,F28 Recipe Download Acknowledge	M,H <- E
S15,F29 Recipe Verify Request	M,H -> E
S15,F30 Recipe Verify Data	M,H <- E
S15,F31 Recipe Upload Request	S,H -> E
S15,F32 Recipe Upload Data	M,H <- E
S15,F35 Recipe Delete Request	M,H -> E
S15,F36 Recipe Delete Acknowledge	M,H <- E

8 GEM Compliance

This section defines compliance to the GEM standard. It describes the fundamental GEM requirements and additional GEM capabilities. It provides references to other sections of the standard where detailed requirements are located. This section also defines standard terminology and documentation that can be used by equipment suppliers and device manufacturers to describe compliance with this standard.

The GEM standard contains two types of specifications:

— fundamental GEM requirements and

— requirements pertaining to additional GEM capabilities.

The fundamental GEM requirements form the foundation of the GEM standard. The additional GEM capabilities provide functionality required for some types of factory automation or functionality applicable to specific types of equipment. Figure 8.1 illustrates the relationship of the fundamental GEM requirements and the additional GEM capabilities.

8.1 *Fundamental GEM Requirements* — All equipment shall comply with the fundamental GEM requirements listed in Table 8.1. Compliance to these requirements involves precise and complete adherence to all sections of the GEM standard referenced in Table 8.1.

Table 8.1 Fundamental GEM Requirements

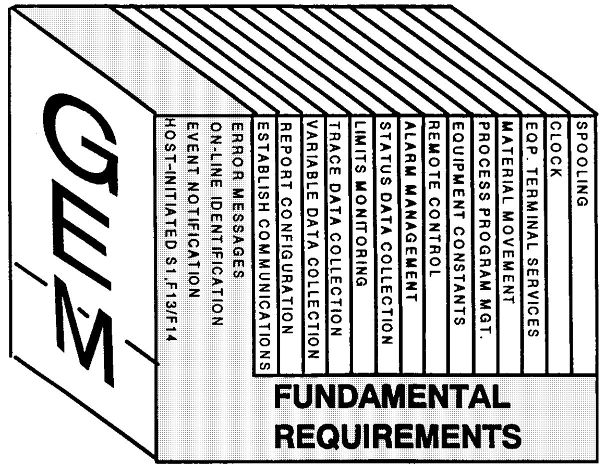
Requirement	*Section References*
State Models	3.0, 3.1, 3.3
Equipment Processing States	3.4
Host-Initiated S1,F13/F14 Scenario	4.1.5.1
Event Notification	4.2.1.1
On-line Identification	4.2.6
Error Messages	4.9
Control (Operator-Initiated)	4.12 (except 4.12.5.2)
Documentation	8.4

In addition, compliance requires adherence to the portions of the following sections that are applicable to the fundamental GEM requirements:

— Variable data items (GEM, Section 5)

— SECS-II data item restrictions (GEM, Section 5)

— Collection events (GEM, Section 6)



Vertical text represents capabilities.
Some capabilities are also fundamental requirements.

Figure 8.1
GEM Requirements and Capabilities

8.2 *GEM Capabilities* — The following table lists all GEM capabilities and the sections of the GEM standard where they are specified. These sections contain the detailed requirements for implementing a GEM capability. Requirements for an individual capability include any referenced portions of the document. As an example, the Alarm Management capability requires implementation of the status variables “AlarmsEnabled” and “AlarmsSet” as defined in Section 5.

Table 8.2 Section References for GEM Capabilities

Capability	*Section References*
Establish Communications	4.1, 3.2
Event Notification	4.2.1.1
Dynamic Event Report Configuration	4.2.1.2
Variable Data Collection	4.2.2
Trace Data Collection	4.2.3
Limits Monitoring	4.2.4
Status Data Collection	4.2.5
On-line Identification	4.2.6
Alarm Management	4.3
Remote Control	4.4
Equipment Constants	4.5
Process Program Management	4.6
Material Movement	4.7
Equipment Terminal Services	4.8
Error Messages	4.9
Clock	4.10

Capability	Section References
Spooling	4.11
Control (Operator-Initiated)	4.12 (except 4.12.5.1)
Control (Host-Initiated)	4.12.5.1

8.3 *Definition of GEM Compliance* — The term "GEM Compliance" is defined with respect to individual GEM capabilities to indicate adherence to the GEM standard for a specific capability. Equipment is GEM-compliant for a specific GEM capability if, and only if, the following three criteria are met:

— The fundamental GEM requirements are satisfied.

— The capability is implemented to conform with all applicable definitions, descriptions, and requirements defined for the capability in this standard.

— The equipment does not exhibit behavior related to this capability that conflicts with the GEM behavior defined for the capability.

For example, equipment that provides SECS-II messages for management of process programs must precisely implement the GEM Process Program Management capability to be "GEM-Compliant for Process Program Management."

Equipment may supply additional functionality not specified in the GEM standard by using any messages defined in the SECS-II standard as long as the additional functionality does not conflict with compliance to GEM capabilities.

Figure 8.2 illustrates the host view of equipment communications in relationship to the components of the GEM standard. The GEM capabilities are built upon the fundamental GEM requirements and present GEM-compliant behavior to the host when they are not obstructed by conflicting functionality. Additional non-GEM capabilities and non-obstructing extensions to GEM capabilities provide additional functionality while maintaining GEM behavior from the host view.

One additional term is defined to facilitate discussion of GEM capability. Equipment is "Fully GEM Capable" if and only if it meets the following two criteria:

— The equipment supplies all the GEM capabilities listed in Section 8.2.

— Every implemented GEM capability is GEM-Compliant.

8.4 *Documentation* — This section describes documentation requirements in addition to those specified in Sections 3 and 4 of this standard. All documentation of the SECS-II interface shall be supplied as a single volume, including Message Documentation, a Compliance Statement and the documentation required by Sections 3 and 4.

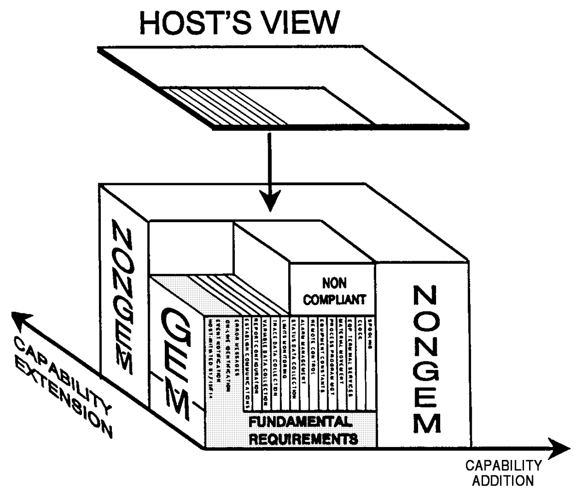


Figure 8.2
Host View of GEM

8.4.1 *Message Documentation* — The equipment supplier shall provide message documentation in conformance with Chapter 8 (Message Documentation) of SEMI E5.

8.4.2 *GEM Compliance Statement* — The SECS-II interface documentation provided by an equipment supplier shall address GEM compliance. This documentation shall include a GEM Compliance Statement that accurately indicates for each capability whether it has been implemented and whether it has been implemented in a GEM-compliant manner. The format for this statement is supplied as Table 8.3.

The table consists of three columns. The first column lists the requirements and capabilities. The other two columns pose questions to the supplier:

Implemented: Does the equipment provide functionality that is similar to that defined for the GEM requirement or capability?

GEM-Compliant: Has that requirement or capability been implemented in a GEM-compliant manner?

8.4.3 The equipment supplier may provide documentation on the format of required data items (see Section 5) using SECS Message Language™ Notation (SML®). The SML formats are provided in Table 8.4.

Table 8.3 GEM Compliance Statement

GEM COMPLIANCE STATEMENT				
FUNDAMENTAL GEM REQUIREMENTS	**IMPLEMENTED**		**GEM-COMPLIANT**	
State Models	❒ Yes	❒ No	❒ Yes (See NOTE 1.) ❒ No	
Equipment Processing States	❒ Yes	❒ No		
Host-Initiated S1= F13/F14 Scenario	❒ Yes	❒ No		
Event Notification	❒ Yes	❒ No		
On-Line Identification	❒ Yes	❒ No		
Error Messages	❒ Yes	❒ No		
Documentation	❒ Yes	❒ No		
Control (Operator Initiated)	❒ Yes	❒ No		
ADDITIONAL CAPABILITIES	**IMPLEMENTED**		**GEM-COMPLIANT** (See NOTE 2.)	
Establish Communications	❒ Yes	❒ No	❒ Yes	❒ No
Dynamic Event Report Configuration	❒ Yes	❒ No	❒ Yes	❒ No
Variable Data Collection	❒ Yes	❒ No	❒ Yes	❒ No
Trace Data Collection	❒ Yes	❒ No	❒ Yes	❒ No
Status Data Collection	❒ Yes	❒ No	❒ Yes	❒ No
Alarm Management	❒ Yes	❒ No	❒ Yes	❒ No
Remote Control	❒ Yes	❒ No	❒ Yes	❒ No
Equipment Constants	❒ Yes	❒ No	❒ Yes	❒ No
Process Program Management	❒ Yes	❒ No	❒ Yes	❒ No
Material Movement	❒ Yes	❒ No	❒ Yes	❒ No
Equipment Terminal Services	❒ Yes	❒ No	❒ Yes	❒ No
Clock	❒ Yes	❒ No	❒ Yes	❒ No
Limits Monitoring	❒ Yes	❒ No	❒ Yes	❒ No
Spooling	❒ Yes	❒ No	❒ Yes	❒ No
Control (Host-Initiated)	❒ Yes	❒ No	❒ Yes	❒ No

NOTE 1: Do not mark YES unless all fundamental GEM requirements are implemented and GEM-compliant.

NOTE 2: Additional capabilities may not be marked GEM-compliant unless the fundamental GEM requirements are GEM-compliant.

Table 8.4 SML Notation

Item Format	*SECS-II Format Code*		*SML Item Format Mnemonic*
	Binary	*Octal*

A. Application Notes

NOTE: The material contained in these Application Notes is not an official part of this SEMI standard and is not intended to modify or supersede the official standard. Rather, these notes are auxiliary information describing possible methods for implementing the protocol described by the standard and are included as reference material. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the materialis solely the responsibility of the user.

A.1 Factory Operational Script

An Operational Script is a series of capabilities arranged in a typical factory operation sequence. The intent of having an Operational Script is to help put the SECS-II message Scenarios into a context. Although this context will vary, it represents a typical operational sequence found in most semiconductor device manufacturers' applications.

— System Initialization

— Synchronization

— Machine Setup

— Production Setup

— Processing

— Post-Processing

— Shutdown

The following script is not intended to be complete, but to serve as an example to be further developed on an implementation basis.

A1.1 *Anytime Capabilities* — All capabilities can generally occur at anytime during the operational script sequence.

A1.2 *System Initialization and Synchronization* — Upon system initialization, the default setting for communication (enabled or disabled) becomes effective, as well as any equipment constants or other information retained in non-volatile storage. The initial communication status is displayed at the equipment.

Assuming the communication state is enabled, the equipment will attempt to establish communication with a host computer. See Section 4.1 for a description of the scenario for establishing communications.

Upon receiving an indication that the equipment was previously not communicating, the host would typically perform synchronization activities including setting the equipment's clock and requesting selected status information. Note that synchronization activity is host application-dependent and may be implemented using various scenarios.

A1.3 Production Set-Up — The host typically has the following information:

— what material

— what process step

— what process program to use (PPID)

— current equipment status, VID's, SVID's

— data collection requirements (trace data & event data)

— VID's needed

— Equipment constants (ECID's)

Based upon the above information, the host will perform setup activities as required. It must be verified that the correct process program is available and selected at the equipment.

A1.3.1 *Auxiliary Material and Manual Set-Up* — Auxiliary material can be checked and verified at this point. If status variables exist for auxiliary material, they may be requested by the host.

Any other manual, non-process, and/or non-product specific set-up also may take place at this point. The operator may interact with the equipment and the host. If the operator interacts with the equipment, the equipment communications link with the host should stay operational.

The operator and the host may exchange information via equipment terminal services.

A1.3.2 *Product/Process Set-Up* — Specific product and/or process information is communicated to the equipment prior to processing material.

A1.3.3 *Material Load* — The host may instruct an operator or a material handling system to deliver material to the equipment.

Once the material has arrived at the equipment, the equipment or the operator will notify the host.

A1.3.4 *Production Data Collection Set-Up* — The host instructs the equipment to collect event-based data. Reports are defined and linked to events. Event reports can be enabled or disabled.

The host instructs the equipment to collect data from the equipment based on time intervals.

The host configures the equipment to monitor specific variables and to send event reports when variables transition between monitoring zones.

A1.4 *Processing*

A1.4.1 *Start Process Executing* — The host or operator issues a command to start.

A1.4.2 *Equipment Signals End of Run* — When process execution is completed, the equipment generates events. If any of the events are enabled, they will be sent as event reports.

A1.5 *Post-Processing* — The equipment has completed processing material. It now makes the material available to the operator or material handling system for removal. The equipment signals the host that it is available for more work.

A1.5.1 *Material Unload* — Material is unloaded from the equipment by an operator or material handling system.

A.2 Equipment Front Panel

In the GEM standard, several requirements are stated that involve the display or input of information at the equipment front panel. The "equipment front panel" refers to an area on the equipment that is available to the operator under normal use (i.e., without removing maintenance access panels). This may include a CRT display, keyboard, switches, and lights.

This application note provides some guidance for implementation of the GEM front panel capabilities. All of these requirements map directly to state models and capabilities defined in Sections 3 and 4. All capabilities may be implemented in either hardware (buttons, switches, lights) or in a software/CRT equivalent.

A2.1 *Displays and Indicators* — The intent of various displays is to inform the operator of either the current state of the equipment or of a recent change of state (or both). Therefore, it is most useful if these displays are continuously visible and easily recognized at a distance. Required displays/indicators include:

Communications State: This means that three distinct states must be represented: DISABLED, ENABLED/NOT COMMUNICATING, and ENABLED/COMMUNICATING.

Terminal Services: An "New Host Message" indicator must be supplied.

A2.2 *Switches/Buttons* — Note that discrete switches also contain information for the user. However, these tend to represent the desired states of the operator/user. The equipment's response to a change of a switch may not be instantaneous. Still, the current position of switches should be available to the operator.

It may be appropriate to limit the access to some switches and buttons. This might be done via any of the standard methods, keys, passwords, combinations, etc. This is especially true for system default switches that would not often be changed. Required switches/buttons include:

Communications State System Default: In what communications state should the equipment be when system initialization is complete? The choices are DISABLED and ENABLED.

Communications State Selector: This is a toggle or button that will initiate a transition from ENABLED to DISABLED or vice versa.

Message Recognition Button: This button is used to initiate an event message to the host which indicates that the "New Host Message" has been read. This button should function only when the New Host Message Indicator is activated and when the received message is displayed in the terminal display.

A.3 Examples of Equipment Alarms

Table A.3 provides alarm examples pertaining to various configurational aspects of equipment.

NOTE: It is important to stress that these are just examples intended to illustrate that alarms pertain to situations in which there exists a potential for exceeding physical safety limits associated with people, equipment, and material being processed as per the GEM definition of an alarm.

NOTE: The alarm capability is intended as an addition to standard safety alarms (e.g., lights, horns). There is no intent to replace direct operator reaction to such problems. Nor is there the expectation that the host can necessarily prevent or directly address such alarms.

An actual machine shall have an associated set of alarms defined by the manufacturer that pertains to its specific configuration and design. The equipment manufacturer is responsible for supplying documentation associated with these alarm definitions.

Table A.3 Alarm Examples Per Equipment Configuration

Subsystem	*Alarm Description*	*ALID*	*Trigger*	*Reset*	*Operator*	*Equipment*	*Material*
Mainframe Power Supply	Overvoltage		Voltage supply over maximum limit			X	
	Undervoltage		Voltage supply under minimum limit			X	
Internal Power Distribution Bus	AC Low		AC under minimum limit			X	X
Cooling System	Overtemp		Temperature over maximum		X		X
	Pressure Low		Pressure below minimum				X

Subsystem	The subsystem of the equipment to which the alarm is related
Alarm Description	Description of the alarm
ALID	The Alarm ID as specified by SECS-II
Trigger	Text description of what caused the alarm
Reset	Description of how to resolve the alarm condition
Affected	Who or what is affected by the alarm trigger: Operator, Equipment, and Material

A.4 Trace Data Collection Example

This example shows an implementation of the Trace Data Collection capability defined in Section 4.2.3.

S2,F23 sent by host:

```
    TRID = ABCD
    DSPER = 000100 (One minute per
 period)
    TOTSMP = 9
    REPGSZ = 3
    SVID1 =  Temperature
    SVID2 =  Relative humidity
```

S6,F1 looks like this (starting at time 1 a.m.):

1st transmission <L,4>

```
    1. ABCD (trace ID)
    2. 3 (last sample of the
 transmission)
    3.    88   5   01   01   03   00
        Year Month Day  Hour Min  Sec
    4. <L, n> n = 2 SVID's x REPGSZ of
       3 = 2 x 3 = 6
       72 (temperature)
       0.29 (relative humidity)
       73 (temp.)
       0.30 (r.h.)
       71 (temp.)
       0.30 (r.h.)
```

2nd transmission <L,4>

```
    1. ABCD
    2. 6
    3. 88  05  01  01  06  00
                   hr  min
    4. <L,6>
          73
          0.31
          71
          0.32
          71
          0.31
```

3rd and last transmission <L,4>

```
1. ABCD
2. 9
3. 88  05  01  01  09  00
               hr  min
4. <L,6>
   71
   0.30
   72
   0.30
   71
   0.31
```

A.5 Harel Notation

Harel's statecharts extend traditional state-transition diagrams with several additional concepts, most important of which are hierarchy and concurrence. Statecharts depict the behavior of a system by showing states it may take, events that prompt a change of state, and the composition of states. What follows is a very brief description of the symbols defined for use and how these are useful to describe a system. See Figure A.5.1 for the basic notational symbols.

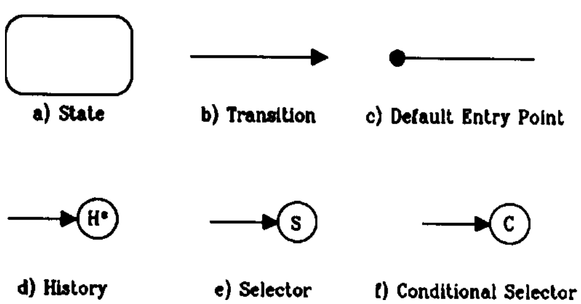

Figure A.5.1
Harel Statechart Symbols

States are represented by rounded boxes. A state transition is shown graphically with a line from the old state terminating with the arrow symbol at the new state. Transitions are unidirectional-while the reverse transition may be possible, it is considered a different transition with different conditions for initiation and different resultant actions.

States may be subdivided into substates to facilitate more concise definition of behavior. Thus, a hierarchy is defined whereby any state may be a substate of some parent state and in turn be the parent of its own substates. Substates must be one of two types, termed AND substates and OR substates.

A parent maybe divided into two or more OR substates of which one and only one is the active substate at any time. The accepted term for this exclusivity is XOR. Figure A.5.2 gives an example of a simple case of OR substates. In this example, some system (perhaps a motor) has a state named FUNCTIONAL. When the motor is FUNCTIONAL, it may be either ON or OFF, but never both.

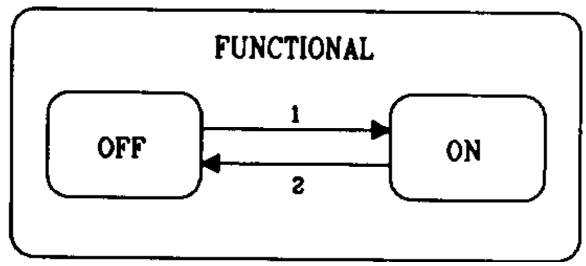

Figure A.5.2
Example of OR Substates

Another way of dividing a parent state corresponds roughly to subsystems. These AND substates represent parallelism, such that every AND substate of an active parent state is considered active. Harel also uses the term "Orthogonal Component" to refer to AND substates. However, these parallel substates tend to be highly interactive and interdependent. For this reason, the word orthogonal is considered confusing and has been excluded from use in this document. Figure A.5.3 shows an example of AND substates representing (in part) an automobile. Note the convention of attaching the name of the parent state AUTOMOBILE to the outside of the state in a small box. The substates shown are independent components and may have their own substates (of either the AND or OR type):

— LIGHTS may be ON or OFF;

— DOOR may be OPEN or CLOSED;

— ENGINE is constructed of components such as pumps, pistons, carburetor, etc.

Exiting one of a set of AND substates requires the exit of all others. In some cases, a transition arrow will be shown from only one of the substates with the others implied.

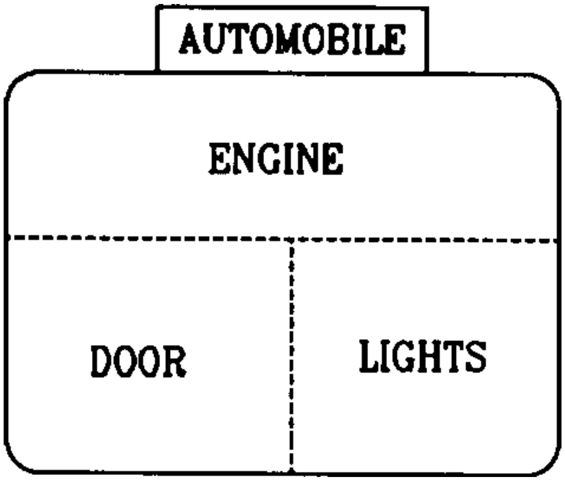

Figure A.5.3
Example of AND Substates

A simplification that also helps to prevent in determinacy is implemented with the symbol for default entry point. This symbol will indicate which OR substate is initially active when there is not an explicit choice. This lack of specification is indicated by a transition arrow from one state to another that does not cross the boundary of the parent to point specifically to a substate.

An entrance to a state terminating in a history symbol (see Figure A.5.1) indicates that the OR substate to be entered should be that which was active the last time the parent state was active (i.e., last time the car was running, the radio was on). The history symbol H refers to the choice of substates of the parent. The symbol H* extends further to the lowest level substates defined. In the absence of memory of a "last time", the default entry is used.

The selector and conditional selector symbols serve to abbreviate complex entrances to states. Their meaning is similar and indicate that the choice of OR substate upon entry of a parent state depends on some condition that is not shown. The selector is usually used to combine several similar transition events, while the conditional selector will typically require some computation or test of conditions external to the stimulus for state transition. Please examine the referenced article for more detail.

NOTE: Within the body of this document, the term statechart is not used in favor of the more traditional term state diagram.

A5.1 *State Definitions* — The state diagram provides a concise description of the function of a system. However, a full definition requires detail that cannot be included on the diagram. A description of each state is required that covers the boundaries of the state and any responses that occur within that state to the environment. The convention in this document is to provide state names in ALL CAPS to help the reader identify where these are used. A sample state description of the ON state depicted in the Figure A.5.2 might be:

ON

The switch is in the on position. Power is available to the motor. Speed of the motor will change in proportion to the speed knob adjustment.

A5.2 *Transition Table* — The last piece of the state model is the transition table. It consists of several columns that list the transition number from the diagram, the starting and ending state for the transition, and three columns titled trigger, action, and comment. The trigger column describes the combination of events and conditions that initiates the transition (e.g., message Sx,Fy received). The trigger should be related to a single clearly defined event at the equipment. The action column identifies the activities associated directly with the transition. These activities may be of three types: a) actions taken upon exit of the old state, b) actions taken upon entry to the new state, and c) actions not associated with either state. These are not differentiated in this document. The final column allows for additional comments that help to clarify the transition. Table A.5, an example of transition table, illustrates the motor example in Figure A.5.2.

Table A.5 Transition Table for Motor Example

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	OFF	Switch turned to on position.	ON	Power supplied to motor.	Power supply assumed available. Motor begins to turn.
2	ON	Switch turned to off position.	OFF	Power supply to motor dis-connected.	Motor begins deceleration.

A.6 Example Control Model Application

This section provides one example of a host's interaction with an equipment's control model. A host system must have a view of the control model to understand and predict equipment behavior. However, the implementor may simplify the host's view by assuming that some configuration settings are fixed and that the host-initiated features are not implemented. Applying these assumptions simplifies the behavior the host expects to see.

Figure A.6.1 shows the effective control model[24] based on the following host assumptions:

— The fundamental requirements are met, but the additional host-intiated control capability is not implemented.

— The configuration for the default entry to CONTROL is set to an OFF-LINE substate (either ATTEMPT ON-LINE or EQUIPMENT OFF-LINE).

— The destination state for transition 4 (failure of S1,F1 transaction) is configured to EQUIPMENT OFF-LINE.

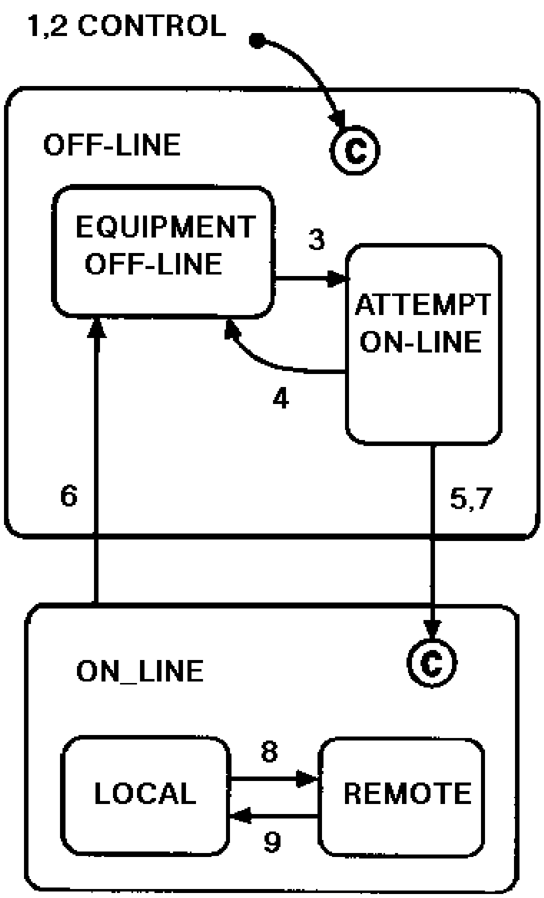

Figure A.6.1
Example of the Simplified "Effective" Control Model

This view of the model has two further settings that the host recognizes as changeable at the equipment. The first is the configuration of which substate of OFF-LINE to be activated upon system initialization. The second is the front panel switch that determines whether the active system substate is LOCAL or REMOTE when ON-LINE.

This application has the following implications:

— This application requires that the equipment begin with the OFF-LINE state active. Thus, an equipment initiated S1,F1/F2 transaction must be completed before the equipment will begin sending all messages to the host.

— If a failed attempt to go ON-LINE is made by the equipment, it will not allow the host to complete the transition at a later time. An operator will be required to re-initiate the transition to ON-LINE when the host becomes ready.

— Once ON-LINE, the equipment will remain ON-LINE until an operator sets the equipment OFF-LINE at the equipment front panel.

— Since all transitions into the HOST OFF-LINE state are eliminated, this state is effectively eliminated from the host view of the control model.

This application retains the following features:

— The ON-LINE state is achieved only after the host acknowledges the equipment by replying to the S1,F1 with and S1,F2. This confirms to the operator attempting to put the equipment ON-LINE that the host application is ready for work to begin.

— It provides the operator the means to set the equipment OFF-LINE for non-host-related activities[25] (e.g., maintenance, test lots).

— The operator has the ability to operate the equipment with either the REMOTE or LOCAL state active. As the equipment transitions to ON-LINE, the preferred substate is automatically chosen (based on a front panel switch).

— The user may configure which substate of OFF-LINE the equipment will initially activate at system initialization. If ATTEMPT ON-LINE is chosen, the equipment will automatically attempt the transition to the ON-LINE state as system initialization.

24 See Section 3.3 for details of the control model.

25 Which activities are "non-host-related" varies from factory to factory. In general, fewer activities are "non-host-related" as a factory's automation level increases.

A.7 Examples of Limits Monitoring

A7.1 *Introduction*

A7.1.1 Four limits monitoring examples are included below to help clarify the use of limits and to illustrate typical applications. The first example shows how to apply limits to boolean values. The second illustrates application of several limits to a floating point variable in a classical control zone style. The third example shows an integer counter variable used to prompt for equipment maintenance.

A7.2 *Examples*

A7.2.1 Example 1 — Valve Monitoring

A7.2.1.1 The ACME Shine-Um-Rite Model 13 includes a sump which contains the chemical agent used to clean bare wafers. A chemical feeder system serves to refill the sump when the level drops below a certain level. The fill is accomplished via an on-off value driven by sensors in the sump. Facilities must be informed of the proportion of the time the valve is open (approximates usage) and any time the value remains open for more than 5 minutes (valve likely broken).

A7.2.1.2 To implement this requirement, a limit was defined for the Boolean status variable which contains the current state of the valve (i.e., 0 = Closed, 1 = Open). See Figure A7.1 for illustration. LIMITID1 was defined with UPPERDB = LIMITMAX = 1 (Open) and LOWERDB = LIMITMIN = 0 (Closed). As a result, any time the valve opens, a collection event is generated with TransitionType = 0 and when the valve closes, a collection event is generated with TransitionType = 1. An event report containing the DVVAL LimitVariable was attached to each collection event and reporting for the event was enabled.

NOTE: Boolean values are defined as 0 = False/Closed/Off and any value > 0 = True/Open/On — never depend on a value of 1.

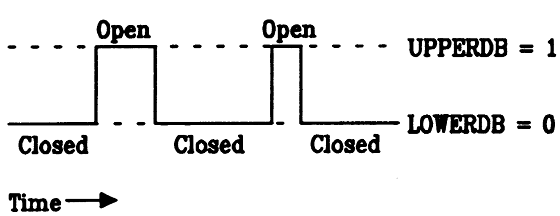

Figure A7.1
Valve Monitoring Example

A7.2.2 Example 2 — Environment Monitoring

A7.2.2.1 ACME also makes a Model 2 Stepper. The environmental control system of this equipment is designed to hold the internal temperature relatively constant, but is sensitive to large changes in the external environment, opening of access doors, etc. To ensure that processing conditions are appropriate, the internal stepper temperature is monitored to ensure it remains in a safe operating zone (within "Shutdown" limits). In addition, a second set of limits are used within the Shutdown limits to bound the "Normal" operating range. Frequent excursions from the normal range into the "warning" range will prompt service on the environmental control system. The target temperature range is specified as 98–100°, the shutdown limits as 95–103°.

A7.2.2.2 Event reports are desired when the internal temperature moves outside of the normal operating zone into a warning zone (above or below), when the temperature moves back into the normal operating zone from the warning zones, and when the temperature moves out of the warning zones into the shutdown zones. Furthermore, temperature fluctuations of 0.5° should not trigger multiple event reports.

A7.2.2.3 Probably the most intuitive use of the limits monitoring capability is in establishing normal, warning, and shutdown zones for a particular equipment variable. Limits may be combined to provide such a scenario. The method is described below and illustrated in Figure A7.2. Please note that in the figure, limits are denoted as solid lines for simplicity, with deadbands indicated using the ± notation.

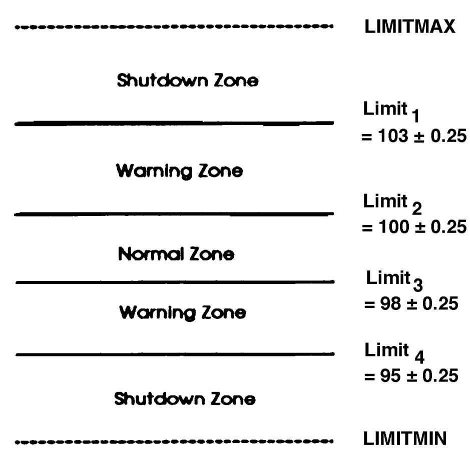

Figure A7.2
Environment Monitoring Example

A7.2.3 Example 3 — Calibration Counter

A7.2.3.1 Another ACME equipment is the multi-chamber Duz-It-All Model 7. This machine includes redundant chambers to increase throughput. One particular chamber on this equipment requires periodic calibration. The need for calibration is a non-linear function of the number of wafers processed in that chamber. A status variable exists which contains the number of wafers processed since the last calibration was performed. Maintenance is definitely required after every 8 cycles, but the machine must be checked after 5 and 7 cycles to determine whether early calibration is necessary. This checking may be done by examining certain other equipment status variables.

A7.2.3.2 To meet this need, three limits are defined for the counter variable. Three limits were set, at 5, 7, and 8. Deadbands are set to zero, since chattering is not a problem. All the pertinent information is placed in an event report which is attached to the CEID for the limits of the counter to negate the need for further message exchange. Event reports are generated as each limit is reached (one zone transition each), and when the counter is reset following calibration (one, two, or three zone transitions referenced in one report). Figure A7.3 illustrates this example. Note that disabling the report upon counter reset (downward transitions) is not possible.

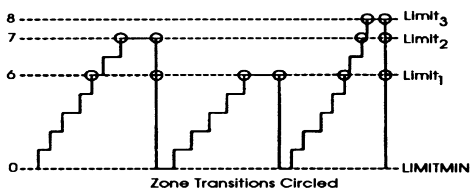

Figure A7.3
Calibration Counter Example

A7.2.4 Example 4 — Derived Variables

A7.2.4.1 The flagship of the ACME line is the new HotDog Furnace. This is a vertical furnace which exposes wafers to a variety of temperatures during processing. The temperature profile during the run is critical to the process and is typically contains a number of plateau's at different levels during the run. The owner wishes to monitor the temperature and be alerted whenever the actual temperature profile differs from the ideal by > 0.5°. The derived variable was created to provide a steady target range during the run, no matter what the desired temperature range happened to be. Deviation from "ideal temperature profile" was chosen as the new variable to be monitored. The equipment already had access to the profile for the run, which described the desired temperature at a given time into the process. The manufacturer added a calculation each time the actual temperature was sampled, subtracting the ideal temperature from the actual. They provided as status variables the actual temperature, the ideal temperature, and the new "deviation from profile" variable. One limit was activated and set to 0.5 degrees and a second set to –0.5 degrees (each with a deadband width of 0.05). Thus, when the temperature deviation from setpoint exceeds ± 0.5, an event is generated containing the current desired temperature and the actual temperature. For good measure, additional data was added, providing time since start of run to document the precise point in the process that the problem occurred.

A7.2.4.2 In order to achieve the desired behavior, the host defines four monitoring limits. Two of the limits establish the target zone. These are responsible for reporting transitions from normal to warning zones in either direction. The other two limits establish the transitions between the warning zones and the error zones. The difference between UPPERDB and LOWERDB for each limit is 0.5. This may also be expressed as limit ± 0.25. Combining limits does not change the way the equipment treats limits monitoring, but rather builds a method of interpreting limits from the host's point of view.

A.8 Process Parameter Modification for Process and Equipment Control

A8.1 *Introduction*

A8.1.1 In many equipment control applications there is a need for a GEM host to modify one or a small set of process parameters associated with a recipe. The number of parameters modified, frequency of modification (e.g., wafer-to-wafer, batch-to-batch, etc.), range of modification, etc., is largely a function of the equipment control application. Utilizing GEM, at least two methods are envisioned for modifying process parameters on a tool. With the first method, "Equipment Constants" can be used to relate process parameters of the updated recipe. Equipment Constants can also be used in a mode where they relate suggested modifications to process parameters from the stored recipe, i.e., the constants contain only the +/- differential from a nominal value. The former mode is preferred because it better ensures data integrity between the controller and tool. With the second method the entire recipe could be downloaded, but this results in an enormous amount of communication overhead. Note that, in all cases, the Equipment Constants do not replace the process parameters inside a recipe, but are associated with (e.g., linked to) these parameters to relate modifications. The remainder of this application note provides a description of how process parameter modification can be implemented using existing GEM capabilities. The method may be used in a GEM compliant system provided that the specific GEM capabilities described are supported.

A8.2 *Equipment Constants*

A8.2.1 Incremental process parameter modification for process and equipment control can be supported over a GEM interface by using the *Equipment Constants* GEM capability (see Section 4.5). With this capability, each process parameter (or process parameter at a step) that can be modified, e.g., for purposes of process control, is associated with an equipment constant. Using the Equipment Constant GEM scenarios (see Section 4.5.5) the host can (1), send process parameters or parameter modifications, (2), request current values of modifiable recipe parameters, (3), retrieve name lists of equipment constants associated with modifiable parameters, and (4), be informed by the equipment when an operator changes one of the modifiable process parameters.

A8.2.2 The equipment constants should represent the actual values of the process parameters with which they are associated. Depending on the equipment operation and control application, the equipment constant could represent the actual value of a process parameter at a recipe step, or over the entire recipe. The equipment constants could also be utilized to represent the differentials of process parameters from nominal values. However it is important to note that, when using differential values to relate process parameter modifications, any loss of synchronization between equipment and host could result in an incorrect assessment of the value of a process setpoint by the host. Note also that, upon system startup, and whenever the appropriate process parameters are modified, the equipment constants should also be modified as necessary to always reflect the (absolute or relative) values of the associated process parameters.

A8.2.3 In order to maintain synchronization between equipment and host, it is recommended that equipment constants associated with recipe parameters be applied to only override the currently selected and active recipe. A selected recipe is considered to be active whenever the equipment is in the "PROCESSING" state and the recipe is the currently selected recipe (process program). If multiple recipes are utilized during one process event, e.g., cluster tool scenario, it is recommended that separate equipment constants be utilized for each recipe/process parameter pair.

A8.2.4 Note that timing and traceability issues associated with utilizing the equipment constants capability (for process control) are application specific and beyond the scope of this application note. Equipment that provides for recipe parameter overrides though setting of Equipment Contstants should also provide additional Equipment Constants for the set that includes the name of the associated process program and a Boolean variable to enable and disable the override feature. In addition, the supplier should document for each parameter: (1), the associated Equipment Constant, and (2), any restrictions on the state (active or not) or the recipe in which the parameter may be modified. Also, since override of the process setpoints may be provided by a Host controller application element, it is recommended that the equipment provide an event report whenever the associated recipe has been modified.

A8.3 *Example*

A8.3.1 In the example of Figure A.8.1, a Chemical-Mechanical Planarizer (CMP) single wafer "polishing" system includes a GEM compliant planarizer (equipment), a thickness metrology unit and a (host) controller. The tool polishes a wafer to a target thickness. The post-process thickness is measured by the metrology unit and reported to the host controller. The controller utilizes a feedback control algorithm to determine the appropriate polish "time" recipe parameter for the next wafer. This time should be reported to the CMP equipment utilizing the equipment's GEM interface so that the information can be utilized for the next wafer processing event.

A8.3.2 The mechanism described in this application note could be utilized to implement process control as follows. A settable equipment constant is associated or "linked" with the "time" parameter on the equipment. Equipment system documentation indicates the linkage and the conditions under which the linkage is valid. When the controller determines an appropriate "time" parameter value for the next wafer to be polished, it sets the equipment constant to this value (see Section 4.5). The equipment is configured to accept this equipment constant change and, if the equipment is in (or possibly when the equipment reaches) the appropriate state, the recipe parameter is modified.

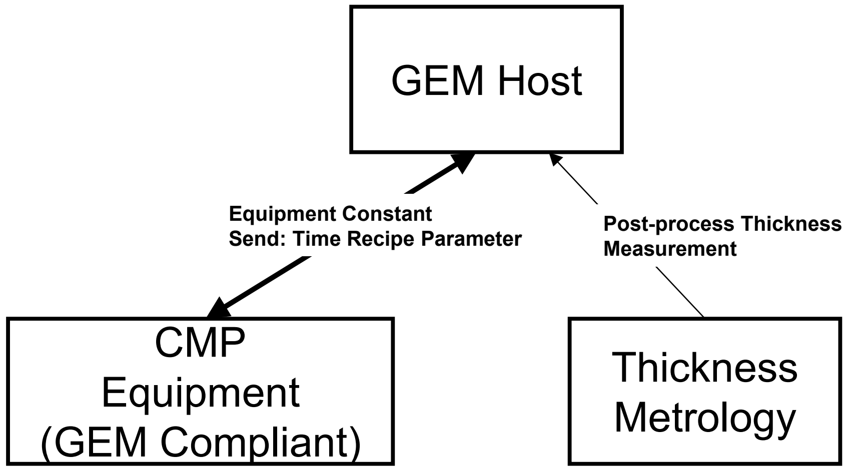

Figure A.8.1
CMP Single Wafer "Polishing" System with Host Recipe Parameter Modification Capability

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. SEMI E30.1-0200
INSPECTION AND REVIEW SPECIFIC EQUIPMENT MODEL (ISEM)

This standard was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on September 3, 1999. Initially available at www.semi.org November 1999; to be published February 2000. Originally published June 1998.

CONTENTS

SEMI E30.1-0200
INSPECTION AND REVIEW SPECIFIC EQUIPMENT MODEL (ISEM)

This standard was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on September 3, 1999. Initially available at www.semi.org November 1999; to be published February 2000. Originally published June 1998.

1 Purpose

1.1 This standard establishes a Specific Equipment Model (SEM) for Inspection and Review Equipment (ISEM). The model consists of equipment characteristics and behavior that are to be implemented in addition to the SEMI E30 fundamental requirements and additional capabilities. The intent of this standard is to facilitate the integration of ISEM equipment into an automated (semiconductor fabrication) factory. This document accomplishes this by defining an operational model for ISEM equipment as viewed by a factory automation controller. This definition provides a standard host interface and equipment operational behavior (e.g., control, state models, data reports, and reporting levels). Several topics require additional activity that are within the scope of this standard: substrate pattern maps; defect classification code management; and review data management.

2 Scope

2.1 The scope of this standard is limited to the definition of Inspection, Review, and Inspection/ Review equipment behavior as perceived by a SEMI Equipment Communications Standard II (SEMI E5/SECS-II) host that complies with SEMI E30. It defines the external view of the equipment through the SECS link; it does not define the internal operation of the equipment. This standard expands the SEMI E30 requirements and capabilities in the areas of the processing state model, remote commands, variable items, alarms, and data collection.

2.2 This standard is intended for ISEM equipment that generates data and information about anomalies and defects found on substrates. Inspection equipment finds anomalies. Anomalies are occurrences on a substrate that have been judged to be unexpected, abnormal, incongruous, or inconsistent. Anomalies may be examined using review equipment, at which time they may be classified as defects or non-defects. Some inspection equipment may generate, and some review equipment may use, coordinate data to locate anomalies on a substrate. The accuracy of the coordinate data generated or used is equipment-dependent.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document addresses three distinct types of equipment: inspection, review, and inspection/review. The term ISEM equipment refers to all three types of equipment. These three equipment types are differentiated by the basic functions they perform:

3.1.1 Inspection Equipment that looks for anomalies on a substrate and reports information regarding those anomalies. Inspection equipment may determine the location of anomalies relative to a coordinate system. Inspection equipment may also provide other types of data related to the anomaly.

3.1.2 Review Equipment that accepts information about anomalies on a substrate, gathers information on those anomalies, and reports that data.

3.1.3 Inspection/Review Equipment having the characteristics of both inspection and review equipment.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *GEM* — generic equipment model

5.1.2 *PE* — pattern element

5.1.3 *TCP/IP* — Transmission Communication Protocol/Internet Protocol

5.2 *Definitions*

5.2.1 *align* — to put into proper relative position or orientation.

5.2.2 *alignment* — a procedure in which a coordinate system is established on a substrate.

5.2.3 *alignment mark* — a feature on the substrate selectively used for alignment.

5.2.4 *anomaly* — an occurrence on a substrate that has been judged to be unexpected. Something abnormal, incongruous, or inconsistent.

NOTE 2: After an anomaly is reviewed, it may be classified as a defect.

5.2.5 *batch* — a group of substrates or lots intended for a process sequence versus single substrate processing.

5.2.6 *carrier* — a container with one or more fixed positions at which material can be held.

5.2.7 *carrier location* — a physical place within the equipment capable of holding a carrier.

5.2.8 *cassette* — a container with one or more substrate locations (see *slot*).

5.2.9 *defect* — 1) A physical, optical, chemical, or structural irregularity that degrades the ideal substrate structure or the thin films built over the substrate. 2) An undesirable classified anomaly.

5.2.10 *defect classification* — the categorization of defects according to some systematic division based on their physical, optical, chemical, or structural properties.

5.2.11 *die* — 1) A field sub-unit. 2) An area of substrate that contains the device being manufactured.

5.2.12 *ended* — the end of a state that may be when it is normally completed, or its early end due to an allowed or atypical condition (e.g., a STOP command, or an error or alarm condition).

5.2.13 *factory automation controller* — a computer system that provides integration of factory shop control and business systems with semiconductor equipment.

5.2.14 *feature* — 1) A line or a point (as a feature within a pattern). 2) A physical characteristic of the substrate (e.g., a substrate flat).

5.2.15 *field* — the printed pattern from a reticle.

5.2.16 *field of view* — the imaging area as seen at magnification of the inspection or review equipment.

5.2.17 *global alignment* — a procedure which establishes a coordinate system for the entire substrate (see *alignment*).

5.2.18 *group* — a logical collection of regions.

5.2.19 *group alignment* — a procedure which establishes a coordinate system for an area, which is a contiguous group (see *alignment*).

5.2.20 *inspect* — to detect anomalies and/or information about anomalies.

5.2.21 *inspection* — an examination to detect anomalies.

5.2.22 *inspection equipment* — equipment that looks for anomalies on a substrate and reports information regarding those anomalies. Inspection equipment may determine the location of anomalies relative to a coordinate system. Inspection equipment may also provide other types of data related to the anomaly.

5.2.23 *inspection/review equipment* — equipment having the characteristics of both inspection and review equipment.

5.2.24 *ISEM job* — the information required to specify an inspection or review that may include material identification and location and process program identifications as well as any other parameters required to obtain a desired result.

5.2.25 *layer* — one of a sequential series of overlaying photomasks that make up a device series.

5.2.26 *lot* — a group of one or more substrates of the same type (e.g., wafers, masks, CDs).

5.2.27 *major flat* — the flat of longest length that is commonly located with respect to a specific crystal plane (ASTM F 1241-89).

5.2.28 *mask* — a selective barrier to the passage of radiation. For example, a transparent plate containing an opaque pattern that is used to transfer that pattern to another substrate.

5.2.29 *material* — a piece or pieces of substrate, one or more substrates, a lot, a batch, or a run.

5.2.30 *metrology equipment* — any equipment that collects and reports information on specific predetermined locations or features on a substrate with consistent data structure or that reports general information about the entire substrate.

5.2.31 *notch* — a U-shaped cut on the edge of a substrate that is commonly located with respect to a specific crystal plane.

5.2.32 *overlay* — the actual distance between two features on different layers of a substrate, compared to the expected distance.

5.2.33 *pattern* — 1) The physical features on a substrate surface. 2) An ideal pattern is the arrangement of features expressed in a calculated or mathematical manner.

5.2.34 *pattern element* — 1) Any recognizable set of features. 2) A rectangular sub-unit of a pattern or a pattern element. There may be multiple levels of pattern elements.

5.2.35 *primary fiducial* — a key characteristic of a substrate used to align the substrate during processing (such as a *notch* or *major flat*).

5.2.36 *region* — a single field of view which may be a collection of sites.

5.2.37 *registration* — the actual distance between two features on the same layer of a substrate, compared to the expected distance.

5.2.38 *reticle* — a mask that contains the patterns to be reproduced on a substrate; the image may be equal to or larger than the final projected image.

5.2.39 *review* — the process of classification of anomalies which may result in the appending of additional data to inspection data. Used to create a field on a substrate.

5.2.40 *review equipment* — equipment that accepts information about anomalies on a substrate, gathers information on those anomalies, and reports that data.

5.2.41 *run (noun)* — the material processed during the EXECUTING state.

5.2.42 *run (verb)* — the actions of a process between the READY state and the STOPPING state.

5.2.43 *safe state* — a state in which the equipment presents no danger to the product or user. This implies that safety interlocks are in place such that the equipment can be serviced without harm to the operator and that the material being processed has been removed from the processing station into an accessible location.

5.2.44 *site* — a single x,y coordinate where an action can be performed (e.g., *alignment* or *review*). The area associated with a site is determined by the equipment accuracy (e.g., optics, stage algorithms).

5.2.45 *slot* — a physical location within a Carrier capable of containing a substrate. Also referred to as a carrier location.

5.2.46 *substrate* — the basic unit of material, processed by semiconductor equipment, such as wafers, CDs, flat panels, or masks.

6 Communication Requirements

6.1 It is required that any ISEM-compliant equipment follow the Communications State Model in SEMI E30. In addition, ISEM-compliant equipment shall support the High Speed Messaging Service Standard (SEMI E37/HSMS). It is a minimum requirement to support Single Session (SEMI E37.1/HSMS-SS) sending SECS-II messages over TCP/IP. The reason behind this requirement is the size of the process programs used by this class of equipment and the amount of data produced.

7 State Models

7.1 *Processing State Model Requirements*

7.1.1 The processing state model included in this standard is a requirement for ISEM equipment. This standard requires implementation of all SEMI E30 state models (such as control, communication, and on-line/off-line). A state model consists of state model diagrams, state definitions, and a state transition table. All state transitions in this standard, unless otherwise specified, shall correspond to collection events.

7.1.2 A state model is the host's view of the equipment and does not necessarily describe the internal equipment operation. All ISEM state model transitions shall be mapped sequentially into the appropriate internal equipment events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the ISEM state model for transition to another state. The equipment makes the required transition without any additional actions in this situation.

7.1.3 Some equipment may need to include additional states other than those in this standard. Additional states may be added but shall not change the ISEM-defined state transitions. All expected transitions between ISEM states shall occur.

7.2 *Processing State Model Diagram* — Processing state models are detailed for ISEM equipment in Figure 1. This diagram contains all states and transitions that are common to all three types of ISEM equipment. The WORKING state is different for each type of equipment. The same state names and transition identifiers are used to identify common states and transitions of the three types of equipment. The working states for the three types of equipment are presented in the following sections. All states and transitions are described in the section following the diagrams.

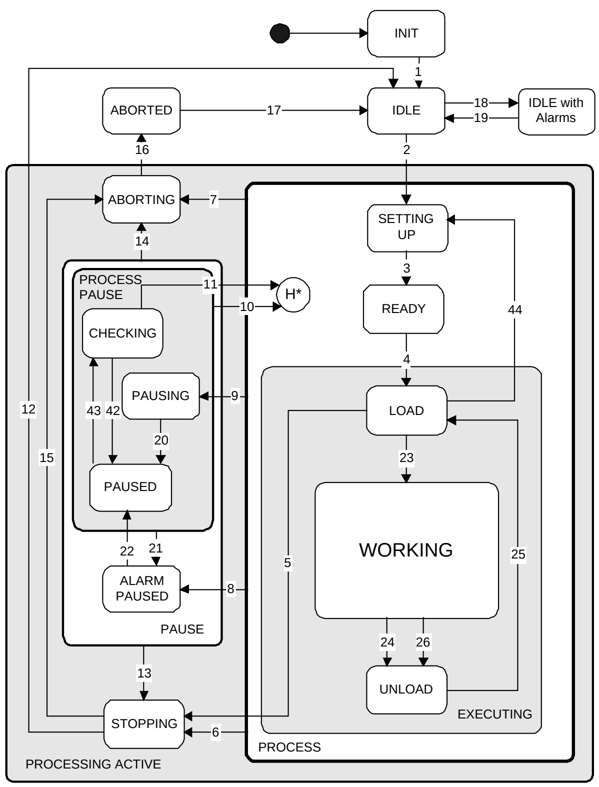

Figure 1
Generic ISEM Processing State Model Diagram

7.2.1 *Working State for Inspection Equipment Model* — The processing state model for inspection equipment is identical to the Generic ISEM Processing State Model (Figure 1). Only the WORKING state is unique to the inspection equipment processing state model. This is shown in Figure 2.

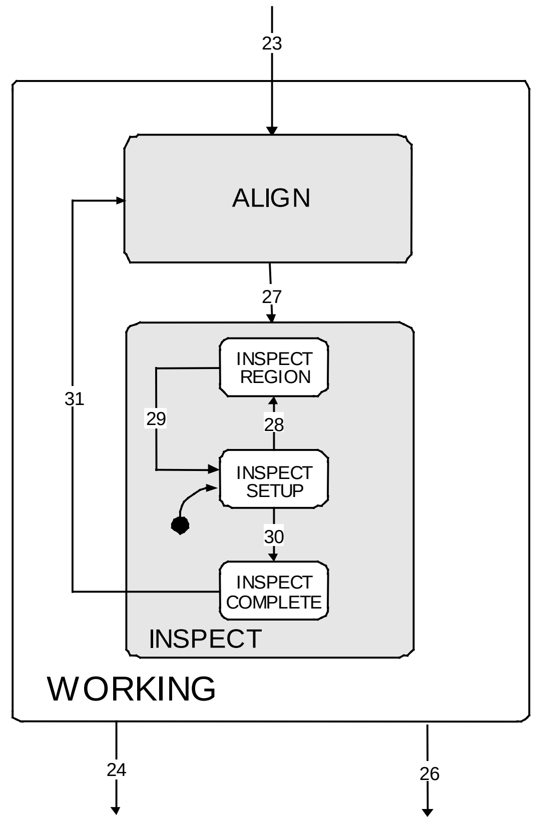

Figure 2
Working State for Inspection Equipment

7.2.2 *Working State for Review Equipment* — The processing state model for review equipment is identical to the generic ISEM Processing State Model (Figure 1). Only the WORKING state is unique to the review equipment processing state model. This is shown in Figure 3.

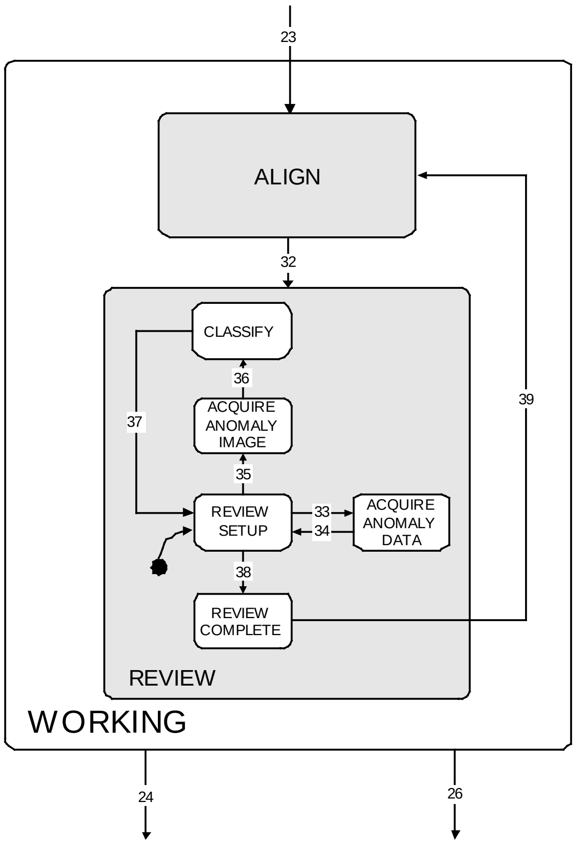

Figure 3
Working State for Review Equipment

7.2.3 *Working State for Inspection/Review Equipment* — The processing state model for inspection/review equipment is identical to the generic ISEM Processing State Model (Figure 1). Only the WORKING state is unique to the inspection/review equipment processing state model. This is shown in Figure 4.

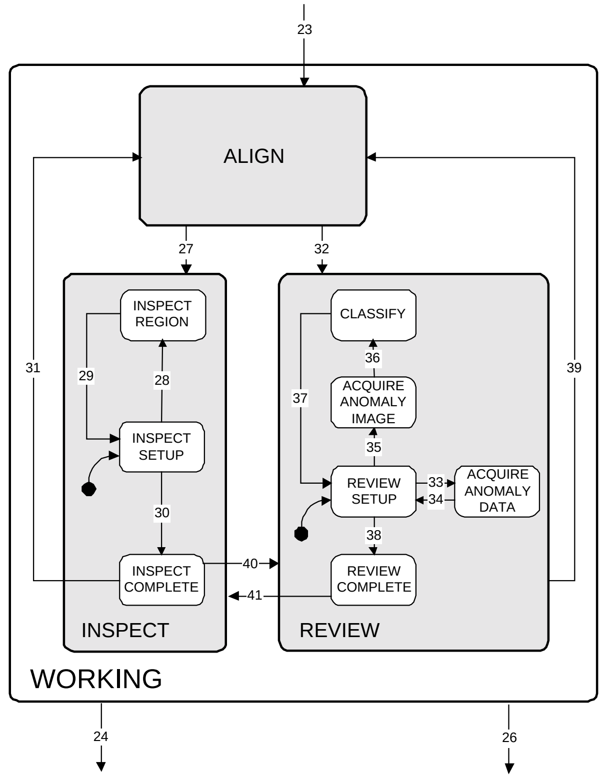

Figure 4
Working State for Inspection and Review Equipment

7.3 *Processing State Definitions*

7.3.1 *ABORTED* — All activity is suspended as a result of an ABORT command. Any alarm and abort conditions shall be cleared before exit from this state. The CLEANUP command is available to the operator or host to transition the equipment from the ABORTED state to IDLE state.

7.3.2 *ABORTING (PROCESSING ACTIVE Sub-State)* — The equipment has received an ABORT command. All normal activity is suspended. The equipment is taking appropriate action to put the equipment and material in a "safe state" where possible. Data may be invalid or not available.

7.3.3 *ACQUIRE ANOMALY DATA (REVIEW Sub-State)* — Data is being acquired about anomaly locations.

7.3.4 *ACQUIRE ANOMALY IMAGE (REVIEW Sub-State)* — The equipment is obtaining a view of the anomaly.

7.3.5 *ALARM PAUSED (PAUSE Sub-State)* — An alarm has occurred in the PROCESS or PROCESS PAUSE states, and the equipment is waiting for the alarm to be cleared or a command (STOP or ABORT).

7.3.6 *ALIGN (WORKING Sub-State*) — The equipment or operator is performing an alignment of the material to the equipment. If needed, within this state, the equipment shall refine or establish its SEMI M20 coordinate system and establish any secondary coordinate systems.

7.3.7 *CHECKING (PROCESS PAUSE Sub-State)* — The equipment verifies that the process program update request is valid. No process program parameters are changed unless "all" reported updates are valid. This is a similar procedure to that which is done in SETTING UP before the equipment is ready to transition to the READY state. Valid commands in this state are STOP, ABORT, and RESUME.

7.3.8 *CLASSIFY (REVIEW Sub-State)* — The operator or equipment is determining the classification of an anomaly.

7.3.9 *EXECUTING (PROCESS Sub-State)* — The equipment is processing material automatically and can continue to do so without external intervention but normally may include interaction with the host or operator.

7.3.10 *IDLE* — Checks for queued ISEM jobs or awaits a PP-SELECT, MAP-CARRIER, or PP-ASSIGN command. IDLE is free of alarm and error conditions. Any transition into this state shall deselect any selected Process program(s).

7.3.11 *IDLE with ALARMS* — An alarm has occurred in the IDLE state, and the equipment is waiting for all alarms to be cleared.

7.3.12 *INIT* — Equipment initialization is occurring. Equipment remains in this state unless initialization is successful.

7.3.13 *INSPECT (WORKING Sub-State)* — The current alignment area of the substrate is being inspected for anomalies.

7.3.14 *INSPECT COMPLETE (INSPECT Sub-State)* — The equipment has completed inspection of the current alignment area. Based on the recipe, the equipment determines if (a) additional alignment areas are required to do more inspections, (b) the recipe on this material is complete, or (c) a review of the current inspection area is required.

7.3.15 *INSPECT REGION* — A region on a substrate is being inspected for anomalies.

7.3.16 *INSPECT SETUP (INSPECT Sub-State)* — The equipment is in this sub-state immediately upon entering the INSPECT state. The equipment is determining if all conditions are satisfied to begin inspecting the regions in the current alignment as defined by the recipe and any commands.

7.3.17 *LOAD (EXECUTING Sub-State)* — The equipment is determining if the process program has completed. When additional processing is required, then the next unprocessed substrate shall be transferred to the equipment processing location, such as the stage. If equipment determines that there are more process programs in the "CARRIERBLD" ISEM job, the equipment makes the transition to setup for the next process program specified. Otherwise, the equipment transitions to IDLE through STOPPING.

7.3.18 *PAUSE (PROCESS ACTIVE Sub-State)* — PROCESS shall be suspended at the next opportunity. Actions to put the equipment in a "safe state" shall be performed. The equipment is awaiting a command (STOP or ABORT).

7.3.19 *PAUSED (PROCESS PAUSE Sub-State)* — PROCESS has been suspended, and the equipment is waiting for a command (RESUME, PP-UPDATE, STOP, or ABORT).

7.3.20 *PAUSING (PROCESS PAUSE Sub-State*) — PROCESS shall be suspended at the next opportunity, and the equipment shall be put in a "safe state." ABORT, STOP, and RESUME commands are valid in this state.

7.3.21 *PROCESS (PROCESSING ACTIVE Sub-State)* — This state is the parent of those sub-states which refer to the active preparation and execution of a process program.

7.3.22 *PROCESSING ACTIVE* — This state is the parent of all sub-states where the context of a process program execution exists.

7.3.23 *PROCESS PAUSE (PAUSE Sub-State)* — The equipment is free of alarm conditions in the PAUSE state. The equipment is awaiting for a command (ABORT, RESUME, or STOP).

7.3.24 *READY (PROCESS Sub-State)* — The equipment is ready to begin processing and is awaiting a START command from the operator or host.

7.3.25 *REVIEW (WORKING Sub-State)* — Classification is being done on anomalies previously found in the current alignment area of the substrate.

7.3.26 *REVIEW COMPLETE (REVIEW Sub-State)* — The equipment has completed review of the current alignment area. Based on the recipe, the equipment determines if (a) additional alignment areas are required to do more classifications, (b) the recipe on this material is complete, or (c) an inspection is required.

7.3.27 *REVIEW SETUP (REVIEW Sub-State)* — The equipment is in this sub-state immediately upon entering the REVIEW state. The equipment is determining if all conditions are satisfied to begin reviewing the anomalies in the current alignment as defined by the recipe and any commands.

7.3.28 *SETTING UP (PROCESS Sub-State)* — The equipment is being setup so that external conditions are satisfied to start processing the material. This includes the receipt of any process programs and material to be processed and their validation. Any of these conditions may be satisfied on entry to SETTING UP. For example, the selected process program may have already been loaded (e.g., if it was the default process program), or the specified material may have already been placed on the equipment material port. Additional information may come from the host during the execution of this state.

7.3.29 *STOPPING (PROCESSING ACTIVE Sub-State)* — The equipment has completed all process programs within a "CARRIERBLD" ISEM job or has been instructed to stop processing and shall do so gracefully at the next opportunity. All cleanup necessary is being completed within this state with regard to material, data, control system, etc. Data is normally preserved. Any alarm or error condition in this state causes a transition to ABORTING.

7.3.30 *UNLOAD (EXECUTING Sub-State)* — The substrate is being removed from the processing location.

7.3.31 *WORKING (EXECUTING Sub-State)* — The equipment is processing a specific material.

7.4 *Processing State Transition Table*

Table 1 Processing State Transition Table

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	INIT	All equipment initialization is complete with no alarms or error conditions.	IDLE	Equipment awaits for a PP-SELECT, PP-ASSIGN, or MAP-CARRIER command.	All equipment requires INIT to be free of errors and alarms when exited. IDLE state entry requires that no process program is selected.
2	IDLE	A ISEM job has been or is queued (PP-ASSIGN) or selected (PP-SELECT).	SETTING UP	The setup procedure is equipment-dependent.	Commit has been made to setup. Material may have been placed on the equipment before SETUP is entered. When the job becomes active, the process program gets selected.
3	SETTING UP	All setup activity has completed, and the equipment is ready to receive a START command.	READY	The equipment is waiting for a START command. START may be initiated by an operator or may be included in the process program.	The selected process program is available for execution. When running multiple process programs within a ISEM job, the equipment makes the next process program available for execution.
4	READY	The equipment receives a START command from the user or from within the body of the process program selected for execution.	LOAD	The equipment determines if processing is completed. If not, it transfers the next substrate to the processing location.	Equipment transitions to STOPPING when all process programs in the selected ISEM job are executed. If a new process program within the ISEM job needs to be executed, the equipment transitions to SETTING UP.
5	LOAD	The processing job is complete, and there are no more substrates to load or process programs to run.	STOPPING	Equipment initiates a cleanup to remove the completed ISEM job and process program.	Normal completion of the run.
6	PROCESS	The equipment has received a STOP command.	STOPPING	The equipment unloads the material and brings the equipment to a "safe state."	Data is typically preserved and is valid.

Transition #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
7	PROCESS	The equipment has received an ABORT command.	ABORTING	The equipment is put in a “safe state” if necessary.	Data may be invalid or not available.
8	PROCESS	An alarm occurs.	ALARM PAUSED	PROCESS activity is suspended, and the equipment is waiting for all alarms to be cleared.	ALARM PAUSED is a PAUSE Sub-State.
9	PROCESS	The equipment has received a PAUSE command.	PAUSING	PROCESS shall be suspended at the next opportunity. Actions to put the equipment in a “safe state” will be performed.	This transition is required if the user wants to make changes to the current process program being executed.
10	PROCESS PAUSE	The equipment has received a RESUME command.	Previous PROCESS State	Proceed with the suspended process Sub-State.	If a RESUME command is received in the CHECKING state, then the PP-UPDATE command is canceled. Some equipment may only allow RESUME remote command from the PAUSE state.
11	CHECKING	The equipment has validated “all” requested updates to the current process program being executed; changes are done before entering into the next state.	Previous PROCESS State	Verification is appropriate in this state to check the changes made to the process program updated.	If an alarm occurs in the CHECKING state, then the PP-UPDATE command is canceled.
12	STOPPING	The equipment cleanup is complete, and the equipment is free of alarms.	IDLE	Equipment waits for a command/or determines if there is a ISEM job queued.	IDLE state entry requires that no process program is selected.
13	PAUSE	The equipment has received a STOP command.	STOPPING	The equipment proceeds with cleanup.	Normally, data is preserved and is valid.
14	PAUSE	The equipment has received an ABORT command.	ABORTING	Any unsafe condition is resolved if possible.	Data may be invalid or not available.
15	STOPPING	The equipment has received an ABORT command or an alarm was received while STOPPING.	ABORTING	Any unsafe condition is resolved if possible.	Data may be invalid or not available.
16	ABORTING	Unsafe conditions have been resolved where possible.	ABORTED	The equipment is waiting for alarm and ABORT conditions to be cleared.	The only state change allowed is to IDLE.
17	ABORTED	All alarms and abort conditions have been cleared.	IDLE	Equipment is waiting for a command (PP-SELECT, PP-ASSIGN, or MAP-CARRIER).	If needed, the CLEANUP command clears the abort conditions. IDLE state entry requires that no ISEM job or process program be selected.
18	IDLE	An alarm is set.	IDLE with ALARMS	The equipment waits for all alarms to be cleared.	None
19	IDLE with ALARMS	All alarms have been cleared.	IDLE	None	IDLE is free of alarms.

Transi-tion #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
20	PAUSING	The equipment has achieved a "safe state."	PAUSED	The equipment is waiting for a command (PP-UPDATE, RESUME, STOP, or ABORT).	None
21	PROCESS PAUSED	An alarm is set.	ALARM PAUSED	The equipment waits for all alarms to be cleared or for a STOP or ABORT command.	None
22	ALARM PAUSED	All alarms are cleared.	PAUSED	The equipment is waiting for a command (RESUME, PP-UPDATE, STOP, or ABORT).	None
23	LOAD	Material transfer to processing location is complete.	WORKING	The substrate is being processed.	None
24	WORKING	The processing of the specific material being processed successfully completed.	UNLOAD	This material is transferred from the processing location.	Normal completion of the substrate.
25	UNLOAD	The material unload is complete.	LOAD	The equipment returns to LOAD and determines if processing is complete, if not, transfers the next substrate to the processing location.	None
26	WORKING	The processing of the specific material being processed abnormally ended.	UNLOAD	This material is transferred from the processing location.	Error exit from WORKING. Data may be invalid.
27	ALIGN	The material alignment is complete, and inspection is required.	INSPECT	The equipment determines if another region needs to be inspected.	This transition is to the INSPECT SETUP Sub-State of INSPECT.
28	INSPECT SETUP	All inspect setup activity is complete, and the inspection is not complete.	INSPECT REGION	The equipment inspects the current alignment region.	None
29	INSPECT REGION	The region inspection has ended.	INSPECT SETUP	The equipment determines if another region needs to be inspected.	None
30	INSPECT SETUP	Inspection of this alignment group is complete.	INSPECT COMPLETE	The equipment determines if (a) additional alignment areas are required to do more inspections, (b) the recipe on this material is complete, or (c) a review of the current alignment area is required.	The next transition is conditional.
31	INSPECT COMPLETE	The inspection of this alignment area ended, and additional inspections may be required.	ALIGN	An inspection group is complete, and additional inspections may be required.	None
32	ALIGN	The material alignment is complete, and review is required.	REVIEW	The material is reviewed.	This transition is to the REVIEW SETUP Sub-State of REVIEW.
33	REVIEW SETUP	Anomaly data is needed to perform the review.	ACQUIRE ANOMALY DATA	Anomaly data is being acquired.	Anomaly data may come from the host or equipment.

Transi-tion #	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
34	ACQUIRE ANOMALY DATA	Anomaly data has been acquired for the review, or no more anomaly data is available.	REVIEW SETUP	The equipment determines what to do.	
35	REVIEW SETUP	The equipment has anomaly data, and the review is not complete.	ACQUIRE ANOMALY IMAGE	The equipment acquires the anomaly image at the specified site.	The image may be a stored image or from an imaging device.
36	ACQUIRE ANOMALY IMAGE	The equipment has acquired the anomaly image for the specified site.	CLASSIFY	The operator or equipment classifies the anomaly.	None
37	CLASSIFY	All anomalies have been classified for the site.	REVIEW SETUP	The equipment determines what to do.	None
38	REVIEW SETUP	The review of the align area is complete.	REVIEW COMPLETE	Transition to next state is to be determined.	None
39	REVIEW COMPLETE	The review of this alignment area ended, and additional review is required.	ALIGN	A review group is complete, and additional alignment is required.	None
40	INSPECT	The alignment area inspection is complete, and review is required.	REVIEW	The material is reviewed.	This transition is to the REVIEW SETUP Sub-State of REVIEW.
41	REVIEW COMPLETE	The review is complete, and inspection is required.	INSPECT	The material is inspected.	This transition is to the INSPECT SETUP Sub-State of INSPECT.
42	CHECKING	Validation of requested process program changes failed.	PAUSED	The equipment is waiting for a new command.	No process program parameters have been changed.
43	PAUSED	The equipment receives a PP-UPDATE command.	CHECKING	The equipment begins validating requested changes to the process program.	No process program parameters are updated or changed before “all” requested changes are validated.
44	LOAD	Previous process program has completed, and there are additional process programs assigned to the “CARRIERBLD”. See Section 13.	SETTING UP	The equipment performs setup according to specifications of the next process program.	PROCESS-BLD-GROUP may include an AUTOSTART command within its body. Otherwise, the equipment waits for a START command.

8 Collection Event List

This section identifies data collection events and defines (Stream 6) reporting levels for variable items. The host can use the report definition scenario defined in SEMI E30 to define reports at ISEM-defined levels. The intent of this section is to ensure data is available at specific events and to optimize data reporting to the SECS-II host by allowing data to be grouped at reporting levels.

8.1 *Requirements*

8.1.1 This standard requires all collection events listed in the SEMI E30 standard. This standard requires the ISEM events in Table 2 for data collection (RunDataComplete, SubstrateDataComplete, GroupDataComplete, RegionDataComplete, and AnomalyDataComplete). These events are separate from the processing state transitions. These collection events shall occur before or on the processing state transition specified in Table 1. This was done to ensure that the data and the material remain synchronous. As a result, in some cases material processing may be delayed due to extended data processing time.

8.1.2 The most fundamental level of data defined for ISEM equipment is the anomaly level for review equipment and region level for inspection equipment. For example, review equipment has data available for individual anomalies at the AnomalyDataComplete event. Anomaly data may be grouped for level reporting. For example, data for anomalies found within a region on a substrate would be available at the RegionDataComplete event. This data would be available as a list variable item for Region Anomalies. All anomalies found on a substrate would be available at the SubstrateDataComplete event. This could either be 1) a list of list variable items for Region Anomaly, or 2) a single list variable item of all Substrate Anomalies. In this way, data can be reported with less high-level event reports, rather than as more low-level event reports.

8.1.3 Data produced by ISEM equipment is customarily grouped for reporting by processing, material, and equipment constraints which are called reporting levels (i.e., run, substrate, group, site, and anomaly data). Level data is grouped by these constraints for a reporting level. Data shall be grouped within a reporting level according to other constraints by degree of processing (e.g., raw sensor, basic, or analyzed data), or statistically (e.g., summary, correlation, or comparison).

Table 2 Collection Events for ISEM Data Reporting

Reporting Level	*Data Collection Event*	*Inspection Equipment*	*Review Equipment*
Run	RunDataComplete	STOPPING → IDLE and LOAD → SETTING UP	STOPPING → IDLE and LOAD → SETTING UP
ProcessGroup	ProcessBuildGroup-Complete	LOAD → SETTING UP	LOAD → SETTING UP
Substrate	SubstrateDataComplete	UNLOAD → LOAD	UNLOAD → LOAD
Group	GroupDataComplete	INSPECT COMPLETE → ALIGN *or* WORKING → UNLOAD	REVIEW COMPLETE → ALIGN *or* WORKING → UNLOAD
Region	RegionDataComplete	INSPECT REGION → INSPECT SETUP	*Not Defined*
Anomaly	AnomalyDataComplete	*Not Defined*	CLASSIFY → REVIEW SETUP

NOTE 1: The data collection event shall occur before or on the processing state transition.

9 Variable Items

The purpose of this section is to define the list of variable item requirements for inspection and review equipment. Values of these variables shall be available to the host via collection event reports and host status queries. These variable items are separated into three categories: (a) common to all ISEM equipment; (b) specific to inspection equipment; (c) and specific to review equipment.

If equipment supports the data item functionality defined by ISEM, then it is required and shall be implemented as specified in Table 4 “Variable Item Dictionary”. That is, a variable item is only required if the equipment supports the functionality necessary to support it. For example, if an inspection instrument only has the hardware to count detected anomalies and lacks the hardware to determine their size, then the ISEM requires it to report anomaly count (e.g., as SubstrateAnomalyCount), but reporting anomaly size (as AnomalySize) is not required by the ISEM.

9.1 *Requirements*

- All variable items and data item restrictions defined in SEMI E30 are required on ISEM equipment.
- All variable items in the ISEM Variable Item Dictionary for specific equipment classifications are required for ISEM equipment. The data item restrictions are also required.

9.1.1 Variable items are categorized in the Variable Item Dictionary as follows:

- *Common Variables (CV)* — variables common to all ISEM equipment.
- *Inspection-Specific Variables (ISV)* — variables required only for inspection equipment.
- *Review-Specific Variables (RSV)* — variables required only for review equipment.

9.2 *Variable Items and Reporting Levels* — Table 3 defines reporting levels and associated Data Collection Events for which Variable Items are valid for.

Table 3 Variable Items and Reporting Levels

Level	*Reporting Level*	*Data Collection Event*
R	Run	RunDataComplete
P	ProcessGroup	ProcessGroupComplete
S	Substrate	SubstrateDataComplete
G	Group	GroupDataComplete
X	Region	RegionDataComplete
A	Anomaly	AnomalyDataComplete
ALL	Run, Substrate, Group, Region, and Anomaly	All of the above.

9.2.1 Variable items are documented in the ISEM Variable Item Dictionary using the following format:

Variable Name	*Type*	*Description*	*Level*	*Class*	*Format*	*Comments*

Where:

Variable Name: A unique name for the variable item (this name is for reference only).

Type: Defined as Common (CV), Inspection (ISV), Review (RSV), or Inspection/Review specific variables (IRSV).

Description: If class is DVVAL, then the description shall contain a statement of when data is valid in terms of ISEM events.

Level: The report level at which this variable is used <R| S| G| X| A| ALL> as defined in Table 3. It also indicates when the variable item is valid.

Class: The data type of the item.

Format: <SECS Message Language (SML) mnemonic> acceptable formats are SEMI E5 lists, ASCII, floating point, unsigned integer, or signed integer. A description of "ANY" indicates that only the above formats are acceptable and is left to the tool vendor to decide.

Comments: Any additional information pertinent to the variable name.

9.3 *Variable Item Types*

9.3.1 *Equipment Constants (ECV)* — The value can be changed by the host using S2,F15. The operator may have the ability to change some or all of the values. The value of an equipment constant may be queried at any time by the host using the S2,F13/14 transaction or Stream 6 reports.

9.3.2 *Status Variables (SV)* — The values are valid at all times. A SV may not be changed by the host or operator but may be changed by the equipment. A host or operator command may change an equipment status, thus changing an SV. The value of status variables may be queried by the host at any time using the S1,F3/4 or Stream 6 reports.

9.3.3 *Data Variables (DVVAL)* — These are variables which are valid upon the occurrence of a specific collection event and which may or may not be valid at other times, depending upon the equipment. An attempt to read a variable item when it is invalid will not result in an error, but the data reported may not have relevant meaning.

9.4 *Variable Item Dictionary*

9.4.1 *Data Validity* — The "Level" column in Table 4 defines when the variable item is valid. The entry in this column corresponds to a reporting level defined in Section 9.2 "Variable Items and Reporting Levels". For example, "RunAnomalyCount" is valid at the "RunDataComplete" event, and "AnomalySize" is valid at all reporting level data collection events.

Table 4 Variable Item Dictionary

Variable Name	*Type*	*Description*	*Level*	*Class*	*Format*	*Comment*
ActiveLocation	CV	The current carrier location that has substrates in the executing state of the processing state model.	ALL	SV	U2	Valid in all data collection events as defined in Table 3.
AlignList	CV	A list of alignment sites information being used by the current active process program.	ALL	DVVAL	L,n 1. <AlignName> : n.	The order in which the alignment name appears in the list is important and is equipment-dependent.
AlignName	CV	Alignment name	ALL	DVVAL	A[1..16]	An item in the AlignList variable.
AnomalyArea	CV	The area within the bounds of an anomaly (in units of $micron^2$).	ALL	DVVAL	F4	
Anomaly-Attributes	CV	Miscellaneous anomaly information that is equipment-dependent and defined by the equipment supplier.	ALL	DVVAL	L,n 1. <$attribute_1$> : n. <$attribute_n$>	Mainly used as part of other anomaly-related data (list) (i.e., AnomalySize).
Anomaly-Comment	RSV	Operator-generated comment associated with the anomaly.	A	DVVAL	A[1..80]	
AnomalyData2D	CV	Coordinate data for an anomaly.	A	DVVAL	L,5 1. <AnomalyID> 2. <CoordSys> 3. <Coord2D> 4. <Anomaly-Attributes>	
AnomalyID	CV	A unique anomaly identifier.	A	DVVAL	A[1..16]	
AnomalySize	CV	The X,Y extent of the anomaly in microns. The dimensions of the smallest rectangle that contains the anomaly whose sides are parallel to the X and Y axis.	A	DVVAL	L,2 1. <XExtent> 2. <YExtent>	XExtent and YExtent are of Format F4.
AnomalyTable-Name	CV	Name identifier of anomaly table.	ALL	SV	A[1..80]	
AnomalyTable-Type	CV	Type of anomaly table. (See Section 11.)	ALL	SV	A[1..20]	"TABLE-AREA-DEF", "TABLE-ALIGN-DEF", "TABLE-ANOMALY-DEF", "TABLE-M21-ANOMALY-DEF"
BatchID	CV	The batch identification of the current material inspected/reviewed.	ALL	DVVAL	A[1..16]	
CarrierBuild	CV	ID of the CARRIERBLD ISEM job that the inspection/review data is associated with.	ALL	SV	A[1..80]	See Section 14.
CarrierID	CV	Physical identification of the current material inspected/reviewed.	ALL	DVVAL	A[1..16]	
CarrierNumber	CV	Used to identify carriers in	ALL	DVVAL	A[1..16]	

Variable Name	*Type*	*Description*	*Level*	*Class*	*Format*	*Comment*
		multi-lot runs (batch).				
Classification	RSV	Classification code of an anomaly.	A	DVVAL	A[1..80]	
Coord2D	CV	The two-dimensional coordinate of an anomaly.	ALL	DVVAL	L,2 1. <CoordX> 2. <CoordY>	
CoordSys	CV	The identification for a coordinate system definition. SEMI M20, M20P, or SEMI M21.	ALL	DVVAL	A[1..16]	“M20” “M21” “M20P”
CoordX	CV	The coordinate in the X direction of a site (anomaly, alignment site, or the lower left-hand of an area or element).	ALL	DVVAL	F4	
CoordY	CV	The coordinate in the Y direction of a site (anomaly, alignment site, or the lower left-hand of an area or element).	ALL	DVVAL	F4	
DefaultPriority	CV	The default priority given a material location if none is assigned.	ALL	EC	U2	
DeltaX	CV	The X-axis translation of M20P coordinate system relative to the SEMI M20 coordinate system.	ALL	DVVAL	F4	
DeltaY	CV	The Y-axis translation of M20P coordinate system relative to the SEMI M20 coordinate system.	ALL	DVVAL	F4	
ElementID	CV	The SEMI M21 address for a specific rectangular element on a substrate.	ALL	DVVAL	I4[2]	May refer to a field or die.
ElementList	CV	A list of SEMI M21 elements where processing can be attempted.	ALL	DVVAL	L,n 1. <ElementID> : n.	
Fiducial	CV	The physical feature used to associate a fiducial line used for orientation (i.e., flat or notch on a substrate).	ALL	DVVAL	A[1..16]	“FLAT” “NOTCH”
GroupAnomaly-Count	CV	Anomaly count for the current or last group (i.e., field or die inspected).	G	DVVAL	U2	
GroupArea	CV	Square Area (microns^2) of the last group inspected.	G	DVVAL	F4	
GroupComment	RSV	Operator-generated comment associated with the group.	G	DVVAL	A[1..80]	
GroupID	CV	Inspection/review group identification for the current inspection/review.	ALL	DVVAL	U2	
InspectionPPID	CV	Process program used on the inspection/review tool	ALL	DVVAL	A[1..80]	

Variable Name	*Type*	*Description*	*Level*	*Class*	*Format*	*Comment*
		for the current inspection/review.				
InspectionRunID	CV	Run identification in the current inspection/review.	ALL	DVVAL	A[1..16]	
LotID	CV	Lot identification of the current material inspected/reviewed.	ALL	DVVAL	A[1..16]	
M20Data	CV	The silicon substrate size, fiducial type, and orientation to use.	ALL	DVVAL	L,3 1. <SubstrateSize 2. <Fiducial> 3. <Orientation>	
M21Data	CV	The data necessary to establish an ISEM SEMI M21 layout on a substrate.	ALL	DVVAL	L,2 1. L,3 1. <M21XSize> 2. <M21YSize> 3. <Tile> 2. L,n 1. L,3 1. <ElementID> 2. <CoordX> 3. <CoordY> : n.	
M21XSize	CV	The value of the SEMI M21 coordinate system in the X-direction.	ALL	DVVAL	F4	
M21YSize	CV	The value of the SEMI M21 coordinate system in the Y-direction.	ALL	DVVAL	F4	
Offset	CV	The distance of the actual or found location of a site relative to its defined or expected location.	ALL	DVVAL	L[2]	Refers to SiteDeltaX, SiteDeltaY which are of Format F4.
OperatorAction	CV	The action taken by the operator on the equipment's operator I/O.	ALL	DVVAL	A[1..80]	
OperatorComment	CV	Operator-generated comment, not associated with any reporting level.	ALL	DVVAL	A[1..80]	(See also Run-Comment, Substrate-Comment, Area-Comment, RegionComment, Site-Comment, and AnomalyComment.)
OperatorID	CV	Identification of the operator of the inspection/review equipment.	ALL	DVVAL	A[1..16]	This information may be added by the host in the ISEM Tables. (See Section 11.)
Orientation	CV	How the wafer is loaded on the equipment.	ALL	EC	F4	"0" degrees indicates that the wafer has the primary fiducial towards the operator.
ProcessBuild-GroupID	CV	Name of the current or last process program executed.	ALL	SV	A[1..80]	See Section 14.
ProcessEquipmentID	CV	Identification of the process equipment used with the	ALL	DVVAL	A[1..16]	This information may be added by the host in

Variable Name	Type	Description	Level	Class	Format	Comment
		current material immediately prior to the inspection/review.				the ISEM Tables. (See Section 11.)
ProcessEquipmentLocation	CV	Location (code) of the process equipment used with the current material immediately prior to the inspection/review.	ALL	DVVAL	A[1..16]	This information may be added by the host in the ISEM Tables. (See Section 11.)
ProcessEquipmentPPID	CV	Identification of the process program used with the process equipment used on the current material immediately prior to the inspection/review.	ALL	DVVAL	A[1..80]	This information may be added by the host in the ISEM Tables. (See Section 11.)
ProcessLevel	CV	Identification of the processing level of the current material.	ALL	DVVAL	A[1..16]	This information may be added by the host in the ISEM Tables. (See Section 11.)
ProcessRunID	CV	Run identification for the process prior to current inspection/review.	ALL	DVVAL	A[1..16]	This information may be added by the host in the ISEM Tables. (See Section 11.)
ProductID	CV	The product identification of the current material inspected/reviewed.	ALL	DVVAL	A[1..16]	This information may be added by the host in the ISEM Tables. (See Section 11.)
RegionComment	CV	Operator-generated comment associated with the region.	X	DVVAL	A[1..80]	
RunAnomaly-Count	ISV	Total number of all anomalies found on all substrates in the last run.	R	DVVAL	U2	
RunComment	CV	Operator-generated comment associated with the run.	ALL	DVVAL	A[1..80]	
RunInspected-AreasCount	ISV	The total number of inspected/reviewed areas on all substrates in the last run.	RS	DVVAL	U2	
RunInspection-PPCount	ISV	The total number of process programs used for the current or last run.	RS	DVVAL	U2	
RunSubstrate-Count	CV	The total number of substrates completed in the current inspection run, which remains valid until the next START command.	ALL	DVVAL	U2	
ScaleFactor	CV	A correction factor applied to the translation of one coordinate system to another.	ALL	DVVAL	F4	In most cases, a scaling of 1 (one) is expected.
SiteID	CV	Inspection/Review group identification for the current site inspection/review.	ALL	DVVAL	U2	
SlotID	CV	Carrier slot number from which the current substrate was taken.	ALL	DVVAL	U2	

Variable Name	*Type*	*Description*	*Level*	*Class*	*Format*	*Comment*
SlotList	CV	The list of carrier slots with substrates to be processed.	ALL	DVVAL	L,n 1. <SlotID> : n.	
SubstrateAnomalyCount	ISV	The total number of anomalies for the current substrate.	S	DVVAL	U2	For the most recent inspection.
Substrate-Comment	CV	Operator-generated comment associated with the substrate.	ALL	DVVAL	A[1..80]	
SubstrateID	CV	Substrate identification for the current inspection/review.	ALL	DVVAL	A[1..16]	
Substrate-InspectedAreas-Count	ISV	The total number of inspected areas on the current substrate.	S	DVVAL	U2	
SubstrateRegion-Count	CV	Total area count for the current or last substrate inspected.	ALL	DVVAL	U2	
SubstrateSize	CV	The nominal diameter (in mm) of the current or last substrate inspected/reviewed.	ALL	DVVAL	U2	
SubstrateTotal-AreaInspected	ISV	Total square area inspected/reviewed (micron^2) of the current substrate.	S	DVVAL	F4	
Theta	CV	The rotational difference in radians between a primary and secondary coordinate system.	ALL	DVVAL	F4	
Tile	CV	The layout of the pattern in the substrate.	ALL	DVVAL	A[1..16]	“NTILE” non-tiled, “CTILE” column-tiled, and “RTILE” row-tiled.
XLateData	CV	Variable for the equipment to report offset of the found or actual pattern-based coordinate system relative to the substrate-based coordinate system on the substrate being tested.	ALL	DVVAL	L,4 1. <DeltaX> 2. <DeltaY> 3. <Theta> 4. <ScaleFactor>	

10 Alarm List

Since each model of equipment differs in configuration, it is not practical to provide an exhaustive list of all possible alarms. Instead, the ISEM is requiring the two tables provided as described in SEMI E30 (document section). Alarm List Table, which is intended to provide for equipment configuration-specific alarms and Alarm ID, Alarm Set/Cleared Event Table.

10.1 *Alarm List Table*

10.1.1 The alarm list table contains examples of alarms that pertain to various configuration aspects of equipment. These examples are intended to illustrate that alarms pertain to situations in which there exists a potential for exceeding physical safety limits associated with people, equipment, and material being processed as per the SEMI E30 definition of an alarm. (See SEMI E30 for further reference.)

10.2 *Alarm ID, Alarm Set/Cleared Event Table*

10.2.1 The Alarm ID, Alarm Set/Cleared Event Table documents the association of each ALID to a set and cleared event as required by SEMI E30. (See SEMI E30 for further reference.)

11 ISEM Tables

A fundamental requirement of ISEM equipment is to transfer anomaly and review data between itself and the host. ISEM equipment may also be required to transfer “Area” and “Alignment Site” data needed for run setup. Anomaly and review data sets (as well as area and alignment site data sets) are commonly handled as lists and tables. ISEM equipment shall use tables when transferring this kind of data between itself and the host. List shall be used to refer to sub-sets of this table data.

11.1 *ISEM Table Data*

11.1.1 ISEM Tables are used to specify area, alignment site, and anomaly coordinate lists for ISEM equipment. ISEM Tables are transferred between the host and the equipment using SECS-II Stream 13 messages (Unformatted Data Set Transfers). For example, an ISEM Table may be used to transfer anomaly data (e.g., “M21” coordinates) generated by inspection equipment to the host, which in turn may then be transferred to review equipment from the host. ISEM Tables also include attributes items that are associated with the table, not with the table data. ISEM Table attributes are used to include information associated with table data, like the number of columns (NumCols), number of rows (NumRows), and table size (DataLength). (See SEMI E58 for additional information.) Product or process-related information may also be included on the attribute section of the ISEM Tables (e.g., LotID, ProductID, OperatorID, ProcessEquipmentID) (see Table 4). The ISEM does not specify additional table attribute variable items that may be associated with the table.

11.2 *TABLE-DEFs*

11.2.1 ISEM Tables are documented using TABLE-DEF structures (Figure 5). Each TABLE-DEF structure has a unique name (TableID) and type (TableType). Each column in the TABLE-DEF has a name (e.g., “AREANAME”, “ALIGNNAME”, OR “ANOMALYID”); row names are specific instances or values that correspond to the column headers in TABLE-DEF. A specific TABLE-DEF row is designated by referring to the TABLE-DEF name and the specific row name. ISEM Tables are transferred using standard (SECS-II message) Stream 13 messages (Figure 6), and each ISEM-defined TABLE-DEF item maps into a Stream 13 message item. Align and area data tables are host-defined, and anomaly tables are equipment-defined.

TableType = <*TableDef*> TableID = <*TableName*>

Row Name	*Column*$_1$	*Column*$_2$	*Column*$_3$	…	*Column*$_n$

```

Figure 6
S13,F13 with ISEM TABLE-DEF Data

11.3 *Required ISEM Tables* — ISEM equipment shall support all three table types: area, align, and anomaly. SEMI M21 anomaly table type may be supported, but it is optional. The ISEM equipment shall be able to store simultaneously at least 3 (three) defined tables of each type supported to guarantee the validity of any table while that table is being transferred (a table transfer transaction is in process).

ISEM align and area tables are stored by the equipment during the current inspection or review run (i.e., until a new remote command PP-SELECT or PP-ASSIGN is sent, or until they are modified with PP-UPDATE).

Table 5 ISEM Table Types (TABLE-DEFs)

Table Type	*Req/Opt*	*Description*
“TABLE-AREA-DEF”	R	*Area Definition* — A set of areas and their attributes, typically the list of areas to be inspected.
“TABLE-ALIGN-DEF”	R	*Alignment Site Definition* — A set of alignment sites and their attributes.
“TABLE-ANOMALY-DEF”	R	*Anomaly Coordinate Data Definition* — A set of anomalies and their attributes, with coordinates given in the SEMI M20 or M20P coordinate system.
“TABLE-M21-ANOMALY-DEF”	O	*Anomaly SEMI M21 Coordinate Data Definition* — A set of anomalies and their attributes, with coordinates given in the SEMI M21 coordinate system.

As indicated in Table 5, the SEMI M21 anomaly definition table “TABLE-M21-ANOMALY-DEF” is optional. The others are required.

ISEM requires that the following columns be included in the TABLE-DEFs. Table 6 defines the column headers and the allowed formats. Anomaly attributes and attribute headings are defined by the supplier, based on equipment capability.

11.3.1 “TABLE-AREA-DEF”

TableType: “TableAreaDef” TableID: <*AreaTableName*>

Area Name	*Coordx*	*Coordy*	*Coordsys*	*Xtentx*	*Xtenty*	*Attribute (1)*	…	*Attribute*

11.3.2 “TABLE-ALIGN-DEF”

TableType: “TableAlignDef” TableID: <*AlignTableName*>

AlignName	*Coordx*	*Coordy*	*Coordsys*	*Attribute (1)*	…	*Attribute(N)*

11.3.3 “TABLE-ANOMALY-DEF”

TableType: “TableAnomalyDef” TableID: <*AnomalyTableName*>

Anomalyid	*Coordx*	*Coordy*	*Coordsys*	*AnomalyAttribute*	…	*AnomalyAttribute*

11.3.4 “TABLE-M21-ANOMALY-DEF”

TableType = “TableM21AnomalyDef” TableID = <*M21AnomalyTableName*>

Anomalyid	*Coordx*	*Coordy*	*Elementid*	*AnomalyAttribute*	…	*AnomalyAttribute*

Defect data shall be transferred between the host and inspection/review/analysis equipment using SEMI E5, S13,F13. Columns in the table are defined by Table 11.3.5 below.

11.3.5 TABLE-STANDARD-DEFECT-DATA-SET-DEF

NOTE 1: Data for each substrate should be reported in column order shown below. Inspection tools should support relevant columns (see NOTE 6). Review and analysis tools should support all columns. Multiple data entries (list format data items) are allowed for a given attribute on a single defect.

NOTE 2: The inspection equipment must add a table attribute called “Substrate Header” (ATTRID). It must be a list that includes the following items in the given order: LotID (A[1..16]), SubstrateID (A[1..16]), ProcessEquipmentID (A[1..16]), substrate center[1] (L[2], CoordX (F4), CoordY (F4)) and centering method[2] (A[1..16]). Refer to Table 4, Variable Item Dictionary for descriptions of these items.

NOTE 3: See SEMI M21 for (0,0) die location methodology.

1 Vector from the origin of the substrate coordinate system to nominal substrate center location.
2 CoordSys (e.g., “SEMI M20”, “SEMI M21”, “M21P”, etc).

NOTE 4: Die origin is located at lower left-hand corner (LLHC).

NOTE 5: Data format must comply with the ISEM standard.

NOTE 6: In order to signify tool context, anomaly attributes are labeled as follows:

Column name starts with "insp*_" for inspection data, "rev*_" for defect review data, "and "anal*_" for analysis data, where "*" is a numeric string that ensures each set of columns added is uniquely named (e.g., "rev1_" and "rev2_").

NOTE 7: Inspection, review and analysis tools must add a table attribute called "insp*_ Header," "rev*_Header" and "anal*_Header" respectively (ATTRID) each time they add data to the table.[3] It must be a list that includes the following items in the given order: EquipmentID (A[1..16]), EquipmentType (A[1..16]), OperatorID (A[1..16]), and CLOCK[4] (A[16]).

Column #	*Column Name*	*Description*
1	Insp_Anomaly ID	ID # for the defect
2	Insp_Table specifier	Specifies table with other relevant information
3	Insp_Coordinate X	Intra die X Coordinate wrt LLHC of die in um
4	Insp_Coordinate Y	Intra die Y Coordinate wrt LLHC of die in um
5	Insp_X index	X axis die index wrt center of wafer (COW)
6	Insp_Y index	Y axis die index wrt center of wafer (COW)
7	Insp_X size	Defect size along X axis in microns
8	Insp_Y size	Defect size along Y axis in microns
9	Insp_Defect area	Defect area in square microns
10	Insp_Defect size	Linear measure of defect size in microns
11	Insp_Scatter intensity	Anomaly scattering intensity
12	Insp_Defect class number	Previously defined class number assigned to the defect
13	Insp_Test number	Inspection test in which defect was found
14	Insp_# Optical image count	Number of optical images stored for a given defect
15	Insp_Optical image data	Optical image data specifier
16	Insp_Cluster	= 1 if defect is part of a systematic defect cluster
17	Insp_Cluster class	Systematic defect class name
18	Sampled for SEM	= 1 if defect chosen for SEM review
19	Rev_SEM image data	SEM image data specifier
20	Rev_SEM class	SEM defect class name
21	Rev_Defect height	Defect height in microns
22	Sampled for analysis	= 1 if defect chosen for EDX, = 2 if defect chosen for FIB or other analysis
23	Anal_EDX data	EDX data specifier
24	Anal_FIB data	FIB data specifier

3 Where "*" is a numeric string that corresponds to the one in the column names the header refers to.

4 Date and time of the start of inspection, review, or analysis per SEMI E5 CLOCK data item variable.

11.4 TABLE-DEF Column Header Descriptions and Formats

Table 6 Description and Formats for ISEM Table Data

Column Header	*Description*	*Format*	*Comments*
"ALIGNNAME"	The identifier given to an alignment site.	A[1..16]	
ANOMALYATTRIBUTE (n) NOTE: String defined by equipment supplier.	Tool-specific information associated with an ANOMALY for which no specific ISEM data item has been defined.	U2, F4, F8, A[1..16]	Examples: Include information such as magnification, voltage, current, wavelength, brightness, color, height, or chemical spectra. The equipment supplier shall document all attributes that are supported.
"ANOMALYID"	A unique identifier for an anomaly.	A[1..16]	
"AREANAME"	A unique identifier given to an inspection area.	A[1..16]	
ATTRIBUTE(n) NOTE: String defined by equipment supplier.	Tool-specific information associated with an alignment or measurement site for which no specific ISEM data item has been defined.	U2, F4, F8, A[1..16]	Examples: Include information such as magnification, voltage, current, wavelength, number of scans, integration time, or film stack. The equipment supplier shall document all attributes that are supported.
"COORDSYS"	The identification for applicable coordinate system.	A[1..16]	Options are "M20", "M20P", and "M21".
"COORDX"	The x-coordinate for a site.	F4	Units are in microns.
"COORDY"	The y-coordinate for a site.	F4	Units are in microns.
"ELEMENTID"	The SEMI M21 address for a specific rectangular element on a substrate.	I4[2]	
"XTENTX"	The extent in the X-direction of an area to inspect as measured from the lower left-hand corner of the area given by CoordX.	F4	Units in microns.
"XTENTY"	The extent in the Y-direction of an area to inspect measured from the lower left-hand corner of the area given by CoordY.	F4	Units in microns.

12 Process Program Management

12.1 *Definition and Rules for ISEM Process Programs*

12.1.1 A process program contains information and/or instructions required for the Inspection/Review equipment to process a given run of material. The process program shall supply all of the information required for a remotely executed run to be processed without operator intervention.

12.2 *Requirements*

12.2.1 The ISEM requires that the SEMI E30 capability of Process Program Management be fully supported for this class of equipment. ISEM requires that the process program have a structure that enables the user to build process programs with default conditions that can be overridden for a run. ISEM requires the ability to vary the quantity of substrates processed, the alignment information used, and the number and/or location of the areas/anomalies to be inspected/reviewed through the uses of process program variable parameters. The concepts of process program structure and process program variable parameters are discussed in the following sections.

12.3 *Process Program Structure*

12.3.1 The purpose of this process program structure and the related concepts is to provide flexibility in using process programs to reduce the number of process programs needed. This structure enables the user or host to vary certain parameters of a given process program as needed for any particular run.

12.3.2 Often a process program may be very similar from one run to another and may differ only in a few parameters such as: which substrate slots to run, which areas to inspect, which parameters to run on each substrate, etc. Previously this small variation from run to run would require a large number of process programs to be created and maintained. The flexibility of the method described in this section will reduce the number of process programs.

12.4 *Process Program Variable Parameters* — A process program parameter specifies a value that temporarily modifies the value of a process program variable parameter. A process program variable parameter is formally defined within a process program body and contains (1) a variable parameter name that is unique in the body (CPNAME), and (2) a parameter default value for use when the process program is selected for execution without specification of an override value for this variable parameter (CPVAL/CPEVAL).

12.4.1 *Overriding Process Program Variable Parameters Default Values*

12.4.1.1 Any process-related information that is normally requested from the operator console in manual operation shall have a process program variable parameter identified in the process program and default values assigned in the body of the process program. An equipment would run the process program using the default values unless those values were overridden.

12.4.1.2 These process program variable parameters allow a host to tailor a process program for a specific run of material by temporarily modifying (replacing) the process program default values using a remote command of PP-UPDATE. The modification does not permanently change the process program; the modifications remain in effect only until the next run or until the next PP-UPDATE remote command is received.

12.4.2 *Requirements and Rules*

12.4.2.1 ISEM equipment is required to support variable process program parameters. Additionally, ISEM process programs are required to contain variable process program parameters that specify a name for each of the four previously defined ISEM table types. Specifically, parameters for "TABLE-AREA-DEF", "TABLE-ALIGN-DEF", "TABLE-ANOMALY-DEF", and "TABLE-M21-ANOMALY-DEF" table names are required. Only the names that refer to these TABLE-DEFs are required to be included in the process program body. The actual TABLE-DEF data is external to the process program body. The host may always assume that there are variable process program parameters for these four ISEM tables.

12.4.2.2 Before execution of a CARRIERBLD can begin, the presence of all the ISEM Tables that it references shall be verified by the equipment. If they are not all present, an error shall be reported. The equipment shall support data items that may be linked to the event report that specifies the name of missing ISEM Tables. S7,F27 is used for reporting this error condition.

12.4.2.3 The following table summarizes the variable process program parameters that ISEM equipment shall support and the remote command parameters that the host may use to override their values (as defined in Section 13 and Table 9).

Table 7 Required Variable Process Program Parameters

Variable Process Program Parameter and Host Command Parameter Name (CPNAME)	*Description*
"ALIGNLIST"	A list of location identifiers to be reviewed.
"ANOMALYLIST"	A list of location identifiers to be reviewed.
"AREALIST"	A list of area identifiers to be inspected or reviewed.
"ELEMENTLIST"	A list of array element identifiers to be inspected.
"SLOTLIST"	A list of carrier slot numbers with material to be inspected or to be reviewed.
"SUBSTRATELIST"	A list of substrate IDs with material to be inspected or to be reviewed.
"TABLE-ALIGN-DEF"	A set of alignment site definitions.
"TABLE-ANOMALY-DEF"	A set of (SEMI M20) anomaly location and attribute definitions.
"TABLE-AREA-DEF"	A set of area definitions.
"TABLE-M21-ANOMALY-DEF"	A set of SEMI M21 anomaly location and attribute definitions.

12.4.3 *Modifying Process Program Variable Parameters* — The remote commands of PP-SELECT, PP-ASSIGN, or PP-UPDATE are used to modify any of the identified process program variable parameters within the process program. The modification is done by including CPNAME/CPVAL pairs within the "PROCESS-BLD-GROUP", which is part of the remote commands of PP-SELECT or PP-ASSIGN, or by including a different list name in the PP-UPDATE remote command. A CPNAME in a process program shall be identical to the process program variable parameter name as specified in the "PROCESS-BLD-GROUP". See next section for details of these parameters.

12.5 *Use of Process Programs, Remote Commands, and "PROCESS-BLD-GROUP"* — This is a brief description of the steps involved in using the process program structure, the process program variable parameters, the TABLE-DEFs, and the modification of process program variable parameters through the use of "PROCESS-BLD-GROUP" and CPNAME/CEPVAL pairs in the enhanced remote command (S2,F49).

- A process program is created with certain items in the body identified as process program variable parameters, along with their default values.
- The host sends to equipment one or more TABLE-DEFs: such as "TABLE-AREA-DEF" and "TABLE-ALIGN-DEF", along with the names of those tables using Stream 13 commands (See SEMI E5). These tables are now resident on the equipment.
- The host sends an enhanced remote command (S2,F49) to the equipment (either PP-SELECT or PP-ASSIGN) that contains the information needed for processing ("CARRIERBLD"). The "CARRIERBLD" contains a "PROCESS-BLD-GROUP" for each different set of run parameters that are needed during the inspection or review process.
- "PROCESS-BLD-GROUP" shall contain the ProcessBuildGroupID to identify which program is selected.
- If the default list of slots in the process program needs to be changed for this run, then "PROCESS-BLD-GROUP" contains a "MATERIALLIST" and the list of selected slots or substrates, designated by SlotIDs or SubstrateIDs.
- If the default set of inspection areas in the process program needs to be changed for this run, then "PROCESS-BLD-GROUP" contains the name of a specific "TABLE-AREA-DEF" (in AreaTable Name). If not all of the inspection areas given in that "TABLE-AREA-DEF" are needed for this run, then "AREALIST" is used and includes a list of the names of the specific inspection areas which are needed. Those names refer to inspection areas defined in the "TABLE-AREA-DEF".
- If the default set of alignment sites in the process program needs to be changed for this run, then "PROCESS-BLD-GROUP" contains the name of a specific "TABLE-ALIGN-DEF" (in AlignTable Name). If not all of the alignment sites given in that "TABLE-ALIGN-DEF" are needed for this run, then "ALIGNLIST" is used and includes a list of the names of the specific alignment sites which are needed. Those names refer to alignment sites defined in the "TABLE-ALIGN-DEF".
- If the SEMI M21 coordinate system is being used and a pattern has been defined with pattern element names and if only certain of those elements need to be inspected for this run, then "PROCESS-BLD-GROUP" contains an "ELEMENTLIST" and the list of selected elements, designated by ElementIDs.
- If certain equipment-specific process program variable parameters need to have different values for this run, then for each needed parameter, "PROCESS-BLD-GROUP" contains a CPNAME (unique name of a specific process program variable parameter) and the new CEPVAL (new value for that parameter).
- The equipment executes the process program with the new values.
- If indicated in the process program, the equipment generates the list of anomalies found and sends it to the host in the format of a "TABLE-ANOMALY-DEF" using the ISEM table definition and Stream 13 transfer messages (see SEMI E5 for format specification).
- The host would send the "TABLE-ANOMALY-DEF" to a review equipment. The host might need to modify part of the table if required by the review equipment. This anomaly table is now resident on the review equipment. (NOTE: The host might choose to not send all of the table of anomalies, but rather a desired selection of them.)
- The host sends the equipment the enhanced remote command (PP-SELECT or PP-ASSIGN) that contains a "CARRIERBLD". The "CARRIERBLD" has a "PROCESS-BLD-GROUP" for each different set of run parameters that is needed by the review equipment. It is required for the host to use the Enhanced Remote Command S2,F49 for transferring the information

to the equipment. “PROCESS-BLD-GROUP” includes the name of a specific “TABLE-ANOMALY-DEF” in the parameter AnomalyTableName. If not all of the anomalies given in that “TABLE-ANOMALY-DEF” are needed for this run, then either “ANOMALYLIST” or “M21-ANOMALYLIST” is used and includes a list of the names of the specific anomalies which are desired. Those names refer to anomalies defined in the named “TABLE-ANOMALY-DEF”.

- The equipment runs the process program using the selected values and reviewing the specific anomalies indicated.
- The equipment adds review information to the ANOMALYATTRIBUTE list. Then the review equipment sends this modified “TABLE-ANOMALY-DEF” to the host.

13 Remote Commands

The purpose of this section is to identify remote commands, command parameters, and valid commands versus states pertinent to the SEM.

13.1 *Requirements*

- The equipment shall support the SEMI E30 required remote commands.
- All the remote commands defined by ISEM are required unless they have been qualified by the statement “if the equipment supports this functionality, it shall use this command.” In this case, they are only required if the equipment supports the functionality necessary to support the command. A good example of this is the MAP-CARRIER command. If the equipment does not have the hardware necessary to scan a carrier for the presence of substrates in slots, then the command is not required by the ISEM.
- The alphanumeric strings defined by ISEM for RCMD and CPNAME are required.

Host Command Parameter (CPNAME/CPVAL) — A parameter name/value associated with a particular host command when using stream function (S2,F41) and a (CPNAME/CEPVAL) parameter name/value when using the enhanced remote command (S2,F49). This document specifies unique names (CPNAMEs) and values (CPVALs and CEPVALs) for many command parameters. Note that if there are no associated parameters, a zero length list is sent.

The purpose of the remote commands is to allow host control over the following capabilities:

- Start processing
- Stop processing
- Temporarily suspend processing
- Resume processing
- Abort processing
- Select process programs, material, and/or sites to measure
- Report location of material found

The following remote commands (RCMDs) shall be supported as described below:

NOTE 3: The terms “current cycle” and “safe point” used below are to be defined by the supplier.

13.2 *Remote Commands Description*

1. *ABORT* — Terminate the current cycle prior to its completion. ABORT has the intent of immediately stopping the process and is used because of abnormal conditions. ABORT makes no guarantee about the subsequent condition of material except as noted in the “ABORTLEVEL” description.
2. *CLEANUP* — De-selection of the current ISEM job (“CARRIERBLD”) and process program (“PROCESS-BLD-GROUP”), including the removal of all material to output locations and any equipment-specific activities needed to transition into the IDLE state. Completion of this command should generate a collection event report. If the equipment supports this functionality, it will use this command.
3. *MAP-CARRIER* — Requests the equipment to provide a list of carrier slots that contain material. MAP-CARRIER has the intent of providing the host with enough information about the location and/or ID of material so it may select material for processing accordingly. Completion of this command shall generate a collection event report. If the equipment supports this functionality, it must use this command.
4. *NEXT-MATERIAL* — Processing of the current substrate is halted at the first safe point and unloaded to the target carrier location. NEXT-MATERIAL has the intent of allowing the host to skip measurement of the current substrate. This is a trigger for processing state transition from WORKING to UNLOAD. If the equipment supports this functionality, it will use this command.
5. *PAUSE* — Suspend processing temporarily at the next safe point. PAUSE has the intent of resuming the process at the same point where it was paused.

RESUME or PP-UPDATE may be used to resume the process.

6. *PP-ASSIGN* — Instructs the equipment that supports queuing to create a new ISEM job (“CARRIERBLD”) for the specified port (“LOCATIONID”) when more than one port is available for processing. If only one port is available, “LOCATIONID” is not required. Priority may optionally be specified with this command. The “PRIORITY” specifies the priority of the newly created job in the ISEM job queue (a value of 0 (zero) assigns the highest priority to the job). Without specifying a priority, the job is queued with the default priority. Jobs with equal priority are queued in the order the PP-ASSIGN commands are received. This command is valid in all PROCESSING states.

7. *PP-SELECT* — Instructs the equipment to make the requested ISEM job(s) (“CARRIERBLD”) available in the execution area. This is a trigger for the processing state transition from IDLE to SETTING UP. The first process program (“PROCESS-BLD-GROUP”) specified in the “CARRIERBLD” is also validated during SETTING UP.

8. *PP-UNASSIGN* — Removes the ISEM job assignment (“CARRIERBLD”) for a carrier or port. The carrier or port is removed from the process queue.

9. *PP-UPDATE* — Provides the ability to alter the current process program being executed during the PAUSED state. The process program variables specified in the PP-UPDATE command will replace previous definitions in the “PROCESS-BLD-GROUP”. This command will trigger transition to CHECKING for process program parameter verification. A RESUME command is implied with the validation of “all” replaced values to resume the process. If the PP-UPDATE fails, the process program variables present prior to the PP-UPDATE are retained. If no parameters values are specified, the defaults are used.

10. *RESUME* — Resume processing from the point where the process was paused. This is the trigger for processing state transition from PROCESS PAUSE to the previous PROCESS state.

11. *START* — Instructs the equipment to initiate processing. This is the trigger for the processing state transition from READY to LOAD. An “AUTOSTART” command parameter may be included to allow for continuous processing.

12. *STOP* — Complete the current cycle, stop in a safe condition, and return to the IDLE processing state. Stop has the intent of stopping the process entirely. This command can be used to both: stop the current ISEM job or to stop all queued jobs. The equipment is not required to support the continuation of processing.

13.2.1 *Remote Commands and Associated Host Command Parameters* — This table describes the allowable command parameters (CPNAME) for each remote command (RCMD). Equipment shall support all parameters. The column marked Req/Opt specifies which parameters are required to be sent by the host and which parameters may be optionally sent by the host.

Table 8 Allowable Command Parameters

Remote Command	*Parameters*		
	CPName	*Req/Opt*	*Comments*
ABORT	“ABORTLEVEL”	R	
CLEANUP	“CARRIERID” “LOCATIONID” “SLOTID”	O O O	PORT and SLOT may be used to define a different carrier/slot destination for the substrates.
MAP-CARRIER	“CARRIERID” “LOCATIONID”	R* R*	* One is required.
NEXT-MATERIAL	“CARRIERID” “LOCATIONID” “SLOTID”	O O O	PORT and SLOT may be used to define a different carrier/slot destination for the substrates.
PAUSE	None	NA	None
PP-ASSIGN	“PRIORITY” “CARRIERBLD”*	O R	* More than one “CARRIERBLD” may be specified.
PP-SELECT	“CARRIERBLD”*	R	* More than one “CARRIERBLD” may be specified.
PP-UNASSIGN	“CARRIERBLD”	R	None

PP-UPDATE	"PPBUILDID" "ALIGNLIST" "ANOMALYLIST" "AREALIST" "ELEMENTLIST" "SLOTLIST" "SUBSTRATELIST" "TABLE-ALIGN-DEF" "TABLE-AREA-DEF" "TABLE-ANOMALY-DEF" "TABLE-M21-ANOMALY-DEF"	R R* R* R* R* R* R* R* R* R* R*	* At least one is required.
RESUME	None	N/A	None
START	"CARRIERBLD"	0	None
STOP	"CARRIERBLD"	0	None

13.2.2 *Host Command Parameter Names and Values*

Table 9 Host Command Parameters CPNAMES

CPName	*Parameter Value*		
	Description	*Range*	*Format*
"ABORTLEVEL"	ISEM-defined abort levels: HALT — Process halts, and the ABORTING process state is entered. CLEANUP — Process halts, material cleanup is performed, and the ABORTING process state is entered.	"1= HALT" "2 = CLEANUP"	U2
"ALIGNLIST"	L,n 1. AlignName$_1$: n. For the SEMI M20 or M20P coordinate system.		List of A[1..16] data items
"ALIGNNAME"	Alignment name See the "TABLE-ALIGN-DEF" definition for further explanation.		A[1..16]
"ANOMALYLIST"	L,n 1. AnomalyID$_1$: n. For the SEMI M20 or M20P coordinate system.		List of A[1..16] data items
"ANOMALYID"	Anomaly identifier See the "TABLE-ANOMALY-DEF" or the "TABLE-M21-ANOMALY-DEF" definition for further explanation.		A[1..16]
"AREALIST"	L,n 1. AreaName$_1$: n.		List of A[1..16] data items
"AREANAME"	Unique identifier for an area to be inspected. See the "TABLE-AREA-DEF" definition for further explanation.		A[1..16]
"AUTOSTART"	Specifies whether a START command is required from an external source (operator or host) to exit the READY state. 0 = NoAutoStart (A START command required.) 1 = AutoStart (No external START command required to begin execution.)	0–1	U2
"CARRIERID"	Identifier of the carrier that the inspection/review data is associated with.		A[1..16]

CPName	Parameter Value		
	Description	*Range*	*Format*
“ELEMENTLIST”	L,n 1. ElementID$_1$: n. For the SEMI M21 coordinate system.		List of A[1..16] data items
“LOCATIONID”	Unique identifier of the location to be used for the “CARRIERBLD” assignment.		U2
“PPBUILDID”	ProcessProgramBuildID		A[1..80]
“PPNAME”	ProcessProgramName		A[1..80]
“PRIORITY”	Assignment priority	0–9 Highest priority corresponds to 0.	U2
“SLOTLIST”	Specifies carrier slots containing substrate for the ISEM job. L,n 1. SlotID$_1$: n. SlotIDn	Zero length list specifies all slots.	List of U2 data items
“STOPLEVEL”	Stop levels defined by the ISEM.	“1 = LOCATIONID” “2 = CARRIERID”	Use defined CPVALs
“SUBSTRATELIST”	Specifies identifiers of substrate for the ISEM job. L,n 1. SubstrateID$_1$: n. SubstrateID$_n$	Zero length list specifies all substrate (independent of substrate identifier).	List of A[0..16] data items
“CARRIERBLD” E5 Format	L, 3 Three ISEM required parameters 1. L, 2 ❖ 1. “CARRIERID” **A[9]** -- CPName 2. CarrierID **A[1..16]** -- CPValue 2. L, 2 ❖ 1. “LOCATIONID” **A[10]** -- CPName 2. LocationID **U2** -- CPValue 3. L, 2 1. “PROCESS-BLD-LIST” 2. L, n ❖ List of n jobs 1. L, 2 1. “PROCESS-BLD-GROUP” 2. L, m First ISEM job 2. L, 2 1. “PROCESS-BLD-GROUP” 2. L, m Next ISEM job . . . n. L, 2 1. “PROCESS-BLD-GROUP” 2. L, m Last ISEM job	m = 3	List
“PROCESS-BLD-GROUP” (for Inspection)	L,m 1. L,2 1. “PPBUILDID” 2. ProcessBuildGroupID	*m* ≥ 2	List of *m* data items

CPName	Parameter Value		
	Description	Range	Format
	2. L,2 1. "PPNAME" 2. ProcessProgramID 3. L,2 1. "SLOTLIST" 2. L,n 1. $SlotID_1$: n. ***Or*** 1. "SUBSTRATELIST" 2. L,n 1. $SubstrateID_1$: n. 4. L,2 1. "AUTOSTART" 2. AutoStart 5. L,2 1. 14 Scenarios

14.1 *Run Level Reporting Scenario* — This scenario only has expected events (i.e., no alarms or errors).

COMMENT	HOST	EQUIPMENT	COMMENT
			The equipment is in the IDLE processing state and in The ONLINE REMOTE control state. The host has defined, linked, and enabled RUN level report for CEIDs 2, 3, and 5.
Host sends a PP-SELECT command specifying a ”CARRIERBLD”	S2,F49-->		
		<--S2,F50	Command Acknowledge
			The equipment transitions from IDLE to SETTING UP, and material arrives at input port.
		<--S6,F11	SETTING UP -> READY (CEID 3)
Event Report Acknowledge	S6,F12-->		
START	S2,F41-->		
		<--S2,F42	Host Command Acknowledge

			READY -> LOAD.
			[WHILE] Note End of Run
			   LOAD -> WORKING
			   WORKING -> UNLOAD
			   UNLOAD -> LOAD
			[END WHILE]

		<--S6,F11	LOAD -> STOPPING (CEID 5)
Event Report Acknowledge	S6,F12-->		
		<--S6,F11	Run Processed Data Valid event.
Event Report Acknowledge	S6,F12-->		
			The equipment transitions from STOPPING to IDLE.

14.2 *PP-UPDATE Remote Command Scenario* — Host issues the PP-UPDATE remote command.

COMMENT	HOST	EQUIPMENT	COMMENT
START	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	READY -> LOAD
Positive Acknowledge.	S6,F12-->		
			[WHILE] Not End of Run 1) LOAD -> WORKING 2) WORKING -> UNLOAD 3) UNLOAD -> LOAD [END WHILE]
Sometime during the [WHILE]:			
PAUSE	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	Transition to PAUSING
Positive Acknowledge.	S6,F12-->		
		<--S6,F11	PAUSING -> PAUSED
Positive Acknowledge.	S6,F12-->		
PP-UPDATE	S2,F49-->		
		<--S2,F50	Positive Acknowledge.
		<--S6,F11	PAUSED -> CHECKING
Positive Acknowledge.	S6,F12-->		
		<--S6,F11	CEID is posted. [IF] the updates are valid: Return to the previous process state through history. [ELSE] Return to the PAUSED state. The Process program remains unchanged. [ENDIF]
Positive Acknowledge.	S6,F12-->		

14.3 *PP-SELECT Remote Command Scenario*

COMMENT	HOST	EQUIPMENT	COMMENT
			The equipment is in the IDLE processing state and in the ONLINE REMOTE control state.
Host sends a TABLE-DEF to the equipment.(See Section 11.)	S13,F13-->		
		<--S13,F14	Table Data Acknowledge
Host sends more tables if needed.	S13,F13-->		
		<--S13,F14	Table Data Acknowledge
Host prepares the remote command to initiate an inspection run, including the “TABLE-AREA-DEF”, ”TABLE-ALIGN-DEF”, and ”ELEMENTLIST”, if required.			
Host sends a PP-SELECT command specifying a ”CARRIERBLD”.	S2,F49-->		
		<--S2,F50	Command Acknowledge The equipment transitions from IDLE to SETTING UP to READY.
START	S2,F41-->		
		<--S2,F42	Host Command Acknowledge READY -> LOAD. [WHILE] Not End of Run LOAD -> WORKING WORKING -> UNLOAD UNLOAD -> LOAD [END WHILE] LOAD -> STOPPING
		<--S13,F13	Equipment sends anomaly table with additional data, including the table name using Table Data Send command.
Table Data Acknowledge	S13,F14-->		
			The equipment transitions from STOPPING to IDLE.

14.4 *Event Report and ISEM Table Transfer Command Scenario*

COMMENT	HOST	EQUIPMENT	COMMENT
			The equipment is in the IDLE processing state and in the ONLINE REMOTE control state.
Host defines report with AnomalyTableName and AnomalyTableType	S2,F33-->		
		<--S2,F34	Define Report Acknowledge
Link report to RunDataComplete event	S2,F35-->		
		<--S2,F36	Link Event Report Acknowledge
Enable event	S2,F37-->		
		<--S2,F38	Enable Event Acknowledge
Host sends an ISEM table to the equipment.	S13,F13-->		
		<--S13,F14	Table Data Acknowledge
Host sends more tables if needed.	S13,F13-->		
		<--S13,F14	Table Data Acknowledge
Host sends a PP-SELECT command specifying a ”CARRIERBLD”	S2,F49-->		
		<--S2,F50	Remote Command Acknowledge The equipment transitions from IDLE -> SETTING UP -> READY.
START	S2,F41-->		
		<--S2,F42	Host Command Acknowledge READY -> LOAD. [WHILE] Not End of Run LOAD -> WORKING WORKING -> UNLOAD UNLOAD -> LOAD [END WHILE] LOAD -> STOPPING STOPPING -> IDLE
		<--S6,F11	RunDataComplete event with AnomalyTableName and AnomalyTableType.
Event Report Acknowledge	S6,F12-->		
Host sends Table DataRequest	S13,F15-->		
		<--S13,F16	Equipment sends requested table TBLACK = 0 if no errors.

15 GEM Capabilities

The purpose of this section is to specify any SEMI E30 additional capabilities that are required to be supported by this class of equipment.

15.1 *Requirements*

15.1.1 This standard requires that the SEMI E30 fundamental requirements and additional capabilities have been implemented on the ISEM equipment with the exception of limits monitoring and trace reporting. If these capabilities are implemented, they shall be implemented as required by the SEMI E30 document. The following SEMI E30 additional capabilities required by ISEM are:

- Dynamic Event Report Configuration
- Variable Data Collection
- Status Data Collection
- Alarm Management
- Remote Control
- Equipment Constants
- Process Program Management
- Spooling
- Trace Data Collection (optional)
- Control (Host-Initiated)

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E30.1 and was approved for publication by full letter ballot procedures on September 3, 1999.

R1-1 Defect Classification Code Management

The purpose of this section is to provide a method and specific formats to define, identify, and communicate coordinate systems and site locations on substrates for alignment sites, anomaly locations, and other sites used by the ISEM equipment.

R1-1.1 *Classification Codes and Defect Classification* — One function of review equipment is to view previously identified anomalies and to associate a defect classification code with each anomaly. A classification code is an identifier for a classification description.

Typically, the review equipment has a set of defect classification codes and their descriptions available to the operator. Then, for each anomaly, the operator selects a particular code to be associated with that anomaly. This action is defect classification.

The set of valid classification codes and their descriptions may change from one run to another. For example, the same main process program could be used with different substrate levels, and each level may use a different set of classification codes. The purpose of this section is to provide the requirements so that a user can both define several sets of classification codes and their descriptions and can also manage these sets on ISEM equipment.

R1-1.2 *Requirements*

- Each set of classification codes and their descriptions shall have an identifier, known as a classification code set ID.
- Review equipment shall provide a means for the user (the host or the operator) to define a classification code set, consisting of (a) the classification code set ID and (b) the list of classification codes and their descriptions.
- Equipment shall provide a means to manage the various classification code sets.
- A main process program shall include a process program variable that specifies the particular classification code set ID to be used.
- Equipment vendor shall provide documentation to the user regarding how to define and manage classification code sets.

Comment: In one implementation, the equipment considers a classification code set to be a sub-process program or an ISEM table. This would allow the user to identify a classification code set by name (using a PPID) or a table name and thereby managing this sub-process program with the SEMI E30 Process Program Capability or with SEMI E58 ARAMS tables.

R1-2 Reporting Coordinates and Coordinate Systems

The purpose of this section is to provide a method and specific formats to define, identify, and communicate coordinate systems and site locations on substrates for alignment sites, anomaly locations, and other sites used by ISEM equipment.

The ISEM-required formats are intended to minimize the number and type of site location format transformations needing to be supported by both equipment suppliers and users.

All ISEM-required site location formats involve the use of an ISEM-defined right-handed Cartesian coordinate system, established on substrates in an ISEM-defined manner. The scope of the detailed methods in this section are specific to unpatterned and patterned wafers in this release, but the section is intended to be general enough in methodology so that it can be extended to other substrate types in future revisions of ISEM, if required.

The purpose of inspection and review equipment is to locate, evaluate, classify, and report anomalies on substrates. ISEM equipment may deal with either unpatterned or patterned substrates or both. In most cases, the anomaly location is part of the information reported and/or used by ISEM equipment. An anomaly location is reported at a particular site with x,y coordinates in a particular coordinate system. Site coordinates are also used by ISEM equipment for the alignment sites for defining a coordinate system on a substrate. A standard method is needed to define a coordinate system and to report site coordinates for both alignment sites, anomaly locations, and any other reference sites needed by ISEM equipment. A standard method is essential in order to transfer the anomaly site information from one equipment to another.

R1-2.1 *Site Location Accuracy* — Each equipment has an accuracy with which it can define or locate a site as being within a certain area. This area associated with a site is determined by the equipment accuracy, based on the accuracy of its motion and imaging systems to locate a site, as well as on the accuracy with which it can define the coordinate system on the substrate.

When equipment shall locate a particular site on a substrate based on the expected or design-based location, then the location of a site or feature on an actual substrate is further affected by the accuracy of the equipment which placed the pattern on the substrate.

R1-2.2 *Expected or Designed Locations vs. Actual Locations* — The placement of patterns, sites, and coordinate systems is designed to be at certain mathematically described locations relative to one another and to an ideal substrate. These are the expected or designed locations. When a pattern is written by equipment onto a specific substrate, the actual placement of the pattern, the pattern-elements, and their features may differ from the expected locations, due to variations in equipment performance and variations in substrate shape and dimensions.

R1-2.3 *Substrate Coordinate Systems (Unpatterned)* — A substrate coordinate system is a coordinate system which has both origin and axes defined by the shape and dimensions of the substrate and which does not depend on whether there is a pattern on the substrate or whether it is unpatterned. This coordinate system is used to locate or define sites relative to the substrate.

R1-2.4 *Substrate Pattern Coordinate System* — A substrate pattern coordinate system is a coordinate system which has its origin and axes defined by the pattern as a whole on the substrate. This coordinate system is used to locate or to define sites relative to the pattern on the substrate. The expected or designed location of the pattern on the substrate can be defined in terms of the placement of the origin and axes of the substrate pattern coordinate system relative to those of the substrate coordinate system. The actual location of a pattern on a substrate may differ from the expected location. The actual location is determined by locating two or more alignment sites on the patterned substrate. The alignment sites are specific points of certain features in the pattern. The coordinates of the alignment sites are given in the substrate pattern coordinate system. In many cases, equipment does not align to the specific pattern elements but instead uses the defined locations of the pattern elements within the substrate pattern coordinate system.

R1-2.5 *Pattern Element Coordinate System* — A pattern-element coordinate system is a coordinate system which has its origin and axes defined by the pattern of one specific rectangular element in a pattern (a defined arrangement) of equal-sized rectangular elements. This coordinate system is used to locate or to define sites relative to that specific pattern-element. The expected or designed location of the pattern-element within a pattern can be defined in terms of the placement of the origin and axes of the pattern-element coordinate system relative to those of the pattern coordinate system. The actual location of a pattern-element within a pattern on a substrate may differ from the expected location. The actual location is determined by locating two or more alignment sites within the pattern-element. The coordinates of the alignment sites are given in the pattern-element coordinate system.

R1-2.6 *Parallel Coordinate Systems* — A second coordinate system is considered to be parallel to a first coordinate system if the origin of the second can be defined as a translation from the origin of the first and if the axes of the second are parallel and in the same direction as those of the first.

R1-2.7 *Requirements* — The following is a list of requirements for ISEM equipment regarding coordinate systems and reporting site locations:

- ISEM equipment shall document whether it deals with coordinate systems based on (a) a substrate, (b) a substrate pattern, or (c) a pattern-element or whether it deals with several of these coordinate systems.
- ISEM equipment shall establish a substrate coordinate system using a standard, documented method. This coordinate system is not based on any pattern on the substrate. This coordinate system shall be a right-hand Cartesian coordinate system and shall be identified by a name.

  NOTE: For wafers, this method is defined in SEMI M20 (Specification for Establishing a Wafer Coordinate System), and the coordinate system is named “M20.”
- For equipment dealing with substrate pattern coordinates, the substrate pattern coordinate system shall be established in a standard, documented method relative to the substrate coordinate system (the “unpatterned” coordinate system). This substrate pattern coordinate system shall be a right-hand Cartesian coordinate system and shall be designed to be parallel to the substrate coordinate system. The substrate pattern coordinate system shall be identified by a name. The location of its origin and axes relative to the substrate coordinate system shall be communicated in terms of the substrate coordinate system.

  NOTE: For wafers, this method is the one described below, and the substrate pattern coordinate system is named “M20P”, and its origin and axis relative to the SEMI M20 coordinate system are given in terms of “M20” coordinates and are communicated using XlateData.
- For equipment dealing with pattern-element coordinates, the pattern-element coordinate system shall be established in a standard, documented

method relative either to the substrate pattern coordinate system or to another pattern-element coordinate system. The pattern-element coordinate system shall be a right-hand Cartesian coordinate system which is designed to be parallel to the substrate pattern coordinate system. The pattern-element coordinate system shall be identified by a name. The location of its origin and axis relative to the substrate pattern coordinate system shall be communicated in terms of the substrate pattern coordinate system.

NOTE: For wafers, this method is based on SEMI M21, and the coordinate system is named “M21” and its origin and axis relative to the “M20P” coordinate system are given in terms of the M20P coordinates.

- ISEM requires that equipment have the capability to use site location information that is based on the user’s product designs, which the user shall provide in the appropriate ISEM-required format.
- ISEM-compliant equipment shall have the capability to define, locate, and report site information using only the ISEM-defined right-handed Cartesian coordinate system formats. This requirement does not preclude equipment from having additional capability for defining or reporting site location information using other formats.
- Coordinate system name and placement relative to the “higher” coordinate system shall be defined and communicated using the following ISEM data items, in terms of either expected or actual placement: CoordSys, XlateData, and their included data items.
- Alignment site information shall be defined and communicated using the following ISEM items: the variable item AlignList, the “ALIGNLIST”, the Process program class of “TABLE-ALIGN-DEF”, and their included information.
- Areas to be inspected shall be reported using the specific coordinate system defined by the user. The following ISEM items are used to define and communicate area locations: the variable item “AREALIST”, the “AREALIST”, and the Process program class of “TABLE-AREA-DEF”, and their included information.
- The displacement of an actual coordinate system relative to its expected location shall be communicated using the ISEM data item: XlateData and its included data items.
- The displacement of an actual site location relative to its expected site location shall be communicated using the ISEM data item: Offset and its included data items.
- The equipment vendor shall document the requirements for the ISEM data items used in alignment of a coordinate system.
- The equipment vendor shall provide and document a means for the user to define and communicate a pattern map using SEMI M21 data. A pattern map defines the layout of equal-sized rectangular pattern-elements which make up a pattern. Each pattern-element shall have a name, using the SEMI M21 naming convention.

  NOTE: For patterned wafers, the naming method shall be that described in SEMI M21, and the pattern-element information shall be communicated using the ISEM data item of SEMI M21Data.

- For ISEM compliance, inspection equipment shall report various anomaly data; AnomalyID, coordinates, and attributes. Review equipment shall receive this data for anomalies and be able to locate them and perhaps modify the coordinates. Anomaly coordinates shall be reported using ISEM table named “TABLE-ANOMALY-DEF” and its included data.

R1-3 Coordinate System for a Substrate

R1-3.1 *SEMI M20 Coordinate System* — The SEMI M20 standard (Specification for Establishing a Wafer Coordinate System) describes how to map a right-handed Cartesian coordinate system to a substrate so that its origin is at the center of the substrate, and its negative *y*-axis bisects the substrate’s primary fiducial. This coordinate system is defined by ISEM to be the “M20” coordinate system. The only information required by equipment in order to establish an “M20” coordinate system is the substrate size and the type of fiducial, which are communicated using the ISEM data items named **SubstrateSize** and **Fiducial**. Another ISEM data item named **Orientation** identifies how the substrate is loaded on the equipment. Note that the SEMI M20 standard requires that the “M20” coordinate system is fixed on the substrate and is not affected by how the substrate is loaded on equipment. Also, as stated in the SEMI M20 standard, an orientation of “0” degrees designates a substrate loaded on equipment, with the primary fiducial towards the operator or “down.”

R1-3.2 *M20P Coordinate System* — ISEM defines the M20P coordinate system to be one which is aligned to the pattern on the substrate. The M20P coordinate system is useful because in many cases, it is more significant to the user to know the location of an anomaly relative to the pattern on the substrate rather than relative to the substrate shape and dimensions. ISEM also defines the M20P coordinate system to be one which is designed to be "parallel" to the SEMI M20 coordinate system. In practice, because of experimental errors, both the origins and the axes may differ slightly from their intended values of a simple translation and no rotation. Equipment should be designed to be able to locate the alignment sites, given the various possible experimental errors.

R1-3.3 *Establishing an M20P Coordinate System* — A minimum of two alignment sites is necessary to establish an M20P coordinate system on a substrate. Additional sites are often used to determine a scaling ratio of the dimensions of the actual coordinate system relative to the dimensions of the expected coordinate system and are reported using the ISEM data item of **ScaleFactor**.

XlateData is used to report actual coordinate system location. Most equipment cannot distinguish whether patterned substrate site location errors are due to the substrate, the layout on the substrate, or the equipment's ability to locate the sites. However, information that is available through the use of patterned-substrate alignment sites can provide a means for identifying potential equipment problems. For instance, assume that the only pattern-layout location error on a substrate is that due to the establishment of the location of the substrate center and fiducial. For many users and equipment systems, this is a good assumption. If this is the case, then the ISEM data item named **XlateData** can be used to track this error. Although the error may result from multiple sources, being able to track it on various equipment will enable users to apply statistical process control techniques to identify the specific sources.

Offset sites may be found by equipment at actual locations which deviate from their expected locations through either pattern layout errors or equipment "stage" or imaging errors. Again, in a controlled manufacturing process, these combined errors should be normally distributed, and non-normal deviations may indicate possible equipment problems. The actual position of a site relative to its expected position shall be reported through the use of the ISEM data item named **Offset**.

R1-4 Layout of Rectangular Pattern Elements on a Substrate Using SEMI M20 Coordinate System

Equipment shall be capable of routine, automated operation without needing substrate layout information (e.g., field or die maps). However, having the capability to provide substrate layout information to equipment from the host can be desirable. ISEM defines a means to do this in this section for substrates, based on SEMI M21 (Specification for Assigning Addresses to Rectangular Elements in a Cartesian Array.) The SEMI M21 standard is limited to defining how to assign "addresses" to elements and how to find the "array center" element. It does not specify how the rectangular pattern-elements are located on the substrate. In this section, ISEM defines how these pattern-elements are located on a substrate, using the data item named M21Data, and how to establish within-element coordinate systems. Any additional layout information, such as within-element structure details or element attribute information, is beyond the scope of ISEM.

R1-4.1 *ISEM "M21" Layouts*

- An "M21" layout consists of an array of equal-sized rectangular pattern-elements with no space between the pattern elements.
- ISEM defines the "M21" layout on a substrate to include all pattern-elements which are either wholly or partially within the circumference of the substrate.
- The ISEM approach is to define the pattern map by specifying the M20P coordinate for the lower left corner of the minimum number of pattern-elements needed to define the layout, along with the pattern-element addresses (names). For a non-tiled layout, the location and name of a single pattern-element is sufficient to establish the "M21" layout. For tiled layouts, the location and name of one pattern-element in each row or column are required. Note that the location of the lower left corner of some pattern-elements may be outside the circumference of the substrate.
- The "M21" pattern-element coordinate system shall have its *x* and *y* axes parallel to the respective M20P coordinate system axes and shall have their origins at the lower left corner of each element. The pattern-element coordinate system shall have a name and a specific pattern-element address identifier per SEMI M21.
- Layout definition is supported only for host-to-equipment communications. The user is responsible for ensuring that the pattern-element addresses provided to the equipment agree with the SEMI M21 specification. The equipment need not check this, other than to ensure that there are not conflicts within the provided layout, and shall report results with pattern-element addresses as provided by the user.

- "M21" layouts are established within the M20P coordinate system and need not require any additional alignment site data than is needed to establish the M20P coordinate system. However, as with M20P, additional alignment may be necessary because of errors in either the pattern layout or the equipment's ability to locate features. Offset shall be used to report the location corrections that result from any within-element alignments.

R1-5 How an M20P Coordinate System Is Established on a Substrate

The following example is fairly basic. For this example, the M20P coordinate system has a zero translation from the SEMI M20 coordinate system. Also, the equipment documentation states that 4 alignment sites are required. The equipment does M20P alignment on two alignment sites and does a low resolution and then a high resolution alignment at each site. Note that the specific alignment point is different at the two resolutions, so the coordinates are slightly different. The alignment sites are defined to the equipment via the process program class named "TABLE-ALIGN-DEF", as detailed below. The order of the sites in "TABLE-ALIGN-DEF" is not important. The sites are then selected via the CPNAME named "ALIGNLIST", which is included in the PP-SELECT command. The order of the sites listed in "ALIGNLIST" is important and is as-specified in the equipment's documentation. The first item is the alignment site for the first low resolution site, the second item is for the first high resolution site, the third item is the second low resolution site, and the fourth is the second high resolution site.

"TABLE-ALIGN-DEF"

AlignName	*Coordx*	*Coordy*	*Coordsys*	*Attribute (1)*
Coarse1	-60000	-200	"M20P"	
Fine1	-60020	-205	"M20P"	
Coarse2	+60000	+200	"M20P"	
Fine2	+59980	+195	"M20P"	

"ALIGNNAME"

L,4

1. <Coarse1>
2. <Fine1>
3. <Coarse2>
4. <Fine2>

Using this information, the equipment will go to the nominal "M20" location for Coarse1, then "find" where it actually is. The offset between the nominal "M20" location and the actual "M20" location is then used to "find" Fine1. The actual M20 location of Fine1 is saved. The process is then repeated for Coarse2 and Fine2. The equipment can now determine the "M20" to M20P offset from the nominal and actual coordinates. First, a summary of the data:

xN1 = -60020 yN1 = -205 Nominal *x* and *y* data for the first fine site

xA1 = -59800 yA1 = -150 Actual *x* and y data for the first fine site

xN2 = +59980 yN2 = +195 Nominal *x* and *y* data for the second fine site

xA2 = +60060 yA2 = +175 Actual *x* and *y* data for the second fine site

The equipment first calculates Theta, using, for example, the formula:

$$\Theta = tan^{-1}\left[\frac{MA - MN}{1 + MA \quad MN}\right]$$

where *MA* and *MN* are, respectively, the slopes of the lines connecting the two actual fine sites and the line connecting the two nominal sites, in “M20” coordinates, calculated as follows:

$$MA = \left[\frac{yA_2 - yA_1}{xA_2 - xA_1}\right] \quad MN = \left[\frac{yN_2 - yN_1}{xN_2 - xN_1}\right]$$

The equipment then calculates *DeltaX* and *DeltaY*, using, for example, the formulas:

$$DeltaX = \left[\frac{C\sin(\Theta) + D\cos(\Theta)}{(\sin(\Theta))^2 + (\cos(\Theta))^2}\right]$$

$$DeltaY = \left[\frac{C\sin(\Theta) - D\cos(\Theta)}{(\sin(\Theta))^2 + (\cos(\Theta))^2}\right]$$

where *C* and *D*, the adjusted site 1 coordinates in a rotation-adjusted coordinate system, are calculated, for example, using the formulas:

$$C = yA1 - ((xN1 \ \sin\Theta) + ((yN1 \ \cos\Theta)$$

$$D = xA1 - ((xN1 \ \cos\Theta) - ((yN1 \ \sin\Theta)$$

The equipment can also calculate a ScaleFactor term to indicate the relative ratio between the length of the vector connecting the nominal alignment sites and the length of the vector connecting the actual alignment sites. This can be used, for example, to judge whether there is a problem with the alignment process, since the difference between these two vectors should be small.

$$ScaleFactor = \frac{VA}{VN}$$

where *VA* and *VN* are the length of the vectors connecting the actual and nominal alignment sites, calculated using the formulas:

$$VN = \sqrt{(yN_2 - yN_1)^2 + (xN_2 - xN_1)^2}$$

$$VA = \sqrt{(yA_2 - yA_1)^2 + (xA_2 - xA_1)^2}$$

RELATED INFORMATION 2
APPLICATION NOTES

NOTE: The material contained in these Application Notes is not an official part of SEMI E30.1 and is not intended to modify or supersede the official standard. Rather, these notes describe possible methods for implementing certain ISEM requirements described by the standard and are included as reference material.

R2-1 Using ISEM Table Attributes to Specify Process Related Data Item Variable Values

R2-1.1 Section 11.1 (ISEM Table Data) allows the host to use ISEM Table attributes to specify product and process related information related to the table data. The ISEM Variable Item Dictionary (Table 4) includes seven data items intended to be used for this purpose. They are identified with the comment "This information may be added by the host in the ISEM Tables." Identifying the value of variable data items in Table attributes is not covered in use of ISEM Tables. One method to accomplish this is to use attribute identifiers (ATTRID*n*) that are the same identifiers that are used for the equipment variable data items (Table R2-1). (This is very similar to the method specified in Section 12.5 to identify values to override the default values of variable process program parameters using the "PP-SELECT" remote commands).

Table R2-1 ISEM Variable Items and Their Equivalent ISEM Table Attribute Identifiers

Variable Item (Table 4)		*ISEM Table Attribute Identifier*	*Description*
Name	*Type*		
OperatorID	DV	OperatorID	Identification of the operator of the inspection/review equipment.
ProcessEquipmentID	DV	ProcessEquipmentID	Identification of the process equipment used with the current material immediately prior to the inspection/review.
ProcessEquipmentLocation	DV	ProcessEquipmentLocation	Location (code) of the process equipment used with the current material immediately prior to the inspection/review.
ProcessProgramID	DV	ProcessProgramID	Identification of the process program used with the process equipment used on the current material immediately prior to the inspection/review.
ProcessLevel	DV	ProcessLevel	Identification of the processing level of the current material.
ProductID	DV	ProductID	The product identification of the current material inspected/reviewed.
ProcessRunID	DV	ProcessRunID	Run identification for the process prior to current inspection/review.

NOTE 1: The variable item may be identified using any appropriate SECS II data item format.

HANDLER EQUIPMENT SPECIFIC EQUIPMENT MODEL (HSEM)

CONTENTS

List of Figures

List of Tables

SEMI E30.2-0698
HANDLER EQUIPMENT SPECIFIC EQUIPMENT MODEL (HSEM)

1 Purpose

1.1 This document establishes a Specific Equipment Model (SEM) for Handling equipment (HSEM). The SEM consists of equipment characteristics and behaviors that are applicable to this class of equipment and are required to be implemented in addition to the SEMI E30 fundamental requirements and additional capabilities. The intent of this document is to facilitate the integration of Handling equipment into an automated (semiconductor) factory. This document accomplishes this by defining an operational model for Handling equipment as viewed by a factory automation controller. This definition provides a standard host interface and equipment operational behavior.

2 Scope

2.1 The scope of this document is limited to the definition of Handling equipment behavior as perceived by a SECS-II host that complies with the SEMI E30 model. It defines the view of the equipment through the SECS communications link. It does not define the internal operation of the equipment. It includes a specific processing state model as the basis for the behavior of all equipment of this class.

2.2 This document requires that the SEMI E30 fundamental requirements and applicable additional capabilities (see Section 13, Additional SEMI E30 Capabilities) have been implemented on the handling equipment. This document expands the SEMI E30 standard requirements and capabilities in the areas of the processing state model, collection event, alarm documentation, remote commands, variable item, and process program management.

3 Limitations

3.1 *Communications* — It is required that any HSEM-compliant equipment follow the Communications State Model in SEMI E30. In addition, HSEM-compliant equipment shall support the High Speed Messaging Service (HSMS) communication standard sending SEMI E5 messages over TCP/IP. The reason behind this requirement is the amount of data available for monitoring from this class of equipment. This specification deals only with the behavior of the handler in communicating with the host. It is recognized that the handler may also have a communications link with other process equipment and that the other equipment may also have a communications link with the host. This specification is intentionally non-specific on the communications link requirements between handler and other process equipment to allow the user the greatest amount of flexibility in specific factory configurations.

3.2 *Multi-Process-Site HSEM Implementations* — This SEM makes some demands and assumptions about the Handler with multiple process-sites in a configuration. These requirements are as follows:

Handling equipment in a multiple process-site configuration (i.e., lead conditioning site, electrical test-site) provides identification and status information (see Variable Item) at both the site level and the subsite level. An example could be a handler with both a lead conditioning site and an electrical test-site, with the electrical test-site containing multiple subsites (i.e., test heads).

4 Referenced Documents

4.1 *SEMI Standards*

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E37 — High-Speed SECS Message Services (HSMS) Generic Services

SEMI E37.1 — High-Speed SECS Message Services Single-Session Mode (HSMS-SS)

SEMI E58 — Automated Reliability, Availability, and Maintainability Standard (ARAMS): Concepts, Behavior, and Services

5 Terminology

5.1 *alignment location* — Location that individual packaged units are placed at the process-site (e.g., electrical test).

5.2 *chaining* — The process of execution over multiple lots or runs with the same Process Program and the same handler operating conditions.

5.3 *electrical test-site* — A process-site on the equipment which is coupled with electrical testing equipment for purposes of performing package electrical testing.

5.4 *execution area* — The area from which a current copy of the process program instructions is executed.

5.5 *handling equipment* — An equipment class generally consisting of integrated mechanisms and controls for the purpose of manipulating packaged devices, trays, and tubes during the manufacturing process.

5.6 *indexing* — The controlled stepped movement of material through the handler.

5.7 *kit* — Specific items of hardware and software as specified by the equipment manufacturer that adapt the equipment for a specific unit or unit package.

5.8 *leadconditioning site* — A process-site on the handler where some form of conditioning occurs on the package leadfingers (i.e., warming).

5.9 *leadfinger (or substrate connector lead)* — (1) In ceramic packages, an area of refractory metal that has been plated and is designated for the attachment to a process-site. (2) The area of the unit designated for attachment to a process-site.

5.10 *leadframe* — A sheet metal framework upon which a chip (sometimes chips) is attached, wire-bonded, and then either molded with plastic epoxy or with ceramic and/or metal.

5.11 *media* — A temporary material carrier used to hold and transport units/devices (tubes, trays, etc.).

5.12 *media map* — Formatted data used to map functionally good and bad units/devices to an X, Y, Z location in the media. Maps can be requested by the handler for use prior to processing and then updated after processing.

5.13 *off-line programming (OLP) utility* — Utility to create, edit, and format process programs on a computer, as opposed to creating process programs at the equipment.

5.14 *process-site* — A location on the equipment where work is performed on a packaged device (i.e, electrical test-site, lead conditioning site).

5.15 *process subsite* — An addressable portion of a process-site.

5.16 *reset* — The action of changing the value of a variable, such as wafer count (usually to zero).

5.17 *safe state* — A state in which the equipment presents no danger to the product or user. This implies that safety interlocks are in place such that the equipment can be serviced without harm to the operator and that the material being processed has been removed from the processing station into an accessible location.

5.18 *slot* — A position in a carrier where a leadframe, tray, tube, or other media element may reside.

5.19 *tray* — A flat rectangular form of media for holding singulated packaged units. Also referred to as waffle packs or matrix trays. A tray is generally molded plastic with a defined matrix of cells or pockets tailored for specific packages.

5.20 *tube* — A hollow form of media for holding packaged units. Also referred to as rails or sticks. A tube is generally composed of extruded polymer with internal section dimensions and features tailored for a specific package.

5.21 *unit* — The functional integrated circuit (or chip) that is being handed to a specific process-site.

6 Requirements

6.1 *State Models* — The purpose is to define the equipment-specific processing state model and other state models necessary to portray the expected operational states of the equipment to enable host tracking and control in place of a local operator.

6.2 *State Model Requirements*

6.2.1 The processing state models in this document are required for implementing an HSEM-compliant handler in addition to the required state models in SEMI E30. A state model consists of the following state model diagram, state definitions, and state transition tables.

6.2.2 A state model represents the host's view of the handler, not necessarily the actual handler's internal operations.

6.2.3 All HSEM state model transitions shall be mapped sequentially into the actual equipment events that satisfy the requirements of those transitions. In certain implementations, the handler may enter a state and have already satisfied all of the conditions required by the HSEM state model for transition to another state. The handler makes the required transition without any additional actions in this situation.

6.2.4 Some equipment may need to include additional states. However, any additional states must not change the HSEM-defined state transitions. All expected transitions between HSEM states must occur.

6.3 *HSEM State Model*

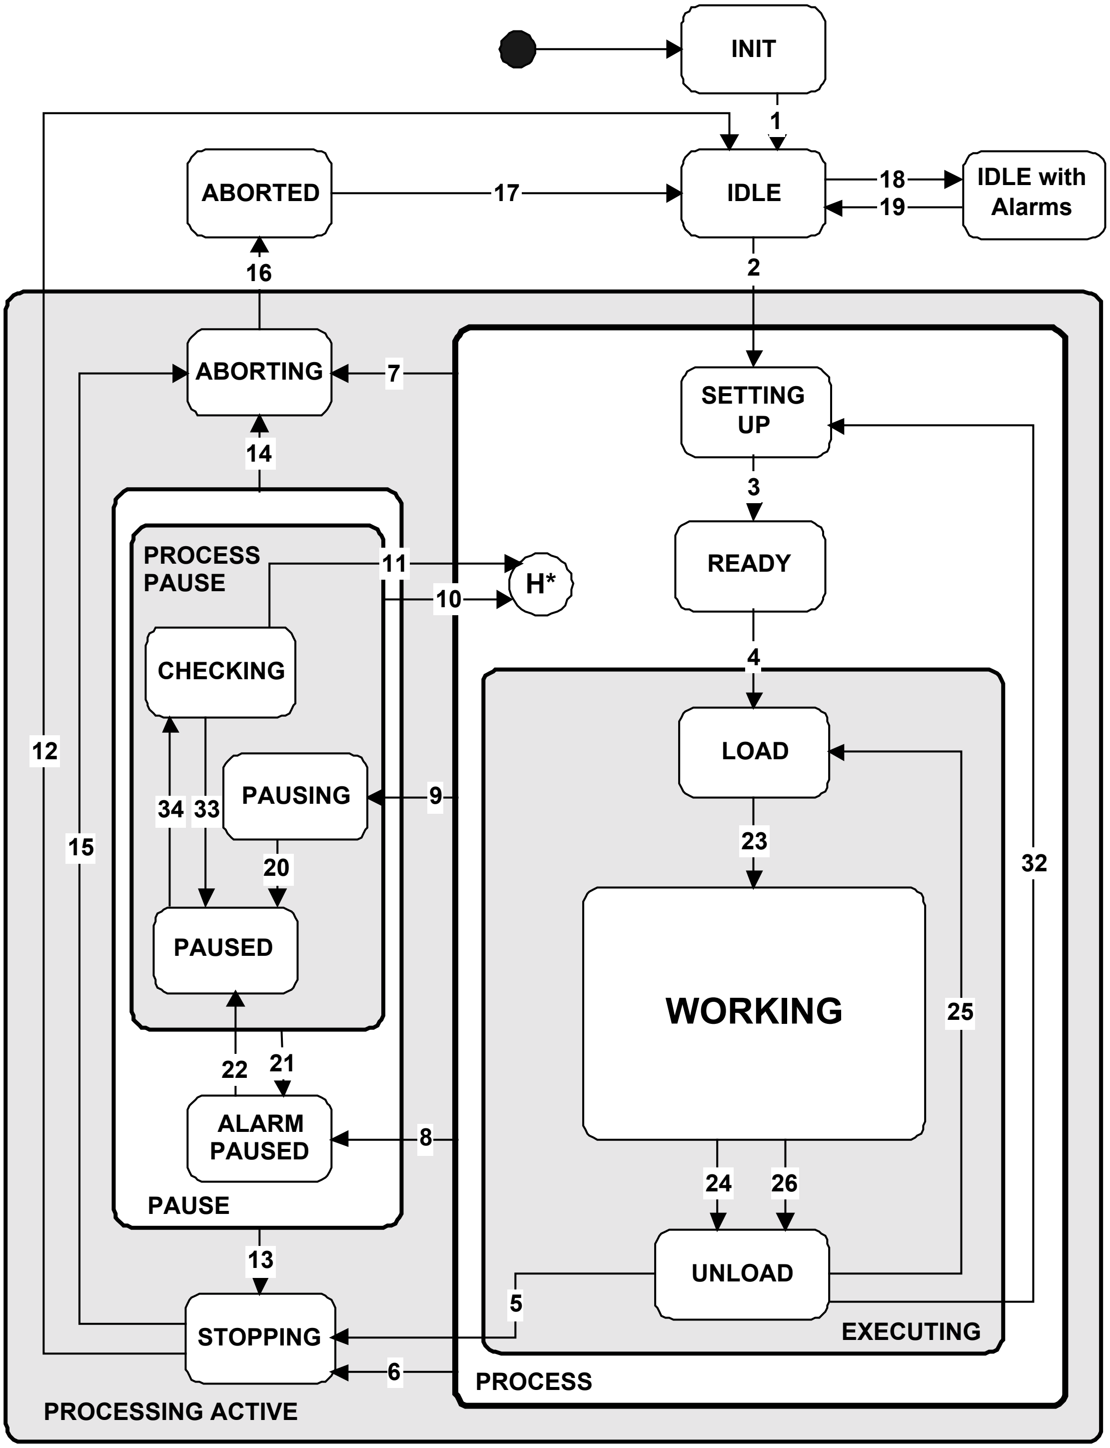

Figure 1
HSEM Processing State Model

6.4 *Description of Handler Processing States*

6.4.1 *ABORTED* — All activity is suspended as a result of an ABORT command. Any alarm and abort conditions must be cleared and verified by an operator before exit from this state.

6.4.2 *ABORTING (PROCESSING ACTIVE Sub-State)* — The handler has received an ABORT command. All activity is suspended. The handler is taking appropriate action to bring itself and material to a "safe" state where possible. Unit or Lot data may be invalid or not available.

6.4.3 *ALARM PAUSED (PAUSE Sub-State)* — An alarm has occurred in the PROCESS or PROCESS PAUSE states, and the handler is waiting for the alarm to be cleared.

6.4.4 *CHECKING (PROCESS PAUSED Sub-State)* — The handler verifies that updates made to the process program are valid (i.e., possible errors induced via an operator during the pause). This is a similar procedure to that which is done in SETTING UP before the handler is ready to transition to the READY state. At the completion of verification, an event is generated when the verification succeeds, and the operator or host must issue a RESUME command to the handler before it will resume processing from the point where it was paused.

6.4.5 *EXECUTING (PROCESS Sub-State*) — The handler is processing material automatically and can continue to do so without external intervention. This state may include interaction with the host or operator.

6.4.6 *IDLE* — Awaiting a command. IDLE is free of ALARMS and error conditions.

6.4.7 *IDLE with ALARMS* — An alarm has occurred in the IDLE state, and the handler is waiting for all alarms to be cleared.

6.4.8 *INIT* — Handler initialization is occurring.

6.4.9 *LOAD (EXECUTING Sub-State)* — This is the state the next unit or units are transferred from the input media to the process-site.

6.4.10 *PAUSE (PROCESSING ACTIVE Sub-State)* — The PROCESS state will be suspended at the completion of the current unit or next opportunity. Actions to put the handler in a safe state are performed. The handler is awaiting a command (RESUME, STOP, or ABORT) or for alarm(s) to be cleared.

6.4.11 *PAUSED (PROCESS PAUSE Sub-State)* — The PROCESS state has been suspended, and the handler is waiting for a command (RESUME, STOP, or ABORT). In this state, the operator may correct error conditions that do not affect the current Process Program selection. One of the possible corrective actions is for the operator to manually align the units being processed.

6.4.12 *PAUSING (PROCESS PAUSE Sub-State)* — The PROCESS state will be suspended at the completion of the current unit or next opportunity. The handler cannot transition to PAUSED state until the current unit is completed and the handler is in a "safe state".

6.4.13 *PROCESSING (WORKING Sub-State)* — Unit is moved to process-site (e.g., for electrical test, to insert into contactor).

6.4.14 *PROCESS COMPLETE (WORKING Sub-State)* — Unit process is complete. Unit is unloaded or returns to alignment for a step and repeat.

6.4.15 *PROCESS (PROCESS Sub-State)* — This state is the parent of those sub-states which refer to the preparation and execution of a process program.

6.4.16 *PROCESS PAUSE (PAUSE Sub-State)* — The handler is free of alarm conditions in the PAUSE state.

6.4.17 *READY (PROCESS Sub-State)* — The handler is ready to begin processing and is awaiting a START command from the operator or host.

6.4.18 *SETTING UP (PROCESS Sub-State)* — The handler is satisfying conditions so that processing can begin. This includes the receipt of any process programs, the material to be processed, and machine-specific calibration. While in this state, the handler can be single-stepped through each process in order for the operator to ensure that the handler is moving the unit correctly.

6.4.19 *STOPPING (PROCESSING ACTIVE Sub-State)* — The handler has completed a Process Program or has been instructed to stop processing and shall do so at the next opportunity. All necessary cleanup is completed within this state with regard to material, data, control system, etc. Data is preserved. Any error condition is cleared before exiting from this state.

6.4.20 *UNLOAD (EXECUTING Sub-State)* — The unit is being removed from the process-site, and the handler determines which transition to take.

6.4.21 *WORKING (EXECUTING Sub-State)* — The handler is processing a specific unit.

6.5 *HSEM Processing State Transitions Table*

Table 1 Processing State Transitions Table

#	*Current State*	*Trigger*	*New State*	*Actions*	*Comments*
1	INIT	All handler initialization is complete with no alarms or error conditions.	IDLE	None	None
2	IDLE	A Process Program is selected.	SETTING UP	Handler-dependent	Commit has been made to setup.
3	SETTING UP	All setup activity has completed, and the handler is ready to receive a START command.	READY	The handler is waiting for a START command.	The selected Process Program is available for execution, and material is present at the input port.
4	READY	The handler receives a START command.	LOAD	Transfers the next unit to the process-site.	LOAD is an EXECUTING sub-state.
5	UNLOAD	The material unloaded completes.	STOPPING	The handler completes the last unit.	None
6	PROCESS	The handler has received a STOP command.	STOPPING	The handler completes the current unit in the WORKING state and unloads it.	The handler begins its cleanup procedure.
7	PROCESS	The handler has received an ABORT command from operator, host, or self-generated.	ABORTING	The handler is put in a “safe” state.	Unit or lot data may be invalid or not available.
8	PROCESS	An alarm occurs.	ALARM PAUSED	PROCESS activity is suspended, and the handler is waiting for all alarms to be cleared.	ALARM PAUSED is a PAUSE sub-state.
9	PROCESS	The handler has received a PAUSE command.	PAUSING	The PROCESS state shall be suspended at the completion of the current unit. Any necessary actions to put the handler in a safe state are performed.	PAUSING is a PAUSE sub-state.
10	PROCESS PAUSE	The handler has received a RESUME command.	Previous PROCESS State	Proceeds from the point where processing was previously suspended.	None
11	CHECKING	Parameter checking completes successfully.	STATE based on conditional table.	Return to previous state.	None
12	STOPPING	The handler cleanup is complete, and the handler is free of alarms.	IDLE	None	None
13	PAUSE	The handler has received a STOP command.	STOPPING	The handler proceeds with cleanup.	Data is preserved and is valid.
14	PAUSE	The handler has received an ABORT command.	ABORTING	Any unsafe condition is resolved, if possible.	Data may be invalid or unavailable.
15	STOPPING	The handler has received an ABORT command.	ABORTING	Any unsafe condition is resolved, if possible.	Data may be invalid or unavailable.
16	ABORTING	Unsafe conditions have been resolved where possible.	ABORTED	The handler is waiting for alarm and ABORT conditions to be cleared.	The only state change allowed is to IDLE.
17	ABORTED	An operator has verified that all alarms and abort conditions have been cleared.	IDLE	None	None
18	IDLE	An alarm is set.	IDLE with ALARMS	The handler waits for all alarms to be cleared.	None

#	*Current State*	*Trigger*	*New State*	*Actions*	*Comments*
19	IDLE with ALARMS	All alarms have been cleared.	IDLE	None	The IDLE state is free of alarms.
20	PAUSING	The handler has completed Processing the Current unit in the WORKING state and achieved a safe condition.	PAUSED	The handler is waiting for a command (RESUME, STOP, or ABORT).	None
21	PROCESS PAUSED	An alarm is set by the handler.	ALARM PAUSED	The handler waits for all alarms to be cleared or for a STOP or ABORT command.	None
22	ALARM PAUSED	All alarms are cleared.	PAUSED	The handler is waiting for a command (RESUME, STOP, or ABORT).	None
23	LOAD	A unit(s) is loading to the process-sites.	WORKING	The unit(s) is being processed.	None
24	WORKING	The processing of the current unit(s) completes normally.	UNLOAD COMPLETED UNIT	This unit(s) is transferred from the process sites.	"Normal" completion of the unit(s).
25	UNLOAD COMPLETED	The material unloaded is complete, and material is available.	LOAD	Transfers the next unit(s) to the processing location.	None
26	WORKING	The processing of the current unit(s) completes abnormally.	UNLOAD COMPLETED	This unit(s) is transferred from the process-site.	"Abnormal" completion of the unit(s).
32	UNLOAD UNIT	The last unit *p* of a lot completes, and a new lot or last carrier is received.	SETTING UP	The handler waits for another SELECT command.	None
33	CHECKING	Error was detected in new parameter setting being validated in the CHECKING state.	PAUSED	None	None
34	PAUSED	A RESUME command was received.	CHECKING	Validation of the Process Program Parameters.	Host or operator is required to issue a RESUME command before processing shall continue.

6.6 *Process Model Conditions Table*

Condition	*Next State*
Checking determines that process program conditions were changed.	SETTING UP
Previous State WORKING.	UNLOAD
Previous State READY.	READY
Previous State was SETTING UP.	SETTING UP

7 Collection Event List

7.1 *Requirements*

7.1.1 ALL SEMI E30-required Events are required by the HSEM. Since a Processing State Model is required by the HSEM, all state transitions are required Events.

7.1.2 All SEMI E30-required Events associated with the GEM Control, Communications, Alarm, and Spooling State Models are required.

7.1.3 This section of the HSEM lists only those collection events that are not associated with a change of state or those requiring specific data variables (DVVALs) or Reports defined in the HSEM.

7.2 *Collection Event Tables* — The first table contains required events and associated reports. The second table contains required events and associated data variables.

Table 3 Processing State Transitions Requiring Report Levels

Transition	*From State*	*To State*	*Required DVVALs or Report*
SETUP COMPLETE (3)	SETTING UP	READY	Setup Report

Table 4 Other Required Collection Events

Collection Event Name	*Required DVVALs*
LotComplete	See Lot Report.
DockStatusChange	DockingStatus
BinDataAvailable	See Bin Data Report.
LotStart	Lot/SubLot Start Report
CarrierEmpty	Media-ID, Lot-ID
CarrierFull	Media-ID, Lot-ID
SubLotComplete	SubLot-Report
ReaderFailed	Reader-Type, Barcode-Error-Type
UnitCntInterval	Unit-Count-Interval, Time-Stamp
MediaCntInterval	Media-Count-Interval
SkipCntInterval	Skip-Count-Interval
MediaChange	Media-ID, Product-ID, Media-Type
SubLotStart	Lot/SubLot Start Report

8 Variable Items

The purpose of this section is to define the list of variable items required by the HSEM. Values of these variables are available to the host through collection event reports and host status queries.

8.1 *Requirements*

8.1.1 All generic variable items defined in SEMI E30 are required by all HSEM equipment.

8.1.2 Variable items required by HSEM are categorized as follows:

- *Common Variables (CVs)* — Variables common to all testers.
- *Configuration-Specific Variables (CSVs)* — Variables associated with a specific configuration of the above equipment class.

8.1.3 Any supplier-defined variables shall be documented in the same format used by this document. The following minimum information is required:

<variable name> **Class:** <ECV, SV, or DVVAL> **Format:** <SML>

Description: <If class = DVVAL, description must contain statement of when data is valid.>

<If format = ASCII, then a length is required. It is assumed to be left-justified unless otherwise noted.>

8.2 *Data Types*

8.2.1 Equipment Constants (ECVs) can be changed by the host using S2,F15. The operator may be able to change some values, but the equipment does not change the values on its own. The value of an equipment constant may be queried by the host at any time, using the S2,F13/14 transaction. They reside in non-volatile memory of the equipment. Equipment constants remain in effect until they are overwritten, either by manual entry or by a NEW EQUIPMENT CONSTANT SEND.

8.2.2 Equipment constants have various uses in HSEM, including the following:

- Equipment offsets that match the performance of several pieces of equipment that would otherwise perform differently due to inherent manufacturing differences. Examples are home values and motion axis scaling factors.
- Setting the configuration of the equipment to allow for different material specifications, equipment options, material flows, frequency of automatic functions, etc. Examples are media and yield check frequency.
- Managing optional machine features. Examples are constants that indicate whether optional features, such as automated media stackers, are present and control the configuration and function of these optional subsystems when they are present.

8.2.3 Status Variables (SVs) are valid at all times. An SV may not be changed by the host but may be changed by the equipment or operator. The value of status variables may be queried by the host at anytime using the S1,F3/4 or S6,F19/20 transactions.

8.2.4 DVVALs are variables that are valid only upon the occurrence of specific collection events. An attempt to read a data variable at the wrong time shall not generate an error, but the data reported may not have relevant meaning.

8.2.5 *Data Item Requirements for Multi-Head, Multi-Site Equipment* — The identification for multi-head and multi-site data (data variable, status variables, events, etc.) is addressed in this specification through the use of status variables with list structures. In the table below, the subheading "Process-Site Group" contains variables which must be available for all process-sites on the handler equipment. When multiple process-sites exist, either a list structure or table structure may be used to show multiple occurrences of a specific variable.

8.3 *Variable Item Table*

Table 5 Variable Item Table

Variable Name	*Category*	*Description*	*Class*	*Format*	*Comments*
		Physical Handler Group			
EquipSerialID	CV	Identification of Equipment	SV	A[1..16]	Valid in all states.
HandlerComStatus	CSV	Status of comm link between handler/s (0 = Disabled, 1 = 1-way enabled, 2 = 2-way enabled, 3 = Not communicating)	SV	U4	Valid in all states.
KitID	CSV	ID of unique tooling unit	SV	A[1..24]	Valid in all states.
LightPoleStatus	CSV	Color/status (i.e., Red/flash)	SV	A[1..16]	Valid in all states.
LinkPortStatus	CSV	(3 = Input/Output linked, 2 = Input linked, 1 = Output linked, 0 = HANDLER not Linked)	SV	U4	Valid in all sub-states.
MediaID	CV	Media Serial Number	SV	A[1..24]	Valid in Executing state.
OperationType	CSV	Current Operation Mode (i.e., maintenance, production)	ECV	A[1..24]	Valid in all states.
OperatorID	CSV	Current Operator ID	ECV	A[1..24]	Valid in all states.
QueueStatus	CV	PPID Queued to be run	SV	U4	Valid in all states.
ReaderErrorType	CSV	Type of error detected by the material reader.	DVVAL	A[1..24]	Supplier-defined.
		Process-Site Components			

Variable Name	Category	Description	Class	Format	Comments
AlignmentCount	CSV	Number of units since last alignment (i.e., Homing/Adjustment).	SV	U4	Valid in all states.
DockingStatus	CSV	Information on handler/docking status (0 = Yes, 1 = No)	SV	U4	Valid in all states.
HardBinID	CV	Process-Site Bin Out Number	DVVAL	U4	Valid at BIN-DATA-AVAILABLE Event.
HardBinName	CV	Process-Site Bin Out Name	DVVAL	A[1..40]	Valid at BIN-DATA-AVAILABLE Event.
InsertionForce	CSV	Insertion-Force energy	DVVAL	F8	Valid in PROCESSING state.
InsertionForceSetpoint	CSV	Insertion-Force set point (setpoint)	ECV	F8	Valid in all states.
LotID	CV	Lot Identification	SV	A[1..40]	Valid in all states.
LotProcessingTime	CV	The time since start of current Lot. HHMMSSCC	DVVAL	A[16]	Valid in Process-Sub-State.
MediaChangeTime	CV	Elapsed time to replace media and send ready.	SV	A[16]	Valid in all states.
MediaCount	CV	Number of media since last reset.	SV	U4	Valid in all states.
MediaCountInterval	CV	Event generated when number of media is completed.	SV	U4	Valid in all states.
PresentPositionActual	CSV	Present position actual.	ECV	U4	Valid in all states.
PresentPositionSetpoint	CSV	Present position set points (setpoint).	ECV	U4	Valid in all states.
ProcessSiteTemp	CSV	Process-site temperature (setpoint).	SV	F8	Celsius - Set point.
ProcessSiteID	CV	ID of process-site in configuration.	SV	U4	Valid in all states.
ProcessSiteStatus	CV	$Site_n$ Availability (1 = enabled, 0 = disabled)	DVVAL	F8	Valid in all states.
ProcessSubsiteID	CV	Subsite matrix location within process-site.	SV	U4	Valid in all states.
ProcessSubsiteStatus	CV	$Subsite_n$ Availability (1 = enabled, 0 = disabled)	DVVAL	F8	Valid in all states.
ProductID	CV	ID of product for which tester is currently configured.	DVVAL	A[1..40]	Valid in PROCESS states.
SkipCount	CSV	Number of units skipped since last reset (Skip + Process = Total)	SV	U4	Valid in all states.
SkipCountInterval	CSV	Event generated when number of units is skipped.	SV	U4	Valid in all states.
StartProcessPortID	CSV	Start process source (i.e., hand, keyboard, host)	SV	U4	Valid in all states.
SubLotID	CV	SubLot Identification	SV	A[1..40]	Valid in all states.
UnitCount	CV	Number of units since last reset.	SV	U4	Valid in all states.
UnitCountInterval	CV	Event generated when number of units is completed.	SV	U4	Valid in all states.
UnitPosition	CSV	X, Y, Z media location of a unit.	SV	U4	Valid in all states.
UnitStatus	CSV	(1 = Processed, 0 = Skipped)	SV	U4	Valid in all states.

8.4 *HSEM Required Reports* — The reports below are required as "canned" or preconfigured reports by HSEM. HSEM does not require the equipment to guarantee the accuracy of data identified in these reports outside the PROCESSING ACTIVE state defined in the HSEM process state model.

8.4.1 *Setup Report* — Table 6 contains variables that are required to be available at the setup complete event.

Table 6 Required Variables at Setup Complete Event

Variable Name	*Notes*
KitID	Configuration Kit
MediaID	Serial # of Media
LotID	
PPExecName	(per SEMI E30)
EquipID	
ProductID	Current
InsertionForceSetPoint	

8.4.2 *Process Report* — Table 7 contains variables that must be available when the equipment is in the PROCESSING state.

Table 7 Required Variables for PROCESSING State

Variable Name	*Notes*
AlignmentCount	
ProcessSiteTemp	
LotProcessTime	
OperatorID	
OperationType	

8.4.3 *Lot/SubLot Report* — Table 8 below contains variables that must be available at the completion of a wafer.

MediaID	
OperatorID	

9 Process Program Management

9.1 *Process Program Requirements*

9.1.1 The HSEM requires that the SEMI E30 capability of process program management be fully supported for this class of equipment. The HSEM also requires that the process program have a structure that enables the user to build process programs with default conditions that can be overridden for a run. The concepts of process program structure and process program variable parameters are discussed in the following sections. The HSEM also requires the following:

- Minimum, maximum, and default parameter values must be defined for all process programs.
- Verification will occur when a process program is downloaded to the equipment; the program syntax must be verified by the equipment manufacturer.
- Parameter validation will occur when a process program is downloaded. Parameters must be type and range checked.
- Equipment should provide the functionality to manually or interactively modify the parameters set in the process program.
- An error message must be generated from the handler if the process program parameters are outside the range of the machine calibration.

9.2 *Process Program Structure*

9.2.1 A handler process program must contain the following information:

- Machine-specific configuration parameters
- Process-Site-specific information section
- Media-Type-specific information section
- Unit (Unit/Package) information section

9.2.2 When combined, this information constitutes a complete process program. It is emphasized that the HSEM does not enforce the exact format and data type of each section. However, it does provide direction as to what each section should consist of.

9.2.3 *Machine-Specific Configuration Parameters* — Each brand or type of handler may have one or more machine-specific configuration parameters. Examples of such parameters would be input configuration, number of process-sites, and output configuration. Even though they are supplier-specific, these parameters nevertheless play a vital role in the overall generation or creation of a process program. Since the machine-specific parameters can differ from one equipment manufacturer to another, the HSEM does not specify the exact number, data types, and format of these parameters. These details are left to the sole discretion of the equipment manufacturer.

9.2.4 *Process-Site-Specific Information* — This process-site-specific section contains information necessary for the configuration and execution of the various process-sites configured on the equipment. Each equipment may contain different process-site configurations. Since these configurations will differ, the HSEM does not specify the exact number, data types, and format of these parameters. HSEM does recommend a minimum list of data items for the common handler process-sites. These include:

9.2.5 *Thermal Conditioning Site Parameters*

- Temperature Set Point
- Upper-Temp Guardband Set Point
- Lower-Temp Guardband Set Point
- Soak Time
- Test-Site Temp

9.2.6 *Test-Site Parameters*

- Device Pick Up/Place
- Speed of Device Pick Up/Place
- Device Insertion/Retraction
- Speed of Device Insertion/Retraction
- Speed of Index Mechanism
- Insertion/Place Force/Stroke

9.2.7 *Lead Condition Site Parameters*

- Device Pick Up/Place
- Speed of Device Pick Up/Place
- Speed of Insertion
- Insertion Force/Stroke

9.2.8 *Sort Sites Parameters*

- Device Pick Up/Place
- Speed of Device Pick Up/Place
- Device Index
- Insertion Force/Stroke
- Sort Category Set
- *Sort Category* – Full/Empty/Partial
- *Sort Media* – In place or empty.

9.2.9 *Unit/Device-Specific Information* — The unit/device-specific section contains information necessary for the configuration and execution of the specific units to be handled by the equipment. HSEM requires a minimum list of data items be available to determine package dimensions, terminal dimensions, package height, and coplanarity.

9.2.10 *Media-Type-Specific Information* — The media-type-specific information section contains information necessary for the configuration and execution of the specific media type in use on the equipment. HSEM requires a minimum list of data items be available to determine row/column count, X/Y distance to a cell, device height in tray, media height, and X/Y pitch.

9.3 *Methods of Process Program Creation* — The method by which an equipment manufacturer creates a process program may be unique to that manufacturer. However, it is required that the customer at least be given both of the following options for the creation of a process program.

9.3.1 *Off-Line Development* — Using this method, the customer is given a set of software tools (process program compilers, decompilers, and debuggers) that enables him/her to generate or create a process program using the above mentioned information (flow, parameter, functional test, etc.). The newly generated process program then is downloaded onto a specific handler, verified, and is now ready to be selected and executed locally by the operator or remotely by the host computer. If this process is used, the supplied software tools should closely mimic or simulate a handler so that a user can create a complete process program. In many situations, minor adjustments may be needed to the process program on the equipment before it is completely ready for execution.

9.3.2 *On-Line Development* — The second option is to enable the user to download the above-mentioned information (tables or files) onto the equipment and create the actual process program on the equipment itself.

10 Remote Commands

The purpose of this section is to identify remote commands, command parameters, and valid commands versus states in the processing state models.

10.1 *Requirements*

- The equipment must support the GEM-required remote commands. (Some of the SEMI E30-required remote commands are restated here to define HSEM-specific requirements.)
- All the remote commands defined by HSEM are required.
- The alphanumeric strings defined by HSEM for remote commands (RMCD) and command parameters (CPNAME) are required.
- If additional remote commands are supported, then the “Remote Command Versus Valid States” matrix must be generated for these additional commands. Place an “X” in the table for each state in which a given command is valid.

10.2 *Remote Command Descriptions*

10.2.1 *ABORT-LOT* — This command terminates the current processing. ABORT makes no guarantee about completion of the current unit. Levels of ABORT may be specified (see Table 10, Remote Command Descriptions, for details).

10.2.2 *PAUSE* — This command transitions the handler to the PAUSING process state when the current unit/media completes processing.

10.2.3 *RESUME* — This command resumes processing from the point where the process was PAUSED. This command is only recognized if the handler is in the PAUSED state.

10.2.4 *PP-SELECT* — This command instructs the handler to copy the indicated Process Program from non-volatile storage to the handler's Process Program execution area. Process Program Variable Parameters can be specified in this command which modify the default values for these Variable Parameters in the Process Program.

10.2.5 *START* — This command is only available to the host or operator when a process program has been selected and the handler is in the READY processing state. The START command instructs the handler to initiate processing.

10.2.6 *STOP* — This command completes the current unit, stops in a safe condition, and returns to the IDLE processing state. STOP has the intent of bringing about a normal termination after completion of the current unit.

10.2.7 *LAST-CARRIER* — This command instructs the handler to treat the current carrier being processed on the handler as the last carrier of the lot. This forces the subsequent carrier to be considered the first carrier of the next lot.

10.2.8 *NEW-LOT* — This command instructs the handler to treat the next carrier to be processed as a new lot. A new LOT-ID and carrier-list must accompany the new lot command. This command forces subsequent carriers to be considered part of the lot, until all carriers in the carrier list have been processed or until a LAST-CARRIER command is received.

10.2.9 *RESET-TOOL-COUNTS* — This command will initialize equipment tool counts. The minimum set are those contained in the Variable Items section.

10.2.10 *PURGE* — Purge flush or clean the equipment of process material.

10.3 *Associated Remote Command Parameters*

Table 10 Remote Command Descriptions

Command	*Parameter*			
Name	*Name*	*Opt./Req.*	*Description*	*Format*
ABORT	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
	"CLEANUP"	OPT	The handler finishes processing the current unit and removes all carriers that belong to the lot and enters the Aborting state.	A[7]
ABORT-CARRIER	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
	"CLEANUP"	OPT	The handler will finish processing the current carrier.	A[7]
NEW-LOT	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
	"LOTID"	REQ	ID of new LOT.	A[1..40]
PAUSE	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
PP-SELECT	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
	"LOTID"	OPT	Lot to be processed with thisprogram.	A[1..40]
	"PPID"	REQ	The ID of the program to be used.	A[80]
	"MEDIALIST"	OPT	One or more media to be processed with this program.	ASCII List
RESET-TOOL-COUNTS	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
	"SVIDLIST"	REQ	List of SVIDs to reset.	ASCII List
RESUME	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
START	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
STOP	"PROCESSSITEID"	OPT	ID of handler process-site.	U4
	"CLOSELOT"	OPT	Automatically close lot.	BOOL
PURGE			Purge handler of all material.	NO PARAMS

10.4 *Remote Commands and HSEM Process Model Mapping* — Table 11 illustrates the relationship between remote commands and states of the HSEM processing state model. An "X" indicates that a command is valid for use in this state. If a remote command is attempted during a non-valid state, the equipment would reject the remote command.

Table 11 Remote Commands vs. Process States

PROCESSING STATE \ COMMAND	STOP	START	RESUME	PP-SELECT	PAUSE	ABORT-MEDIA	ABORT
IDLE				X			
PROCESSING ACTIVE							
PROCESS							
SETTING UP					X		X
READY	X	X			X		X
EXECUTING							
LOAD	X					X	X
WORKING	X				X	X	X
UNLOAD	X					X	X
PROCESS PAUSE							
PAUSING							X
PAUSED	X		X			X	X
CHECKING				X			X
ALARM PAUSED			X				X
ABORTED						X	

Table 12 Remote Commands vs. Process States (cont.)

PROCESSING STATE \ COMMAND	PURGE	NEW-LOT	LAST-CARRIER	RESET-TOOL-COUNTS
IDLE		X		X
PROCESSING ACTIVE				
PROCESS				
SETTING UP			X	
READY	X	X	X	X
EXECUTING

ALARM PAUSED	X			
ABORTED	X			

11 Scenarios

The purpose of this section is to document possible HSEM-specific operational scenarios.

11.1 *Normal Run Scenario*

This is an error-free run of a single lot with a single test-site. All optional SEMI E30 events are turned off by default.

COMMENT	HOST	EQUIPMENT	COMMENT

Idle

Host requests             S6,F15-->
end-of-lot report.

                                    <--S6,F16          Handler sends report.
```

12 Additional GEM Requirements

The purpose of this section is to specify any GEM additional capabilities that are required to be supported by this class of equipment.

12.1 *Requirements* — The following GEM additional capabilities required by HSEM are:

- Establish Communications
- Dynamic Event Report Configuration
- Variable Data Collection
- Status Data Collection
- Alarm Management
- Remote Control
- Equipment Constants
- Process Program Management
- Equipment Terminal Services
- Clock
- Spooling
- Control (Host-Initiated)

mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E30.3-0698
TESTING EQUIPMENT SPECIFIC EQUIPMENT MODEL (TSEM)

CONTENTS

List of Figures

List of Tables

SEMI E30.3-0698
TESTING EQUIPMENT SPECIFIC EQUIPMENT MODEL (TSEM)

1 Purpose

1.1 This document establishes a Specific Equipment Model for testing equipment (TSEM). The TSEM consists of equipment characteristics and behaviors that apply to this class of equipment and are required to be implemented in addition to the fundamental requirements and additional capabilities specified in the Generic Equipment Model (GEM), SEMI E30. The intent of this document is to facilitate the integration of testing equipment into an automated semiconductor factory. This document accomplishes this by defining an operational model for testing equipment as viewed by a factory automation controller. This definition provides a standard host interface and equipment operational behavior.

2 Scope

2.1 The scope of this document is limited to the definition of testing equipment behavior as perceived by a Semiconductor Equipment Communications Standard (SEMI E5) host that complies with SEMI E30. The document defines the view of the equipment through the SECS communications link but does not define the internal operation of the equipment. It includes a specific processing state model as the basis for the behavior of all equipment of this class.

2.2 This document requires that the SEMI E30 fundamental requirements and applicable additional capabilities have been implemented on the test equipment. This document expands SEMI E30 Standard requirements and capabilities in the areas of the processing state model, collection events, alarm documentation, remote commands, variable items, and process program management.

3 Limitations

3.1 *Communications*

3.1.1 It is required that any TSEM-compliant equipment follow the Communications State Model in SEMI E30. In addition, TSEM-compliant equipment shall support the High-Speed Messaging Service (SEMI E37) Communication Standard sending SEMI E5 messages over TCP/IP to maximize the amount of data available for monitoring from this class of equipment. This specification deals only with the behavior of the tester in communicating with the host. It is recognized that the tester may also have a communications link with a test handler or prober and that the handler and/or prober may also have a communications link with the host. This specification is intentionally non-specific on the communications link requirements between handler and tester to allow the user the greatest amount of flexibility in specific factory configurations.

3.2 *Multi-Head and Multi-Site TSEM Implementation*

3.2.1 This SEM makes some demands and assumptions about the tester when it supports multiple test heads containing multiple sites per head. These requirements are as follows:

- Test systems that are capable of operating more than one virtual (or logical) test system at a time provide the virtual tester configuration data via the VirtualConfig variable specified in Section 8.
- The identification for multi-head and multi-site data (data variable, status variables, events, etc.) will be provided via list structures in SEMI E5 messages as detailed in Section 8.
- In the case where equipment supports more than one virtual (or logical) tester, all events and data items must have distinct CEIDs, DVIDs, and SVIDs for each virtual (or logical) tester.

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E37 — High-Speed SECS Message Services (HSMS) Generic Services

SEMI E37.1 — High-Speed SECS Message Services Single-Session Mode (HSMS-SS)

SEMI E58 — Automated Reliability, Availability, and Maintainability Standard (ARAMS): Concepts, Behavior, and Services

5 Terminology

5.1 *alignment location* — Site location that individual packaged units are aligned to at the process-site (e.g., electrical test).

5.2 *calibration fixture* — Any electromechanical fixture required to perform system calibration. May consist of multiple components with different part and serial numbers.

5.3 *class* — Classes represent the most coarse view of the test results. At a minimum, there should be two classes defined for each process program: one representing good devices and another representing failed devices.

5.4 *class, hard-bin, and soft-bin* — Equipment is to maintain DVVALs which provide three levels of granularity for test results: class, hard-bin, and soft-bin. Classes, hard-bins, and soft-bins are expected to be defined within a process program, and their names are made available as DVVALs. When device testing has completed, the process program is to determine the class, hard-bin, and soft-bin with which the device is to be associated, based on the results of the testing. Finally, a summation of the number of devices associated with each class, hard-bin, and soft-bin is also maintained throughout the execution of a process program, and these are also made available as DVVALs.

5.5 *diagnostic fixture* — Any electromechanical fixture required to perform system diagnostics. May consist of multiple components with different parts and serial numbers.

5.6 *execution area* — The area from which a current copy of the process program instructions is executed.

5.7 *hard-bin* — Hard-bins represent the typical view of the test results. Within a process program, each hard-bin is associated with a single class. Generally, multiple hard-bins are associated with a particular class.

5.8 *kit* — Specific items of hardware and software as specified by the equipment manufacturer that adapt the equipment for a specific unit or unit package.

5.9 *leadfinger (or substrate connector lead)* — (1) In ceramic packages, an area of refractory metal that has been plated and is designated for the attachment to a process-site. (2) The area of the unit designated for the attachment to a process-site.

5.10 *leadframe* — A sheet metal framework upon which a chip (sometimes chips) is attached, wire-bonded, then molded with plastic epoxy or with ceramic and/or metal.

5.11 *off-line programming (OLP) utility* — Utility to create, edit, and format process programs on a computer as opposed to creating process programs at the equipment.

5.12 *soft-bin* — Soft-bins represent the most detailed view of the test results. Within a process program, each soft-bin is associated with a single hard-bin. Generally, multiple soft-bins are associated with a particular hard-bin.

5.13 *system calibration* — Test system process required to bring the test system into compliance with the test system manufacturer's system specifications.

5.14 *test executive* — The tester software which controls test program execution.

5.15 *test head* — A resource of the tester. The electromechanical interface between the device/unit and the tester.

5.16 *test-site* — A specific site on a test head.

5.17 *test-board* — The electromechanical interface necessary to enable temporary electrical contact between the device/unit to be tested and the tester resource. May consist of multiple components.

5.18 *testing equipment* — An equipment class generally consisting of integrated mechanisms and controls for performing electrical tests of packaged devices and/or wafer die during the manufacturing process.

5.19 *unit* — The functional integrated circuit (or chip) that is to be electrically tested.

5.20 *virtual (or logical) tester* — That portion or portions of the complete test system that is capable of operating as an independent tester in accordance with the state model shown in this document. For a single test system with one test head and a single test-site on the test head, the physical and virtual (or logical) tester are the same. In a two-headed test system, where each head can execute a unique process program autonomously and there is only one test-site on each head, two virtual (or logical) testers may be operating at the same time. If there are multiple test-sites on multiple heads, each capable of autonomous execution of a unique program, there are as many virtual (or logical) testers in operation as there are autonomous sites. The number of virtual (or logical) testers operating at any time depends on how the test system is currently configured (hardware and software) and may range from one to the maximum capability of the particular test system.

6 Requirements

6.1 *State Models*

6.1.1 The purpose is to define the equipment-specific processing state model and other state models necessary to portray the expected operational states of the equipment to enable host tracking and control in place of a local operator.

6.2 *State Model Requirements*

6.2.1 The processing state models in this document are required for implementing a TSEM-compliant tester, in addition to the required state models in SEMI E30. A state model consists of a processing state model diagram, processing state definitions, and a processing state transitions table. A state model represents the host's view of the tester, but not necessarily the actual tester operations. All TSEM state model transitions shall be mapped sequentially into the actual equipment events that satisfy the requirements of those transitions. In certain implementations, the tester may enter a state and have already satisfied all of the conditions required by the TSEM state model for transition to another state. In this situation, the tester makes the required transition without any additional actions.

6.2.2 Some equipment may need to include additional states. However, any additional states must not change the TSEM-defined state transitions. All expected transitions between TSEM states must occur.

6.3 *TSEM Process State Model*

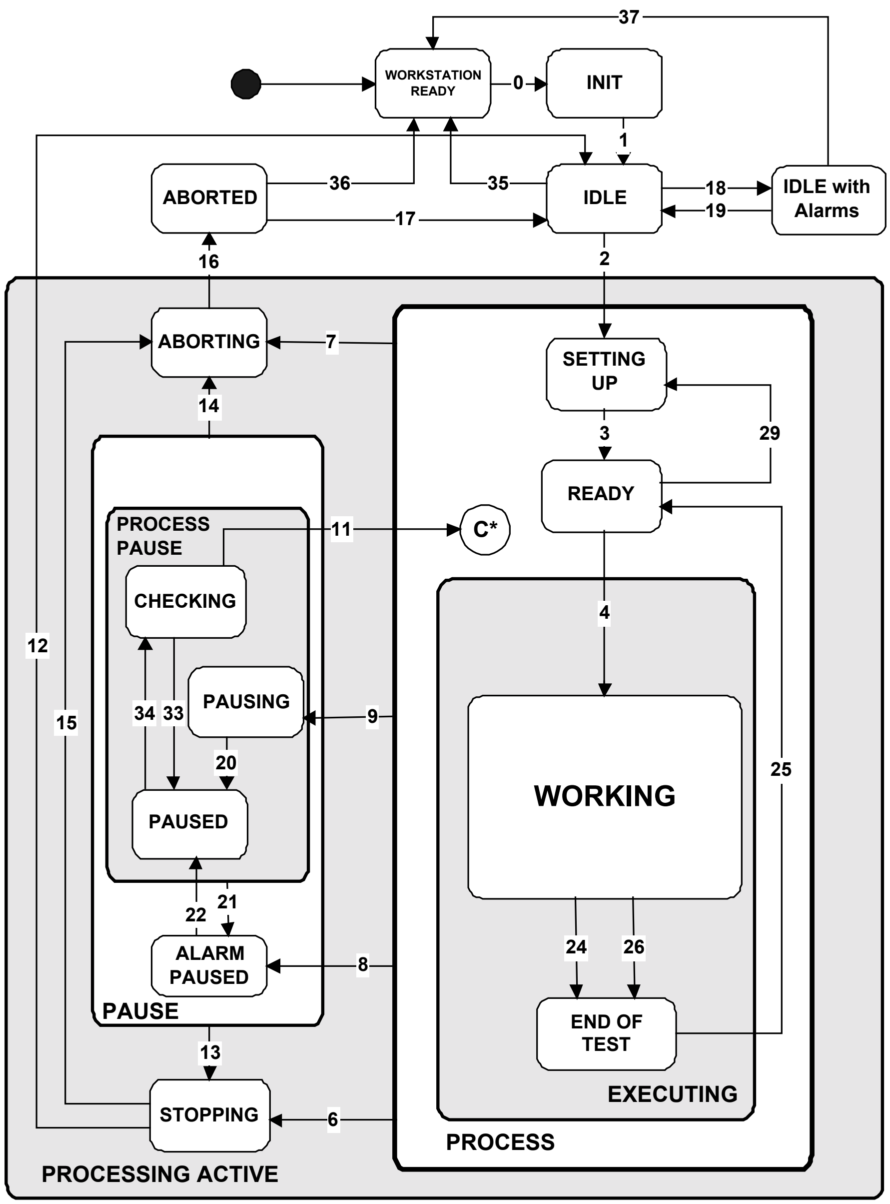

Figure 1
TSEM Processing State Model

6.4 *Description of Tester Processing States*

6.4.1 *ABORTED* — All activity is suspended as a result of an ABORT command. Any alarm and abort conditions must be cleared and verified by an operator before exit from this state.

6.4.2 *ABORTING (PROCESSING ACTIVE Sub-State)* — The tester has received an ABORT command. All activity is suspended. The tester is taking appropriate action to bring itself and material to a “safe” state where possible. Unit or Lot data may be invalid or not available.

6.4.3 *ALARM PAUSED (PAUSE Sub-State)* — An alarm has occurred in the PROCESS or PROCESS PAUSE states, and the tester is waiting for the alarm to be cleared.

6.4.4 *CHECKING (PROCESS PAUSE Sub-State)* — The tester verifies that updates made to the process program are valid. This is a similar procedure to that which is done in SETTING UP. At the successful completion of verification, a transition is made to the process state, based on the process model condition table.

6.4.5 *EXECUTING (PROCESS Sub-State)* — The tester is processing material automatically and can continue to do so without external intervention. This state may include interaction with the host or operator.

6.4.6 *IDLE* — Awaiting a command. IDLE is free of ALARMS and error conditions. A program may or may not be loaded in the execution space during this state.

6.4.7 *IDLE with ALARMS* — An alarm has occurred in the IDLE state, and the tester is waiting for all alarms to be cleared.

6.4.8 *INIT* — Tester initialization is occurring.

6.4.9 *PAUSED (PROCESS PAUSE Sub-State)* — The PROCESS state has been suspended, and the tester is waiting for a command (RESUME, STOP, or ABORT). In this state, the operator may correct error conditions and modify some conditions of the current Process Program selection.

6.4.10 *PAUSING (PROCESS PAUSE Sub-State)* — The current state will be suspended at the completion of the current unit(s), if any, and the tester will be brought to a “safe state.”

6.4.11 *PROCESS (PROCESS Sub-State)* — This state is the parent of those sub-states that refer to the preparation and execution of a process program.

6.4.12 *PROCESS PAUSE (PAUSE Sub-State)* — The tester is free of alarm conditions in the PAUSE state.

6.4.13 *READY (PROCESS Sub-State)* — The tester is ready to begin processing and is awaiting a START command.

6.4.14 *SETTING UP (PROCESS Sub-State)* — The tester is satisfying conditions so that processing can begin. This includes the initialization of any process programs and process program-specific calibration. This may be accomplished independently by the tester or may require interaction with the operator and/or host.

6.4.15 *STOPPING (PROCESSING ACTIVE Sub-State)* — The tester has completed a Process Program or has been instructed to stop processing and shall do so at the next opportunity. All necessary cleanup is completed within this state with regard to material, data, control system, etc. Data is preserved. Any error condition is cleared before exiting from this state.

6.4.16 *END OF TEST (PROCESS Sub-State)* — The UNITS testing is complete.

6.4.17 *WORKING (EXECUTING Sub-State)* — The tester is processing a specific unit or units.

6.4.18 *WORKSTATION READY* — The tester workstation is running and ready for tester initialization. The START EXEC remote command is valid in this state.

6.5 *TSEM Processing State Transitions Table*

Table 1 Processing State Transitions Table

#	*Current State*	*Trigger*	*New State*	*Actions*	*Comments*
0	WORK-STATION-READY	Power on	INIT	None	None
1	INIT	All tester initialization is complete with no alarms or error conditions.	IDLE	None	None
2	IDLE	A Process Program is selected.	SETTING UP	Tester-dependent	Commit has been made to setup.
3	SETTING UP	All setup activity has completed, and the tester is ready to receive a START command.	READY	None	The selected Process Program is available for execution.
4	READY	The tester, operator, or host executes a START command, and auto-start is enabled.	WORKING	Begins testing the unit(s) at the test-site(s).	WORKING is an EXECUTING sub-state.
6	PROCESS	The tester has received a STOP command.	STOPPING	The tester completes the current unit(s) before entering the STOPPING state.	The tester begins its cleanup procedure.
7	PROCESS	The tester has received an ABORT command from operator, host, or self-generated.	ABORTING	The tester is put in a “safe” state.	Unit or lot data may be invalid or not available.
8	PROCESS	An alarm occurs.	ALARM PAUSED	PROCESS activity is suspended, and the tester is waiting for all alarms to be cleared.	ALARM PAUSED is a PAUSE sub-state.
9	PROCESS	The tester has received a PAUSE command.	PAUSING	The current state is suspended at the completion of the current unit(s). Any necessary actions to put the tester in a “safe” state will be performed.	PAUSING is a PROCESS PAUSE sub-state.
11	CHECKING	Parameter checking completes successfully.	STATE based on conditional table.	None	This is a conditional re-entry to the PROCESS state. (See Table 2.)
12	STOPPING	The tester cleanup is complete, and the tester is free of alarms.	IDLE	None	Data is preserved and is valid.
13	PAUSE	The tester has received a STOP command.	STOPPING	The tester proceeds with cleanup.	Data is preserved and is valid.
14	PAUSE	The tester has received an ABORT command.	ABORTING	Any unsafe condition is resolved, if possible.	Data may be invalid or unavailable.
15	STOPPING	The tester has received an ABORT command.	ABORTING	Any unsafe condition is resolved, if possible.	Data may be invalid or unavailable.
16	ABORTING	Unsafe conditions have been resolved, where possible.	ABORTED	The tester is waiting for alarm and ABORT conditions to be cleared.	The only state change allowed is to IDLE. Data is preserved and is valid.
17	ABORTED	An operator has verified that all alarms and abort conditions have been cleared.	IDLE	None	The IDLE state is a “clean” state.
18	IDLE	An alarm is set.	IDLE with ALARMS	The tester waits for all alarms to be cleared.	None

#	*Current State*	*Trigger*	*New State*	*Actions*	*Comments*
19	IDLE with ALARMS	All alarms have been cleared.	IDLE	None	The IDLE state is free of alarms.
20	PAUSING	The tester has completed Processing the Current unit(s) and achieved a “safe” condition.	PAUSED	The tester is waiting for a command (RESUME, STOP, or ABORT).	None
21	PROCESS PAUSE	An alarm is set.	ALARM PAUSED	The tester waits for all alarms to be cleared or for a STOP or ABORT command.	None
22	ALARM PAUSED	All alarms are cleared.	PAUSED	The tester is waiting for a command (RESUME, STOP, or ABORT).	None
24	WORKING	The processing of the current unit(s) has completed normally.	END OF TEST	The tester processes end of test data.	“Normal” completion of the test program execution.
25	END OF TEST	Tester is ready to receive a new start of test command.	READY	Waiting for start of next test.	
26	WORKING	The processing of the current unit(s) has completed abnormally.	END OF TEST	The tester processes end of test data.	“Abnormal” completion of the test program execution, etc.
29	READY	New Lot is received by tester.	SETTING UP	The tester performs setup based on the new command.	None
33	CHECKING	Error detected in a new parameter setting.	PAUSED	The tester waits for the parameter correction by operator or host.	None
34	PAUSED	A RESUME command with variable parameters was received.	CHECKING	Validation of the process program parameters begins.	None
35	IDLE	The tester executive has been stopped by the operator.	WORKSTATION READY	Waiting for a START EXECUTIVE command.	None
36	ABORTED	The tester executive has been aborted by the operator.	WORKSTATION READY	Waiting for a START EXECUTIVE command.	None
37	IDLE with ALARMS	The tester executive has been stopped by the operator.	WORKSTATION READY	Waiting for an ALARM Clear and START EXECUTIVE command.	None

7 Collection Event List

7.1 *Requirements*

7.1.1 ALL SEMI E30-required Events are required by the TSEM. Since a Processing State Model is required by the TSEM, all state transitions are required Events.

7.1.2 All SEMI E30-required events associated with the SEMI E30 Control, Communications, Alarm, and Spooling State Models are required.

7.1.3 This section of the TSEM lists only those collection events that are not associated with a change of state or those requiring specific data variables (DVVALs) or Reports defined in the TSEM.

7.2 *Collection Event Tables* — The first table contains required events and associated reports. The second table contains required events and associated data variables.

Table 3 Processing State Transitions Requiring Report Levels

Transition	*From State*	*To State*	*Required DVVALs or Report*
SETUP COMPLETE (3)	SETTING UP	READY	Setup Report

Table 4 Other Required Collection Events

Collection Event Name	*Required DVVALs*
LotComplete	See Lot Report.
BoardChg	TestBoardID, CalFixtureID, or DiagFixture ID (Valid in CHECKING and SETTING UP.)
DockStatusChange	DockingStatus
BinDataAvailable	See Bin-Data Report.
SubLotComplete	See SubLot Report.
LotStart	Lot/SubLot Start Report
SubLotStart	Lot/SubLot Start Report

8 Variable Items

The purpose of this section is to define the list of variable items required by the TSEM. Values of these variables will be available to the host through collection event reports and host status queries.

8.1 *Requirements*

8.1.1 All generic variable items defined in SEMI E30 are required by all TSEM equipment.

8.1.2 Variable items required by TSEM are categorized as follows:

- *Common Variables (CVs)* — Variables common to all testers.
- *Configuration-Specific Variables (CSVs)* — Variables associated with a specific configuration of the above equipment class.

8.1.3 Any supplier-defined variables shall be documented in the same format used by this document. The following minimum information is required:

<variable name> **Class:** <ECV, SV, or DVVAL> **Format:** <SML>

Description: <If class = DVVAL, description must contain statement of when data is valid.>

<If format = ASCII, then a length is required. It is assumed to be left-justified unless otherwise noted.>

8.2 *Data Types*

8.2.1 Equipment Constants (ECVs) can be changed by the host using S2,F15. The operator may be able to change some values, but the equipment does not change the values on its own. The value of an equipment constant may be queried by the host at any time, using the S2,F13/14 transaction. They reside in non-volatile memory of the equipment. Equipment constants remain in effect until they are overwritten either by manual entry or by a S2,F15 (NEW EQUIPMENT CONSTANT SEND).

8.2.2 Equipment constants have various uses in TSEM, including the following:

- Equipment offsets that match the performance of several pieces of equipment that would otherwise perform differently due to inherent manufacturing differences. Examples are home values and motion axis scaling factors.
- Setting the configuration of the equipment to allow for different material specifications, equipment options, material flows, frequency of automatic functions, etc. An example is yield check frequency.
- Managing optional machine features. Examples are constants that indicate whether optional features such as automated media stackers are present and control the configuration and function of these optional subsystems when they are present.

8.2.3 Status Variables (SVs) are valid at all times. An SV may not be changed by the host but may be changed by the equipment or operator. The value of status variables may be queried by the host at anytime using the S1,F3/4 or S6,F19/20 transactions.

8.2.4 DVVALs are variables that are valid only upon the occurrence of specific collection events. An attempt to read a variable item at the wrong time does not generate an error, but the data reported may not have relevant meaning.

8.2.5 *Data Item Requirements for Multi-Head, Multi-Site Equipment* — The identification for multi-head and multi-site data (variable items, status variables, events, etc.) is addressed in this specification through the use of status variables. In Table 5, the subscript “v” is used to denote the number of virtual testers, “h” is used to denote the number of tester heads, “s” to denote the number of tester head sites, and “b” to denote the number of bins or classes.

8.3 *Variable Item Table*

Table 5 Variable Item Table

Variable Name	*Category*	*Description*	*Class*	*Format*	*Comments*
		Physical Tester Group			
BaseConfig	CV	Base Tester Configuration listing all physical heads and sites.	SV	L, h TestHeadID L, s TestBoardSiteID	Valid in all states. Contains number of possible heads and sites for the tester.
ConfigInfo	CSV	Configuration Information	SV	A[256]	Valid in all states.
ConfigInfoType	CSV	Configuration information source (0 = Auto, 1 = Manual/File)	SV	U4	Valid in all states.
DatalogConfig	CV	Data Log Configuration	SV	A[256]	Valid in all states.
EquipSerialID	CV	Identification of Equipment	SV	A[1..40]	Valid in all states.
HandlerComStatus	CV	Status of comm link between handler/s (0 = Disabled, 1 = 1-way enabled, 2 = 2-way enabled, 3 = Not communicating)	SV	U4	Valid in all states.
LightPoleStatus	CSV	Color/status (i.e., Red/flash)	SV	A[1..16]	Valid in all states.
VirtualConfig	CSV	Current Virtual Configuration listing all virtual IDs.	DVVAL	L, v ...VirtualID L, h TestHeadID L, s TestBoardSiteID	Valid in PROCESS states. Contains active heads and sites for tester. List by virtual tester, head, and site.
		Virtual Tester Group			
CalDate	CV	Date of last successful calibration.	SV	A[16]	Valid in all states. List by head.
CalInterval	CS	Time limit between calibrations.	SV	A[16]	Valid in all states. List by head.

Variable Name	*Category*	*Description*	*Class*	*Format*	*Comments*
CalStatus	CV	Status of last calibration (1 = OK, 0 = Failure)	SV	U4	Valid in all states. List by head.
ClassName	CV	Name tag for high-level class information.	DVVAL	A[1..40]	Valid at BIN-DATA-AVAILABLE state. List by bin.
DiagStatus	CV	Status of last diagnostic (1 = OK, 0 = Failure)	SV	U4	Valid in all states. List by head.
HardBinName	CV	Test-Site Bin Out Name	DVVAL	A[1..40]	Valid at BIN-DATA-AVAILABLE Event. List by bin.
LotProcessingTime	CV	The time since start of current Lot.	DVVAL	A[16]	Valid in Process-sub-state.
OperatorID	CV	Current Operator ID	ECV	A[1..40]	Valid in all states.
ProductID	CV	ID of product for which tester is currently configured.	DVVAL	A[1..40]	Valid in PROCESS states.
SoftBinName	CV	Test-Site Category Name	DVVAL	A[1..40]	Valid at BIN-DATA-AVAILABLE Event. List by bin.
TestSiteInterval	CV	Interval count to generate event for a specific site $_{(n)}$ test.	ECV	U4	Valid in all states.
VirtualID	CV	ID of each virtual configuration.	SV	U4	
		Test Head Group			
CalFixtureID	CV	ID of calibration fixture in current configuration.	SV	A[1..40]	Valid in all states. List by head.
DiagDate	CV	Date of last diagnostic execution.	SV	A[16]	Valid in all states. List by head.
DiagFixtureID	CV	ID of diagnostic fixture in current configuration.	SV	A[1..40]	Valid in all states. List by head.
DiagFixtureList	CV	List of current diagnostic, calibration, and test boards in current configuration.	SV	L, h DiagFixtureID, CalFixtureID, TestBoardIDList	Valid in all states. List by head.
DockingStatus	CSV	Information on handler/docking status (0 = Yes, 1 = No)	SV	U4	Valid in all states. List by head.
HeadConfig	CV	Number of sites currently configured per head.	SV	U4	Valid in PROCESS states. List by head.
LotID	CV	Lot Identification	DVVAL	A[1..40]	Valid in all states.
StartTestPortID	CSV	Start Test Source (i.e., hand, keyboard, host)	SV	A[1..40]	Valid in all states. List by head.
SubLotID	CV	SubLot Identification	DVVAL	A[1..40]	Valid in all states.
TestBoardID	CV	ID of current test board.	SV	A[1..30]	Valid in all states. List by head.
TestBoardIDList	CV	List of IDs in current test board configuration.	SV	A[1..32]	Valid in READY state. List by head.
TestHeadID	CV	The ID of a test head.	SV	U4	Valid in READY state. List by head.
TestHeadStatus	CV	(2 = Not Available, 1 = enabled, 0 = disabled)	SV	U4	Valid in IDLE state. List by head.
		Test-Site Group			
ClassCnt	CV	Current count for a particular class.	DVVAL	U4	Valid in PROCESS states. List by head, bin, and site.
ClassID	CV	High-level class ID	DVVAL	U4	Valid in PROCESS states. List by head, bin, and site.
DeviceUnitID	CV	Unit Serial Number	DVVAL	U4	Valid in all states. List by head and site.

Variable Name	*Category*	*Description*	*Class*	*Format*	*Comments*
ExecutionCnt	CV	Number of test executives since last reset for the current PPID and current LOT at this test-site.	DVVAL	U4	Valid at END OF TEST sub-state. List by head and site.
HardBinCnt	CV	Test-Site Bin Out Count	DVVAL	U4	Valid in PROCESS states. List by head, bin, and site.
HardBinID	CV	Test-Site Bin Out Number	DVVAL	U4	Valid in PROCESS states. List by head, bin, and site.
LotUnitOutput	CSV	Bin output for a specific site by lot.	DVVAL	U4	Valid in PROCESS states. List by head and site.
SoftBinCnt	CV	Test-Site Category Count	DVVAL	U4	Valid in PROCESS states. List by head, bin, and site.
SoftBinID	CV	Test-Site Category Number	DVVAL	U4	Valid in PROCESS states. List by head, bin, and site.
SiteContacts	CSV	Number of contacts for a specific site.	DVVAL	U4	Valid in PROCESS states. List by head and site.
SubLotUnitOutput	CV	Bin output for a specific site by SubLot.	DVVAL	U4	Valid in PROCESS states.
TestBoardSiteContacts	CSV	Number of contacts for a specific site since last reset.	DVVAL	U4	Valid in PROCESS states. List by head and site.
TestBoardSiteID	CV	X, Y location within test board or probe card. (First element is the X coordinate, and second element is the Y coordinate.)	SV	U4(x)	Valid in all states. List by head and site.
TestBoardSiteInserts	CSV	Insertion-count on a test board site.	DVVAL	U4	Valid in PROCESSING state. List by head and site.
TestBoardSiteStatus	CV	Test Board Availability (1 = enabled, 0 = disabled)	DVVAL	U4	Valid in PROCESS states. List by head and site.
TestBoardStatus	CV	Test Board Availability (1 = enabled, 0 = disabled)	DVVAL	U4	Valid in PROCESS states. List by head and site.

8.4 *TSEM-Required Reports* — The reports below are required as “canned” or preconfigured reports by TSEM. TSEM does not require the equipment to guarantee the accuracy of data identified in these reports outside the PROCESSING ACTIVE state defined in the TSEM process state model.

8.4.1 *Setup Report* — Table 6 contains variables that are required to be available at the setup complete event.

Table 6 Setup Variables

Variable Name	*Notes*
DiagFixtureList	
LotID	
PPExecName	(per SEMI E30)
ProductID	Current
OperatorID	
TestBoardSiteStatus	
TestHeadID	
HandlerComStatus	
DockingStatus	

8.4.2 *Lot Complete Report* — Table 7 contains variables that must be available and reported at the completion of a lot.

Table 7 Lot Complete Variables

Variable Name	*Notes*
LotID	
PPExecName	(per SEMI E30)
DiagFixtureList	
SoftBinCnt	
HardBinCnt	
ClassCnt	
TestHeadID	
ContactCnt	
ExecutionCnt	
ProductID	
LotUnitOutput	
LotContacts	
LotProcessingTime	
OperatorID	

8.4.3 *SubLot Complete Report* — Table 8 below contains variables that must be available and reported at the completion of a SubLot.

Table 8 SubLot Complete Variables

Variable Name	*Notes*
SubLotID	
LotID	
PPExecName	(per SEMI E30)
DiagFixtureList	
SoftBinCnt	
HardBinCnt	
ClassCnt	
TestHeadID	
SubLotContacts	
SubLotUnitOutput	
ExecutionCnt	
ProductID	
OperatorID	

8.4.4 *Bin-Data-Report* — Table 9 contains variables that must be available once bin data is available.

Table 9 Bin-Data Variables

Variable Name	*Notes*
UnitID	
TestBoardSiteID	
HardBinID	
SoftBinID	
ClassID	

8.4.5 *Process Report* — Table 10 contains variables that must be available when the equipment is in the PROCESSING state.

Table 10 Process Variables

Variable Name	*Notes*
OperatorID	
LotID	
SubLotID	
PPExecName	(per SEMI E30)
OperationType	
DockingStatus	
HandlerCommStatus	
TestBoardSiteStatus	
LotProcessingTime	

8.4.6 *Lot/SubLot Report* — Table 11 contains variables that must be available at the completion of the lot or SubLot events.

Table 11 Lot/SubLot Start Variables

Variable Name	*Notes*
OperatorID	
LotID	
SubLotID	
PPExecName	(per SEMI E30)
DiagFixtureList	
TestHeadID	

Calibration Report — Table 12 below contains variables that must be available at the completion of a calibration.

Table 12 Calibration Variables

Variable Name	*Notes*
CalibrationInt	
PPExecName	(per SEMI E30)
OperatorID	
CalStatus	
TestHeadID	
CalFixtureID	

8.4.7 *Diagnostic Report* — Table 13 below contains variables that must be available at the completion of a diagnostic.

PPExecName	(per SEMI E30)
DiagFixtureList	
TestHeadID	
DiagStatus	

9 Process Program Management

9.1 *Process Program Requirements*

9.1.1 The TSEM requires that the GEM capability of process program management be fully supported for this class of equipment. The TSEM also requires that the process program have a structure that enables the user to build process programs with default conditions that can be overridden for a run. The concepts of process program structure are discussed in the following sections. The TSEM also requires the following:

- Minimum, maximum, and default parameter values must be defined for all process programs.
- *Verification* — When a process program is downloaded to the equipment, the program syntax must be verified by the equipment manufacturer. The process program may be rejected or may fail verification if the equipment is not in an allowable state to accept process program downloads (i.e., IDLE or SETUP).
- *Validation* — The downloaded process parameters must by type- and range-checked before execution.
- PPBODY — The contents of the downloaded process program body may contain the explicit parameters and data necessary for the runtime process program, or the body may contain reference information (i.e., PATH location) on where the explicit data is stored. In the latter case, it is required that the equipment combine or compile the reference data prior to the verification step.
- An error message must be generated from the tester if the process program parameters are outside the range of the machine capability.
- Diagnostic and calibration routines are considered process programs and must be verified and validated the same as a typical process program.

9.2 *Process Program Structure*

9.2.1 A tester process program must contain the following information:

- *Flow Information* — This provides information such as execution order of individual tests.
- *Parametric Information* — This section provides information such as AC/DC/IDC levels and timing.
- *Parameter Options/Values* — This section provides information such as test temperature, part frequency, etc.
- *Data Log Information* — This section provides information such as scope of data collection.
- *Functional Test Information* — This section provides information about vector and patterns.

9.2.2 This information must be supplied in a format that can be referenced as a complete process program. It is emphasized that the TSEM does not specify the exact number, data types, and format of this process program.

9.3 *Methods of Process Program Creation* — The method by which an equipment manufacturer creates a process program may be unique to that manufacturer. However, it is required that the customer at least be given both of the following options for the creation of a process program.

9.3.1 *Off-Line Development* — Using this method, the customer is given a set of software tools (process program compilers, decompilers, and debuggers) that will enable him/her to generate or create a process program using the above mentioned information (flow, parameter, functional test, etc.). The newly generated process program then is downloaded onto a specific tester, is verified, and is now ready to be selected and executed locally by the operator or remotely by the host computer. If this process is used, the supplied software tools should closely mimic or simulate a tester so that a user can create a complete process program. In many situations, minor adjustments or tweaks may be needed to the process program on the equipment before it is completely ready for execution.

9.3.2 *On-Line Development* — The second option made is to enable the user to download the above-mentioned information (tables or files) onto the equipment and create the actual process program on the equipment itself.

10 Remote Commands

The purpose of this section is to identify remote commands, command parameters, and valid commands versus states in the processing state models.

10.1 *Requirements*

- The equipment must support the GEM-required remote commands. (Some of the SEMI E30-required remote commands are restated here to define TSEM-specific requirements.)
- All the remote commands defined by TSEM are required.
- The alphanumeric strings defined by TSEM for remote commands (RMCD) and command parameters (CPNAME) are required.
- If additional remote commands are supported, then the “Remote Command vs. Valid States” matrix must be generated for these additional commands.

Place an "X" in the table for each state in which a given command is valid.

10.2 *Remote Command Descriptions*

10.2.1 *ABORT* — This command terminates the current processing. ABORT makes no guarantee about completion of the current test(s). Lot level data will be preserved. Levels of ABORT may be specified (see Table 14 for details).

10.2.2 *PAUSE* — This command transitions the tester to the PAUSING process state when the current test(s) completes processing.

10.2.3 *RESUME* — This command resumes processing from the point where the process was PAUSED. This command is only recognized if the tester is in the PAUSED or CHECKING state.

10.2.4 *PP-SELECT* — This command instructs the tester to copy the indicated Process Program from non-volatile storage to the tester's Process Program execution area. Process Program Variable Parameters can be specified in this command which modify the default values for these Variable Parameters in the Process Program. Process program verification (CHECKING state) must occur when variable parameters accompany this command.

10.2.5 *START* — This command is only available to the host or operator when a process program has been selected and the tester is in the READY processing state. The START command instructs the tester to initiate processing. Parameters can be specified in this command.

10.2.6 *STOP* — This command completes the current test(s), stops in a safe condition, and returns to the IDLE processing state. STOP has the intent of bringing about a normal termination after completion of the current test(s). Parameters can be specified in this command. Lot level data will be preserved.

10.2.7 *UNLOAD-PGM* — This command instructs the tester to unload the specified process program, or programs in the case of multiple heads, from the execution area. Parameters can be specified in this command.

10.2.8 *NEW-LOT* — This command instructs the tester to treat the next units to be processed as a new lot. A new-lot ID and process program variables must accompany the new lot command. This command will force subsequent units to be considered part of the lot. Parameters can be specified in this command.

10.2.9 *CLOSE-LOT* — This command instructs the tester to close the current lot. The next lot will require the setup procedure to be performed.

10.2.10 *CALIBRATE* — This command instructs the tester to execute its calibration program. Parameters can be specified in this command.

10.2.11 *START-EXEC* — This command instructs the tester to start the tester executive.

10.2.12 *STOP-EXEC* — This command instructs the tester to stop the tester executive. Lot level data will be preserved.

10.2.13 *RUN-DIAGNOSTICS* — This command instructs the tester to run the specified preventive maintenance diagnostic routine. Parameters can be specified in this command.

10.2.14 *RUN-CONTINUITY* — This command instructs the tester to run the specified continuity routine. Valid in PAUSE state only. Parameters can be specified in this command.

10.2.15 *ENABLE-SITE* — This command instructs the tester to enable a specified test board site(s). Parameters can be specified in this command.

10.2.16 *DISABLE-SITE* — This command instructs the tester to disable a specified test head site. Parameters can be specified in this command.

10.2.17 *RESET-SITE-CNT* — This command instructs the tester to reset the counts on the specified board test board site(s) to zero.

10.3 *Associated Remote Command Parameters*

Table 14 Remote Command Descriptions

Command	*Parameter*			
Name	*Name*	*Opt./Req.*	*Description*	*Format*
ABORT	“VIRTUALID”	OPT	ID of virtual tester to abort.	U4
	“LOTCLOSE”	OPT	The tester will close out the current lot and enter the ABORTING state.	A[7]
CALIBRATE	“PPID”	OPT	The ID of the program to be used.	A[80]
CLOSE-LOT	“VIRTUALID”	OPT	ID of virtual tester.	U4
DISABLE-SITE	“TESTHEADID”	REQ	ID of test head containing the site.	U4
	“TESTSITEID”	REQ	ID of test-site to be disabled.	U4
	“VIRTUALID”	OPT	ID of virtual tester.	U4
ENABLE-SITE	“VIRTUALID”	OPT	ID of virtual tester.	U4
	“TESTHEADID”	REQ	ID of test head containing the site.	U4
	“TESTSITEID”	REQ	ID of test-site to be enabled.	U4
NEW-LOT	“VIRTUALID”	OPT	ID of virtual tester.	U4
	“LOTID”	REQ	ID of New LOT.	A[1..40]
PAUSE	“VIRTUALID”	OPT	ID of virtual tester.	U4
PP-SELECT	“VIRTUALID”	OPT	ID of virtual tester.	U4
	“LOTID”	OPT	Lot to be processed with this program.	A[1..40]
RESET-SITE-CNT	“VIRTUALID”	OPT	ID of virtual tester.	U4
	“TESTHEADID”	REQ	ID of test head containing the site.	U4
	“TESTSITEID”	REQ	ID of test-site to be reset.	U4
RESUME	“VIRTUALID”	REQ	ID of virtual tester.	U4
RUN-CONTINUITY	“PPID”	OPT	The ID of the program to be used.	A[80]
RUN-DIAGNOSTICS	“PPID”	OPT	The ID of the program to be used.	A[80]
START	None			
START-EXEC	None			
STOP	“VIRTUALID”	REQ	ID of virtual tester.	U4
	“CLOSELOT	OPT	Automatically close lot.	BOOL
STOP-EXEC	“VIRTUALID”	REQ	ID of virtual tester.	U4
UNLOAD-PGM	“VIRTUALID”	OPT	ID of virtual tester to unload.	U4
	“PPID”	REQ	ID of program to unload.	A[80]
	“ALL”	OPT	Will unload all test programs.	BOOL

10.4 *Remote Commands and TSEM Process Model Mapping* — Table 15 illustrates the relationship between remote commands and states of the TSEM processing state model. An "X" indicates that a command is valid for use in this state. If a remote command is attempted during a non-valid state, the equipment would reject the remote command.

Table 15 Remote Commands vs. Process States

PROCESSING STATE \ COMMAND	STOP	START	RESUME	UNLOAD-PGM	PP-SELECT	PAUSE	NEW-LOT	STOP-EXEC	START-EXEC	ABORT
INIT									X	
IDLE				X	X			X		
IDLE with Alarms								X		
PROCESSING ACTIVE										
PROCESS										
SETTING UP	X					X	X			X
READY	X	X				X	X			X

11 Scenarios

The purpose of this section is to document possible TSEM-specific scenarios illustrating the possible virtual configurations. The example below is for a single tester configured as two virtual testers configured as follows:

```
Physical Tester #1  EquipSerialID = T1000A
2 Virtual Equipment Instances,
          where VirtualID #10 represents
          Tester #0, Head #0, Sites 0 - 3.

          where VirtualID #20 represents
          Tester #0, Head #0, Sites 4 - 7,
          Head #1, ALL Sites (1-3).

Status Variable Request Scenario
Status Variable Request S1,F3 -->
L,1
  1. U4 1001 (SVID for VirtualConfig)
                              <--S1,F4 (status variable return)
                                     L,1
                                       1. L,2 = # of virtual testers
                                          1. L,2
                                             1. 10 (VirtualID = 10)
                                             2. L,1 = # of heads for Tester 10
                                                1. L,2
                                                   1. 0 (TestHeadID)
                                                   2. L,3 = # of sites for head 1
                                                      1. 01 = TestBoardSiteID #1
                                                      2. 02 = TestBoardSiteID #2
                                                      3. 03 = TestBoardSiteID #3
                                          2. L,2
                                             1. 20 (VirtualID = 20)
                                             2. L,2 = # of heads for Tester 20
                                                1. L,2
                                                   1. 0 (TestHeadID)
                                                   2. L,4 = # of sites for head 0
                                                      1. 04 = TestBoardSiteID #4
                                                      2. 05 = TestBoardSiteID #5
                                                      3. 06 = TestBoardSiteID #6
                                                      4. 07 = TestBoardSiteID #7
                                                2. L,2
                                                   1. 1 (TestHeadID)
                                                   2. L,3 = # of sites for head 1
                                                      1. 01 = TestBoardSiteID #1
                                                      2. 02 = TestBoardSiteID #2
                                                      3. 03 = TestBoardSiteID #3
```

11.1 *Normal Run Scenario* — This is an error-free run of a single lot, with no additional lots queued. The Host determines the available resources of the tester by requesting the status variable, VirtualConfig. This variable returns a list of virtual testers and the resources assigned to each of them.

```
COMMENT                        HOST      EQUIPMENT                                COMMENT
```

The Host would initiate a PP_SELECT using an available resource. PP_SELECT requires at least 2 parameters (PPID and VirtualID). Optional parameters are not shown.

```
Host Command Send              S2,F41-->
1. PP-SELECT
2. L,2
   1. L,2
        1. PPID
        2. A[80] "/home/recipes/tester_recipe"
   2. L,2
        1. VirtualID
        2. U4 10

                                         <--S2,F42    (host command acknowledge)
                                                              L,2
                                                                1. HCACK "0"
                                                                2. L,0
```

The tester then starts sending several events back to the host to identify transitions and non-transition events.

```
                                         <--S6,F11            (Event #2 Setting Up)
                               S6,F12-->
                                         <--S6,F11            (Event #3 Ready)
                               S6,F12-->
```

The host then sends a start to the tester. The START command requires the VirtualID only.

```
Host Command Send              S2,F41-->
1. START
2. L,1
     1. L,2
          1. VirtualID
          2. U4 10

                                         <--S2,F42    (host command acknowledge)
                                                              L,2
                                                                1. HCACK "0"
                                                                2. L,0
```

The tester then starts sending several events back to the host to identify transitions and non-transition events.

```
                                         <--S6,F11            (Event #4 Working)
                               S6,F12-->
                                         <--S6,F11            (Event # EndOfTest)
                               S6,F12-->
                                         <--S6,F11            (Event # EndOfTest)
                               S6,F12-->
                                         <--S6,F11            (Bin data available)
                               S6,F12-->
                                         <--S6,F11            (Event #25 Ready)
                               S6,F12-->
```

After several of these starts and events sequences, the tester notifies the host that the SubLot is complete and then receives close-lot and stop commands from the host.

```
                                          <--S6,F11            (Sub-lot complete)
                               S6,F12-->

   Host Command Send           S2,F41-->
   1. CLOSE_LOT
   2. L,0

                                          <--S2,F42    (host command acknowledge)
                                                               L,2
                                                                 1. HCACK "0"
                                                                 2. L,0

                                          <--S6,F11            (Lot-complete)
                               S6,F12-->
   Host Command Send           S2,F41-->
   1. STOP
   2. L,0

                                          <--S2,F42    (host command acknowledge)
                                                               L,2
                                                                 1. HCACK "0"
                                          <--S6,F11              (Event #12 IDLE)
                               S6,F12-->
```

11.2 *Run Diagnostics/Calibration Scenario*

```
Run Diag/Calibration
Host Command Send              S2,F41-->
1. CALIBRATE
2. L,1
   1. L,2
        1. START
        2. A[80] "DIAG-ID"

                                          <--S2,F42    (host command acknowledge)
                                                               L,2
                                                                  1. HCACK "0"
                                                                  2. L,0
                                          <--S6,F11    (Event #2)
   S6,F12-->
                                          <--S6,F11    (Event #3)
                               S6,F12-->

Host Command Send              S2,F41-->
1. START
2. L,0

                                          <--S2,F42    (host command acknowledge)
                                                               L,2
                                                                  1. HCACK "0"

                                          <--S6,F11            (Event #4)
                               S6,F12-->
                                          <--S6,F11            (Event #24)
                               S6,F12-->
                                          <--S6,F11            (Diag Report)
                               S6,F12-->

Host Command Send              S2,F41-->
1. STOP
2. L,0

                                          <--S2,F42    (host command acknowledge)
                                                               L,2
                                                                  1. HCACK "0"
```

12 Additional SEMI E30 Requirements

The purpose of this section is to specify any GEM additional capabilities that are required to be supported by this class of equipment.

12.1 *Requirements* — The following GEM additional capabilities required by TSEM are:

- Establish Communications
- Dynamic Event Report Configuration
- Variable Data Collection
- Status Data Collection
- Alarm Management
- Remote Control
- Equipment Constants
- Process Program Management
- Equipment Terminal Services
- Clock
- Spooling
- Control (Host-Initiated)

13 TSEM Unique Capabilities

The purpose of this section is to specify additional capabilities required for the TSEM that are unique to this class of equipment.

13.1 *Test Handling Equipment Common Data* — The purpose of this subsection is to specify test handling variable item data and event data that must be available to the host during the electrical test process. Because equipment configurations vary regarding handling and test equipment, passing control and process information to the host system also can vary. By providing this information from either class of equipment, a greater variety of configurations is available to the user. The handler data identified in this section must be made accessible from the tester manufacturer's interface (i.e., placeholder IDs, events, and commands). The validity of the data will depend on the specific field configuration of the equipment. For example, if the field configuration places the handler as the primary contact to the host, the data identified in this section would not be needed, and the TSEM capability would be disabled. On the other hand, if the field configuration places the tester as the primary contact to the host, the data identified in this section would be necessary, and the TSEM capability then would be enabled.

13.2 *Variable Item Requirements* — Table 17 identifies variable items that must be available from the tester in addition to those identified in Section 8.

Table 17 Common Handler Variable Items

Variable Name	*Category*	*Description*	*Class*	*Format*	*Comments*
EquipID (Handler)	CV	Identification of Handler Equipment (per Head)	SV	A[16]	Valid in all states.
LotID	CV	Lot ID	SV	A[16]	Valid in EXECUTING.
OperatorID	CSV	Current Operator ID	ECV	A[24]	Valid in all states.

13.3 *Collection Event Data Item Requirements* — Table 18 identifies common collection events that the tester must be able to provide to the host, if available from the handler.

Table 18 Common Handler Collection Events

Collection Event Name	*Event #*
LotComplete	Equipment Specific #
SetupComplete	Equipment Specific #
LotStart	Equipment Specific #

13.4 *Host Access to Tester Data Log Information* — TSEM requires the equipment manufacturer to make data log information available to the host via the SEMI E5, Stream 13 data set message. Because equipment configurations vary for data log content and format, the only requirement TSEM makes is that the equipment manufacturer document the format and content of data log information used by the equipment and make that information available across the communications interface via Stream 13. (See SEMI E5.)

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI E30.3 and is not intended to modify or supercede the official standard. These notes are presented as possible methods for SEM implementations and are included only as reference material.

R1-1 TSEM ARAMS Sub-State Codes

For TSEM implementations which are also compliant with SEMI E58, the equipment will support the following ARAMS sub-states:

A. PRODUCTIVE

1. 1XYY "PRD/Initialization for process program"

2. 1XYY "PRD/Testing units"

3. 1XYY "PRD/Determining result information"

4. 1XYY "PRD/Cleanup for process program"

B. STANDBY

1. 2XYY "SBY/Waiting for process program selection"

2. 2XYY "SBY/Waiting for start test"

3. 2XYY "SBY/Waiting for user input, equipment-initiated"

4. 2XYY "SBY/Waiting for user input, user-initiated"

NOTE: The *X* sub-state codes are reserved by SEMI E58 for standard codes and the *Y* is for supplier usage.

R1-1.1 *Mapping of TSEM Processing State Model to ARAMS State Model* — The TSEM Processing state model and the ARAMS state model are separate models which must both be maintained and supported if the equipment is to be both TSEM-compliant equipment and ARAMS-compliant. Although these state models are separate, there is a definite relationship between the two. All TSEM-compliant equipment which is also ARAMS-compliant will support the following mapping between the TSEM Processing state model and the ARAMS state model. This mapping only applies while the equipment is performing its intended function, that is, while it is in the Manufacturing superstate defined by ARAMS.

R1-1.2 *ARAMS State Mapping to TSEM Processing States*

Table 19 ARAMS/TSEM Processing State Transitions Table

#	*Current State*	*Trigger*	*New State*	*ARAMS Actions*	*Comments*
0	WORK-STATION-READY	Power on.	INIT	Based on previous ARAMS.	Based on previous ARAMS state.
1	INIT	All tester initialization is complete with no alarms or error conditions.	IDLE	SBY/Waiting for PP selection.	Equipment is capable of performing the intended function.
2	IDLE	A Process Program is selected.	SETTING UP	PRD/Initialization for PP selection.	None
3	SETTING UP	All setup activity has completed, and the tester is ready to receive a START command.	READY	SBY/Waiting for start test.	Start Test may be received.
4	READY	The handler, operator, or host executes a START command, and auto-start is enabled.	WORKING	PRD/Testing Units	None
6	PROCESS	The tester has received a STOP command.	STOPPING	PRD/Cleanup	None
7	PROCESS	The tester has received an ABORT command from operator, host, or self-generated.	ABORTING	PRD/Cleanup	None
8	PROCESS	An alarm occurs.	ALARM PAUSED	UDT	Not capable of performing intended function.

#	Current State	Trigger	New State	ARAMS Actions	Comments
9	PROCESS	The tester has received a PAUSE command.	PAUSING	No state change.	PAUSING is incomplete, so no change.
11	CHECKING	Parameter checking completes successfully.	STATE based on conditional table.	Condition based on conditional state.	Reference # 2, 3, 4, 24, 26, and 29.
12	STOPPING	The tester cleanup is complete, and the tester is free of alarms.	IDLE	SBY/Waiting for PP selection.	Equipment is capable of performing the intended function.
13	PAUSE	The tester has received a STOP command.	STOPPING	PRD/Cleanup	None
14	PAUSE	The tester has received an ABORT command.	ABORTING	UDT or PRD Cleanup.	If uncleared alarms exist, then ARAMS state is UDT, else cleanup.
15	STOPPING	The tester has received an ABORT command.	ABORTING	UDT or no state change.	If uncleared alarms exist, then ARAMS state is UDT, else stopping.
16	ABORTING	Unsafe conditions have been resolved, where possible.	ABORTED	SBY/Waiting for input or UDT.	If uncleared alarms exist, then ARAMS state is UDT, else waiting for clear.
17	ABORTED	An operator has verified that all alarms and abort conditions have been cleared.	IDLE	SBY/Waiting for PP selection.	None
18	IDLE	An alarm is set.	IDLE with ALARMS	UDT	Equipment is NOT capable of performing the intended function.
19	IDLE with ALARMS	All alarms have been cleared.	IDLE	SBY/Waiting for PPselection.	Equipment is capable of performing the intended function.
20	PAUSING	The tester has completed processing the Current unit(s) and achieved a safe condition.	PAUSED	SBY/Waiting for input.	Waiting for resume.
21	PROCESS PAUSE	An alarm is set.	ALARM PAUSED	UDT	Equipment is NOT capable of performing the intended function.
22	ALARM PAUSED	All alarms are cleared.	PAUSED	SBY/Waiting for input.	Alarms cleared, waiting for resume.
24	WORKING	The processing of the current unit(s) has completed normally.	END OF TEST	PRD	ARAMS sub-state is active until the BIN-Data Available event occurs or the next start test is received.
25	END OF TEST	Tester is ready to receive a new start of test command.	READY	Either SBY/Waiting for start test or PRD determining results.	PRD/Determining sub-state has entered at END OF TEST. This sub-state is active until BIN-Data Available or until the next start test.
26	WORKING	The processing of the current unit(s) has completed abnormally.	END OF TEST	PRD determining results.	The sub-state is active until BIN-Data Available or until the next start test.
29	READY	New Lot is received by tester.	SETTING UP	PRD/Initialization for PP selection.	New lot requires process program initialization.
33	CHECKING	Error detected in a new parameter setting.	PAUSED	No state change.	None
34	PAUSED	A RESUME command with variable parameters was received.	CHECKING	No state change.	None

#	*Current State*	*Trigger*	*New State*	*ARAMS Actions*	*Comments*
35	IDLE	The tester executive has been stopped by the operator.	WORKSTATION READY	No state change.	The equipment may not be aware of this transition. ARAMS specifies the rules to be followed upon reinitialization.
36	ABORTED	The tester executive has been aborted by the operator.	WORKSTATION READY	No state change.	The equipment may not be aware of this transition. ARAMS specifies the rules to be followed upon reinitialization.
37	IDLE with ALARMS	The tester executive has been stopped by the operator.	WORKSTATION READY	No state change.	The equipment may not be aware of this transition. ARAMS specifies the rules to be followed upon reinitialization.

R1-1.3 *Additional ARAMS Capabilities* — ARAMS specifies fundamental ARAMS requirements which must be met to be ARAMS-compliant. ARAMS also specifies additional capabilities which may be provided by ARAMS-compliant equipment. All TSEM-compliant equipment which is also ARAMS-compliant is required to provide the following additional capabilities as defined by ARAMS:

a. Dynamic Event Report Configuration

b. Accumulator Data

c. User-Generated ARAMS Sub-State Table(s)

d. Equipment-Generated ARAMS Sub-State Table(s)

e. User-Generated ARAMS Symptom Table(s)

SEMI E30.5-0302
SPECIFICATION FOR METROLOGY SPECIFIC EQUIPMENT MODEL

This specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Global Information and Control Committee. Current edition approved by the North American Information and Control Committee on October 14 and November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published July 2001.

The complete specification for this product includes all general requirements of SEMI E30.

1 Purpose

1.1 This document establishes a Specific Equipment Model (SEM) for Metrology equipment (MSEM). The MSEM consists of equipment characteristics and behaviors that are applicable to this class of equipment and are required to be implemented in addition to the SEMI E30 fundamental requirements and additional capabilities.

2 Scope

2.1 The scope of this document is limited to defining the behavior of Metrology equipment as perceived by a SEMI Equipment Communications Standard II (SECS II/SEMI E5) host that complies with the SEMI E30 model. It defines the view of the equipment through the SECS II link. It does not define the internal operation of the equipment. It includes a specific processing state model as the basis for all equipment behavior of this class.

2.2 This document assumes that the SEMI E30 fundamental requirements and all additional capabilities except those noted in SEMI E30 Capabilities Section in this document have been implemented on the MSEM equipment. This document expands the SEMI E30 Standard requirements and capabilities in the areas of the processing state model, collection events, Process Program management, remote commands, data item variables, and coordinate systems.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The intent of this document is to facilitate the integration of Metrology equipment into an automated semiconductor factory. This document accomplishes this by defining an operational model for Metrology equipment as viewed by a factory automation controller. This definition provides a standard host interface and equipment operational behavior. This document applies specifically to Metrology equipment as used in a semiconductor factory environment. It is possible that this methodology and techniques may apply to other industries.

3.2 MSEM job parameters that specify material (e.g., carrier ID and substrate ID) and material locations (e.g., carrier location ID and carrier slot ID) are intended for metrology equipment for 200 mm and smaller substrate.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard II (SECS II)

SEMI M20 — Specification for Establishing a Wafer Coordinate System

SEMI M21 — Assigning Addresses to Rectangular Elements in a Cartesian Array

SEMI E37.1 — High Speed Messaging Service (HSMS-SS) Single Session

SEMI E58 — Automated Reliability and Availability Standard (ARAMS)

5 Terminology

5.1 *Definitions*

5.1.1 *alignment, n.* — a procedure in which a coordinate system is established on a substrate or a portion of a substrate.

5.1.2 *alignment mark, n.* — a feature on a substrate selectively used for alignment.

5.1.3 *alignment site, n.* — a point within a feature on a substrate selectively used for alignment.

5.1.4 *cleanup, n.* — deselection of the current Process Program and removal of all material to output locations and any equipment specific activities required to transition the equipment into the IDLE state.

5.1.5 *factory automation controller, n.* — a computer system that provides integration of factory shop control and business systems with semiconductor equipment.

5.1.6 *feature, n.* — a distinctive item in a pattern, or a physical characteristic of the substrate. (e.g., line, point, a wafer flat).

5.1.7 *field, n.* — an exposure repeated in a regular manner on a substrate.

5.1.8 *global alignment, n.* — procedure which establishes a coordinate system for the entire substrate (see alignment). For silicon wafers, this coordinate system is defined in MSEM as the SEMI M20 coordinate system.

5.1.9 *global pattern alignment, n.* — a procedure which establishes a coordinate reference system relative to repeating features on an entire substrate. For silicon wafers, this coordinate system is defined in MSEM as the M20P coordinate system.

5.1.10 *logical port, n.* — one or more physical input or input/output ports that are controlled by the same execution of a Process Program.

5.1.11 *M20P, adj.* — a designation used for the global coordinate system defined within MSEM, that is established relative to a pattern on a silicon wafer.

5.1.12 *material, n.* — a piece or pieces of substrate, one or more substrate, a lot, a batch, or a run.

5.1.13 *metrology equipment, n.* — any equipment that collects and reports information on specific predetermined sites or features on a substrate with consistent data structure, or reports general information about the entire substrate.

5.1.14 *notch, n.* — a cut on the edge of a wafer that is commonly located with respect to a specific crystal plane that adheres to the SEMI M1 standard.

5.1.15 *pattern, n.* — the physical features on a substrate.

5.1.16 *pre-align, n.* — any alignment done prior to placing a substrate on a measurement process location.

5.1.17 *registration, n.* — positioning error between two features on different layers of a substrate.

5.1.18 *safe state, n.* — a state in which the equipment presents no danger to the product or user. This implies that safety interlocks are in place such that the equipment can be serviced without harm to the operator and that the material being processed has been removed from the processing station into an accessible location.

5.1.19 *secondary alignment, n.* — a procedure which improves the accuracy of the coordinate system mapping on a substrate in a limited area of the substrate.

5.1.20 *site, n.* — a single point on a substrate used for alignment, or the center of an area of the substrate within which measurements are made.

5.2 *Abbreviations and Acronyms*

5.2.1 *GEM, n.* — Generic Equipment Model

5.2.2 *SEM, n.* — Specific Equipment Model

5.2.3 *SEM, n.* — Scanning Electron Microscope

5.2.4 *TCP/IP, n.* — Transmision Communication Protocol/Internet Protocol.

6 Communication Requirements

6.1 It is required that any MSEM compliant equipment follow the Communications State Model in SEMI E30. In addition MSEM compliant equipment shall support the High Speed Messaging Service (HSMS-SS) communication Standard, and the SECS-I standard for sending SECS II messages over TCP/IP or RS232. The user may determine which of these two lower level transmission protocols is used in each installation. The reason for HSMS-SS requirement is the large volume of data that can be generated by this class of equipment.

7 State Models

7.1 In this section are defined the equipment-specific processing state model and other state models necessary to portray the expected operational states of the equipment to enable host tracking and control in place of a local operator. See SEMI E30 and Other References section for additional information on state charts general rules and utilization.

7.2 *Processing State Model Requirements* — The Processing state model is required to be implemented as defined in the next sections of this document. A state model consists of the following: state model diagram, state definitions and a state transition table. A state model represents the host's view of the equipment, not necessarily the actual equipment operation. All MSEM state model transitions shall be mapped sequentially into the appropriate actual equipment events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the MSEM state model for transition to another state. The equipment makes the required transition without any additional actions in this situation.

7.3 Some equipment may need to include additional states. Additional states may be added, but shall not change the MSEM defined state transitions. All expected transitions between MSEM states must occur.

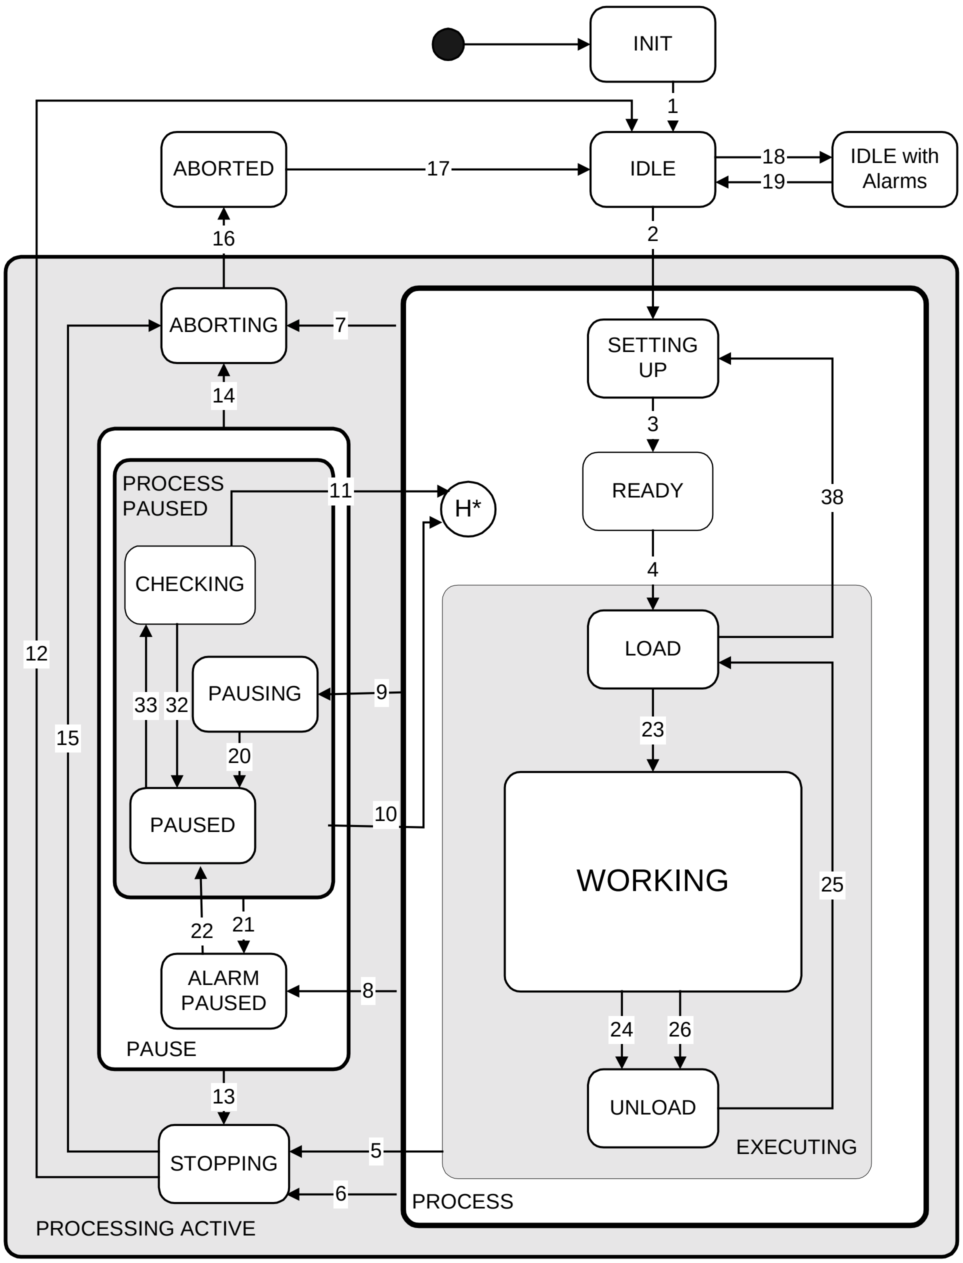

Figure 1
Generic MSEM Processing State Model Diagram

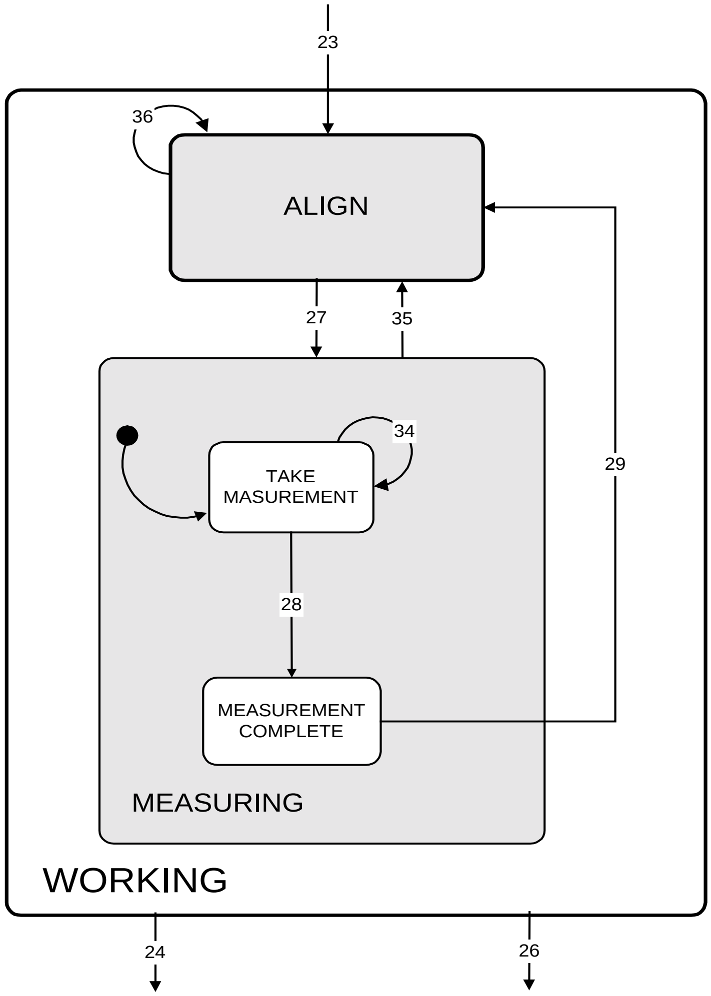

Figure 2
Working State of Processing State Model

7.4 *Processing State Model Diagram*

7.4.1 *Working State of Processing State Model*

7.4.2 *Working Sub-states of Processing State Model* — These states need not to be implemented in all Metrology equipment but if the equipment has the ability to multiple measurements at a site or provide raw scan date to the user this is how it is to be implemented.

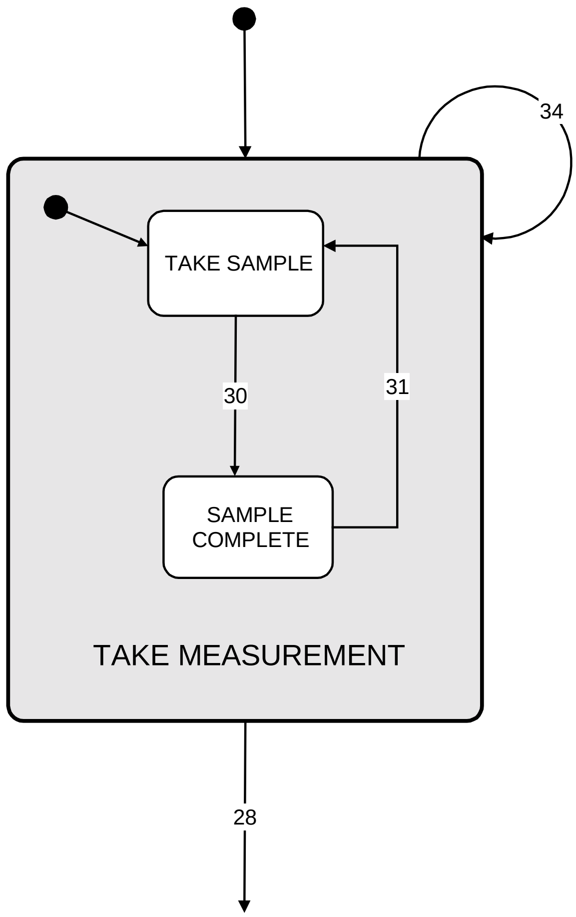

Figure 3
Working Sub-State of Processing State Model

7.5 *Processing State Definitions*

7.5.1 *ABORTED* — all activity is suspended as a result of an ABORT command. Any alarm and abort conditions must be cleared before exit from this state. The CLEANUP command is available to the operator or host to transition the equipment from the ABORTED state to IDLE state.

7.5.2 *ABORTING (PROCESSING ACTIVE Sub-state)* — the equipment has received an ABORT command. All normal activity is suspended. The equipment is taking appropriate action to put the equipment and material in a "safe state" where possible. Data may be invalid or not available.

7.5.3 *ALARM PAUSED (PAUSE Sub-state*) — an alarm has occurred in the Process or Process Pause states and the equipment is waiting for the alarm to be cleared.

7.5.4 *ALIGN (WORKING Sub-state)* — the equipment or operator is performing an alignment of the material to the equipment. Within this state the equipment shall refine or establish its SEMI M20 coordinate system and establish any secondary coordinate systems required.

7.5.5 *CHECKING (PROCESS PAUSE Sub-state)* — the equipment verifies that the updates made to the Process Program are valid. This is a similar procedure to that which is done in SETTING UP before the equipment is ready to transition to the READY state.

7.5.6 *EXECUTING (PROCESS Sub-state)* — the equipment is processing material automatically and can continue to do so without external intervention, but normally may include interaction with the host or operator.

7.5.7 *IDLE* — checks for queued process or awaits a command. IDLE is free of ALARM and error conditions. Any transitions into this state will clear the process area.

7.5.8 *IDLE with ALARMS* — an alarm has occurred in the IDLE state and the equipment is waiting for all alarms to be cleared.

7.5.9 *INIT* — equipment initialization is occurring.

7.5.10 *LOAD (EXECUTING Sub-state*) — the equipment is determining if processing is complete. If not, then the substrate is being transferred to the equipment processing location, such as the stage. A pre-alignment procedure may be performed prior to the LOAD state.

7.5.11 *PAUSE (PROCESS ACTIVE Sub-state*) — PROCESS is suspended at the next opportunity. Actions to put the equipment in a "safe state" shall be performed. The equipment is awaiting a command (RESUME, PP-UPDATE, STOP or ABORT), or for alarm(s) to be cleared.

7.5.12 *PAUSED (PROCESS PAUSE Sub-state*) — PROCESS shall be suspended and the equipment is waiting for a command (RESUME, PP-UPDATE, STOP or ABORT).

7.5.13 *PAUSING (PROCESS PAUSE Sub-state)* — PROCESS has been suspended at the next opportunity and the equipment is put in a "safe state".

7.5.14 *PROCESS (PROCESSING ACTIVE Sub-state)* — this state is the parent of those sub-states which refer to the active preparation and execution of a Process Program.

7.5.15 *PROCESSING ACTIVE* — this state is the parent of all sub-states where the context of a Process Program execution exists.

7.5.16 *PROCESS PAUSE (PAUSE Sub-state)* — the equipment is free of alarm conditions in the PAUSE state.

7.5.17 *MEASUREMENT COMPLETE (MEASURING Sub-State)* — the equipment has completed collecting data relative to an alignment location.

7.5.18 *MEASURING (WORKING Sub-State)* — the equipment is preforming an action between alignments.

7.5.19 *READY (PROCESS Sub-state)* — the equipment is ready to begin processing and is awaiting a START command from the operator or host. If an AUTOSTART is included, then the equipment starts processing immediately.

7.5.20 *SAMPLE COMPLETE (TAKE MEASUREMENT Sub-state)* — the equipment determines if additional samples need to be taken at this site.

7.5.21 *SETTING UP (PROCESS Sub-state)* — the equipment is being set up so that external conditions are satisfied to start processing the material. This includes the receipt of any Process Programs and material to be processed and their validation. Additional information may come from the host during the processing.

7.5.22 *STOPPING (PROCESSING ACTIVE Sub-state)* — the equipment has completed a Process Program or has been instructed to stop processing and shall do so gracefully at the next opportunity. All cleanup necessary is being completed within this state with regard to material, data, control system, etc. Data is normally preserved. Any alarm or error condition is cleared before exit from this state.

7.5.23 *TAKE MEASUREMENT (MEASURING Sub-state)* — the equipment is in the process of collecting data relative to an alignment location. (e.g. Site, Region, Substrate).

7.5.24 *TAKE SAMPLE (TAKE MEASUREMENT Sub-state)* — the equipment collects data from a single structure or of a single sample.

7.5.25 *UNLOAD (EXECUTING Sub-state)* — the substrate is being removed from the processing location.

7.5.26 *WORKING (EXECUTING Sub-state)* — the equipment is processing a specific material.

7.5.27 *Processing State Transition Table*

Table 1 Processing State Transition Table

Transition #	*Current state*	*Trigger*	*New State*	*Actions*	*Comments*
1	INIT	All equipment initialization is complete with no alarms or error conditions.	IDLE	None	If an alarm or error occurs during INIT, the equipment shall remain in this state.
2	IDLE	A process is queued or a command is received.	SETTING UP	The set up procedure is equipment dependent.	Commit has been made to set up.
3	SETTING UP	All setup activity has completed and the equipment is ready to receive a START command.	READY	The equipment is waiting for a START command. Start may be initiated by an operator.	The selected Process Program is available for execution.
4	READY	The equipment receives a START command.	LOAD	The equipment determines if processing is completed. If not, it transfers the next substrate to the processing location.	LOAD is an EXECUTING Substate.
5	EXECUTING	The processing is complete.	STOPPING	None	Equipment specific. Supplier must chose beween LOAD or UNLOAD states for completion.
6	PROCESS	The equipment has received a STOP command.	STOPPING	The equipment unloads the material and brings the equipment to a clean and safe state.	Data is typically preserved and is valid.
7	PROCESS	The equipment has received an ABORT command	ABORTING	The equipment is put in a "safe state" if necessary.	Data may be invalid or not available.
8	PROCESS	An alarm occurs.	ALARM PAUSED	PROCESS activity is suspended and the equipment is waiting for all alarms to be cleared.	ALARM PAUSED is a PAUSE Substate.
9	PROCESS	The equipment has received a PAUSE command.	PAUSING	PROCESS shall be suspended at the next opportunity. Actions to put the equipment in a "safe state" shall be performed.	PAUSING is a PAUSE Substate.
10	PROCESS PAUSED	The equipment has received a RESUME command.	Previous PROCESS State	Proceed with the suspended Substate.	PAUSED is a PROCESS PAUSE Substate.
11	CHECKING	The equipment has completed validating any updates made to the current Process Program being executed. Including a PP_UPDATE	Previous PROCESS State	Action is appropriate to the state and the changes made to the Process Program updated.	None

Transition #	*Current state*	*Trigger*	*New State*	*Actions*	*Comments*
12	STOPPING	The equipment clean up is complete and the equipment is free of alarms.	IDLE	None	None
13	PAUSE	The equipment has received a STOP command.	STOPPING	The equipment proceeds with clean up.	Normally, data is preserved and is valid.
14	PAUSE	The equipment has received an ABORT command.	ABORTING	Any unsafe condition is resolved if possible.	Data may be invalid or not available.
15	STOPPING	The equipment has received an ABORT command.	ABORTING	Any unsafe condition is resolved if possible.	Data may be invalid or not available.
16	ABORTING	Unsafe conditions have been resolved where possible.	ABORTED	The equipment is waiting for alarm and ABORT conditions to be cleared.	The only state change allowed is to IDLE.
17	ABORTED	All alarms and abort conditions have been cleared.	IDLE	None	If needed the CLEANUP command clears the abort conditions. IDLE is a “clean” state.
18	IDLE	An alarm is set.	IDLE w/ ALARMS	The equipment waits for all alarms to be cleared.	None
19	IDLE w/ ALARMS	All alarms have been cleared.	IDLE	None	IDLE is free of alarms.
20	PAUSING	The equipment has achieved a “safe state”.	PAUSED	The equipment is waiting for a command (RESUME, STOP or ABORT).	None
21	PROCESS PAUSE	An alarm is set.	ALARM PAUSED	The equipment waits for all alarms to be cleared, or a STOP or ABORT command.	None
22	ALARM PAUSED	All alarms are cleared.	PAUSED	The equipment is waiting for a command (RESUME, PP_UPDATE, STOP or ABORT).	None
23	LOAD	Material transfer to processing location is complete and global alignment has been completed.	WORKING	The substrate is being processed.	None
24	WORKING	The processing of the specific material being processed ended normally.	UNLOAD	This material is transferred from the processing location.	“Normal” completion of the substrate.
25	UNLOAD	The material unload is complete.	LOAD	The equipment checks if processing is complete and, if not, transfers the next substrate to the processing location.	None

Transition #	*Current state*	*Trigger*	*New State*	*Actions*	*Comments*
26	WORKING	The processing of the specific material being processed ended abnormally.	UNLOAD	This material is transferred from the processing location.	Abnormal exit from WORKING or Next Material command received.
27	ALIGN	The material alignment is complete.	MEASURING	The equipment determines if additional sites are required.	None
28	TAKE MEASURE-MENT	All data collection has been completed for the current site or alignment location.	MEASURE-MENT COMPLETE	The equipment determine if additional sites are required.	Determine if additional alignments are required or unload is required.
29	MEASURE-MENT COMPLETE	Additional sites are required.	ALIGN	The equipment moves and aligns to new data collection site.	None
30	TAKE SAMPLE	Data collection from scan or structure.	SAMPLE COMPLETE	Determine if additional samples are required.	None
31	SAMPLE COMPLETE	Additional samples are required.	TAKE SAMPLE	Start collecting next scan or structure data.	None
32	CHECKING	Validation of Process Program change fails or is cancelled. Includes PP_UPDATE.	PAUSED	The equipment is waiting for a new PP-UPDATE or RESUME command.	Process Program reverts to the conditions that existed prior to the PP-UPDATE.
33	PAUSED	The equipment receives a PP-UPDATE command.	CHECKING	The equipment begins validating the changes made to the Process Programs to be executed.	None
34	TAKE MEASURE-MENT	Another measurement is required at an alignment location.	TAKE MEASURE-MENT	The equipment performs a measurement.	None
35	MEASURING	An error or failure occurred during the measurement and a new alignment is required.	ALIGN	The equipment moves and aligns to new data collection site.	None
36	ALIGN	An error or failure occurred during alignment and a new alignment is required.	ALIGN	The equipment moves and aligns to new data collection site.	None
37	ASSIST	A failure occurred while executing and external assistance was required to continue.	PROCESS PAUSE	The execution is stopped and equipment waits for a resume command.	Resume command must be issued.
38	LOAD	Previous PROCESS-BLD-GROUP program has completed and there are additional process programs assigned to the “CARRIERBLD”. See Section 12.	SETTING UP	The equipment performs set up according to specifications of the next process program.	PROCESS-BLD-GROUP may include a AUTOSTART command within its body. Otherwise, the equipment waits for a START command.

Table 2 Processing State Events and Associated Reports

CENAME	*From State*	*To State*	*Required DVVAL's or Reports*
END of RUN	STOPPING	IDLE	RUN complete report available. All jobs specified by PROCESS-BLD-GROUP command parameter(s) in a CARRIERBLD command parameter complete.
END of JOB	LOAD	SETTING UP	JOB complete report available. A job specified by a PROCESS-BLD-GROUP command parameter in a CARRIERBLD command parameter that specifies multiple jobs for the same material completes.
END of SUBSTRATE	UNLOAD	LOAD	SUBSTRATE complete report available.
END of SITE	TAKE MEASURE	MEASURE COMPLETE	SITE complete report available. Only required if supporting sampling.
END of SAMPLE	TAKE SAMPLE	SAMPLE COMPLETE	SAMPLE complete report available. Only required if equipment performs measurements on individual sites.

8 Collection Event List

8.1 The purpose of this section is to identify data collection events for Metrology equipment and define reporting levels.

8.2 *Requirements* — Only those collection events that are not associated with a change of state, and those requiring specific DVVAL's or Reports defined in the SEM, are required to be included in this section. All SEMI E30 required events are required by this SEM.

8.2.1 *Common collection events* — collection events common to, and required on, all equipment of the class being addressed.

8.2.2 *Configuration-specific collection events*— collection events associated with a specific configuration of the equipment class being addressed.

8.3 *Collection Event Tables* — The first table contains processing state event transitions and associated reports. The second table contains additional events or actions and associated reports.

8.3.1 All remote commands (S2F41) that are not preformed by the equipment before responding to the host (S2F42) must generate an event indicating when the task was completed and whether it was successful.

Table 3 Additional Required Collection Events

ACTION or COMPLETED EVENT	*Required DVVAL's or Reports*
Remote command MAP-CASSETTE completed successfully.	SlotList
Operator hits button on equipment control panel.	OperatorAction

9 Data Item Variables

9.1 The purpose of this section is to define the list of data item variables pertinent to the specific equipment. Values of these variables shall be available to the host via collection event reports and host status queries.

9.2 *Requirement* — all generic variable data items defined in SEMI E30 are required by all Measurement equipment. Data item variables are categorized as follows:

9.2.1 *Common Variables (CV)* — variables common to all equipment of the class being addressed. These variables are covered in Table 4 and must be used to regardless of the measurement tool type.

9.2.2 *Configuration-specific variables (CSV)* — variables associated with a specific configuration of the above equipment class.

9.2.2.1 The following rules should be adhered to in the reporting of these variables.

- The information should be sent using the corresponding formats defined on Table 4 and 5.
- For ASCII variables A[n]. If the actual data does not fill the entire field, blanks shall be used to complete the field.
- For ASCII variables A[1..n]. All fields should be left justified.

9.3 Since MSEM is generic to all equipment it tries not to specify the names of the measurement variables to be sent to the host. MSEM does require that the data be reported at site, wafer and lot levels. It should include the option of reporting data at the individual scan level if supported by the equipment. It is a requirement that the equipment report at least: max, min, mean, standard deviation. Additional statistic calculations may be added by the equipment supplier. For each type of data collected by the equipment at the site level; the data must be summarized and available for reporting at the wafer and lot levels.

9.4 The following rules should be applied when reporting measurement values taken by the tool. The rules specify the units to be used whenever these values are reported.

- All values specified should be reported in floating point format.
- All critical dimensions (lines and spaces) should be in microns.
- All overlay measurements should be in microns.
- All FTIR transmittance values and corresponding wavelengths should be reported in percent units and microns, respectively.
- All film stress values should be reported in teradynes/cm-cm.
- All resistivity measurements should be reported in Ohm-cm.
- All film thickness measurements should be reported in Angstroms.

9.5 Data item variables should be documented in the MSEM data item variable dictionary using the following format:

Variable Name	*Category*	*Description*	*Class*	*Format*	*Comments*

Where:

Variable Name:	A unique name for the data item variable (this name is for reference only).
Category:	Defined as Common or Configuration-Specific variables.
Description:	If class is DVVAL, then the description must contain a statement of when data is valid in terms of MSEM events.
Class:	Data type of the item.
Format:	Acceptable formats are SEMI E5 lists, ASCII, floating point, unsigned integer or signed integer. A description of “ANY”, indicates that any of the above formats are acceptable and is left to the tool vendor to decide. When required use SECS Message Language format.
Comments:	Any additional information pertinent to the variable name.

9.6 *Data Item Variable Types*

9.6.1 *Equipment Constants (ECV)* — can be changed by the host using S2F15. The operator may have the ability to change some of the values, but the equipment does not change the values on its own. The value of the equipment constant may be queried by the host at any time using the S2F13/14 transaction.

9.6.2 *Status Variables (SV)* — are valid at all times. A SV may not be changed by the host but may be changed by the equipment or the operator. The value of status variables may be queried by the host at anytime using the S1F3/4 or S6F19/20 transactions.

9.6.3 *Data Variables (DVVAL)* — are variables which are valid only upon occurrence of specific collection events. An attempt to read a data variable at the wrong time shall not generate an error, but the data reported may not have relevant meaning.

9.6.4 *Variable Data (V)* — this is a class of variable data which includes all the previously defined types of variables.

Table 4 Data Item Variable List

Variable name	*Category*	*Description*	*Class*	*Format*	*Comments*
AlignList	CSV	A list of alignment site information being used by the currently active Process Program.	DVVAL	L,n 1. <AlignName> . . n.	See Table 5 for additional information.
CarrierID	CV	ID of the Carrier that the measurement data is associated with.	DVVAL	A[1..16]	Valid in processing substate.
Coord	CV	The X,Y coordinate for a site in microns.	DVVAL	L,2 1.<CoordX> 2.<CoordY>	See Table 5 for additional information.
Coordsys	CV	The identification for applicable coordinate system.	DVVAL	A[1..16]	Options for silicon wafers are: SEMI M20, M20P, SEMI M21.
Default-Priority	CV	The default priority given a location or carrier ID if none is assigned.	EC	U4	
DeltaX	CSV	The x axis translation between the origins of two coordinate systems, in µm.	DVVAL	F4	Units are in microns.
DeltaY	CSV	The y axis translation between the origins of two coordinate systems, in µm.	DVVAL	F4	Units are in microns.
ElementID	CSV	The M21 address for a specific rectangular element on a patterned silicon wafer.	DVVAL	I4[2]	M21 row number, M21 column number.
ElementList	CSV	A list of M21 elements where measurements were attempted.	DVVAL	L,n 1. <ElementID> . . n	See Table 5 for additional information.
EquipID	CV	Unique ID of measurement equipment.	SV	A[1..16]	Valid in all sub states.
EquipName	CV	Name of equipment	SV	A[1..16]	Valid in all sub states.
LotID	CV	Lot ID that is associated with the measurement data.	DVVAL	A[1..80]	
M20Data	CV	The silicon wafer size, fiducial type, and orientation to use.	DVVAL	L,3 1.<WaferSize> 2.<Fiducial> 3. <Orientation>	See Table 5 for additional information.

Variable name	*Category*	*Description*	*Class*	*Format*	*Comments*
M21Data	CSV	The data necessary to establish an MSEM SEMI M21 layout on a silicon wafer.	DVVAL	L,2 1. L,3 1.<M21XSize> 2.<M21YSize> 3. <Tile> 2. L,n 1. L,3 1.<ElementID> 2.<CoordX> 3.<CoordY> : n	Coord x and Coord y are the X and Y coordinates in the M20P coordinate system of the lower left-hand corner of the element. See Table 5 for additional information.
QueuedJobList	CSV	An ordered list of CarrierID data items (A[1..16]) of material that is queued to run. The first item in the list is the ID of next carrier to run. A soon as a job specified by a PROCESS-BLD-GROUP starts, the CarrierID it specifies is removed from the head of the list.	SV	L	
Offset	CSV	The difference between the defined location of a site and the location at which it is found.	DVVAL	F4[2]	SiteDeltaX, SiteDeltaY
Operator Action	CV	Action taken by operator on equipment's front panel.	DVVAL	A[1..80]	
OperName	CV	Tool Operator name	ECV	A[1..16]	
Orientation	CV	The direction, in degrees, from the equipment's "0" location for a wafer's primary fiducial when initially positioned for measurements.	ECV	F4	This parameter has no effect on the "M20" based wafer coordinate system as discussed in SEMI standard SEMI M20.
PP-Name	CV	The PPID that is being used for measuring.	SV	A[1..80]	
Process SlotList	CV	The list of cassette slots whose contents are to be processed.	DVVAL	L,n 1. <SlotID> . . .	L,0 indicates all slots are to be processed. See Table 5 for additional information.
SiteDeltaX	CSV	The x axis translation between the defined and found locations of a site, in µm.	DVVAL	F4	Units are in microns.
SiteDeltaY	CSV	The y axis translation between the defined and found locations of a site, in µm.	DVVAL	F4	Units are in microns
SiteList	CV	The list of sites where measurements are made.	DVVAL	L,n 1.<SiteName> . . n	See Table 5 for additional information.
SiteName	CV	A unique identifier for a site.	DVVAL	A[1..16]	

Variable name	Category	Description	Class	Format	Comments
SlotID	CV	The cassette slot number.	DVVAL	U4	
WaferID	CSV	Physical wafer identifier.	SV	A[1..24]	
WaferIDRead	CSV	Tool read wafer identifier.	SV	A[1..24]	
WaferSize	CV	The nominal diameter of a silicon wafer.	EC	A[1..16]	mm
XlateData	CSV	Variable for the equipment to report the pattern-based coordinate system offset from the wafer-based coordinate system found on the wafer being tested.	SV	L,4 1 <DeltaX> 2 <DeltaY> 3 <Theta> 4 <ScaleFactor>	See Appendix 1 for an example. See Table 5 for additional information.

9.6.5 *Data Item Sub-variable List*

Table 5 Data Item Sub-Variable List

Data Item Sub-variables	*Description*	*Format*	*Comment*
AlignName	The identifier given to a alignment site.	A[1..16]	
CoordX	The x coordinate for a site.	F4	Units are in microns.
CoordY	The y coordinate for a site.	F4	Units are in microns.
DeltaX	The x axis translation between the origins of two coordinate systems, in µm.	F4	Units are in microns.
DeltaY	The y axis translation between the origins of two coordinate systems, in µm.	F4	Units are in microns.
ElementID	The M21 address for a specific rectangular element on a patterned silicon wafer.	I4[2]	M21 row number, M21 column number
Fiducial	The type of primary fiducial on a silicon wafer.	A[1..16]	Options are “FLAT” or “NOTCH”
M21XSize	The M21 element size in the x direction, in µm.	F4	Units are in microns.
M21YSize	The M21 element size in the y direction, in µm.	F4	Units are in microns.
ScaleFactor	The scaling factor required by the equipment to adjust from its SEMI M20 coordinate system to the coordinate system established through the use of pattern alignment “alignment site” information. In most cases, a scaling factor of 1 is expected.	F4	
SiteDeltaX	The x axis translation between the defined and found locations of a site, in µm.	F4	Units are in microns.
SiteDeltaY	The y axis translation between the defined and found locations of a site, in µm.	F4	Units are in microns.
SiteName	A unique identifier for a site.	A[1..16]	
THETA (Θ)	The clockwise rotation, in radians, between the SEMI M20 and M20P coordinate system axes.	F4	Radians
Tile	A flag to indicate whether the SEMI M21 layout is tiled, and in which direction.	A[1..16]	Options are: “NTILE” is untitled “CTILE” is column tiled “RTILE” is row tiled

10 Alarm List

10.1 Since each model of equipment differs in configuration, it is not practical to provide an exhaustive list of all possible alarms. Instead, the MSEM is requiring the two tables provided as described in SEMI E30 (Document Section). Alarm List Table which is intended to provide for equipment configuration specific alarms and Alarm ID, Alarm Set/Cleared Event Table.

10.2 *Alarm List Table*

10.2.1 The alarm list table contains examples of alarms that pertain to various configurational aspects of equipment. These examples are intended to illustrate that alarms pertain to situations in which there exists a potential for exceeding physical safety limits associated with people, equipment, and material being processed as per the SEMI E30 definition of an alarm. See SEMI E30 for further reference.

10.3 *Alarm ID, Alarm Set/Cleared Event Table*

10.3.1 The Alarm ID, Alarm Set/Cleared Event table documents the association of each ALID to a set and cleared event as required by SEMI E30. See SEMI E30 for further reference.

11 Process Program Management

11.1 *Requirements* — The MSEM requires that the SEMI E30 capability of Process Program Management be fully supported for this class of equipment. The MSEM is also requiring that the Process Program have a structure that enables the user to build Process Programs with default conditions that can be overridden for a run. MSEM is requiring the ability to vary; the quantity of substrates measured, the alignment information used and the number and/or location of the sites to be measured through the uses of Process Program variable parameters. The concepts of Process Program Structure and Process Program variable parameters are discussed in the following sections.

11.2 *Process Program Structure*

11.2.1 *Definition and Rules for Process Programs* — A Process Program contains information and/or instructions required for the metrology equipment to process a given run of material. Equipment constants can be used to supplement the information contained in a Process Program.

11.2.1.1 The Process Program shall supply all of the information required for a remotely executed run to be processed without operator intervention. Any information that is normally requested from the operator console in manual operation shall have default values assigned in the body of the Process Program.

11.2.1.2 Process-program parameters are used to tailor a specific run of material and do not permanently modify the Process Program. They will remain in effect only until the next run or until the next PP-UPDATE or PP-SELECT, PP-ASSIGN remote command.

11.2.1.3 MSEM is requiring the ability to define specific Process Program variable parameters to; define what substrates are to be measured (Process SlotList), what sites are to be measured (SiteList or M21SiteList) and what aligns are used by the Process Program (AlignList or M21AlignList). If the MSEM equipment is using the SEMI M21 coordinate system then an additional Process Program variable parameter is required what elements are to be measured (ElementList).

11.2.2 *Definition of Process Program Variable Parameters* — A process-program parameter specifies a value that temporarily modifies the value of a variable parameter in a Process Program. A variable parameter is formally defined within a process-program body and contains:

- a variable parameter name that is unique in the body
- a parameter initial value, known as default value, for use when the Process Program is selected for execution without specification of an override value for this variable parameter.

11.2.3 The Equipment may also support the definition including:

- a parameter restriction that represents one or more conditions that any value specified for the parameter must satisfy.
- a CP-NAME in a remote command must be identical to a variable parameter name in the Process Program specified in the remote command. If the Equipment allows Sub-process Programs, a Sub-process Program reference may also specify parameters.

11.2.4 *Relationship of Process Program Variable Parameter* — The PP-SELECT, PP-ASSIGN or PP-UPDATE remote commands can be used to modify variables within the Process Program. The modification to process-program variables is done by using CP-NAME/CP-VAL pairs within the command.

11.2.5 *Sub-Process Programs* — Equipment may allow a main Process Program to reference Sub-process Programs. A main Process Program is one that can be referenced by the host. A Sub-process Program is a Process Program that is referenced by a main Process Program or by other Sub-process Programs. No Sub-process Program may reference its main Process Program. If the Equipment supports sub-process-program references, it must be possible for the host to determine which Sub-process Programs are referenced in all Process Programs.

11.2.5.1 Before execution of a main Process Program can begin, the presence of all the Sub-process Programs that it references must be verified by the Equipment. If they are not all present, an error collection event must occur. It must be possible to include in the event report which Sub-process Programs are missing. For a formatted Process Program, the error is reported using an S7F27 message.

11.2.6 *Component Descriptions and Allowed Formats*

Table 6 Process Program Component Description and Format Table

Component Name	*Description*	*Format*	*Comments*
ALIGN-ATTRIBUTE (n)	Tool specific information associated with alignment site for which no specific MSEM data item has been defined.		Examples include information such as magnification, voltage, current, wavelength, number of scans, integration time, or film stack. The equipment supplier shall document all attributes that are supported.
ALIGN-NAME	The identifier given to a alignment site.	A[1..16]	
COORDSYS	The identification for applicable coordinate system.	A[1..16]	Options for silicon wafers are: SEMI M20, M20P, SEMI M21
COORDX	The x coordinate for a site or the lower left hand corner of an element.	F4	Units are in microns.
COORDY	The y coordinate for a site or the lower left hand corner of an element.	F4	Units are in microns.
ELEMENTID	The element identifier in the SEMI M21 coordinate system	U4[2]	
M21XSIZE	The SEMI M21 element size in the x direction in µm.	F4	
M21YSIZE	The SEMI M21 element size in the y direction in µm.	F4	
SITE-ATTRIBUTE (n)	Tool specific information associated with a measurement site for which no specific MSEM data item has been defined.		Examples include information such as magnification, voltage, current, wavelength, number of scans, integration time, or film stack. The equipment supplier shall document all attributes that are supported.
SITENAME	A unique identifier for a site.	A[1..16]	

11.2.7 *DEF-LIST-TABLE Description* — DEF-LIST types of tables are used by the equipment in conjunction with the Process Programs. The DEF-LIST table structures provide a means to transfer to equipment a list of a particular type of information. The DEF-LIST table structures are used by the host to send information to equipment for later use in association with a Process Program. Each DEF-LIST that is sent has a unique Table name and each list element in the DEF-LIST has several components including a name (Site-Name, or Align-Name) as well as other components. A specific list row can be accessed for use with a specific Process Program by giving the DEF-LIST table name and the specific row name.

11.2.7.1 There are five types of DEF-LIST tables:

- SITE-DEF-LIST: A list of Sites and their attributes, typically the list of sites to be measured.
- ALIGN-DEF-LIST: A list of alignment sites and their attributes.
- M21-ELEMENT-DEF-LIST: A list of element ID and their low left hand location in M20P or SEMI M20 coordinates.
- M21-ELEMENT-SITE-DEF-LIST: A list of ElementID's and what sites are to be measured within that element.
- M21-ELEMENT-ALIGN-DEF-LIST: a list of ElementID's and the alignment sites to be used at each.

NOTE 2: The attributes are equipment-defined.

11.2.7.2 To support the SiteList, and AlignList, for SEMI M20, M20P and SEMI M21, the following types of tables must be implemented: SITE-DEF-LIST, ALIGN-DEF-LIST, or M21-ELEMENT-SITE- DEF-LIST, M21-ELEMENT-ALIGN-DEF-LIST and M21-ELEMENT-DEF-LIST. A host would send a DEF-LIST to equipment using standard transfer methods for tables as defined by ARAMS (SEMI E58). MSEM requires that the following columns be included in the DEF-LIST tables. The DEF-LIST-TABLE components table defines the DEF-LIST column names and their allowable format is given below.

Table 7 SITE-DEF-LIST

Sitename	*Coordx*	*Coordy*	*Coordsys*	*Site- Attribute(n)*

11.2.7.3 For SEMI M21 Coordinate system an additional table is required.

Table 8 M21-ELEMENT-SITE-DEF-LIST

Element id	*Sitename*

Table 9 M21-ELEMENT-DEF-LIST

Element id	*Coordx*	*Coordy*	*Coordsys*	*m21xsize*	*m21ysize*

Align-Name	*Coordx*	*Coordy*	*Coordsys*	*Align- Attribute(n)*

Table 11 M21-ELEMENT-ALIGN-DEF-LIST

Element id	*Align-Name*

12 Remote Commands

12.1 The purpose of this section is to identify the MSEM required remote commands, command parameters, and valid commands versus MSEM states.

12.2 *Requirements* — The following capabilities are required:

- StartProcessing
- Stop Processing
- Temporaly Suspend Processing
- Resume Processing
- Abort Processing
- Select Process Programs, Material and/or Sites to Measure
- Report Location of Material Found within a cassette

12.3 All the remote commands defined by MSEM are required unless they have been qualified by the statement “if the equipment supports this functionality it shall use this command”. Then, they are only required if the equipment supports the functionality necessary to support the command. A good example of this is the MAP-CASSETTE command if the equipment does not have the hardware necessary to scan a cassette for the presence of substrates in slots then the command is not required by the MSEM. The alphanumeric strings defined by MSEM for RCMD and CPNAME are required.

12.4 *Definitions*

12.4.1 *Host Command Parameter (CPNAME/CPVAL)* — a parameter name/value associated with a particular host command (S2,F49). This document will specify unique names (CPNAMEs) and values (CPVALs) for many command parameters. Note that if there are no associated parameters a zero-length list is sent.

12.5 *Remote Commands Description* — this section describes required functionality, suppliers may implement additional commands. The following remote commands (RCMDs) must be supported as described below.

NOTE 2: The terms “current cycle” and “safe point” used below are to be defined by the supplier.

12.5.1 *ABORT* — terminate the current cycle prior to its completion. Abort has the intent of immediately stopping the process and is used because of abnormal conditions. Abort makes no guarantee about the subsequent condition of material except as noted in the CPNAME ABORT-LEVEL description.

12.5.2 *CLEANUP* — Process Program deselection, removal of all material to output locations and any equipment specific activities needed to transition into the IDLE state. Completion of this command should generate a collection event report.

12.5.3 *NEXT-MATERIAL* — processing of the current substrate is halted at the first safe point and unloaded to the target cassette location. Next-material has the intent of allowing the host to skip measurement of the current substrate. This is a trigger for processing state transition from WORKING to UNLOAD.

12.5.4 *PAUSE* — suspend processing temporarily at the next safe point. Pause has the intent of resuming the process at the same point where it was paused. RESUME or PP-UPDATE may be used to resume the process.

12.5.5 *PP-ASSIGN* — instructs the equipment to assign a process to a carrier ID(s)/location(s) and place the exchange station in the process queue with the given priority. Only one assignment is allowed for a exchange station. Without specifying a priority, the material is queued with the default priority. Material with equal priority are queued in the order the PP-ASSIGN commands are received. If the equipment supports the functionality of queuing material, it will use this command.

12.5.6 *PP-SELECT* — instructs the equipment to make the requested Process Program(s) available in the execution area. Additionally, to reduce the number of Process Programs on the equipment, PP-SELECT may define the material to be measured, measurement site locations, and/or the information needed for site alignment; default values shall be used if this information is not specified. This is a trigger for the processing state transition from IDLE to SETTING UP. All Process Programs specified in the command are to be validated

12.5.7 *PP-UPDATE* — provides the ability to alter Process Program variables during the PAUSED processing state. Any CPNAMEs specified in PP-UPDATE will replace the previous definitions. This command will RESUME the process. If the PP-UPDATE fails, the Process Program variables present prior to the PP-UPDATE are retained. If no parameters values are specified, the defaults are used.

12.5.8 *RESUME* — resume processing from the point where the process was paused. This is the trigger for processing state transition 10, from PROCESS PAUSE.

12.5.9 *START* — instructs the equipment to initiate processing. This is the trigger for the processing state transition from READY to LOAD.

12.5.10 *STOP* — complete the current cycle, stop in a safe condition and return to the IDLE processing state. Stop has the intent of stopping the process entirely. The equipment is not required to support the continuation of processing.

12.6 *Host Command Parameters Names (CPNAME)*

Table 12 Host Command Parameter Table

CPNAME	*CPVAL*		
	Description	*Range*	*Format*
CARRIERBLD	L,2 1. L,2 1. CP-CARRIERID ** 2. CARRIERID or 1. L,2 1. CP- LOCATIONID ** 2. (STORAGE)ID 2. L,N 1. L,2 1. PROCESS-BLD-GROUP 2. L,M : N. L,2 1. PROCESS-BLD-GROUP ** Both CP-CARRIERID and CP-LOCATION may be included if no carrier ID reader is available.		
CP-ABORT-LEVEL	MSEM defined abort levels HALT - halt, goto ABORTED CLEANUP - halt, preform cleanup procedure, goto ABORTED	"HALT" "CLEANUP"	A[7]
CP-ALIGNLIST	L,n 1. CP-ALIGNNAME : n. For the SEMI M20 or M20P Coordinate system		
CP-ALIGN-DEF-LIST	**As defined in Section 9**		
CP-ALIGNNAME	Alignment name		A[1..80]
CP-AUTOSTART	Defines if a START command is required from an external source (operator or host) to exit the READY state. 0 = START command required, 1 = AUTOSTART no external START command required to begin execution.	0–1	U1
CP-CARRIERID	ID of carrier that the measurement data is associated with.		A[1..16]
CP-ELEMENTID	The M21 address for a specific rectangular pattern on the wafer.		I4[2]

CPNAME	*CPVAL*		
	Description	*Range*	*Format*
CP-ELEMENTLIST	L,n 1. <CP-ELEMENTID> : n.		
CP-LOCATIONID	Unique identifier of the location to be used for the "CARRIERBLD" assignment.		U4
CP-LOTID	lot id		A[1..80]
CP-MATERIALLIST	L,n 1. <CP-SLOTID or CP-WAFERID> : n.		
CP-M21-ALIGNLIST	L,n 1. CP-ALIGNNAME : n. For the SEMI M21 Coordinate system		
CP-M21-SITELIST	L,n 1. CP-SITENAME : n. For the SEMI M21 coordinate system		
CP-PPNAME	Process Program name		A[1..80]
CP-PRIORITY	assignment priority	0–9 0–highest priority	U4
CP-SITELIST	L,n 1. CP-SITENAME : n. For the SEMI M20 or M20P coordinate system		
CP-SITE-DEF-LIST	As defined in Section 9.		
CP-SITENAME	unique identifier for a site		A[1..16]
CP-SLOTID	slot number	1–n	U4
CP-SLOTLIST	Specifies carrier slots that contains substrate to measure. L,n 1. CP-SLOTID : n.	0 indicates all slots	
CP-WAFERID	Physical wafer identifier		A[1..24]

CPNAME	*CPVAL*		
	Description	*Range*	*Format*
PROCESS-BLD-GROUP	L, n 1. L, 2 1. CP-PPBUILDID 2. PPBUILDGROUPID 2. L, 2 1. CP-PPNAME 2. PPNAME 3. L, 2 1. CP-LOTID 2. LOTID 4. L, 2 1. CP-AUTOSTART 2. START 5. L, 2 1. CP-MATERIALLIST 2. L, n 1. CP-SLOTID : n. ***or*** 1. CP-WAFERID 2. L, n : n.	$n \geq 2$	List of *n* data items

CPNAME	*CPVAL*		
	Description	*Range*	*Format*
PROCESS-BUILD-GROUP(continues)	6. L, 2 1. CP-SITE-DEF-LIST 2. SITE-TABLE-NAME 7. L, 2 1. CP-SITELIST 2. L, n 1. CP-SITENAME : n. 8. L, 2 1. CP-ALIGN-DEF-LIST 2. ALIGN-TABLE-NAME 9. L, 2 1. CP-ALIGNLIST 2.L, n 1. CP-ALIGN-NAME : n. 10. L, 2 1. CP-ELEMENTLIST ** 2. L, n 1. CP-ELEMENTID : n. **CP-ELEMENTLIST is required when using the SEMI M21 coordinate system in the definition of an ALIGNNAME or SITENAME . 10. L, 2 1. CPNAME supplier defines Process Program Variable Parameters 2. CPVAL CP-PPNAME is required, CP-SLOTLIST, CP-SITELIST, and CP-ALIGNLIST are optional.		

12.7 *Remote Commands and Associated Host Command Parameters* — This table describes the allowable command parameters (CPNAME) for each remote command (RCMD). Equipment must support all parameters. The column marked Req/Opt, specifies which parameters are required to be sent by the host and which parameters may be optionally sent by the host.

Table 13 Remote Command and Associated Host Command Parameters Table

Remote Command	*Parameter(s)*		
	CPNAME	*Req/opt*	*Description*
ABORT	CP-ABORT-LEVEL	O	
CLEANUP	CP-LOCATIONID CP-SLOTID	O O	Location and SLOT may be used to define a different cassette / slot destination for the substrates.
NEXT-MATERIAL	CP-LOCATIONID CP-SLOTID	O O	If no command parameters are specified, then the substrate is returned to its original source carrier and slot. If a CP-SLOT command parameter is specified, then the substrate is placed in that slot of its original source carrier. If a CP-LOCATIONID command parameter is specified, then the substrate is placed in an available slot of the carrier at the specified location. If both CP-SLOT and CP-LOCATION command parameters are specified, then the substrate is placed in specified slot of the carrier at the specified location.
PAUSE	None	N/A	None
PP-ASSIGN	CP-PRIORITY CARRIERBLD*	O R	* More than one CARRIERBLD may be specified. There may be more than one PROCESS-BLD-GROUP in each CARRIERBLD.
PP-SELECT	CARRIERBLD*	R	* More than one CARRIERBLD may be specified. There may be more than one PROCESS-BLD-GROUP in each CARRIERBLD.
PP-UNASSIGN	CP-LOCATIONID CP- CARRIERID	R* R*	* At least one is required.
PP-UPDATE	CP-SLOTLIST CP-SITELIST CP-ALIGNLIST	R* R* R*	* At least one is required. By default use the current active input port.
RESTAGE	CP-LOCATIONID	R*	* Some equipment may not support this feature.
RESUME	None	N/A	None
START	None	N/A	None
STOP	None	N/A	None

12.8 *Remote Command and Processing State Relationship*

13 Scenarios

13.1 The purpose of this section is to document any MSEM specific scenarios that must be performed by this class of equipment.

13.2 *Normal Reporting*

COMMENTS	*HOST*	*EQUIPMENT*	*COMMENTS*
			The equipment is in the IDLE processing state and in the ONLINE REMOTE control state. Material arrives on input port 1.
PP-ASSIGN	S2,F63-->		
		<--S2,F64	Positive Acknowledge.
		<--S6,F11	IDLE -> SETTING UP
Positive Acknowledge.	S6,F12-->		
		<--S6,F11	SETTING UP -> READY
Positive Acknowledge.	S6,F12-->		
START	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	READY -> LOAD.
Positive Acknowledge.	S6,F12-->		
			[WHILE] Not End of Run
			1) LOAD->WORKING
			2) Sample and/or Site level data reporting.
			3) WORKING->UNLOAD
			4) Substrate level data reporting.
			5) UNLOAD->LOAD.
			[ENDWHILE].
		<--S6,F11	LOAD->STOPPING.
Positive Acknowledge.	S6,F12-->		
			Run level data reporting.
		<--S6,F11	STOPPING->IDLE.
Positive Acknowledge.	S6,F12-->		

13.3 *ABORT/ CLEANUP Remote Command Scenario* — Host issues the ABORT/CLEANUP remote command

COMMENTS	*HOST*	*EQUIPMENT*	*COMMENTS*
ABORT	S2,F41-->		("CLEANUP" not specified)
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	Transition to ABORTED.
Positive Acknowledge.	S6,F12-->		
CLEANUP	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
			Equipment performs cleanup activities.
		<--S6,F11	CEID is posted.
			[IF] cleanup is successful:
			Transition to IDLE
			[ELSE]
			Remain in the ABORTED state.
			[ENDIF].
Positive Acknowledge.	S6,F12-->		

13.4 *PP-UPDATE Remote Command Scenario* — Host issues the PP-UPDATE remote command.

COMMENTS	*HOST*	*EQUIPMENT*	*COMMENTS*
START	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	READY -> LOAD
Positive Acknowledge.	S6,F12-->		
			[WHILE] Not End of Run 1) LOAD->WORKING 2) WORKING->UNLOAD 3) UNLOAD->LOAD [ENDWHILE]
Sometime during the [WHILE]:			
PAUSE	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	Transition to PAUSING
Positive Acknowledge.	S6,F12-->		
		<--S6,F11	PAUSING -> PAUSED
Positive Acknowledge.	S6,F12-->		
PP-UPDATE	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
		<--S6,F11	PAUSED->CHECKING
Positive Acknowledge.	S6,F12-->		
		<--S6,F11	CEID is posted. [IF] the updates are valid: Return to the previous process state thru history [ELSE] Return to the PAUSED state. The Process Program remains unchanged. [ENDIF]
Positive Acknowledge.	S6,F12-->		

13.5 *PP-ASSIGN / PP-UNASSIGN Scenario* — Host issues the PP-ASSIGN/PP-UNASSIGN remote commands.

COMMENTS	*HOST*	*EQUIPMENT*	*COMMENTS*
PP-ASSIGN	S2,F41-->		
		<--S2,F42	Positive Acknowledge.
PP-UNASSIGN	S2,F41-->		
		<--S2,F42	Positive Acknowledge. This may occur during the STOPPING state.

13.6 The host may setup the material for additional processing without the cassette being removed and replaced on the equipment.

14 SEMI E30 Capabilities

14.1 The purpose of this section is to specify any SEMI E30 Capabilities required by MSEM class equipment.

14.2 *Requirement* — The following SEMI E30 additional capabilities required by MSEM are:

- Dynamic Event Report Configuration
- Variable Data Collection
- Status Data Collection

RELATED INFORMATION 1
SEM UNIQUE CAPABILITIES

NOTE: This related information is not an official part of SEMI E30.5 and was derived from work developed in the Metrology Specific Equipment Model Task Force in North America. This related information was approved for publication by full letter ballot on April 30, 2001.

R1-1. *Measurement Site Location* — Metrology equipment most often is used to make measurements and report results at specific sites on a substrate. Unfortunately, equipment suppliers and users have adopted different formats for describing measurement site location information. This has led to three problems which increase the cost of metrology. First, metrology equipment suppliers must provide formats which meet conflicting requirements of their customers, adding to equipment development costs. Second, users must transpose information from different systems to their own format in order to use metrology data. Third, site location information is often an integral part of recipe set up, often requiring that an actual product sample be available for "training" the site location information on the equipment. For users who manufacture many different products on common substrates, multiple metrology "recipes" must be developed where the only differences are site location information. This information is known to the user from product design data, and should not need to be "learned" uniquely on various metrology equipment.

R1-1.1 In order to avoid these problems, MSEM defines specific formats for identifying and reporting site location information on substrates. The MSEM-required formats are intended to minimize the number and type of site location format transformations needing to be supported by both metrology equipment suppliers and users. All MSEM-required site location formats involve the use of an MSEM-defined right-handed Cartesian coordinate system, established on substrates in an MSEM-defined manner. This release of MSEM defines these only for silicon wafer substrates, based on SEMI standard M20. Additional substrate types may be included in future revisions of MSEM, if required.

R1-1.2 MSEM requires that equipment have the capability to use site location information that is based on the user's product designs, which the user must provide in the appropriate MSEM-required format. In other words, equipment shall not require that a sample substrate be used to "train" site locations when users can provide this information from product design data.

R1-1.3 MSEM-compliant equipment shall have the capability to define, locate, measure, and report site information using only the MSEM-defined right-handed Cartesian coordinate system formats. This requirement does not preclude equipment from having additional capability for defining or reporting site location information using other formats. One such additional format is defined in MSEM for patterned silicon wafer substrates, based on SEMI standard SEMI M21. MSEM-compliant equipment is not required to have this "M21" format capability, but must use the MSEM "M21" format if it is provided.

R1-1.4 Specific MSEM information that defines site location information includes ; the data items AlignList and SiteList; the CPNAMEs CP-ALIGNLIST and CP-SITELIST and the TABLE type named ALIGN-DEF-LIST and SITE-DEF-LIST. Notice that multiple sites can first be Defined using the appropriate Process Program class named ALIGN-DEF-LIST or SITE-DEF-LIST, then selected by using the ALIGN-NAME or SITENAME in an MSEM defined remote command that use CP-ALIGNLIST AND CP-SITELIST. This information is similarly defined for the "M21" coordinate system plus an additional CPNAME of ELEMENTLIST which lists the ElementIDs to be measured on the silicon wafers.

R1-2 *Coordinate Systems For A Silicon Wafer*

R1-2.1 *Requirements* — MSEM defines two right-handed Cartesian coordinate systems for use on silicon wafers. These are identified as the "M20" and "M20P" coordinate systems. Both are based on SEMI standard M20. The SEMI M20 standard describes how to map a right-handed Cartesian coordinate system to a wafer so that its origin is at the center of the wafer, and its negative y-axis bisects the wafer's primary fiducial. This coordinate system is defined by MSEM to be the "M20" coordinate system. MSEM defines the "M20P" coordinate systems to be one which is aligned to the pattern on the wafer. Ideally, there is no difference between the "M20P" and "M20" coordinate system. In the real world, there is a difference, due to experimental errors. This is explained further in the following sections.

R1-2.2 *Implementation* — The only information required by equipment in order to establish an "M20" coordinate system is the wafer size and type of fiducial. This is provided by way of the MSEM data items named WaferSize and Fiducial. Another data item named Orientation provides for control over how the wafer is loaded on equipment. Note that the SEMI

M20 standard requires that the "M20" coordinate system is fixed on the wafer, and is not affected by how the wafer is loaded on equipment. Also, as stated in the SEMI M20 standard, an orientation of "0" is for a wafer loaded on equipment with the primary fiducial towards the operator or "down".

R1-2.2.1 Often, no other information is required for measurements to be made on a wafer. However, the "M20" coordinate system may not provide sufficient accuracy to locate measurement sites on patterned wafers. This is a result of any of a number of possible reasons, all of which can be described as "experimental errors". For instance, wafers are not perfectly round, fiducial dimensions may vary, and equipment (both steppers that place patterns on wafers and metrology equipment) capabilities to determine the location of the wafer center and fiducial vary.

R1-2.2.2 In order to deal with these errors, metrology equipment suppliers have developed various strategies, as discussed in the introduction section. Perhaps because the SEMI M20 standard's reference to "origins" of "other coordinate systems" is in the same sentence with "reference points", many suppliers adopted the location of one (or more) reference point(s) as the origin for their pattern-based coordinate system(s). Without a common reference site, multiple coordinate systems resulted. More nefarious strategies were developed to compensate for "stage errors" on equipment. These usually entail a series of reference points required to "zero in" on the measurement site, and this made comparison of locations determined on different equipment next to impossible.

R1-2.2.3 MSEM defines the "M20P" coordinate system to be one which is identical to the "M20" coordinate system, if there were no experimental errors. In other words, the location of the origin and axes of the "M20P" coordinate system are offset slightly from the origin and axes of the "M20" coordinate system because of experimental errors. If the location of reference points, called "alignment sites" in MSEM, is defined to be the "M20" coordinates where they are "expected" to be, and equipment is designed to be able to "find" the alignment sites, given the various possible experimental errors, the "found" and "expected" SEMI M20 coordinates can be used to determine the "M20-to-M20P" coordinate system transformation, as explained in appendix 1. Alignment site information is specified through the use of the MSEM data items named AlignList, the CPNAME CP-ALIGNLIST and, the table type named ALIGN-DEF-LIST.

R1-2.2.4 Most metrology equipment cannot distinguish whether patterned wafer site location errors are due to the wafer, the layout on the wafer, or the equipment's ability to locate the sites. However, information that is available through the use of patterned-wafer alignment sites can provide a means for identifying potential metrology equipment problems. For instance, assume that the only pattern-layout location error on a wafer is that due to the establishment of the location of the wafer center and fiducial. For many users and metrology systems, this is a good assumption. If this is the case, then the MSEM data item named XlateData can be used to track this error. Although the error may result from multiple sources, being able to track it on various metrology equipment will enable users to apply statistical process control techniques to identify the specific sources.

R1-2.2.5 Sites specified for measurements or additional alignments may be found by metrology equipment at locations which deviate from their expected locations through either pattern layout errors or metrology equipment "stage" errors. Again, in a controlled manufacturing process, these combined errors should be normally distributed, and non-normal deviations may indicate possible metrology equipment problems. These types of errors shall be reported through the use of the MSEM data item named Offset.

R1-2.2.6 A minimum of two alignment sites are necessary to establish an "M20P" coordinate system on a wafer. Additional sites are often used, as in the example given in appendix 1. The system supplier shall document the requirements for ALIGNLIST information, and detail how any "site-by-site" alignment sites (that is, those needed to obtain better location accuracy in the neighborhood of measurement site) are associated with the specific SITELIST measurement sites.

R1-2.2.7 Alignment site location information may be either provided to or by equipment. Some equipment have the capability to find and report the locations of "reference sites" without prior knowledge of their locations on the wafer. In this case, the equipment shall report the location of both alignment and measurement sites in "M20" coordinates. When alignment site information is provided to equipment to establish an "M20P" coordinate, measurement site locations shall be reported in the "M20P" coordinate system.

R1-2.2.8 MSEM encourages users to define "M20P" locations in reference to the user's device layout design within an ideal SEMI M20 wafer coordinate system. An alternative is to define "M20P" locations by "training" on a "benchmark" system.

R1-3 *Layout of Rectangular Elements on a Silicon Wafer* — Equipment shall be capable of routine, automated operation without needing wafer layout information (e.g., field or die maps). However, having the capability to provide wafer layout information to metrology equipment from the host can be desirable. In some cases, the amount of information required to define measurement site locations is less if a pattern-element-based format is used. MSEM defines a means to do this in this section, if desired, based on SEMI standard SEMI M21.

R1-3.1 SEMI standard SEMI M21, "Specification for assigning addresses to rectangular elements in a Cartesian array", is limited (for MSEM purposes) by the fact that nothing is specified about how the rectangular elements are located on the wafer. The SEMI M21 standard details how to assign "addresses" to elements and how to find the "array center" element. In this section, MSEM defines how these elements are located on a wafer, using the data item named "M21Data", and how to establish within-element coordinate systems.

R1-3.2 There are users who want or require much more layout information than is provided for by SEMI M21, such as within-element structure details or element attribute information. This additional layout information is beyond the scope of MSEM, since it is considered to be information which only is needed to aid operator-interactive use of metrology systems.

R1-3.3 *MSEM "M21" Layout* — The first pattern element layout issue to be addressed is that of determining which SEMI M21 elements are to be included in the MSEM "M21" layout. MSEM defines the "M21" layout to include all elements which either wholly or partially are within the circumference of the wafer. Thus the MSEM "M21" element layout does not correspond to the pattern layout exactly, since some "M21" elements may not contain patterns.

R1-3.4 The second layout issue is that of how best to specify the element locations on the wafer. The MSEM approach is to specify the "M20P" coordinate for the lower left corner of the minimum number of elements needed to define the layout, along with the element addresses. For a non-tiled layout, the location of a single element is sufficient to establish the "M21" layout. For tiled layouts, the location of one element in each row or column is required. Note that the location of the lower left corner of an element may be outside the circumference of the wafer.

R1-3.5 Layout definition is supported only for host-to-equipment communications. The user is responsible for ensuring that the element addresses provided to the equipment agree with the SEMI M21 specification. The equipment need not check this, other than to ensure that there are not conflicts within the provided layout, and shall report results with element addresses as provided by the user.

R1-3.6 M21 layouts are established within the "M20P" coordinate system, and need not require any additional alignment site data than is needed to establish the "M20P" coordinate system. However, as with "M20P", additional alignment may be necessary because of errors in either the pattern layout or the equipment's ability to locate features. OFFSET shall be used to report the location corrections that result from any within-element alignments.

R1-3.7 MSEM provides a means for element-based coordinate systems, if required. This capability is provided by the option of specifying "M21" as the coordinate system for ALIGN-DEF-DATA and SITEDEFDATA items. For element-based site locations, MSEM requires that SEMI M21 element coordinate systems have x and y axes parallel to the respective M20-based coordinate system axes, with their origins at the lower left corner of each element.

R1-4 *An Example of How an M20P Coordinate System is Established on a Silicon Wafer*

R1-4.1 The following example is fairly basic. For this example, the equipment does M20P alignment via a repeated two-step process. The first step is done at a low resolution, the second at a high resolution, and the process is done at two positions on the wafer.

R1-4.2 The equipment documentation states that 4 alignment sites are required. These are defined to the equipment via the table type named ALIGN-DEF-LIST, as detailed below. The order of the sites in ALIGN-DEF-LIST is not important. The sites are then selected via the CPNAME item named CP-ALIGNLIST, which is included in the PP-SELECT command. The order of the sites listed in CP-ALIGNLIST is important, and is as specified in the equipment's documentation. The first site is the alignment site for the first low resolution site, the second item is for the first high resolution site, the third item is the second low resolution site, and the fourth is the second high resolution site.

Table R1-1 ALIGN-DEF-LIST

Align-Name	*Coordx*	*Coordy*	*Coordsys*	*Align- Attribute(n)*
Coarse1	-60000	-200	M20P	
Fine1	-60020	-205	M20P	
Coarse 2	60000	200	M20P	
Fine2	59980	195	M20P	

R1-4.3 ALIGN-DEF-LIST

L,4

1. <Coarse1>
2. <Fine1>
3. <Coarse 2>
4. <Fine2>

R1-4.4 Using this information, the equipment will go to the nominal M20 location for Coarse, then "find" where it actually is. The offset between the nominal M20 location and the actual M20 location is then used to "find" Fine1. The actual M20 location of Fine1 is saved. The process is then repeated for Coarse 2 and Fine2. The equipment can now determine the M20 to M20P offset from the nominal and actual coordinates.

First, a summary of the data:

xN1=-60020	yN1=-205	Nominal x and y data for the first fine site
xA1=-59800	yA1=-150	Actual x and y data for the first fine site
xN2= 59980	yN2= 195	Nominal x and y data for the second fine site
xA2= 60060	yA2= 175	Actual x and y data for the second fine site

R1-4.5 The equipment first calculates THETA (Θ), using, for example, the formula:

$$\Theta = \tan^{-1}\left[\frac{MA - MN}{1 + MAMN}\right]$$

where MA and MN are, respectively, the slopes of the lines connecting the nominal and actual fine sites, in M20 coordinates, calculated as follows:

$$MA = \left[\frac{yA_2 - yA_1}{xA_2 - xA_1}\right] \quad MN = \left[\frac{yN_2 - yN_1}{xN_2 - xN_1}\right]$$

R1-4.6 The equipment then calculates DELTAX and DELTAY, using, for example, the formulas:

$$DELTAX = \left[\frac{C\,sin\,(\Theta) + D\,cos\,(\Theta)}{(sin\,(\Theta))^2 + (cos\,(\Theta))^2}\right]$$

$$DELTAY = \left[\frac{C\,sin\,(\Theta) - D\,cos\,(\Theta)}{(sin\,(\Theta))^2 + (cos\,(\Theta))^2}\right]$$

Where C and D are the adjusted site 1 coordinates in a rotation-adjusted coordinate system calculated, for example, using the formulas:

$$C = yA1 - ((xN1 \sin \Theta) + ((yN1 \cos \Theta)$$

$$D = xA1 - ((xN1 \cos \Theta) - ((yN1 \sin \Theta)$$

R1-4.7 The equipment can also calculate a SCALEFACTOR term to indicate the relative difference between the length of the vector connecting the nominal alignment sites and the length of the vector connecting the actual alignment sites. This can be used, for example, to judge whether there is a problem with the alignment process, since the difference between these two vectors should be small.

$$SCALEFACTOR = \frac{VA}{VN}$$

where VA and VN are the length of the vectors connecting the actual and nominal alignment sites, calculated using the formulas:

$$VN = \sqrt{\left(yN_2 - yN_1\right)^2 + \left(xN_2 - xN_1\right)^2}$$

$$VA = \sqrt{\left(yA_2 - yA_1\right)^2 + \left(xA_2 - xA_1\right)^2}$$

M20/M20P COORDINATE SYSTEMS EXAMPLE (EXAGGERATED)

MATERIAL MOVEMENT MANAGEMENT (MMM)

CONTENTS

List of Figures

SEMI E32-0997
MATERIAL MOVEMENT MANAGEMENT (MMM)

1 Introduction

Automated material movement represents a significant milestone in the evolution of automation in semiconductor manufacturing. The standardization of the transfer process is critical to the economic viability of material movement automation. This standard addresses the communications needs of the semiconductor manufacturing facility with respect to material movement.

1.1 *Purpose* — This standard addresses automated material movement on the semiconductor factory floor—the task of transporting objects (material, et al) from one processing or storage location to another. It defines the concepts of material movement, the behavior of the equipment (including transfer devices) in relation to material movement, and the messaging services which are needed to accomplish the task.

1.2 *Scope* — The scope of this standard is defined from two viewpoints. The first is the breadth of the functionality covered. The second is the depth to which it is covered.

The breadth of functionality covered by this standard is limited to the activity required to transfer an object from a location on entity "A" to a location on entity "B" under the supervision of a factory host. This transfer may occur directly between two factory process equipment, or may involve the assistance of a "transfer agent", a device dedicated to material transfer. Thus, the material movement domain includes a maximum of four types of entities (see Figure 1.1):

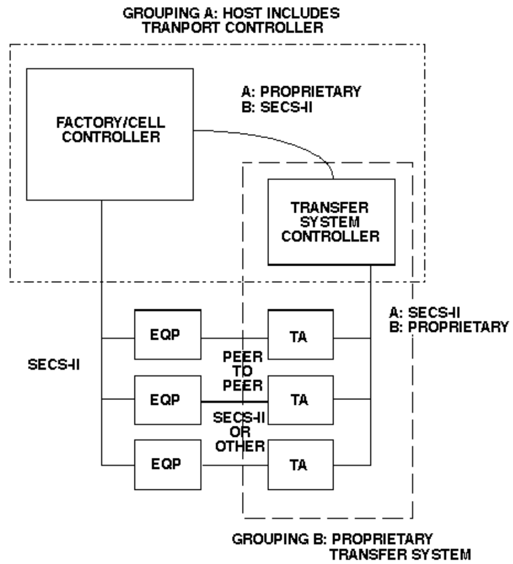

Figure 1.1
Illustration of Material Movement Scope

1. The factory host, which might, for example, be a factory controller or cell controller.
2. The set of process-related equipment, to which the host communicates.
3. The transfer agent, which performs the physical transport of the material in the factory. The transfer agent might communicate directly with the host or be controlled by an intermediate system.
4. This intermediate system, the transfer system controller, is the fourth type of entity.

This document assumes that the transfer system controller is either a part of the host or a part of a potentially complex transfer agent (as shown by the dotted boxes in Figure 1.1). Thus, the term "transfer system controller" seldom appears. The case where a "transfer agent" is actually a transfer system controller plus multiple transport devices is discussed further in Section 4.1.6.

There are some forms of material movement that do not fall within the domain of this standard and thus are not applicable to the methods described below. One example might be a non-deterministic system, such as a conveyer where generic parts are placed onto the system and circle until randomly selected by a workstation needing that type of part.

The subject of alarm reporting is not covered in this document. While material movement-related alarm situations will exist, the definition of the mechanism for reporting such alarms is left to other standards documents.

This standard presents a solution from the concepts and behavior down to the messaging services. It does not define the messaging protocol.

A messaging service includes the identification that a message shall be exchanged and definition of the data contained within that message. It does not include information on the structure of the message, how the data is represented within the message, or how the message is exchanged. This additional information is contained with the message protocol.

The defined services may be applied to multiple protocols. Information on the mapping of material movement services to specific protocols (e.g., SECS-II) are added as adjunct standards.

1.3 *References* — The following SEMI standards are related to the Material Movement standard:

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E23 — Specification for Cassette Transfer Parallel I/O Interface

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

Other References:

ISO/TR 8509:1987, Information Processing Systems, Open Systems Interconnection — Service Conventions

Harel, D., "Statecharts: A Visual Formalism for Complex Systems," Science of Computer Programming 8 (1987) 231–274[1]

1.4 *Conventions*

1.4.1 *State Models*

Definition of behavior of systems or subsystems is based upon state models using the Harel notation. A discussion of this notation is available in the article by David Harel referenced above.

The Harel notation does not include the concept of "creation" and "deletion" of state models to represent transient entities. The "transfer job" described in this document is such an entity, where each new transfer job created uses a copy of the same state model. In this document, the use of an oval is used to denote the creation of an entity and also the deletion of that entity.

Transition tables are provided in conjunction with the state diagrams to describe explicitly the nature of each state transition. A transition contains columns for Transition #, Current State, Trigger, New State, Action(s), and Comment. The "trigger" (column 3) for the transition occurs while in the "current" state. The "actions" (column 5) include a combination of (1) actions taken upon exit of the current state, (2) actions taken upon entry of the new state, and (3) actions taken which are most closely associated with the transition. No differentiation is made.

1.4.2 *Object Services* — SEMI E39 Object Services Standard (OSS) requires that standardized objects be subtypes of the Top Object, that their attributes be defined in a table format and include specification of the value for object type, and that the objects support the GetAttr and SetAttr services. See SEMI E39 for details.

1 A brief tutorial on the Harel Statechart Notation is provided as Application Note A.5 of the SEMI E30 (GEM) standard.

Standardized objects are supported by an attribute definition table with the following column headings:

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
The formal text name of the attribute.	Description of the information contained.	RO or RW	Y or N	Any valid form. (See below.)

Access — RO (Read Only) or RW (Read and Write) to indicate the access that users of the service have to the attribute.

Reqd — A "Y" or "N" in the Required (Reqt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

Form — Indicates the format of the attribute. (See Section 4.5.2 for definitions.)

2 Definitions

The following definitions are arranged in alphabetical order. Some are defined using terms defined elsewhere within this section. Please reference such definitions as needed. No references beyond this section should be necessary for a basic understanding of these terms.

Active Transfer Partner — (Opposite of Passive Transfer Partner) A transfer partner is considered active when it physically participates in the micro level portion of the transfer, either by moving the transfer object or by moving impediments within the transfer envelope (e.g., doors, clamps). This term refers to the micro level transfer phase only, and not to any setup activities prior to the transfer (e.g., a port door may be opened during setup phase by passive partner).

Atomic Transfer — The basic unit of movement. The transfer of a single transfer object from Equipment A directly to Equipment B where only one change in ownership occurs.

Compound Transfer — Combination of two or more atomic transfers executed sequentially or concurrently to achieve a single goal (e.g., exchange carriers or move a carrier between process machines using a transfer agent).

Dynamic Port — (Opposite of Static Port) A port with associated mechanisms capable of assisting with the physical movement of a transfer object or of interfering with the transfer of an object during the transfer. Such mechanisms may include doors, elevators, and robot arms. A transfer partner using a dynamic port for the transfer may be active or passive as required.

NOTE 1: The concepts of "dynamic" and "static" are associated with a port rather than equipment, as equipment may have both dynamic and static ports.

Equipment — Mechanical entity in the factory which plays a role in the manufacturing process. The equipment referenced in this document include machines used for processing, transport, and/or storage of material (see definition of material).

Host — In the context of material movement, the host is an entity, generally separate from either transfer partner, which coordinates and supervises a transfer job.

Interactive Transfer — A transfer in which both partners are active and must interact in the performance of the transfer.

Interfering — A dynamic port is interfering when any of its associated mechanisms are positioned where they are capable of physically obstructing the transfer.

Macro Level — Level of material movement that involves coordination by the host but may not require knowledge of the physical process used to accomplish the material transfer.

Material — A term used interchangeably with "transfer object" to refer to discrete objects which may be transferred to and from equipment. This may include product, carriers, reusable fixtures, etc. See transfer object definition.

Material Location — A physical position on a piece of equipment at which a transfer object may reside. Many material locations may be accessed directly through a port, but this is not a requirement. Some material locations internal to the equipment may not be accessible by a transfer agent.

Message Service/Service — A service (or a message service) represents a set of functions offered to a user by a provider. An unconfirmed service consists of a sequence of service primitives — the request from the sender to the communications facility and an indication to the receiver from the communications facility. Each of these service primitives is described by a list of parameters. A confirmed service adds a response to the initial request. The primitives for a response are called the response and the confirmation. A service excludes definition of message structure and protocol.

Micro Level — Level of material movement characterized by peer-to-peer interaction of the transfer partners to achieve synchronization of the detailed mechanical steps of material transfer.

Object — Webster's defines an object as "something perceptible." In the software world, an object is a combination of attributes and behavior. It may refer to something concrete, such as a transfer object, or to a concept, such as a transfer job.

Ownership — An equipment is said to "own" a transfer object from the time the object is transferred into one of its ports until it is transferred out of the equipment. This indicates that the equipment has physical control of the transfer object.

Passive Transfer — A transfer that involves one active and one passive partner. During a passive transfer, the active partner retains control of the transfer envelope during the entire physical transfer.

Passive Transfer Partner — (Opposite of Active Transfer Partner) A transfer partner is considered passive when it takes no part in the physical micro level transfer, moving nothing within the transfer envelope. This term refers to the physical micro level transfer phase only. Setup activities prior to the transfer may be performed by a Passive Transfer Partner (e.g., a port door may be opened during setup phase).

Port — A point on the equipment at which a change of equipment ownership of a transfer object occurs. A port is not itself a material location, but shall have an associated location. A port may be thought of as an access point to an a material location on an equipment. The definition of the term port includes any dedicated mechanisms that either prepare for, facilitate, or are capable of interfering with the transfer. All equipment shall have a minimum of one port.

NOTE 2: While they are of use to the host system, the commonly used designations "Input Port" and "Output Port" are irrelevant in the context of this document. They are based on a flow of material through an equipment rather than the movement of transfer objects (which may be carriers rather than the material itself). Transfer objects may have to be moved into and out of both these types of ports.

Receiving Port — For a specific transfer, the port into which a transfer object is to be placed.

Sending Port — For a specific transfer, the port from which a transfer object is to be removed.

Static Port — (Opposite of Dynamic Port) A port with no associated mechanisms capable of assisting or interfering with the transfer of an object. A transfer partner utilizing a static port for the transfer shall always be passive.

Transfer Agent — An equipment specialized to the transport of material from one equipment (or storage area) to another.

Transfer Envelope — The three-dimensional space occupied during the transfer by the transfer object and all associated transfer mechanisms of both transfer partners. This defines the space in which transfer activity occurs and in which the potential for physical interference with the transfer exists.

Transfer Job — The set of atomic transfers constructed by the host to accomplish a cohesive material movement objective. See the section on compound transfers below.

Transfer Object — A physical object that is transferred to and from equipment, such as a product material, an empty carrier, or a carrier containing material to be processed. Tools (e.g., stepper reticles) and expendable materials also may be transfer objects. The term "material" is used interchangeably with "transfer object."

Transfer Partners — In a given atomic transfer, the equipment sending a transfer object and the equipment receiving the transfer object are transfer partners.

Transfer Specification — The list of data provided by the host to define an atomic transfer.

Transfer System Controller — Entity that is responsible for management of multiple transfer agents. The transfer system controller presents a single communications interface to its host representing these multiple agents.

3 Overview

Material movement is concerned with the transfer of objects (WIP, tools, expendable materials, etc.) among process equipment, buffers, and storage facilities. These objects may optionally be contained (singly or in mass) within a carrier. Empty carriers may also be considered objects.

Material movement may include several different types of entities. These are divided into two classes: Host and Equipment. The host is the supervising entity which organizes the transfer and gives the appropriated instructions to each equipment involved. An equipment physically participates in the transfer, either sending or receiving material. The class of equipment may be divided into three types:

Process Equipment — Equipment which performs value-added operations on the factories' products. This includes those equipment which physically changes the product and those which measure/test the product.

Transfer Agent — A type of equipment specialized to the movement of transfer objects from place to place within a factory. Transfer agents themselves may be of different types and with widely-differing characteristics. These may be fixed-arm robots, robot arms on a fixed track, AGVs with or without robot arms, overhead gantries, cars on tracks, or even transfer systems containing a heterogenous collection of other transfer agents. Humans also may act as transfer agents.

Storage Areas — A type of equipment used to hold transfer objects pending further processing (if product) or use (if reticles, etc.) within the factory. A storage area may be as sophisticated as an automated WIP Bin or as simple as a shelf.

3.1 *Macro and Micro Levels* — Material movement is separated into two levels. The more abstract level, called the macro level, consists of all message transactions used by the host in its coordination role. At the macro level, the host is responsible for determining what material is to be moved, from where, to where, and when. The host shall provide each party involved in a transfer job with the information necessary to perform its part of that transfer job.

A transfer job may be composed of multiple handoff operations, or "Atomic Transfers." Each atomic transfer involves only two equipment, termed "Transfer Partners." In order to perform this handoff operation, the transfer partners must achieve a level of synchronization. The communications between the transfer partners is called the micro level of material movement.

These communications occur between the two partners in a "peer-to-peer" fashion. Micro communications may be implemented via a direct equipment-to-equipment connection[2] or by passing messages indirectly through the host.

The macro and micro levels are designed to work together so that the host may initiate the transfer and then allow the transfer partners to perform the job interactively. However, these two levels may be used separately. For instance, the macro level may be combined with functionality of the SEMI E23 (Cassette Transfer Parallel I/O Interface Specification) standard. Additionally, under some conditions there may not be a host coordinating the transfer. Instead, one of the transfer partners might be in control. Here, the micro level may still be used to accomplish the transfer. The controlling partner would perform the coordination functions normally in the domain of the host.

In this standard, the macro and micro levels are defined separately, each with its concepts, behavior, and services.

2 In this context, connection is intended to mean a direct logical link, rather than a hard wired connection.

3.2 *Ports and Locations* — A port may be considered a point of entry to the equipment. A location is a receptacle for a transfer object. At any time, a port shall be linked to at least one location. However, some locations may be internal and never be linked to a port.

For "typical" factory equipment, there is a permanent one-to-one correspondence between the port and a location. However, not all semiconductor equipment follows this pattern. For instance, the port on a transfer agent that includes a robot arm and multiple on-board storage locations is actually the gripper on the robot arm. The gripper is also a location. In another case, a port may actually feed a rotating carousel containing multiple locations. The port in this example would be the access door to the carousel. The location linked to this type of port would be the one in front of the door at transfer time and would change whenever the carousel rotates. Figure 3.1 helps to illustrate the difference between ports and locations.

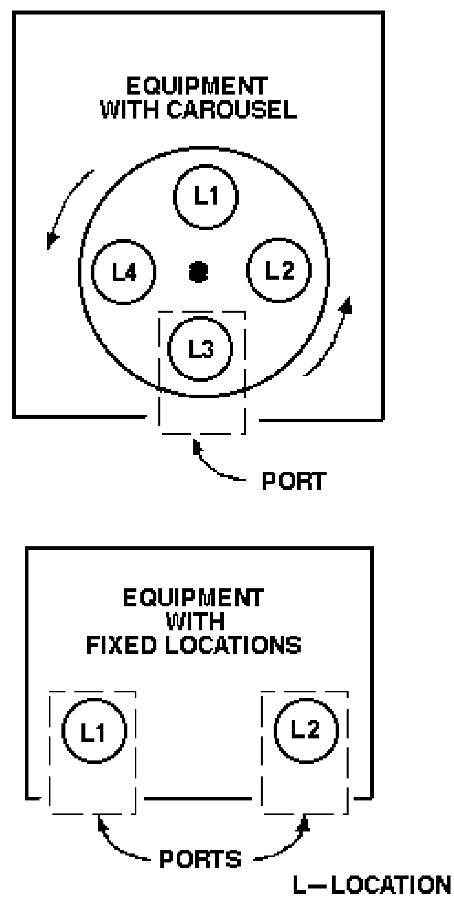

Figure 3.1
Port vs. Location

It is important to note that the attribute of “full” or “empty” belongs to a location rather than a port. A port that has just *received* a transfer object may be able to receive another immediately. Likewise, a port that has *sent* a transfer object may have more material available to send.

3.3 *Compliance* — Compliance to this standard includes adherance to all stated requirements in this document. This includes all defined messages services, state models, and communications scenarios.

This standard may be divided into two parts:

- Material Movement Macro Level, and
- Material Movement Micro Level.

An equipment may be compliant to one of these parts without the other. Details of compliance to each of these parts are defined in the body of this document.

4 Macro Level

The set of host<->equipment interactions needed to facilitate a transfer is called the macro level. These interactions concentrate on the definition of the transfer specification, and leave the details of the physical transfer to the micro level interactions.

In addition to the services defined in Section 4, the GetAttr service defined by SEMI E39, Object Services Standard, is supported by this standard. The definition for the GetAttribute service defined in Section 4 will be removed and no longer supported in 1998.

4.1 *Macro Level Concepts* — The macro level is designed with the intent of creating a widely applicable, host coordinated material movement capability. The result is a sequence of interactions from host to equipment that is used to accomplish the coordination of material movement required on the manufacturing floor.

The elements of material movement common to all transfers make up the framework. Other elements which differ from implementation–to–implementation are pushed, as much as possible, into the data portions of communications. The common elements identified are as follows:

- The host is responsible for designating the transfer partners which are compatible for transfer.
- The host must supply the necessary information for the transfer to each partner.
- Once transfer is defined, the responsibility moves to the transfer partners, especially the designated “primary” partner[3] . The host may monitor the transfer, but leaves the details to the transfer partners.
- The transfer partners inform the host of milestones during the process and of process completion.

Some of the elements which are more implementation-specific are:

- Which partner is the sender and which is the receiver of material. This has no intrinsic relationship to other details, such as the selection of the primary transfer partner.
- Whether a transfer partner is passive or actively participates in the transfer. This also becomes a data issue.
- The method (mechanism) of an interactive transfer. This may vary depending on the transfer partners' capabilities and system design. Interaction with different partners may require different methods. Transfer recipes containing this information may be specified by the host as a part of the transfer specification.

The host must have some knowledge of the capabilities of the transfer partners it designates to perform a transfer. It must understand which partners are compatible. If compatible, it must know the proper role for each partner of the transfer and what methods must be used. If an interactive transfer is warranted, the host must be able to determine which partner should be the primary. Definition of the mechanism for such determinations by the host is beyond the scope of this document.

4.1.1 *Macro Level Definitions*

Abort — The immediate termination of an active job, including a complete stop of all transfer job-related movement. An abort may be initiated by the host (and optionally by the operator). An abort by the host is directed at a transfer job, not at an individual atomic transfer. When told to abort, a transfer job shall, in turn, abort its atomic transfers. The abort command is intended to be used only in situations where there is risk of material or hardware damage.

Allocate — The formal reservation of an entity's resources for a specific purpose. In this document, it refers to the reservation of an equipment's resources for a specific transfer job or atomic transfer. Allocation of needed material locations for a transfer job occurs just prior to that job becoming active. Allocation of required port-related resources occurs just prior to the start of an atomic transfer.

Commit — The commit by the equipment indicates a readiness to begin the actual material handoff. The

3 See the definition for “primary transfer partner” in Section 4.1.1.

commit follows any setup activities and coincides with entry to the HANDOFF state. For example, an AGV may not be allowed to commit until it has moved to the point of transfer. The point at which an equipment may commit is equipment-specific. There is a separate commit for each atomic transfer in a job.

Deallocate — The release of allocated resources. In this document, it refers to the equipment's release of the resources reserved for a transfer job or an atomic transfer.

Port Resources — Equipment-controlled mechanisms that serve a port. An example of a port resource is a cassette indexer that changes to elevation of the material location. A port resource is available only to the atomic transfer that has allocated that port.

Primary Transfer Partner — The partner that controls the micro level transfer and that would receive the optional host command to initiate the transfer. The primary transfer partner shall always be an active partner for the transfer. For an interactive transfer, the nature of the transfer partners may determine which should be primary. Otherwise, the host may choose.

Restore — An operation associated with a transfer job which causes the resources used by that job to be returned to the preferred idle conditions (e.g., port access door closed). When a transfer job involves multiple ports on an equipment, restore activities are done on a port-by-port basis as each port is no longer needed by the transfer job.

Secondary Transfer Partner — The opposite of the primary transfer partner. This partner is either passive during the transfer or is controlled by the primary transfer partner. If active, this partner shall await communications from the primary partner before acting (see micro level).

Setup — A process associated with an atomic transfer that causes the port resources to achieve required pre–transfer conditions (e.g., port access door open).

Stop — A command available to the host that causes an orderly termination of a transfer job. Upon receipt of a stop command, the equipment shall complete all currently active atomic transfers, execute the "restore" process, and then terminate.

4.1.2 *Atomic Transfer* — An atomic transfer is the handoff of a transfer object from one equipment to another. This is the fundamental building block of material movement. An atomic transfer includes the minimum number of physical participants in the move: one sender and one receiver. Thus, only one change of ownership shall occur in an atomic transfer. All transfers required in practice can be constructed as a series of atomic transfers. A set of atomic transfers combined to make a complex but cohesive transfer is called a compound transfer.

4.1.3 *Compound Transfer* — On the factory floor, many material transfer situations will require multiple atomic transfers. For example, the host may determine that a material carrier needs to be moved from equipment "X" to equipment "Y" by transfer agent "T." To accomplish the transfer would require two atomic transfers, first "T" acquires the carrier from "X," then it delivers it to "Y." A compound transfer might involve several equipment and include parallel as well as sequential execution of atomic transfers.

4.1.4 *Parallel Transfers* — Each port on an equipment is a separate entity. It is possible, within the limitations of the equipment and transfer agents, to execute parallel transfers involving separate ports on an equipment. These parallel transfers may be with the same transfer partner, or with multiple partners. There are no inherent restrictions to a transfer job simultaneously executing multiple atomic transfers on an equipment. If an equipment's ports are static (i.e., always passive), the equipment should allow parallel transfers. If the ports are dynamic, there may be some sharing of resources which could limit this (e.g., use of the same robot arm). An equipment is not required to allow parallel transfers.

4.1.5 *Transfer Recipe* — The transfer recipe is an element of the transfer specification. The scope of a transfer recipe is one atomic transfer. A transfer recipe may contain information defining the following aspects of a transfer:

- setup/restore operations,
- sequence of handoff operations (see micro level),
- micro level commands to be issued by the primary partner to the secondary transfer partner,
- parameters relating to the transfer.

Thus, the host may use the transfer recipe to communicate the details that make it possible to prepare for and carry out the micro level transfer.

Use of transfer recipes is not a requirement. However, these recipes provide for dynamically "programming" an equipment to interact properly with what may be a completely different type of equipment. For instance, it may be possible to "teach" one transfer partner the proprietary commands that the other partner understands by embedding those commands in a transfer recipe. During the transfer, the primary partner could issue those commands at the proper time using standard micro level messages (see Section 5).

Transfer recipes should be created and managed according to applicable SEMI standards and in a similar manner to other types of recipes on the equipment (e.g., process recipes).

4.1.6 *Transfer System Controller as Transfer Agent* — A transfer agent is an entity to which transfer-related commands are given in order to carry out transfer jobs. A transfer system, which might include several material transport devices, can be described the same way. However, there are some important differences.

There are a number of ways that a host could view a transport system, including:

- as a single transfer agent with numerous ports,
- as a single transfer agent with a single port and numerous internal locations,
- as multiple logical transfer agents with their own ports, or
- as the set of real transfer agents that the transfer system controls.

The transfer system may conceal from the host the various internal operations (e.g., handoffs, travel paths) that it uses to complete a transfer. It may even hide the actual physical location (or series of locations) and provide a logical location for host reference.

4.1.7 *Transfer Job* — The host's material transfer objectives are defined in a transfer job. This transfer job may be a single atomic transfer or a compound transfer. A compound transfer job consists of multiple atomic transfers grouped together to accomplish a more complex objective. A typical compound transfer may also be accomplished by creating a separate transfer job for each required atomic transfer. The decision to group atomic transfers into a transfer job is application-dependent.

The key advantages to the use of compound transfer jobs are the reduction of the communication overhead to the host and the streamlining of the transfer process. The communication overhead is reduced by the fact that the host can define a number of atomic transfer operations with a single message to the equipment. The equipment are not required to wait for host commands between these atomic transfers.

The process is streamlined by virtue of the removal of redundant physical activities during the transfer job. Total setup and restore time for a port may be reduced if the setup for consecutive atomic transfers is similar.

One example of streamlining would be the "exchange" of carriers between equipment, where a transfer agent might bring an empty carrier to replace a full carrier on the "output port" of a machine. If the port has a door that is opened during transfer preparation and closed during the restore phase, the door would be better left open for both atomic transfers. Upon completion of the removal of the first transfer object, rather than close the door, the new transfer is begun and the door left open. The two atomic transfers would thus be executed as one smooth "swap" transfer without wasted time.

Equipment View of Transfer Job — A transfer job may involve a number of equipment and ports. Each of the involved equipment is given a Transfer Job Create request that specifies only the portion of the overall transfer job that involves that equipment. Only the host is guaranteed a complete picture of a compound transfer. In the example where a transfer job was created to move a transfer object from "X" to "Y" via transfer agent "T,"

- "X" would see send material to "T,"
- "Y" would see receive material from "T," and
- "T" would see get material from "X" and put material on "Y."

Atomic Transfer Sequencing Guidelines — When the transfer job given to an equipment contains multiple atomic transfers, the guidelines for performing those transfers are:

- Atomic transfers for a specified port are performed in the sequence given.
- When a transfer job references multiple ports on the equipment, these ports may execute their atomic job sequences in parallel to the other ports.

See Figure 4.1 for an illustration of the flow of a complex transfer job from the view of one equipment. The three parallel paths show a possible chronology for a transfer job.

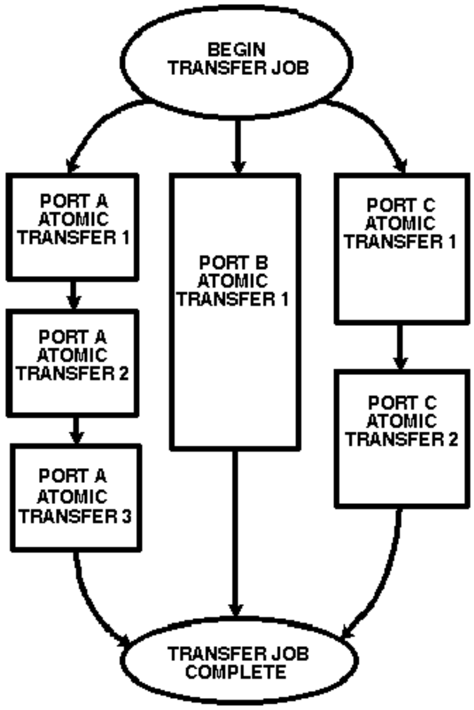

Figure 4.1
Transfer Job Sequencing

There are exceptions to the sequencing guidelines above. One case would be a device designed to simultaneously transfer from multiple ports on one machine to corresponding ports on another. This would translate into synchronized parallel atomic transfers on separate ports. Another case would be two atomic transfers involving the same port that might happen concurrently. That is, a transfer object is transferred out of the port at the same time[4] another is transferred in. In either of these cases, the equipment is responsible for:

1. recognizing that such transfers can and should be combined and
2. synchronizing the execution of the transfers.

Multiple Transfer Jobs — Multiple transfer jobs may exist simultaneously on an equipment. Although not a requirement, an equipment may

1. queue transfer jobs for later execution or
2. allow them to execute in parallel with other transfer jobs.

4 "At The Same Time" in this case means that both atomic transfers are in progress. It does not imply that both transfer objects must move simultaneously.

Queued transfer jobs and parallel transfer jobs are separate concepts, either of which may be supported.

Resource Allocation/Deallocation — Transfer jobs allocate the needed material locations prior to beginning. These material locations remain allocated until the transfer job chooses to release them. In many cases, a material location is physically linked with a single port, and the allocation of that location infers allocation of the port. However, this is not a requirement.

If the material locations for a transfer job are not available or are not in the proper state, the job shall be rejected or queued (if queuing supported and queue not full). For the transfer job to begin, each location referenced in the equipment's transfer job must contain the proper material for the first atomic transfer which would use that location.

If parallel transfer jobs are supported and the necessary locations are available, a second (or third, etc.) transfer job may begin execution.

In some cases a port may provide direct access to multiple locations. This may be true for the specialized ports described in Section 3.2 and in cases where the port serves as a pass–through to internal locations. For each atomic transfer, the needed port and its resources are allocated just prior to the start and released (deallocated) at the end of that atomic transfer.

4.2 *Macro Level Behavior*

4.2.1 *Macro Level Communications* — This section provides a high-level definition of the communications between the host and each transfer partner needed to achieve the macro level of material transport. This is not intended to define the messages, but rather to describe the concepts. The message detail is addressed in the Macro Level Services Section (4.4). Section 4.2.2 shows how these messages are integrated into the transfer job behavior model.

First, the control message flow is presented as Figure 4.2. Then additional informational messaging is described (see Figure 4.3). The arrows represent significant information exchange. Some replies that do not contain significant information may not be shown.

The ordering of the messages between one partner and host shall be retained. The key synchronization point between the partners at the macro level is that both partners shall complete their setup activities before the "atomic transfer started" event may occur.

4.2.1.1 *Macro Level Job Control* — Figure 4.2 illustrates the job control-related message flow expected on a normal transfer as seen by the host. These messages are used to control the material movement process. This diagram assumes a simple transfer job involving only two partners and only one port on each. It also assumes that the partners take the same role (primary or secondary) for each atomic transfer that occurs. The messaging is no different if these assumptions are not made, but diagrams become quite difficult to create.

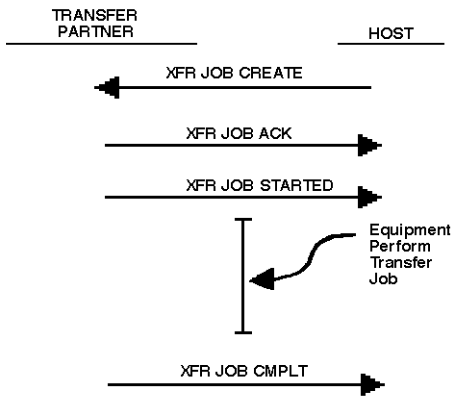

Figure 4.2
Macro Level Message Flow

Transfer Job Create — The host requests that the device participate in a specified transfer job. This may consist of a single atomic transfer or a compound job. This request may be acted upon immediately, or, if necessary resources are currently busy, saved for later execution[5]. The request shall supply a transfer specification for each atomic transfer, in which the host supplies such information as

- which port is to be used,
- whether the port is to send or receive material,
- identification of the material to be transferred,
- role of the equipment (primary or secondary transfer partner),
- mechanism or recipe to be used in the transfer,
- identification of the other transfer partner, and
- an identifier for the atomic transfer.

Upon receipt of the Transfer Job Create request and before acknowledging, the equipment should check the transfer specification(s) to ensure that they are valid. That is, that the specified parameters (ports, transfer recipes, role of the equipment, etc.) have legal values. Depending upon its ability to queue jobs, it may check such dynamic information as presence of transfer object, availability of resources, etc. to determine whether to accept or reject.

Transfer Job Create Acknowledge — The equipment responds to the host that the requested job is accepted or rejected, and if rejected, supplies the reason.

Transfer Job Complete — Once a transfer partner completes the restore operation, it declares the transfer job to be complete. This message is also used should a transfer job end abnormally. It declares the end of job. All movement of the involved mechanisms shall have ceased before this message is sent. This message shall provide information on the success or failure of the transfer.

Transfer Job Started — This message marks the beginning of the transfer job. It signifies that the setup activities for the first atomic transfer are beginning.

Get Attribute — The host may request information relating to a specific job. This may include portions of the transfer specification and current status information.

4.2.1.2 *Macro Level Information Messaging* — There are a number of material transfer-related events which may be of significance to the host. These are designated as "collection events" and shall be available for reporting to the host. This section describes those collection events and shows how they fit into the chronology of a transfer job. Refer to Figure 4.3 as each event is described.

Collection event messages provide valuable information to the host, but are not strictly required to perform material movement. Therefore, it is expected that some message protocol implementations will provide a method by which the factory host may disable those events which are not needed in a particular implementation.

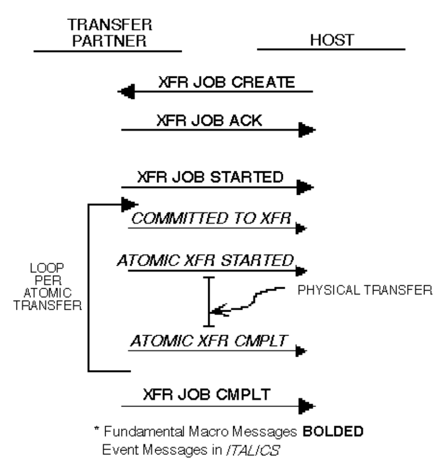

Figure 4.3
Macro Level Messaging With Events

5 If the equipment does not support queuing or if the queue is full, the request may be rejected.

Committed To Transfer — The equipment informs the host when it is fully prepared for a specific atomic transfer. This signifies the completion of the setup activities. It does not indicate that the two transfer partners have agreed to begin the physical handoff. This event coincides with the "Transfer Ready" message defined in the micro level (see Section 5 below).

Atomic Transfer Started — The transfer partners inform the host, via an event, when the atomic transfer has begun[6] . This may represent a logical start rather than physical movement. This indicates that any necessary coordination of the transfer partners has been done to ensure that the atomic transfer may start. A secondary partner may sense the start of transfer later than the primary partner.

NOTE 3: The physical transfer begins following the Atomic Transfer Started event and ends prior to the Atomic Transfer Complete event message.

Atomic Transfer Complete — This event indicates that an atomic transfer has completed. This indicates that either the next atomic transfer for this port will begin the setup phase, or, if none remain, restore activities may begin.

4.2.2 *Transfer Job State Model* — Message flow diagrams are useful to show simple situations. Material movement may range from very simple to quite complex. The transfer job state model presented in this section provides the information necessary to extrapolate the message flow diagrams above to fit all situations within the scope of this report. It does not cover the states of the various hardware which may exist (e.g., elevators, doors). See Section A1-1 for a discussion of the port hardware and related mechanisms.

The state model notation used in this report is that defined by Harel and is described in a reference cited in Section 1.3 above.

The transfer job is a transient entity. It is created by the host (Transfer Job Create message), executes, and then is dissolved by the equipment.

Figure 4.4 shows a basic state diagram for a transfer job. The ovals at top and bottom show where the job is created and then deleted. The portion between the ovals is standard Harel notation. This model is from an equipment view and assumes that only one port on the equipment is used by the transfer. It also assumes that pause, resume, abort, and stop activities do not exist (these are addressed later in the document).

6 The primary transfer partner will determine readiness to start based on micro level handshaking with the secondary transfer partner.

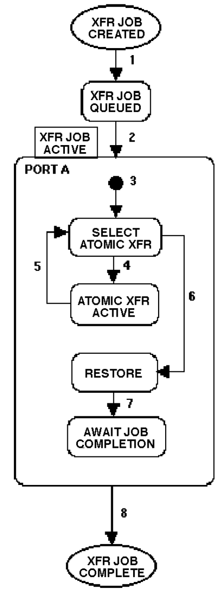

Figure 4.4
Transfer Job State Diagram for a Single Port

State definitions and then the state transition table follow.

TRANSFER JOB QUEUED

In this state, the transfer job has been accepted by the equipment through the Transfer Job Create/Acknowledge messages and is awaiting execution. Transfer jobs are begun sequentially in the order received by the equipment. Execution may not begin until all previously queued transfer jobs have been started and the material locations needed for this transfer job may be allocated.

All transfer jobs pass through this state. If the equipment allows queuing of transfer jobs, they may remain in this state for prolonged periods. A transfer job remains queued until the material locations needed for that transfer are available.

TRANSFER JOB ACTIVE

In the TRANSFER JOB ACTIVE state, all atomic transfers defined in the transfer job are performed.

PORT A

This substate of TRANSFER JOB ACTIVE encloses the job activities related to a single port on the equipment. Within this state, the atomic transfers involving this port are executed sequentially (except as noted in Section 4.1.7 under Atomic Transfer Sequencing Guidelines). Substates of PORT A (or PORT B, etc.) include SELECT ATOMIC

TRANSFER, ATOMIC TRANSFER ACTIVE, RESTORE, and AWAIT JOB COMPLETION.

SELECT ATOMIC TRANSFER

In this state, the next atomic transfer for this port is selected. Any prerequisites for the atomic transfer are checked (e.g., is material XYZ in Port A, Location 1). Atomic transfers are executed sequentially per port (except as noted in Section 4.1.7 under Atomic Transfer Sequencing Guidelines).

Prior to exiting this state, the port resources for the selected atomic transfer are allocated.

If no atomic transfer is ready for selection (e.g., the port resources are not available), the transfer job shall remain in this state, awaiting a change in conditions which would allow an atomic transfer to be selected.

ATOMIC TRANSFER ACTIVE

In this state, the next atomic transfer for this port is executed. See the atomic transfer state model for details on this process.

RESTORE

While in the RESTORE substate, the equipment shall perform any necessary post–transfer operations to return the port to the desired idle condition. These tend to be physical activities. No physical actions are required for restore, but some mechanism for determining port status is recommended.

The setup[7] and restore operations are expected to be "goal oriented," that is, oriented toward satisfying specific conditions (e.g., states such as "door open"). They should not depend on a fixed sequence of actions such as "initiate the door opening mechanism." Thus, a port left in a post–transfer condition from a previous atomic transfer would still be able to prepare properly for the next.

When queuing is allowed, the equipment may provide a look ahead capability so it may alter its restore phase to better accommodate the next transfer job. Such functionality is not required.

AWAIT JOB COMPLETION

In this substate, all atomic transfers on this port for the transfer job have completed. The transfer job continues to exist until all ports have completed their atomic transfers and restore operations. If only one port is used, this state will be occupied only briefly.

The following transition table defines the transitions between states for the transfer job state model. It applies to Figures 4.4 and 4.5.

7 Setup is more fully described in Section 4.2.3.

Table 4.1 Transfer Job State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
1	(Transfer Job Created)	The equipment accepts a Transfer Job from the host.	TRANSFER JOB QUEUED	Place the transfer job in the queue.	None.
2	TRANSFER JOB QUEUED	Necessary material locations have been allocated to transfer job and any equipment-specific prerequisites met.	TRANSFER JOB ACTIVE	Remove the transfer job from the queue. Send "Transfer Job Started" message.	None.
3	Any...	Default entry into the PORT A (or PORT B, etc.) state	SELECT ATOMIC TRANSFER	All atomic transfers are queued (by port).	None.
4	SELECT ATOMIC TRANSFER	Atomic transfer selected for execution on this port.	ATOMIC TRANSFER ACTIVE	Cause selected atomic transfer to transition from queued to setup.	See Sec. 4.2.3 for the atomic transfer state model.
5	ATOMIC TRANSFER ACTIVE	Atomic transfer complete event from the atomic transfer state model.	SELECT ATOMIC TRANSFER	None.	None.
6	SELECT ATOMIC TRANSFER	No atomic transfers remain for this port.	RESTORE	None.	None.
7	RESTORE	Port returned to desired idle conditions.	AWAIT JOB COMPLETION	None.	None.
8	TRANSFER JOB ACTIVE	All atomic transfers for the transfer job are completed.	(Transfer Job Complete)	Send "Transfer Job Complete" message.	None.

Figure 4.5 begins with the model in Figure 4.4 and is expanded to cover a transfer job with multiple ports. Each transfer job, as seen by the equipment, may include from one port to the total number of ports on the equipment.

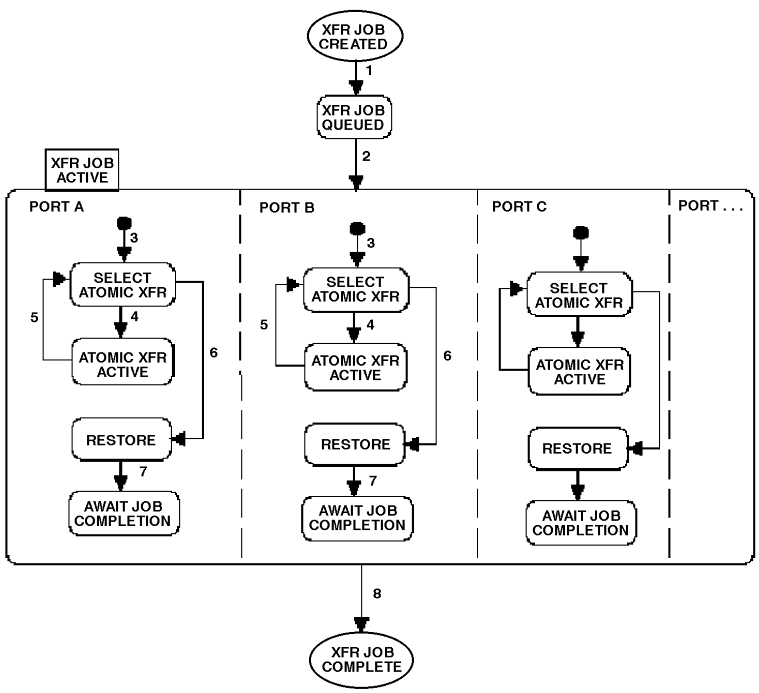

Figure 4.5
Transfer Job State Model for Multiple Ports

4.2.3 *Atomic Transfer State Model* — When a transfer job becomes active, it creates a queue of atomic transfers for each port (see Transition 2 of the transfer job state model). These atomic transfers are executed as described in the transfer job state model above. This section describes the behavior of the atomic transfer as it is created, executed, and finally deleted.

Figure 4.6 shows the state model for an atomic transfer as it moves through its life cycle. Each atomic transfer of an active transfer job is represented by a separate copy of this state model. These state models are not substates of the transfer job state model. Rather, transfer job and atomic transfers are separate entities which interact.

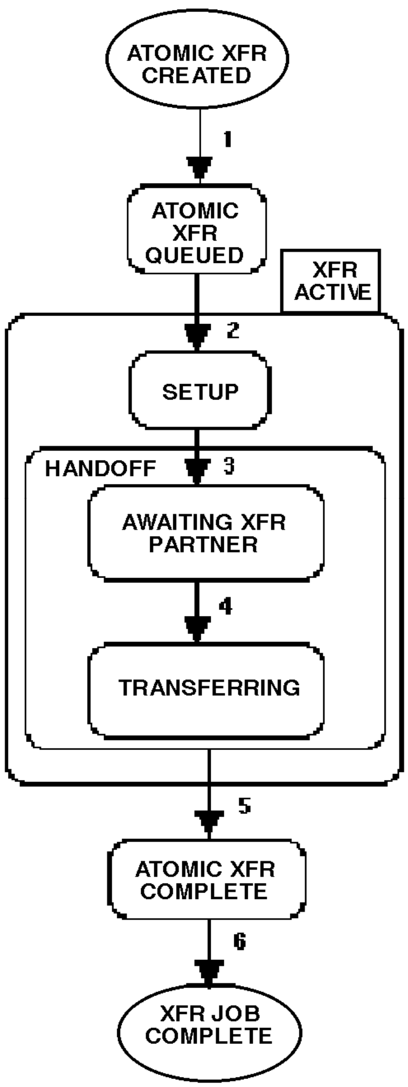

Figure 4.6
Atomic Transfer State Diagram

The definitions for the states and state transitions follow.

ATOMIC TRANSFER QUEUED

In this state, the atomic transfer is awaiting its turn to execute at the port.

TRANSFER ACTIVE

In this state, the transfer job has activated this atomic transfer. The atomic transfer is performed entirely within this state. The substates of TRANSFER ACTIVE are SETUP and HANDOFF.

The TRANSFER ACTIVE state in this model corresponds to the ATOMIC TRANSFER ACTIVE state in the transfer job state model. Thus, when the transfer job activates an atomic transfer on a port, both state models shall be in the (ATOMIC) TRANSFER ACTIVE state during the atomic transfer. This applies only to the specific atomic transfer being performed.

SETUP

While in the SETUP substate, the equipment performs any pre–transfer setup operations necessary for the current atomic transfer. These operations might include (but are not limited to) opening doors, unclamping carriers, and homing elevators. For transfer agents, it is reasonable to include as part of the setup such actions as a transfer agent moving into position near a specified process equipment.

The setup and restore[8] operations are expected to be "goal oriented," that is, oriented toward satisfying specific conditions (e.g., states such as "door open"). They should not depend on a fixed sequence of actions such as "initiate the door opening mechanism." Thus, a port left in a post–transfer condition from a previous atomic transfer would still be able to prepare properly for the next.

If no setup time is required for the transfer, this state may be exited immediately. This is the case for a static port since it can perform no physical actions related to setup.

HANDOFF

The equipment is committed to the transfer when no setup operations remain and the port is capable of performing the transfer. Entry into the HANDOFF state indicates that the port shall take no further action without the (expressed or implicit) cooperation of its transfer partner. Both transfer partners shall be in the HANDOFF state when the atomic transfer begins.

8 Restore is described in Section 4.2.2.

The HANDOFF substate is divided into two further substates: AWAITING TRANSFER PARTNER AND TRANSFERRING.

NOTE: If one transfer partner has not yet reached the HANDOFF substate when the other begins the transfer, interference could occur on the part of the uncommitted partner, with potential to damage equipment or material. The micro level Transfer Ready exchange will help prevent this (see Section 5 below).

AWAITING TRANSFER PARTNER

Once the port is ready for the transfer, the AWAITING TRANSFER PARTNER substate is entered. The port shall remain in this state until its transfer partner is ready.

TRANSFERRING

In this state, the physical handoff portion of the atomic transfer is in progress. Most micro level coordination occurs while the transfer partners are both in the TRANSFERRING state.

ATOMIC TRANSFER COMPLETE

In this state, the atomic transfer has completed and is awaiting the completion of the job. Upon entry to this state, the equipment shall release (deallocate) the port resources used for this atomic transfer. It shall also deallocate any material location used by this atomic transfer that is not needed by any further atomic transfer in this transfer job. This state exists primarily to allow the host to poll for current status of the individual atomic transfers (there is no status if the atomic transfer no longer exists).

The following transition table defines the transitions between states for the atomic transfer state model. It applies to Figure 4.6.

Table 4.2 Atomic Transfer State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
1	(Atomic Transfer Created)	The parent transfer job becomes active (see Table 4.1).	ATOMIC TRANSFER QUEUED	None.	None.
2	ATOMIC TRANSFER QUEUED	The parent transfer job selects this atomic transfer as next for a port and transitions to ATOMIC TRANSFER ACTIVE.	SETUP	None.	None.
3	SETUP	All preparation for this atomic transfer is complete.	AWAITING TRANSFER PARTNER	None.	"Committed To Transfer" event occurs. See micro level Transfer Ready message.
4	AWAITING TRANSFER PARTNER	Transfer partner is ready for transfer (see micro level).	TRANSFERRING	None.	"Atomic Transfer Started" event occurs. This transition might not occur for a static port.
5	HANDOFF	The atomic transfer is completed.	ATOMIC TRANSFER COMPLETE	None.	The "Atomic Transfer Complete" event occurs. This transition will occur after the appearance or removal of the material at the port. See the micro level Transfer Verify message.
6	ATOMIC TRANSFER COMPLETE	The parent transfer job is completed.	(Transfer Job complete)	The atomic transfer is deleted.	After this transition, the equipment maintains no status of the atomic transition.

4.3 *Extended Behavior Models* — In this section, the concepts of Pause/Resume, Stop/Cancel/Abort, and AutoStart/StartHandoff are added to the state models for the transfer job and the atomic transfer. In addition, the possibility that some transfers will end abnormally is discussed. While not every implementation requires these capabilities, all face the prospect of problems during transfer. This section describes how the basic state models provided above may be extended to include such features.

4.3.1 *Extended Communications* — This section describes the new commands the host may use to affect current transfer jobs and the events associated with these new capabilities.

Pause — The host may issue a command to pause a transfer job[9]. A command to pause shall cause the subject to continue to the first safe, continuable pausing place and then cease activity. The pause shall occur only at points that allow for the resumption of the activity (see the resume command). Pausing a transfer job results in the pausing of each atomic transfer for that transfer job (see Figure 4.8). The points where a pause may fall should be defined by the supplier. Note that a paused transfer job may be aborted or stopped as an alternative to the resume command. In this case, the stop command may cause the equivalent of a resume in order to allow the current atomic transfers to complete.

There are two actions that may cause a pause. The first is a host command as described in the paragraph above. The second is a decision by the equipment that a problem exists that requires outside intervention. For instance, if a port hardware problem exists, the equipment may pause the job automatically. The user or host may then resume the transfer job when the hardware problem is corrected, or alternately abort/stop the transfer job if the problem is severe.

Resume — The resume command is used to continue a previously paused transfer activity.

Stop — The host may command the involved partners to stop a transfer job. The stop command terminates a job in an orderly manner. The object of the stop command is to complete currently executing atomic transfers and leave the equipment and material in a safe state. While the time needed to stop should be kept as short as possible, this goal should be a lower priority.

If the specified transfer job is queued, the stop command acts as a cancel command.

9 It is expected that a host may also pause a port or other hardware. However, this document does not specify these hardware-related commands.

Cancel — The host may cancel a transfer job which has not yet become active (e.g., a job which is queued). This is useful when it is unacceptable to affect transfer which is in–progress. A canceled job is removed from the queue and discarded. No physical action may be associated with canceling a transfer job. If the specified transfer job is active, the equipment shall reject this command.

Abort — The host may command the involved partners to abort a transfer job. The goal of the abort command is to end the transfer activities (especially movement) as quickly as possible, while retaining equipment and material integrity. Aborting a transfer job shall cause the individual atomic transfers to also abort. As with stop, the abort command terminates the transfer job. Different from the stop command is that equipment executing an abort command shall require manual intervention before further material movement operations are performed. Abort is intended for use when serious problems are detected and further damage needs to be prevented.

The abort command takes precedence over the stop, pause, and cancel commands. If the specified transfer job is queued, the abort command acts as a cancel command.

Transfer Job Create — The Transfer Job Create is not new, but is extended to include the "AutoStart" option. There is a parameter added to each atomic transfer definition which allows selection of this option. If not selected, the atomic transfer shall enter a WAIT state after completing SETUP operations, but before informing its transfer partner that it is ready to begin. An event signals the host that the equipment is awaiting instructions.

This feature allows the host added flexibility in synchronizing material movement activities. The host may manually synchronize two transfer partners or it may wish to align a material movement activity with another equipment or factory-related activity.

StartHandoff — The StartHandoff command is issued by the host to cause a specific atomic transfer to transition from the WAIT state to the TRANSFER ACTIVE state.

4.3.2 *Extended Transfer Job State Model* — Figure 4.7 presents an extended transfer job state model. This model provides for the capability to pause/resume, stop, and abort. Except for the extensions, this model is the same as that in Figure 4.5. Therefore, only the extensions are discussed in this section.

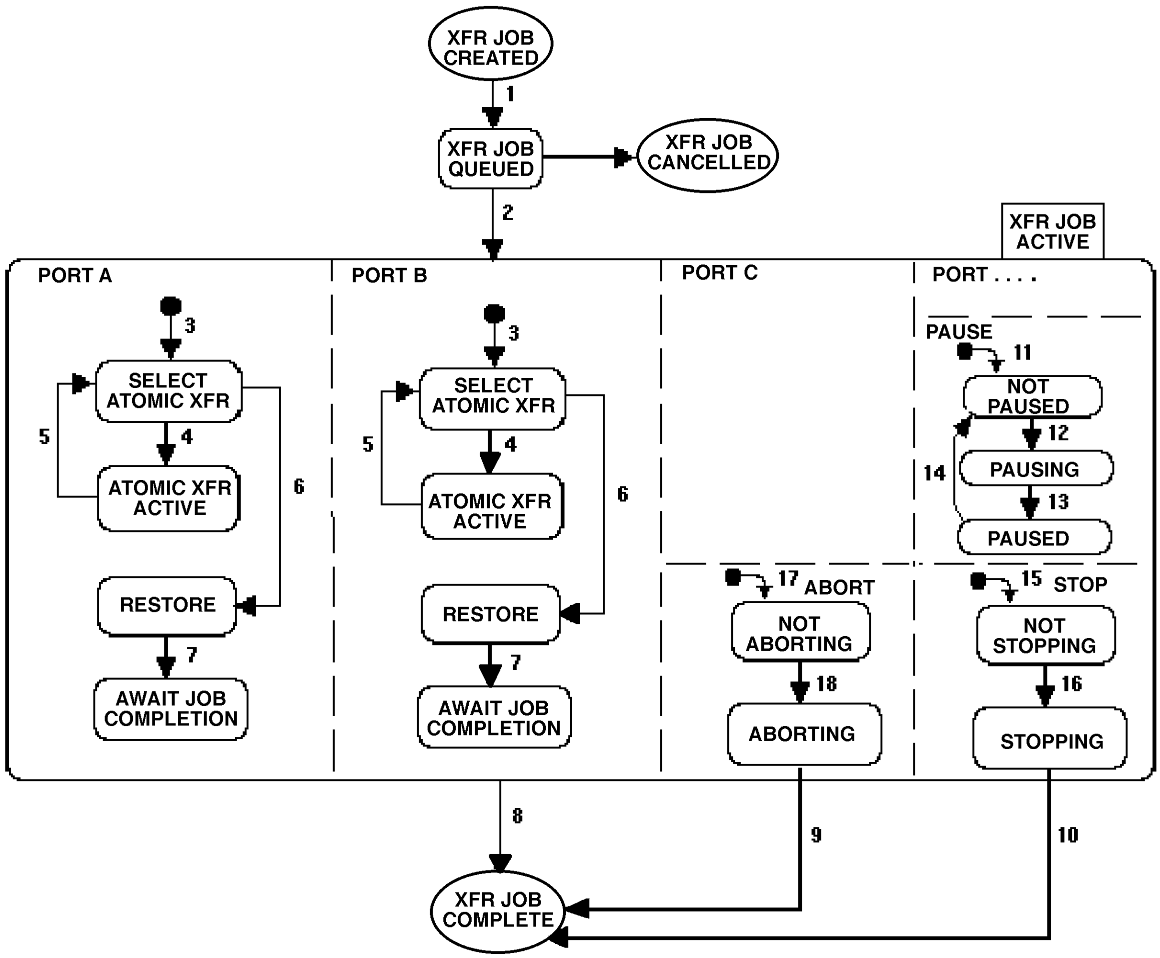

Figure 4.7
Extended Transfer Job State Model

ABORT

The ABORT state is an AND substate of TRANSFER JOB ACTIVE. This state is responsible for coordination of any activities necessary to abort[10] the active transfer job. The ABORT state has two substates: NOT ABORTING and ABORTING.

NOT ABORTING

In this state, the abort process is not in effect. The transfer job proceeds normally.

ABORTING

In this state the transfer job is causing its active atomic transfers to abort. This state is active only so long as any of the transfer job's atomic transfers remains active.

STOP

The STOP state is an AND substate of TRANSFER JOB ACTIVE. This state is responsible for coordination of any activities necessary to stop[11] the active transfer job. STOP has two substates: NOT STOPPING and STOPPING.

NOT STOPPING

In this state, the STOP process is not in effect. The transfer job proceeds normally.

STOPPING

In this state the process of stopping occurs. When the STOPPING state is active and the SELECT ATOMIC TRANSFER state is entered, that atomic transfer shall transition to the AWAIT JOB COMPLETION state. When all ports have reached that state, transition 10 from the STOPPING state occurs (see Figure 4.7).

10 See Section 4.1 for the defintion of abort.

11 See Section 4.1 for the definition of stop.

PAUSE

The PAUSE state is an AND substate of TRANSFER JOB ACTIVE. That is, the pause feature is concurrent with the execution of the transfer job. The PAUSE state has three substates: NOT PAUSED, PAUSING, and PAUSED.

NOT PAUSED

A newly activated job is NOT PAUSED by default. In this state, the transfer job proceeds as normal.

PAUSING

This state is coordinating the movement of the transfer job from NOT PAUSED to PAUSED. It is responsible for making sure that the current activity for each port for the job has ceased at an appropriate point. The transfer job is PAUSING until all of its active atomic transfers are paused.

PAUSED

All activity has ceased. The transfer job is awaiting a Resume command. Note that the PORT A, PORT B, etc., substates retain their current states, but their activity ceases when PAUSED.

The following transition table defines the added transitions between states for the extended transfer job state model. It applies to Figure 4.7.

Table 4.3 Extended Transfer Job State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
9	ABORTING	Abort process is complete.	(Transfer Job Complete)	Send “Transfer Job Complete” message to host indicating abnormal termination.	Host or equipment previously issued abort.
10	STOPPING	Stop process is complete.	(Transfer Job Complete)	Send “Transfer Job Complete” message to host indicating abnormal termination.	Host or equipment previously issued abort.
11	(Undefined)	Default entry into PAUSE state.	NOT PAUSED	None.	None.
12	NOT PAUSED	Host or equipment issued a directive to pause.	PAUSING	None.	None.
13	PAUSING	All transfer job activity has ceased.	PAUSED	None.	“Transfer Job Paused” event has occurred.
14	PAUSED	Host issued a directive to resume the transfer job.	NOT PAUSED	None.	“Transfer Job Resumed” event has occurred.
15	(Undefined)	Default entry into STOP state.	NOT STOPPING	None.	None.
16	NOT STOPPING	Stop initiated.	STOPPING	Begin stop activities.	None.
17	(Undefined)	Default entry into ABORT state.	NOT ABORTING	None.	None.
18	NOT ABORTING	Abort initiated.	ABORTING	Begin abort activities.	None.
19	TRANSFER JOB QUEUED	Cancel, Abort, or Stop command received.	TRANSFER JOB CANCELLED	Remove the transfer job from the queue.	None.

4.3.3 *Extended Atomic Transfer State Model* — Figure 4.8 presents an extended atomic transfer state model. This model extends the atomic transfer model in a way similar to the transfer job extension. It provides for the capability to pause/resume and to abort[12]. Except for the extensions, this model is the same as that presented as Figure 4.6. Therefore, only the extensions are discussed in this section.

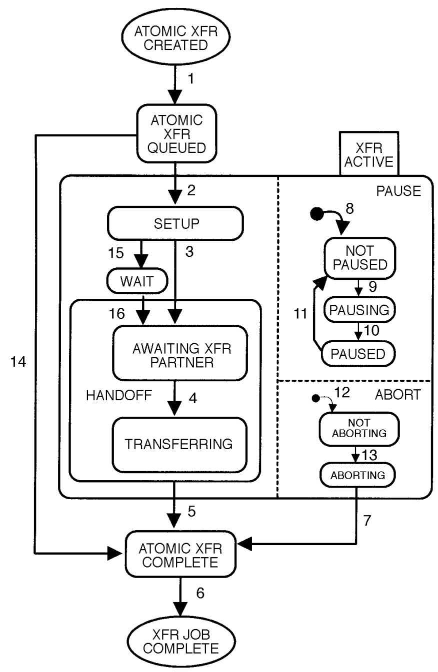

Figure 4.8
Extended Atomic Transfer State Diagram

WAIT

The atomic transfer stops activity and awaits a StartHandoff command from the host. This capability allows the host to precisely orchestrate the timing of the handoff in time critical operations.

ABORT

The ABORT state is an AND substate of TRANSFER ACTIVE. This state is responsible for coordination of any activities necessary to abort the active atomic transfer. The ABORT state has two substates: ABORTING and NOT ABORTING.

NOT ABORTING

In this state, the abort process is not in effect. The atomic transfer proceeds normally.

ABORTING

In this state, the process of aborting is performed. It is the responsibility of the equipment to cease physical activity as quickly as possible and end the current atomic transfer. This process is application-specific. It is the responsibility of the supplier to document this method.

PAUSE

The PAUSE state is an AND substate of ATOMIC TRANSFER ACTIVE. That is, the pause states are concurrent with the execution states of the atomic transfer. The PAUSE state has three substates: NOT PAUSED, PAUSING, and PAUSED.

NOT PAUSED

A newly activated atomic transfer is NOT PAUSED by default. In this state, the atomic transfer proceeds as normal.

PAUSING

This state is coordinating the movement of the atomic transfer from NOT PAUSED to PAUSED. It is responsible for making sure that the current activity for the atomic transfer has ceased at an appropriate point.

PAUSED

All activity has ceased. The atomic transfer is awaiting a Resume command. Note that the PORT A, PORT B, etc., substates retain their current states, but their activity ceases when PAUSED.

The following transition table defines the added transitions between states for the extended atomic transfer state model. It applies to Figure 4.8.

12 Note that "stop" does not apply to atomic transfers, since the active atomic transfers are allowed to complete when the transfer job is stopped.

Table 4.4 Extended Atomic Transfer State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*	*Comment*
3	SETUP	Preparation for atomic transfer is complete, and TRAutoStart parameter is TRUE.	AWAITING XFR PARTNER	None.	"Committed to Transfer" event
7	ABORTING	Abort process is complete.	ATOMIC TRANSFER COMPLETE	None.	"Atomic Transfer Complete" event occurs noting abnormal termination.
8	(Undefined)	Default entry into PAUSE.	NOT PAUSED	None.	None.
9	NOT PAUSED	The transfer job transitioned to PAUSING state (Transition 12, Figure 4.7).	PAUSING	None.	None.
10	PAUSING	All atomic transfer activity has ceased.	PAUSED	None.	None.
11	PAUSED	The host issued a directive to resume the atomic transfer.	NOT PAUSED	None.	None.
12	(Undefined)	Default entry into ABORT.	NOT ABORTING	None.	None.
13	NOT ABORTING	Transfer job transitioned to ABORTING state (Transition 18, Figure 4.7).	ABORTING	Begin abort activities.	May be host- or equipment- initiated.
14	ATOMIC TRANSFER QUEUED	Abnormal Transfer Job termination.	ATOMIC TRANSFER COMPLETE	None.	May be caused by transfer job abort or stop.
15	SETUP	Preparation for atomic transfer is complete, and TRAutoStart parameter is FALSE.	WAIT	Wait for host command.	None.
16	WAIT	StartHandoff command is received from host.	AWAITING XFR PARTNER	None.	"Committed to Transfer 2" event

4.4 *Macro Level Services* — This section defines the messaging services required to implement the material movement concepts. The messages were introduced in Sections 4.2.1 and 4.3.1. These services are independent of the messaging protocol to be used. They may be mapped to SECS–II (SEMI E5) or to other comparable protocols.

These messaging services define the messages to be used, the nature of the data items or parameters to be contained within the messages, and data type of the parameters. Not defined here is the internal structure of the actual messages as transferred, including order of the parameters and how various data structures and data types are represented.

4.4.1 *Service List* — The following messages are exchanged between host and equipment for the purpose of accomplishing material movement tasks.

Host Initiated Services

Service Name	*Description*	*Confirmed**
TRJobCreate	Host request that a transfer job be performed.	Yes
TRJobCommand	Command which affects a transfer job.	Yes
GetAttribute	Request for attributes of an object (e.g., transfer job or atomic transfer). This message service has applicability beyond material movement.	Yes

* An unconfirmed service requires no response to the request message. This means that no data is required in the response. This does not preclude the implementation of a response message in the message protocol.

Equipment Initiated Services

Service Name	*Description*	*Confirmed*
TRJobAlert	Notification to host that transfer job is started or complete.	No
TrJobEvent	Notification to host that a transfer-related event has occurred.	No

4.4.2 *Service Detail* — The tables below define the parameters for each service. In some cases, parameters have additional detail which is defined in a following section. These parameters are marked with the "*" character.

The columns labelled REQ/IND and RSP/CONF link the parameters to the direction of the message. The message send by the initiator is called the "Request." When receiver terms this message the "Indication" or the request. The receiver may then send a "Response," which the original sender terms the "Confirmation."

The following codes appear in the REQ/IND and RSP/CONF columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M" — Mandatory Parameter—must be given a valid value.

"C" — Conditional Parameter—may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of other parameter.

"U" — User Defined Parameter.

"–" — Not Used.

"=" — (for Response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

The column labelled "Form" is used to indicate the type of data contained in a parameter. The forms used in this document are defined below.

Unsigned Integer — May take the value of any non–negative integer. Messaging protocol may impose a limit on the range of possible values.

Enumerated — The parameter may take on one of a limited set of possible values. These values are generally given logical names but may be represented by any data type excluding lists and structures.

Boolean — The parameter may take on one of two possible values, equating to "True" and "False."

Text — A text string.

Structure — A complex structure which consists of a collection of values of one of the possible forms. The breakdown of all "Structure" parameters is provided within this document.

NOTE 4: To prevent the definition of numberous variables named "XxxList", this document adopts the convention of referring to the list as "(List of) Xxx." In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates an ordered collection (or set) of zero or more items of the same data type. List order is retained from the message request to the response. For this document, a list must contain at least one element unless zero elements are specifically allowed.

TRJobCreate

The host requests that the equipment participate in a material transfer job.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
TRJobName	C	-	Host created identifier of the transfer job. This allows the host to use a common name for the transfer job on each participating equipment.	Text
(List of) AtomicSpec	M	-	Specifications for the atomic transfer(s).	Structure
TRJobID	-	M	Equipment created ID of the transfer job.	Unsigned Integer
(List of) TRAtomicID	-	M	The equipment-created identifier of the atomic transfer(s).* Order matches that given in the (List of) AtomicSpec in the message req.	Unsigned Integer
TRStatus	-	M	Reports acceptance or rejection of the transfer job.	Structure

*All object IDs created by the equipment must be unique within that equipment for that object type. This includes TRJobID and TRAtomicID. These IDs are used by the host to inquire about those objects.

TRStatus Parameter Detail

Parameter	*RSP/CONF*	*Description*	*Form*
TRAck	M	Tells whether the activity was successful (=true) or unsuccessful (=false).	Boolean
(List of) Status	C	Reports any errors found. (May be list of 0.)	Structure

Status Parameter Detail

Parameter	*RSP/CONF*	*Description*	*Form*
ErrorCode	M	Contains the code for the specific error found.	Enumerated
ErrorText	M	Text in support of the error code.	Text

AtomicSpec Parameter Detail

Many of these parameters are conditional. The equipment shall decide if it has a sufficient amount of information to perform each atomic transfer.

Parameter	*REQ/IND*	*Description*	*Form*
TRLink	M	Used by the transfer partners to assure that their communications relate to the same atomic transfer. The host is responsible for assuring uniqueness.	Unsigned integer
TRPort	C	Material I/O port on the equipment through which the transfer is to occur. If not specified, the equipment shall select the port.	Unsigned integer
TRObjName	C	Textual identifier of the object to be transferred.	Text
TRObjType*	C	Identifies the type of transfer object. Not required if only one type is acceptable.	Enumerated
TRRole	M	Equipment's role (i.e., Primary or Secondary).	Enumerated
TRRecipe	C	Name of the transfer recipe (if needed).	Text
TRPartner	M	Identifier (Name* attribute of equipment) of the transfer partner.	Text
TRPartnerPort	C	Material I/O port on the equipment's partner to be used for this atomic transfer.	Unsigned integer
TRDirection	M	Send or Receive the transfer object?	Enumerated
TRType	M	Is the equipment to be Passive or Active?	Enumerated
TRLocation	C	Identifier of the location on the equipment of the source (or destination) of the transfer object.	Unsigned integer
TRAutoStart	M	Should the equipment start the handoff without waiting for the "StartHandoff" command.	Boolean

TRJobCommand

The host requests a change in an active transfer job. Possible commands include Pause, Resume, Stop, Cancel, Abort, StartHandoff.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
TRObjID	M	-	Equipment's identifier of the transfer job to which the command applies.	Unsigned integer
TRCmdName*	M	-	Indicates which command to perform.	Text
(List of) CmdParameter	C	-	Parameter(s) corresponding to the command type. (May be list of 0)	Structure
TRStatus	-	M	Describes the acceptance or rejection of the command.	Structure

CmdParameter Detail

Parameter	*RSP/CONF*	*Description*	*Form*
CmdParmName	M	The name of the parameter.	Text
CmdParmValue	M	Value of the parameter.	Varies per Parameter

TRJobAlert

The equipment indicates the start or completion of a transfer job.

Parameter	*REQ/IND*	*Description*	*Form*
TRJobID	M	Equipment's identifier of the transfer job.	Unsigned integer
TRJobName	M	Host created identifier of the transfer job.	Text
TRJobMS*	M	Transfer job milestone.	Enumerated
TRStatus	M	Status of the transfer milestone (i.e., success or failure).	Structure

GetAttribute

Information related to a specific object (e.g., transfer job) is requested.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
ObjType*	M	-	Type of object for which attributes are desired.	Enumerated
(List of) ObjectID	C	-	Identifier of each object for which attributes are desired. If omitted (i.e., list of zero elements), it implies a request for all objects of the specified ObjType.	Varies according to ObjType.
(List of) AttributeID*	M	-	Identifier of requested attribute.	Enumerated
(List of) AttrData	-	C	Attribute data. Returns the requested attribute list for each specified ObjectID (e.g., grouped per ObjectID). If the object does not exist, an empty list is returned for that object, if an attribute does not exist, a null member of the list is returned. If the ObjType is unknown, a single null list is returned.	Varies per attribute.
(List of) Status	-	C	Reports any errors found in the GetAttribute request. (May be list of 0.)	Structure

TRJobEvent

The equipment reports pertinent state changes related to a transfer job.

Parameter	*REQ/IND*	*Description*	*Form*
TREventID*	M	Identifier of the specific event which occurred.	Enumerated
TRJobID	M	Equipment's identifier of the job to which the event refers.	Unsigned integer
TREventData	C	Data related to the specific event. May be repeated if multiple data parameters are reported.	Varies per parameter reported.

4.4.3 *Parameter/Attribute Definitions* — This section gives further details on parameters not sufficiently defined above. It also defines attributes of the defined object types. Note that some parameters also serve as attributes (e.g., TRJobName).

AtomicSpec — If a list of AtomicSpec parameters is supplied, the order is important. The equipment shall execute atomic transfers in the order specified on a per–port basis.

AttributeID/AttrData — An attribute is a characteristic which applies to all instances of that (type of) object. Thus, the attributes available for an object depend upon the ObjType. The three object types available for material movement are TransferJob and AtomicTransfer, and Equipment. Below are listed the defined attributes for each.

Object (i.e., any object): ObjectID, ObjType.

TransferJob: TRJobState, TRAtomicList, TRJobName, TRJobID (=ObjectID).

AtomicTransfer: TRAtomicState, TRLink, TRPort, TRObjName, TRRole, TRRecipe, TRPartner, TRPartnerPort, TRDirection, TRType, TRLocation, TRAutoStart, TRObjType, TRAtomicID (=Object ID).

Equipment: Name (=ObjectID).

ErrorCode — This parameter is used to report the reasons why an activity was unsuccessful. This applies to the TRJob Create, TRJobComplete, and the TRJobCommand. While it is impossible to define all possible errors, the following is a list of values which may apply in many cases:

TRJobCreate:

- Parameters improperly specified.
- Insufficient parameters specified.
- Queue full or queuing not allowed.
- Error in atomic transfer specification.
- Material Location Status does not match Transfer Specification.
- Primary Transfer Partner Role not supported.
- Active Participation not supported.

TRJobComplete:

- Failed due to hardware error.
- Failed due to transfer partner error.
- Failed due to error during atomic transfer.
- Transfer Job aborted by host.
- Transfer Job stopped by host.
- Transfer Job canceled by host.

TRJobCommand:

- Parameters missing or improperly specified.
- Requested service not available from this equipment.
- Cancel not allowed after transfer start.
- Unknown Transfer Job.

GetAttribute:

- Invalid object type.
- Unknown objectid.
- Invalid attribute.

ObjType — The type or class of the object of interest. The three types of objects contained in this document are TransferJob, AtomicTransfer, and Equipment.

Timestamp — The format for this Text string is YYYYMMDDhhmmsscc where:

YYYY= Year

MM= Month (01–12)

DD= Day (01–31)

hh= Hour (00–23)

mm= Minute (00–59)

ss= Second (00–59)

cc= Hundredths of Second (00–99)

TRCmdName/CmdParameter — Possible values are:

Command	*Parameter*
CANCEL	none
PAUSE	none
RESUME	none
ABORT	none
STOP	none
STARTHANDOFF	TRAtomicID

TREventID/TREventData — The following table shows the defined events and the data which are required to be available. Any attribute of the object should be available for reporting with an associated collection event.

Event	*Typical Data*
Committed To Transfer	TRAtomicID, Timestamp
Waiting for StartHandoff	TRAtomicID, Timestamp
Transfer Job Paused	Timestamp
Transfer Job Started	Timestamp
Atomic Transfer Started	TRAtomicID, Timestamp
Atomic Transfer Complete	TRAtomicID, Timestamp

TRJobMS — Identifies which transfer job milestone is being alerted to the host. Possible values are:

- Transfer Job Started.
- Transfer Job Complete.

TRObjType — Identifies the type of object to be transferred. This parameter is used only in cases where a port is capable of transfers involving different object types. As an example, a list of possible values might include:

- Wafer Reticle Cassette
- 100 mm Wafer Carrier
- 125 mm Wafer Carrier
- 150 mm Wafer Carrier
- 200 mm Wafer Carrier
- 100 mm Wafer
- 125 mm Wafer
- 150 mm Wafer
- 200 mm Wafer

Attributes: (Note: Some parameters above are also attributes.)

Name — Each equipment must have a unique Name attribute, a factory-defined Text string.

TRAtomicList — List of the atomic transfers (TRAtomicIDs) contained within the specified transfer job. This is an attribute of a transfer job and is specified in the GetAttribute service.

TRAtomicState — Attribute of an atomic transfer. Possible values are defined by the state models defined in Sections 4.2.3 and 4.3.3.

TRJobState — An attribute of transfer job. Possible values are defined by the state models defined in Sections 4.2.2 and 4.3.2.

4.5 *Object Attribute Definitions* — This section defines the attributes of those objects required for Material Movement Management: Equipment, TransferJob, and AtomicTransfer.

4.5.1 *Equipment* — The attributes of the Equipment object are defined in Table 4.5.

Table 4.5 Equipment Object Definition Table

Attribute Name	*Definition*	*Access*	*Requirement*	*Form*
ObjType	Object type.	RO	Y	Text = “Equipment”
ObjID	User-definable name.	RW	Y	Text

4.5.2 *TransferJob Object* — The attributes of the TransferJob object are defined in Table 4.6. A TransferJob is created by the equipment when it accepts a transfer job create request from the host, and its attributes are based upon that request.

Table 4.6 TransferJob Object Definition Table

Attribute Name	*Definition*	*Access*	*Requirement*	*Form*
ObjType	Object type.	RO	Y	Text = "TransferJob"
ObjID	Textual version of TRJobID.	RO	Y	Text
TRJobID	Identifier assigned by the equipment.	RO	Y	Unsigned integer
TRJobName	Host-created job identifier.	RO	Y	Text
TRJobState	Current state.	RO	Y	Enumerated: TRJobQueued, TRJobActive, TRJobComplete
TRAtomicList	List of (TRAtomicID).	RO	Y	List of unsigned integers

4.5.3 *AtomicTransfer Object* — The attributes of the AtomicTransfer object are defined in Table 4.7. AtomicTransfer objects are created by the equipment when it accepts a transfer job create request from the host, and its attributes are based upon that request.

Table 4.7 Atomic Transfer Object Definition Table

Attribute Name	*Definition*	*Access*	*Requirement*	*Form*
ObjType	Object type.	RO	Y	Text = "AtomicTransfer"
ObjID	Textual version of TRAtomicID.	RO	Y	Text
TRAtomicID	Identifier assigned by the equipment.	RO	Y	Unsigned integer
TRAtomicState	Current state.	RO	Y	Enumerated: TRAtomicActive, TRAtomicComplete
TRLink	Assigned by the host to identify an atomic transfer.	RO	Y	Unsigned integer
TRPort	Material I/O Port identifier.	RO	Y	Unsigned integer
TRObjName	Textual identifier of transfer object.	RO	N	Text
TRObjType	Material type of transfer object.	RO	N	Enumerated
TRRole	Equipment's role.	RO	Y	Enumerated: Primary or Secondary
TRRecipe	Recipe identifier for transfer recipe.	RO	N	Text
TRPartner	Name of equipment's partner.	RO	Y	Text
TRPartnerPort	Identifier for partner's port.	RO	N	Unsigned integer
TRDirection	Indicates whether the equipment will send or receive.	RO	Y	Enumerated: Send Receive
TRType	Indicated the equipment is to be active or passive.	RO	Y	Enumerated: Passive Active
TRLocation	Identifies location on the equipment of the source (or destination) of the transfer object.	RO	N	Unsigned integer
TRAutoStart	Indicates whether the equipment may automatically start the handoff without waiting for a StartHandoff command.	RO	Y	Boolean: Automatically start (TRUE). Wait for StartHandoff (FALSE).

5 Micro Level

5.1 *Micro Level Concepts* — The micro level of material movement is defined below to allow for interaction between transfer partners on a step–by–step basis during a handoff. It was designed to be used in conjunction with the macro level defined above but may instead be used with some other transfer coordination mechanism.

5.1.1 *Micro Level Definitions*

Handoff — The process by which the transfer object moves from the sending transfer partner to the receiving transfer partner. The terms "handoff" and "micro level" refer to the same transfer activity.

Micro Move — One of a sequence of moves required during a micro level process to effect the transfer of an object. This is normally associated with physical activity within the transfer envelope.

5.1.2 *Micro Level Description* — While the macro level of material movement deals with coordination and preparation for a transfer, the micro level addresses the physical synchronization between two transfer partners during an atomic transfer. To control these physical interactions properly, communication between the transfer partners is required. Using these communications, the partners shall ensure that both are ready to perform the same specific transfer, that both agree on the mechanism, and that movement within the transfer envelope is properly coordinated.

There are three parts to the micro level interaction between transfer partners. Each of the three parts must occur in some form for the micro level to integrate properly with the macro level.

1. The first part is the exchange of "I'm ready" type messages, so that the partners can be sure that starting the transfer is appropriate.
2. The second part of the micro level interaction is the coordination of the physical transfer. During a transfer, control of the transfer envelope may belong to only one partner at any time. Joint or parallel movement is never allowed in this space[13]. The transfer itself is a series of steps called micro moves. Each step typically contains all the activities one partner can perform before the other must act. If the secondary partner is passive during the move, no micro level communications are needed for part two, since the primary partner shall control the transfer envelope during the entire physical transfer.
3. The third part of the micro level interaction is the verification that the transfer is complete.

The micro transfer mechanism assumes that the secondary partner will recognize and respond to some list of micro commands known to the primary partner. These commands might range from the very specific (e.g., "reach out and grasp the transfer object") to the very general (e.g., "perform the next step in your sequence").

5.2 *Micro Level Behavior*

5.2.1 *Micro Level Communications* — This section provides baseline definitions of the communications needed by the micro level of material movement. More detailed definitions of the messaging services can be found in Section 5.4 below. Refer to Figure 5.1 while reading the message definitions. In the figure, the messages in *italics* are macro level messages provided for reference. The **bolded** messages are the micro level messages.

The prefix "HO" (for **H**and**O**ff) is appended to the names of micro level messages to differentiate them from the "TR" transfer messages.

<u>HOReady</u> — Upon completion of any setup operations, each transfer partner shall declare to the other that it is prepared for the specified atomic transfer. Either partner may make this declaration first. When the HOReady exchange has been made, the primary partner shall start the transfer. The HOReady messages include a transfer identifier (see TRLink), which the partners match up. Looking back at the macro level atomic transfer state diagram (Figure 4.6), the combination of having sent and received a HOReady message for the specific transfer will spur the transition from the SETUP to AWAITING TRANSFER PARTNER states.

It is possible that an equipment will receive a HOReady message from its partner before it has received the corresponding Transfer Job Create request from the host (e.g., setup is instantaneous). An equipment shall be able to retain such a received message for a time to allow the host to deliver the corresponding Transfer Job Create request.

<u>HOCommand</u> — The HOCommand is the mechanism by which the primary transfer partner orchestrates the sequence of micro moves necessary for the transfer. The primary transfer partner shall successively perform its own micro move, then direct its partner to perform its next move. Thus, the partners may alternate control of the transfer envelope during the transfer. If the secondary partner is passive during the entire transfer and the primary performs all physical activity, no HOCommands are required — they are implicitly

13 The space outside the transfer envelope is not restricted, and some preparations for the next micro move may be possible in this space.

executed by the primary partner. Only one HOCommand may be active at any time.

The list of commands to execute may be included in a transfer recipe. See Section 4.2.4 above for more detail.

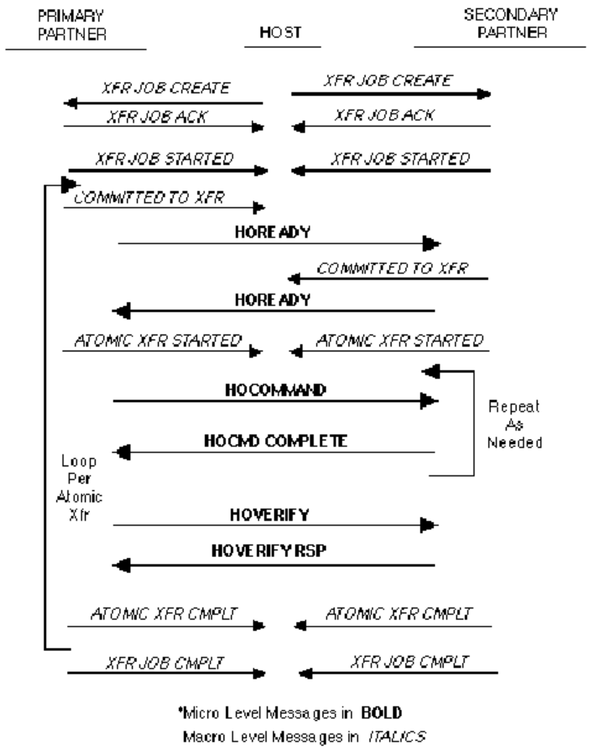

Figure 5.1
Micro Level Message Flow

When the secondary partner is passive, no HOCommands need be issued. In this case, all micro moves are conceived of and executed by the primary partner. The HOReady and HOVerify portions are still required in this case.

<u>HOCommand Complete</u> — Once the secondary partner has completed the task defined in the HOCommand, it uses the HOCommand Complete response message to alert the primary partner. If an HOCommand cannot be accepted or fails, this message shall be used to convey that information.

<u>HOVerify</u> — The primary transfer partner, believing all micro moves complete, shall check its port to ensure that the transfer object has been sent (or received) and that all mechanisms are in a safe position. Next, it shall send the HOVerify message to the secondary partner, asking that it perform the same check.

<u>HOVerify Response</u> — The affirmative response from the secondary partner confirms that the transfer was a success. This message may alternatively signify (through a data field) that the secondary partner does not consider the transfer to be complete. This message coincides with the transition for both partners from the macro level TRANSFERRING state to the ATOMIC TRANSFER COMPLETE state.

5.2.2 *Micro Level Messaging via Host* — As mentioned above, all three parts of the micro level of communications must be carried out in some form. If a direct link from equipment to equipment exists, they should occur via that means, whether using SECS–I, Parallel I/O, or another protocol. If no direct link exists, there is a means by which the host may relay micro level messages from one transfer partner to the other. This is illustrated in Figure 5.2.

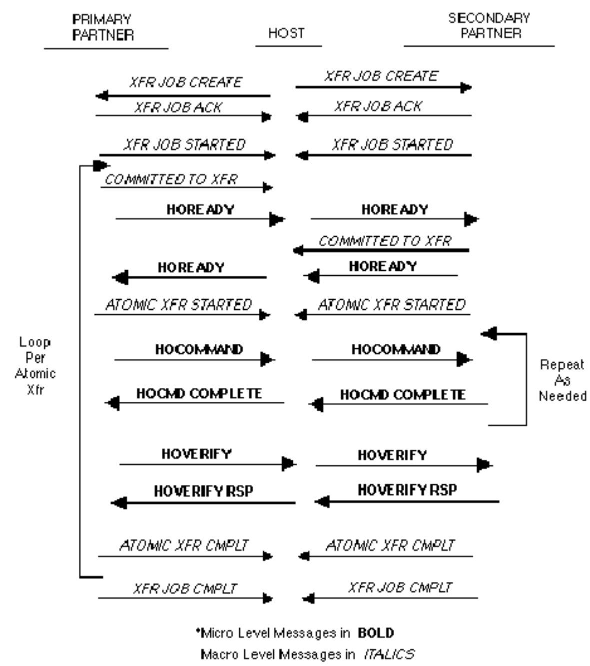

Figure 5.2
Micro Level Message Flow via Host

In this situation, the host may act as a surrogate of each equipment's transfer partner. A piece of equipment would send the same defined micro level message as before, but would deliver it to the host via the standard host link. The equipment would treat the host as its transfer partner, expecting the same response as if it were talking directly to its true transfer partner. The host is responsible for managing the relay of messages from one partner to the other as necessary.

The equipment shall provide the ability to pass micro level messages through the host. If a direct peer–to–peer link is available, the user shall be able to configure the path for the messages (directly to partner or through the standard host link).

5.3 *Extended Behavior* — This section discusses two micro level messages which may be exchanged between the transfer partners as a result of exceptional conditions.

HOCancelReady — Once a transfer partner has sent a HOReady message, it is committed to participate in a transfer. Under some circumstances, an equipment needs to withdraw from that commitment. The HOCancelReady message is used for this purpose.

The HOCancelReady shall be accepted by the transfer partner unless it has already sent the corresponding HOReady. In cases where both transfer partners have sent the HOReady message, the atomic transfer is considered to have begun and cannot be canceled. If the transfer partner receives an HOCancelReady, but has no record of receiving the original HOReady, it should accept the HOCancelReady.

HOHalt — The HOHalt message is used by a transfer partner in situations when the equipment or transfer object are endangered. The receiver of the HOHalt message shall cease all movement related to the atomic transfer immediately. Manual intervention is required before the halted partner may resume movement.

5.4 *Micro Level Services* — This section expands upon the messages defined in Section 5.2.1. It defines the parameters of the messages and discusses the possible values.

5.4.1 *Service List* — The following messages are exchanged between transfer partners during an atomic transfer.

Service Name	*Description*	*Confirmed*
HOReady	Each partner sends this message when it is ready to begin the transfer process.	No
HOCommand	Message sent by the primary transfer partner to cause the secondary partner to perform an activity in the transfer envelope. The response to this message indicates completion of the activity or error.	Yes
HOVerify	Message sent by the primary transfer partner informing the secondary partner that all activities should be complete and asking for confirmation.	Yes
HOCancelReady	Message sent to rescind a previous HOReady message.	Yes
HOHalt	Message sent to stop all action by the transfer partner. This message ends the transfer and requires manual intervention at the halted equipment.	Yes

5.4.2 *Service Detail* — The tables below define the parameters for each service. In some cases, parameters have additional detail which is defined in a following section. These parameters are marked with the "*" character.

The following codes are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M" — Mandatory Parameter—must be given a valid value.

"C" — Conditional Parameter—may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of other parameter.

"U" — User-Defined Parameter.

"–" — Not Used.

"=" — (for Response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

The column labelled "Form" is used to indicate the type of data contained in a parameter. The forms used in this document are defined below.

Unsigned Integer — May take the value of any non–negative integer. Messaging protocol may impose a limit on the range of possible values.

Enumerated — The parameter may take on one of a limited set of possible values. These values are generally given textual names, but may have simpler representations in protocol (e.g., numeric values).

Boolean — The parameter may take on one of two possible values, equating to "True" and "False."

Text — A text string.

Structure — A complex structure which consists of a collection of values of one of the possible forms. The breakdown of all "Structure" parameters is provided within this document.

HOReady

An equipment indicates to its transfer partner a readiness to begin a specific atomic transfer.

Parameter	*REQ/IND*	*Description*	*Form*
EQName	M	Identifier (Name attribute) of the equipment sending this message.	Text
TRLink	M	Used by the transfer partners to assure that their communications relate to the same atomic transfer.	Unsigned integer
TRPort	M	Identifier of the port (on the equipment sending this message) to be used for the transfer.	Unsigned integer
TRObjName	C	Identifier of the object to be transferred.	Text
TRObjType	C	Type of transfer object, required if transfer might involve multiple types.	Enumerated
TRRole	M	Is the sender of this message the primary or secondary transfer partner.	Enumerated
TRPartner	C	Identifier (Name attribute) of the equipment expected to receive this message.	Text
TRPartnerPort	C	Material I/O port on the equipment which receives this message to be used for this atomic transfer.	Unsigned integer
TRDirection	M	Does the sender of this message expect to send or receive the transfer object.	Enumerated
TRType	M	Is the transfer to be passive or interactive?	Enumerated
TRLocation	C	Identifier of the material location (on the sender of this message) which will be the source (or destination) of the transfer object.	Unsigned integer

HOCommand

The primary transfer partner directs the secondary transfer partner to perform an action related to a specific atomic transfer.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
TRLink	M	M(=)	Identifier of the atomic transfer which related to this HOCommand.	Unsigned integer
HOCmdName*	M	-	Specific command to be executed.	Text
(List of) CmdParameter	C	-	Parameter(s) related to the specified HOCommand. (May be a list of 0.) See Section 4.4.2 for definition of CmdParameter.	Structure
HOStatus	-	M	Reports success or failure of the command and, if failure, supplies error detail.	Structure

HOStatus Detail

Parameter	*RSP/CONF*	*Description*	*Form*
HOAck	M	Did the activity succeed or fail, was the inquiry accepted or rejected. True is a positive result, False is negative.	Boolean
(List of) Status	C	Reports any errors found. (May be list of 0) See Section 4.4.2 for details of this structure.	Structure

HOVerify

The primary transfer partner indicates completion of the atomic transfer to the secondary partner and requests confirmation of a successful transfer.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
TRLink	M	M(=)	Identifier of the atomic transfer.	Unsigned integer
HOStatus	M	M	Reports the completion status of the atomic transfer from the standpoint of the sending transfer partner.	Structure

HOCancelReady

Having previously sent an HOReady message, a transfer partner determines that it is no longer ready to begin the transfer and sends the HOCancelReady message.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
TRLink	M	M(=)	Identifier of the atomic transfer.	Unsigned integer
HOCancelAck*	-	M	Acknowledge code for HOCancelReady.	Enumerated

HOHalt

This message may be sent by either transfer partner when the equipment or transfer object is endangered. It requires the receiver to cease all transfer-related movement immediately. Manual intervention is required before the halted partner may again be available for transfer.

Parameter	*REQ/IND*	*RSP/CONF*	*Description*	*Form*
TRLink	M	M(=)	Indentifier of the atomic transfer.	Unsigned integer
HOHaltAccept	-	M	True if the request is accepted. Request may be denied only if referenced atomic transfer does not exist.	Boolean

5.4.3 *Parameter Definitions* — This section gives further detail on certain parameters defined above. Parameters which are defined in Section 4.4 are not repeated here.

ErrorCode

HOCommand:

- Rejected/Unrecognized Command.
- Rejected/Parameter Error.
- Failed (Completed Unsuccessfully) — indicates that the activity was attemped, but failed; the mechanisms continue to be operational.
- Failed (Unsafe) — indicates that the equipment was left in an unrecoverable state at the end of the activity due to the failure of a mechanism or due to the risk of damage to the equipment or material. Manual intervention is required.

HOVerify:

- Sensor-Detected Obstable.
- Material Not Sent.
- Material Not Received.
- Material Lost.
- Hardware Failure.
- Handoff Canceled Externally (by host or operator).

HOCmdName — The set of micro commands is provided below as an example. The commands used are not limited to this set. However, adherence to a common set of commands will speed implementation of material transfer.

This particular example applies to a situation where the secondary partner is active and the primary partner is passive.

Cmd	*Description*
Pick	Commands the secondary partner to take all actions necesary to remove the transfer object from the primary partner's port.
Place	Commands the secondary partner to take all actions necesary to place the transfer object in the primary partner's port.
Extend	Commands the secondary partner to reach into the primary partner's port area in close proximity to the material location.
Acquire	Commands the secondary partner to acquire control of the material.
Release	Commands the secondary partner to release control of the material.
Retract	Commands the secondary partner to withdraw from the primary partner's port area.
Store	Commands the secondary partner to place the transfer object in its final location.
Retrieve	Commands the secondary partner to pick up the transfer object from its initial location.
MoveTo	Commands the secondary partner to move its transfer mechanism (e.g., robot gripper) to a specified position (given as a parameter).

The Pick command might actually be an equivalent of the sequence:

Extend, Acquire, Retract, Store.

The Place command might be an equivalent to the sequence:

Retrieve, Extend, Release, Retract.

HOCancelAck — Conveys the response to the HOCancelReady request. Possible values are:

0 — Accept Cancel.

1 — Atomic Transfer Unknown.

2 — Reject Cancel—Transfer Begun.

HOHaltAck — Conveys the response to the HOHalt request. Possible values are:

0 — Accept Halt.

1 — Atomic Transfer Unknown.

APPLICATION NOTES

A1-1 *Transfer-Related Mechanisms* — A transfer job interacts very closely with port-related hardware. This may include a variety of mechanisms such as port doors, cassette indexers, robot arms, carrier restraints, etc. The state models for the transfer job and atomic transfers shown above relate to this port hardware, but do not define hardware behavior directly. Therefore, an additional state model is needed for the port hardware.

A1-1.1 *Example Port State Model* — Figure A1-1 provides an example of a state model for a port. It is divided into three AND substates: MECHANISM, AVAILABILITY, and PAUSE. These substates represent the three most common areas of interest to the host.

Below, the states shown in Figure A1-1 are described, followed by a transition table. This is presented as an example. The actual model is implementation-dependent.

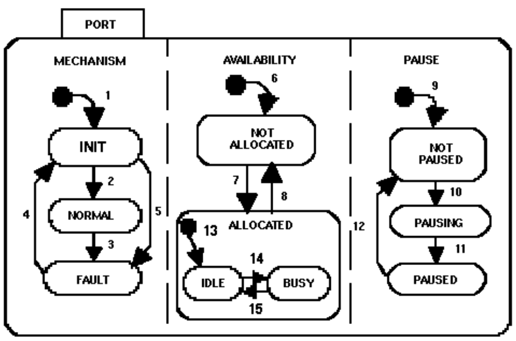

Figure A1-1
Example Port State Diagram

MECHANISM

This state pertains to the port's overall ability to function. It has three substates: INIT, NORMAL, and FAULT.

INIT

This is the default state upon powerup or reset of the port. It includes some unspecified operations to ensure that the port is ready to operate.

NORMAL

When in this substate, the port is in normal working order.

FAULT

In this substate, a problem has been detected with a port mechanism.

AVAILABILITY

This state pertains to the availability of the port to perform a function. This state has two substates: NOT ALLOCATED and ALLOCATED.

NOT ALLOCATED

In the NOT ALLOCATED state, neither the equipment nor the host has allocated the port. The port is waiting to be allocated to either a transfer job or to some process-related task. This is the default state upon equipment system startup.

ALLOCATED

In this state, the port is allocated to either the equipment (typically process-related) or to the host for a transfer job.

NOTE: If the port is allocated to an equipemnt function and the host does not wish to wait for the equipment to release the port, it must take some other action to force the port to become available. One possibility is a “Pause for Transfer” remote command that might be used during a processing cycle.

IDLE

Port is allocated to a task (e.g., processing or transfer job), but activity on the task has not yet begun.

PAUSE

This state pertains to the pausing of current port activity. Pausing of the port is different than pausing a transfer job which might be using the port.

NOT PAUSED

The port defaults to NOT PAUSED upon system startup. In this state, port activities are not hindered by the pause function.

PAUSING

In this state, the port has received a directive to pause and is in the process of bringing the current activity to a halt.

PAUSED

All port activity has ceased. The port is awaiting a directive to resume activity.

Table A1-1 describes the transitions for the example port state model. In the application-specific implementation, events should be defined for all significant occurences related to the model.

Table A1-1 Extended Atomic Transfer State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	(Undefined)	Entry into PORT Model.	INIT	None.	None.
2	INIT	Port mechanisms found to be functional.	NORMAL	None.	None.
3	NORMAL	A malfunction of the hardware occurs.	FAULT	None.	None.
4	FAULT	The malfunction is "fixed." This may be a manual re-initialization of the port.	INIT	None.	None.
5	INIT	A problem occurs during initialization.	FAULT	None.	None.
6	(Undefined)	Entry into PORT Model.	NOT ALLOCATED	None.	None.
7	NOT ALLOCATED	The port is allocated to transfer or process job.	ALLOCATED	None.	None.
8	ALLOCATED	Port is released from current job.	NOT ALLOCATED	None.	None.
9	(Undefined)	Entry into PORT Model.	NOT PAUSED	None.	None.
10	NOT PAUSED	Directive issued to pause port.	PAUSING	None.	None.
11	PAUSING	Port activity has ceased.	PAUSED	None.	None.
12	PAUSED	Directive issued to resume activity.	NOT PAUSED	None.	None.
13	(Undefined)	Entry into ALLOCATED state.	IDLE	None.	None.
14	IDLE	Task activity begins.	BUSY	None.	None.
15	BUSY	Task activity ends.	IDLE	None.	None.

A1-1.2 *Additional Related Mechanisms* — Many equipment material ports have additional related mechanisms that can aid or interfere with a transfer. These mechanisms can be represented as parallel (or orthogonal) states within the port state model. Most such state models will be simple two–state instances (e.g., open/closed, on/off).

In some circumstances, the host will have a need to be able to understand the status of these mechanisms and may wish to be informed of state changes. This is especially true if the host is to do error handling and preliminary diagnosis of problems. The host also may need some level of remote commands to manipulate these mechanisms. Some possible transfer-related mechanisms are discussed below.

<u>Port Material Sensors</u>: These sensors detect the presence or absence of material in a port. The change in this status is important, and an event should be provided to report change in this condition.

<u>Port Doors</u>: Some equipment closes the environment internal to the equipment, except during material transfer. The applicable states are normally open/closed.

<u>Port Elevator</u>: Port elevators have multiple states such as HOME, MOVING, SLOT 5 ACCESS, or interlocks such as BLOCKED BY INTERNAL TRANSFER ARM.

<u>Robot Arm</u>: The transfer arm may be in motion, may be holding material, etc.

<u>Carrier Restraints</u>: On some ports, carriers are clamped in place and cannot be removed unless the restraints are released. There would be a clamped/unclamped state model.

A1-2 *WIP Tracking* — WIP tracking refers to the ability of an entity (host or equipment) to keep accurate track of the material within its domain. Typically, the equipment is expected to track the material's location within its modules and subsystems, while the host may take a more global view, knowing at which equipment (or storage area) a specific transfer object resides.

The process of material movement crosses the boundary of the equipment domain. Therefore, there must be information exchanged between host and equipment about what material is being transferred and what the plans are for the material (e.g., when and how processed).

It is outside the scope of this standard to define WIP tracking capabilities, either at the host or equipment level. However, it is critical for the material movement function to supply enough information that WIP tracking is feasible. Specifically, the material movement messaging must identify the object being transferred. WIP references are kept at a minimum. For example, for a carrier containing wafers, the material movement process would need to know the carrier identifier, but need not be concerned with the specific lot contained within. It is also outside the scope of this standard to be concerned with the detailed contents or status (e.g., processed or not) of a transfer object. These are important issues that should be dealt with elsewhere.

A1-3 *Error Handling* — This section addresses some common problems that may occur during the transfer process. This is not intended to present hard and fast rules for error handling, but rather to raise potential issues and suggest possible solutions. Several primary error or interrupt types are covered. For state model representations of hardware faults, see Section A1-1.

NOTE: Transfer errors are not completely communicated between transfer partners. The host may be responsible for pausing or aborting (as needed) the activities of the partner or equipment with an error condition.

A1-3.1 *Macro Level Error Handling*

1. Transfer Specification Error

This would consist of an error in the data contained in the Transfer Job Create request. Some examples might include specification of a static port as an active transfer partner or the use of a non–existent port on the equipment. Such an error should result in rejection of the Transfer Job Create request.

2. Setup Error

It is during the setup for an atomic transfer that many prerequisites are typically checked. A setup error may be either a hardware or a transfer specification problem. Hardware problems might be such events as cassette elevator fault, door fails to open, etc. If a hardware problem occurs, the transfer job is paused and the hardware state model makes a transition to the FAULT state (see Section A1-1). When the problem is corrected, the host may resume the activity or stop the transfer job.

A transfer specification problem would typically relate to the presence or absence of material at specified locations. If there is a transfer specification problem found, a transition to the RESTORE state is made (transition #5) and the transfer job is terminated.

3. Restore Error

A restore error occurs when the port cannot be brought back to its desired physical condition for the NOT ALLOCATED state. This would be a failure of a hardware mechanism. The hardware should then transition to the hardware FAULT state (see Section A1-1). The “completeness” of the transfer job may not be hindered by problems in the restore activities. However, the next transfer job may be affected.

4. Transfer Error

Transfer errors may be of many types and of varying levels of severity. Any error that occurs must be reported to the host. If the error is caused by failure of a port mechanism, a transition to the hardware FAULT state should occur (see Section A1-1). The problem might also stem from a problem with the transfer specification or in the transfer recipe (i.e., specification is legal, but does not match that of the partner). If failure in the transfer hardware has occurred, the transfer job should transition to the PAUSED state and report it to the host. The host may choose to abort the transfer job, or correct the problem and resume the transfer job.

5. Timeouts

To ensure that all transfer problems are detected, the host should implement a process for timeout monitoring of transfer jobs. The timeout periods need only be very rough estimates of the actual times required for the transfer job (e.g., 2× or 3× actual). The host might choose to monitor individual atomic transfers if tighter tolerances are required. The goal is to ensure that problems are not left undetected over extended periods.

To determine the proper time to allow for a transfer job, the host would sum the estimated maximum times needed for the individual atomic transfers which make up the job[14] . The atomic transfer time estimates would typically be determined by experience, since they rely on the interactions of two different transfer partners. A doubling or tripling of the average observed transfer time would be a good estimate. In some cases, suppliers of dedicated transfer equipment may be able to supply reasonable estimates.

Transfer job timeout monitoring should begin with the receipt of the “Transfer Job Started” message and end with the “Transfer Job Complete” message (both via the TRJobAlert service). If the host is monitoring the atomic transfers, monitoring should begin at the “Atomic Transfer Started” event and end at the “Atomic Transfer Complete” event (both via the TRJobEvent service). The host must ensure that reporting of these events is enabled in this case.

If a transfer job exceeds the timeout period, the host may either pause the transfer job or attempt to end it with the stop command. The former may be preferred, since human intervention is required in either case and may enable a resume command to continue the transfer.

A1-3.2 *Micro Level Error Handling*

1. No Communication With Transfer Partner

If a transfer partner attempts to communicate with its transfer partner and finds that the communications link is not responding, it should inform the host via an event

14 This assumes that atomic transfers proceed sequentially. If they may proceed in parallel, the sequence for each port may be summed and the longest total chosen as the estimated time.

and continue to retry at intervals. Note that a disconnect may be normal in some cases where the link is only made when the transfer partners are in close proximity.

2. TRLink's Not Matched

If two transfer partners are attempting different handoffs using the same physical resources (locations, mechanisms, etc.), the host should be informed via an event. The partners shall continue to await an appropriate HOReady message—allowing the host to “fix” one or the other of the partners. If an equipment has no current transfer and it receives a HOReady message, it should hold that message until a transfer job is defined for it.

3. HOCommand Not Accepted

If the secondary transfer partner cannot accept a micro command from the primary partner, it should use the HOCommand Response message to inform the primary partner that the command was rejected. The primary partner may affect some recovery or inform the host that the transfer has failed.

4. HOCommand Failed in Execution

If the secondary transfer partner fails in the execution of an HOCommand, it should notify the primary partner of the problem. The primary partner may affect some recovery or inform the host that the transfer has failed.

5. Transfer Not Confirmed

If the secondary transfer partner sends a negative HOVerify Response message saying that the transfer object has not been properly transferred, the primary partner should not attempt recovery, but inform the host that the transfer has failed.

6. Timeout Awaiting Partner Readiness (HOReady)

Timeout Awaiting Micro Command Completion (HOCommand Response)

Timeout Awaiting Transfer Verify Response (HOVerify Response)

In some cases, action may be required if a transfer partner has been awaiting communication from its partner. The equipment should monitor timeout periods for each of the three cases. The factory user may need to customize the timeout periods for his/her factory. When a timeout occurs, the equipment should notify the host (via a TRJobEvent message) that the situation has occurred, reset the timer, and continue to await the partner. The host is responsible for taking any further action which is required (e.g., Stop or Pause command).

A1-4 *Practical Applications* — This section provides examples of practical applications of the material movement services as presented in this document. Four examples are provided below. Within these are presented some major variations expected in a factory situation. These are not exhaustive in scope, but the expectation is that reviewing these examples will help the reader understand how to apply these concepts to a real application. These examples are also not intended to represent a cohesive implementation strategy, but rather some alternatives that might be considered. AGVs are used in the examples below because they are familiar to most readers, not because they are favored over other transfer agents. To simplify the explanation, the examples below deal only with movement of cassettes.

A1-4.1 *Passive Transfer* — In this example, a transfer is to be performed between an AGV with robot arm and a piece of processing equipment. A cassette is to be picked up by the AGV for later delivery to another piece of equipment. The equipment has a cassette indexer and a port door, but no other port-related mechanism that would either aid or hinder transfer. The chosen transfer mechanism provides for the equipment to act as a passive transfer partner with no micro level communications required. This is called a passive transfer. The primary transfer partner is the AGV.

The setup for the equipment is to check to make sure that the correct material is in the specified port, drive the cassette elevator to the home position (if not already there), and open the port door. Note that the first two setup activities could have been designed to occur as a part of the micro level transfer if desired. The setup operations for the AGV are to ensure that its receiving port is empty and to drive to the transfer position in front of the designated equipment.

The transfer proceeds in the following steps:

1. The host sends a Transfer Job Create message to each transfer partner.
2. The partners each accept the transfer job.
3. The equipment both have the needed available resources so the transfer job immediately. Thus, Transfer Job Started messages are sent to the host by each.
4. Each partner in turn completes its setup activities for the atomic transfer, sends a “Committed To Transfer” event to the host, and then sends an HOReady message to its transfer partner (via the host).
5. Each partner sends the “Atomic Transfer Started” event to the host as soon as it determines that it has both sent and received an HOReady message for this handoff.

6. The AGV (as primary transfer partner) begins the transfer.
7. The AGV performs the transfer. Notice that no HOCommand messages are needed since this is a passive transfer.
8. The AGV sends an HOVerify message to the equipment via the host.
9. The equipment ensures that the cassette is no longer sensed in its port and then sends an HOVerify Response message (via the host) to the AGV, followed by an "Atomic Transfer Complete" event to the host.
10. Upon receipt of the HOVerify Response message, the AGV sends an "Atomic Transfer Complete" event to the host.
11. Each partner completes its RESTORE operations and then sends a Transfer Job Complete message to the host.

The transfer is now complete. The host may now direct the AGV to deliver the cassette to a new destination.

A1-4.2 *Active Transfer/Exchange of Cassettes* — This example addresses the situation where the factory control system needs to remove a processed lot from an equipment and immediately replace it with an unprocessed lot. The assumptions are that the processing of the lot on the equipment is nearing completion and that the AGV has already acquired the unprocessed lot that will next be placed on the equipment. Direct micro level communications exist between the AGV and the equipment. This will be an interactive transfer.

The setup operations for the equipment are opening the port door, driving the cassette indexer to the home position, and checking for the presence of the proper cassette. AGV setup is movement to the transfer location for that equipment. During the transfer, the equipment acts as the primary transfer partner, and will unclamp/clamp the cassette (clamps hold the cassette in the proper position). The AGV will interact with the equipment as the secondary transfer partner.

The transfer proceeds as follows:

1. The host sends Transfer Job Create requests to the equipment and to the AGV. The timing is chosen so that the time required for the AGV to travel to the equipment is approximately equal to the time left to complete processing of the lot to be transferred. The Transfer Job Create message to each contains two atomic transfers, the first dealing with the removal of the processed cassette from the equipment and the second dealing with the loading of the unprocessed cassette onto the equipment.
2. The AGV accepts the transfer job and begins the first atomic transfer immediately, sending a Transfer Job Started message to the host. Setup begins — the AGV begins traveling toward its transfer partner. The equipment accepts the transfer job and retains it for later execution.
3. When processing completes on the lot, the equipment begins the transfer job. It sends a Transfer Job Started message to the host and begins its setup operations for the first atomic transfer.
4. The AGV completes its setup activity and sends a "Committed To Transfer" event to the host. It also sends a HOReady message to the equipment.
5. The equipment completes its setup, then sends a "Committed to Transfer" event to the host and an HOReady message to the AGV.
6. Since the AGV had previously declared itself ready, the equipment sends an Atomic Transfer Started event to the host and starts the transfer.
7. The equipment begins by sending an HOCommand that results in the AGV reaching out and grasping the cassette.
8. Upon receiving the Command Complete message from the AGV, the equipment unclamps the cassette, allowing its removal.
9. The equipment sends an HOCommand that results in the AGV removing the cassette from the equipment. The material sent and material received events are sent to the host by the respective partners.
10. When the equipment receives the Command Complete message from the AGV, it considers the transfer to be complete. It sends the HOVerify message to the AGV.
11. The AGV sends the HOVerify Response message to the equipment.
12. Each of the transfer partners now determines that another atomic transfer is required in order to complete the transfer job.
13. Each transfer partner now transitions to the second atomic transfer. They each send "Atomic Transfer Complete" events.
14. Each transfer partner now begins the new setup phase. The AGV determines that it has already reached the transfer point and has the unprocessed cassette to be transferred. The equipment determines that the port is now empty, and that the door is open. This setup time was saved.

15. The second atomic transfer now proceeds in a similar fashion through steps 4–12 above. That done, since there are no further moves required, the restore stage begins, including “Atomic Transfer Complete” events to the host.

16. Once restore operations are complete, each sends a Transfer Job Complete message to the host. The transfer is now complete.

A1-4.3 *Sequential Moves* — In this example, the factory control system desires to move a cassette from equipment “A” to equipment “B” using a fixed robot stationed within reach of the two. Each piece of equipment has a static port and will act as passive transfer partners in all cases. The robot will act as the primary partner for all transfers. The host system must do the high-level planning of this move, determining that the lot to be transferred will be ready to go, that the robot is available, and that the receiving equipment is available to receive the cassette.

To accomplish the transfer, two atomic moves are required. First, the robot picks up the cassette at “A.” Second, the robot deposits the cassette on “B.” The gripper on the robot is considered its port in this case, since that is the point at which ownership of the cassette changes.

Since the step–by–step transfer details are similar to the first two examples, they will be omitted. However, a higher-level sequence will be given.

1. The host will send Transfer Job Create messages to “A,” “B,” and the robot. The robot will be given two sequential atomic moves to perform, the equipment one each. Note that the Transfer Job Create request to “B” could be delayed, if desired, until the completion of the first atomic move.

2. The first atomic transfer is performed: the robot removes the cassette from “A.” Note that no HOCommands are issued, since the secondary partner is passive.

3. The second atomic transfer is performed: the robot places the cassette on “B.”

4. Both “A,” “B,” and the robot deliver Transfer Job Complete messages to the host.

The transfer is complete.

An intelligent robot control system could combine the two atomic moves discussed above into a single robot program, achieving a more efficient transfer (e.g., no redundant movement during the transfer). In such a case, both “A” and “B” would need to be ready for transfer before the robot program was executed. The only limitation is that this combination would have to match the model and messaging discussed above.

A1-4.4 *Linked Lithography* — The final example is one where the micro level of material movement might be used without the macro level messaging described in this document. The linked lithography system described below is not patterned after any existing system and may not be the optimal implementation for such a system.

For this example, the challenge is to transfer wafers from a typical track system (following the coat/bake process) into a stepper for imaging, and then back to the track system for the develop process. In this example, the stepper acts as a slave to the track system, accepting wafers as they are given. The non–transfer-related communications will not be discussed.

In the wafer transfer process, the track takes on the macro level duties of the host. It is responsible for informing the stepper that a wafer is to be transferred, which wafer, and by what path and mechanism. It will initiate the transfer in a method analogous to the Transfer Job Create request. There is no transfer agent in this case. Either equipment might act as the primary transfer partner — it is irrelevant to this example.

The stepper and track will then exchange the normal micro communications. First, the HOReady messages will be sent. Next, the track will issue HOCommands to cause the wafer to be physically transferred. Finally, the HOVerify message transaction would occur. Meaningful events would be reported to the host as appropriate.

An alternative would be to design the system such that the track system tells the stepper system, in effect, “I'll be sending a series of wafers to you.” Since the HOReady message contains sufficient information to describe the transfer (assuming a specific transfer recipe is not required), no specifics about the individual transfers need be exchanged until the HOReady is sent. In such a scheme, the stepper would take the HOReady message as description of the specific transfer and respond with an HOReady to match.

A1-4.5 *Non–Compliant Transfer Partner* — There will be situations where only one of the transfer partners is compliant with this standard. It is reasonable to use this transfer methodology in some such cases, especially those involving passive transfer. The host would be responsible for emulating a compliant transfer partner on behalf of the non–compliant partner (for the benefit of the compliant partner). Examples of non–compliant transfer partners might include a WIP rack, a human transfer agent, an older process equipment, or any material handling systems that support other protocols.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

Index

SEMI E32.1-0997
SECS-II SUPPORT FOR MATERIAL MOVEMENT

1 Introduction

This document contains the necessary information to implement the Material Movement Management standard using the SEMI E5 SECS-II communications protocol.

2 Service to Message Mapping

The table below lists each message service defined in the Material Movement standard with the SECS-II message which should be used to perform that service.

Service	*SECS-II Msg*	*Comments*
TRJobCreate	S4,F19[1]	
TRJobCreate Response	S4,F20	
TRJobCommand	S4,F21	
TRJobCommand Response	S4,F22	
TRJobAlert	S4,F23	
TRJobEvent	S6,F11[2]	Corresponding messages to enable reporting, create and link reports, etc. are also assumed.
GetAttribute	S1,F19[3]	
GetAttribute Response	S1,F20[3]	
HOReady	S4,F27	
HOCommand	S4,F29	
HOCommand Response	S4,F31	
HOVerify	S4,F33	
HOVerify Response	S4,F33	
HOCancelReady	S4,F35	
HOCancelReady Response	S4,F37	
HOHalt	S4,F39	
HOHalt Response	S4,F41	

[1] If the S4,F19 message is multi-block, it will require the S4,F25/F26 multi-block inquire/grant transaction.

[2] TRJobEvent is an unconfirmed service. While the required S6,F12 reply must be transferred by the protocol layer, there is no action required on the part of the host. Therefore, it shall be discarded rather than delivered to the application which employs this service.

[3] The GetAttributes request and response will be removed from E32 and E32.1 in 1998. This message transaction is replaced by GetAttr, S14F1/F2. See E39 and E39.1 for details.

3 Parameter to Data Item/Parameter Mapping

In the table below, each parameter used in the SEMI E32 messaging services is listed along with its corresponding SECS-II data item. In some cases, a parameter will correspond to a SECS-II list. These cases are noted.

SEMI E32 defines a number of message parameters as conditional. This means that under certain conditions, these parameters do not need to be included in the message. In SEMI E5, this is done by means of a zero length data item, or if the parameter is a list, a zero length list. Please refer to SEMI E5, “Zero Length Items and Lists,” Sections 6.2.1 and 6.3.1.

Parameter	*SECS-II Data Item*
AtomicSpec	List Structure
AttrData	ATTRDATA
AttributeID	ATTRID
CmdParameter	List Structure
CmdParmName	CPNAME
CmdParmValue	CPVAL
EQName	EQNAME
ErrorCode	ERRCODE
ErrorText	ERRTEXT
HOAck	HOACK
HOCancelAck	HOCANCELACK
HOCmdName	HOCMDNAME
HOHaltAck	HOHALTACK
HOStatus	List Structure
ObjectID	OBJID
ObjType	OBJTYPE
Status	List Structure
TRAck	TRACK
TRAtomicID	TRATOMICID
TRAutoStart	TRAUTOSTART
TRCmdName	TRCMDNAME
TRDirection	TRDIR
TREventData	List Structure (See S6,F11 in SEMI E5.)
TREventID	CEID
TRJobID	TRJOBID
TRJobMS	TRJOBMS
TRJobName	TRJOBNAME
TRLink	TRLINK
TRLocation	TRLOCATION
TRObjName	TROBJNAME
TRObjType	TROBJTYPE
TRPartner	TRPTNR
TRPartnerPort	TRPTPORT
TRPort	TRPORT
TRRecipe	TRRCP
TRRole	TRROLE
TRStatus	List Structure
TRType	TRTYPE

4 Collection Event List

The following collection events must be available for reporting from the equipment via S6,F11:

Committed To Transfer
Waiting for StartHandoff
Transfer Job Paused
Transfer Job Resumed
Atomic Transfer Started
Atomic Transfer Complete

Application Note — SECS-I Equipment-to-Equipment Link

The direct SECS-I link between equipment poses a small problem. That is, it is not clear which partner should be the “SECS-I host” and which the “SECS-I equipment.” As a general rule, if one partner is always the primary transfer partner, it should be configured as the SECS-I host. However, this is not a requirement, since in some cases the choice of which is the primary partner may depend upon the situation. Therefore, where SECS-I is used to link the transfer partners, each partner should be user-configurable as either “host” or “equipment.”

SEMI E36-0699
SEMICONDUCTOR EQUIPMENT MANUFACTURING INFORMATION TAGGING SPECIFICATION

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org February 1999; to be published June 1999. Originally published 1995; previous published revision February 1998.

This document replaces SEMI E36-0298 in its entirety.

NOTE: The Document Type Definitions, schemas, and documentation defined in other parts of Semiconductor Equipment Manufacturing Information Tagging may be used freely without permission or payment of royalties or other licensing charge, provided this source and/or its associated specifications are cited.

1 Purpose

The purpose of Semiconductor Equipment Manufacturing Information Tagging is to define a markup philosophy, a markup framework, and an information markup which is rich enough to facilitate:

- Electronic interchange and distribution of information;
- Quality hardcopy printing and screen display of information;
- Consistent high-precision online searching; and
- Reuse and repurposing of information for such applications as integrating source material into training material and online support applications.

The intent of this document is to create an information interchange specification, not an authoring specification or an electronic presentation specification. Semiconductor Equipment Manufacturing Information Tagging will define the markup necessary for exchanging documents electronically, for facilitating retrieval of information content, and for validating information interchanges.

2 Scope

2.1 *Information Scope* - Semiconductor Equipment Manufacturing Information Tagging is intended to cover the types of technical and commercial information typically needed to support the selection, installation, use, and maintenance of semiconductor manufacturing equipment.

The following list gives examples of information types within scope; this list is not exhaustive.

- *Operations Manuals/Guides* — typically used by equipment operators at customer sites to perform the tasks for which the equipment was designed.
- *Installation Manuals* — typically used by supplier and customer engineers to install the equipment at the customer site.
- *Maintenance Manuals* — typically used by trained maintenance technicians at customer sites to perform repair and upkeep of equipment.
- *Maintenance Schedules* — typically used by site coordinators and customer facility managers to schedule and document normal preventive maintenance.
- *Spares/Parts Lists* — typically used by on-site field service engineers and customers to maintain a sufficient stocking level to ensure prompt delivery of parts.
- *Repair/Troubleshooting Manuals* — typically used by equipment operators and qualified maintenance technicians to identify and correct equipment problems.
- *Release Notes* — typically used by operators, technicians and system administrators to identify changes in software configuration.
- *Training Manuals* — typically used by supplier training personnel and customers to train operators and maintenance technicians.

Additional information on potential use and re-use of these information types in electronic form can be found in the Auxiliary Information for this specification.

2.2 *Content of SEMI E36* - Semiconductor Equipment Manufacturing Information Tagging will be issued in three parts:

- this base document,
- associated information models such as SGML and XML Document Type Definitions (DTDs) and schema, and

- the documentation for these information models, including at least a comprehensive Tag Library.

Semiconductor Equipment Manufacturing Information Tagging does **not** include implementation advice, suggestions, or notes on how to implement the models described here. This material will be presented in the form of Auxiliary Information associated with Semiconductor Equipment Manufacturing Information Tagging.

Semiconductor Equipment Manufacturing Information Tagging by design does not include tutorials on SGML, XML, how to use the defined elements or modules, or how to create document content.

2.3 *SGML and XML* – Any documents marked up according to Semiconductor Equipment Manufacturing Information Tagging will be "valid" XML documents: that is, "well-formed" XML documents that have an associated document type declaration and that comply with the constraints expressed therein. Since valid XML documents are by definition type-valid SGML documents, such documents will be valid SGML documents as well.

Initially, information models will be maintained in both XML and SGML, with all changes made in parallel. SEMI will issue a dual set of models whenever a change is made, and both will always be (within the limits of their syntax) the same. Although parallel maintenance is unfortunate, it is intended to make it easier for members to create documents using current SGML or XML tools. As Web-SGML implementations and alternative XML schema syntax become more common, modules may be maintained in other syntactic forms.

2.4 *Examples of SEMI Content Specifications* - There are other SEMI standards and specifications that regulate the content of a document. Semiconductor Equipment Manufacturing Information Tagging is expressly not in conflict with any of them, since it specifies only how to identify the content present in the documents, and in some contexts, how to electronically structure the content. Semiconductor Equipment Manufacturing Information Tagging does not address what information is to be included. Examples of SEMI content-related or content guideline-related standards and specifications can be seen in section 7.

3 Referenced Documents

Semiconductor Equipment Manufacturing Information Tagging references the following information standards, which should be referred to in their entirety for full details:

3.1 *ISO Standards*[1]

International Standard for SGML; ISO-8879-1986 as modified by Amendment 1, of 1988

HyTime Standard ISO 10744 revision 2, which is referenced for hypertext linking

3.2 *Other references*[2]

The Extensible Markup Language (XML)V 1.0 Recommendation of the World Wide Web Consortium (W3C)

The draft W3C specifications for Extensible Linking Language (XLL).

4 Terminology

4.1 *Attribute* - An attribute is a markup construct that resides within the start tag of an element to provide additional information about the element. (Note: the start tag is the tag that is placed directly before the element in the datastream and determines where the element begins.)

4.2 *Conforming Authoring Application* - A conforming authoring application must be able to produce conforming documents. There is no requirement that all internal work in the application be performed in the markup described by Semiconductor Equipment Manufacturing Information Tagging, only that the end product, exported for interchange, must be a conforming document.

4.3 *Conforming Document* - A conforming document is one that meets the markup rules and specific information models defined in Semiconductor Equipment Manufacturing Information Tagging for the class of document. This specification comprises three parts: this base document, a set of information models, and the documentation for those models. A conforming document must conform to all three parts.

A conforming document created by one application must be interchangeable with a conforming application without significant information loss.

NOTE: Explicit rendering instructions such as font family and type size are not considered to be significant information.

4.4 *Conforming Element* - A conforming element is one that uses the names and markup rules defined in Semiconductor Equipment Manufacturing Information

[1] *ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genevè 20, Switzerland. http://www.iso.ch*

[2] *World Wide Web Consortium, Massachusetts Institute of Technology Laboratory for Computer Science, 545 Technology Square, Cambridge, MA 02139. http://www.w3.org*

Tagging for the class of element. A conforming element created by a conforming application must be interchangeable with another conforming application without information loss.

4.5 *Conforming Rendering Application* - Rendering (presentation) is the process and means by which the elements in a document shall be made visually or otherwise understandable to the end user, for example, printing a document on paper, browsing a series of elements on screen, or stating a series of elements through voice synthesis. A conforming rendering application must be able to print or display conforming documents without significant loss of information. The presentation should be consistent with the intent of the originating system.

A conforming rendering application may not impose structural requirements that are not required by the DTD or other document models as stated in the second part of Semiconductor Equipment Manufacturing Information Tagging. For example, a rendering engine may not require an element which is optional in the models or require an attribute that is implied. A rendering application may require that the rules in this Base Specification and those in the Tag Library are followed.

For example, if the DTDs say that an element is optional, a Rendering Application may not require that it be present. If the Tag Library says that the contents of an element must be some particular information, the Rendering Application may require that it be so. More specifically, if the <description> element is optional, a Rendering Application may not fail to process a document because it does not contain <description>s. If the Tag Library says that the contents of a "datechanged" attribute is a date in YYYYMMDD format, a Rendering Application may fail if the attribute does not contain a valid date.

4.6 *Document* - A logical assembly of elements, that, if correctly ordered, is a means of transmitting an internally consistent piece of information. A document is made up of one or more elements which must all be contained in one "root" element.

4.7 *Document Class* - A document class consists of all of the documents or information fragments that follow a single set of markup rules, including the same elements and element relationships. In general, a class of documents can be considered to be documents that are nearly the same in structure and have similar types of content. A document class is usually (but not necessarily) defined by a structural model (such as a DTD or Schema) that governs its existence.

4.8 *Document Exchange* - For SEMI E36, "document exchange" is synonymous with "document interchange" (see definition).

4.9 *Document Interchange* - Document interchange entails passing one or more elements, usually as a document, from one conforming system to one or more other systems (also known as "exchange").

4.10 *Document Model* - "Document model" is a term for a set of structural rules that describe the legal markup for a particular class of documents. DTDs and Schema are types of document models.

4.11 *Document Type Definition (DTD)* - A DTD is a document model or list of markup rules, which may be used in both SGML and XML. As specified in the SGML standard, ISO 8879, a DTD is:

> "Rules, determined by an application, that apply SGML to the markup of documents of a particular type. A document type definition includes a formal specification, expressed in a document type declaration, of the element types, element relationships and attributes and references that can be represented by markup. It thereby defines the vocabulary of the markup for which SGML defines the syntax." (ISO 8879 4.105)

4.12 *Element* - An element is one named, contiguous piece of information in the information stream. Usually the data within an element has a semantic or structural relationship as well, for example a person's surname, an error code, a pointer to external data, a paragraph, or a procedure that contains steps. In the previous version of this specification (i.e., in SEMI E36-95) an element is also referred to as an "information component."

An element is:

- A uniquely addressable unit of information within the document; and/or
- An identifier to an addressable unit of information outside the document.

4.13 *Markup* - For Semiconductor Equipment Manufacturing Information Tagging, markup is defined as additional data characters that are added to data to provide information about the data and make the data more useable. The markup described by Semiconductor Equipment Manufacturing Information Tagging is internal markup, that is, markup which resides in the same data stream as the data — in specific SGML and XML markup.

4.14 *Nonconforming Document* - A non-conforming document is one that does not use the markup properly or follow the markup rules defined in Semiconductor Equipment Manufacturing Information Tagging.

4.15 *SGML* - SGML is "Standard Generalized Markup Language." The Standard Generalized Markup Language is an International Organization for Standardization (ISO) standard. The ISO Reference Number is ISO 8879:1986(E). SGML is a meta-language for constructing markup. See also XML (Extensible Markup Language).

4.16 *Tag* - A tag is a string of characters delimited by rules set out in the SGML standard (and used in XML and HTML). Tags are placed in the datastream to indicate where an element begins and ends. In Semiconductor Equipment Manufacturing Information Tagging, tags match as closely as possible the names of the elements in English.

4.17 *XLL (Extensible Linking Language)* - When released, XLL is intended to be the syntax and semantics for both simple hypertext linking (as exemplified by HTML) and more complex linking, providing such functionality as multi-way links, multi-ended links, and addressing from an external document based on structure. A W3C Working Group is in the process of producing a draft specification, which uses many of the concepts from HyTime (Hypermedia/Time-based Document Representation Language ISO/IEC 10744) and the TEI (Text Encoding Initiative) extended pointers.

4.18 *XML (Extensible Markup Language)* - XML is a W3C Recommendation that describes a subset of SGML syntax and functionality intended for use on the World Wide Web. XML is, by design, simpler, less complex, and easier to implement than SGML. XML is also, by design, far less flexible than SGML because it includes only the most commonly implemented SGML features.

XML is a family of Recommendations that includes a linking specification (XLL); it may in the future include other specifications such as a stylesheet specification (XSL). The XLL linking specification will provide the syntax for hypertext links defined in Semiconductor Equipment Manufacturing Information Tagging. The XSL stylesheet language will be neither mandated nor prohibited in SEMI E36-98.

5 Design and Principles

5.1 *Information Markup* - For purposes of interchange, information will be marked-up according to the conventions established in Semiconductor Equipment Manufacturing Information Tagging. The defined markup will:

- Identify the start and end of elements, which may contain named information content or structural components;
- Provide information concerning the identified elements; and
- Specify connections among elements and between elements and external objects.

Applications will be able to utilize this markup to:

- Select, limit, and organize specific elements for reuse or interchange;
- Start and stop behavior, such as print formatting, complex screen display, and the actuation of programs;
- Limit retrieval (for increased precision);
- Generate navigation aids such as indexes and tables of contents; and
- Validate document structure or content.

5.2 *SGML Standard and XML Family of Recommendations* - The intent of Semiconductor Equipment Manufacturing Information Tagging is to define the rules and markup that can be used to create XML data (which is, by definition, SGML data) for maximum interchangeability and movement across both internets and intranets. Therefore all markup and rules will be designed to be fully conforming with the W3C XML Recommendation. It is also the intent to describe hypertext linking in conformance with the XLL (Extensible Linking Language), as much as it is known, and to migrate in the direction of that recommendation as the recommendation is finished.

Since the intent of Semiconductor Equipment Manufacturing Information Tagging is to create data that is both valid XML and type-valid SGML:

- The DTDs, which will be written in both SGML and XML syntax, will conform to the XML subset of SGML by not using features and syntax that XML prohibits such as exceptions and #CONREF attributes;
- Tagged data produced according to Semiconductor Equipment Manufacturing Information Tagging will be valid XML. Early implementers using SGML authoring or conversion tools should check with their tool suppliers to make sure those tools will work with their document without modification.

Names of elements, attributes, and entities will be used consistently within the SEMI E36 module set. While some elements may have different content models from module to module, and in fact that is the intent of the parameter entity framework, all name definitions and use will be consistent throughout the SEMI E36 DTD suite. This means that namespace issues, such as those addressed by the XML Namespace Recommendation (currently under development), are not relevant within the scope of SEMI E36. It is likely that mechanisms such as XML Namespaces will be used to incorporate parts of the SEMI E36 markup set in other applications; but this use is outside the scope of SEMI E36 itself.

5.3 *Specification for Interchange* - Semiconductor Equipment Manufacturing Information Tagging defines markup optimized for interchange, not for information development (authoring) nor for information presentation (rendering). Thus, some of the capabilities and functionality that might be desired for authoring or rendering will not be included in the markup rules, by design. For example, few elements may be required and the sequence of elements will not be tightly constrained.

It is anticipated that more specific authoring and rendering models may be developed by other parties as part of conforming applications. All conforming interchange, however, will explicitly follow the markup and structural rules defined in Semiconductor Equipment Manufacturing Information Tagging.

5.4 *General Modeling Principles*

- Document (information) models will be constructed that name the elements, describe the relationships among these elements, and impose certain markup or content constraints. The information markup will be controlled by these models.
- All models will be made available by SEMI and distributed and balloted as additional parts of Semiconductor Equipment Manufacturing Information Tagging. Models will be described in the second part of Semiconductor Equipment Manufacturing Information Tagging rather than included in the base document directly because the models are assumed to be dynamic documents that will grow and change as requirements alter. The data models and the Tag Library may be balloted separately without requiring a re-balloting of this part of the specification.
- The models will initially be in the form of SGML and XML Document Type Definitions (DTDs) and may later include other XML-defining schema.
- There will be no all-inclusive general information models; each DTD or other collection of rules will model specific elements or specific document types.
- Markup will be primarily designed according to the nature of the information being described; such considerations as data volume and ease of implementation will only be considered secondarily.
- DTDs will be constructed in a modular fashion, with content-related or structurally-related modules. The purpose of such modularization is to reuse existing information content models as much as possible. New element structures should be created only when new content is analyzed.

5.5 *Information Modeling*

5.5.1 *Types of Elements* - SGML and XML elements can identify many types of information. There are situations in which each of the following element types are appropriate, and many situations in which several could be used. In designing structures and tagging documents, elements should be designed using the following hierarchy of types, from most- to least-preferred. Only if the information cannot be satisfactorily identified using one type of element should those below it in the following list be considered.

- Content Elements — those that identify the information content, such as Warning, Procedural Step, Part Number, Installation Manual, or Bill of Materials.
- Structural Elements — those that identify the structural role of a part of a document, such as Title, Paragraph, or List Item.
- Pointer Elements — those that point to other locations, either in this document or another, such as Cross-reference, Footnote Reference, or URL.
- Format Elements — those that identify portions of a document that are to be formatted differently from surrounding text and for which there is no Content, Structural, or Pointing reason that they should be so formatted, for example a Bold element. Format elements are to be used as a last resort; use of a content, structure, or pointer element with a format-related attribute is preferable to use of a format element.

5.5.2 *Naming Elements* - Markup in the DTDs will be named consistently across contexts. That is, the same element name will be used for an element that can occur in many places with the same function, regardless of the location. For example, there is only one element for Title, not many separate elements for Section Title, Table Title, Figure Title, etc.

In XML, names are case-sensitive. In the interest of keeping compliant with XML, all names will be case-sensitive. (In SGML, names may not be case-sensitive since such names may be case-folded to upper case at any time.) All element tag names should be in lower case. Entity names and attribute names may be mixed case, lower case, or upper case to match common usage of the name involved. If there is no such consideration, lower case should be used. Attribute values should be in lower case unless there is a good reason to make them another case, such as a list of state or country codes which would naturally appear in upper case.

5.5.3 *Recursive Structures* - In cases where an element may contain one or more of the same elements within itself, there are several styles of modeling the solution:

- Use recursive structures. (In recursion, an element would be allowed to contain itself, thus a <section> could contain one or more <section>s, which could themselves contain <section>s, etc.);
- Create an explicit hierarchy by naming the top level and lower levels. (Thus a <section> could contain one or more <subsections>, which could themselves contain one or more <sub-subsections>, etc.); or
- Create an explicit hierarchy by numbering the top level as "1", and subsequent levels as "2", "3", etc. (Thus a <section1> could contain one or more <section2>s, which could themselves contain one or more <section3>s, etc.).

In such cases, recursion should be used to model an element because it is optimal for authoring, editing, and data reuse; in such an environment an editor can move a section from one level to another without needing to modify the tagging inside the section.

5.5.4 *Content Modeling* - To create SGML elements that are maximally re-useable and compatible with XML, there are several SGML modeling capabilities that are prohibited in SEMI E36:

- RCDATA and CDATA declared content (character data in which elements and entities cannot be recognized) are prohibited.
- The "AND" connector (which specifies that all the elements so connected are required but that order is irrelevant) is prohibited.
- Inclusions and Exclusions to content models are prohibited.
- Pernicious mixed element content is prohibited. This means that if an element model contains character data it must allow character data at any place in the model. In practice this means that any mixed content model groups should be repeatable "| " (or) groups.

In addition, the following rules also will apply:

- Each element must be declared separately;
- No inline comments or empty comments will be permitted; only full comment declarations may be used;
- The replacement text for external parameter entities must be well-formed, as per the XML specification declarations;
- The entity types CDATA, PI, and bracketed text are prohibited;
- No Marked Sections are allowed in the DTDs; and
- External entities must include both a SYSTEM and a PUBLIC identifier.

5.5.5 *Attributes* - The attribute list for each element must be declared separately. Attribute values must not contain references to external entities. If a Declared Value is not a specified list, only the following Declared Value keywords may be used:

- CDATA (character data);
- ID (a unique identifier for the element within its current document);
- IDREF and IDREFS (one or more pointer to the IDs of other elements within the same document);
- ENTITY or ENTITIES (the name of one or more defined entities); and
- NMTOKEN or NMTOKENS (one or more words that consist entirely of name characters).

On all attribute declarations, attribute values specified as defaults must be literals. Only the following Default Values keywords may be used:

- #REQUIRED (must be present);
- #IMPLIED (optional, may be implied by the application); and
- #FIXED (set, not able to be changed).

5.6 *Formatting from Element Context versus from Attributes* - The use of formatting attributes to indicate preferred rendition in display or print should be limited to situations in which no other mechanism is available. That is, if the desired formatting can be accomplished by use of the element name alone, or based on the context in which the element appears, no formatting attributes should be used. Elements should only carry formatting attributes such as "type-size" if there is no other mechanism to pass this information or if an author or editor, rather than the output system, must control the presentation directly. Formatting attributes, when used, should be optional and considered advisory by the rendering agent.

5.7 *Data Markup Rules* - To create SGML documents that are maximally re-useable and compatible with XML, the following restrictions are placed upon the tagged instances produced in accordance with Semiconductor Equipment Manufacturing Information Tagging:

- The characters “<” and “&” must always be escaped as “<” and “&” respectively.
- No Marked Sections will be allowed in data content.
- The replacement text of general text entities must be well-formed, for example, an element that starts within an entity must also end within it.
- All attributes should be present (even default attributes) and attribute values should be well-formed, that is with the name, equal sign, and quotation marks present.
- Processing Instructions are prohibited with the exception of the XML declaration, for example: <?XML version=″1.0″ RMD='INTERNAL'>.

6 How Semiconductor Equipment Manufacturing Information Tagging Should Be Used

6.1 *Conformance* - A conforming document is one that meets the markup rules defined for the document class in Semiconductor Equipment Manufacturing Information Tagging. A non-conforming document is one that does not use the markup properly or follow the markup rules defined in Semiconductor Equipment Manufacturing Information Tagging. A conforming document created by an application must be interchangeable with another conforming application without significant information loss. A conforming application may also deliver the markup rules (information models) for the document or information class being interchanged to another system.

Conforming applications are those that create, render, or work with conforming documents. Such applications may include browsers and online rendering software, print and composition engines, editors and authoring systems, search and retrieval engines, etc. In addition to strictly conforming applications, it is expected that many applications will accept conforming documents as input, converting them to the internal format of the software.

6.1.1 *Conforming Authoring Application* - A conforming authoring application must be able to produce conforming information. An application may state that it is conformant with Semiconductor Equipment Manufacturing Information Tagging if it has the ability to:

- Create and manipulate conforming documents;
- Create and manipulate one or more classes of conforming documents;
- Import conforming documents into the application and output matching conforming documents; or
- Turn non-conforming documents into conforming documents.

6.1.2 *Conforming Rendering Application* - There is no rendering specification stated or required by Semiconductor Equipment Manufacturing Information Tagging at this time. This specification does not define style conventions or endorse any particular language for the interchange of stylistic information. That said, a conforming rendering application is one that can render (print, display, pronounce, etc.) conforming documents without significant loss of information. The presentation should be consistent with the intent of the originating system, but need not be an exact, facsimile-reproduction match.

To call itself conforming, a rendering application must be able to take any conforming document, which is by definition legal according to this base specification and the models defined and explained in other parts of the specification, and render that document in some visual or non-visual fashion. A conforming rendering application may not impose additional requirements or constraints such as content requirements. For example, a rendering engine may not require the presence of an element that is optional in the models or require a more restrictive range of values for an attribute than the models state.

6.1.3 *Validation* - Documents tagged according to Semiconductor Equipment Manufacturing Information Tagging must parse cleanly according to their SGML or XML models and must follow the rules stated in this base document and the Tag Library and other documentation. Tagging validation must be accomplished through the use of validating SGML or XML parsers, in standalone form or as incorporated into other software packages. (Note: Validation of some of the rules described in this base document and the Tag Library documentation cannot be accomplished using only an XML or SGML parser. This does not mean that such rules can be ignored, merely that other validation techniques may be required.) SEMI E36 rules include both rules that can be checked with software and content rules that can only be verified intellectually; a conforming SEMI E36 document must conform to both types of rules.

6.2 *Maintenance of Semiconductor Equipment Manufacturing Information Tagging* - This base portion of the SEMI E36 specification is intended to be debated and balloted once and change little over time. Additional parts of the specification will contain the actual information models that describe the markup to be used. New information models may be proposed at any time. Such models will be distributed, discussed, and balloted individually or in small groups, in the form of one or more SEMI E36 modules, as they are created. Modules that are approved will be appended to Semiconductor Equipment Manufacturing Information Tagging. The documentation will be changed and balloted in parallel, to match any changes in the models.

6.2.1 *Module Library* - A growing module library containing all approved modules will be maintained, adding modules as additional subject areas and document types are defined. Once a module has been approved, it will be provided as part of Semiconductor Equipment Manufacturing Information Tagging. Place-holding modules may be introduced into the library that are designated as "Temporary", for use only until a formal analysis and balloting process can provide a more appropriate module. Initially modules will be XML and SGML DTDs and DTD fragments. As XML alternative modeling syntaxes such as schema become supported by software, these may be used to supplement SEMI E36 information models.

6.2.2 *Modules* - Each module will be given a unique short name (to be used as a file name), a version number, and a unique public identifier written according to the rules of ISO 8879 and incorporating the version number.

File names will be all lower case, constructed by concatenating the following, in order:

- A 3- to 8-character descriptive name;
- A hyphen;
- The file type as "xml" or "sgml";
- A period; and
- A 3-character descriptive extension that defines the type of file (such as "dec", "sgm", etc.) These extensions will be defined in the Tag Library.

Each module will contain:

- An initial comment which names the module, states the purpose of the modules, types the modules as Temporary or Implemented, and states how the module should be integrated with other modules;
- A growing change history comment that describes (in sedimentary order; that is, the most recent at the top) all modifications made to the model. Each item in the change history should be numbered, dated, provide a description of the change, give a brief rationale, and name the changing agent.
- Whatever syntax is employed, internal comments should be used throughout the module to name and describe the elements and provide information that may not be stated directly in the syntax used.

6.2.3 *Consolidated Tag Library* - A single, consolidated Tag Library will be maintained which will describe the elements, attributes, and entities defined in all the modules. Each description will contain sufficient detail to indicate the meaning and correct usage of the data markup. The library (or changes to the library) will be reissued whenever a module is added or modified in a way that affects any of the elements, attributes, or entities.

Modules should use elements (tags) that are already in the Tag Library wherever the definition of the element matches the need. If the definition of an existing tag does not meet the need, a new tag should be created.

A diagram of the structure of each element will be included in the Tag Library, except for elements that are empty, contain only character data, or contain a simple "or" group in which all contents may appear at any point in the model.

For each element, the Tag Library will contain:

- Element Title, consisting of its Tag and Name;
- Definition in clear, plain English, including description of intended use and application when appropriate;
- Remarks (if needed);
- Related Elements (if needed);
- For each Source, or module in which the element is defined:
    - Attributes Associated with the Element (if any);
    - The model of the Element in SGML syntax and narrative form;
    - Presentation information (if needed);
    - Formatted examples of the element (if needed);
    - Tagged examples of the elements (if needed); and
    - The Name of the Source, or module in which the element is defined.

For each Attribute, the Tag Library will contain:

- Attribute Title, consisting of the short form of the attribute which appears in the documents, and the attribute Name;
- Attribute usage, describing how that attribute is used;
- For each possible value of an attribute with a specified set of values, the meaning or implications of each value; and
- The default value of the attribute.

6.3 *Creation of More Specific Authoring or Rendering Models* - The DTDs and models described in Semiconductor Equipment Manufacturing Information Tagging will not be designed for optimal use in document creation. To create and display documents, data creators may wish to create more enforcing authoring models based on this markup. Such authoring models may:

- Require the presence of specific elements;
- Specify the sequence of elements; and/or
- Include additional elements for internal use (which would need to be removed before interchange). For example, such information might include elements for tracking the internal authoring and validation processes or for company-confidential information.

Similarly, it is likely that viewing, print rendition, search and retrieval, or other display applications will create display-only models based on Semiconductor Equipment Manufacturing Information Tagging. To load display tools, it is quite likely that the specified models will be transformed into a form that is optimized for the particular search and retrieval or display system. Such display models might:

- Resequence the data;
- Add additional markup such as "container" tags around structures to be considered one element for formatting purposes;
- Transform the form of some elements; or
- Remove parts of the information that are not relevant to a particular application.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E37-0702
HIGH-SPEED SECS MESSAGE SERVICES (HSMS) GENERIC SERVICES

1 Purpose

HSMS provides a means for independent manufacturers to produce implementations which can be connected and interoperate without requiring specific knowledge of one another.

HSMS is intended as an alternative to SEMI E4 (SECS-I) for applications where higher speed communication is needed or when a simple point-to-point topology is insufficient. SEMI E4 (SECS-I) can still be used in applications where these and other attributes of HSMS are not required.

HSMS is also intended as an alternative to SEMI E13 (SECS Message Services) for applications where TCP/IP is preferred over OSI.

It is intended that HSMS be supplemented by subsidiary standards which further specify details of its use or impose restrictions on its use in particular application domains.

2 Scope

High-Speed SECS Message Services (HSMS) defines a communication interface suitable for the exchange of messages between computers in a semiconductor factory.

4 Terminology

API — Application Program Interface. In the case of TCP/IP, a set of programming conventions used by an application program to prepare for or invoke TCP/IP capabilities.

communication failure — a failure in the communication link resulting from a transition to the NOT CONNECTED state from the SELECTED state. (See Section 9.)

confirmed service (HSMS) — an HSMS service requested by sending a message from the initiator to the responding entity which requires that completion of the service be indicated by a response message from the responding entity to the initiator.

connection — a logical linkage established on a TCP/IP LAN between two entities for the purposes of exchanging messages.

control message — an HSMS message used for the management of HSMS sessions between two entities.

data message — an HSMS message used for communication of application-specific data within an HSMS session. A Data Message can be a Primary Message or a Reply Message.

entity — an application program associated with an endpoint of a TCP/IP connection.

header — a 10-byte data element preceding every HSMS message.

initiator (HSMS) — the entity requesting an HSMS service. The initiator requests the service by sending an appropriate HSMS message.

IP Address — Internet Protocol Address. A logical address which uniquely identifies a particular attachment to a TCP/IP network.

local entity — relative to a particular end point of a connection, the local entity is that entity associated with that endpoint.

1 The IETF documents can be obtained from The Network Information Center, Network Solutions, 14700 Park Meadow Drive, Suite 200, Chantilly, VA 22021 USA

2 POSIX documents can be obtained from Institute of Electrical and Electronic Engineers (IEEE), 345 East 47th Street, New York, NY 10017 USA

local entity-specific — general qualifier to any procedure, option, issue, or other implementation matter which is not a subject of this standard and left to the discretion of the individual supplier.

message — a complete unit of communication in one direction. An HSMS Message consists of the Message Length, Message Header, and the Message Text. An HSMS Message can be a Data Message or a Control Message.

message length — a 4-byte unsigned integer field specifying the length of a message in bytes.

open transaction — a transaction in progress.

port — an endpoint of a TCP/IP connection whose complete network address is specified by an IP Address and TCP/IP Port number.

port number — (or TCP port number). The address of a port within an attachment to a TCP/IP network which can serve as an endpoint of a TCP/IP connection.

primary message — an HSMS Data Message with an odd numbered Function. Also, the first message of a data transaction.

published port — a TCP/IP IP Address and Port number associated with a particular entity (server) which that entity intends to use for receiving TCP/IP connection requests. An entity' s published port must be known by remote entities intending to initiate connections.

receiver — the HSMS Entity receiving a message.

remote entity — relative to a particular endpoint of a connection, the remote entity is the entity associated with the opposite endpoint of the connection.

reply — an HSMS Data Message with an even-numbered function. Also, the appropriate response to a Primary HSMS Data Message.

responding entity (HSMS) — the provider of an HSMS service. The responding entity receives a message from an initiator requesting the service. In the event of a confirmed service, the responding entity indicates completion of the requested service by sending an appropriate HSMS response message to the initiator of the request. In an unconfirmed service, the responding entity does not send a response message.

session — a relationship established between two entities for the purpose of exchanging HSMS messages.

session entity — an entity participating in an HSMS session.

session ID — a 16-bit unsigned integer which identifies a particular session between particular session entities.

stream (TCP/IP) — a sequence of bytes presented at one end of a TCP/IP connection for delivery to the other end. TCP/IP guarantees that the delivered sequence of bytes matches the presented stream. HSMS subdivides a stream into blocks of contiguous bytes - messages.

T3 — reply timeout in the HSMS protocol.

T5 — connect Separation Timeout in the HSMS protocol used to prevent excessive TCP/IP connect activity by providing a minimum time between the breaking, by an entity, of a TCP/IP connection or a failed attempt to establish one, and the attempt, by that same entity, to initiate a new TCP/IP connection.

T6 — control Timeout in the HSMS protocol which defines the maximum time an HSMS control transaction can remain open before a communications failure is considered to have occurred. A transaction is considered open from the time the initiator sends the required request message until the response message is received.

T7 — connection Idle Timeout in the HSMS protocol which defines the maximum amount of time which may transpire between the formation of a TCP/IP connection and the use of that connection for HSMS communications before a communications failure is considered to have occurred.

T8 — network Intercharacter Timeout in the HSMS protocol which defines the maximum amount of time which may transpire between the receipt of any two successive bytes of a complete HSMS message before a communications failure is considered to have occurred.

TCP/IP — Transmission Control Protocol/Internet Protocol. A method of communications which provides reliable, connection-oriented message exchange between computers within a network.

TLI — Transport Level Interface. One particular API provided by certain implementations of TCP/IP which provides a transport protocol and operating system independent definition of the use of any Transport Level protocol.

transaction — a Primary Message and its associated Reply message, if required. Also, an HSMS Control Message of the request (.req) type, and its response Control Message (.rsp), if required.

unconfirmed service (HSMS) — an HSMS service requested by sending a message from the initiator to the responding entity which requires no indication of completion from the responding entity.

5 HSMS Overview and State Diagram

High-Speed SECS Message Services (HSMS) defines a communication interface suitable for the exchange of messages between computers in a semiconductor factory using a TCP/IP environment. HSMS uses TCP/IP stream support, which provides reliable two way simultaneous transmision of streams of contiguous bytes. It can be used as a replacement for SECS-I communication as well as other more advanced communications environments.

The procedure for HSMS communications parallels the more familiar SECS-I communications it replaces. The following steps are followed for any communications (HSMS or otherwise):

1. Obtain a communications link between two entities. In SECS-I, this is the RS232 wire physically connecting host and equipment. In HSMS, the link is a TCP/IP connection obtained by the standard TCP/IP connect procedure. Note that the abstract term "entity" is used instead of "host" or "equipment." This is because, while HSMS is used for SECS-I replacement, it has more general applications as well. In a SECS-I replacement application, the "host" is an "entity" and the "equipment" is an "entity."

2. Establish the application protocol conventions to be used for exchanging data messages between two entities. For SECS-I, this step is implicit in the fact that semiconductor equipment is physically connected on the two ends of the wire: the protocol is SECS-II.

   In the case of HSMS, the communications link is a dynamically established TCP/IP connection on a physical link which may be shared with many other TCP/IP connections using protocols other than HSMS or connections using non TCP/IP protocols. HSMS adds a message exchange (called the Select procedure) which is used to confirm to both entities that the particular TCP/IP connection is to be used exlusively for HSMS communications.

3. Exchange Data. This is the normal intended purpose of the communications link. In both SECS-I and HSMS, the procedure is to exchange SECS-II encoded messages for the control of semiconductor equipment and/or processes. Data exchange normally continues until one or both of the entities are taken off-line for equipment-specific purposes, such as maintenance.

4. Formally end communications. In SECS-I, there is no formal requirement here; the equipment to be taken off-line stops communicating.

   In HSMS, a message exchange (either the "bilateral" Deselect procedure or the "unilateral" separate procedure) is used for both parties to confirm that the TCP/IP connection is no longer needed for HSMS communications.

5. Break the communications link. In SECS-I, this is done by physically unplugging the host or equipment from the communications cable, which only occurs during repair or physical reconfiguration of the factory network environment.

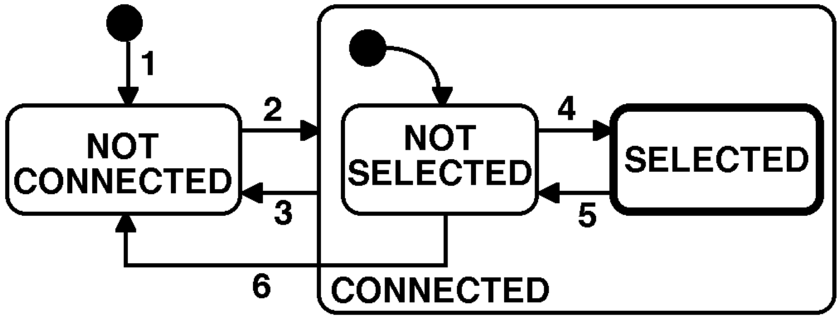
   In HSMS, since it uses the dynamic connection environment of TCP/IP, the TCP/IP connection is logically broken via a release or a disconnect procedure without any physical disconnect from the network medium.

Two additional procedures, of a diagnostic nature, are supported in HSMS, which are generally not required by a simple SECS-I link or a SECS-I direct replacement. These follow:

1. Linktest. This procedure provides a simple confirmation of connection integrity.

2. Reject. Because HSMS is intended to be extended to protocols other than just SECS-II (by means of subsidiary standards), it is possible that two entities can be connected (due to a configuration error) which use incompatible subsidiary standards. Also, during initial implementation, incorrect message types may be sent, or they may be sent out of order due to software bugs. The reject procedure is used to indicate such an occurrence.

5.1 *HSMS Connection State Diagram* — The HSMS state machine is illustrated in the diagram below. The behavior described in this diagram defines the basic requirements of HSMS: subsidiary standards may further extend these or other states.



5.2 *State Descriptions*

5.2.1 *NOT CONNECTED* — The entity is ready to listen for or initiate TCP/IP connections but either has not yet established any connections or all previously established TCP/IP connections have been terminated.

5.2.2 *CONNECTED* — A TCP/IP connection has been established. This state has two substates, NOT SELECTED and SELECTED.

5.2.2.1 *NOT SELECTED* — A substate of CONNECTED in which no HSMS session has been established or any previously established HSMS session has ended.

5.2.2.2 *SELECTED* — A substate of CONNECTED in which at least one HSMS session has been established. This is the normal "operating" state of HSMS: data messages may be exchanged in this state. It is highlighted by a heavy outline in the state diagram.

5.3 *State Transition Table*

Table 1

#	*Current State*	*Trigger*	*New State*	*Actions*	*Comment*
1	...	Local entity-specific preparation for TCP/IP communication.	NOT CONNECTED	Local entity-specific	Action depends on connection procedure to be used: active or passive.
2	NOTCONNECTED	A TCP/IP connection is established for HSMS communication.	CONNECTED - NOT SELECTED	Local entity-specific	none
3	CONNECTED	Breaking of TCP connection.	NOT CONNECTED	Local entity-specific	See Section 6.4.
4	NOT SELECTED	Successful completion of HSMS Select Procedure.	SELECTED	Local entity-specific	HSMS communication is now fully established: data message exchange is permitted.
5	SELECTED	Successful completion of HSMS Deselect or Separate.	NOT SELECTED	Local entity-specific	This transition normally indicates the end of HSMS communication and so an entity would immediately proceed to break the TCP/IP connection (transition 3 above).
6	NOT SELECTED	T7 Connection Timeout.	NOT CORRECTED	Local entity-specific	per Section 9.2.2

6 Use of TCP/IP

6.1 *TCP/IP API* — The specification of a required TCP Application Program Interface (API) for use in implementations is outside the scope of HSMS. A given HSMS implementation may use any TCP/IP API — sockets, TLI (Transport Layer Interface), etc. — appropriate to the intended hardware and software platform, as long as it provides interoperable TCP/IP streams protocol on the network.

The appendix contains examples of the TCP/IP procedures referenced in this standard and sample scenarios using both the TLI (POSIX standard 1003.12) and the popular BSD socket model for TCP/IP communication.

6.2 *TCP/IP Network Addressing Conventions*

6.2.1 *IP Addresses* — Each physical TCP/IP connection to a given Local Area Network (LAN) must have a unique IP Address. IP Addresses must be assignable at installation time, and an HSMS implementation cannot select a fixed IP Address. A typical IP Address is 192.9.200.1.

IP imposes restrictions on these numbers which are outside the scope of the HSMS protocol. Consult Section 2.3 of RFC 791, Internet Protocol (IP) in Section 3.

6.2.2 *TCP Port Numbers* — A TCP Port Number can be considered as an extension of the IP Address.

HSMS implementations should allow configuring TCP Port to the full range of the TCP/IP implementation used. A typical TCP Port Number is 5000.

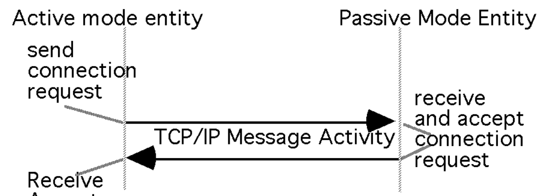
Conventions have been established for selecting TCP Port Numbers which are outside the scope of the HSMS protocol. Consult RFC 793, Transmission Control Protocol (TCP) in Section 3.

6.3 *Establishing a TCP/IP Connection*

6.3.1 *Connect Modes* — The procedures for establishing a TCP/IP connection are defined in RFC 793. However, not all the procedures defined by RFC 793 are supported by commonly available APIs. In particular, while RFC 793 permits both entities to initiate the connection simultaneously, this feature is rarely supported in available

APIs. Therefore, HSMS restricts an entity to one of the following modes:

- Passive Mode. The Passive mode is used when the local entity listens for and accepts a connect procedure initiated by the Remote Entity.
- Active Mode. The Active mode is used when the connect procedure is initiated by the Local Entity.



TCP/IP Connection Procedure Summary

The appendix provides an example of how an entity may operate alternately in the active and passive modes to achieve greater flexibility in establishing communications.

6.3.2 *Passive Mode Connect Procedure* — The procedure followed by the Passive Local Entity is defined in RFC 793. It is summarized as follows:

1. Obtain a connection endpoint and bind it to a published port.
2. Listen for an incoming connect request to the published port from a remote entity.
3. Upon receipt of a connect request, acknowledge it and indicate acceptance of the connection. At this point, the connect procedure has completed successfully, and the CONNECTED state is entered (Section 5).

These procedures are carried out through the API of the local entity' s implementation of TCP/IP. The appendices provide the API-specific procedures for the above steps using both TLI and BSD.

NOTE: A failure may occur during the above steps. The reason for failure may be local entity-specific or may be due to a lack of any connect request after a local entity-specific timeout. The action to be taken (for example: return to step 1 to retry) is a local entity-specific issue.

NOTE: See Section 9, Special Considerations, for issues relating to multiple connection requests to the same passive mode entity.

6.3.3 *Active Mode Connect Procedure* — The procedure followed by the Active Local Entity is defined in RFC 793. It is summarized as follows:

1. Obtain a connection endpoint.
2. Initiate a connection to the published port of a passive mode remote entity.
3. Wait for the receipt of the acknowledge and the acceptance of the connect request from the remote entity. Receipt of the acceptance from the remote

entity indicates successful completion of the connect procedure, and the CONNECTED state is entered (Section 5).

These procedures are carried out through the API of the local entity' s implementation of TCP/IP. The appendix provides the API-specific procedures for the above steps using both TLI and BSD.

NOTE: A failure may occur during the above steps. The reason for failure may be local entity-specific or may be due to a lack of any accept message after a local entity-specific timeout. The action to be taken is a local entity-specific issue. If, however, the local entity intends to retry the connection, it should do so subject to the T5 connect separation timeout (see "Special Considerations").

6.4 *Terminating a TCP/IP Connection* — Connection termination is the logical inverse of Connection establishment. From the Local Entity' s perspective, a TCP/IP connection may be broken at any time. However, HSMS only permits termination of the connection when the connection is in the NOT SELECTED substate of the CONNECTED state.

The procedures for termination of a connection are defined in RFC 793. Either entity may initiate termination of the connection. The NOT CONNECTED state is entered, indicating the end of HSMS communications. The appendix illustrates the procedures for both release and disconnect using the TLI and BSD APIs.

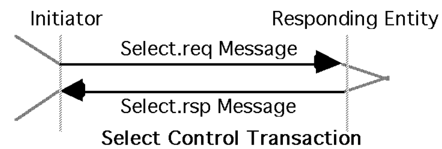
7 HSMS Message Exchange Procedures

HSMS defines the procedures for all message exchange between entities across the TCP/IP connection established according to the procedures in the previous section. As explained in the overview, once the connection is established, the two entities establish HSMS communications with the Select procedure. Then data messages may be exchanged in either direction at any time. When the entities wish to end HSMS communications, the Deselect or Separate procedure is used to end HSMS communications.

7.1 *Sending and Receiving HSMS Messages* — All HSMS procedures involve the exchange of HSMS messages. These messages are sent and received as TCP/IP streams using the previously established TCP/IP connection at standard priority. In particular, the use of "Urgent" data is not supported under HSMS (see RFC 793 for more information on send and receive procedures).

The appendix gives examples of sending and receiving HSMS messages using both TLI and BSD socket APIs.

7.2 *Select Procedure* — The Select procedure is used to establish HSMS communications on a TCP/IP connection using the Select.req and Select.rsp messages in a control transaction.



Although HSMS permits Select at any time in the CONNECTED state, subsidiary standards may further require the connection to be in the NOT SELECTED substate (see "Special Considerations").

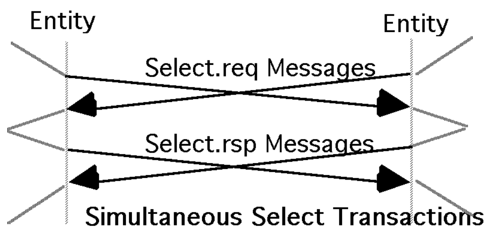
7.2.1 *Initiator Procedure* — The procedure followed by the initiator is as follows.

1. The initiator of the select procedure sends the Select.req message to the responding entity.
2. If the initiator receives a Select.rsp with a Select Status of 0, The HSMS Select procedure completes successfully and the SELECTED state is entered (see Section 5).
3. If the initiator receives a Select.rsp with a non-zero Select Status, the Select completes unsuccessfully (no state transitions).
4. If the T6 timeout expires in the initiator before receipt of a Select.rsp, it is considered a communications failure (see "Special Considerations").

7.2.2 *Responding Entity Procedure* — The procedure followed by the responding entity is as follows.

1. The responding entity receives the Select.req.
2. If the responding entity is able to accept the select, it transmits the Select.rsp with a Select Status of 0. The HSMS Select Procedure for the responding entity is successfully completed, and the SELECTED state is entered (see Section 5).
3. If the responding entity is unable to permit the select, it transmits the Select.rsp with a non-zero Select Status. The HSMS Select Procedure for the responding entity completes unsuccessfully (no state transitions).

7.2.3 *Simultaneous Select Procedures* — If the subsidiary standards do not restrict the use of the Select, it is possible that both entities simultaneously initiate Select Procedures with identical SessionID's. In such a case, each entity will accept the other entity' s select request by responding with a Select.rsp.

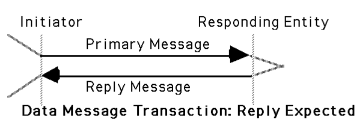


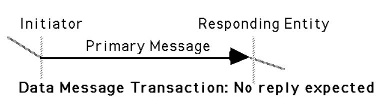
7.3 *Data Procedure* — HSMS data messages may be initiated by either entity as long as the connection is in the SELECTED state. Receipt of a data message when not in the SELECTED state will result in a reject procedure (see Section 7.7).

Data messages may be further defined as part of a data transaction as either a "Primary" or "Reply" data message. In a data transaction, the initiator of the transaction sends a primary message to the responding entity. If the Primary message indicates that a reply is expected, a Reply message is sent by the responding entity in response to the Primary.

The following types of Data Transactions are supported:

1. Primary Message with reply expected and the associated Reply Message.
2. Primary Message with no reply expected.

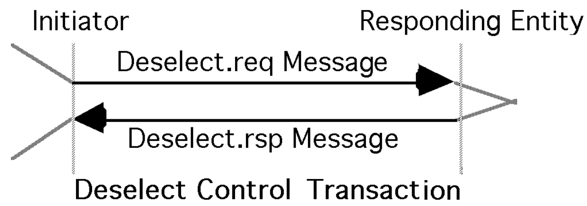




The specific procedures for these transactions are determined by the application layer and are subject to other standards (for example, E5 and E30 for GEM equipment using SECS-II encoded messages).

The applicable upper layer standard is identified by the message type. The type is determined from the specific format defined in Section 8. The normal type for HSMS messages is SECS-II text. Also refer to "Special Considerations" concerning the T3 Reply Timeout.

7.4 *Deselect Procedure* — The Deselect procedure is used to provide a graceful end to HSMS communication for an entity prior to breaking the TCP/IP connection. HSMS requires that the connection be in the SELECTED state. The procedure is as follows.



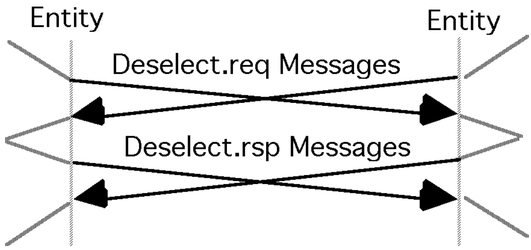
7.4.1 *Initiator Procedure*

1. The initiator of the Deselect procedure sends the Deselect.req message to the responding entity.
2. If the initiator receives a Deselect.rsp with a Deselect Status of 0, its Deselect procedure terminates successfully. The NOT SELECTED state is entered (see Section 5).
3. If the initiator receives a Deselect.rsp with a non-zero Deselect Status, its Deselect procedure terminates unsuccessfully. No state change occurs.
4. If the T6 timeout expires in the initiator before receipt of a Deselect.rsp, it is considered a communications failure (see "Special Considerations").

7.4.2 *Responding Entity Procedure*

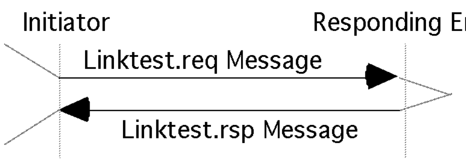
1. The responding entity receives the Deselect.req message.
2. If the responding entity is in the SELECTED state, and if it is able to permit the Deselect, it responds using the Deselect.rsp with a zero response code. The responding entity' s Deselect procedure completes successfully. The NOT SELECTED state is entered (see Section 5).
3. If the responding entity is unable to permit the Deselect, either because it is not in the SELECTED state or because local conditions do not permit the Deselect, it responds using the Deselect.rsp with a non-zero response code. The responding entity' s Deselect procedure terminates unsuccessfully. No state change occurs.

7.4.3 *Simultaneous Deselect Procedures* — If the subsidiary standards do not restrict the use of the Deselect, it is possible that both entities simultaneously initiate Deselect Procedures with identical SessionID's. In such a case, each entity will accept the other entity' s Deselect request by responding with the deselect.rsp.



Simultaneous Deselect Transactions

7.5 *Linktest Procedure* — The Linktest is used to determine the operational integrity of TCP/IP and HSMS communications. Its use is valid anytime in the CONNECTED state.



Linktest Control Transaction

7.5.1 *Initiator Procedure*

1. The initiator of the Linktest procedure sends the Linktest.req message to the responding entity.
2. If the initiator receives a Linktest.rsp within the T6 timeout, the Linktest is successfully completed.
3. If the T6 timeout expires in the initiator before receipt of a Linktest.rsp, it is considered a communications failure (see "Special Considerations").

7.5.2 *Responding Entity Procedure*

1. The responding entity receives the Linktest.req from the initiator.
2. The responding entity sends a Linktest.rsp.

7.6 *Separate Procedure* — The Separate procedure is used to abruptly terminate HSMS communication for an entity prior to breaking the TCP/IP Connection. HSMS requires that the connection be in the SELECTED state when using Separate. The responding entity does not send a response and is required to terminate communications regardless of its local state. The procedure is as follows.

Separate Control Transaction

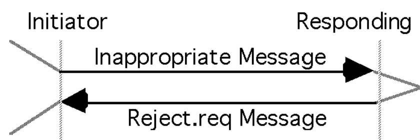
7.6.1 *Initiator Procedure*

1. The initiator of the select procedure sends the Separate.req message to the responding entity. The initiator' s Separate procedure completes successfully. The NOT SELECTED state is entered (see Section 5).

7.6.2 *Responding Entity Procedure*

1. The responding entity receives the Separate.req from the initiator.
2. If the responding entity is in the SELECTED state, its Separate procedure completes successfully.
3. If the responding entity is not in the SELECTED state, the Separate.req is ignored.

7.7 *Reject Procedure* — The Reject procedure is used in response to an otherwise valid HSMS message received in an inappropriate context. Supporting the reject procedure can provide useful diagnostic information during the development of a distributed application using HSMS. The procedure is as follows:



Reject Transaction

7.7.1 *Initiator (Sender of Inappropriate Message) Procedure*

1. The initiator of the inappropriate message, upon receiving the Reject.req, takes appropriate action (local entity-specific).

7.7.2 *Responding Entity Procedure*

1. The entity receiving the inappropriate message responds with a Reject.req message.

HSMS requires the reject procedure for the receipt of a data message in the NOT SELECTED state, or the receipt of a message whose SType or PType (see next section: Message Format) is not defined for the entity receiving the message. Subsidiary standards may define other conditions which require the Reject Procedure. In general, receipt of a reject message is an indication of an improperly configured system or a software programming error.

8 HSMS Message Format

This section defines the detailed format of the messages used by the procedures in the previous section.

8.1 *General Message Format*

8.1.1 *Byte Structure* — Within HSMS, a byte contains eight (8) bits. The bits in a byte are numbered from Bit 7 (most significant) to Bit 0 (least significant).

8.1.2 *Message Format* — An HSMS Message is transmitted as a single contiguous stream of bytes in the following order:

Table 2 HSMS Message Format

Number of Bytes	*Description*
4 Bytes	Message Length. MSB First. Specifies the number of bytes in the Message Header plus the Message Text.
10 Bytes	Message Header.
0–n Bytes	Message Text. Format is further specified by PType field of message header.

8.1.3 *Message Length* — Message Length is a four-byte unsigned integer value which specifies the length in bytes of the Message Header plus the Message Text. Message Length is transmitted most significant byte (MSB) first and least significant byte (LSB) last.

The minimum possible Message Length is 10 (Header only). The maximum possible Message Length is implementation-specific.

8.1.4 *Message Header* — The Message Header is a ten-byte field. The bytes in the header are numbered from byte 0 (first byte transmitted) to byte 9 (last byte transmitted). The format of the Message Header is as follows:

Table 3 HSMS Message Header

Bytes	*Description*
0–1	Session ID (Device ID)
2	Header Byte 2
3	Header Byte 3
4	PType
5	SType
6–9	System Bytes

The physical byte order is designed to correspond as closely as possible to the SECS-I header.

8.1.4.1 *Session ID* — Session ID is a 16-bit unsigned integer value, which occupies bytes 0 and 1 of the header (byte 0 is MSB, 1 is LSB). Its purpose is to provide an association by reference between control messages (particularly Select and Deselect) and subsequent data messages. It is the role of HSMS subsidiary standards to specify this association further.

8.1.4.2 *Header Byte 2* — This header byte is used in different ways for different HSMS messages. For Control Messages (see SType, below) it contains zero or a status code. For a Data Message whose PType (see below) = 0, it contains the W-Bit and SECS Stream. For a Data Message with PType not equal to 0, see "Special Considerations."

8.1.4.3 *Header Byte 3* — This header byte is used in different ways for different HSMS messages. For Control Messages, it contains zero or a status code. For a Data Message whose PType (see below) = 0, it contains the SECS Function. For a Data Message with PType not equal to 0, see "Special Considerations."

8.1.4.4 *PType* — PType (Presentation Type) is an 8-bit unsigned integer value which occupies byte 4 of the header. PType is intended as an enumerated type defining the presentation layer message type: how the Message Header and Message Text are encoded. Only PType = 0 is defined by HSMS to mean SECS-II message encoding. For non-zero PType values, see "Special Considerations."

Table 4 PType

Value	*Description*
0	SECS-II Encoding
1–127	Reserved for subsidiary standards
128–255	Reserved, not used

8.1.4.5 *SType* — SType (Session Type) is a one-byte unsigned integer value which occupies header byte 5.

SType is an enumerated type identifying whether this message is an HSMS Data Message (value = 0) or one of the HSMS Control Messages (other). Those values not explicitly defined in the table are addressed in "Special Considerations."

Table 5 SType

Value	*Description*
0	Data Message
1	Select.req
2	Select.rsp
3	Deselect.req
4	Deselect.rsp
5	Linktest.req
6	Linktest.rsp
7	Reject.req
8	(not used)
9	Separate.req
10	(not used)
11–127	Reserved for subsidiary standards
128–255	Reserved, not used

8.1.4.6 *System Bytes* — System Bytes is a four-byte field occupying header bytes 6-9. System Bytes is used to identify a transaction uniquely among the set of open transactions.

Uniqueness — The System Bytes of a Primary Data Message, Select.req, Deselect.req, or Linktest.req message must be unique from those of all other currently open transactions initiated from the same end of the connection. They must also be unique from those of the most recently completed transaction.

Reply Message — The System Bytes of a Reply Data Message must be the same as those of the corresponding Primary Message. The System Bytes of a Select.rsp, Deselect.rsp, or Linktest.rsp must be the same as those of the respective ".req" message.

8.2 *HSMS Message Formats by Type* — The specific interpretation of the header bytes in an HSMS message is dependent on the specific HSMS message type as defined by the value of the SType field. The complete set of messages defined is summarized in the table below, shown for PType = 0 (SECS-II message format).

Table 6 HSMS Message Format Summary

	Message Header						
Message Type	*Bytes 0-1 SessionID*	*Byte 2*	*Byte 3*	*Byte 4 PType*	*Byte 5 SType*	*Bytes 6–9 System Bytes*	*Message Text*
Data Message	*	W-bit and SECS Stream	SECS Function	0	0	Primary: UniqueReply: Same as primary	Text
Select.req	*	0	0	0	1	Unique	none
Select.rsp	Same as .req	0	Select Status	0	2	Same as .req	none
Deselect.req	*	0	0	0	3	Unique	none
Deselect.rsp	Same as .req	0	Deselect Status	0	4	Same as .req	none
Linktest.req	0xFFFF	0	0	0	5	Unique	none
Linktest.rsp	0xFFFF	0	0	0	6	Same as .req	none
Reject.req	same as message being rejected	PType or SType of message being rejected	Reason Code	0	7	Same as message being rejected	none
Separate.req	*	0	0	0	9	Unique	none

* Indicates further specification by subsidiary standards.

8.2.1 *SType=0: Data Message* — An HSMS message with SType = 0 is used by the HSMS Data procedure to send a Data message, either Primary or Reply. The message format is as follows:

HSMS Message Length is always 10 (the length of the header alone) or greater.

The HSMS Message Header is as follows:

Session ID — As described above. Specific value subject to subsidiary standards.

Header Byte 2 — For messages with PType value = 0 (SECS-II), header byte 2 is formatted as shown below.

7	6 0
W-Bit	Stream

The most significant bit (bit 7) of Header Byte 2 is the W-Bit. In a Primary Message, the W-Bit indicates whether the Primary Message expects a Reply message. A Primary Message which expects a Reply should set the W-Bit to 1. A Primary Message which does not expect a Reply should set the W-Bit to 0. A Reply Message should always set the W-Bit to 0. The low-order 7 bits (bits 6-0) of Header Byte 2 contain the SECS Stream for the message. The Stream is a 7-bit unsigned integer value, which identifies a major topic of the message, and its use is defined within SEMI E5 (SECS-II).

Header Byte 3 — For messages whose PType value=0, header Byte 3 contains the SECS Function for the message. The Function is an 8-bit unsigned integer value which identifies a minor topic of the message (within the Stream), and its use is defined within SEMI E5 (SECS-II). The least significant bit (bit 0) of the Function defines whether the Data Message is Primary or Reply; the value 1 indicates Primary and the value 0 indicates Reply.

PType — Set PType = 0 for SECS-II messages.

SType = 0

System Bytes — For PType=0 (SECS-II), the following definition applies. For a Primary Message, System Bytes contain a value uniquely identifying this transaction from all other open transactions initiated from the same end of the Connection. For a Reply Message, System Bytes contain the same value as the corresponding Primary Message.

The HSMS Message Text contains the text of the Data Message (if any), formatted as specified by the PType field. For PType = 0, the text will be formatted as SECS-II messages.

NOTE 4: Some Data Messages consist of header only, with no text.

8.2.2 *SType=1: Select.req* — An HSMS message with SType 1 is a “Select Request” Control Message, which is used by the initiator of the procedure for establishing HSMS communications. The message format is as follows:

Message Length is always 10 (Header only).

The HSMS Message Header is as follows:

SessionID — As described above. Specific value subject to subsidiary standards.

Header Byte 2 = 0

Header Byte 3 = 0

PType = 0.

SType = 1

System Bytes — A unique value among open transactions.

8.2.3 *SType=2: Select.rsp* — An HSMS message with SType 2 is a “Select Response” Control Message, used as the response to a Select.req Control message in the procedure for establishing HSMS communications. The message format is as follows:

Message Length is always 10 (Header only).

The HSMS Message Header is as follows:

SessionID — must be equal to the value of the session ID in the corresponding Select.req.

Header Byte 2 =0

Header Byte 3 — SelectStatus. A code of zero indicates success of the Select operation. A non-zero code indicates failure.

Table 7 SelectStatus

Value	*Description*
0	Communication Established. Select was successfully completed.
1	Communication Already Active. A previous select has already established communications to the entity being selected in this select.
2	Connection Not Ready. The Connection is not yet ready to accept select requests.
3	Connect Exhaust. The connection was accepted, but the entity is already servicing a separate TCP/IP connection and is unable to service more than one at any given time.

Value	*Description*
4–127	Reserved for subsidiary standard-specific reasons for select failure.
128–255	Reserved for local entity-specific reasons for select failure.

PType = 0

SType = 2

System Bytes — Equal to value of System Bytes in the corresponding Select.req.

8.2.4 *SType=3: Deselect.req* — An HSMS message with SType 3 is a "Deselect Request" Control Message, used by the initiator of the Select procedure for ending HSMS communication. The message format is as follows:

Message Length is always 10 (Header only).

The HSMS Message Header is as follows:

SessionID — The SessionID must match the value of the SessionID of a previously sent Select.req to indicate the particular HSMS session that is ending. Subject to further specification by subsidiary standards.

Header Byte 2 = 0

Header Byte 3 = 0

PType = 0

SType = 3

System Bytes — A unique value among open transactions.

8.2.5 *SType=4: Deselect.rsp* — An HSMS message with SType 4 is a "Deselect Response" Control Message, used as the response to a Deselect.req Control message in the Deselect procedure for ending HSMS communications. The message format is as follows:

Message Length is always 10 (Header only).

The HSMS Message Header is as follows:

SessionID — must equal the session ID in the corresponding Deselect.req

Header Byte 2 = 0

Header Byte 3 — DeselectStatus. A code of zero indicates success of the Deselect operation. A non-zero code indicates failure.

Table 8

Value	*Description*
0	Communication Ended. The Deselect completed successfully.
1	Communication Not Established. HSMS communications has not yet been established with a select, or has already been ended with a previous Deselect.
2	Communication Busy. The session is still in use by the responding entity and so it cannot yet relinquish it gracefully. In this case, if the original requester must terminate communications, the separate procedure should be used as a last resort.
3–127	Reserved for subsidiary standard-specific reasons for Deselect failure.
128–255	Reserved for local entity-specific reasons for Deselect failure.

PType = 0

SType = 4

System Bytes — Equal to System Bytes in corresponding Deselect.req.

8.2.6 *SType=5: Linktest.req* — An HSMS message with SType 5 is a "Linktest Request" Control Message. It is used to verify the integrity of the HSMS Connection, or as a periodic heartbeat. The message format is as follows:

Message Length is always 10 (Header only).

The HSMS Message Header is as follows:

SessionID = 0xFFFF (in binary, all ones)

Header Byte 2 = 0

Header Byte 3 = 0

PType = 0

SType = 5

System Bytes — A unique value among open transactions.

8.2.7 *SType=6: Linktest.rsp* — An HSMS message with SType 6 is a "Linktest Response" Control Message, used as the response to a Linktest.req Control message in the Linktest Procedure. The message format is as follows:

Message Length is always 10 (Header only).

The HSMS Message Header is as follows:

SessionID = 0xFFFF (binary, all ones)

Header Byte 2 = 0

Header Byte 3 = 0

PType = 0

SType = 6

System Bytes — Equal to System Bytes in corresponding Linktest.req.

8.2.8 *SType=7: Reject.req* — An HSMS message with SType 7 is used in response to any valid HSMS message received which is not supported by the receiver of the message or which is not valid at the time. It is intended for dealing with attempts to use subsidiary standards or user-defined extensions which are not supported by the receiver (for example, SType equal to any value not defined in this standard). It must be used when an entity receives a control message which is a response (even numbered SType) for which there was no corresponding open transaction.

The HSMS Message Header is as follows:

SessionID — equal to the value of the Session ID in the message being rejected.

Header Byte 2 — For ReasonCode = PType Not Supported, equal to the PType in the message being rejected. Otherwise equal to the value of the SType in the message being rejected.

Header Byte 3 — reason code (always non-zero)

Table 9 ReasonCode

Value	*Description*
1	SType Not Supported. A message was received whose SType value not defined in the HSMS standard or the particular subsidiary standard(s) supported by the entity.
2	PType Not Supported. As above, but for PType.
3	Transaction Not Open. A Response control message was received when there was no outstanding request message which corresponded to it.
4	Entity Not Selected. A data message was received when not in the SELECTED state.
4–127	Reserved for subsidiary standard-specific reasons for reject.
128–255	Reserved for local entity-specific reasons for reject.

PType = 0

SType = 7

System Bytes — Equal to System Bytes in corresponding message being rejected.

8.2.9 *SType=9: Separate.req* — An HSMS message with SType = 9 is used to terminate HSMS communications immediately. With the exception of the SType value, it is identical to the Deselect.req message. Its purpose is to end HSMS communications immediately and without exception. No response is defined.

9 Special Considerations

9.1 *General Considerations*

9.1.1 *Communications Failures* — If a communications failure is detected, the entity should terminate the TCP/IP connection. Upon termination of the connection, the entity may, at this point, attempt to reestablish communications.

9.2 *TCP/IP Considerations*

9.2.1 *Connect Separation Time (T5)* — The connect procedures initiate some network activity. Frequent use of the active mode connect procedure to the IP Address and Port Number of an entity not yet ready to accept connections can be hostile to TCP/IP operations. The passive mode does not generate network activity and is not considered hostile to the network, although it may affect local application performance. An Entity initiating a connection in the active mode should limit its use of the connect procedure in a manner that is equivalent to the procedure described here.

After an active connect procedure terminates by any means (successfully or unsuccessfully), the Entity should not initiate another active connect procedure (for the same Remote Entity) until the T5 Connect Separation Time has elapsed. The separation of connect operations will be the sum of the T5 Connect Separation Time interval, plus the duration of the connect operation itself.

9.2.2 *NOT SELECTED Timeout (T7)* — Entry into the NOT SELECTED state is achieved either by state transition #2 (establishment of a TCP/IP connection). There is a time limit on how long an entity is required to remain in the NOT SELECTED state before either entering the SELECTED state or by returning to the NOT CONNECTED state.

Some entities, particularly those unable to accept more than a single TCP/IP connection, may be impaired in their operation by remaining in their NOT SELECTED state as they will be unavailable for communications with other entities. Such entities shall disconnect the TCP/IP connection (State Transition Event #3) if communication remains in the NOT SELECTED state for longer than the T7 timeout period.

9.2.3 *Network Intercharacter Timeout (T8)* — Because TCP/IP is a stream rather than a message protocol, it is possible that bytes which are all part of a single HSMS message may be transmitted in separate TCP/IP messages without any violation of the TCP/IP protocol. Since it is possible that these separate messages may be separated by a substantial period of time, the Network Intercharacter Timeout (T8) is defined.

T8 is similar in purpose to the SECS-I T1 timer except that the communications issues which necessitate T8 are not entirely in the control of the sender of the message. Therefore, it is defined only in terms of the receiver of the message. In particular, if after receipt of a partial message, the T8 timeout period expires prior to receipt of the complete message, the receiving entity shall consider such case as a communications failure, as defined above.

9.2.4 *Multiple Connection Requests Directed to a Single Published Port* — Once a passive entity has accepted a connection on its published port, TCP/IP permits (though does not require) the entity to listen for and accept additional connections directed to the same published port.

HSMS permits (though does not require) entities to operate in this manner. However, for the purposes of HSMS compliance, each connection so formed must exhibit the behavior defined in the HSMS state diagram as if it were completely independent of any other connection to the same published port.

9.2.4.1 *Rejection of Additional Connection Requests by a Passive Mode Entity* — A passive mode entity unable to service more than a single TCP/IP connection for HSMS communications will follow one of these three procedures with respect to additional connection requests.

a. Accept the connection, but always respond to any subsequent HSMS select procedures with the Communication Already Active response code. For the purpose of the HSMS State Diagram, the connect procedure terminates successfully (enters CONNECTED state), but HSMS communications are never established (remain in NOT SELECTED substate). This is the preferred option in that it can provide the most information to the remote entity as to why the connection is refused (see HSMS Select Procedure), but places an addition implementation requirement on the local entity.

b. Actively reject the connection request. This can be done in a TLI implementation using the t_snddis procedure. This will cause the connect procedure in the remote entity to terminate unsuccessfully. This option may not be available to all implementations because some API's, notably some implementations of BSD Sockets, do not provide for initiating an active reject. Note, however, that all TCP/IP implementations, including BSD Sockets, properly respond to an active reject from the remote entity.

c. Refuse to listen for or accept the connect request. No action is taken in the local entity: the remote entity's connect procedure will eventually time out. This option is permitted, but not recommended, as it can cause considerable delay on the part of the remote entity. However, it may be the only alternative available to implementations with network resource limitations.

The documentation of the passive local entity shall indicate which means it uses to refuse connections.

9.3 *HSMS-Specific Considerations*

9.3.1 *Control Transactions T6 Control Timeout* — A number of the control messages are part of procedures which require a message exchange or transaction: <xx>.req from the initiator of the control service, followed by an <xx>.rsp from the receiver of the <xx>.req in response to it. A control transaction is considered open from the time the <xx>.req request is sent until the time the <xx>.rsp is received.

The time a control transaction may remain open is subject to the T6 control transaction timeout. Upon initiation of a control transaction, the local entity should set a timer whose duration is equal to the T6 timeout value. If the transaction is properly closed prior to the expiration of the timer, the timer should be canceled. If the timer expires prior to the proper closing of the transaction, the transaction shall be considered closed by the initiator and considered an HSMS communications failure.

9.3.2 *Procedures and "Stateless" Transactions* — Most of the HSMS control procedures involve a transaction: the initiator sends a request message to the responding entity and waits for a response message. The responding entity receives the initiator' s request message and sends a reply.

Note that such transactions are "stateless" in the following sense: while the initiator of a transaction is waiting for a response, it may receive a message other than that response, and this message may be any message valid for the state the initiator was in at the time the original transaction was initiated. For example, the two entities may simultaneously initiate transactions. As a result, no states for "TRANSACTION OPEN" or "TRANSACTION NOT OPEN" are reflected in the HSMS state machine. The use of such state information in an implementation is strictly a local entity-specific issue.

9.3.3 *Alternative Message Types and Header Byte Values* — The HSMS standard does not completely define all possible enumerated values of either the PType or SType field. Further, Header bytes 2 and 3 have a format determined by the PType for messages whose SType is equal to 0, but is otherwise specified for all other SType values. The message text formatting is defined by the PType as well, but only for data messages.

Subsidiary standards must be consistent with this convention. In particular, for SType = 0, subsidiary standards defining PType values not equal to 0 may specify both the message text encoding and the interpretation of header bytes 2 and 3. For STypes not equal to 0 but otherwise specified in this standard, PType must = 0, and no message text may be transmitted. For STypes defined in subsidiary standards, the meaning of header bytes 2 and 3 may be specified on a per SType value basis, and these STypes may optionally define message text as long as the PType field is used in a manner consistent with the preceding paragraph.

9.4 *SECS-II Considerations* — The SECS-II standard (SEMI E5) makes certain references to SECS-I (SEMI E4). This section addresses issues specific to SECS-II when HSMS is used to transport SECS-II messages.

9.4.1 *Reply Matching* — When a Sender sends a Primary Message with W-Bit 1 (Reply Expected), the Sender should expect a Reply message whose header meets the following requirements.

The SessionID of the Reply must match the SessionID of the Primary Message.

The Stream of the Reply must match the Stream of the Primary Message.

The Function of the Reply must be one greater than the Function of the Primary Message, or else the Function of the Reply must be 0 (Function Zero Reply).

The System Bytes of the Reply must match the System Bytes of the Primary Message.

9.4.1.1 *T3 Reply Timeout* — The T3 reply timeout is a limit on the length of time that the HSMS message protocol is willing to wait for a Reply message.

After sending a Primary Message with W-bit 1 (Reply Expected), the sender must begin a reply timer, initialized to the T3 value. If the sender does not receive the Reply Message before the reply timer expires, then a T3 Timeout Error has occurred. The sender should close the transaction and no longer expect the Reply Message.

Each open transaction for which a Reply is expected requires a separate reply timer.

9.4.2 *Stream 9 Messages* — The SECS-II standard defines error messages S9F1, S9F3, S9F5, S9F7, S9F9, and S9F11, with message text containing the SECS-II Data Items MHEAD or SHEAD, which are defined to contain a 10-byte SECS-I block header.

When using SECS-II with HSMS, MHEAD and SHEAD should contain the ten bytes of the HSMS Message Header.

10 HSMS Documentation

An HSMS implementation is required to document the following information:

1. Method for setting protocol parameters (see Section 10.1).
2. Range allowed and resolution for each parameter.
3. The option used for refusing incoming connection requests if the implementation uses the passive mode for TCP/IP connection establishment.
4. Maximum message size which can be received.
5. Maximum expected size of messages sent.
6. Maximum number of supported concurrent open transactions.

10.1 *Parameter Setting* — Implementations of HSMS must provide for installation time setting of the following parameters. The range and resolution of all parameters must be at least as shown in the table. All parameters must be stored in such a manner that the settings will be retained if the power fails or if the system software is reloaded.

Table 10

Parameter Name	*Value Range*	*Resolution*	*Typical Value*	*Description*
T3 Reply Timeout	1-120 seconds	1 second	45 seconds	Reply timeout. Specifies maximum amount of time an entity expecting a reply message will wait for that reply.
T5 Connect Separation Timeout	1-240 seconds	1 second	10 seconds	Connection Separation Timeout. Specifies the amount of time which must elapse between successive attempts to connect to a given remote entity.
T6 Control Transaction Timeout	1-240 seconds	1 second	5 seconds	Control Transaction Timeout. Specifies the time which a control transaction may remain open before it is considered a communications failure.
T7 NOT SELECTED Timeout	1-240 seconds	1 second	10 seconds	Time which a TCP/IP connection can remain in NOT SELECTED state (i.e., no HSMS activity) before it is considered a communications failure.
T8 Network Intercharacter Timeout	1-120 seconds	1 second	5 seconds	Maximum time between successive bytes of a single HSMS message which may expire before it is considered a communications failure.
Connect Mode	PASSIVE, ACTIVE	—	—	Connect Mode. Specifies the logic this local entity will use during HSMS connection establishment.
Local Entity IP Address and Port number	determined by TCP/IP conventions	—	—	Required for any entity operating in PASSIVE mode. Determines the address on which the local entity will listen for incoming connection requests.
Remote Entity IP Address and Port Number	determined by TCP/IP conventions	—	—	Required for any entity operating in ACTIVE mode. Determines the address of the remote entity to which the local entity will attempt to connect.

NOTE: Parameter defaults shown above are for small networks (10 nodes or less). Settings may need to be adjusted for larger network configurations.

APPENDIX 1

NOTE: This appendix was approved as a part of SEMI E37 by full letter ballot procedure.

A1-1 TCP/IP Procedures Using TLI and BSD Socket Interfaces

A1-1.1 *Passive Mode Connect Procedure*

Table 1

Intended Action	*TLI Construct*	*BSD Construct*	*Comment*
Obtain a connection endpoint and bind it to a published port.	tep = t_open(...) t_bind(tep,...)	skt = socket(...) bind(skt,...)	BSD refers to a connection endpoint as a "socket." TLI refers to it as a TEP (transport end point).
Permit socket to listen for connections.	...	listen(skt...)	In TLI, the equivalent of BSD listen is not necessary.
Connect procedure: receive incoming connect request and accept it.	t_listen(tep,...) t_accept(tep,...)	accept(skt,...)	
Connect procedure: receive incoming connect request, but reject it.	t_listen(tep,...) t_snddis(tep,...)	...	The BSD API does not support originating a reject of a connect request, as receiving request and accepting it are a single operation.

A1-1.2 *Active Mode Connect Procedure*

Table 2

Intended Action	*TLI Construct*	*BSD Construct*	*Comment*
Obtain a connection endpoint.	tep = t_open(...) t_bind(tep,...)	skt = socket(...)	TLI requires bind to null address for active entity.
Connect procedure: send connect request and receive accept or reject from passive entity.	t_connect(tep,...) t_rcvconnect(tep,...)	connect(skt,...)	The BSD connect will correctly handle an active reject from the TLI-based remote entity.

A1-1.3 *Terminating the Connection*

Table 3

Intended Action	*TLI Construct*	*BSD Construct*	*Comment*
Release the connection and free connection endpoint.	t_sndrel(tep,..) t_close(tep)	close(skt)	The "gracefulness" of the BSD close is a function of the local implementation.
Disconnect and free the connection endpoint.	t_snddis(tep,..) t_close(tep)	shutdown(skt,2) close(skt)	Shutdown immediately disables further sends and receives if the second arg = 2.

A1-1.4 *Sending and Receiving HSMS Messages*

Table 4

Intended Action	*TLI Construct*	*BSD Construct*	*Comment*

Send an HSMS message	hdr->Len = length;
	t_snd(tep,hdr,14,0);
	t_snd(tep,Text,hdr->Len,0);
		hdr->Len = length;
		write(skt,hdr,14);
		write(skt,Text,hdr->Len);
			The procedure illustrates a "typical" implementation style in which the length bytes and header are combined into a single 14-byte item sent first, followed by the text. This is not to imply that combining everything is not permitted.

Receive and HSMS message	t_rcv(tep,hdr,14,...); t_rcv(tep,Text,hdr->Len,...);	read(skt,hdr,14); read(skt,Text,hdr->Len);	As above, but for receiving.

A1-2 HSMS Scenarios

The following scenarios are provided to illustrate the HSMS procedures as used for a typical complete session. The terminology, procedure names, and message names are further explained in the remainder of this document. Also note that either entity may initiate the HSMS Select procedure, the Deselect or Separate procedures, and HSMS Data Messages and Transactions. For convenience, the scenarios show the left-hand entity as the initiator of all transactions.

A1-2.1 *Begin HSMS Communication* — This scenario illustrates the TCP/IP connection procedure, an HSMS select procedure, and exchange of data messages. Note that the data message activity for TCP is for illustrative purposes only. In fact, the actual network activity can vary. For example, even if the data messages are sent as separate calls to t_snd (or write) as shown, the TCP/IP implementation may buffer the header and transmit it in a single packet with the text, or the text may be split into multiple packets.

Table 5

BSD API Calls	*TLI API Calls*	*Network Activity*	*TLI API Calls*	*BSD API Calls*
Prepare to initiate a connection request.			Prepare to receive a connection request.	
skt = socket(...);	tep = t_open(...); t_bind(tep, ...);		tep = t_open(...); t_bind(tep,...);	skt = socket(...);bind(skt,...); listen(skt,...);
Initiate a connection request and wait for response.			Receive a connection request, accept it, and send response.	
connect(skt,...);	t_connect(tep,...); t_rcvconnect(tep,...);	TCP/IP Connect Req Msg(s) → ← TCP/IP Accept Msg(s)	t_listen(tep,...);t_accept(tep,...);	accept(skt,...);
Initiate an HSMS Select procedure: send request and receive response.			Respond to HSMS select procedure: receive request and send response.	
write(skt,hdr,14); read(skt,hdr,14);	t_snd(tep,hdr,14,0); t_rcv(tep,hdr,14,...);	Select.req Message → ← Select.rsp Message	t_rcv(tep,hdr,14,...); t_snd(tep,hdr,14,0);	read(skt,hdr,14); write(skt,hdr,14);
Send an HSMS data message as length bytes and header, followed by Text.			Receive an HSMS data message as length bytes and header, followed by Text.	

hdr->Len = Length;
write(skt,hdr,14);
write(skt,Text,...);
	hdr->Len = Length;
	t_snd(tep,hdr,14,0);
	t_snd(tep,Text,...);
		HSMS Data Message (hdr) →
		HSMS Data Message (text) →
			t_rcv(tep,hdr,14,...);
			t_rcv(tep,Text,...);
				read(skt,hdr,14);read(skt,Text,...);

A1-2.2 *Ending Communicaiton Using Deselect* — This scenario illustrates ending an HSMS Session using the Deselect procedure to end the HSMS session.

BSD API Calls	*TLI API Calls*	*Network Activity*	*TLI API Calls*	*BSD API Calls*
Send the Deselct.req and receive Deselect.rsp.			Receive the Deselect.req and send the Deselect.rsp.	
write(skt,hdr,14); read(skt,hdr,14);	t_snd(tep,hdr,14,0); t_rcv(tep,hdr,14,...);	Deselect.req Message → ← Deselect.rsp Message	t_rcv(tep,hdr,14,...); t_snd(tep,hdr,14,0);	read(skt,hdr,14); write(skt,hdr,14);
Disconnect the TCP/IP Connection.			Respond to Disconnect of connection.	
shutdown(skt,2); close(skt);	t_snddis(tep; t_close(tep);	← TCP/IP Disconnect Msg(s) →	t_rcvdis(tep,...);	close(skt);

A1-3 HSMS Alternating Mode Connect Procedure

Some users have particular requirements which prevent them from determining which connect mode (active or passive) a given entity will use at any particular time. In such a case, a Local Entity alternately attempts the active mode and passive mode connect procedure until a connection is successfully established. Note that this requires that local entity provide a published port when in the passive phase. The general logic sequence at the Alternating Local Entity is as follows:

1. Attempt an active connect procedure as described in Section 6.3.3 using a timeout value for the t_rcvconnect greater than or equal to the connection separation timeout T5.

2. If the active connect procedure completes successfully, the alternating mode connect procedure completes successfully.

3. If the active connect procedure terminates unsuccessfully, attempt the passive connect procedure as described in 6.3.2 with the timeout for the t_listen greater than or equal to the connection separation timeout T5.

4. If the passive connect procedure completes successfully, the alternating mode connect procedure completes successfully as described in 6.3.2.

5. If the passive connect procedure terminates unsuccessfully, the local entity may either return to step 1 to continue the alternating mode procedure or terminate unsuccessfully. The number of times the above sequence of steps are repeated in attempting to form a connection is a local entity-specific issue.

A1-3.1 *Alternating Mode Cycle Time* — The Alternating Mode Cycle Time is the time between iterations of the Connect Procedure of an Alternating Mode entity. In the above procedure, this corresponds to the duration between the initiation of step 1 and completion of step 5 immediately prior to the reinitiation of step 1. This time is implementation-dependent.

In the case that two entities are both using the Alternating Mode Connect Procedure, it is desirable to ensure that they both have different alternating mode cycle times, to prevent the entities from attempting to connect in lock step: both in active mode, then both in passive mode. Adjusting the Alternating Mode Cycle Time can be readily achieved by adjustment of T5 so that the cycle time is different for the two entities:

A1-3.2 *HSMS Connect Combinations* — An entity configured as alternating between active and passive mode can connect with either an passive or active mode remote entity. The list below summarizes the combinations possible using the standard with this particular connections strategy.

1. An Entity "A" configured as ACTIVE can connect to an Entity "B" configured as PASSIVE or as ALTERNATING, and Entity A always establishes the Connection.

2. An Entity "A" configured as ALTERNATING can connect to an Entity "B" configured as PASSIVE, and Entity "A" always establishes the Connection.

3. An Entity "A" configured as ALTERNATING can connect to an Entity "B" configured as ALTERNATING, and either end can establish the Connection. In implementations which use multi-threaded connect logic, rather than the sequential logic described in this document, it may be possible that both ends of the HSMS connection attempt to connect at the same time. In this case, there can be two separate TCP/IP connections established, and it is necessary to establish a convention so that one connection is allowed to remain and the other is terminated.

4. It is not allowed to connect two Entities both configured as PASSIVE, or both configured as ACTIVE.

A1-4 Non-HSMS TCP/IP Protocols

For typical TCP/IP implementations, HSMS can co-exist with other TCP/IP based protocols on the same IP Address. This can be very useful. For example, a SECS-II message transaction could trigger an application to begin a TCP/IP FTP (File Transfer Protocol) sequence to transfer a large data file.

A1-5 Non-TCP/IP Protocols

The use of protocols other than TCP/IP on the same network as the HSMS entities is possible but beyond the scope of this standard. Typically, other protocols could be used, provided they have no impact on TCP/IP or HSMS entities on the network.

A1-6 Multiple LANs

The HSMS specification considers only a single TCP/IP LAN. Interconnecting multiple LANs is outside the scope of HSMS. However, since TCP/IP implementations typically support such configurations seamlessly through gateways, routers, and similar entities, it may be possible to establish an HSMS Connection across interconnected LAN's.

A1-7 TCP/IP Physical Layer

HSMS does not specify the physical layer of IP. Any physical layer supported by TCP/IP can be used. Most commonly, TCP/IP implementations use Ethernet (IEEE 802.3) as the physical layer. However, some TCP/IP implementations use other protocols (e.g., Token Bus, IEEE 802.4 and .5). To ensure interoperability within a given installation, it may be desirable to establish additional local standards for the physical layer.

A1-8 Well-Known TCP/IP Port Numbers

Some TCP/IP-based protocols specify a particular "Well Known" TCP Port Number, which is published and is not available for other protocols. HSMS does not specify a particular "Well Known" TCP Port Number, but instead requires that it be configurable. The IETF defines "Assigned Well Known Port Numbers" in RFC 1340.

A1-9 Delay between Disconnect and Re-Connect

Some TCP/IP systems exhibit problems with applications which terminate a connection and then quickly re-connect, when using identical TCP ports on both ends of the connection. When using such systems, it may be advisable to delay after disconnect before re-connecting. The delay time varies among TCP/IP implementations, but typically can be calculated as twice the "Maximum Segment Lifetime" or MSL. For example, most TCP/IP systems based on BSD (e.g., Sun, AIX) use a MSL of 30 seconds, so a delay of 60 seconds would be appropriate. If rapid connects are required, your application should use a different Port, if allowed by the Connect Mode you are using. In some TCP/IP systems, this problem does not occur.

A1-10 User-Defined Message Types

It is recognized that equipment suppliers may find it desirable to develop additional features not found in the base level HSMS or any defined subsidiary standards. This will be the case during the testing and development of any proposed new subsidiary standard. User-defined extensions through new message types are permissible as long as they are confined to intra-vendor communication interfaces: any inter-vendor communications interface which requires the use of such extensions is considered to be noncompliant with the HSMS standard.

If a supplier does deem it necessary to extend or otherwise go outside the standard, the use of "reserved, not used," values of PType and SType may simplify their implementation by permitting the reuse of the HSMS implementation rather than the implementation and use of a completely separate parallel standard. By remaining within the "reserved, not used," ranges for SType and PType, the implementor can be assured that future subsidiary standards which define new values for SType and/or PType will not conflict with user-defined extensions.

A1-11 Comparison of SECS-I and HSMS

The following table compares major features of SECS-I and HSMS.

Feature	*SECS-I*	*HSMS*
Communications Protocol Base	RS-232	TCP/IP
Physical Layer	25-pin connector and 4-wire serial cable	Physical layer not defined. HSMS allows any TCP/IP supported physical medium. Typical example is Ethernet (IEEE 802.3) and thin coax (10-BASE-2).
Communications Speed	Typically about 1000 bytes/second (assuming 9600 baud).	Typically 10 MBits/second (assuming typical Ethernet).
Connections	One physical RS-232 cable per SECS-I connection.	One physical network cable can support many HSMS Connections.
Message Format	Message text is SECS-II Data Items. Transmits a SECS-II message as a series of transmittal blocks each approximately 256 bytes in size. Each block has a one-byte block length, a ten-byte Block Header, text, and a two-byte Checksum.	Message Text is SECS-II Data Items. Transmits a SECS-II message as a TCP/IP byte stream. The message has a four-byte Message Length, a ten-byte Message Header, and text. The TCP/IP layer may impose blocking limits which depend on the physical layer used, but this blocking is transparent to the TCP/IP API and is outside the scope of HSMS.

Feature	*SECS-I*	*HSMS*
Header	Ten-byte header on each block of a message. Header bytes 4-5 contains E-Bit and Block Number.	One ten-byte Header for the entire message. Header bytes 4–5 contain PType and SType. Header bytes 2–3 are W-Bit, Stream, and Function when SType = 0 (Data Message). For SType not equal to 0 (Control Message), bytes 2–3 have other uses. No R-Bit.
Maximum message size	Limited to approximately 7.9 million bytes (32767 blocks times 244 text bytes per block).	Message size limited by 4-byte message length (approximately 4 GBytes). Local implementation of TCP/IP and HSMS may further limit this in practice.
Protocol Parameters (Common)	T3 Reply Timeout Device ID	T3 Reply Timeout Session ID (analogous to Device ID).
Protocol Parameters (SECS-I only)	Baud Rate T1 Inter-Character Timeout T2 Block Protocol Timeout T4 Inter-Block Timeout RTY Retry Count Host/Equipment	Not used in HSMS. Corresponding issues addressed by TCP/IP layers.
Protocol Parameters (HSMS Only)	Not needed by SECS-I.	IP Address and Port of Passive Entity. T5 Connect Separation Timeout. T6 Control Transaction Timeout. T7 NOT SELECTED Timeout. T8 Network Intercharacter Timeout.

SEMI E37.1-0702
HIGH-SPEED SECS MESSAGE SERVICE SINGLE SELECTED-SESSION MODE (HSMS-SS or HSMS-SSS)

This standard was technically approved by the Global Information and Control Committee and is the direct responsibility of the Japan Information and Control Committee. Current edition approved by the Japan Regional Standards Committee on April 26, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published in 1995; previoulsy published in 1996.

1 Purpose

1.1 HSMS-SS provides a means for independent manufacturers to produce implementations which can be connected without requiring specific knowledge of one another.

1.2 HSMS-SS is intended as an alternative to SEMI E4 (SECS-I) for applications where higher speed communication is needed.

1.3 HSMS-SS is intended as an alternative to SEMI E13 (SECS Message Services) for applications where TCP/IP is preferred over OSI as a communications basis.

2 Scope

2.1 High-Speed SECS Message Services Single-Session Mode (HSMS-SS) is a subsidiary standard to High-Speed SECS Message Services (HSMS) Generic Services.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Reference Standards

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

3.1 *SEMI Standards*

SEMI E4 — SEMI Equipment Communication Standard 1 Message Transfer (SECS-I)

SEMI E5 — SEMI Equipment Communication Standard 2 Message Content (SECS-II)

SEMI E37 — High-Speed SECS Message Services (HSMS) Generic Services

4 Terminology

4.1 *Definitions*

4.1.1 *device ID* — a 15-bit field in the message header used to identify a subentity within the equipment.

4.2 In addition, all definitions for HSMS Generic Services apply.

4.3 Note that the terms HSMS and HSMS generic services both refer to the HSMS Generic Services standard definition (SEMI E37).

5 HSMS-SS Overview and State Machine

5.1 This definition defines the HSMS-SS-specific use of HSMS Generic Services suitable for applications requiring a simple SECS-I replacement. The purpose of this standard is to explicitly limit the capabilities of the HSMS Generic Services to the minimum necessary for this type of application. Specifically, HSMS imposes the following limitations:

1. HSMS-SS eliminates the use of a number of HSMS procedures. Deselect is not to be used to end HSMS-SS communications (use Separate instead), and the Reject procedure is optional.
2. HSMS-SS limits certain other procedures such as Select to simplify operation for the specific case of SECS-I replacement.

5.2 The remainder of this document describes these limitations in more detail.

5.3 *HSMS-SS State Machine* — The HSMS-SS behavior and state machine differ from that specified in the HSMS Generic Services in the following ways:

1. The SelectionCounter defined in HSMS Generic Services is not required.
2. Various transitions are defined differently as illustrated in the HSMS-SS state machine illustrated below.

5.4 The HSMS-SS state machine is illustrated in the diagram below.

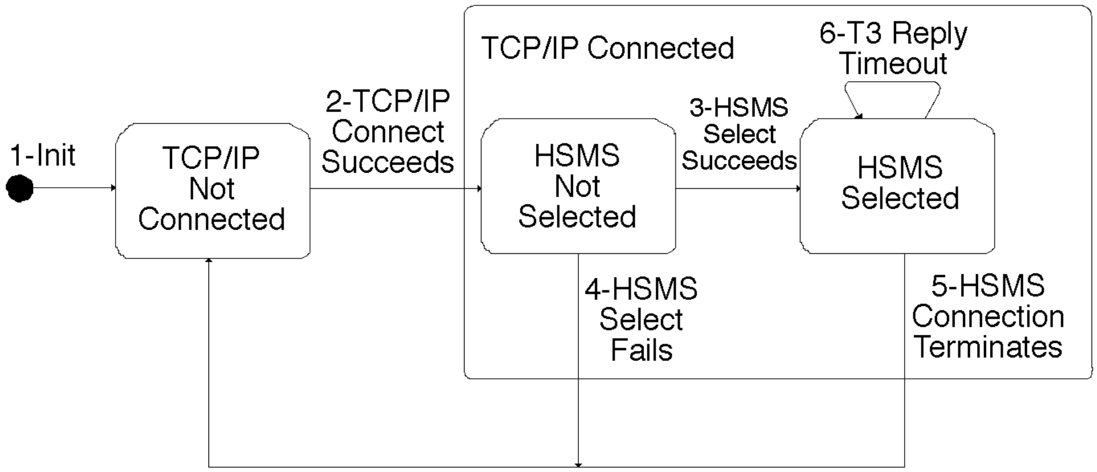


Figure 1

5.5 *State Transition Table for Passive Mode Connect*

Table 1 HSMS-SS Passive Mode Connect State Transitions

#	*Old State*	*New State*	*Trigger*	*Actions*
1	—	TCP/IP NOT CONNECTED	Initialization	
2	TCP/IP NOT CONNECTED	HSMS NOT SELECTED	TCP/IP Connect Succeeds: 1. TCP/IP “accept” succeeds.	Start T7 timeout.
3	HSMS NOT SELECTED	HSMS SELECTED	HSMS Select Succeeds: 1. Receive Select.req and decide to allow it.	1. Cancel T7 timeout; and 2. Send Select.rsp with zero SelectStatus.
4	HSMS NOT SELECTED	TCP/IP NOT CONNECTED	HSMS Select Fails: 1. T7 Timeout waiting for Select.req; or 2. Receive Select.req and decide to reject it and send Select.rsp with non-zero SelectStatus; or 3. Receive any HSMS message other than Select.req; or 4. Receive HSMS message length not equal to 10; or 5. Receive bad HSMS message header; or 6. T8 timeout waiting for TCP/IP; or 7. Other unrecoverable TCP/IP Error (entity-specific).	1. Close TCP/IP connection.

#	*Old State*	*New State*	*Trigger*	*Actions*
5	HSMS SELECTED	TCP/IP NOT CONNECTED	HSMS Connection Terminates: 1. Decide to terminate and send Separate.req; or 2. Receive Separate.req; or 3. T6 timeout waiting for Linktest.rsp; or 4. Receive HSMS message <10; or 5. Receive HSMS message length > maximum supported by entity; or 6. Receive bad HSMS message header; or 7. T8 timeout waiting for TCP/IP; or 8. Other uncorrectable TCP/IP Error (entity-specific).	1. Close TCP/IP connection.
6	HSMS SELECTED	HSMS SELECTED	T3 Timeout waiting for Data Reply Message.	1. Cancel the Data Transaction as appropriate (entity-specific) but do not terminate the TCP/IP connection; and 2. If entity is EQUIPMENT send SECS-II S9F9.

5.6 *State Transition Table for Active Mode Connect*

Table 2 HSMS-SS Active Mode Connect State Transitions

#	*Old State*	*New State*	*Trigger*	*Actions*
1	–	TCP/IP NOT CONNECTED	Initialization	
2	TCP/IP NOT CONNECTED	HSMS NOT SELECTED	TCP/IP Connect Succeeds: 1. Decide to connect.	1. TCP/IP Connect; and 2. Send Select.req; and 3. Start T6 timeout.
3	HSMS NOT SELECTED	HSMS SELECTED	HSMS Select Succeeds: 1. Receive Select.rsp with zero SelectStatus.	1. Cancel T6 timeout.
4	HSMS NOT SELECTED	TCP/IP NOT CONNECTED	HSMS Select Fails: 1. T6 Timeout waiting for Select.rsp; or 2. Receive Select.rsp with non-zero Select.Status; or 3. Receive any HSMS message other than Select.rsp; or 4. Receive HSMS message length not equal to 10; or 5. Receive bad HSMS message header; or 6. T8 timeout waiting for TCP/IP; or 7. Other unrecoverable TCP/IP Error (entity-specific).	1. Close TCP/IP connection; and 2. Start T5 Timeout.

#	*Old State*	*New State*	*Trigger*	*Actions*
5	HSMS SELECTED	TCP/IP NOT CONNECTED	HSMS Connection Terminates: 1. Decide to terminate and send Separate.req; or 2. Receive Separate.req; or 3. T6 timeout waiting for Linktest.rsp; or 4. Receive HSMS message length < 10; or 5. Receive HSMS message length > maximum supported by entity; or 6. Receive bad HSMS message header; or 7. T8 timeout waiting for TCP/IP; or 8. Other uncorrectable TCP/IP Error (entity-specific).	1. Close TCP/IP connection.
6	HSMS SELECTED	HSMS SELECTED	T3 Timeout waiting for Data Reply Message.	1. Cancel the Data Transaction as appropriate (entry-specific) but do not terminate the TCP/IP connection; and 2. If entity is EQUIPMENT, send SECS-II S9F9.

Table 3 When HSMS Transactions are Allowed

HSMS Transition	*Allowed in State(s)*	*Who Initiates Transaction?*
Select	HSMS Not Selected	Active Entity
Link Test	HSMS Selected	Either Entity
Data	HSMS Selected	Either Entity
Separate	HSMS Selected	Either Entity

6 HSMS-SS Use of TCP/IP

6.1 As defined in HSMS.

7 HSMS-SS Procedures

7.1 *Select Procedure* — The Select Procedure shall only be initiated by the entity establishing the TCP/IP connection in active mode. The Passive Mode Entity shall not initiate the Select Procedure.

7.1.1 The Select Procedure is only permitted in the NOT SELECTED state. It uses a SessionID value of 0xFFFF and implies that all device IDs are available for communication. Immediately following any Select Procedure which fails to complete successfully with a zero Select Status, each Entity must close the TCP/IP connection and transit to the NOT CONNECTED state.

7.2 *Data Procedure* — The Data Procedure is as defined in HSMS Generic Services. Note that any SessionID value that corresponds with a DeviceID supported by the Local Entity is valid as long as the Local Entity is in the SELECTED state.

7.3 *Deselect Procedure* — Deselect shall not be used in an HSMS-SS implementation. Communication is ended using the Separate Procedure.

7.4 *Linktest Procedure* — As defined by HSMS. Under HSMS-SS, the use of Linktest is strictly limited to the SELECTED state.

7.5 *Reject Procedure* — The Reject Procedure is optional in HSMS communications. Note, however, that any situation which would require the use of the Reject as described in HSMS Generic Services shall be treated as a communications failure in implementations not supporting reject. Specifically, the TCP/IP connection is immediately closed.

7.6 *Separate Procedure* — Separate shall always use SessionID 0xFFFF (binary, all ones). In HSMS-SS, the Separate.req is valid only in the TCP/IP CONNECTED state and its substates. After either initiating or receiving a Separate.req message, the entity shall immediately close the TCP/IP connection and transit to the TCP/IP NOT CONNECTED state.

7.7 *Communications Failures* — As defined by HSMS. Note that, in addition to the communications failures defined under HSMS, any violation of the restrictions defined in prior sections of this document are also to be treated as communication failures.

8 HSMS-SS Message Format

8.1 *Session ID* — In HSMS-SS Data Messages, the high-order bit of Session ID is zero, and the low-order 15 bits contain Device ID, a 15-bit unsigned integer value, which occupies the low-order 7 bits (bits 6-0) of byte 0 and all of byte 1 of the header. Device ID is a property of the equipment, and can be viewed as a logical identifier associated with a physical device or sub-entity within the equipment. The precise meaning of “device” or “sub-entity” is equipment-defined. A unit of equipment must have at least one Device ID. Equipment which contains several devices may define a unique Device ID for each device.

In HSMS-SS Control Messages, Session ID will always assume the special value 0xFFFF (all one bits).

8.2 *PType* — All HSMS-SS messages are PType 0 (SECS II encoded) as defined in HSMS.

8.3 *SType* — Only HSMS-defined STypes are permitted in HSMS-SS. User-defined SType messages are not permitted.

9 Special Considerations

9.1 *Multiblock Messages* — For each SECS-II message, the SECS-II standard defines whether that message should be transmitted in SECS-I as a single-block message or as a multiblock message. This distinction becomes unimportant with HSMS, which transmits all messages in the same fashion. However, to be compatible with older SECS-I applications, when an HSMS application sends a SECS-II message defined as single block, the HSMS Message Length should not exceed 254 bytes (10 byte header plus 244 text bytes).

10 HSMS-SS Documentation

10.1 An HSMS-SS implementation is required to document the following information in addition to the information required by HSMS.

1. The number of deviceIDs supported and their specific values.
2. Whether or not the implementation supports the normal or the restricted procedure for terminating communications.
3. The setting of the host vs. equipment parameter.

10.2 *Host vs. Equipment* — Many applications using SECS-II will need to designate one end of the communication link as “Equipment” and the other end as “Host.” HSMS-SS itself does not require configuring of “Host” and “Equipment,” but this parameter may be included in configuration where needed. HSMS can also be used in applications where the distinction between Host and Equipment is not used.

RELATED INFORMATION 1
APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E37.1 and is not intended to modify or supercede the official standard. Publication was authorized by full letter ballot. Determination of the suitability of the material is solely the responsiblity of the user.

R1-1

R1-1.1 An entity may have more than one session. If a unit of equipment can be divided into two or more logical sub-equipments, such as process chambers, or process resources, each of these may have separated session ID. If two or more physical sub-equipments are controlled by an equipment controller or communicated to through a TCP/IP network device, each sub-equipment may have a separate session ID. Such a session can be established once HSMS is selected. Each session ID corresponds to a device ID.

R1-1.2 If a unit of equipment has more than one sub-equipment or process resource (e.g. process modules) but the sub-equipment share a common resource (e.g. transfer subsystem), it is not recommended that each sub-equipment have an independent session to communicate with host. Even if the host requests an action to the shared subsystem with a session identifier specific for a sub-equipment, the shared subsystem may not always serve for the sub-equipment. Since the host expects the shared subsystem to perform the service for the sub-equipment, an error will occur if it is not possible to perform the service for the designated sub-equipment. See following figure.

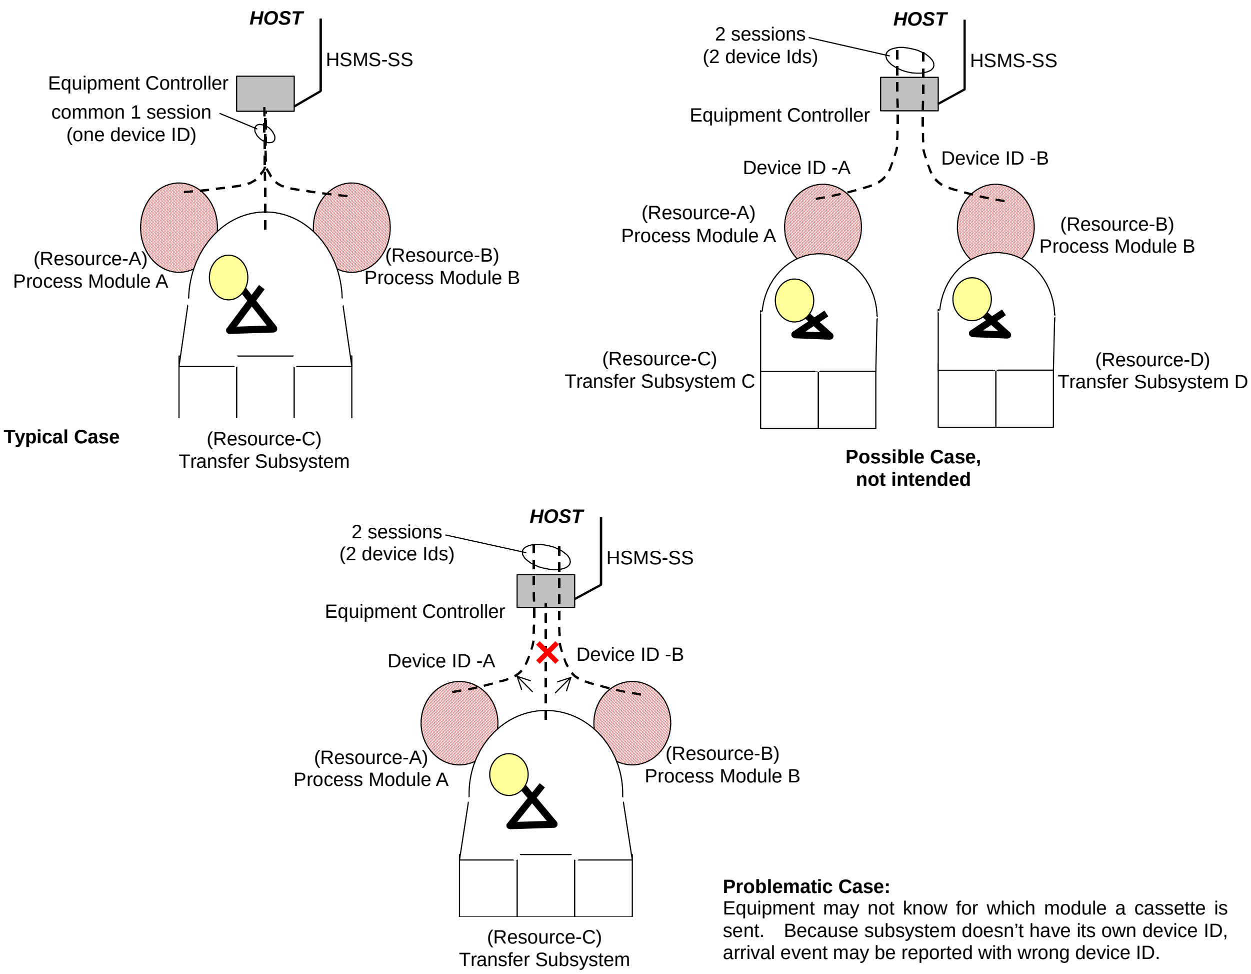

Figure R1-1

R1-2 Multiple HSMS Connections

R1-2.1 Typically, an Equipment will accept only one Host Connection.

R1-2.2 A Host may connect to several units of Equipment, so the Host may have several simultaneously active Connections (each to one Equipment).

R1-2.3 A Cell Controller (or similar entity) might have one Connection by which the Cell Controller appears as "Equipment" to the Factory Host Computer, as well as several Connections by which the Cell Controller appears as "Host" to Equipment.

R1-3 Equipment Support for Multiple Hosts

R1-3.1 HSMS requires Equipment to accept at least one active Connection, and does not require the equipment to support access by multiple concurrent Hosts. That is, if the Equipment has already accepted a Host Connection, but a Host (the same or a different Host) attempts a second Connection, the Equipment will immediately terminate that second Connection attempt.

R1-3.2 For specialized applications, an equipment could accept more than one Host Connection. Coordination of activity by multiple hosts is equipment-defined.

SEMI E37.2-95
HIGH-SPEED SECS MESSAGE SERVICES GENERAL SESSION (HSMS-GS)

1 Purpose

HSMS-GS is intended to support the needs of complex systems containing multiple independently accessible subsystems such as cluster tools or track systems. Specifically, procedures are defined to permit access to any individual subsystem or set of subsystems within any complex system.

2 Scope

High-Speed SECS Message Services General Session (HSMS-GS) is a subsidiary standard to High-Speed SECS Message Services (HSMS) Generic Services.

3 Applicable Documents

3.1 *SEMI Standards*

SEMI E37 — HSMS Generic Services

SEMI E4 — SEMI Equipment Communications Standard 1 Message Transport (SECS-I)

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

4 Selected Definitions

Selected Entity List — a list of session entities currently selected for communication on a given TCP/IP connection.

Selection Count — the number of sessions opened by an HSMS Select procedure and not yet ended by an HSMS Deselect or Separate procedure.

Session Entity — an individually selectable entity within an HSMS-GS system.

Session Entity ID — a 16-bit identifier for a Session-Entity.

SessionEntityList — a list of all available session entities within an HSMS-GS system and associated with a particular IP address and port number.

In addition, all definitions for HSMS Generic Services apply.

Note that the terms HSMS and HSMS Generic Services both refer to the HSMS Generic Services standard definition (SEMI E37).

5 HSMS-GS Overview and State Machine

HSMS-GS provides a set of definitions which permit the individual subentities (e.g., subsystems) of complex entities (e.g., systems) to be separately accessible during HSMS procedures. HSMS-GS defines no new procedures or message types beyond HSMS Generic Services to provide these services. It does, however, require extensions to the HSMS State machine, in the form of additional state transition definitions and additional state information, which are used by the extended state machine which must be maintained by an HSMS-GS implementation to support the extended state machine. The additional information consists of the following:

1. The Session Entity List

2. The Selected Entity List

3. The Selection Count

The Session Entity List consists of the set of all Session Entities having individual accessibility within the HSMS-GS entity. The scope of this list is normally the entire HSMS-GS entity. HSMS-GS, however, does not require this scope: the supplier may provide access to HSMS-GS entity through more than one well known port and provide a different Session Entity List for each.

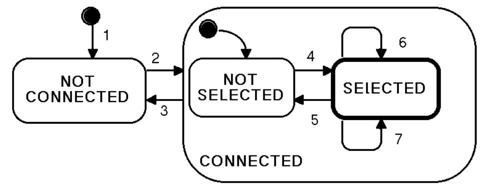
A Session Entity is any individually addressable subentity within the HSMS-GS entity: for example, a Session Entity may be an individual sub-device in a track system or cluster tool, or may be an individual service provider, such as a data server, within an entity. HSMS-GS only provides the conventions for identifying Session Entities. It places no restrictions on the individual supplier as to what constitues a SessionEntity: the supplier must determine what is the most appropriate for the particular implementation.

The Selected Entity List is the list of Session Entities actually selected for access on a given TCP/IP connection. When the TCP/IP connection is established (CONNECTED state entered), an empty Selected Entity List is created. Each time, the Select Procedure is used to select a Session Entity, its Session Entity ID is added to the Selected Entity List created for that TCP/IP connection. Each time the Session Entity is deselected via the Deselect or Separate procedures, its Session Entity ID is removed from the Selected Entity List. At any given time on any given TCP/IP connection endpoint, HSMS Data Messages will only be accepted by an entity if the SessionID of the Data Message is equal to any Session Entity ID in the Selected Entity List.

The Selection Count is simply the number of Session Entity IDs in the Selected Entity List. Its value affects the behavior of the state machine: the transition to NOT SELECTED from SELECT can only take place when the SELECTION COUNT is zero.

Note that the above lists and count are defined for the purpose of explaining state machine operation only. There is no requirement that any of the above lists and count be explicitly implemented.

5.1 *HSMS-GS State Machine* — The HSMS-GS state machine is the same as the HSMS Generic Services state machine with the addition of the two new state transitions (#6 and #7) and the use of the Selection Count in the other transitions as described in the state transition table below.



5.2 *State Descriptions* — The state descriptions are the same as HSMS Generic Services.

5.3 *State Transition Table* — The state transition table is almost identical with the state transition table for HSMS Generic Services. For convenience, however, the entire table is reproduced and extended here, not just those areas which differ from it.

Table 1

#	*Current State*	*Trigger*	*New State*	*Actions*	*Comment*
1	...	Local entity specific preparation for TCP/IP communication.	NOT CONNECTED	Local entity-specific.	Action depends on connection procedure to be used: active or passive.
2	NOT CONNECTED	A TCP/IP connection is established for HSMS communication.	CONNECTED - NOT SELECTED	Set Selection Count = 0 and create empty Selected Entity List.	none
3	CONNECTED	Breaking of TCP Connection.	NOT CONNECTED	Local entity-specific.	none
4	NOT SELECTED	Successful completion of HSMS Select Procedure.	SELECTED	Set Selection Count = 1 and add selected Session Entity to Selected Entity List.	none
5	SELECTED	Deselect or Separate procedure resulting in Selection Count = 0.	NOT SELECTED	Local entity-specific.	See transition 7 below.
6	SELECTED	Successful completion of HSMS Select Procedure when Selection Count > 0	SELECTED	Increment Selection Count and add selected Session Entity to Selected Entity List.	none
7	SELECTED	Successful completion of HSMS Deselect or Separate when Selection Count > 1.	SELECTED	Decrement Selection Count and remove selected Session Entity from Selected Entity List.	If this transition results in Selection Count = 0, immediately trigger state transition 5.

6 HSMS-GS Use of TCP/IP

6.1 There is no additional HSMS-GS specification for the use of TCP/IP beyond the above mentioned creation of the empty "Selected Entity List" upon entry into the CONNECTED state, NOT SELECTED substate.

7 HSMS-GS Specific Procedures

HSMS-GS provides further specification of the following procedures.

7.1 *Select Procedure* — The select procedure is permitted in both the NOT SELECTED state and the SELECTED state. The procedure for both the initiator and the responding entity is the same as HSMS Generic Services, with the following additional conditions:

1. If the responding entity contains no Session Entity in its Session Entity List whose ID matches the SessionID in the Select.req, a Select Status of No Such Entity is used in the Select.rsp.
2. If the responding entity is unable to provide access to the selected entity because it is usable on only a single TCP/IP connection at any one time and it is already in use on a different TCP/IP connection, a response code of Entity In Use is used in the Select.rsp.
3. If the responding entity finds the SessionID already in its Selected Entity List, a response code of Entity Selected is used in the Select.rsp.

The Select Status values referenced above are all defined in Section 8.

If none of the above is true, the Select completes successfully, and a Select Status of 0 is provided in the Select.rsp. Both entities will add the SessionID from the Select.req to the Selected Entity List.

7.2 *Data Procedure* — The Data Procedure is as defined in HSMS Generic Services. Note that the SessionID of any Data Message must match a SessionID in the SelectedEntityList. If a Data Message is received with a SessionID other than one from the Selected Entity List, a Reject.req message is sent in response by the receiving entity. The reason code will be Entity Not Selected.

7.3 *Deselect Procedure* — The Deselect procedure is restricted by the following conditions:

1. The SessionID must be in the Selected Entity List.
2. The corresponding SessionEntity is in a state which permits Deselect. This decision is local entity specific and not subject to the HSMS-GS.

If both of the above are true, then the Deselect can proceed. Assuming that the Deselect completes successfully, the SessionID is removed from the Selected Entity List, and the Selection Count is decremented. The transition to the NOT SELECTED state transpires only if the resulting Selection Count is equal to zero (i.e., an empty Selected Entity List).

7.4 *Linktest Procedure* — As defined by HSMS.

7.5 *Reject Procedure* — As defined by HSMS. Note, in particular, the use of Reject in response to certain data messages (above).

7.6 *Separate Procedure* — The Separate procedures and state transitions are subject to the same restrictions and conditions as the Deselect.

7.7 *Communications Failures* — As defined by HSMS. Note that any abrupt termination has the effect of deselecting all entities in the Selected Entity List.

8 HSMS-GS Message Format Issues

8.1 *Session ID* — In HSMS-GS Select, Data, Deselect, Reject, and Separate messages, the SessionID will equal the Session Entity ID of the target Session Entity which must equal the Session ID of a Session Entity contained in the Session Entity List. In the Linktest, it is 0xFFFF, as in HSMS.

8.2 *PType* — HSMS-GS messages are generally PType = 0 (SECS-II-encoded) as defined in HSMS. Although other PTypes are permitted, specific application domains may restrict the use of HSMS-GS to Ptype = 0.

8.3 *SType* — Only HSMS-defined STypes are permitted in HSMS-GS.

8.4 *Select/Deselect Status* — The following additional enumeration applies to the select/Deselect status in HSMS-GS:

Table 2 SelectStatus

Value	*Description*
4	No Such Entity — Session ID does not correspond to any Session Entity ID available at this connection.
5	Entity In Use (by another connection) — Session Entity corresponding to session ID is not sharable connections and is already selected by another connection.
6	Entity Selected (by current connection) — Session entity corresponding to Session ID is already selected on current connection.

9 Special Considerations

9.1 There are no special considerations above and beyond those described in HSMS Generic Services.

10 HSMS-GS Documentation

10.1 An HSMS-GS implementation is required to document the following information in addition to the information required by HSMS.

1. The Session Entity List — specifically the number of Session Entities available for HSMS-GS communication and the value of their particular Session Entity ID's.

RELATED INFORMATION 1 APPLICATION NOTES

NOTE: This related information is not an official part of SEMI E37.2 and is not intended to modify or supercede the official standard. Publication was authorized by full letter ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Supporting Both HSMS-GS and HSMS-SS Simultaneously

In certain applications, the equipment manufacturer may be faced with a requirement of providing both HSMS-GS and HSMS-SS communications interfaces. For example, a cluster tool may use HSMS-GS as the intra-tool communications and HSMS-SS as a GEM interface to the factory. However, implementing a communications facility that is simultaneously HSMS-SS- and HSMS-GS- compliant is straightforward.

Assuming that one has implemented an HSMS-GS, a simple test can be added to the first Select.req received by the equipment. If it is a Select for any particular SessionID, then operate as HSMS-GS. If its value is a -1, then copy the contents of the Session Entity List corresponding TCP/IP IP address and port number into the Selected Entity List. The Selection Counter would be set to a special value, such as -1, to indicate selection in this manner. The Separate would provide the reverse function. If the passive entity is implemented as an HSMS-SS node and the active entity is an implementation that supports both modes of operation, it must be explicitly configured to initiate the Select with a Session ID of -1 and must have a Session Entity List containing the Device IDs of all the available sub-devices within the passive mode entity.

In the local API for the case where the equipment must originate the select, a configuration parameter for the equipment could indicate which mode to use for a particular remote target.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E38-1296
CLUSTER TOOL MODULE COMMUNICATIONS (CTMC)

1 Purpose

1.1 Cluster tools fulfill a need for modularity and flexibility in semiconductor manufacturing equipment. This standard addresses the communications with and among modules within a cluster tool for automated control.

1.2 The module communications services defined here will enable standard interoperability of modules from independent suppliers. Together with other cluster tool standards, this is intended to result in the emergence of standards-compliant interoperable sub-systems. They should allow applications software to be developed which can assume the existence of these services and allow software products to be developed to offer them.

1.3 The adoption of the standards described will greatly reduce the effort required to integrate cluster tool components from independent suppliers. Compliance requires support of a minimal, but specific, set of standard services.

2 Scope

2.1 Cluster tool module communications address only communications with and among modules within a cluster tool and not the communications between the cluster tool and the factory. It is the modules and their interrelations which are modeled and not the cluster tool seen as a single equipment.

2.2 This standard does not specify cluster controller functionality (e.g., scheduling, human machine interface, cluster tool recipe editing, and management) but will enable development of standards in this area. The cluster controller is included only to the extent that it represents the entity or entities responsible for supervisory control of the modules in a cluster tool.

2.3 This standard identifies the communications services necessary to achieve automated control of independent transport, process, and cassette modules in a cluster tool. It defines the essential module architecture and the concepts and models on which the communications services are based.

2.4 The scope includes primary control services for material processing in process modules, material movement within the cluster tool, and material input/output with the factory. Support services also exist to enable recipe handling, resolution of exception conditions, event reporting, and data access.

2.5 A reliable communications environment is required for distributed control and is specified in supplementary standards.

2.6 This standard specifies the application of more general service standards as required within a cluster tool. This includes the limitations imposed by the cluster tool architecture and the fundamental functionality needed for compliance. The details of the general services, protocols, and communication environment elements are defined in the corresponding standards documents referenced.

2.7 This version of the standard is provisional because a number of the general services on which it relies are not yet standardized. The sections referring to these services have been omitted until they have become standards. These sections will be balloted separately with the corresponding general services and incorporated into this provisional standard.

2.8 The communication between the cluster tool as a single equipment and the factory is beyond the scope of cluster tool module communications standardized here and should follow the applicable SEMI standards (GEM, MMMS).

2.9 These standards place no restriction on where, within the cluster tool control architecture, this specific set of definitions is implemented. However, to have complete compliance to the standards in the area of the communications interface definitions, the entire layered structure as outlined in this document must be implemented.

4 Terminology

4.1 The following terms are those that are appropriate for describing the overall structure of cluster tools. These terms, in addition to the more specific terms located in the individual service, protocol, and communications environment standards, complete the glossary of terms required.

4.1.1 *agent* — an intelligent system within a factory that provides one or more service resources and uses the services of other agents. A generalization of host, equipment, cell, cluster, cluster module, station controller, work station. Agents are associated with a physical system or a collection of physical systems, including computer platforms.

4.1.2 *alarm* — an alarm is related to any abnormal situation on the equipment that may endanger people, equipment, or material being processed. [SEMI E30]

4.1.3 *atomic transfer* — the basic unit of movement. The transfer of a single material between two partners where only one change in ownership occurs.

4.1.4 *attached module* — any component of a cluster tool which mechanically attaches to the transport module at an interface flange. Specifically, the cassette, process, and docking modules are all attached modules. The attached module can be isolated from the transport module by an isolation valve controlled by the transport module. In addition, the attached module may also possess an additional isolation valve. The point of separation between the isolation valve on the transport module and the attached module is called the interface plane.

4.1.5 *am transfer job* — a material transfer job for an attached module specifying all criteria for receiving the material from, or sending the material to, a transport module.

4.1.6 *carrier (material)* — a device for the holding of material for various processing steps in semiconductor manufacturing. [SEMI E1]

4.1.7 *cassette module* — an attached module which provides the means of exchanging material between the intertool environment and the intratool environment of a particular cluster. There is no requirement that the material interface to the intertool environment with the use of cassettes.

4.1.8 *cm input/output transfer job* — a material transfer job for a cassette module, specifying all criteria for receiving the material from, or sending the material to, the factory.

4.1.9 *cluster controller* — the entity or entities responsible for supervisory control within a cluster tool, achieved through communicating with the various modules. The form of the cluster controller is not dictated. It may be a single platform, distributed, or incorporated with one or more modules.

4.1.10 *cluster tool* — an integrated, environmentally isolated, manufacturing system consisting of process, transport, and cassette modules mechanically linked together. There is no requirement that the modules come from the same supplier. [SEMI E21]

4.1.11 *decision authority* — an entity requiring to be notified of significant exception condition changes and which decides how to proceed to resolve abnormal situations related to recoverable error conditions. The decision authority may be represented by a supervisory controller interacting with an operator who may ultimately choose the recovery action.

4.1.12 *docking module* — a component for allowing the exchange, within a cluster tool, of material between multiple transport modules. The docking module presents an attached module interface to both transport modules and is modeled as a multi-port process module for intra-cluster tool communications.

4.1.13 *end effector* — a physical location attached to a transfer resource capable of holding material during an end-to-end material transfer.

4.1.14 *error condition* — an exception condition which is not an alarm and which may support recovery actions requested by a decision authority.

4.1.15 *exception condition* — a managed condition for reporting on and providing recovery from an abnormal situation in the equipment.

4.1.16 *factory* — entities outside the control domain of the cluster tool and from which material is received for processing and returned upon process completion. Also considered to be the intertool environment.

4.1.17 *factory transport resource* — n operator or a piece of equipment specialized in the transport of material from one equipment to another.

4.1.18 *form* — type of data representing information contained in an object attribute or service message parameter. The data types are detailed in Section 4.2.

4.1.19 *fundamental requirements* — the requirement for information and behavior that must be satisfied for compliance to a standard. Fundamental requirements apply to specific areas of application, objects, or services.

4.1.20 *handoff micro move* — an operation requested by an attached module and performed by a transport module to achieve all or part of a material handoff between them.

4.1.21 *interface flange* — the boundary plane separating an attached module and a single transport module.

4.1.22 *intertool environment* — defined relative to a particular cluster tool to be everywhere outside of the intratool environment.

4.1.23 *intertool material transfer job* — a transfer job in the cluster controller to receive material from, or send the material to, the factory. In automated transfer, it may be an element of a factory transfer job.

4.1.24 *intertool port resource* — a module resource associated with a particular cassette module which operates on behalf of the said module during material transfer between the cassette module and the intertool environment.

4.1.25 *intratool environment* — the entire environmentally isolated volume contained within a cluster tool.

4.1.26 *intratool port resource* — a module resource associated with a particular interface plane of a particular attached module which operates on behalf of the said module during material transfer between the transport module and the attached module.

4.1.27 *intratool material transfer job* — a transfer job in a cluster controller for transfer of material from one attached module to another through the linking transport module.

4.1.28 *isolation valve* — a mechanical component used at an interface plane to permit environmental isolation between the transport module and an attached module.

4.1.29 *material handoff* — the process by which material moves from the sending transfer partner to the receiving transfer partner.

4.1.30 *material location* — a physical position capable of holding a single material.

4.1.31 *material slot* — a material location in a carrier capable of holding a single material with an assigned identifier.

4.1.32 *module* — an independently operable unit that is part of a tool or system. [SEMI E21]

4.1.33 *module resource* — an entity which provides specific capabilities required of the module to be accessed or controlled externally. This includes the physical capability and the associated control and access management. It may contain material in one or more material locations.

4.1.34 *namespace* — a domain within which object identifiers are unique.

4.1.35 *port* — a point on the cluster at which a change of ownership of material occurs. A port is not itself a location but must have an associated location, such as an interface plane.

4.1.36 *process job* — a material processing job for a process module, specifying and tracking the processing to be applied to the material while in the module.

4.1.37 *process module* — an attached module which provides manufacturing value to material in a cluster tool.

4.1.38 *processing resource* — a module resource within a module which is independently capable of providing manufacturing value to material.

4.1.39 *protocol (communications)* — the message encoding used when transferring a message across some communication facility.

4.1.40 *recipe* — the pre-planned and reusable portion of the set of instructions, settings, and parameters under control of a processing agent that determines the processing environment seen by the material. Recipes may be subject to change between runs or processing cycles.

4.1.41 *recipe executor* — a component of a module that stores and executes recipes.

4.1.42 *recipe namespace* — a logical management domain with the responsibility for the storage and management of recipes. It ensures the uniqueness of recipe identifiers and provides services pertaining to recipes stored within that domain.

4.1.43 *recovery action* — an operation associated with an error condition with the aim of resolving the abnormal situation detected. It may supply information to the exception agent or request the exception agent to perform some activity.

4.1.44 *service* — the set of messages and definition of the behavior of a service provider that enables remote access to a particular functionality.

4.1.45 *service-provider* — the software control entity that is the provider of any of the related services.

4.1.46 *service-user* — the software control entity that is the user of any of the related services.

4.1.47 *transport module* — a module containing one or more transfer resources and a number of interface planes. It is capable of end-to-end transfer between any of the interface planes.

4.1.48 *tm transfer job* — a material transfer job for a transport module specifying all criteria for receiving the material from the source-attached module and sending the material to the destination module.

4.1.49 *transfer resource* — a module resource within a transport module independently capable of transferring material from one attached module to another.

4.2 *Data Type*

4.2.1 *form* — type of data: positive integer, unsigned integer, integer, enumerated, boolean, text, formatted text, structure, list, ordered list.

4.2.2 *positive integer* — may take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

4.2.3 *unsigned integer* — may take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

4.2.4 *integer* — may take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

4.2.5 *enumerated* — may take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

4.2.6 *boolean* — may assume one of two possible values, equating to TRUE or FALSE.

4.2.7 *text* — a text string. Messaging protocol may impose restrictions, such as length or ASCII representation.

4.2.8 *formatted text* — a text string with an imposed format. This could be by position, by use of special characters, or both.

4.2.9 *structure* — a complex structure consisting of a specific set of items, of possibly mixed data types, in a specified arrangement.

4.2.10 *list* — a set of one or more items that are all of the same form (one of the above forms).

4.2.11 *ordered list* — a list for which the order in which items appear is significant.

5 Conventions

5.1 *Harel State Model*

5.1.1 This document uses the Harel State Chart notation to describe the dynamic behavior of the objects defined. An overview of this notation is presented in an Appendix of SEMI E30. The formal definition of this notation is presented in *Science of Computer Programming 8*, “Statecharts: A Visual Formalism for Complex Systems,” by D. Harel, 1987.

5.1.2 Transition tables are provided in conjunction with the state diagrams to describe explicitly the nature of each state transition. A transition contains columns for Transition #, Current State, Trigger, New State, Action(s). The “trigger” (column 3) for the transition occurs while in the “current” state. The “actions” (column 5) include a combination of (1) actions taken upon exit of the current state, (2) actions taken upon entry of the new state, and (3) actions taken which are most closely associated with the transition. No differentiation is made.

5.2 *OMT Object Information Model* — The object models are presented using the Object Modeling Technique developed by Rumbaugh, James, et al., in “Object-Oriented Modeling and Design,” Prentice Hall, Englewood Cliffs, NJ, ©1991. Overviews of this notation are provided in an appendix to SEMI E39.

5.3 *Object Attribute Representation* — The object information models for standardized objects will be supported by an attribute definition table with the following column headings:

Attibute Name	*Definition*	*Access*	*Rqmt*	*Form*
The formal text name of the attribute.	Description of the information contained.	RO or RW	Y or N	(see below)

The Access column uses RO (Read Only) or RW (Read and Write) to indicate the access that service-users have to the attribute.

A ‘Y’ or ‘N’ in the requirement (Rqmt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

The Form column is used to indicate the format of the attribute. (See Section 4.1 for definitions.)

6 Overview

The Cluster Tool Module Communications standard specifies the communications services necessary to achieve automated control within a cluster tool. It defines the essential cluster tool architecture and the concepts and models on which the communications services are based.

Cluster tools provide a means of grouping a number of independent process steps into a single equipment. The primary function of a cluster tool is material processing. Material enters the cluster tool, undergoes a number of sequential process steps which adds value to the material, and then exits.

From a mechanical viewpoint, Cluster Tool Module Interface standards-compliant equipment has a physical structure where process modules and cassette modules are attached in a standardized way to some form of transport module, a robotic material handler operating in an isolated environment. Cassette modules provide the input and output of material for the cluster tool, usually in cassettes.

This communications standard enables the distributed control of these cluster tools, and of other cluster tools and multi-resource equipment which can be decomposed into process, transport, and cassette modules, whether environmentally isolated or not. A basic assumption is made that the primary human-machine interfaces are not located at the individual modules.

Communication and control services are specified among service-users and service-providers within a cluster tool. The service-providers are the controlled processing, transfer, intratool port, and intertool port resources in the appropriate modules. The service-users are the application entities responsible for supervisory control and data acquisition within the cluster tool.

The services are fully defined in terms of the service-providers, and as such, do not dictate the architecture of the service-user(s). An example of cluster tool control architecture is shown in Figure 1, where the service-user is a single cluster controller platform providing internal scheduling, human-machine interface, and standardized communications interface to the factory.

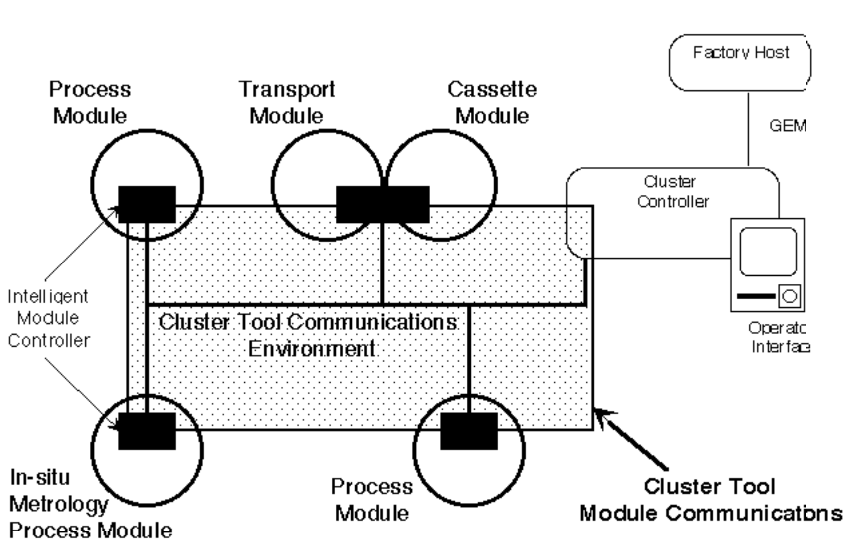

Figure 1
Example Cluster Control Architecture

The communication services include primary control services for material processing in process modules (processing management) and material movement within the cluster tool and material input/output with the factory (material movement management). The cluster controller, which is responsible for supervisory control within the cluster tool, is the service-user of these primary control services. The form of the cluster controller is not dictated. It may be a single platform, distributed, or incorporated with one or more modules.

Support services are also specified to enable resolution of exception conditions, recipe handling, event reporting and data access. The decision authority, which is responsible for making error recovery decisions, is the service-user for exception management. Appropriate agents are the designated service-users for the recipe management and event reporting support services. All service-users access data using the Object Services.

The communications services are defined independently of protocol in order to allow future standardization of alternative protocols without invalidating the services. Figure 2 shows the full communications stack needed for compliance, where the services are mapped to the communications environment, which is defined in supplementary standards.

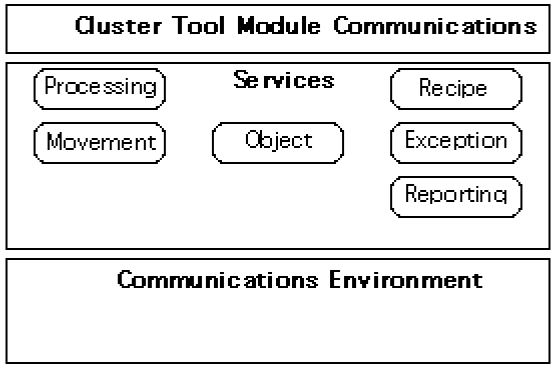

Figure 2
Cluster Tool Module Communications Standards

This standard describes the cluster tool model on which the communications are based. It then defines the application of each of the services required within a cluster tool. This includes limitations imposed by the cluster architecture as well as clear a statement of the fundamental requirements in order to minimize the implementation effort. Connection establishment and maintenance are defined together with the requirements of the communications environment. Communications environment is described in a subsection in order to allow additional options to be standardized in the future. The application notes include factory integration issues and an example scenario of standard communications for the lifecycle of a single material in a cluster tool.

6.1 *Compliance* — Cluster tool module communications compliance between entities in a cluster tool requires that all applicable exposed interfaces conform to the standards specified in this document.

The standardized interfaces are:

- Process module to Service-user (cluster controller)
- Transport module to Service-user (cluster controller)
- Cassette module to Service-user (cluster controller)
- Transport module to Cassette module
- Transport module to Process module

The exposed interfaces are those which result from a particular partition of the control entities in a cluster tool which are from independent suppliers. Three examples follow:

1. All modules independent, single cluster controller platform: Interfaces are required between the cluster controller and each module, and between the transport module and each process and each cassette module.
2. Material handler, process modules independent, single cluster controller platform: Interfaces are required between the cluster controller and each process module, between the cluster controller and each logical module in the material handler (transport and cassette modules), and between the material handler and each process module.
3. One independent process module integrating to a cluster tool control system: Interfaces are required between the cluster tool control system and the process module supporting the process module to cluster controller communications, and the process module to transport module communications.

For fundamental compliance, each exposed interface shall support the fundamental requirements of each of the service groups required by the entities communicating. The required service groups for each interface are detailed in Section 8.6, and the required services for each service group are detailed in Sections 8.1 to 8.6.

7 Concepts

The Cluster Tool architecture and requirements are modeled in order to extract only the entities necessary for robust automated control and monitoring communications within a cluster tool.

Figure 3 illustrates the major module domains and the primary relationships between them. Module resources and material domains are represented differently to others because they embody the physical entities acting and being acted upon respectively.

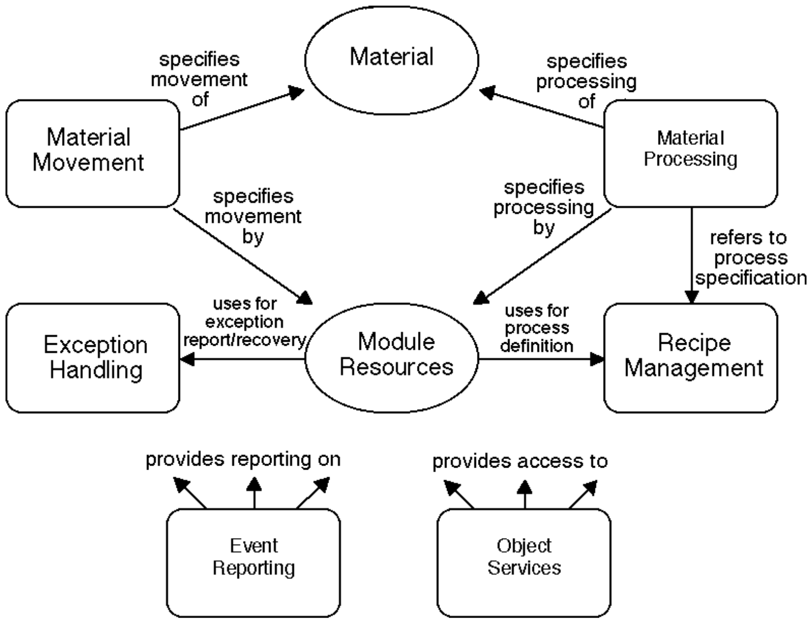

Figure 3
Cluster Tool Module Illustration

The domains illustrated are as follows:

Material — The material, or carrier of material, which is being received and processed in the cluster tool.

Material Processing — Specifies the required application of processing to material as defined by the assigned recipe, adding value to the material.

Material Movement — Includes exchange of material with the factory and material movement within the cluster, to get the material to the correct processing resource at the right time.

Module Resources — Perform and coordinate the processing and material movement activities.

Recipe Management — Provides the services to transfer recipes to be loaded as required for material processing, and manages recipe change control.

Exception Handling — Provides for interactive handling of exception conditions, including reporting and error recovery.

Event Reporting — Enables flexible event-based reporting of variable data as required by service-users.

Object Services — Provide services to obtain and modify standard object attribute data.

Each partition is presented in a subsection below with detailed information models.

The concepts are presented in this section using two types of formal models: OMT object information models describing entities and relationships, and Harel state models describing the behavioral characteristics of the cluster tool. The graphical representations of these models are described in Conventions, Section 5.

The events and actions which result from objects dynamically interacting form the basis for the communication requirements embodied in the standards. It is this mapping that specifies the communication services messages to be used.

The major requirement of the cluster tool control system is that it provide robust supervisory control with minimal overhead. Within a cluster tool there is a significant amount of parallel processing. In addition to concurrent processing in multiple independent process modules, each material processing requires the use of recipe management (to get the correct recipe with the correct material) and the use of material movement (to get the correct material to the correct processing resource at the right time).

The cluster controller maintains the overall mission of the system. Sub-missions are defined for, and responsibility given to, particular available module resources for execution. Once this responsibility is given, that module resource is fully in control, including direct communication with resources of other modules as required to attain the objective.

7.1 *Object Information Models* — The cluster tool objects relevant to distributed control in a number of models, each emphasizing a particular aspect of the system as partitioned (see Figure 4).

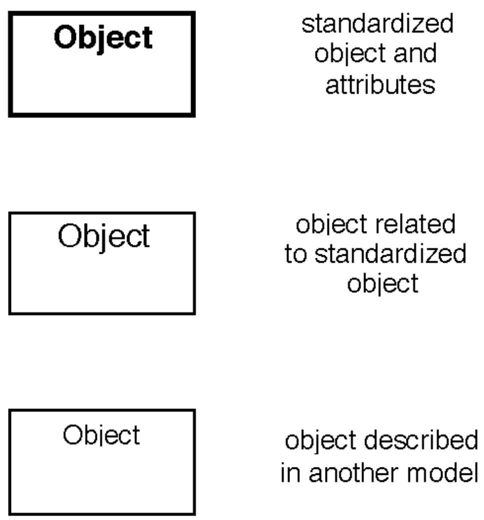

Figure 4
Object Designation

In addition to OMT conventions (see Section 5.2), each object in the information models has one of three designations: service objects with standardized attributes (thick border); other objects described in the sub-section (medium border); and objects described in other subsections but included to show significant relationships (thin border).

The models are process- and configuration-independent and do not dictate the internal architecture of the controlled modules beyond the physical requirements of cluster tools.

The first two models show major entities of the processing equipment and material being processed. Subsequent models are oriented towards one of the major functional domains.

7.1.1 *Cluster Tool Module Model* — The fundamental component of a cluster tool is the module. Figure 5 shows that there are three module types within a cluster tool:

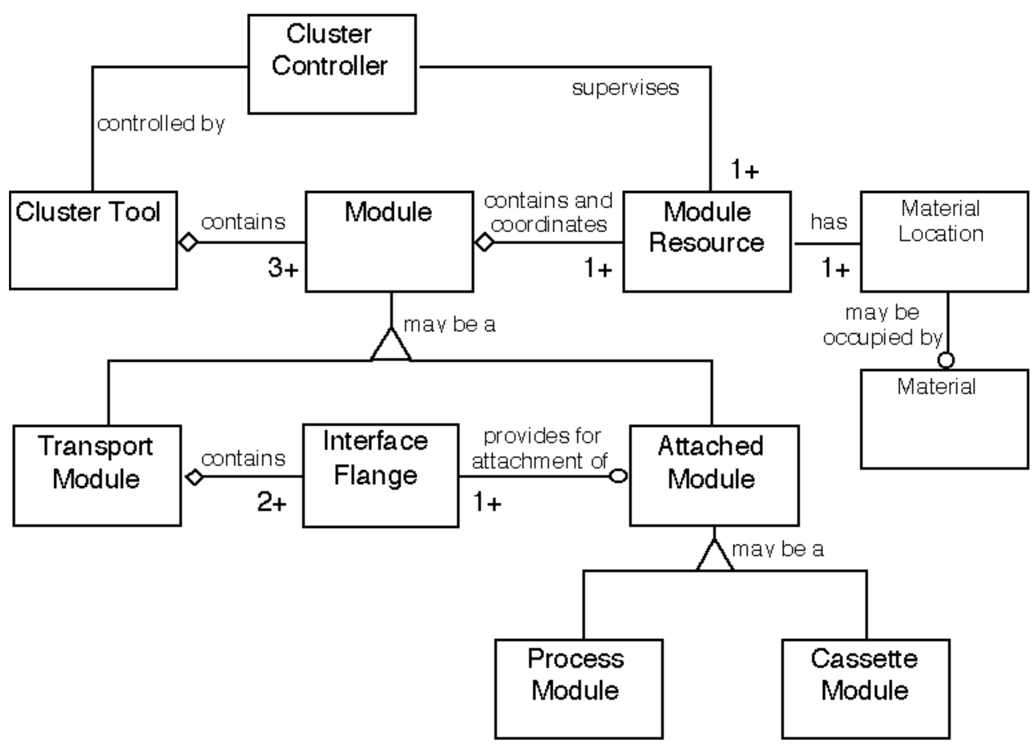

Figure 5
Cluster Tool Module Information Model

- process module (PM)— provides manufacturing value to material
- transport module (TM) — transfers material within cluster
- cassette module (CM) — exchanges material with factory

A cluster tool must contain one or more of each of these module types, as each performs a critical function in the cluster tool mission. Any module can contain processing resources.

Supervisory control within the cluster tool is the responsibility of the cluster controller. The cluster controller achieves this by supervising the various module resources using the standard communications services. It is the primary service-user in the cluster tool. The form of the cluster controller is not specified in this standard. It may be a single platform, distributed, or incorporated with one or more modules.

A module contains and coordinates a number of module resources dedicated to fulfilling a particular control function. Each module resource contains at least one material location, which may or may not contain material. Note that the location for material processing is defined separately from the location where the material is received or sent. This may be virtual if they are physically the same position, but they cannot be assumed to be so as this would exclude certain architectures.

The purpose of each type of module is described in detail below.

Cassette Module — The component of a cluster used to interface the cluster to the rest of the factory. It provides material input and output for the cluster. It makes only one material at a time available to the cluster transport (the intratool environment), regardless of how the material enters the cassette module from outside the cluster (the intertool environment). It is a specialization of attached module (AM).

Process Module — A process module is any component within a cluster which provides one or more steps of material processing for the cluster system. Material enters the process module through an interface flange, undergoes some transformation, and exits through the same or another interface flange. It is also a specialization of attached module (AM).

Transport Module — The transport module is responsible for transfer of material from one cluster-attached module to another. It consists of a robotic handler capable of exchanging material with each of the attached modules at the interface flanges. It can be a variety of physical topologies (radial or linear, for example). In SEMI standard cluster tools, the transport module has an interface isolation valve at each point of attachment to the attached modules. The transport module is responsible for managing constraints on the simultaneous opening of isolation valves as it relates to contamination of the transport module's environment by that of an attached module, as well as cross contamination between attached modules.

The attributes of modules and related objects in Figure 5 are not standardized as these objects are equipment and process-dependent.

7.1.2 *Material Model* — Material is received from the factory, in a carrier or singly, at an intertool port resource. They are transported within the cluster and processed by processing resources. Once processed, they are returned to the factory at the same, or another, intertool port resource.

The processing which is to be performed on material is determined from the process specification for that material.

The material model in Figure 6 establishes the relationships between the material and material locations. Two material types are of interest in cluster tool module communications, single material and carriers. Single material may be grouped in carriers. This is modeled by defining the material slot object, which is a type of material location. A carrier is made up of an ordered set of material slots. A single material occupies a material slot when in the carrier. In addition, a single material may be assigned a particular material slot which it does not yet occupy, indicating that it is to be received into that material slot when it arrives.

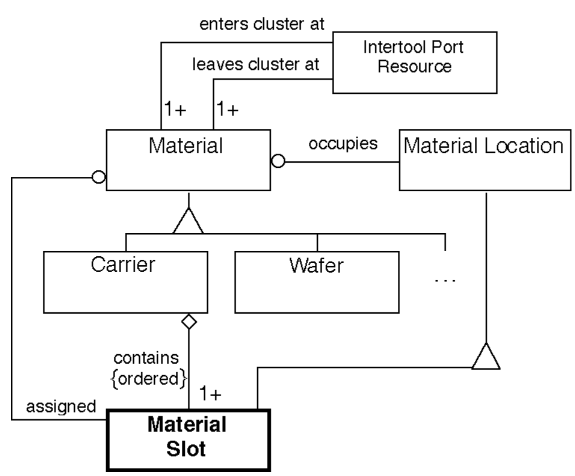

Figure 6
Material Information Model

Carriers may be cassettes used to transport single material in the factory and to input single material to the cluster tool, or they may be material boats in batch process modules.

The attributes of the material slot object are standardized to enable mapping of single material in carriers. Other objects in the diagram are not standardized. However, the identifier of the material, MaterialID, is an attribute of the material slot object.

Other materials (consumable gases and fluids, etc.) are present in the cluster tool, but outside the scope of these standards.

7.1.3 *Material Processing Model* — The material processing model in Figure 7 shows the use of the process job to direct the processing resource to apply the appropriate process, as specified by the recipe, to one or more materials in a process module. A processing resource in a process module has processing capabilities which are specified by corresponding recipes.

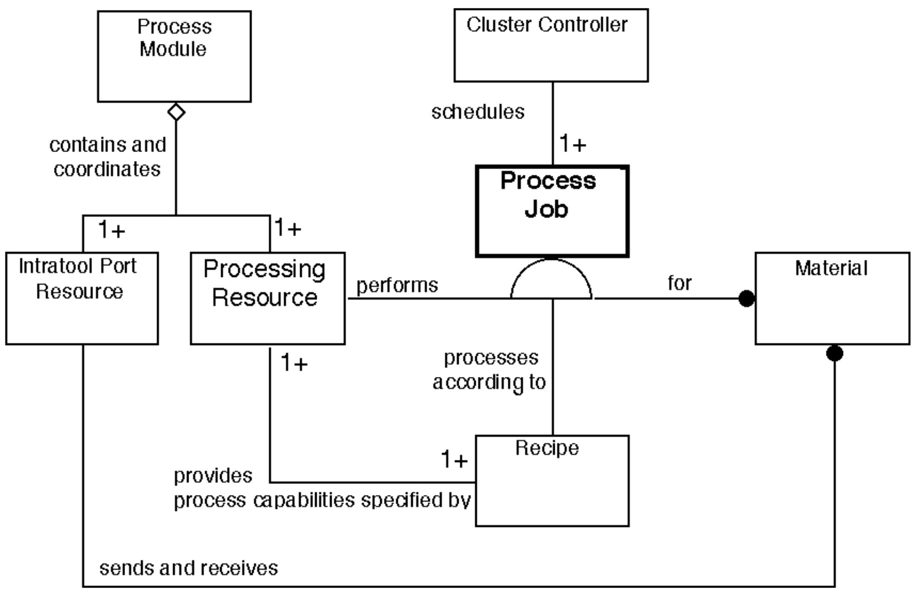

Figure 7
Material Processing Information Model

A process job can control multiple material only if identical processing is applied to all. Processing should begin and end simultaneously, synchronized with the arrival of the whole group of material.

The process job lifecycle extends beyond the active processing of the material. It exists from just before material arrival at the intratool port resource, through setup and processing, and until just after the material departure at the same, or another, intratool port resource. This allows for material-related pre-conditioning and post-conditioning of the processing resource before the material is received and after it is sent. As material input and output is controlled by the intratool port resource, it is the responsibility of the process module to ensure coordination of the intratool port and processing resources.

This is the model used to establish the Processing Management definition. There is no standardization beyond creation and control (starting, canceling, stopping, aborting, and pausing) of the high-level process job since the low-level control of process modules is application-dependent.

There is a component of scheduling embodied in this model. The material, recipes, and processing resources are scheduled by the cluster controller according to the process specification to a particular process module through the use of the process job. In order to perform the required processing, material is transferred to the processing resource, as directed by the cluster controller.

7.1.4 *Material Movement Models* — Material movement in a cluster tool includes all services required within the cluster tool to move material from the factory to a sequence of process modules in order to be processed and then back to the factory. Material is moved individually within a cluster tool and may be received from the factory in cassettes or individually.

The material movement model is divided into three parts as follows:

- intratool material movement defines the transfer of material between attached modules, with the transfer agent being a transport module.
- intertool material movement defines the exchange of carriers and single material with the factory at the cluster tool cassette module.
- carrier mapping defines presence and identifiers of single material contained in carriers.

These three models are used to establish the Material Movement Management definition within a cluster tool.

7.1.4.1 *Intratool Material Transfer* — The intratool material movement model is shown in Figure 8. An intratool material transfer is the movement of material from one attached module to another attached module through the linking transport module.

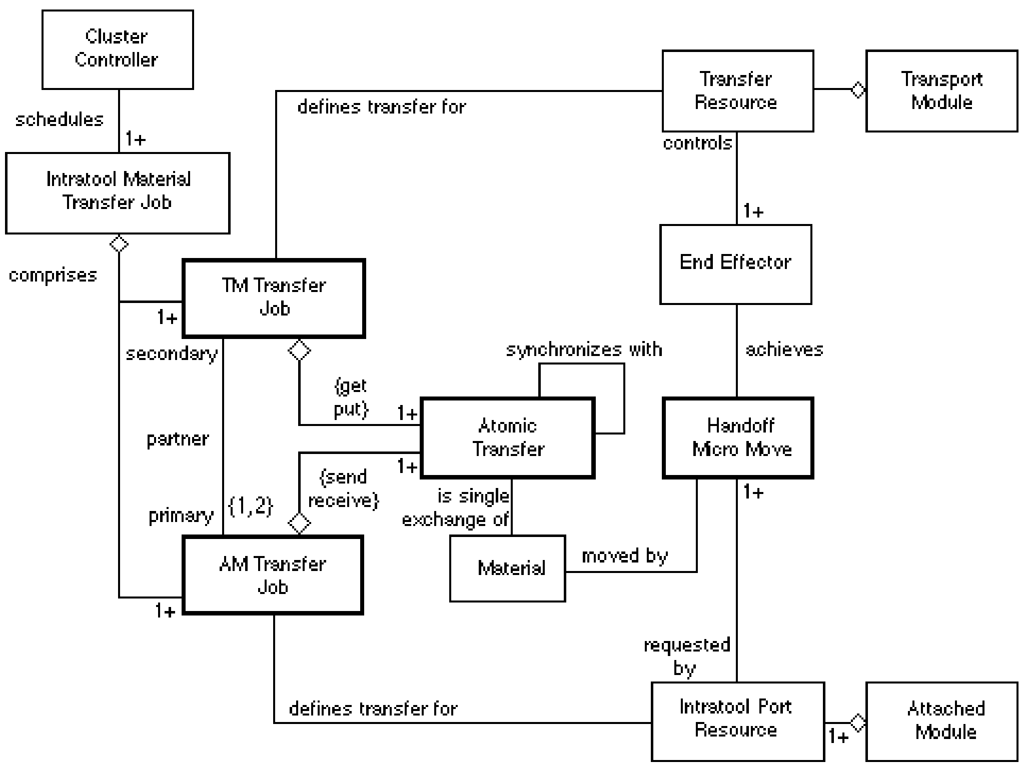

Figure 8
Intratool Material Movement Information Model

The cluster controller schedules an intratool material transfer job when intratool material transfer is required. This is achieved by TM and AM transfer jobs assigned to the appropriate module resource in each of the participating modules:

- to the transfer resource in the transport module to get the material from the source attached module and put it into the destination attached module.
- to the intratool port resource in the source attached module to send the material to the transport module.

- to the intratool port resource in the destination attached module to receive the material from the transport module.

Transfer jobs are made up of atomic transfers. An atomic transfer in one transfer partner synchronizes with the corresponding atomic transfer in the other partner to achieve the material transfer through handoff micro moves. In a cluster tool, the attached module is the primary partner, requesting the handoff micro moves, and the transport module is the secondary partner achieving those micro moves by controlling the end effector on which the material is transported.

The transport module is responsible for managing constraints on the simultaneous opening of isolation valves as it relates to contamination of the transport module's environment by that of an attached module, as well as cross contamination between modules. The attached module ensures that its environment will not contaminate the transport module before synchronizing for handoff. The rules for re-establishing isolation at verification are determined by the transport module.

7.1.4.2 *Intertool Material Transfer* — The cassette module performs material exchange with the factory. The material generally consists of cassettes with single material or empty cassettes, but may be individual single material. The intertool material movement model, shown in Figure 9, is similar to the intratool material movement model. An intertool material transfer is a transfer in the factory which includes the cluster tool as one of the transfer partners.

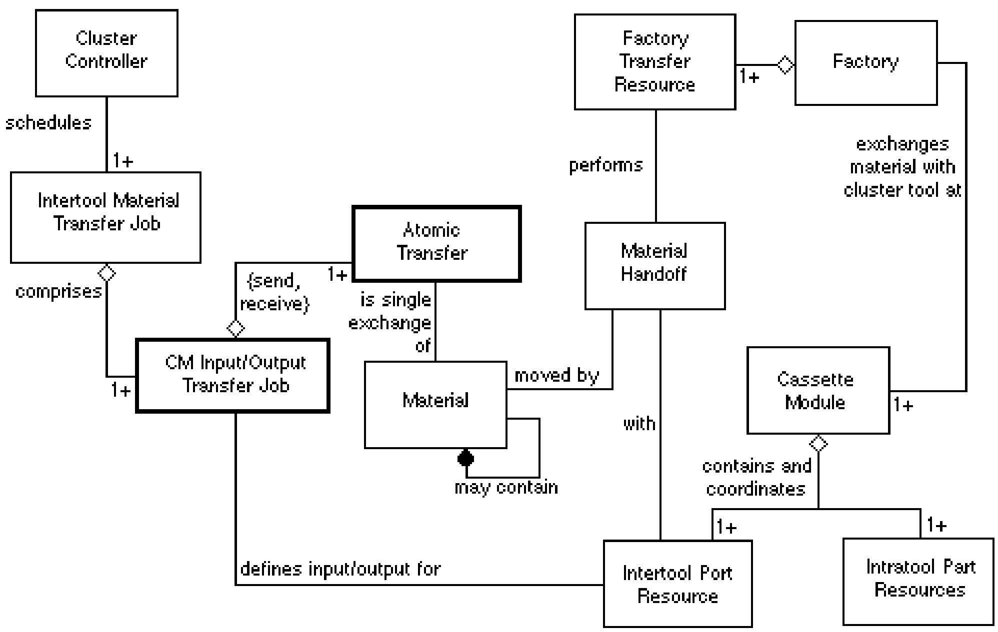

Figure 9
Intertool Material Movement Information Model

In the cluster tool, the cluster controller schedules an intertool material transfer job when material exchange with the factory is required. This job may be an element of a factory material transfer job in which the cluster tool is a partner.

The intertool material transfer job is achieved by a CM input/output transfer job assigned to the intertool port resource in the participating cassette module. It defines the material exchange with the factory for the cassette module. The CM input/output transfer job comprises an atomic transfer, which defines the roles in the material handoff.

In the cassette module, material transfer with the transport module is controlled by the intratool port resource. It is the responsibility of the cassette module to coordinate its intertool and intratool port resources.

The factory transfer resource may be an operator, SMIF, AGV, or other mechanism. Its definition, associated transfer jobs, and the handoff, are beyond the scope of this standard. Factory material movement may be achieved automatically using applicable SEMI standards.

7.1.4.3 *Carrier Mapping* — The final element of material movement in a cluster tool is the mapping of single material in a carrier. Once a cassette is received by the cluster tool, it is necessary to communicate the presence and identifiers of the material it contains. Batch process modules also require these carrier mapping services in order to define loading of the process carrier.

In carrier mapping, the carrier may be a cassette used to hold single material loaded at the cassette module from the factory, or a process carrier used to hold multiple material for batch processing. For the purposes of carrier mapping, these are equivalent, and the relationships are shown in the material model, Figure 6.

A carrier has an ordered set of material slots, a specialization of material location, each of which can hold a single material. The material slot of a carrier is only of interest when the carrier is in the cluster tool, so it is viewed as a location of the module which contains the carrier. In addition to occupancy, a single material may be assigned to a material slot, indicating, for example, the particular slot to which a single material is to be moved when available. Information on material presence and assignment of the material identifier may be detected in the module or determined by the cluster controller or a supervisory controller.

7.1.5 *Exception Model* — In an automated control system where the operator interface is remote from the module controller, it is necessary to have interactive exception handling for error recovery. In addition to exception reporting, a module requires input from a decision authority to resolve recoverable abnormal situations. These include exception conditions which extend beyond the module domain and those for which the module has insufficient information, such as in hardware failure.

The decision authority in a cluster tool is the cluster controller. It may interact with an operator to determine the appropriate recovery action to perform.

Figure 10 shows the exception model. Module resources detect appropriate exception conditions, which may be set or cleared. An abnormal situation is indicated by the corresponding exception condition being in the set state. A significant change in exception condition information generates an exception report to notify the decision authority. Both detection of the abnormal situation and its resolution generate exception reports. Reporting of each exception condition may be enabled and disabled independently in order to mask nuisance exceptions.

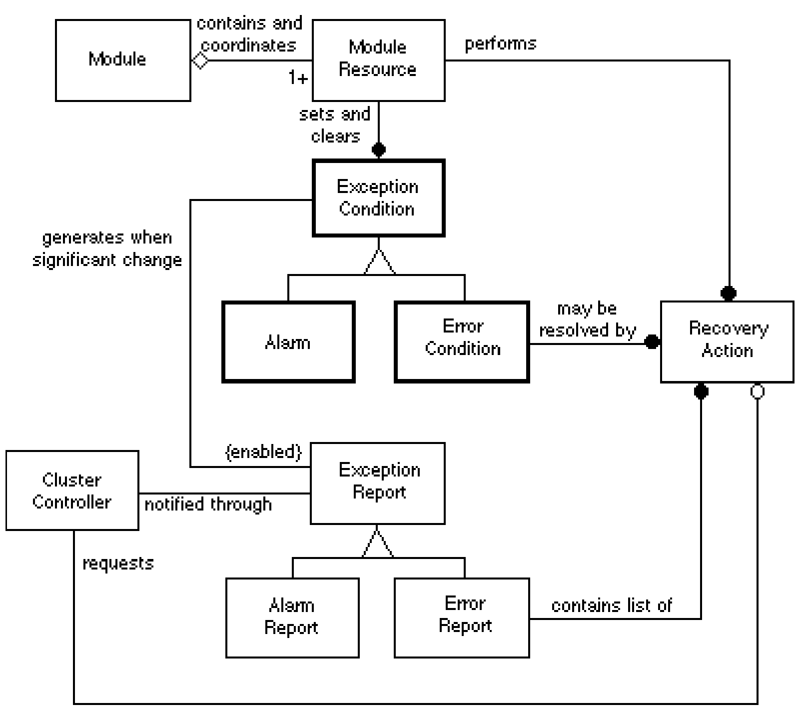

Figure 10
Exception Information Model

Error exception conditions may have associated recovery actions which can be performed by the module resource to attempt to recover from the abnormal situation. Alarm exception conditions cannot, by definition, be resolved using recovery actions.

A list of possible recovery actions is included in a posted error report. The decision authority can request one of the offered recovery actions to resolve the error condition. The selected recovery action is performed by the appropriate module resource and may result in clearing the error condition.

This model is used to establish the Exception Management definition.

7.1.6 *Recipe Management Model* — Recipe management in a module varies with the requirements of the application. Simple modules do not provide local recipe editing and don't require management of multiple logical domains (namespaces) and local recipe version control.

Figure 11 shows the full recipe management model for a sophisticated module.

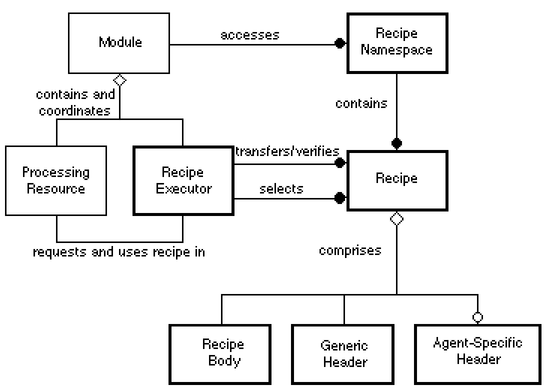

Figure 11
Recipe Management Information Model

Process recipes specify the actual parameters of the processing to be achieved. The module processing resource identifies, through the process job, the required recipe(s) to be loaded by the recipe executor in order to process a particular material.

The recipe executor accesses and selects recipes for execution. It uploads and downloads recipes from the cluster controller and is capable of verifying that a recipe is syntactically correct. The recipe executor also provides for a service-user to select a recipe to be loaded into the recipe execution area. The recipe is made up of a recipe body and may have headers if the module supports recipe namespace management.

The module accesses recipe namespaces where requested by service-users. A module which does not provide local editing and linking of recipes does not need recipe namespace management. Recipe namespace management requires management of recipe generic and agent (module) specific headers. For example, a process module could manage a recipe namespace containing its process and service recipes.

This model is used to establish the Recipe Management services requirements for cluster tool modules.

7.1.7 *Event Reporting Model*

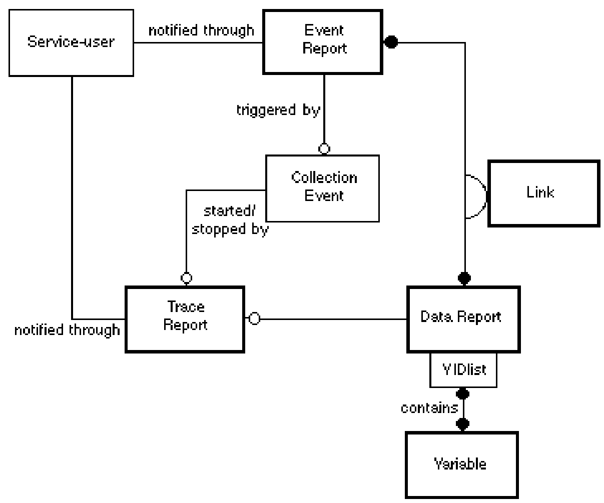

Figure 12
Event Reporting Information Model

Event reporting provides a dynamic and flexible means by which a service-user can receive notification of events and data relating to module resources.

The services-user can define and enable two types of reporting, event reporting and trace reporting. Both may convey data, the values of identified variables at the data collection time. The variable identifiers required to be reported are specified in the data report definition.

In event reporting, data reports are linked to event report definitions associated with each collection event type. On occurrence of the collection event, an event report message is generated according to the event report definition and the linked data report definitions. Reporting may be enabled and disabled for each collection event type. Data reports and links may be predefined or specified dynamically by the service user.

Trace reporting is time-based data reporting. Trace reporting is specified by the service-user dynamically as required. Collection events may initiate and terminate the tracing in order to link reporting to significant conditions, such as processing. The trace data is collected at a frequency specified by the service-user. Trace reports are generated according to the trace report definition and the associated data report definition.

Through associating the event report and trace report definition with the service-user, the model provides for the association of multiple service-users to a single service-provider. This allows for event reporting between modules where needed as well as the ability for direct connection of a data acquisition entity independent of the cluster controller.

7.2 *Cluster Tool Module Message Flow* — The appropriate objects in the information models in the previous section are grouped in the cluster tool module types. The communications with the essential objects are shown in the message flow diagrams in this section.

The diagrams show message flow between entities within an agent (in this case a module) and those outside the agent. Entities are rectangular boxes, and the agent is a rounded box. As emphasis is on the module and its services, only one agent is shown on each diagram. Outside entities in the cluster tool module communications domain appear within an agent on another diagram. The messaging is shown by arrows in each direction, with a brief label indicating the services requested or provided.

The communications are shown for the primary control of the process module (Figure 13), cassette module (Figure 14), and transport module (Figure 15). Note that the transport module transfer resource communicates with multiple process and cassette module intratool port resources.

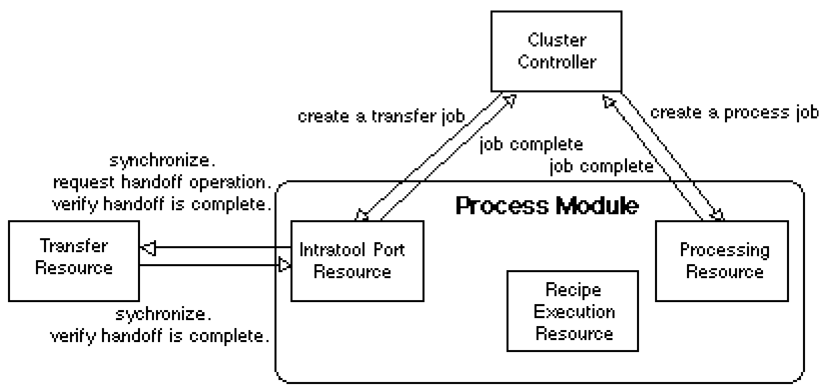

Figure 13
Process Module Primary Control Message Flow

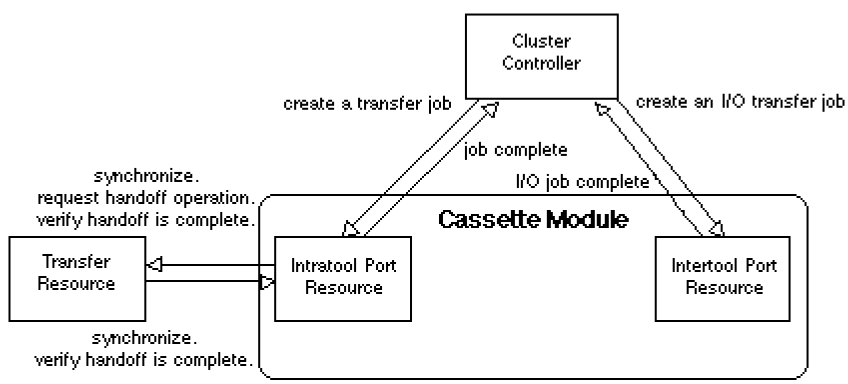

Figure 14
Cassette Module Primary Control Message Flow

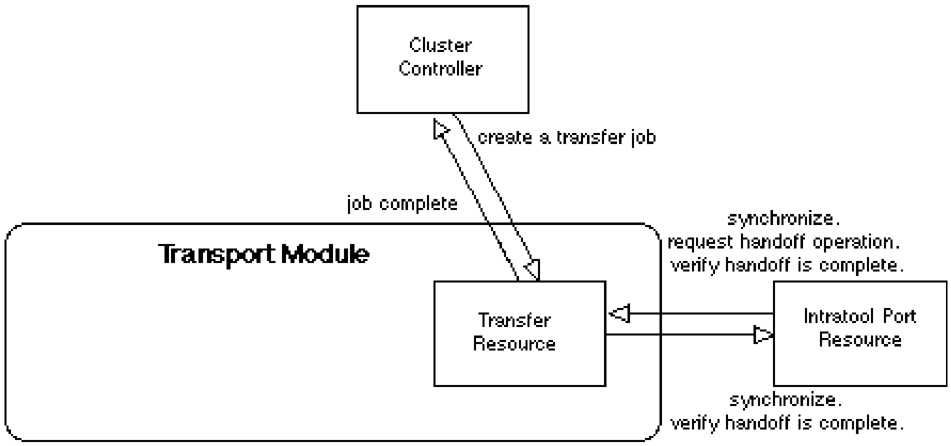

Figure 15
Transport Module Primary Control Message Flow

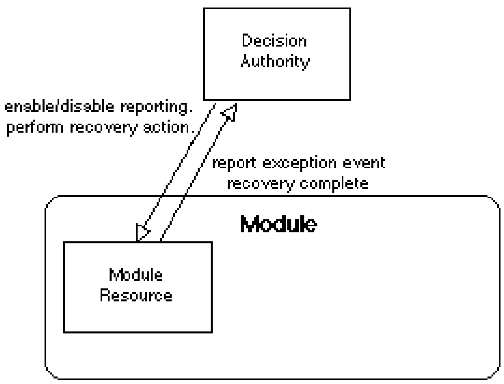

Figure 16
Module Exception Message Flow

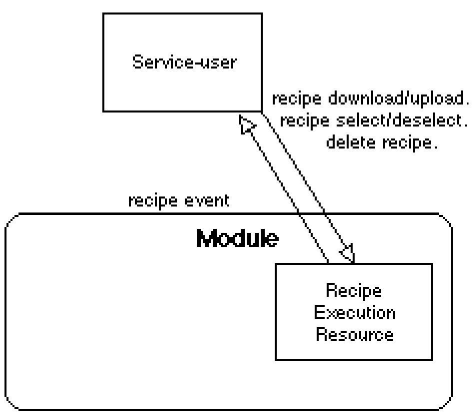

Figure 17
Module Recipe Message Flow

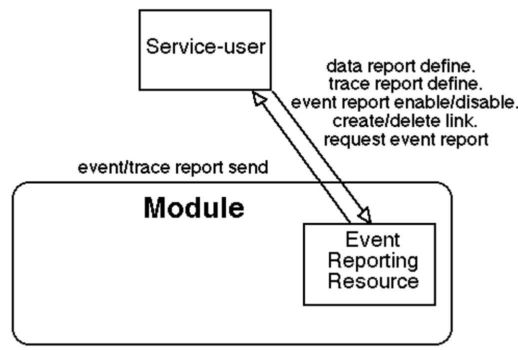

Figure 18
Module Event Reporting Message Flow

The communications for support functionality are shown for any module, as the services are common to all module types. The support functionality modeled includes exception handling (Figure 16), recipe management (Figure 17), and event reporting (Figure 18). A typical decision authority or service-user is the cluster controller.

7.3 *Cluster Tool Behavioral Model* — The process material is the fundamentally important object in a cluster tool and its lifecycle is the key component to establishing cohesiveness in the communication and controls standards.

The finite state model in Figure 19 presents the high-level behavior of a single material within the domain of the cluster tool. Bold transitions trace the normal lifecycle of the material and are described in the transition table, Table 1. Other transitions occur in exception situations and are not detailed here. The transition table actions indicate the primary control operations which are requested of the modules by the cluster controller.

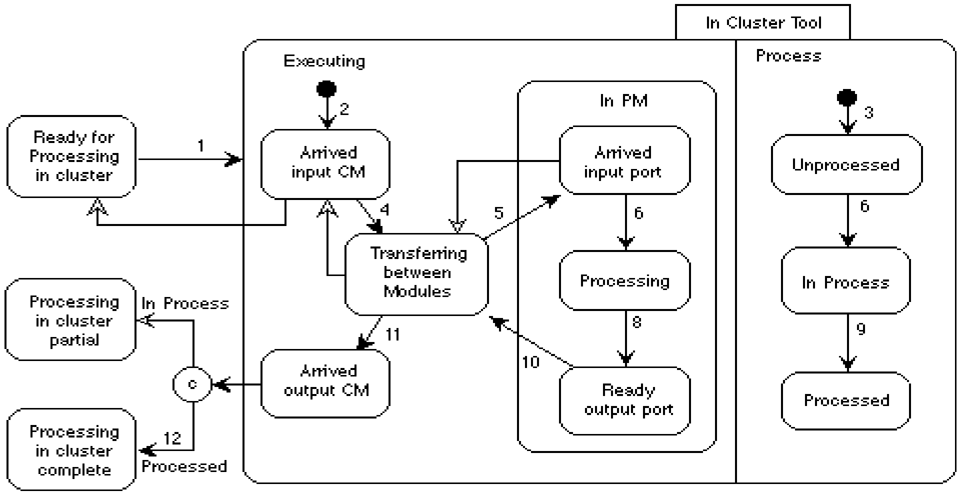

Figure 19
Cluster Tool Material State Model

When ready to be processed in the cluster tool, the material is presented and loaded at the input cassette module (intertool material transfer). It is usually contained with other single material in a cassette. The material process sub-state in the scope of this visit to the cluster tool is initially unprocessed. The material is then transferred to the first process module (intratool material transfer), ready for process. At this point, the material may be returned to the input cassette module and back to the factory, as the material has not been physically altered.

The material then begins processing in the process module according to the recipe for that process step (process job), and the process sub-state changes to in-process.

On successful completion of the process step, the material is then ready to be transferred to the next module (intratool material transfer). This may be another process module for the next process step or to the output cassette module if processing in the cluster tool is complete, in which case the process sub-state changes to processed. It is also possible that the next process step be performed in the same process module.

Table 1 Cluster Material State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*
1	Ready for Processing in cluster	Material being received at cluster CM.	In cluster tool	CM Input/Output Transfer Job. CM Carrier mapping.
2	Not in Cluster tool	Material being received at cluster CM.	Arrived input CM	
3	Not in Cluster tool	Material being received at cluster CM.	Unprocessed	
4	Arrived input CM	Initiate material transfer to PM.	Transferring between modules	Initiate PM Process Job. TM Transfer Job. Source AM Transfer Job (CM send). Dest. AM Transfer Job (PM receive).
5	Transferring between Modules	Material arrived in PM.	In PM/Arrived input port	
6	In PM/Arrived input port	Processing initiated on material.	In PM/Processing	PM Process the material.
7	Unprocessed	Processing initiated on material.	In Process	
8	In PM/Processing	PM processing complete.	In PM/Ready output port	
9	In Process	All required process steps in cluster completed.	Processed	
10	In PM/Ready output port	Initiate intratool material transfer.	Transferring between modules	Initiate next PM Process Job if material processing still required. TM Transfer Job. Source AM Transfer Job (send). Dest. AM Transfer Job (receive).

#	*Current State*	*Trigger*	*New State*	*Action(s)*
11	Transferring Between Modules	Arrived output CM.	Arrived output CM	CM Input/Output Transfer Job.
12	Arrived output CM	Transfer back to factory complete.	Processing in cluster complete	

The material is finally unloaded from the output cassette module to the factory (intertool material transfer). If all process steps in the cluster tool were completed and were successful, the processing in the cluster tool is complete; otherwise, processing in the cluster tool was only partially accomplished.

Detailed behavioral models are documented in the individual Cluster-Specific Services and in the standards which they reference. The Typical Operating Scenario in the application notes illustrates the behavioral characteristics of cluster tool control by showing the detailed messaging among modules and supervisory controller through the lifecycle of material as it enters the cluster, is processed, and then leaves the cluster.

7.4 *Cluster Tool Control Topology* — The natural decomposition of a cluster tool is into its modules. The module controller is the entity which performs internal control of a module and provides standard services. Module controllers provide certain application-specific functions (providers of services and user of services) and consist of hardware and software components that interact with the communications and control environment of the cluster tool.

Traditional definitions of controllers have implied certain PHYSICAL, hardware control topologies (such as distributed or centralized processors). These cluster tool standards specify the communications in terms of services-providers, enabling the module controllers to be based on LOGICAL control topologies.

The list of possible physical controllers which could be used to implement the logical services of the standards are listed below. It is emphasized, however, that the standard is not based on any constraint that each of these physical controllers be present in a cluster control system, but instead requires that the logical services (i.e., software functional components) be present somewhere in the cluster control system.

Possible Controllers:

- Cassette Module Controller
- Process Module Controller
- Transport Module Controller
- Cluster Controller

The logical control topology allows any combination of module controllers on a single control unit. Standard communication is not required among them. A common example is the grouping of transport module and cassette module control into a single material handler control unit as shown in Figure 1. For interface compliance, all communication between a logical module controller and remote controller or service-user must be compliant with the standard services.

8 Cluster Tool Module Services

The Cluster Tool control system elements, as represented in the object information, object communications, and behavioral models, require standard services in order to interface with one another.

The objects which are fully standardized (attributes, behavior, and operations) are only those essential to this communication, and the services are the interactions with these standard objects.

The services are grouped into the following functional areas:

- Object Services
- Processing Management
- Material Movement Management
- Exception Management
- Recipe Management
- Event Reporting
- Clock

The services of each of these groups are described in detail in this section. The services are defined in terms of services provided by independent SEMI standards, specifying their application and limitations with respect to the fundamental requirements of cluster tool module communications.

8.1 *Object Services* — All standardized service object attribute access across a cluster tool module communications interface is achieved using object services. Access may be to read attribute values of objects, to get a list of objects corresponding to certain criteria, and to set the values of writable attributes of objects. The message services provided to accomplish this are Get and Set.

The specific object types, relations, attributes, and access rules are defined in each specific services group.

The object services are defined in SEMI E39 (Object Services Standard: Concepts, Behavior, and Services). Cluster tool module communications require only the fundamental requirements of that standard except where stated in a specific services group below.

8.2 *Processing Management Services* — Processing management across a cluster tool module communications interface is achieved using the processing management services. These services provide the communications and behavior required of the processing resource by the material processing models through defining the process job object and its operations.

The processing management services follow SEMI E40 (Standard for Processing Management). Cluster tool module communications require full compliance with the information, behavior, and messaging services of the fundamental requirements of that document.

The process job creation is requested by the cluster controller using the PRJobCreate service. If the processing resource accepts the job, it performs the required processing to completion once the material arrives. The processing resource shall support the PRJobCommand Abort service, which ceases any processing and terminates the job. The processing resource reports process job milestones achieved to the cluster controller using the PRJobAlert service.

Process job object attributes required to be accessible through object services follow:

Attribute Name	*Description: Requirements*
ObjType	The object type: process job.
PRJobID	Identifier for the process job.
PRMtlType	MaterialType.
PRMtlNameList	Material identifier: single material only.
PRRecipeMethod	Recipe specification type: recipeID only.
RecID	Identifier of the recipe applied.
PRJobStateList	All concurrent substates of the process job.

Processing management messaging services required:

Message Name	*Description: Requirements*
PRJobCreate	Create process job: single material, recipe identifier only, auto-start.
PRJobCommand	Command on a process job: abort.
PRJobAlert	Notification: setup, processing, processing complete, complete.

Processing resource capabilities required, but not already specified above:

- Detect and report success or failure of a process job.
- Reject incomplete, invalid, and unsupported requests.

Processing resource capabilities permitted, but not to be required, by a service-user:

- Pre-conditioning and post-conditioning.
- Stop, Pause, and Resume of a process job.
- Manual process start.
- Process job queuing and queued job Cancel.
- Process tuning.
- Processing of material groups.
- Multiple concurrent process jobs.
- Multiple consecutive process jobs.
- Process job with no material.
- Notification of waiting for material and of process job state changes.

8.3 *Material Movement Services* — Each material movement in a cluster tool involves interaction among the cluster controller and all of the modules participating in the transfer. The communications interfaces and behavior resulting from the material movement models are defined for each association by the material movement services.

The material movement services are partitioned into intratool material movement services, intertool material movement services, and carrier mapping, as in the models.

The material movement services follow the Material Movement Management Standard [SEMI E32] and Object Services Standard: Concepts, Behavior, and Services [SEMI E39]. Cluster tool module communications require full compliance with the information, behavior, and messaging services of the fundamental requirements of those standards.

8.3.1 *Intratool Material Movement Services* — From the intratool material movement models, an intratool material transfer — the transfer of material from one attached module to another through a transport module — requires the following interactions:

1. The cluster controller decides that material is to be moved as the result of either arrival of material or the completion of some processing step on the material. It determines which material is to be

moved and the source and destination of that movement (cluster-application-specific). It requests all the modules involved to perform the appropriate TM or AM transfer job.

2. The source- and destination-attached modules inform the transport module that they are prepared to do their specific activities during the material transfer. The transport module informs the source- and destination-attached modules, each at the appropriate point in time, that it is synchronized for material handoff.

3. The detailed transactions required to handoff the material during the transfer are accomplished, first at the source and then at the destination.

These interactions may require a number of communications interfaces for intratool material transfer from the following:

- Cluster controller to transport module
  - transfer resource: TM transfer job source AM to destination AM
- Cluster controller to source-attached module
  - intratool port resource: AM transfer job send
- Cluster controller to destination-attached module
  - intratool port resource: AM transfer job receive
- Transport module to source-attached module
  - intratool port to transfer resource: handoff get
- Transport module to destination-attached module
  - intratool port to transfer resource: handoff put

The material movement services define the communications and behavior required of the attached module intratool port resource and the transport module transfer resource. They define the TM transfer job, TM atomic transfer, AM transfer job, and AM atomic transfer objects and their operations, as well as the handoff operations between the transfer resource and the intratool port resource.

Each interface is described below.

Cluster Controller to Transport Module Interface — The TM transfer job creation is requested by the cluster controller using the TRJobCreate service. If the transfer resource accepts the job, it performs the transfer of the material to completion, coordinating with the attached modules. The TM transfer job comprises two atomic transfers for the material, one to get (receive) it from the source-attached module and another to put (send) it to the destination-attached module.

The transfer resource shall support the TRJobCommand Abort service, which ceases any transfer activity and terminates the job. The transfer resource reports transfer job milestones achieved to the cluster controller using the TRJobAlert service.

The transfer resource coordinates material handoff with each attached module through the transport module/attached module interface, described below.

TM transfer job object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: transfer job.
TRJobID	Identifier for the transfer job.
(Ordered list of) TRAtomicID	Ordered list of identifiers for the atomic transfers in the transfer job: two atomic transfers for the material.
(List of)TRJobState	All concurrent substates of the transfer job.

TM atomic transfer object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: atomic transfer.
TRAtomicID	Identifier for the atomic transfer.
TRLink	Identifier to coordinate handoff.
TRObjType	Material Type.
TRObjName	Material identifier.
TRRole	Role in transfer control: secondary.
TRPartner	Identifies partner-attached module.
TRDirection	Handoff direction: receive from source AM, send to destination AM.
TRType	Active/passive in transfer: active.
(List of)TRAtomic-State	All concurrent substates of the atomic transfer.

Material movement messaging services required:

Message Name	*Description: Requirements*
TRJobCreate	Create transfer job: single material, source to destination AM, auto-start.
TRJobCommand	Command on transfer job: abort.
TRJobAlert	Notification: started, complete.

Transfer resource capabilities required, but not already specified above:

- Detect and report success or failure of a transfer job.

- Reject incomplete, invalid, and unsupported requests.

Transfer resource capabilities permitted, but not to be required, by a service-user:

- Stop, Pause, and Resume of a transfer job.
- Manual atomic transfer start.
- Transfer job queuing and queued job Cancel.
- Transferring of material groups.
- Multiple concurrent transfer jobs.
- Notification of transfer events.

Cluster Controller to Attached Module Interface — The AM transfer job creation is requested by the cluster controller using the TRJobCreate service. If the intratool port resource accepts the job, it coordinates with and directs the transport module to achieve the material handoff. The AM transfer job comprises an atomic transfer for material which is to receive it from, or send it to, the transport module.

The intratool port resource shall support the TRJobCommand Abort service, which ceases any transfer activity and terminates the job. The intratool port resource reports transfer job milestones achieved to the cluster controller using the TRJobAlert service.

The intratool port resource coordinates material handoff with the transport module through the transport module to attached module interface, described below.

AM transfer job object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: transfer job.
TRJobID	Identifier for the transfer job.
(Ordered list of) TRAtomicID	Ordered list of identifiers for the atomic transfers in the transfer job: one atomic transfer for each material.
(List of)TRJobState	All concurrent substates of the transfer job.

AM atomic transfer object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: atomic transfer.
TRAtomicID	Identifier for the atomic transfer.
TRLink	Identifier to coordinate handoff.
TRPort	AMPort through which transfer occurs.
TRObjType	Material type.
TRObjName	Material identifier.
TRRole	Role in transfer control: primary.
TRPartner	Identifies partner transport module.
TRDirection	Handoff direction: receive or send.
TRType	Active/passive in transfer.
(List of)TRAtomicState	All concurrent substates of the atomic transfer.

Note that TRLocation is not required to be supported as it is the responsibility of the attached module to determine the appropriate location to be used based on the material identifier.

Material movement messaging services required:

Message Name	*Description: Requirements*
TRJobCreate	Create transfer job: single material, send or receive, auto-start.
TRJobCommand	Command on transfer job: abort.
TRJobAlert	Notification: started, complete.

Transfer resource capabilities required, but not already specified above:

- Detect and report success or failure of a transfer job.
- Reject incomplete, invalid, and unsupported requests.

Transfer resource capabilities permitted, but not to be required, by a service-user:

- Stop, Pause, and Resume of a transfer job.
- Manual atomic transfer start.
- Transfer job queuing and queued job Cancel.
- Transferring of material groups.
- Multiple concurrent transfer jobs.
- Notification of transfer events.

Transport Module to Attached Module Interface — The control interface for the handoff of material between the end effector of a transport module and any attached module supports a sequence of three phases:

1. a synchronization phase that establishes that both the attached module intratool port resource and the transport module transfer resource are ready to handoff the material.
2. a physical handoff phase controlled by the intratool port resource.

3. a verification phase to determine that actual handoff took place. This action completes the handoff.

The transport module is responsible for managing constraints on the simultaneous opening of isolation valves as it relates to contamination of the transport module's environment by that of an attached module, as well as cross-contamination between modules. The attached module ensures that its environment will not contaminate the transport module before synchronizing. The rules for re-establishing isolation at verification are determined by the transport module.

The synchronization between the transfer resource and the intratool port resource is achieved by each, indicating readiness to transfer the material, using the HOReady service. Once both partners have received the HOReady, the intratool port resource directs the physical handoff. The intratool port resource commands the transfer resource using the defined HOCommand services. Once the physical handoff is complete, the intratool port resource requests verification using the HOVerify service.

The transfer resource and intratool port resource shall support the HOCancelReady service which cancels a previously sent HOReady while still in the synchronization phase. The transfer resource shall support the HOHalt service, which ceases any transfer activity and terminates the handoff.

Material movement messaging services required:

Message Name	*Description: Requirements*
HOReady	Synchronize with partner.
HOCommand	Command to the transport resource to perform an activity in the transfer envelope. Detailed below.
HOVerify	Verification of handoff completion with transfer resource.
HOCancelReady	Rescinds previous HOReady message.
HOHalt	Command to the partner to stop all action.

HOCommands to be supported by the transfer resource:

Command	*Description: Requirements*
Pick	Commands the transfer resource to take all actions necessary to remove the material from the intratool port.
Place	Commands the transfer resource to take all actions necessary to place the material in the intratool port.
Extend	Commands the transfer resource to reach into the intratool port to a predefined position at which the material can be accepted or released.
Retract	Commands the transfer resource to withdraw from the intratool port.

Where the robotic hardware does not provide for vertical motion, Pick and Place are not required to be supported.

Transfer partner capabilities required, but not already specified above:

- Detect and report success or failure of handoff commands.
- Detect and report success or failure of the handoff, through the verification.
- Reject incomplete, invalid, and unsupported requests.

Transfer resource capabilities permitted, but not to be required, by either partner:

- Multiple concurrent handoffs.
- Additional handoff commands.

8.3.2 *Intertool Material Movement Services* — Factory-to-cluster tool carrier or single material input/output management across a cluster tool module communications interface is achieved using the intertool material movement services. These services provide the communications and behavior required of the intertool port resource by the intertool material movement models through defining the CM input/output transfer job object and its operations.

This standard specifies only the required communication between the cluster controller and the cassette module and does not assume automated material movement in the factory. The CM input/output transfer job is compliant with SEMI E32 (Material Movement Management) and may be extended to support automated material movement in the factory.

The CM input/output transfer job creation is requested by the cluster controller using the TRJobCreate service. If the intertool port resource accepts the job, it coordinates with the operator or some entity to achieve the material handoff. The CM input/output transfer job comprises an atomic transfer for a cassette or single material which is to receive it from, or send it to, the factory.

The intertool port resource shall support the TRJobCommand Abort service, which ceases any transfer activity and terminates the job. The intertool port resource reports transfer job milestones achieved to the cluster controller using the TRJobAlert service.

CM input/output transfer job object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: transfer job.
TRJobID	Identifier for the transfer job.
(Ordered list of) TRAtomicID	Ordered list of identifiers for the atomic transfers in the transfer job: one atomic transfer for each material.
(List of)TRJobState	All concurrent substates of the transfer job.

Atomic transfer object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: atomic transfer.
TRAtomicID	Identifier for the atomic transfer.
TRLink	Identifier to coordinate handoff: none.
TRPort	CMPort through which transfer occurs.
TRObjType	Material Type: cassette or single material.
TRObjName	Material identifier.
TRRole	Role in transfer control: secondary.
TRPartner	Identifies partner if automated: none.
TRDirection	Handoff direction: receive or send.
TRType	Active/passive in transfer: passive.
(List of)TRAtomicState	All concurrent substates of the atomic transfer.

The requirements above indicate the settings if the transfer is to be manual, with the operator. The attributes TRLink, TRRole, TRPartner, and TRType are not significant in this situation. These become significant in automated material transfer.

Material movement messaging services required:

Message Name	*Description: Requirements*
TRJobCreate	Create transfer job: single material send or receive, auto-start.
TRJobCommand	Command on transfer job: abort.
TRJobAlert	Notification: started, complete.

Intertool port resource capabilities required, but not already specified above:

- Detect and report success or failure of a transfer job.
- Reject incomplete, invalid, and unsupported requests.

Intertool port resource capabilities permitted, but not to be required, by a service-user:

- Automated transfer of material within factory.
- Stop, Pause, and Resume of a transfer job.
- Manual atomic transfer start.
- Transfer job queuing and queued job Cancel.
- Transferring of material groups.
- Multiple concurrent transfer jobs.
- Notification of transfer events.

8.3.3 *Carrier Mapping Services* — Mapping of material in carriers across a cluster tool module communications interface is achieved using the carrier mapping services. These services provide the communications required of the appropriate module resources by the material models through defining the material slot object.

The carrier-mapping services are fully specified in terms of the material slot attributes accessed through the get and set services of SEMI E39 (Object Services Standard: Concepts, Behavior, and Services). Cluster tool module communications require full compliance with the information, behavior, and messaging services of the fundamental requirements of that standard.

The mapping information is only of interest to the cluster tool for a carrier contained in the module resource. The material slot objects are, therefore, associated with, and managed by, the module resource which uniquely identifies all of its material slots. The carrier-mapping services provide for communication of material slot information in both directions between the cluster controller and the module resource. The information communicated is material presence and material identification. Whether the material presence is detected by the module resource or determined by the cluster controller is application-specific. This is also the case for material identification.

A material slot may be assigned the identifier of material which is not yet occupying the material slot. This provides for determination by the cluster controller of which material slot the material is to be moved into when it arrives at the module.

Material slot object attributes required to be accessible through object services are detailed in Table 2.

Table 2 Material Slot Attributes

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	The object type.	Y	RO	Text: "MATERIALSLOT"
ObjID	Module unique identifier for the material slot.	Y	RO	Text: Unique with respect to the module.
MtlName	Identifier of the material occupying or assigned to the slot.	Y	RW	Text
OccState	Current state of the material slot.	Y	RW	Text: SlotUnknown SlotEmpty SlotOccupied SlotActive SlotDisabled

The material slot occupancy attribute indicates the presence of material as follows:

- SlotUnknown — the carrier is present and slot occupancy is not known, such as from when a carrier is loaded until the material is detected or the state is set by the cluster controller.
- SlotEmpty — no material in the slot.
- SlotOccupied — material is present in the slot.
- SlotActive — material is being removed from, or is arriving at, the slot.
- SlotDisabled — material slot unusable, such as when the carrier is not present.

Module resource capabilities required, but not already specified above:

- Reject incomplete, invalid, and unsupported requests.

Module resource capabilities permitted, but not to be required, by the cluster controller:

- Detection of the presence of material in a material slot.
- Detection of the identifier of material in a material slot.

Table 3 lock Attributes

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	The object type.	Y	RO	Text: "CLOCK"
ObjID	Module unique identifier for the clock.	Y	RO	Text: Unique with respect to the module. Services timestamp clock is "SERVICESCLOCK"
DateTime	Current time.	Y	RW	Text: yyyymmddhhmmsscc

8.4 *Exception Management Services* — Exception management across a cluster tool module communications interface is achieved using the exception management services. These services provide the communications and behavior required of the module resource by the exception models described in Section 7.1.5 through defining the exception condition object and its operations.

The exception management services follow SEMI Draft Document 2013C (SECS II Support for SEMI E41 (Exception Management Standard)). Cluster tool module communications require full compliance with the information, behavior, and messaging services of the fundamental requirements of that standard.

Exception conditions (alarms and error conditions) are created and managed by the module resource detecting the related abnormal situation. The module resource uses the EXPost service to report the occurrence of the abnormal situation or some significant change in exception condition information while the situation exists. EXCleared reports that the abnormal situation is no longer apparent or relevant. Reporting on an exception condition is enabled and disabled by setting its EXEnabled attribute.

The cluster controller may direct recovery of error conditions using the EXRecover service. The module resource performs the recovery action and reports its completion using the EXRecoveryComplete service. The module resource is only required to permit a single recovery action at a time on all set exception conditions, but may support multiple recovery actions. The module resource shall support the EXRecoveryAbort service, which ceases any activity and terminates the recovery action.

Exception condition object attributes required to be accessible through object services:

Attribute Name	*Description: Requirements*
ObjType	The object type: EXCEPTION.
EXID	Identifier for the exception condition.
EXType	Type of exception condition:alarm or error condition.
EXMessage	Text message describing the abnormal situation monitored.
EXEnabled	Indicates reporting to decision authority enabled/disabled.
EXRecActList	Possible recovery actions (none for alarms).
EXStateList	All concurrent substates of the exception.

Exception management messaging services required:

Message Name	*Description: Requirements*
EXPost	Notify/update on abnormal situation.
EXCleared	Notify resolution of abnormal situation.
EXRecover	Command to perform recovery action.
EXRecoveryComplete	Notify completion of recovery action.
EXRecoveryAbort	Command to abort a recovery action.

Reporting of all exception conditions is set to be enabled on establishment of an association, and those in the set state are posted.

Module resource capabilities required, but not already specified above:

- Reject incomplete, invalid, and unsupported requests.

Module resource capabilities permitted, but not to be required, by a service-user:

- Multiple concurrent recovery actions.
- Dynamic update of exception condition message and valid recovery actions.

8.5 *Recipe Management Services* — Recipe management across a cluster tool module communications interface is achieved using the recipe management services. These services provide the communications and behavior required of the module by the recipe models described in Section 7.1.6 of this document.

The recipe management services follow SEMI E42 (Recipe Management Standard). Cluster tool module communications require full compliance with the information, behavior, and messaging services of the fundamental requirements of a recipe executor, and optionally the recipe namespace management, as defined in that standard.

The module requiring recipe services contains a recipe executor that is capable of performing recipe download, verification, selection, deselection, and deletion as requested by the cluster controller. The module may also support recipe namespace services.

In certain configurations, the module may require recipe management services to be provided by the cluster controller, in order that it may request a selected recipe that is not stored locally. The module is the service-user in this case, and the cluster controller should support the necessary recipe namespace services.

The module coordinates the activities of the processing resource and the recipe executor to ensure the appropriate recipes are loaded into the execution area for material processing.

Recipe executor object attributes required to be accessible through object services:

Attribute Name	*Description*
ObjType	The object type: “RcpExec”
ObjID	Identifier for the recipe executor
DefaultNamespace	Namespace for all hardware-dependent recipes
RecipeSelectID	List of recipe identifiers for the currently selected recipe

Recipe management messaging services required:

Message Name	*Description: Requirements*
RMEDnldVer	Receive a recipe, optionally verify it, and put it into storage
RMEDelete	Delete a recipe from storage
RMESelect	Select recipes for execution
RMEDeselect	Deselect a recipe to prevent its execution
RMEComplete	Notify service-user of completion of an action

Modules that require more than one recipe class for an execution cycle shall support multi-part recipes. That is, the ability to select multiple recipes in a single process job request is not supported in processing management.

Recipe executor capabilities required and not already specified above:

- Reject incomplete, invalid, and unsupported requests

Recipe executor and module capabilities permitted by not to be required by a service-user:

- Support for variable parameters (attributes and select service),
- Support for multi-part recipes,
- Upload a recipe,
- Support recipe namespace services for local recipe management,
- Local editing.

8.6 *Event Reporting Services* — Event reporting services are to be supported in accordance with the models described in Section 7.1.7. Both event-based reporting and tracing are required. Support for user-defined reports is not required.

Event reporting for CTMC-compliant modules shall be based on services as described in SEMI E53.

8.6.1 The attributes defined in the following table shall be supported by CTMC compliant modules.

Attribute Name	*Description: Requirements*
ObjID	The identifier for Data Reports, Event Reports, and Trace Reports.
DataReportList	List of data report identifiers.
Enabled	A flag which controls generation of Event and Trace Reports.
SamplePeriod	Time delay between samples in a Trace report.
TotalSamples	Maximum number of samples to include in a Trace report.
GroupSize	Number of samples to include before sending a report to a service user.

8.6.2 Support for the following messages from SEMI E53 shall be provided.

Message Name	*Description: Requirements*
EventReportRequest	User can ask for a report to be generated and sent.
EventReportSend	Provider generates and sends report on an event.
DataReportCreate	Define attributes to be sampled for a report.
DataReportDelete	Delete report definitions
DataReportRequest	User requests sample and send of a report.
CollectionEventLink	Link data reports to a collection event.
CollectionEventUnlink	Unlink a data report
TraceReportCreate	Define a trace report
TraceReportDelete	Delete trace report definitions
TraceReportRequest	User requests a sample and send of a trace data.
TraceReportSend	Service provider sends a trace report to the user.
TraceReportReset	A trace reporting is set to its IDLE state.

8.6.3 Support for dynamic and user defined reports is optional. However, implementations which support these advanced capabilities, shall comply with the specifications of SEMI E53 and SEMI E39. SEMI E39 service messages shall use the optional object specifier arguments, such as EvtSrcSpec. Object services can then be used to interrogate objects for their reportable attributes.

8.7 *Clock Services* — The clock services provide for synchronization of the clocks on the modules with that of the cluster controller. These services provide the communications required of the appropriate module resources through defining the clock object.

The clock services are fully specified in terms of the clock attributes accessed through the get and set services of SEMI E39 (Object Services Standard: Concepts, Behavior, and Services). Cluster tool module communications require full compliance with the information, behavior, and messaging services of the fundamental requirements of that standard.

The clock object is uniquely identified for the module. Table 3 describes the attributes of the clock object. The identifier of the clock used for communications services is defined. The clock attribute Time is kept current and used to determine the value of the timestamp used in service messages. The module returns the current Time when it receives a get.

The clock time is synchronized by using the object set service on the Time attribute. On receipt of a set request, the module performs the operations necessary to set the clock to the value supplied, within its resolution, from which it shall continue immediately.

The DateTime attribute of the Clock object as used in Clock Services has a resolution in the range of seconds to centiseconds. If it is possible to specify the DateTime accurate to centiseconds, then centiseconds should be specified. If it is not possible to resolve time to less than a second, then centiseconds shall be reported as “00.” This requirement is for the reporting of the DateTime attribute of the Clock object in Clock Services only; other services may require greater resolution, in which case the Clock Services DateTime attribute resolution shall also be greater.

8.8 *Required Services* — Within a standards-compliant Cluster Tool, a number of services must be supported, at least to the fundamental requirements level. Due to the specialization of the modules in a Cluster Tool as detailed in the concepts section above, each module type only needs to support a subset of the service groups as shown in the message flow diagrams.

The services requirements for each module controller are described in this section. An example of use of services by a cluster controller is also given.

8.8.1 *Transport Module Controller*

- Material transfer functions for the end-to-end establishment of material movement within the cluster (supported through the Material Movement services). Material transfer is set up through a Transfer Job requested of the transport module by the service-user (e.g., cluster controller).
- Material Handoff between the process and cassette modules and the transport module (supported through the Material Movement services).
- Exception capabilities to post and manage exception conditions within the transport module (supported through the Exception Management services).
- Reporting of module variable data linked to events to the service-user (supported through the Event Reporting services).
- Access to standard objects of the specific services above as required by the service-user (supported through the Object services).

8.8.2 *Cassette Module Controller*

- Material I/O functions for the management of moving cassettes in and out of the cluster as well as for moving material between the cassette module and the transport module (supported through the Material Movement services). Material I/O is set up through a Transfer Job requested of the cassette module by the service-user (e.g., cluster controller).
- Material Handoff between the cassette module and the transport module (supported through the Material Movement services).
- Exception capabilities to post and manage exception conditions within the transport module (supported through the Exception Management services).
- Reporting of module variable data linked to events to the service-user (supported through the Event Reporting services).
- Access to standard objects of the specific services above as required by the service-user (supported through the Object services).

8.8.3 *Process Module Controller*

- Material processing functions (supported through the Processing Management services). Processing is specified through a Process job requested of the process module by the service-user (e.g., cluster controller).
- Recipe Management to verify and transfer recipes between the process module and the service-user (supported through the Processing Management services).
- Material I/O functions for the management of moving material in and out of the process module (supported through the Material Movement services). Material I/O is set up through a Transfer job requested of the process module by the service-user (e.g., cluster controller).
- Material Handoff between the process module and the transport module (supported through the Material Movement services).
- Exception capabilities to post and manage exception conditions within the transport module (supported through the Exception Management services).
- Reporting of module variable data linked to events to the service-user (supported through the Event Reporting services).
- Access to standard objects of the specific services above as required by the service-user (supported through the Object services).

8.8.4 *Example Cluster Controller*

- Scheduling and primary module control. Schedules Transfer and Process jobs in order to achieve the mission of the cluster tool, the processing of material.

- Recipe management for storage, archival, and editing of process module recipes (supported through the Recipe Management services).
- Human interfaces for the attached process, transport, and cassette modules (supported through the Event Reporting and Object Service definitions).
- Exception resolution services for making recovery decisions on exception conditions within the cluster (supported through the Exception Management services).

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was approved as a part of SEMI E38 by full letter ballot procedure.

A1-1 Factory Integration

The Cluster Tool Module Communications (CTMC) Standard and its associated services define the interactions of the cluster modules and the cluster controller. The standard does not address the communications between the cluster and an external factory "host." The SEMI standard which addresses the equipment to host communications interface is SEMI E30 (GEM).

The purpose of this application note is to discuss the requirements and possible pitfalls of the factory host-cluster tool interface. The bulk of the text will address the use of the current (at this writing) version of GEM (SEMI E30). However, some consideration will be given to the possibility of direct access to the components of the cluster through the cluster communications environment.

A1-1.1 *Direct Access to Cluster Modules* — The CTMC was designed to allow for interoperability among the entities in a cluster. It is possible to add a new entity to the cluster and share in this interoperability. This means that a software application that is "plugged" into the cluster communication environment will have access to all of the cluster modules via the standard message set. In this way, a factory host computer can gain direct access to cluster modules, by-passing the cluster controller.

While direct access to the cluster modules has some advantages, intrusions into the cluster tool communications environment can have a profound effect on the system. Below are listed a few of the positive benefits direct access can bring, followed by some of the negatives of such an approach.

Positives:

- If the cluster controller does not have to act as the intermediary in transactions between module and host, it may be simplified.
- Direct access of the modules can be a more efficient means of obtaining information.
- The factory host would have the flexibility to perform scenarios which the cluster controller suppliers had not imagined.

Negatives:

- A new, unplanned load on the cluster network may have a negative impact on system performance. If the delivered system's network is highly loaded and has been tuned for that load, added pressure on the system may have unexpected results.
- Direct access of the cluster modules may have a negative impact on system performance. The cluster modules are performing the physical work for the cluster. If they become busy answering inquiries, it may detract from their speed of processing. For example, a simple query, such as temperature of chamber, may actually result in messaging to the sensor itself along the same real-time communication path used to open and close valves, ect.
- System integrity of the cluster tool may be at risk if an external entity (e.g., Factory Host) takes even minor control actions. A changed equipment constant may put the cluster controller out of synch with its module. An external command to perform an action may directly conflict with the cluster's current actions.
- The CTMC defines no access security to prevent undesirable actions on the part of external entities.

If there is to be this sort of direct communication with cluster modules, the implementer should exercise extreme caution in the design of the add-on application. It is recommended that no active control be attempted and that no changes to the system configuration be attempted (e.g., do not set attributes). If data is to be accessed, it is best done by asynchronous event based reporting, rather than by polling. Above all, it is recommended that any plans to access the cluster through the cluster communication environment be discussed thoroughly with the system supplier.

A1-1.2 *GEM Control of a Cluster Tool* — This section discusses the interactions between a cluster tool and factory host. The basis for that communication is assumed to be SEMI E30, the Generic Equipment Model.

GEM was designed relative to the prevalent class of equipment at that time: proprietary, single supplier, and limited to a single process run at a time. The advent of multi-chamber processing equipment and later of multi-supplier cluster tools has changed the general requirements set for the factory-equipment interface. In the future, GEM may evolve to meet these new requirements. Regardless, the point of this application note is to explore how best to apply the existing factory host communication standards to cluster-based equipment.

Below, each GEM capability will be addressed separately, followed by a look at capabilities which GEM does not cover. The capabilities are taken in roughly the order given by SEMI E30 (GEM) table of contents.

Communications State Model/Establish Communications — The Communications State Model is related to the ability to communicate. It is independent of the functionality offered by the equipment. There is no conflict with the cluster tool supporting this GEM capability.

Control State Model — The control state model assumes a single operator interface at the equipment. A cluster tool is expected to supply such an interface connected to the cluster controller.

However, there is a potential disconnect with attached modules which supply user interfaces. Since CTMC does not provide anything similar to the control state model at this time, the cluster controller has no control over access to these separate user interfaces, nor even any knowledge of what might be happening. In this situation, the cluster controller cannot guarantee compliance to the control state model.

To assure GEM compliance, it is recommended that a module request and receive closure of all control-related service connections before allowing use of its local operator interface in a control mode. This assumes the use of the communication environment as defined in SEMI E38.1.

Equipment Processing States — GEM specifies that there be a processing state model. The model given in the document is only an example, which shows the approximate depth needed and suggests a form. The example applies to the classic single chamber, single-process machine. Thus, it may not be directly applicable to a cluster tool. The cluster tool is required to provide a processing state model, but the form should match the cluster tool's function. The Plasma Etch Specific Equipment Model (document available from SEMI) suggested one way to model a multi-chamber, multi-process job machine.

Data Collection — Data collection is a combination of several different capabilities. Each will be discussed in turn.

There is also a high-level issue with data collection. GEM assumes a flat address space. That is, it assumes that the smallest granularity of object is “equipment.” The equipment has attributes. Some attributes are read-only (Status Variables). Some have read/write access (Equipment Constants). There are a few read-only attributes which are valid only at certain times (DVVALs).

Cluster tools do not fit this model well. The CTMC was based on a model which includes a hierarchy of objects which contain (or control) other objects. The CTMC requirements are a subset of that model and include a cluster controller (which does not have to be a single entity), attached modules, transport module, and specific objects associated with the services. Thus, to request information about the processing of a wafer in a process module, the attributes of the process job must be accessed. The chain then includes Cluster Controller->Process Module->Process Job->Job Attribute. It is quite a challenge to present this attribute as SVID #532678. And yet, this is what must be done.

The cluster controller should provide a flat name space from which to access critical module data. Object services with scopeing capabilities may also be supported through the host interface, but if used, this would be an extension to the host's GEM interface. The data collection categories below give more detail on the challenge and possible solutions.

Event Notification — Many of the events of interest to the host actually occur at the attached modules (e.g., “Etch step complete for wafer x”). The cluster controller is responsible for assigning each of these events a unique CEID. There are two challenges: (1) to assure uniqueness of events from duplicate modules, and (2) to provide a scheme whereby the host can determine the source of the event. Embedding a module number within the CEID is one solution which has been used to address both challenges. For instance, the highest order byte of a four-byte integer might contain the module ID.

Dynamic Event Report Configuration — The host must be able to attach the information of interest to the event notifications. The cluster controller is responsible for providing access to the attributes of the cluster modules. It is also responsible for assuring that the data contained in the event reports is representative of the state of the cluster at the time the event occurred.

There are three sources of data for the event reports.

1. Cluster Controller: Data which is local to the cluster controller may be accessed directly.
2. Module (not source of collection event): This data must be polled unless a data trace for the attributes of interest is in progress.
3. Module (source of collection event): This data tends to be most closely related to the event and thus the most time-critical. While polling and data trace may be used in this case, it is better to use the

CTMC Event Reporting Services to attach the data of interest directly to the module collection event.

Variable Data Collection/Status Data Collection — Again, the cluster must take measures to present a flat address space. See various discussions above.

Limits Monitoring — Clearly, most variables which would be of interest for limits monitoring reside in the cluster modules. The CTMC does not provide specific services for configurable limits monitoring. A module may provide for some limits checking via "limits" attributes of objects which may be set via object services. Notification of excursions beyond limits would be via exceptions and/or collection events. If this method is not available, the cluster controller would have to institute a data trace on the attribute of interest and then itself perform the limits checking activity. The time period of the trace would be crucial to assuring that short-term excursions are not missed.

Trace Data Collection — Trace data collection maps well from GEM to CTMC. In fact, the CTMC services in this area are a superset of the GEM functionality.

On-Line Identification — At first glance, this seems to be an easy requirement to meet. However, the model number and software revision included in the message are ambiguous on a cluster with separate model numbers for each module (and the cluster controller itself) and separate software releases running on each. The purpose of these data items is to allow the host to determine when the equipment has been changed in such a way that it may no longer be compatible with the host software. At a minimum, the data items should indicate a change to the cluster controller software (e.g., a new revision of the software, or a significant reconfiguration such as the addition of a new module).

Alarm Management — GEM alarm management is a subset of the functionality of the CTMC exception services. Any exception message from a module can, where desired, be translated into a GEM-compliant alarm message. The set of CTMC exceptions is a superset of GEM alarms. GEM alarms are of a serious nature and expect human intervention to be required. The CTMC extends this set to include problems which the controller may be able to solve, and provides for modules to suggest appropriate recovery actions.

Those CTMC exceptions which fall into the GEM alarm category should be passed on via the GEM Alarm capability. Exceptions which are not GEM alarms should be reported only as events.

Remote Control — Cluster tools need to be able to handle multiple tasks simultaneously. Most need to handle multiple lot or batch jobs at once. GEM's support for (process) job control is minimal. The implicit assumption in GEM is that only one job at a time will occur on a machine. It provides for a "START" command, collection events when the job is actually started and when it finishes, and also job control commands (e.g., PAUSE, RESUME, ABORT, STOP). What GEM lacks is differentiation of one job from another (e.g., a job ID).

However, the GEM remote command message does provide for parameters. A cluster tool may be able to implement a scheme which is similar to that defined by the Process Management Services. For instance, a "job ID" parameter may be included in all job-related messages. Thus, the equipment would set a job ID in the "Start" or the "PP-Select" message (whichever first refers to the job), and would then refer to that ID in any subsequent job control commands. The job ID could also be available as a data value in collection event reports. While it might be preferable to have the equipment assign the job ID, this scheme may be workable.

Equipment Constants — Again, the flat address space issue applies. (See the Data Collection section above.)

Process Program Management — The CTMC uses Recipe Management Services (RMS) to manage recipes internal to the cluster. GEM's processing services is a different mechanism. The two can be made to interact, but the combination is not ideal. It is possible for the cluster to translate a "recipe" to a "process program" for communication with the host. However, if a recipe is created or modified at the host and then downloaded, the editor at the host must be compatible with RMS concepts, and care must be taken to maintain the integrity of the RMS system.

Material Movement — GEM requires only collection events when material is received or sent. A cluster can easily satisfy this requirement.

Equipment Terminal Services, Error Messages, and Spooling — Equipment Terminal Services, Error Messages, and Spooling are in the domain of the cluster controller. Cluster modules do not provide these functions, nor do they contribute to the cluster controller's delivery of the services.

Clock — A key purpose of clock is to allow the host to determine ordering of events from an equipment. The cluster controller should ensure that this need is met. The cluster should attempt to report consistent time relative to its modules. Also, when the factory host sets the time on the cluster, the cluster controller should resynchronize the time on its modules. There should be no compatibility problems in this area.

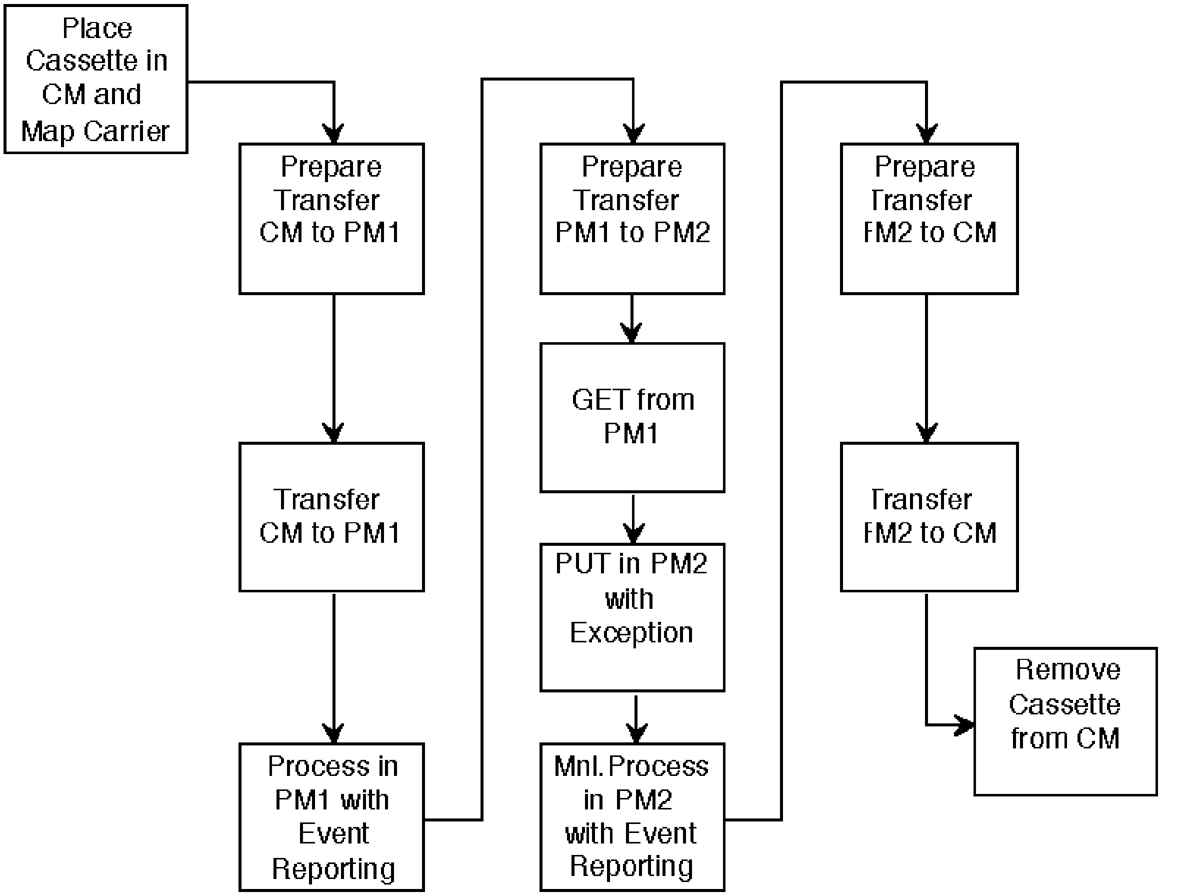

Figure 20
Typical Operating Scenario

A1-2 Typical Operating Scenario

The purpose of this section is to give an example of a typical operating scenario that will illustrate the various services being used to perform cluster tool control functionality. This operating scenario is **NOT** intended to be the only scenario to be implemented in a standards-compliant cluster. The intent is to provide guidance in navigating the various services standards. An exhaustive use of Object Services and Exception Management Services will not be done since these two areas tend to be very application-specific.

This scenario concentrates on the material processing, material movement aspects of the cluster-specific services.

The operating scenario shown in Figure 20 will be given in the form of a communication timing diagram with messages being sent between the various cluster tool components and will be indicated in the following manner:

ServiceGroup_ServiceName.Request or Response (Service Parameters)

Example: TRJobCreate.Req(...)

- TR is the service group that contains the service, the material movement services.
- JobCreate is the service being used to cause communication to take place between two cluster tool components. Specifically, this service is the material movement service that initiates the transfer of material between modules.
- Req indicates that the service is a Request.
- (...) indicates any other parameters that might be present with the service definition and will be service-dependent.

Definitions:

CC = Cluster Controller

CM = Cassette Module

TM = Transport Module

PM1 = Processing Module #1

PM2 = Processing Module #2

The general routing for the scenario is illustrated in the message sequence below:

1. A cassette of wafers arrives from the factory and is given to the cassette module.
2. A mapping of the wafers in the various slots of the cassette is determined for use inside the cluster.
3. A transfer job is initiated to move a wafer from the cassette to a process module (in this case PM1).
4. The cassette module is commanded to send the wafer to the transport module.
5. The PM1 is instructed to create the process job and to retrieve any pertinent recipe information in order to process the wafer.
6. The wafer is handed off between the cassette module and the transport module (Wafer GET operation).
7. The wafer is handed off between the transport module and PM1 (this is a Wafer PUT operation).
8. The wafer is processed in PM1.
9. A transfer job is initiated to the transport module to move a wafer from PM1 to PM2.
10. The PM1 is commanded to send the wafer to the transport module.
11. The PM2 is instructed to create the process job and to retrieve any pertinent recipe information in order to process the wafer.
12. The wafer is handed off between the PM1 and the transport module with a GET.
13. The wafer is handed off between the transport and PM2 with a PUT.
14. The wafer is processed in PM2 when manually started.
15. A transfer job is initiated to the transport module to move a wafer from PM2 back to the cassette module.
16. The PM2 is commanded to send the wafer to the transport module.
17. The cassette module is instructed to receive the wafer.
18. The wafer is handed off between PM2 and the transport module.
19. The wafer is handed off between the transport module and the cassette module.
20. The cassette module is instructed to send the cassette to the factory.

1. FACTORY TO CM CASSETTE HANDOFF

The cassette containing a single wafer in wafer slot 1 to be processed by the cluster tool is passed from the factory environment to the cluster tool.

At this point the user (human or host) will be prompted to place the cassette on the cassette module loading system. The cassette module is then informed to receive a cassette from the external environment.

```
CC                                      CM
>>-------------------------------------->>
TRJobCreate.Req(MID="Carrier1",Port=Port2
, Dir=Receive)
CC                                      CM
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob1,Status=OK)
```

The cassette module prepares to receive the cassette by such actions as loadlock venting, door opening, and then requesting handoff from the Factory.

```
CC                                      CM
<<--------------------------------------<<
TRJobStarted.Req(JobID=IOJob1, TimeStamp)
```

The actual cassette transfer takes place, the cassette module takes such actions as door closing and loadlock pumping down to internal transfer pressures, and then reports completion of the material transfer.

```
CC                                      CM
<<--------------------------------------<<
TRJobComplete.Req(JobID=IOJob1,TimeStamp,
Status=OK))
```

2. WAFER MAPPING

The wafers in each of the cassette wafer slots are assigned a unique wafer ID. In this case, the wafer is identified as “Wafer1.” If there were more than one wafer, this process would be repeated until all the wafers had been given their appropriate identification that is used later when specific wafers are requested for transfer and processing.

```
CC                                      CM
>>-------------------------------------->>
Set.Req("WAFERSLOT",SlotID=1,MID=
"Wafer1")
CC                                     CM
<<-------------------------------------<<
Set.Rsp("WAFERSLOT",SlotID=1,Status=OK)
```

3. CC TO TM TRANSFER JOB SETUP

The CC informs the TM that a wafer transfer is required from the CM to PM1.

```
CC                                     TM
>>------------------------------------->>
TRJobCreate.Req(MID="Wafer1",TRSourceAmID
="CM",TRDestinationAmID="PM1")
```

The transport module assigns an identifier for this particular transfer job. This is important in an actual cluster implementation since multiple transfer jobs may be queued and active at any given time. The transfer job is then started by the transport module.

```
CC                                      TM
<←-------------------------------------<<
TRJobCreate.Rsp(JobID=TMJob1,Status=OK)
CC                                      TM
<<--------------------------------------<<
TRJobStarted.Req(JobID=TMJob1,TimeStamp)
```

4. CC TO CM SEND WAFER

The CC informs the CM that a wafer is to be transferred to the TM.

```
CC                                      CM
>>-------------------------------------->>
TRJobCreate.Req(MID="Wafer1",PortID=
"Port1",Dir=Send)
CC                                      CM
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob2,Status=OK)
```

When the cassette module is ready, it directly communicates with the cluster controller and the transport module to indicate its readiness for wafer handoff.

```
CC                                      CM
<<--------------------------------------<<
TRJobStarted.Req(JobID=IOJob2, TimeStamp)
TM                                      CM
<<--------------------------------------<<
HOReady.Req(PortID="Port1",AmID="CM",
HODir=GET,MID="Wafer1")
```

5. CC TO PM1 PROCESSING JOB SETUP

The CC informs PM1 that a wafer will be delivered (which requires a TRJob to be created) and is to be processed (this requires that a process job be established). This involves creating the jobs and transferring the appropriate recipes to the process module as required. At some point in this process, the PM will inform the transport module that it is ready to receive the wafer with the issuing of the HOReady Request.

The CC informs PM1 that a wafer is to be transfered from the TM.

```
CC                                     PM1
>>-------------------------------------->>
TRJobCreate.Req(MID="Wafer1",Port="Port1"
, Dir=Receive)
CC                                     PM1
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob3,Status=OK)
```

When the process module is ready, it directly communicates with the cluster controller to indicate its readiness for wafer handoff.

```
CC                                      PM1
<<--------------------------------------<<
TRJobStarted.Req(JobID=IOJob3, TimeStamp)
```

The process job is created on the process module.

```
CC                                      PM1
>>-------------------------------------->>
PRJobCreate.Req(RecID="PP1",MID="Wafer1")
CC                                      PM1
<<--------------------------------------<<
PRJobCreate.Rsp(JobID=PM1Job1,Status=OK)
CC                                      PM1
<<--------------------------------------<<
PRJobSetup.Req(JobID=PM1Job1)
```

The process module requests that all sections (headers and the body) of the recipe be downloaded.

```
CC                                        PM1
<<---------------------------------------<<
RCRequest.Req(RecID="PP1",RCTransfer=all)
CC                                        PM1
>>--------------------------------------->>
RCRequest.Rsp(RecID="PP1",Status=OK)
CC                                        PM1
>>--------------------------------------->>
RCSend.Req(RecID="PP1",<Headers & Body>)
CC                                        PM1
<<---------------------------------------<<
RCSend.Rsp(RecID="PP1",Status=OK)
```

The process module informs the transport module that it is ready to receive the material.

```
TM                                        PM1
<<---------------------------------------<<
HOReady.Req(Port=Port1,AmID="PM1",HODir=P
UT,MID="Wafer1")
```

6. CM TO TM WAFER HANDOFF

The CM transfers the wafer to the TM through the handoff sequence, and the CM and TM will keep the cluster controller informed of its transfer progress.

The transport module informs the cassette module that it is proceeding with the "getting" of the wafer.

```
CM                                         TM
<<---------------------------------------<<
HOReady.Req(Port=Port1,AmID="CM",HODir=GE
T, MID="Wafer1")
```

The cassette module informs the transport module to use the PICK sequence to get the wafer.

```
CM                                         TM
>>--------------------------------------->>
HOPick.Req(Port=Port1,AmID="CM")
CM                                         TM
<<---------------------------------------<<
HOPick.Rsp(Port=Port1,AmID="CM",
Status=OK)
```

When the getting of the wafer has been successful, the cassette module informs the transport module with a verify sequence.

```
CM                                         TM
>>--------------------------------------->>
HOVerify.Req(Port=Port1,AmID="CM")
CM                                         TM
<<---------------------------------------<<
HOVerify.Rsp(Port=Port1,AmID="CM",
Status=OK)
```

The cassette module then informs the cluster controller of its current status.

```
CC                                         CM
<<---------------------------------------<<
TRJobComplete.Req(JobID=IOJob2,TimeStamp,
Status=OK)
```

7. TM TO PM1 WAFER HANDOFF

The TM now has possession of the wafer and is ready to proceed with the putting of the wafer into the process module. The TM and PM1 will inform the cluster controller of the progress of the transfer of material.

The TM informs the PM that it is proceeding with the putting of the wafer.

```
PM1                                        TM
<<---------------------------------------<<
HOReady.Req(Port=Port1,AmID="PM1",HODir=P
UT,MID="Wafer1")
```

The process module informs the TM to use the PLACE scenario as the put operation.

```
PM1                                        TM
>>--------------------------------------->>
HOPlace.Req(Port=Port1,AmID="PM1")
PM1                                        TM
<<---------------------------------------<<
HOPlace.Rsp(Port=Port1,AmID="PM1",
Status=OK)
```

When the putting of the wafer has been successful, the PM informs the transport module with a verify sequence.

```
PM1                                    TM
>>------------------------------------>>
HOVerify.Req(Port=Port1,AmID="PM1")
PM1                                    TM
<<------------------------------------<<
HOVerify.Rsp(Port=Port1,AmID="PM1",
Status=OK)
CC                                    PM1
<<------------------------------------<<
TRJobComplete.Req(JobID=IOJob3,
TimeStamp)
```

The TM then informs the cluster controller that the putting phase of the transfer is complete and then that the requested transfer job is complete.

```
CC                                     TM
<<------------------------------------<<
TRJobComplete.Req(JobID=TMJob1,
TimeStamp,Status=OK)
```

8. PM1 JOB PROCESSING

The process module informs the cluster controller, now that is has received the material and having previously entered the setup state, that it is ready to initiate processing on the wafer. When actual processing is initiated, the PM informs the cluster controller of its current status.

```
CC                                    PM1
<<------------------------------------<<
PRJobProcessing.Req(JobID=PM1Job1,TimeSta
mp)
```

A data collection is enabled to allow parameters to be sent from the PM to the cluster controller while the wafer processing is taking place. A previously defined event is enabled and the report structure is established.

```
CC                                    PM1
>>------------------------------------>>
Set.Req(EREvent,EventID=Event1,
Enabled=TRUE)
CC                                    PM1
<<------------------------------------<<
Set.Rsp(EREvent,EventID=Event1,Status=OK)
```

Two variables for time and temperature will be reported based on Event1 occurring.

```
CC                                    PM1
<<------------------------------------<<
ERReport.Req(EventID=Event1,ReportID=Rpt1
, ValueList={time,temp})
```

When wafer processing is complete on the PM, the cluster controller is informed of the current status.

```
CC                                    PM1
<<------------------------------------<<
PRJobProcessingComplete.Req(JobID=PM1Job1
, TimeStamp,Status=OK)
```

Data collection is then disabled.

```
CC                                    PM1
>>------------------------------------>>
Set.Req(EREvent,EventID=Event1,
Enabled=FALSE)
CC                                    PM1
<<------------------------------------<<
Set.Rsp(EREvent,EventID=Event1,Status=OK)
```

9. PM1 to PM2 TRANSFER JOB SETUP

The CC informs the TM that a wafer transfer is required from the PM1 to PM2.

```
CC                                     TM
>>------------------------------------>>
TRJobCreate.Req(MID="Wafer1",
TRSourceAmID="PM1",
TRDestinationAmID="PM2")
```

The transport module assigns an identifier for this particular transfer job. The transfer job is then started by the transport module.

```
CC                                     TM
<<------------------------------------<<
TRJobCreate.Rsp(JobID=TMJob2,Status= OK)
CC                                     TM
<<------------------------------------<<
TRJobStarted.Req(JobID=TMJob2, TimeStamp)
```

10. CC TO PM1 SEND WAFER

The CC informs PM1 that a wafer is to be transferred to the TM.

```
CC                                    PM1
>>------------------------------------>>
TRJobCreate.Req(MID="Wafer1",Port=
"Port1", Dir=Send)
CC                                    PM1
<<------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob4,Status=OK)
CC                                    PM1
<<------------------------------------<<
TRJobStarted.Rsp(JobID=IOJob4, TimeStamp)
```

When the process module is ready, it directly communicates with the transport module to indicate its readiness for wafer handoff.

```
TM                                    PM1
<<------------------------------------<<
HOReady.Req(PortID="Port1",AmID="CM",
HODir=GET,MID="Wafer1")
```

11. CC TO PM2 PROCESSING JOB SETUP

The CC informs PM2 that a wafer will be delivered (requires a TRJob) and is to be processed (requires that a process job be established). This involves creating the jobs and transferring the appropriate recipes to the process module as required. At some point in this process, the PM will inform the transport module that it is ready to receive the wafer with the isssuing of the HOReady Request.

```
CC                                    PM2
>>------------------------------------>>
TRJobCreate.Req(MID="Wafer1",Port="Port1"
, Dir=Receive)
CC                                    PM2
<<------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob5,Status=OK)
CC                                    PM2
<<------------------------------------<<
TRJobStarted.Req(JobID=IOJob5, TimeStamp)
CC                                    PM2
>>------------------------------------>>
PRJobCreate.Req(RecID="PP2",MID="Wafer1",
ManualStart)
CC                                    PM2
<<------------------------------------<<
PRJobCreate.Rsp(JobID=PM2Job1,Status=OK)
CC                                    PM2
<<------------------------------------<<
PRJobSetup.Req(JobID=PM2Job1)
```

The process module requests that all sections (headers and the body) of the recipe be downloaded.

```
CC                                    PM2
<<------------------------------------<<
RCRequest.Req(RecID="PP2",RCTransfer=all)
CC                                    PM2
>>------------------------------------>>
RCRequest.Rsp(RecID="PP2",LinkedID=0,{Bod
y: "TEMP 250 TIME 40"})
CC                                    PM2
>>------------------------------------>>
RCSend.Req(RecID="PP1",<Headers & Body>)
CC                                    PM2
<<------------------------------------<<
RCSend.Rsp(RecID="PP1",Status=OK)
```

The process module then informs the transport module to proceed with the putting of the wafer.

```
TM                                    PM2
<<-------------------------------------<<
HOReady.Req(Port=Port1,AmID="PM2",HODir=P
UT,MID="Wafer1")
```

12. PM1 TO TM WAFER HANDOFF

The PM1 transfers the wafer to the TM through the handoff sequence, and the TM will keep the cluster controller informed of its transfer progress. The transport module informs the process module that it is proceeding with the "getting" of the wafer.

```
PM                                     TM
<<-------------------------------------<<
HOReady.Req(Port=Port1,AmID="PM1",HODir=G
ET,MID="Wafer1")
```

The process module informs the transport module to use the PICK sequence to get the wafer.

```
PM1                                    TM
>>------------------------------------->>
HOPick.Req(Port=Port1,AmID="PM1")
PM1                                    TM
<<-------------------------------------<<
HOPick.Rsp (Port=Port1,AmID="PM1",
Status=OK)
```

When the getting of the wafer has been successful, the process module informs the transport module with a verify sequence.

```
PM1                                    TM
>>------------------------------------->>
HOVerify.Req(Port=Port1,AmID="PM1")
PM1                                    TM
<<-------------------------------------<<
HOVerify.Rsp(Port=Port1,AmID="PM1",
Status=OK)
```

Process module #1 then informs the cluster controller of its current status.

```
CC                                    PM1
<<-------------------------------------<<
TRJobComplete.Req(JobID=IOJob4,TimeStamp,
Status=OK)
```

The cluster controller is informed that the processing job performed in PM1 is complete.

```
CC                                    PM1
<<-------------------------------------<<
PRJobComplete.Req(JobID=PM1Job1,
TimeStamp,Status=OK)
```

13. TM TO PM2 WAFER HANDOFF

The TM informs the cluster controller that it is proceeding with the transfer of the wafer. The TM informs the PM that it is proceeding with the putting of the wafer.

```
PM2                                    TM
<<-------------------------------------<<
HOReady.Req(Port=Port1,AmID="PM2",HODir=P
UT,MID="Wafer1")
```

The process module informs the TM to use the EXTEND scenario as the put operation.

```
PM2                                    TM
>>------------------------------------->>
HOExtend.Req(Port=Port1,AmID="PM2")
PM2                                    TM
<<-------------------------------------<<
HOExtend.Rsp(Port=Port1,AmID="PM2",
Status=OK)
```

During this particular handoff, an exception is generated stating that the pins in the process module failed to come up and receive the wafer from the end effector. The cluster controller is given three recovery options to select from in attempting to resume operation in the presence of this exception.

```
CC                                    PM2
<<-------------------------------------<<
EXPost.Req(EXID=Error1, EXType=Error,
EXMessage="pins failed to raise",
EXRecoveryList=
{"Abort","Retry","Continue"}, TimeStamp)
```

The cluster controller selects the “continue” option.

```
CC                                     PM2
>>-------------------------------------->>
EXRecover.Req(EXID=Error1,
EXRecoverySelected= "Continue")
CC                                     PM2
<<--------------------------------------<<
EXRecover.Rsp(EXID=Error1, Status=OK)
CC                                     PM2
<<--------------------------------------<<
EXRecoveryComplete.Rsp(EXID=Error1,
Status=OK)
```

This action is successful, and the alarm (exception type) clears.

```
CC                                     PM2
<<--------------------------------------<<
EXCleared.Rsp(EXID=Error1,EXType=Error,
TimeStamp)
```

When the putting of the wafer is now successful, the PM commands the transport module to Retract.

```
PM2                                     TM
>>-------------------------------------->>
HORetract.Req(Port=Port1,AmID="PM2")
PM2                                     TM
<<--------------------------------------<<
HORetract.Rsp(Port=Port1,AmID="PM2",
Status=OK)
```

Upon successful completion of the handoff, a verify sequence is used to complete the transaction.

```
PM2                                     TM
>>-------------------------------------->>
HOVerify.Req(Port=Port1,AmID="PM2")
PM2                                     TM
<<--------------------------------------<<
HOVerify.Rsp(Port=Port1,AmID="PM2",
Status=OK)
CC                                     PM2
<<--------------------------------------<<
TRJobComplete.Req(JobID=IOJob5,TimeStamp,
Status=OK)
```

The TM then informs the cluster controller that the putting of material is complete and that the requested transfer job is complete.

```
CC                                      TM
<<--------------------------------------<<
TRJobComplete.Req(JobID=TMJob2,
TimeStamp,Status=OK)
```

The process module informs the cluster controller that now that is has received the material, it is ready to initiate processing on the wafer upon Start command.

```
CC                                     PM2
<<--------------------------------------<<
PRJobWaitingStart.Req(JobID=PM2Job1)
```

14. PM2 JOB PROCESSING

The cluster controller commands the PM to start processing the wafer.

```
CC                                     PM1
>>-------------------------------------->>
PRJobStart.Req(JobID=PM2Job1)
CC                                     PM1
<<--------------------------------------<<
PRJobStart.Rsp(JobID=PM2Job1,Status=OK)
```

When actual processing is initiated, the PM informs the cluster controller of its current status.

```
CC                                     PM2
<<--------------------------------------<<
PRJobProcessing.Req(JobID=PM2Job1,
TimeStamp)
```

A data collection is enabled to allow parameters to be sent from the PM to the cluster controller while the wafer processing is taking place. A previously defined event is enabled and the report structure is established.

```
CC                                     PM2
>>-------------------------------------->>
Set.Req(EREvent,EventID=Event1,
Enabled=TRUE)
CC                                     PM2
<<--------------------------------------<<
Set.Rsp(EREvent,EventID=Event1,Status=OK)
```

Two variables for time and temperature will be reported based on Event1 occurring.

```
CC                                     PM2
<<--------------------------------------<<
ERReport.Req(EventID=Event1,ReportID=Rpt1
, ValueList={time,temp})
```

When wafer processing is complete on the PM, the cluster controller is informed of the current status.

```
CC                                     PM2
<<--------------------------------------<<
PRJobProcessingComplete.Req(JobID=PM2Job1
, TimeStamp,Status=OK)
```

Data collection is then disabled.

```
CC                                      PM2
>>-------------------------------------->>
Set.Req(EREvent,EventID=Event1,
Enabled=FALSE)
CC                                      PM2
<<--------------------------------------<<
Set.Rsp(EREvent,EventID=Event1,Status=OK)
```

15. PM2 to CM TRANSFER JOB SETUP

The CC informs the TM that a wafer transfer is required from the PM2 to CM.

```
CC                                       TM
>>-------------------------------------->>
TRJobCreate.Req(MID="Wafer1",
TRSourceAmID="PM2",
TRDestinationAmID="CM")
```

The transport module assigns an identifier for this particular transfer job. The transfer job is then started by the transport module.

```
CC                                       TM
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=TMJob3,Status= OK)
CC                                       TM
<<--------------------------------------<<
TRJobStarted.Req(JobID=TMJob3, TimeStamp)
```

16. CC TO PM2 SEND WAFER

The CC informs the PM2 that a wafer is to be transferred to the TM.

```
CC                                      PM2
>>-------------------------------------->>
TRJobCreate.Req(MID="Wafer1",Port=
"Port1", Dir=Send))
CC                                      PM2
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob6,Status=OK)
CC                                      PM2
<<--------------------------------------<<
TRJobStarted.Req(JobID=IOJob6, TimeStamp)
```

When the process module is ready, it directly communicates with the transport module to indicate its readiness for wafer handoff.

```
TM                                      PM2
<<--------------------------------------<<
HOReady.Req(PortID="Port1",AmID="PM2",
HODir=GET,MID="Wafer1")
```

17. CC TO CM RECEIVE WAFER

The CC informs the CM that a wafer is to be transfered from the TM.

```
CC                                       CM
>>-------------------------------------->>
TRJobCreate.Req(MID="Wafer1",Port=
"Port1", Dir=Receive)
CC                                      PM2
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob7,Status=OK)
CC                                      PM2
<<--------------------------------------<<
TRJobStarted.Req(JobID=IOJob7, TimeStamp)
```

When the cassette module is ready, it directly communicates with the transport module to indicate its readiness for wafer handoff.

```
TM                                       CM
<<--------------------------------------<<
HOReady.Req(PortID="Port1",AmID="CM",
HODir=PUT,MID="Wafer1")
```

18. PM2 TO TM WAFER HANDOFF

The PM2 transfers the wafer to the TM through the handoff sequence, and the TM will keep the cluster controller informed of its transfer progress. The transport module informs the process module that it is proceeding with the “getting” of the wafer.

```
PM2                                      TM
<<--------------------------------------<<
HOReady.Req(Port=Port1,AmID="PM2",HODir=G
ET,MID="Wafer1")
```

The process module informs the TM to use the EXTEND scenario as the put operation.

```
PM2                                      TM
>>-------------------------------------->>
HOExtend.Req(Port=Port1,AmID="PM2")
PM2                                      TM
<<--------------------------------------<<
HOExtend.Rsp(Port=Port1,AmID="PM2",
Status=OK)
```

When the putting of the wafer is now successful, the PM commands the transport module to Retract.

```
PM2                                      TM
>>-------------------------------------->>
HORetract.Req(Port=Port1,AmID="PM2")
PM2                                      TM
<<--------------------------------------<<
HORetract.Rsp(Port=Port1,AmID="PM2",
Status=OK)
```

Upon successful completion of the handoff, a verify sequence is used to complete the transaction.

```
PM2                                      TM
>>-------------------------------------->>
HOVerify.Req(Port=Port1,AmID="PM2")
PM2                                      TM
<<--------------------------------------<<
HOVerify.Rsp(Port=Port1,AmID="PM2",
Status=OK)
CC                                      PM2
<<--------------------------------------<<
TRJobComplete.Req(JobID=IOJob6,
TimeStamp)
```

The cluster controller is informed that the processing job in PM2 is complete.

```
CC                                      PM2
<<--------------------------------------<<
PRJobComplete.Req(JobID=PM2Job1,
TimeStamp,Status=OK)
```

19. TM TO CM WAFER HANDOFF

The TM now has possession of the wafer and is ready to proceed with the putting of the wafer into the cassette module. First, the TM informs the cluster controller that it is proceeding with the transfer of the wafer to CM through the handoff sequence.

```
CM                                       TM
<<--------------------------------------<<
HOReady.Req(Port=Port1,AmID="CM",
HODir=PUT,MID="Wafer1")
```

The cassette module informs the transport module to use the PLACE sequence to put the wafer.

```
CM                                       TM
>>-------------------------------------->>
HOPlace.Req(Port=Port1,AmID="CM")
CM                                       TM
<<--------------------------------------<<
HOPlace.Rsp(Port=Port1,AmID="CM",
Status=OK)
```

When the putting of the wafer has been successful, the cassette module informs the transport module with a verify sequence.

```
CM                                       TM
>>-------------------------------------->>
HOVerify.Req(Port=Port1,AmID="CM")
CM                                       TM
<<--------------------------------------<<
HOVerify.Rsp(Port=Port1,AmID="CM",Status=
OK)
```

The cassette module then informs the cluster controller of its current status.

```
CC                                       CM
<<--------------------------------------<<
TRJobComplete.Req(JobID=IOJob7,
TimeStamp,Status=OK)
```

The TM then informs the cluster controller that the putting of material is finished and that the requested transfer job is complete.

```
CC                                       TM
<<--------------------------------------<<
TRJobComplete.Req(JobID=TMJob3,
TimeStamp,Status=OK)
```

20. CM TO FACTORY CASSETTE HANDOFF

The cassette is passed from the cluster tool to the factory environment.

```
CC                                       CM
>>-------------------------------------->>
TRJobCreate.Req(MID="Carrier1",
Port=Port2,Dir=Send)
CC                                       CM
<<--------------------------------------<<
TRJobCreate.Rsp(JobID=IOJob8,Status=OK)
CC                                       CM
<<--------------------------------------<<
TRJobStarted.Req(JobID=IOJob8, TimeStamp)
```

At this point, it is assumed that the cassette module performs actions such as loadlock venting, door opening, and initiating communication with the user (human or host) to perform the handoff to the factory. The cluster controller is informed of progress. When the transfer to the factory is complete, the cluster controller is informed.

```
CC                                     CM
<<-------------------------------------<<
TRJobComplete.Req(JobID=IOJob8,
TimeStamp,Status=OK)
```

SEMI E38.1-95
COMMUNICATIONS ENVIRONMENT HSMS/SECS-II FOR CLUSTER TOOL MODULE COMMUNICATIONS

1 Purpose

The purpose of this standard is to specify the communication environment for communication with and among modules in a cluster tool.

2 Scope

The scope of this standard is communication within a cluster tool as defined in the standard Cluster Tool Module Communication Standard (CTMC, SEMI E38). This standard specifies the transmission of SECS-II messages by HSMS (SEMI E37), HSMS-GS (SEMI E37.2), and Ethernet. Other methods of message communication are possible but beyond the scope of this standard.

This standard is intended to be one of possibly several supplements to the CTMC SEMI E38.

3 Referenced Documents

3.1 *SEMI Standards*[1]

The following SEMI standards are related to the Communications Environment standard:

SEMI E5 — SEMI Equipment Communication Standard 2 - Message Content (SECS -II).

SEMI E37 — High-Speed SECS Message Services (HSMS) Generic Services

SEMI E37.2 — High-Speed SECS Message Services General Session (HSMS-GS)

3.2 *IEEE Standards*[2]

The following IEEE standard is related to the Communications Environment standard:

IEEE 802.3 — Carrier Sense Multiple Access with Collision Detection

4 Definitions

The following definitions are arranged in alphabetical order. Some are defined using terms defined elsewhere within this section. No definitions beyond this section and the referenced standards should be necessary for a basic understanding of these terms.

10 BASE 2 — a common physical medium for the transmission of Ethernet signals.

AUI (Attachment Unit Interface) — a specification of the connector, pins, and signals used to interface a computer to a MAU. Defined formally in IEEE 802.3.

Cluster Tool Environment — a collection of interconnected modules forming a cluster tool.

Communications Stack — a specification of successive layers of interfaces through which communication services are provided.

Ethernet — a method of transmitting signals. Ethernet is defined formally by IEEE 802.3

MAU (Medium Attachment Unit) — an adaptor from the AUI interface to a physical wire or medium such as 10 BASE 2. Defined formally in IEEE 802.3

Platform — a physical computer in a cluster tool that contains the Ethernet Interface or station as defined in IEEE 802.3. In a cluster tool, a platform may have one or more logical modules residing on it.

5 Required Sessions

In order to support the Services specified in the CTMC standard, there is an associated set of Protocol standards that specify a set of SECS-II messages to support these Services. This standard specifies the transmission of these SECS-II messages using HSMS sessions.

In order to communicate with a given logical module, a separate HSMS connection (TCP/IP connection) is required per logical module.

For correct operation of a cluster tool using these facilities, a set of standard sessions, given in Table 1, is required. Other sessions are possible, but are not required. In order to be compliant a module must not require further sessions in order to operate.

Table 1 Required Sessions

Client	*Server*	*Services*
Cluster Controller	Transport Module	Object Services, Material Movement, Exception Management, Event Reporting
Cluster Controller	Cassette Module	Object Services, Material Movement, Exception Management, Event Reporting

[1] Semiconductor Equipment & Materials International, 805 East Middlefield Road, Mountain View, CA 94043

[2] Institute of Electrical and Electronics Engineers, 345 East 47th Street, New York, NY 10017

Client	*Server*	*Services*
Cluster Controller	Process Module	Object Services, Processing Management, Recipe Management, Material Movement, Exception Management, Event Reporting
Cassette Module	Transport Module	Object Services, Material Movement
Process Module	Transport Module	Object Services, Material Movement

6 Communication Stack Specification

There are many layers of software required in order to communicate using a facility such as HSMS. In order to interoperate, modules shall have identical or equivalent protocols at each layer on both sides of a physical connection.

HSMS does not specify a particular physical layer. In order to ensure interoperability between modules, of possibly different origin, a complete interoperable communication stack is required.

6.1 *SECS-II Messages* — The Cluster Tool Module Communications (CTMC) standard specifies a set of messaging services from applicable standards for use by a cluster tool module. Each service standard has a supplemental protocol standard which defines the SECS-II message support. This standard specifies a method for transporting these SECS-II messages. In order to be compliant with this standard, these SECS-II messages must be used. The detail of the SECS-II messages is found in SEMI E5. SECS-II message definitions refer to messages communicating between a host and equipment. With reference to implementing CTMC, the host is the service-user or cluster-controlling entity, and the equipment is the service-provider or cluster module entity.

6.2 *HSMS Messaging* — For the purposes of communication of SECS-II messages within the cluster tool communication environment, SEMI High-Speed SECS Message Service (HSMS) shall be used (SEMI E37).

CTMC defines a number of services. For inter-module, and service user-to-module communication, many services will be required simultaneously. As a result, the capabilities of the HSMS General Session (SEMI E37.2) are required and shall be used for communication of all services specified by the CTMC.

6.2.1 *IP Addresses, Port Numbers, and Session IDs* — HSMS defines the setting of IP Addresses, Port Numbers, and Session IDs. In order to uniquely specify a service, all three are required as configuration parameters. The actual numbers shall be within the allowed range and unique within their respective domains. Table 2 shows these parameters, what they define, and their respective domains.

Table 2 Configuration Parameters

Parameter	*Defines*	*Domain of Uniqueness*
IP Address	Platform	Network
Port Number	TCP/IP Connection	Platform
Session ID	CTMC Service	TCP/IP Connection

6.2.2 *Session ID's* — Each association required by CTMC (such as Processing, Material Movement, Exception, etc.) shall have a session within a connection. These Session ID's shall be documented by the service provider, and, if configurable, the method of configuration shall be documented.

The Session ID for a given service shall be defined and may be dictated by the service provider (at the server end of a connection).

In order to use a service, the service user (which is the client end of the connection) shall select the service by Session ID. Thus, the Session ID shall be configurable for the service user and the method of configuring shall be documented for each service user. Session IDs shall be as shown in Table 3.

Object services shall use Session ID 1; all other services shall use Session ID's from the range labeled "Available" in Table 3.

Table 3 Allowed Session ID's

Session ID	*Service*
0	Reserved
1	Object Services
2-63	Reserved (future)
64-65534	Available
65535 (OxFFFF)	Reserved (HSMS)

6.2.3 *Linktest* — The linktest procedure is an optional facility of HSMS. For the purposes of cluster tool communications, the linktest procedure as described in the HSMS standard shall be supported. On detection of a linktest timeout, a communication failure will be considered to have occurred, and higher communication layers shall be notified of this failure.

6.2.4 *Connection Mode* — HSMS provides for Active, Passive, and Alternating Connection Modes. For the purposes of establishing connections in a cluster tool, either Active or Passive shall be used. For each service provided, there is a service provider (server) and a service user (client). With respect to each service, the client shall connect in the Active mode and the server in the Passive mode. Table 1 specifies the client and server (and hence connection mode) of the required sessions.

In addition to establishing the connection, the client shall initiate the sessions with the Select message, as defined in HSMS. As a result, all sessions at the client end of a connection shall be service users and all sessions at the server end of the connection shall be service providers.

6.3 *Use of TCP/IP* — HSMS defines the use of TCP/IP for communication of messages. Other simultaneous uses of TCP/IP are possible but beyond the scope of this standard.

Within TCP, Port Numbers are used to uniquely identify the connection on a given platform. A port number may be any value between 0 and 65535, but TCP reserves port numbers starting at 0. Refer to HSMS and the references given in HSMS for the definition of the reserved port numbers.

Multiple logical modules may exist on a given platform. Each service for a logical module on a given platform must use a unique session within a connection. It is possible to configure a module so that each logical module uses a separate connection, but it is also possible for several logical modules to share a connection. Each service requires a unique connection for each external entity, but an external entity may, depending on the configuration, access the services of several logical modules on a platform, identifying them by unique session, except for Object Services. Object Services is always identified by Session ID 1.

Connection to a specific module shall be established using a non-reserved port number which is unique among modules on that platform. A given service may have several simultaneous connections.

6.3.1 *Setting Port Number* — The port numbers used for establishing HSMS connections shall be configurable for both the service user and service provider. This is because the port numbers may be used by some other software entity on the same platform. Port numbers shall be chosen that are not in the reserved range and do not conflict with any other software entity on the platform. The method of configuration of the port numbers shall be documented.

6.4 *Physical Layer* — HSMS allows for many different physical layers. In order for modules to interoperate, a single physical layer is required. This standard specifies Ethernet — as defined in the standard IEEE 802.3 — to be used for physical layer transmission of HSMS messages.

Other physical layers could be used, but the use of other such physical layers is not supported by this standard. It is anticipated that other related standards will be developed to support other physical layers. In such a case, only those modules compliant with the same standard would be interoperable.

6.5 *Media and Connectors* — With Ethernet, there is a choice of media used (twisted pair, coax, etc.). It is beyond the scope of this standard to specify the media used. The media is thus left to the configuration of a specific cluster tool and may depend on the available media used in the factory.

Most Ethernet interfaces provide a media-independent AUI interface. A transceiver is then used to access the physical media. In order to be compliant with this standard, a module shall provide an AUI interface. Many interfaces also provide a media-specific interface. This media specific interface may be used in the event that the cluster tool media is the same as the media specific interface.

7 Compliance

Compliance with this standard includes adherence to all stated requirements where implemented. In order to be compliant to this standard, an implementation shall:

1. use SECS-II messages as specified by CTMC document,
2. use SEMI E37 (HSMS) and SEMI E37.2 (HSMS-GS),
3. allow and document IP Address configuration,
4. allow and document Session ID configuration,
5. allow and document Port ID configuration,
6. use Ethernet as defined in IEEE 802.3,
7. provide an AUI connector.

Some Ethernet interfaces provide additional connectors (such as 10 BASE 2 or thinnet). These may be used in cases where this is the medium chosen, but for compliance, an AUI connector shall be provided.

APPENDIX 1
APPLICATION NOTES

NOTE: This appendix was approved as a part of SEMI E38.1 by full letter ballot procedure.

A1-1 Example Configuration

The following example shows configuration of a cluster tool consisting of an existing process module with a new cluster controller and other modules.

The cluster consists of a Cluster Controller, two Process Modules (PM1, PM2), and a combined Transport/Cassette Module (TM/CM).

A1-1.1 *IP Addresses* — IP addresses are chosen so that they are unique to each platform on the network and consistent with the conventions used at the facility. For this example, the convention is to use 192.25.63.X for IP Addresses, where X is between 0 and 255. PM1 had an existing IP address of 192.25.63.122, which will not be changed. IP addresses starting at 205 are unused and thus available. Thus, the following IP addresses are chosen:

```
Cluster Controller       192.25.63.205
TM and CM                192.25.63.206
PM1                      192.25.63.122
PM2                      192.25.63.207
```

As part of the configuration, the IP Address of each module is identified as shown above, on all of the platforms. This configuration depends on the TCP/IP software used on the respective platforms.

A1-1.2 *Port Numbers* — TCP reserves port numbers below 1024 in RFC1340. There are no other TCP/IP programs on any of the platforms in the cluster using port number in the range 2000-10000, so the following port numbers are chosen:

```
2000 first TM
5000 first CM
8000 first PM
8001 second PM
```

The cluster controller is always a client and initiates the connections, so no port number assignment is required.

A1-1.3 *Session ID Assignment* — Before defining the Session ID's, recall that the following connections are required:

Client	**Server**
CC	TM
CC	CM
CC	PM1
CC	PM2
CM	TM
PM1	TM
PM2	TM

The Session ID's are arbitrary. PM1 already has ID's which are as follows:

PM1 IDs		
Clients		
Object Services	1	CC, TM
Processing Management	100	CC
Recipe Management	101	CC
Material Movement	102	CC, TM
Exception Management	103	CC
Event Reporting	104	CC

The other modules have not yet been set, so we choose to begin with ID 64.

The session IDs are established as follows:

PM2 Ids		
Clients		
Object Services	1	CC, TM
Processing Management	64	CC
Recipe Management	65	CC
Material Movement	66	CC, TM
Exception Management	67	CC
Event Reporting	68	CC

TM IDs		
Clients		
Object Services	1	CC
Material Movement	64	CC
Exception Management	65	CC
Event Reporting	66	CC

CM IDs		
Clients		
Object Services	1	CC, TM
Material Movement	64	CC, TM
Exception Management	65	CC
Event Reporting	66	CC

SEMI E39-1101
OBJECT SERVICES STANDARD: CONCEPTS, BEHAVIOR, AND SERVICES

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the Japanese Information & Control Committee. Current edition approved by the North American Information and Control Committee on July 19 and August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1995; previously published June 2000.

CONTENTS

APPENDIX 1

LIST OF TABLES

SEMI E39-1101
OBJECT SERVICES STANDARD: CONCEPTS, BEHAVIOR, AND SERVICES

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the Japanese Information & Control Committee. Current edition approved by the North American Information and Control Committee on July 19 and August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1995; previously published June 2000.

1 Purpose

1.1 The purpose of the Object Services Standard (OSS) is to provide general terminology, conventions, and notation for describing behavior and data in terms of objects and object attributes. In addition, it provides basic services for reading object attributes, setting their values, and for asking for an object's contents. This standard is intended to be referenced by other standards which define specific objects to reduce redundancy.

2 Scope

2.1 The scope of this standard is to provide concepts, behavior, and services common to a variety of public objects.

2.2 Object models are common to multiple standards. Object Services provide basic object-related definitions, and basic services for getting object attributes and setting attribute values, that can be used by all standards defining public objects. These services allow basic management of data based on objects.

2.3 The object services defined in this document may be included in the services provided by other standards. They may also be provided independently of such other standards.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *ISO Standard*[1]

ISO 9595 — Common Management Information Service (CMIS)

3.2 *Other Standards*

James Rumbaugh, Michael Blaha, William Premerlani, Frederick Eddy, William Lorensen, *Object-Oriented Modeling and Design*, Englewood Cliffs, New Jersey: Prentice-Hall, 1991.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Definitions

4.1 The following basic definitions are provided in a logical order.

4.2 *Requirements*

4.2.1 *fundamental compliance* — conformance to all fundamental requirements for an object or service resource.

4.2.2 *fundamental requirements* — the requirements for information and behavior that must be satisfied for compliance with a standard. Fundamental requirements apply to specific areas of application, objects, or services.

4.3 *Objects*

4.3.1 *object*[2] — an entity with a specific set of data and behaviors. Objects may be physical or conceptual.

4.3.2 *standardized object* — a object formally defined in SEMI standards and in compliance with the fundamental requirements of SEMI E39 (Object Services Standard: Concepts, Behavior, and Services).

4.3.3 *object model* — a static graphic model of objects to show structure — the identity of objects, their attributes and operations, and their relationships with one another.

4.3.4 *object type* — a formal classification of a group of similar objects. Synonym: *object class*. Examples: *equipment*, *wafer*, *carrier*.

4.3.5 *object instance* — an instance of an object type. An object type is like a template, while an object

1 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

2 The term "object" may refer to either an object class or an instance of a class.

instance is the actual object. Example: an actual and specific optical stepper installed in a particular fab is an instance of the type "Optical Stepper."

4.3.6 *object attribute (attribute)* — information concerning an object. Examples for object type "equipment": manufacturer, model, serial number.

4.3.6.1 Attributes are classified in various ways, according to their visibility (public/private), optionality, and access:

- *fundamental attribute* — an attribute that is required for fundamental compliance with a standard service.
- *optional attribute* — an attribute that is required only in support of one or more optional standard services.
- *private attribute* — an attribute that is used strictly for internal purposes and is unknown (invisible) through public services.
- *public attribute* — an attribute that is known (visible) and whose current value is provided as a service to other entities upon request.
- *read-only attribute (RO)* — may not be changed through public services.
- *read/write attribute (RW)* — may be changed through public services.

4.3.7 *attribute name* — the formal name of the attribute that is used to identify it. The names (and data types) of public attributes are included with the object's definition and are unique for that object.

4.3.8 *object identifier* — a set of one or more items of information, concerning a particular instance (instantiation) of an object of a given type, that together uniquely distinguish that instance from all other instances of that object within a defined scope. NOTE: An object may have more than one identifier. An identifier may be *simple* (consist of only one attribute) or *complex* (consist of more than one attribute). Example: The combination of equipment's manufacturer, model, and serial number serve as an identifier that uniquely identifies a specific installation.

4.3.9 *object handle* — a numeric or binary identifier assigned by an application for internal use. NOTE: A handle may also be available as a *public attribute* but cannot generally be guaranteed to be either persistent or unique outside of the current relationship between service user and service provider. The persistence of the handle is specified by the standard that defines the object.

4.3.10 *operation* — a function performed by, or inherent to, an object. Example: for equipment, "run," "stop," "abort."

4.3.11 *aggregation object* — an object that is composed (made up) of other objects. An aggregation may lose some degree of integrity if one of its components is missing.

4.3.12 *component object* — an object that is part of an aggregation.

4.3.13 *container object* — an object that is intended to hold other types of objects. The contents may or may not be ordered.

4.3.14 *contents* — an object that is in a container. Examples: a wafer in a cassette, a book in a library.

4.3.15 *owner object* — an object that is an aggregation, container, or supervisor of another object. The owner object is said to *own* the other object.

4.3.16 *owned object* — an object that is a component of, contained in, or supervised by, another object. The owned object is said to be *owned by* the other object.

4.3.16.1 An object may have multiple owners. For example, it may be a shared resource.

4.4 *Services*

4.4.1 *scope* — the specification of one or more objects that starts with a specific owner object and proceeds downward through a hierarchical sequence of "owns" relationships.

4.4.2 *service (or message service)* — represents a function offered to a user by a provider. A service consists of a sequence of service primitives, each described by a list of parameters. A service excludes definition of message structure and protocol.

4.4.2.1 A service may or may not be processed by the provider of the service. The invocation of some service may have to interact with other objects to fulfil its requirement completely; an exception will be raised if the service can not fulfill all its pre or post conditions. The object that provides the service may reject the service request or restrict the completion of the service to prevent an illegal action due to the equipment condition.

4.4.3 *notification service* — initiated by the service provider and sent to the service consumer/subscriber. No response is expected.[3]

4.4.3.1 Notifications consist of two service primitives — a message from the sender to the communications

3 This does not preclude the implementation of a response message in the message protocol.

facility and an indication to the receiver from the communications facility.

4.4.4 *request service* — initiated by the service consumer. Requests ask for data or for an activity (operation) from the provider. Requests expect a specific response message.

4.4.4.1 A request consists of a message that requires a response from the receiver. The primitives for a request are the same as those of the notification, while the response defines additional primitives called the *response* and the *confirmation*.

4.4.5 *service resource* — a logical group of one or more services within a specific area of functionality.

4.5 *Data Type*

4.5.1 *form* — type of data: positive integer, unsigned integer, integer, enumerated, boolean, text, formatted text, structure, list, ordered list.

4.5.2 *positive integer* — may take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

4.5.3 *unsigned integer* — may take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

4.5.4 *integer* — may take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

4.5.5 *floating point* — may take on any single (real) numeric value, positive or negative. Messaging protocol may impose a limit on the range of possible values.

4.5.6 *enumerated* — may take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

4.5.7 *boolean* — may take on one of two possible values, equating to TRUE or FALSE.

4.5.8 *text* — A text string. Messaging protocol may impose restrictions, such as length or ASCII representation.

4.5.9 *formatted text* — a text string with an imposed format. This could be by position, by use of special characters, or both.

4.5.10 *structure* — a complex structure consisting of a specific set of items, of possibly mixed data types, in a specified arrangement.

4.5.11 *list* — a set of one or more items that are all of the same form (one of the above forms).

4.5.12 *ordered list* — a list for which the order in which items appear is significant.

5 Conventions

- Defined terms are presented in boldface when introduced for the first time.
- Formally reserved text strings, such as attribute names, are underlined.

5.1 *OMT Object Information Model* — The object models are presented using the Object Modeling Technique (OMT) developed by Rumbaugh, James, et al, in *Object-Oriented Modeling and Design*, Prentice Hall, Englewood Cliffs, NJ, c1991.[4]

5.1.1 Overviews of this notation are provided in the Appendix. A brief discussion of terminology is also provided in the Appendix.

5.2 *Object Attribute Representation* — The object information models for standardized objects will be supported by an attribute definition table with the following column headings:

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
The formal text name of the attribute	Description of the information contained	RO or RW	Y or N	(See Section 4.4.)

5.2.1 The Access column uses RO (Read Only) or RW (Read and Write) to indicate the access that users of the service have to the attribute.

5.2.2 A "Y" or "N" in the Requirement (Reqt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

5.2.3 The Form column is used to indicate the format of the attribute. (See Section 4.4 for definitions.)

5.3 *Service Message Representation*

5.3.1 *Service Resource Definition* — A service resource definition table defines the specific set of messages for a given service group, as shown in the following table:

Message Service Name	*Type*	*Description*
Message name	N or R	The intent of the service.

5.3.1.1 Type can be either N = Notification or R = Request.

5.3.1.2 Notification type messages are initiated by the service provider, and the provider does not expect to get a response from the consumer/subscriber.

4 For a full description of the Object Modeling Technique, see Object-Oriented Modeling and Design, Rumbaugh, Blaha, Premerlani, Eddy and Lorenson, Prentice Hall, 1991.

5.3.1.3 Request messages are initiated by a service consumer or subscriber. Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

5.3.2 *Service Parameter Dictionary* — A service parameter dictionary table defines the parameters for one or more services, as shown in the following table:

Parameter	*Form*	*Description*
Parameter X	Data type	A parameter called X is B in A.

5.3.2.1 A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and contents of the corresponding primitive.

5.3.2.2 The Form column is used to indicate the type of data contained in a parameter. (See Section 4.4 for definitions.)

5.3.2.3 The Description column in the Service Parameter Dictionary table describes the meaning of the parameter, the values it can assume, and any interrelationships with other parameters.

5.3.2.4 To prevent the definition of numerous parameters named "XxxList," this document adopts the convention of referring to the list as "(List of) Xxx." In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type. Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element unless zero elements are specifically allowed.

5.3.3 *Service Message Definition* — A service message definition table defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Parameter X	(see below)	(see below)	A description of the service.

5.3.3.1 The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message. The message sent by the initiator is called the "Request." The receiver terms this message the "Indication" or the request. The receiver may then send a "Response," which the original sender terms the "Confirmation."

5.3.3.2 The following codes appear in the Req/Ind and Rsp/Conf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

- "M" — *Mandatory Parameter* — must be given a valid value.
- "C" — *Conditional Parameter* — may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the values of other parameters.
- "U" — *User-Defined Parameter*
- "-" — The parameter is not used.
- "=" — (for response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

6 Background

6.1 During the development of proposals for several other service standards, it was discovered that they shared a common need for terminology and services related to objects. Originally each proposal included a service-specific message for getting the values of an object's attributes, and some also provided a service-specific message for setting these values.

6.1.1 The decision was made to eliminate this redundancy through provision of a standard to provide those definitions and services used by the other separate service standards.

8 Basic Concepts and Behavior

8.1 This section defines the concepts and behavior that are common to public objects.

8.1.1 Object-oriented analysis is a widely accepted tool, both for applications that are implemented using

5 This set of documents may be obtained from SEMI, 3081 Zanker Road, San Jose, CA 95134.

6 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

object-oriented technologies and those using traditional technologies. Object information models provide a powerful method for describing relationships that can be intuitively understood.

8.1.2 For those unfamiliar with object-oriented terminology, a brief discussion of terms is provided in the Appendix.

8.2 *Object Attributes* — An *object attribute* is a data value that is held by all instances of a given object type. For communication purposes, public attributes are assigned a logical *name* that is unique for that object. An object's attributes may be individually referenced either by an enumerated numeric value or by a reserved *attribute name* that conforms to the use of text defined in Section 8.1.1.

8.2.1 An attribute that can be requested or referenced through formal public *services* is a *public attribute*. Other attributes may exist in specific implementations but are invisible through public services and are called *private attributes*.

8.2.2 Specific attributes may be designated as *fundamental* for a specific object. These shall be supported by all implementations that use or reference the specified object. Attributes that are not fundamental are *optional*.

8.2.3 *Use of Text* — Values defined as text, when given in ASCII, are subject to certain restrictions. This includes object attribute values, attribute names, and service parameters.

8.2.3.1 Text in ASCII is restricted to the characters between 20_{16} and $7E_{16}$, excluding the question mark "?", the asterisk "*", and the tilde "~".

8.2.3.2 The question mark and asterisk are reserved for use as "wild characters" in filters and searches, while the tilde is reserved to allow systems that cannot use spaces to convert spaces to tildes for internal use.

8.2.3.3 Text used in specific contexts may have additional restrictions.

8.2.3.4 Unless otherwise stated, case is not significant for purposes of comparison. However, case is used to improve readability and should be preserved whenever possible.

8.2.4 *Object Type* — An object always knows its type. For this reason, the attribute for object type, ObjType, is required for all public objects. ObjType is a text string containing the formal classification of an object. The text string shall conform to the convention defined in Section 8.1.1, with the additional restriction that the "greater than" symbol ">" and the colon ":" are also excluded. The text string shall not start or end with a space.

8.2.4.1 Object types (the values for ObjType) for standardized objects are reserved. Types reserved are specific to individual standards.

8.2.5 *Object Identifier* — Every instance of an object shall have one or more attributes that together uniquely distinguish that instance from all other instances of objects of the same object type. An object may have more than one identifier. The identifier(s) are defined as part of the object definition.

8.2.5.1 ObjID is a text-based fundamental attribute of all public objects and provides an attribute of a known form to serve as an identifier for an object of any type. The text string shall conform with the convention defined in Section 8.1.1 and with the additional restriction that the "greater than" symbol ">" and the colon ":" are also excluded. The text string shall not start or end with a space.

8.2.5.2 From the point of view of objects such as managers, aggregates, and containers that have responsibilities for other objects (see Sections 9.1 and 9.2) the combination of ObjType and ObjID for these other objects shall be unique. For example, if several process chambers have a single vacuum pump, each process chamber may have direct access to at most one ObjType:ObjID> combination of "Pump:Vacuum". However, the combination is not required to be unique across the different chambers. The host differentiates between the several vacuum pumps by their belonging to different aggregations.

8.2.5.3 The object definition for each object shall specify the particular identifier used for general access. For objects that normally use an identifier with a numeric value as an identifier (such as "handle," described below), the value of ObjID is a numeric text string set to the value of that attribute.

8.2.5.4 An object may also have other identifiers in addition to ObjID.

8.2.6 *Object Handle* — An object's *handle* is an attribute with a numeric value that is assigned by the application that created the object. The handle may be used for the object's identifier. It is generally intended for local use and may or may not be defined as a public attribute in the object's formal definition.

8.2.6.1 Where used, the handle may be guaranteed to be unique only within a specific context and within a single association between service-provider and service-user for a specific service resource. The handle may or may not be persistent beyond a certain context within that association or beyond it. Persistence of the handle is specified as part of the definition of the object and is beyond the scope of OSS.

8.3 *Object Definition* — An object definition includes an attribute definition table described in Section 5.3.

8.3.1 The object that is the super-type of all public objects is called the *top object*. The attributes and operations of the top object, shown in Figure 1, are fundamental requirements for all public objects. That is, all objects shall respond to the object attributes ObjType and text strings, and all public objects shall recognize and respond to the operations *get attributes* and *set attributes*.

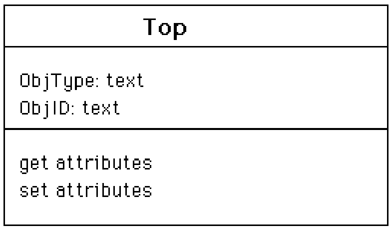

Figure 1
Top Object

8.3.2 Formal definition of an object shall include a table defining the object's public attributes. The Object Attribute Definition table for the top object is given in Table 1 below. It contains the two fundamental attributes required of all public objects.

Table 1 Top Object Attribute Definition

Name	*Definition*	*Access*	*Req*	*Form*
ObjType	The object type.	RO	Y	Text
ObjID	The object's identifier.	RO	Y	Text

8.3.3 Access refers to the ability to read and write the value of the attribute through OSS services. An object's type and identifier may not be changed through OSS services. However, it may be possible for the service user to assign a value for the object's identifier at the time the object (instance) is created. This depends on the object and the services provided.

9 Object Relationships

9.1 This section addresses relationships between objects that affect communications, either by restricting communications or through information concerning relationships.

9.2 *Object Hierarchy* — Certain objects may be specified as *aggregation objects* or as *container objects* when they are defined.

9.2.1 An aggregation object is composed of other objects called the *components* of the aggregation. This is illustrated in Figure 2. Components may be of one or more different types, or they may be of the same type.

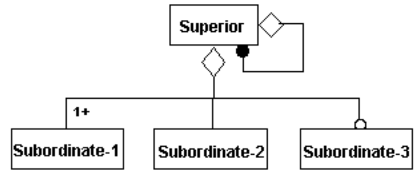

Figure 2
Aggregation with Two Component Types

9.2.2 Container objects *contain* other objects, of the same or different types, but are not made up of them.

9.2.3 Figure 3 shows two object types that are associated with a relationship called "contains." The solid circle indicates that Type-1 may contain zero or more objects of Type-2 type. An example of a common container type is a file directory.

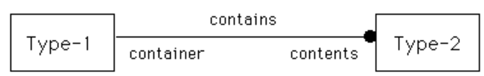

Figure 3
Container and Contents

9.2.4 An aggregation loses some degree of integrity if certain of its components are missing, while a container retains full integrity even if it has no contents. An automobile is an aggregation of many components, some of which are themselves aggregations. An automobile may also have contents (driver, passengers, belongings) which are removable and not considered as components. Other examples of container objects include lists, dictionaries, and libraries. A container that has no contents is said to be *empty*.

9.2.5 The aggregation or container is called the *superior object* and its components or contents are called *subordinate objects*.

9.2.6 In addition to the relationships of "is composed of" (roles: aggregate/component) and "contains" (roles: container/contents), the other hierarchical relationship that occurs naturally in factories and in control systems is that of "*supervises*" (roles: supervisor/supervised). This denotes a control relationship where the supervised object accepts part or all of its directions from the supervisor. The supervisor, in turn, has responsibilities that it delegates to the supervised. The supervisor typically will also have a relationship of "*is composed of*" or "*contains*" with its supervised subordinates.

9.3 *Scope and Ownership* — The hierarchical relationships of aggregations, containers, and supervisors may at times be required for pointing to a specific object. These relationships may be shown with a multi-level tree structure, as shown in Figure 4. Subordinate objects at one level may be the superior objects at the next lower level. The superior object at the highest level is called the *root* of the tree.

NOTE 2: Figure 4 is not drawn in OMT notation.

9.3.1 An *owner object* is an object that is an aggregate, container, or supervisor. An *owned object* is an object that is a component of, contained in, or supervised by, an owner object.

9.3.2 *Scope*[7] is the concept and method of pointing to a specific owned object through the use of sequence of hierarchical relationships. Scope allows any particular object (type or instance) within such a hierarchical tree to be fully specified by providing a unique path down this tree using a concatenation of object types and identifiers.

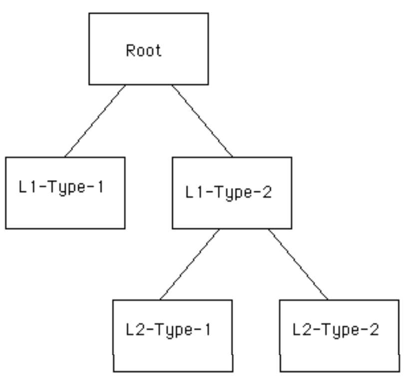

Figure 4
Example of Owner Hierarchy

9.3.3 This path is used to create an *object specifier* that is represented as a sequence of concatenated text strings of the form “type:id>”, which may be repeated as necessary to form the complete path. The character “>” is used to terminate the object type field, and the colon character “:” is used to terminate the identifier field. The object specifier uniquely identifies an object within the entire domain of objects and is able to extend the domain within which a search for an object would otherwise occur.

9.3.4 Formally, an object specifier is a formatted text string of the form:

“$type_1$:id_1>...$type_n$:id_n>”

where “$type_i$” and “id_i” represent the object type and object identifier, respectively, of the ith object instance in the sequence, and where the ith object is owned by the (i-1)th object and is the owner of the (i+1)th object.

9.3.5 Figure 5 shows an example of a typical set of hierarchical relationships in the factory. An application of scope might be through Cell AB, Cluster BB, Process Module (PM) CB, to Device DB. In this example, the object specifier for Device DB would be:

“FactoryHost:Hilda>Cell:AB>Cluster:BB>PM:CB>
Device:DB>”

9.3.6 It is generally not necessary to start with the root object. It is sufficient to start with an object that is owned by the communications partner. However, it is invalid to omit a level in the hierarchy that is between the starting object and the final object in the path.

9.3.7 Some systems may be able to guarantee the uniqueness of object identifiers for their owned objects. For example, equipment may be able to guarantee that all of its owned objects have unique identifiers regardless of type. In this case, an object’s identifier is sufficient to point to a specific object instance. Object type may be omitted without ambiguity, as it may be obtained as an attribute of the specified object. The form of the path then becomes "id_1>id_2>.id_n>". In the previous example, this might be "AB>BB>CB>DB>".

9.3.8 Object type may also be omitted in applications where it may be inferred without ambiguity within a particular context. A service that is dedicated to a specific object type X, for example, that is always owned only by another specific object type Y, may specify usage for object type X. Since object type may then be inferred from the context, object types X and Y need not be included in a specifier for an object of type X.

9.3.9 The terminator of the final identifier is optional. This allows a single object identifier to be used as a simple object specifier. As a result, however, it may be necessary to provide string delimiters to prevent premature termination of string parsing in the event an identifier contains one or more embedded spaces.

9.3.10 Scope can be applied to any set of hierarchical relationships, given a minimum set of requirements for public objects:

- an object always knows its own type (<u>ObjType</u>),
- an object always knows its own identifier(s) (including <u>ObjID</u>),
- an owner object knows the types of objects that are its components and/or contents, or that it otherwise

7 Scoping is used in material ISO 9595 (CMIS).

supervises, and is able to determine their identifiers (see GetType, Section 10.5),

- an owner object is able to determine the types and identifiers of its owned objects.

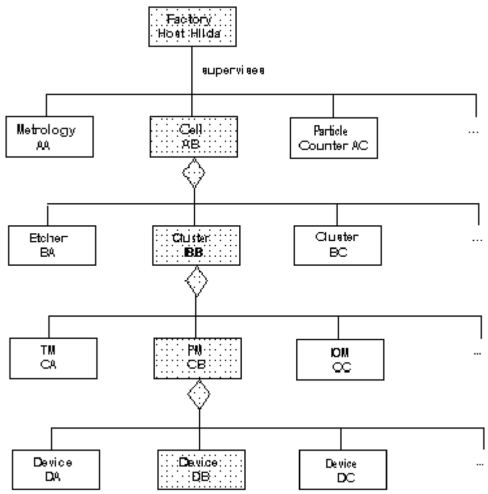

Figure 5
Hierarchical Relationships in the Factory

9.4 *Multiple Inheritance Hierarchy* — Multiple hierarchical inheritance may be required as an optional capability for pointing to a specific object that provides the same services from the inherited objects. Usually, inherited services are implemented by the domain object such that specifying "overrides" of attributes or services from inherited objects is not required. Sometimes the capability to override specified attributes and services from inherited object is necessary to resolve duplicated attribute names or services or to allow duplicated names in user extended objects.

9.4.1 If Andy an object TypeA inherits from object TypeB and TypeC and a service requestor is focusing services or attributes of the object TypeB rather than those with the same name in the object TypeC, the following text string form could specify the focused part of the object Andy:

```
TypeA@TypeB:Andy
```

9.4.2 If any names of service and/or attribute that TypeB provides are the same as those provided by TypeA or TypeC, then, the object Andy will have to be specified with the complete explanation from the supplier as how the object handles the exception and the differences from the original attribute or services. So, the above expression is the same as "TypeA:Andy" without notes to describe difference.

10 Additional Operations

10.1 This section defines operations that are common to many types of public objects but are not required for all types of public objects. These operations are not required for OSS compliance. However, they may be required for support of specific object types defined by other standards that use OSS services.

10.2 *Create and Delete* — Creation and deletion are optional services for object lifecycle management. Object definitions may specify conditions under which the services are supported. Objects may be created and/or deleted in other ways. For example, the creation and deletion of certain types of persistent objects may be outside of the scope of OSS services, while transient objects may be created and/or deleted automatically by their owners as the result of other activities.

10.2.1 *Create* — The create operation creates an instance of an object type.

10.2.1.1 Initial settings for one or more attributes may be specified by the service user. Initial settings may be required, prohibited, or optional, depending upon the specific object type. The ability to set attribute values through the create operation shall be clearly identified as part of the object definition for those objects supporting the create operation. For example, the ability to set the value of the object identifier ObjID may be required, optional, or prohibited, depending upon the type of object.

10.2.1.2 The object definition may also specify attributes of the new object instantiation that are returned to the service user by the service provider.

10.2.1.3 A request to create an object is invalid if it does not provide all required attribute settings, if it attempts to set prohibited attributes, or if it provides values invalid for a given attribute.

10.2.1.4 The definitions of certain objects may specify that the delete service only be provided to, or under the authority of, the service user that requested the original create operation. In this case, a private attribute (that is, an attribute not accessible through services defined in Section 11) named Delete Token shall return a unique integer as an attribute of the new object. This attribute is then used in a subsequent request to delete the object. The service user may delegate this token at its own discretion.

10.2.1.5 The create operation is invoked by the service Create sent to the owner that is to instantiate the specified object. In order for the Create service to be accepted if no owner for the object to be created is defined in the target entity or if it is physically outside of the domain of the entity; the object specifier shall define the owner as " " (an empty string). If the entity is just the equipment rather than a component of the equipment; the owner may be defined as“Equipment” even if no such object is defined.

10.2.2 *Delete* — The delete operation is the inverse of the create operation. Individual object types may restrict deletion based on well-defined set of criteria. For example, the definition of a type of container may specify that a container may only be deleted when it is empty.

10.2.2.1 If an object to be deleted requires the authority of the service user that invoked the original create operation, then the Delete Token attribute of the target object shall be provided by the user of the delete service.

10.2.2.2 A request to delete an object is invalid if it does not provide all required attribute settings or if it provides values invalid for a given attribute.

10.2.2.3 The delete operation is invoked by the service Delete sent to the object to be deleted.

10.3 *Attachment* — When an object receives a remote request for an operation, it may be unable to identify the requestor. At the same time, it may be necessary for an object to determine if certain messages were sent by its supervisor. This conflict is resolved by formalizing the relationship between a supervised object and its supervisor.

10.3.1 Attachment is a dynamic behavioral binding between two objects in a hierarchical relationship where it is important that the attached (supervised) object be able to differentiate certain service requests made by its supervisor from other requests. An attached object has exactly one supervisor, as illustrated in Figure 6.

10.3.2 An attached object may be detached from its current supervisor, or it may be reattached to a different supervisor. The latter operation is used when the previous supervisor has become damaged and is not intended as a general method for moving the object’s attachment, as the former supervisor is not notified of the change.

10.3.3 *Attach* — When sent to an unattached object, the attach operation creates a logical connection between the object and a supervisor. The object that is being attached creates a unique, private, non-zero numeric value, called an attach token. The attach token is treated as an attribute named AttachToken. It is a private attribute of the attached object, not visible through basic OSS services (see Section 11).

10.3.3.1 When an object is first created, it is unattached, and the value of its attach token is set to a default value of zero. An object is attached to another object as a formal relationship. The operation of attach generates the attach token, which is returned to the service user. The supervisor uses this token in subsequent critical service requests to identify itself to the attached object.

10.3.3.2 The attach operation also may accept settings for one or more attributes of the attached object, as defined for the attached object type. This allows the supervisor to provide values for attributes that are otherwise regarded as read-only values and cannot be set through the SetAttr service defined in Section 11. An example of an attribute value that it is often desirable to access in this way is the object specifier of the supervisor.

10.3.3.3 Requests to attach an object that attempt to set attributes shall be denied unless the attributes are among those accessible to the supervisor and all specified settings represent valid values of those attributes. The object type and identifier shall not be changed by the supervisor.

10.3.3.4 An attached object is owned by its supervisor.

10.3.3.5 The attach operation is invoked by the message service Attach by an intended supervisor. Requests to attach an already attached object shall be denied.

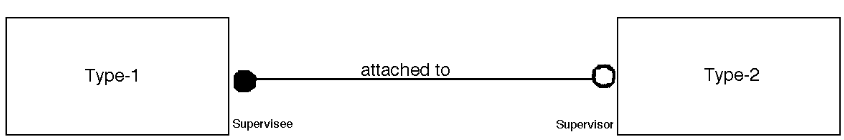

Figure 6
The Attachment Relationship

10.3.4 *Attach Set Attributes* — A supervisor may need the ability to set certain read-only attributes of one of its attached objects subsequent to the attach operation. The set attached attributes operation provides this capability to a supervisor of attached objects. The supervisor identifies itself by using the attach token for that object.

10.3.4.1 The definition of the attached object type may restrict the attributes that may be set by this operation. The attach set attributes operation shall be denied if the attributes or settings are invalid for this operation.

10.3.4.2 The attach set attributes operation is invoked by the message service AttachSetAttr sent by the object's supervisor and is otherwise invalid.

10.3.5 *Detach* — The detach operation breaks the logical connection between an attached object and its supervisor. The attach token is reset to zero, and the object becomes unattached.

10.3.5.1 The detach operation is invoked by the message service Detach sent by the object's supervisor and is otherwise invalid.

10.3.6 *Reattach* — The reattach operation is similiar to the attach operation, except that it is sent only to an attached object to change the logical connection from the attached object to a new supervisor. This operation is used to replace a damaged supervisor. Any existing connections to the old supervisor shall be closed. Note the reattach operation is vulnerable to misuse. Applications supporting the reattach operation may have additional requirements, such as notification sent to the previous supervisor, to provide a trace of misuse.

10.3.6.1 The reattach operation provides a unique attach token that has not been previously used by the attached object. This effectively disables its previous supervisor.

10.3.6.2 An attempt to reattach an object shall be denied unless the attributes and settings are valid for the operation.

10.3.6.3 The reattach operation is invoked with the message service Reattach sent to an attached object by the object's new supervisor and is otherwise invalid.

10.3.7 *Attach Supervised Object* — The attach supervised object operation is invoked by a service user to request a supervisor to attach to itself a valid target object. If the supervised object does not already exist or is not a valid target type for the supervisor, then the attached supervised object operation shall fail. The results of the operation are returned to the service user.

10.3.7.1 The attach supervised object operation is invoked with the service AttachSupervisedObject.

10.3.8 *Detach Supervised Object* — The detach supervised object operation is invoked by a service user to request a supervisor to detach from itself an attached object. The supervisor sends a detach request to the specified attached object. Regardless of any response from the specified supervised object, the supervisor shall consider it thereafter as unattached. This is required to allow a damaged attached object to be removed. This operation is successful except when the target object is not already attached to the supervisor.

10.3.8.1 The detach supervised object operation is invoked with the service DetachSupervisedObject.

11 Services and Scenarios

11.1 The services defined by OSS are contained in Table 2.

Table 2 Object Services

Message Service Name	*Type*	*Description*
GetAttr	R	Get values of specified attributes based on attribute filters.
SetAttr	R	Set values of specified attributes based on attribute filters.
GetAttrName	R	Set names of attributes of objects owned by the service provider.
GetType	R	Get types for objects owned by the service provider.

11.2 *Scope* — Scope is supported through the object specifier parameter. The object specifier provides a method for pointing to objects owned by the service provider that are otherwise not accessible to the service user. That is, the service provider may not provide direct services for, or to, that object. This can occur when an object for which the service provider offers services is an owner object, such as an aggregate or file directory, as described in Section 9. In some cases, the owned object may itself be remote from the service provider. For example, the owned object may be provided by a separate system.

11.2.1 The service provider may be an owner object with managerial responsibilities, and therefore it may prohibit direct access to one of its component or contained objects. In this case, requests concerning an owned object from a service consumer shall be directed to the owner object instead.

11.2.2 Object services use the *object specifier* for the owner of the target object(s). The construction of the object specifier is defined in Section 9.

11.2.3 Object type may be omitted from the object specifier where it may be otherwise determined without ambiguity. However, inclusion of type is always valid.

11.3 *Filtering* — An *attribute filter* is an optional set of one or more *attribute qualifications*. An *attribute qualification* is a boolean expression that makes a statement about the presence or values of attributes in a target object. It identifies an attribute, a *qualifying value* of that attribute, and a *qualifying relationship* that the value has to the target attribute. The attribute filter is a boolean that consists of the expression formed by an AND of the set of qualifications.

11.3.1 If the attribute is of text form, the qualifying value may be used as a *mask* with the embedded *wild characters* "?" (question mark) and "*" (asterisk). The character "?" may be used within the mask to represent "any single character" and may be repeated. The string "?????" represents any text string with a length of five characters.

11.3.2 The character "*" may be used in the mask to represent a variable-length string, including a null string. The string "*x" represents a string of any length that ends in "x"; the string "x*" represents any string that begins with "x".

11.3.3 When the character "*" is used by itself as the string "*", however, it represents any string of any non-zero length. It may also be repeated within a string, as in "*x*y*", which represents any string with embedded characters "x" and "y", such as "abxaby", "x_y", and "xy".

11.3.4 The comparison for text characters shall be case insensitive.

11.3.5 The qualifying value specifies a qualifying relationship, "R", between the value specified in the attribute qualification and the matching attribute of object instances. The qualifying value for the attribute is compared with the attribute of an instance of the target object to test the relationship.

11.3.6 If the qualifying value has the relationship "R" to the attribute of the target object, then the instance *qualifies* for the relationship and is included in the set of objects for which requested attributes are returned. For example, if the attribute name is "Length," qualifying value is the number 5, and the qualifying relationship is "is less than," then the Length attributes of all instances of the target object are tested. All instances with a "Length" attribute greater than 5 or equal to 5 qualify.

11.4 *Object Services Parameter Dictionary* — Table 3 defines all of the parameters, including the elements of complex parameters, used in object services.

Table 3 Object Services Parameter Dictionary

Parameter	*Definition*	*Form*
AttrData	The value of an attribute.	Varies with attribute. The form of an attribute's value is specified as part of the definition of an object type.
AttrFilter	Attribute filter.	Structure composed of AttrName, AttrData, AttrReln.
AttrName	The attribute's name.	Text. Varies with object type.
AttrReln	Qualifying relationship between the qualifying value and the matching attribute of object instances.	Enumerated: Equal To Not Equal To Less Than Less Than or Equal To Greater Than Greater Than or Equal To Present (specified attribute is present) Absent (specified attribute is absent) Contained (The qualifying value is in (i.e., equal to a member of) the set of the attribute's values.) Not Contained (If omitted, the relationship "Equal to" is assumed.)
AttrSetting	The name and value of an attribute.	Structure composed of AttrName and AttrData.
ErrorCode	Contains the code for the specific error found.	Enumerated: Unknown Object in Object Specifier Unknown Target Object Type Unknown Object Instance Unknown Attribute Name

		Read-Only Attribute — Access Denied
ErrorText	Text in support of the error code to provide additional information.	Text.
ObjAck	Acknowledgement code.	Unsigned integer. Possible values: Successful completion of request Error
ObjectAction	The name of an action to be performed on, or by, an object.	Text. Enumerated per individual object.
ObjectActionReportSatus	Status of receipt of an ObjectActionComplete-Notification.	Binary.
ObjectActionResult	List of return parameters, as name/value pairs, concerning the result.	List of ServiceParameters.
ObjectActionStatus	Status of action request.	Enumerated: Action was performed successfully. Action does not exist. Can not perform now – try later. Action will be performed and notification sent later. Action is prohibited. Target object unknown.
ObjectServiceList	Specified the services supported by a given object type.	Structure composed of ObjType, ServiceName
ObjID	Object identifier (ObjID).	Varies with object type.
ObjSetting	Attribute values for an object instance.	Structure composed of ObjID and (List of) AttrSetting.
ObjSpec	The object specifier, used to specify the owner of the target object.	Formatted text.
ObjStatus	Information concerning the success or failure of the operation.	Structure consisting of ObjAck and (List of) Status.
ObjType	Object type.	Object types are text strings reserved by individual standards. Object Services do not reserve object types.
OperationID	Identifies a specific request.	Unsigned Integer.
ServiceName	The name of a service or action to be performed on, or by, an object.	Text.
ServiceParameter	One or more arguments (parameters) providing additional information concerning the action requested.	Structure composed of ServiceParameterName and ServiceParameterValue.
ServiceParameterDef	A list of the parameter names that are supported for a specific service and object type.	A list of ServiceParameterName.
ServiceParameterName	Parameter name.	Text.
ServiceParameterValue	Parameter value.	Any. Varies depending on the parameter.
Status	Error information.	Structure composed of ErrorCode and ErrorText.

11.5 *Get and Set Attributes* — The GetAttr and SetAttr services are provided for reading and setting values of an object's attributes. They address attribute values of instances of objects. Figures 7 and 8 show the message flow for the GetAttr service.

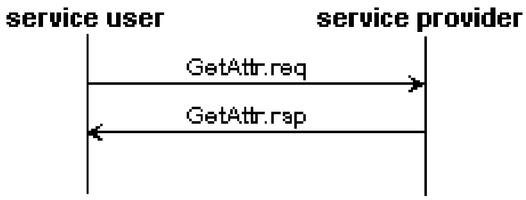

Figure 7
GetAttr Message Flow

Figure 8
SetAttr Message Flow

11.5.1 GetAttr and SetAttr allow access to attributes of objects that are owned by another object and are capable of addressing multiple levels of ownership (object hierarchy).

11.5.1.1 For example, GetAttr may be used as a "get directory" request to find the identifiers of all instances of one or more owned objects.

11.5.2 GetAttr and SetAttr may be used for objects that use a complex identifier, such as recipes with separate attributes for name and version.

11.5.3 GetAttr and SetAttr allow searching for those instances of an object that satisfy certain conditions through the specification of one or more qualifiers or filters. Only attributes of those instances of the desired object type that satisfy the conditions defined in the filters are returned by the service provider.

11.5.3.1 The filter is familiar to users of file services as a convenient way to obtain a partial directory of files, such as files with a date later than a specified date. This is particularly useful when the list of contents may be quite long.

11.5.4 The attribute value (all or a part of the list of ObjSetting) returned by the GetAttr service may be invalid if the acknowledge code of ObjStatus indicates a failure. In that case; the value(s) requested by the invocation of GetAttr service may be unknown, invalid or unavailable by any reason (e.g. corresponding hardware status, lack of privilege, mutual exclusion or other requirement not fulfilled by the application). Supplier shall document all conditions or timing requirements of any attributes if they are not always available.

11.5.5 The attribute value (all or a part of the list of ObjSetting) replied by the SetAttr service may be still unchanged if the acknowledge code of ObjStatus indicates a failure. In that case; the attribute value may be unchangeable, inhibited or blocked internally by any reason (e.g. corresponding hardware status, lack of privilege, mutual exclusion or other requirement not fulfilled by the application. The object providing the SetAttr service shall identify whether or not it is valid to change or set an attribute value. Supplier shall document all conditions and timing requirements of each attribute if they are not always allowed to be set.

11.5.6 *Object Specifier* — This parameter is used for specifying an owner object and may be omitted from the message. When included, it is a formatted text string that conforms to the description in Section 9. An object specifier is rejected by service providers that do not use owner or owned objects.

11.5.7 *Filter* — This is a optional list of qualifications to be applied to specifed attribute and may be omitted from the message. When included, the complete filter is formed by a logical AND of each attribute qualification in the list.

11.5.8 *Requested Attribute* — The final parameter in the GetAttr service gives the names of one or more attributes of interest. These are the attributes whose values shall be returned in the response, in the order requested.

11.5.9 *Settings* — In the SetAttr service, a list of one or more attribute name/value pairs is specified. This is the set of desired attribute values. SetAttr rejects any attempt to set a read-only attribute and returns information in Status, indicating the error and the attribute.

11.5.10 *ObjStatus* — This is a required parameter in the response message. It is a structure that consists of an acknowledge code and a list of status parameters. The acknowledge code is used to indicate errors that apply to the response as a whole. A status parameter is a structure consisting of a code indicating a specific error and accompanying text providing additional information. Text is often used to inform a person of the results of an operation.

11.5.11 Tables 4 and 5 define the parameters for the GetAttr and SetAttr services, respectively.

Table 4 GetAttr Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier, used to specify the owner of the target object.
ObjType	M	-	The type of the target object.
(List of) ObjID	C	-	The identifier of the target object. If present, identifiers are treated as a pre-filter of the form “ObjID = <identifier>”, where the individual identifiers are joined with logical OR’s.
(List of) AttrFilter	C	-	An attribute filter to be applied to the target object. If both AttrFilter and ObjID are omitted, attributes are requested for all instances of the target object type.
(List of) AttrName	C	-	The name of a desired attribute. If the name is “ObjType,” and if ObjType (above) is omitted, then the object type of all subordinate objects is requested. If omitted, then all public attributes of the target object are requested.
(List of) ObjSetting	-	M	Attributes that match the specified characteristics, per qualifying object instance. Setting value may not be valid if corresponding ObjStatus shows a failure.
ObjStatus	-	M	Information concerning the success or failure of the request.

Table 5 SetAttr Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier, used to specify the owner of the target object.
ObjType	M	-	The type of the target object.
(List of) ObjID	C	-	The identifier of the target object. If present, is treated as a primary filter of the form “ObjID = <identifier>”.
(List of) AttrSetting	M	-	An attribute’s name and desired value.
(List of) ObjSetting	-	M	The attributes’ resulting values. Requested setting value(s) may have not changed if corresponding ObjStatus shows a failure.
ObjStatus	-	M	Information concerning the success or failure of the request.

11.6 *GetType* — GetType is a service that is directed at object types rather than object instances. It is used to ask an owner object for the object types that it owns.

11.6.1 Figure 9 shows the message flow for the GetType service.

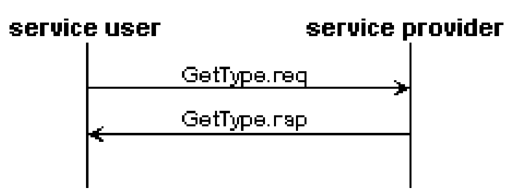

Figure 9
GetType Message Flow

11.6.2 Comments for the ObjSpec and ObjStatus parameters of GetAttr and SetAttr also apply to the parameters for the GetType service.

11.6.3 Table 6 defines the parameters for the GetType service.

Table 6 GetType Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier, used to specify the owner of the target object.
(List of)ObjType	-	M	The types of objects owned by the service provider.
ObjStatus	-	M	Information concerning the success or failure of the request.

11.7 *GetAttrName* — GetAttrName is a service that is directed at object types rather than object instances. It is used to ask for the names of the attributes of one or more objects owned by the service provider.

11.7.1 Figure 10 shows the message flow for the GetAttrName service.

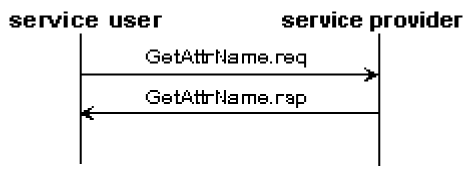

Figure 10
GetAttName Message Flow

11.7.2 Wild characters may be used in the object types requested.

11.7.3 Comments for the ObjSpec and ObjStatus parameters of GetAttr and SetAttr also apply to the parameters for the GetAttrName service.

11.7.4 Table 7 defines the parameters for the GetAttrName service.

Table 7 GetAttrName Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier, used to specify the owner of the target object.
(List of)ObjType	M	-	The type of the target object owned by the service provider. ObjType may use wild characters.
(List of)AttrName	-	M	The names of the attributes of each of the target object(s).
ObjStatus	-	M	Information concerning the success or failure of the request.

12 Additional Services

12.1 Additional services described in this section may have some restrictions when invoked. In some cases, services that are invoked may report a failure. For example: the owner of an object shall not delete the object during its lifecycle or while it is valid and required by another agent. Existence of an object may depend on preconditions, provided parameters, state of another object, corresponding operation, context of application, etc. Supplier shall document any restrictions or information regarding the validity of the additional services listed below.

12.1.1 This section defines the services required for additional operations defined in Section 10. These services are listed in Table 8.

Table 8 Additional Object Services

Message Service Name	*Type*	*Description*
Create	R	A request is made to create an object.
Delete	R	A request is made to delete an object.
Attach	R	A supervisor requests an object to attach itself to the supervisor.

AttachSetAttr	R	A supervisor requests to set one or more attributes of an attached object.
AttachSupervisedObject	R	A request is made to a supervisor to attach another object to the supervisor.
Detach	R	A supervisor requests an object to detach itself from the supervisor.
DetachSupervisedObject	R	A request is made to a supervisor to detach a specified attached object.
Reattach	R	A supervisor requests an object to reattach to itself to the new supervisor.
ObjectAction	R	A request for an object to perform an action.
ObjectActionCompletion	N	Notification that a delayed action has been completed, sucessfully or unsuccessfully.
GetServiceNames	R	A request to an object owner for a list of services supported by its owned objects.
GetServiceParameters	R	A request to an object for the service parameters supported for specified services.

12.2 *Object Services Parameter Dictionary* — Parameter definitions are provided in Section 11.1.

12.2.1 Table 9 defines the parameters used in services defined in Section 12, in addition to those parameters defined in Table 3.

Table 9 Additional Object Services Parameter Dictionary

Parameter	*Definition*	*Form*
AttachToken	Attach token provided by an object at the time it is attached or reattached.	Unsigned integer
TargetSpec	Object specifier of target object to attach or detach.	Formatted text for object specifier.

12.3 *Create* — The service user may request the service provider to create a new object and assign the value of one or more of its attributes. The request may be denied if an attempt is made to set attributes that are not allowed for that object type.

12.3.1 Parameters for Create are listed in Table 10.

Table 10 Create Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	M	In the request, the object specifier of agent providing the object create service. In the response, the object specifier of the new instance. NOTE: The values may be different in the request and the response. The parameter in the request may be “ ” (an empty string) if there is no object or the owner object is outside of the domain of the receiving entity. If the entity is the equipment itself rather than a component of equipment, the owner may be defined by “Equipment” even if no such object is defined.
ObjType	M	-	The object type to be created.
(list of) AttrSetting	C	C	Initial attribute settings. Conditions for inclusion of an attribute are object-specific in both request and response.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.4 *Delete* — The service user may request to delete an object.

12.4.1 Parameters for Delete are listed in Table 11.

Table 11 Delete Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	The object specifier of the object to be deleted.
(list of) AttrSetting	C	C	Conditions for inclusion of an attribute are object-specific both request and response.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.5 *Attach* — A service user may request an object to attach itself to the service user.

12.5.1 Parameters for Attach are listed in Table 12.

Table 12 Attach Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Specifier of server object to be attached.
AttachToken	-	M	Attach token. A value of zero shall be used if and only if the request to attach is denied.
(list of) AttrSetting	C	C	Settings for specific attributes. Object-dependent. Attributes in the list sent in the request and the response may be different.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.6 *AttachSetAttr* — A supervisor may request an attached object to set one or more attributes at any time while the object is attached.

12.6.1 Parameters for AttachSetAttr are listed in Table 13.

Table 13 AttachSetAttr Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Specifier of server object to be attached.
AttachToken	M	-	Attach token.
(list of) AttrSetting	C	C	Settings for specific attributes. Object-dependent. Attributes in the list sent in the request and the response may be different.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.7 *Detach* — The supervisor of an attached object may request the object to detach itself.

12.7.1 Parameters for Detach are listed in Table 14.

Table 14 Detach Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	The specifier of the attached object.
AttachToken	M	-	Attach token.
(list of) AttrSetting	C	C	Attribute settings. Object-dependent. Attributes in the list sent in the request and the response may be different.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.8 *Reattach* — An object may request an object attached to another supervisor to reattach to itself to the service user as its new supervisor.

12.8.1 Parameters for Reattach are listed in Table 15.

Table 15 Reattach Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Specifier of object to reattach.
AttachToken	-	M	Attach token. A value of zero shall be used if and only if the request to reattach is denied.
(list of) AttrSetting	C	C	Specific attribute settings. Object-dependent. Attributes in the list sent in the request and the response may be different.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.9 *AttachSupervisedObject* — A service user may request a supervisor to attach a specified object.

12.9.1 Parameters for AttachSupervisedObject are listed in Table 16.

Table 16 AttachSupervisedObject Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	The object specifier for the supervisor.
TargetSpec	M	-	The object specifier of the object to attach.
(list of) AttrSetting	C	C	Attribute settings. Object-dependent. May be omitted. Attributes in the list sent in the request and the response may be different.
ObjStatus	-	M	Information concerning the result of the requested operation.

12.10 *DetachSupervisedObject* — A service user may request a supervisor to detach a specified attached object.

12.10.1 Parameters for DetachSupervisedObject are listed in Table 17.

Table 17 DetachSupervisedObject Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	The object specifier of the supervisor.
TargetSpec	M	-	The object specifier of the object to be detached.
(list of) AttrSetting	C	C	Attribute settings. Object-dependent. May be omitted. Attributes in the list sent in the request and the response may be different.
ObjStatus	reserved	reserved	Information concerning the result of the requested operation.

12.11 *ObjectAction* — A service user may request a specific action to be performed by, or on, a particular object. The object specifier represents either the target object as its owner, depending upon the object and action.

12.11.1 Completion, either normal (successful) or abnormal, may be indicated in either of two ways. If the action can be completed in a very short time, then it should be completed before a response to the request is sent. If the action takes more time than would be normal for the response, or if the action must wait for one or more conditions to be fullfilled, then a response to the request indicating the action will be performed later and the notification sent of its completion. See Section 12.12 below.

12.11.2 Figure 11 illustrates the first case, where the action is completed before the response is sent. The value of ObjectActionStaus should be set to any value other than “Action will be performed and notification sent later”.

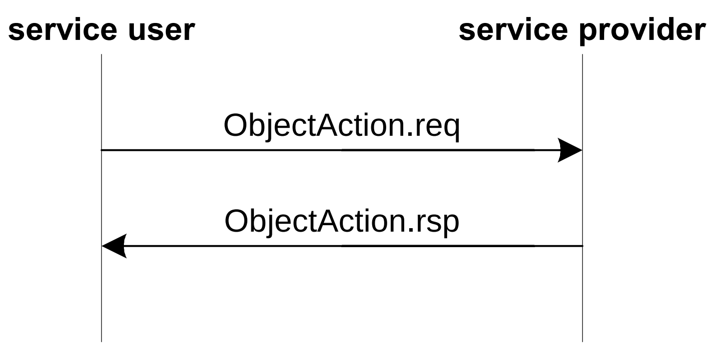

Figure 11
ObjectAction Request and Response

12.11.3 It is recommended that OperationID be always set to a unique non-zero value. However, if a value of zero is used, then the host should not send additional request until informed of the results of the outstanding request. Otherwise it may be ambiguous to which request an ObjectActionCompletion notification pertains. The definition of the target object type must include specification of the specific actions that it supports, together with the arguments that are required and the arguments that are optional for each action.

Table 18 ObjectAction Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
OperationID	M	M(=)	Operation identifier. Used where the service user may send multiple requests to link subsequent events to the original requests. May be zero otherwise.
ObjSpec	C	-	The object specifier of the target object or owner of the target object.
ObjectAction	M	-	Specific action requested.
(list of) ServiceParameter	C	C	A list of name/value pair arguments providing additional information about the request.
ObjectActionStatus	-	M	Information concerning the result of the requested action.
(list of) ObjectActionResult	-	C	List of return parameters, as name/value pairs, concerning the result.

12.12 *ObjectActionCompletion Notification* — This notification is sent to the requestor of an earlier action when the completion of that action occurred after the response to the request was sent.

12.12.1 Figure 12 illustrates the scenario where the notification message is sent. The value of ObjectActionStatus should be set to “Action will be performed and notification sent later”.

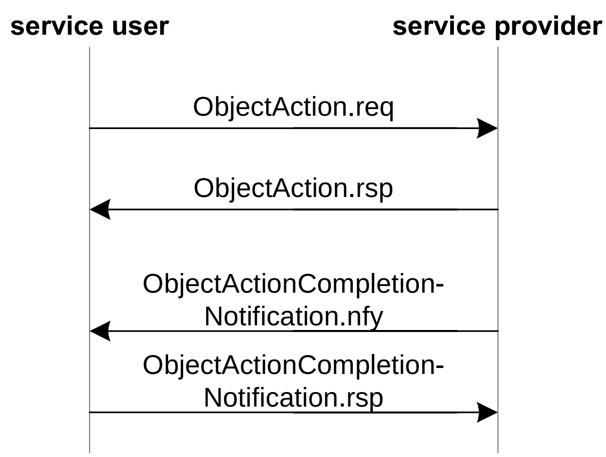

Figure 12
ObjectAction Request, Response, and Notification

Table 19 ObjectActionCompletion Notification

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
OperationID	M	-	Operation identifier. Set to the same value as in the original request.
(list of) ServiceParameter	M	-	A list of name/value pair arguments providing information about the status of the completion.
(list of) ObjectActionResult	C	-	List of return parameters, as name/value pairs, concerning the result.
ObjectActionReportStatus	-	M	Indicates whether the report has been received with no errors.

12.13 *GetServiceNames* — A service user may ask an object owner for a list of the services supported by its owned objects.

12.14 The definition of the target object type must include specification of the specific actions that it supports, together with the arguments that are required and the arguments that are optional for each action.

Table 20 GetServiceNames Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier of the owner object.
(list of) ObjType	M	M	A list of object type values
ObjStatus	-	M	Information concerning the result of the requested action.
(list of) ObjServiceList	-	M	List of structures of the form ObjType, (list of) service names.

12.15 *GetServiceParameters* — This message may be sent to an object to determine the service parameters that are used by that object for a set of different services that it supports.

Table 21 GetServiceParameters

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	C	-	The object specifier of the owner object.
ObjType	M	-	The type of object referenced.
(list of) ServiceName	M	-	A list of service names.
ObjStatus	-	M	Information concerning the result of the requested action.
(list of) ServiceParameterDef	-	C	List of structures that contain a service name with a list of parameter names.

13 Applications

13.1 This section provides examples of applications of object services.

13.2 *Get All of an Object's Attributes* — In the most straight-forward case, GetAttr is used to get all of the current attribute values of a single target object known to the provider of the GetAttr service. The object specifier is omitted, and the object type is set to the type of the target object. To get all of the object’s attributes, both the attribute filter and the names of requested attributes are also omitted.

13.3 *Determine All Objects of a Specific Type and with Specific Characteristics* — To determine subordinate objects with specific characteristics, such as of type “Module” with an identifier *ObjID* starting with “ABC”, set object type to “Module”. In the attribute filter, set the attribute name to “ObjID”, set the attribute value to “ABC*”, and set the qualifying relationship to “is equal to” (or omit it).

13.4 *Determine Specific Attributes of a Specific Object Instance* — To determine the current value of certain attributes of a specific object, set the object type appropriately. Either set the list of ObjID to a list containing the one identifier of the target instance, or alternatively, in the attribute filter, set the attribute name to “ObjID”, set the attribute value to the identifier, and set the qualifying relationship to “is equal to” (or omit it).

13.5 *Determine Types of Subordinate Objects* — To determine all object types that are owned by another object, the GetType service is used with the single parameter of the object specifier of the owner. The service provider returns an error of “Unknown object type” if it has no types of owned objects.

13.6 *Determine Names of Attributes of Subordinate Objects* — To determine the names of the attributes of specific objects owned by the service provider, the GetAttrName service is used with two parameters: the object specifier of the owner and a list of the types of the target objects. The service provided returns an error of “Unknown object type” if it has no types of owned objects.

14 Requirements for Compliance

14.1 Object Services are common to all service resources that define public objects with operations for getting (reading) and setting (writing) attribute values and for getting object types and attribute names for objects. Object services provide common definitions for public objects and object services that may be incorporated into these service resources, thereby avoiding unnecessary duplication.

14.2 *Fundamental Requirements* — All objects compliant to any part of OSS shall be subtypes of the top object. That is, they shall inherit (provide) the *ObjType* and *ObjID* attributes as described in Section 8.2.

14.2.1 They shall provide documentation of their public attributes in the form of an Object Attribute Definition table as described in Section 5.3.

14.2.2 They shall also provide the services GetAttr and SetAttr as defined in Section 11.4. Support for an owner's object specifier and filter are not required for fundamental compliance with OSS. If the service user provides parameters for scope or filter in its request, they may be ignored by the service provider. However, they shall not cause errors in the response due to their presence.

14.3 *Additional Capabilities*

14.3.1 *Filters* — Support for attribute filters in GetAttr and SetAttr requests is an optional capability.

14.3.2 *Owner Objects* — All owner objects (aggregates, containers, and supervisors) shall support both scope and filters for the GetAttr and SetAttr services, as defined in Sections 9.2, 11.1, and 11.2.

14.3.2.1 In addition, they shall provide the service GetType as defined in Section 11.5, with support for wild characters in the specification of object types.

14.3.3 *Multiple Inheritance Hierarchy* — Inheriting objects shall identify inherited objects with an inheritance expression in the object specifier.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI E39 and was approved by full letter ballot procedures on March 16 and April 21, 2000 by the Japanese Regional Standards Committee.

A1-1 Overview of Object Terminology

A1-1.1 This section provides an introduction to the basic terminology for object models.

A1-1.2 A *model* is an abstraction of a problem, a real-world phenomena, things, etc. for the purpose of understanding it. A model typically is a simplification that omits nonessential details. *Examples: architectural scale models, behavioral state models.*

A1-1.3 An *object* is an entity (concept, abstraction, or “real world” thing) with a particular behavior and with associated properties (information, or attributes). An *object type* (class) refers to a group of objects that have common (1) properties (but not specific values), (2) behavior, (3) relationships with other objects, and (4) semantics (public interfaces). The term “object” may be used either to refer to a type of object or to a particular instance of an object type.[8] The notation used for diagrams of objects used in this document is described in Section A1-2.

A1-1.4 An *object model* is a static graphic model of objects to show structure — the identity of objects, their attributes and operations, and their relationships with one another.

A1-1.5 An *instance* of an object is an instantiation of an object type. For example, a specific installation of equipment is an instance of the object type “Equipment.”

A1-1.6 Objects have items of associated information called *attributes*. For example, for an object “Equipment,” attributes of interest include the manufacturer, model, serial number, and a logical user-assigned name (nickname). Attributes used to uniquely identify a particular instance of an object type is called an identifier. An object may have more than one *identifier*. Also, a set of more than one attribute may be used as an identifier. In the example of “Equipment,” name could be used as an identifier, and the combination of manufacturer and serial number also could be an identifier.

A1-1.7 Objects have *operations* that may be applied to or by an object type. Operations are functions or transformations that are either performed by, or on, an object. Operations of interest to Object Services are “get (read) attributes,” “set (write) attributes,” and “get type.” A *service* provides a *service user* with an interface to the functionality of the operation.

A1-1.8 A high-level model may show a particular type of object with certain operations, while a more detailed model shows that a second type of object actually performs one or more of the operations on the first object. As an example, a model might show a process program object with the operation “delete,” to show that the “delete” operation is inherently associated with the process program. A more detailed model might show that a “process program manager” actually performs the operation of deleting a process program.

A1-1.9 A *method* is an implementation of an operation (e.g., the software code that performs the operation).

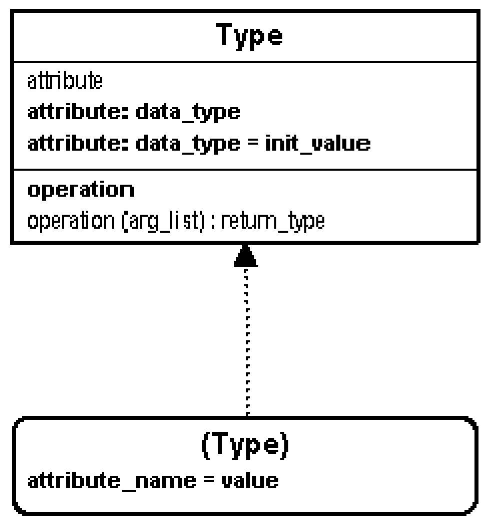

Figure A1-1
Object Type and Instance

8 The term “object” is used by some authors to only refer to instances and by other authors as a synonym for object type.

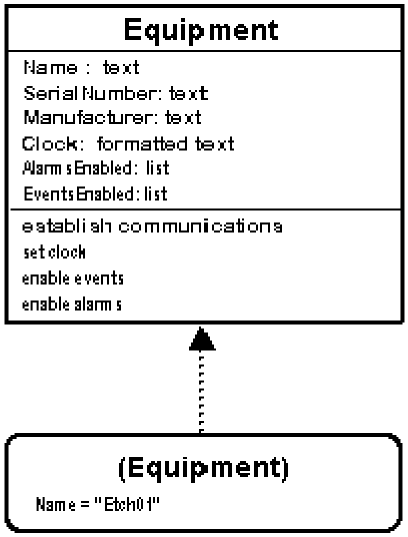

Figure A1-2
Example of Object Type and Instance

A1-2 Object Modeling Technique (OMT) Notation

A1-2.1 The material contained in this section is provided as a reference for auxiliary information.

A1-2.1.1 Object Modeling Technique (OMT) is a graphical notation for models of objects that is useful for analyzing a wide variety of problems, in all phases of software design and development, and in preparing documentation. OMT was developed by Rumbaugh, Blaha, et al., in *Object Modeling and Design*, Prentice Hall, Englewood Cliffs, NJ, ©1991. OMT has been adopted by different standards to describe requirements in terms of objects and relationships between objects. The purpose of this document is to provide a description of OMT notation as a reference for such SEMI standards and other SEMI documents.

A1-2.2 *Basic Notation* — Figure A1-1 illustrates notation for object type, showing object type, object attributes, object operations, object instance, and the relationship between an object type and instance. Figure A1-2 provides an example.

A1-2.2.1 Object *types* in OMT are shown as rectangles. The rectangle may be further subdivided into two or three parts. The object type always appears at the top. Object *attributes* are shown in a second part of the rectangle. *Operations* are shown in a third part of the rectangle. High-level models often omit the operations section and sometimes omit the attributes section.

A1-2.2.2 The *name* of an attribute may be followed by additional details, such as data type and initial value.

A1-2.2.3 *Instances* of objects are shown as rounded rectangles. The *instantiation* relationship is shown by a dotted arrow from an instance of an object type to the type.

A1-2-2.4 The example for an object type "Equipment" is shown in Figure A1-2; here "Etch01" is a specific real-world installation of type "Equipment."

A1-2.3 *Associations* — An association describes a set of potential bi-directional relationships between instances of objects. An association uses a formal structure and semantics.

A1-2.3.1 An association shows a specific multiplicity at both ends of the relationship. For example, a single factory manufacturing system may be associated with many equipment (one-to-many). Possible multiplicities of association types are shown in Figure A1-3.

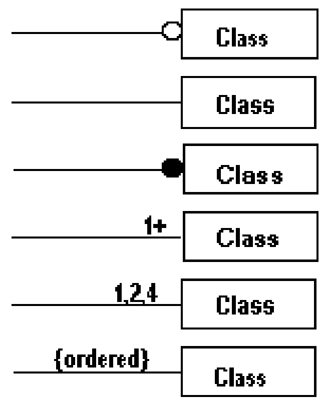

Figure A1-3
Multiplicities of Associations

A1-2.3.2 Figure A1-4 shows an example of a one-to-one relationship. The name of the association (using a verb) appears above the line connecting a pair of objects and describes the relationship that the object to the left (or above) has to the object to the right (or below).

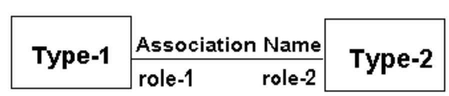

Figure A1-4
Association of Objects

A1-2.3.3 The name of the role of each object within the relationship may be placed beneath the line and near that object. Role names are nouns. In the example above, the roles might be "supervisor" and "subordinate." Role names are optional.

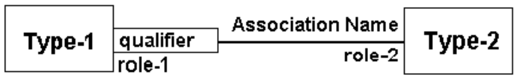

Figure A1-5
Qualified Association

A1-2.3.4 A *qualified association*, shown in Figure A1-5, uses a *qualifier* to reference an object. *Qualifiers* may be shown to specify the identifier used by one object to associate with instances of the other object. If Type-1 object is "Factory Host" and Type-2 object is "Equipment," a user-assigned "name" attribute may be used as a qualifier for the equipment.

A1-2.3.5 Figure A1-6 illustrates a *link object*, where link attributes are placed in an object box that is attached to the association with a loop. A *link object* may be used to show attributes that are dependent on the association between instances of one object type to instances of another type.

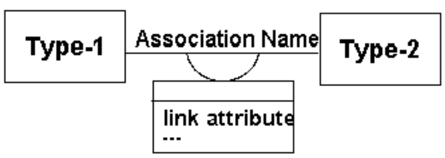

Figure A1-6
Link Object

A1-2.3.6 Figure A1-7 gives an example of a link object for the association "Authorized On" between an "Authorized User" and "Equipment."

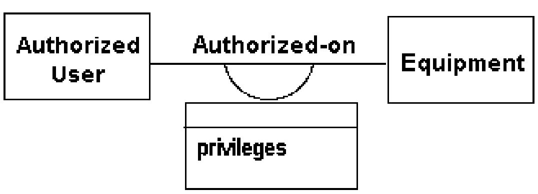

Figure A1-7
Example of a Link Object

A1-3 Generalization and Inheritance

A1-3.1 Figure A1-8 shows the concept of *generalization*. Generalization categorizes a set of object types and allows the abstraction of their common features into a supertype, with refinements of the *supertype* shown as *subtypes*. The subtype may be thought of as a specialization of the supertype. For example, "vehicle" is a supertype with many subtypes, including "aircraft," "automobile, "cart," and "robot."

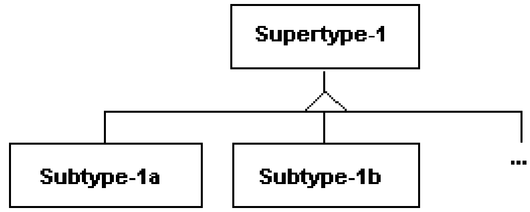

Figure A1-8
Non-Overlapping Subtypes

A1-3.1.1 An instance of a subtype is also an instance of its supertype. Attributes and operations of the supertype are inherited by all the subtypes. That is, the subtype has all of the same attributes and operations of the supertype, and in addition it adds attributes and operations of its own.

A1-3.1.2 The OMT notation for the generalization (supertype/subtype) relationship is shown by a solid triangle. White triangles indicate that the subtypes are *non-overlapping*; an instance of one subtype may not be an instance of another subtype.

A1-3.1.3 The method for a subtype of an object might be different from that of the supertype or from a different subtype, perhaps due to more specialized knowledge that allowed a more efficient implementation for the subtype. As an example, a Geometrical Figure object type might have the operation "draw." The methods for subtypes of "circle" and "rectangle" would differ, however.

A1-3.1.4 Figure A1-10 gives an example of an "agent" as a generalization of various types of active entities that might be found in a factory, and "equipment" as a generalization of specific kinds of equipment.

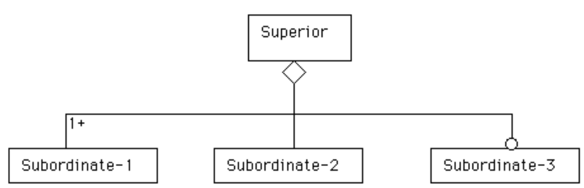

Figure A1-9
Aggregation with Two Component Types

A1-3.2 *Object Composition and Containment* — Figures A1-9 and A1-10 illustrate the diamond notation used to show aggregation. An aggregation object is also referred to as an assembly in object-oriented literature.

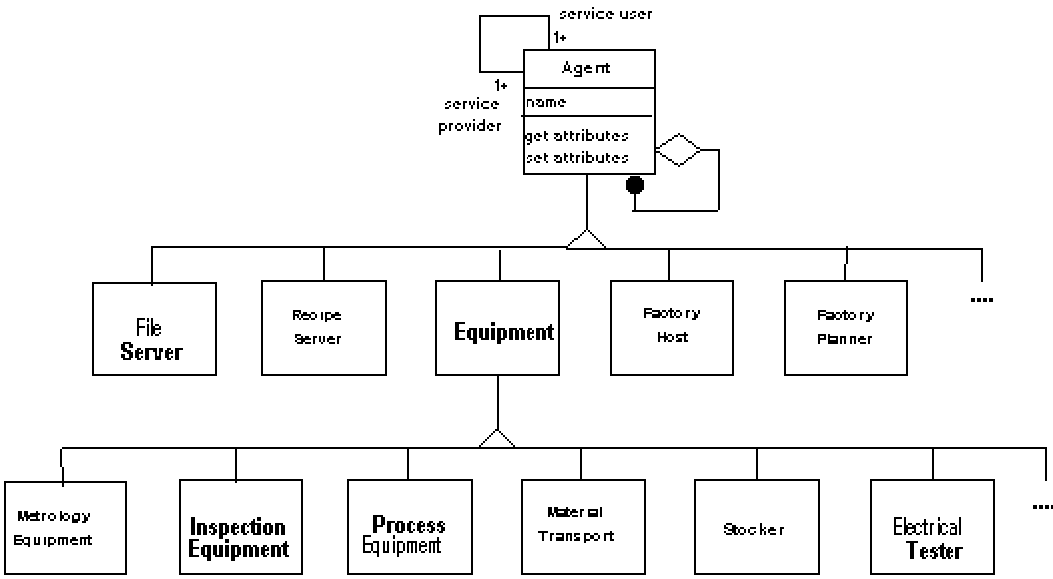

Figure A1-10
An Example of Generalization

A1-3.2.1 An aggregation object is composed of other objects called the *components* of the aggregation. Components may be of the same type as the aggregation (illustrated in Figure A1-10), or they may be of one or more different types.

A1-3.2.2 In Figure A1-9, the “Superior” object type is composed of one or more objects of type “Subordinate-1,” of exactly one component of object type “Subordinate-2,” and of zero or one objects of type “Subordinate-3.”

A1-3.2.3 In addition, an aggregate also may be optionally composed of other objects of the same type, as Figure A1-10 illustrates. The “agent” in this figure is a very general supertype of a factory system. Additional subtypes of agents, not shown in the figure, could include cells, clusters, and cluster modules. Cells, with equipment as components, and clusters, with modules as components, are examples of types of agents that are aggregates composed of other subtypes of agent.

SEMI E39.1-1101
SECS-II PROTOCOL FOR OBJECT SERVICES STANDARD (OSS)

This standard was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1995; previously published December 1996.

1 Purpose

1.1 This document maps the services and data of the parent document to SECS-II streams and functions and data definitions.

2 Scope

2.1 This document applies to all implementations of Object Services that use the SECS-II message protocol (SEMI E5).

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Applicable Documents

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

4 Mapping of Object Services

4.1 Table 1 shows the specific SECS-II streams and functions that shall be used for SECS-II implementations for the object services defined in OSS.

Table 1 Services Mapping Table

Message Name	*Stream, Function*	*SECS-II Name*
GetAttr.req	S14,F1	GetAttr Request
GetAttr.rsp	S14,F2	GetAttr Data

5 Service Parameter Mapping

5.1 Table 2 shows the mapping between message parameters defined by OSS and data items defined by SECS-II. For parameters specified in the definitions of an OSS service, either the parameters themselves, or individual elements of complex parameters, map to a specific data item.

Table 2 Service Parameters Item Mapping Table

Parameter Name	*SECS-II Data Item*
AttachToken	OBJTOKEN
AttrData	ATTRVAL
AttrName	ATTRID
AttrRein	ATTRRELN
ErrCode	ERRCODE
ErrText	ERRTEXT
ObjAck	OBJACK
ObjectAction	SVCNAME
ObjectActionReportStatus	DATAACK
ObjectActionStatus	SVCACK
ObjID	OBJID
ObjSpec	OBJSPEC
ObjType	OBJTYPE
OperationID	OPID
ServiceParameter	L,2 <SPNAME> <SPVAL>
ServiceParameterName	SPNAME
ServiceParameterValue	SPVAL
TargetSpec	TARGETSPEC

5.2 *SECS-II Data Items Without Corresponding SEMI E94 Parameters*

5.2.1 Table 3 contains the SECS-II data items that do not correspond to SEMI E39's service parameters.

Table 3 Additional Data Item Requirements Table

Function	*SECS-II Data Item*
Used to satisfy SECS-II conventions for linking a multi-block inquiry with a subsequent multi-block message. Neither required nor specified by OSS.	DATAID
Used to inform receiver of total message length size for SECS-II multi-block conventions. Neither required nor specified by SEMI E39.	DATALENGTH
Used to satisfy SECS-II multi-block requirements. Neither required nor specified by OSS.	GRANT

6 Data Item Format Restrictions

ATTRID Format: 20

The ASCII version of ATTRID is restricted to the characters from 20_{16} through $7E_{16}$, excluding the following characters: the "greater than" symbol ">", the colon ":", the question mark "?", the asterisk "*", and the tilde "~". The space character (20_{16}) may not be used as the first or last character. Maximum length is 40 characters.

OBJTYPE Format: 20

The ASCII version of OBJTYPE is restricted to the characters from 20_{16} through $7E_{16}$, excluding the following characters: the "greater than" symbol ">", the colon ":", the question mark "?", the asterisk "*", and the tilde "~". The space character (20_{16}) may not be used as the first or last character. Maximum length is 40 characters.

OBJID Format: 20

The ASCII version of OBJID is restriced to the characters from 20_{16} through $7E_{16}$, excluding the following characters: the "greater than" symbol ">", the colon ":", the question mark "?", the asterisk "*", and the tilde "~". The space character (20_{16}) may not be used as the first or last characer. Maximum length is 80 characters.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E40-0702
STANDARD FOR PROCESSING MANAGEMENT

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published in 1995; previously published November 2001.

1 Purpose

1.1 Automated management and command of material processing in equipment is a crucial aspect enabling factory automation. This standard addresses the communications needs within the semiconductor manufacturing environment with respect to the processing of material in an equipment.

1.2 This standard specifies the application of the appropriate processing to specified material received at the processing agent. It describes the concepts of material processing, the behavior of the equipment in relation to processing, and the messaging services which are needed to accomplish the task.

1.3 The communications services defined here enable standards-based interoperability of independent systems. They allow application software to be developed that can assume the existence of these services and allow software products to be developed which offer them.

1.4 Implementation of automated processing management will help eliminate misprocessing of material. The adoption of the standards described will greatly reduce the effort required to integrate compliant equipment components and reduce time to set up for processing. Compliance requires a minimal but specific set of standard services.

2 Scope

2.1 The scope of this standard is automated material processing based on discrete processing jobs. It provides the functionality required for process management for modules within a cluster tool. It may be applied to sub-systems of other multi-resource equipment, as well as to host control of many types of equipment.

2.2 This standard supports individual management of jobs for identical processing of material within a group and concurrent processing of independent groups. Where material contains other material (such as carriers containing wafers), processing may be specified in terms of either material type.

2.3 A simple tuning mechanism is provided for limited feedforward and feedback control between process steps. A method is defined for taking advantage of recipe variable parameters. This is not expected to satisfy all closed loop control requirements. Other mechanisms are anticipated with greater flexibility for late tuning and handling complex data.

2.4 This standard does not provide services for receiving material for processing, or disposing of it after processing is complete. Automation of material transfer is assumed to be provided through other services, such as those defined in applicable SEMI standards.

2.5 This standard presents a solution from the concepts and behavior down to the messaging services. It does not define the messaging protocol.

2.6 A messaging service includes the identification that a message shall be exchanged and a definition of the data which is contained in that message. It does not include information on the structure of the message, how the data is represented within the message, or how the message is exchanged. This additional information is contained within the message protocol.

2.7 The defined services may be applied to multiple protocols. Information on the mapping of processing management services to special protocols (e.g., SECS-II) are added as adjunct standards.

2.8 The services assume a communications environment in which a reliable connection has been established between the user of the services and the provider of the services. Establishing, maintaining, releasing a connection, and handling communication failures are beyond the scope of this standard.

2.9 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E53 — Event Reporting

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 The following definitions are arranged in alphabetical order. Some definitions use terms defined elsewhere within this section. No references beyond this section should be necessary for a basic understanding of these terms.

4.2 *Definitions*

4.2.1 *agent* — an intelligent system within a factory that provides one or more service resources and uses the services of other agents. A generalization of host, equipment, cell, cluster, cluster module, station controller, and work station. Agents are associated with a physical system or a collection of physical systems, including computer platforms.

4.2.2 *form* — type of data representing information contained in an object attribute or service message parameter.

4.2.3 *fundamental requirements* — the requirements for information and behavior that must be satisfied for compliance to a standard. Fundamental requirements apply to specific areas of application, objects, or services.

4.2.4 *post-conditioning* — activities performed by the processing resource after departure of the material being processed but related to the processing of that material (e.g., cleanup).

4.2.5 *pre-conditioning* — activities performed by the processing resource before arrival of the material being processed but related to the processing of that material.

4.2.6 *processing agent* — an intelligent system within a factory which is independently capable of providing manufacturing value added to material.

4.2.7 *processing resource* — an entity within a processing agent which provides the manufacturing value added to material.

4.2.8 *process job* — a material processing job for a processing resource specifying and tracking the processing to be applied to the material.

4.2.9 *recipe* — the pre-planned and reusable portion of the set of instructions, settings, and parameters under control of a processing resource that determines the processing environment seen by the material. Recipes may be subject to change between runs or processing cycles.

4.2.10 *recipe executor* — a component of a module that stores and executes recipes.

4.2.11 *recipe namespace* — a logical management domain with the responsibility for the storage and management of recipes. It ensures the uniqueness of recipe identifiers and provides services pertaining to recipes stored within that domain.

4.2.12 *service* — the set of messages and definition of the behavior of a service-provider that enables remote access to a particular functionality.

4.2.13 *service-provider* — the software control entity that is the provider of a particular functionality which may be accessible remotely.

4.2.14 *service-user* — the software control entity that is the user of any of the related services.

4.2.15 *supervisor* — an entity or entities having supervisory control responsibilities for one or more processing resource. It is the service-user of the processing management services.

4.2.16 *tuning* — specification of information which supplements the pre-defined recipe used to achieve the particular process goals.

4.3 *Data Type*

4.3.1 *boolean* — may take on one of two possible values, equating to TRUE or FALSE.

4.3.2 *enumerated* — may take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

4.3.3 *form* — type of data: positive integer, unsigned integer, integer, enumerated, boolean, text, formatted text, structure, list, ordered list.

4.3.4 *formatted text* — a text string with an imposed format. This could be by position, by use of special characters, or both.

4.3.5 *integer* — may take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

4.3.6 *list* — a set of one or more items that are all of the same form (one of the above forms).

4.3.7 *ordered list* — a list for which the order in which items appear is significant.

4.3.8 *positive integer* — may take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

4.3.9 *structure* — a complex structure consisting of a specific set of items, of possibly mixed data types, in a specified arrangement.

4.3.10 *text* — a text string. Messaging protocol may impose restrictions, such as length or ASCII representation.

4.3.11 *unsigned integer* — may take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

5 Conventions

5.1 *Harel State Model* — This document uses the Harel State Chart notation to describe the dynamic behavior of the objects defined. An overview of this notation is presented in an appendix of SEMI E30. The formal definition of this notation is presented in *Science of Computer Programming 8*, “Statecharts: A Visual Formalism for Complex Systems,” by D. Harel, 1987.

5.1.1 The Harel notation does not include the concept of “creation” and “deletion” of state models to represent transient entities. The “job” described in this document is such an entity, where each new job created uses a copy of the same state model. In this document, an oval is used to denote the creation of an entity and also the deletion of that entity.

5.1.2 Transition tables are provided in conjunction with the state diagrams to describe explicitly the nature of each state transition. A transition contains columns for Transition #, Current State, Trigger, New State, Action(s). The “trigger” (column 3) for the transition occurs while in the “current” state. The “actions” (column 5) include a combination of (1) actions taken upon exit of the current state, (2) actions taken upon entry of the new state, and (3) actions taken which are most closely associated with the transition. No differentiation is made.

5.1.3 The state models included in this standard are a requirement for Processing Management compliance. A state model consists of a state model diagram, state definitions, and a state transition table. When using SEMI E30, E53 or similar style collection events, all state transitions in this standard, unless otherwise specified, shall correspond to collection events.

5.1.4 A state model represents the host’s view of the equipment, and does not necessarily describe the internal equipment operation. When using collection events, all Processing Management state model transitions shall be mapped sequentially into the appropriate internal equipment collection events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the Processing Management state models for transition to another state. In the case, the equipment makes the required transition without any additional actions in this situation.

5.2 *Object Attribute Representation* — The object information models for standardized objects will be supported by an attribute definition table with the following column headings:

Attribute Name	*Definition*	*Access*	*Requirement*	*Form*
The formal text name of the attribute.	Description of the information contained.	RO or RW	Y or N	(see below)

5.2.1 The Access column uses RO (Read Only) or RW (Read and Write) to indicate the access that service-users have to the attribute.

5.2.2 A ‘Y’ or ‘N’ in the requirement (Rqmt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

5.2.3 The Form column is used to indicate the format of the attribute. (See Section 4.1 for definitions.)

5.3 *Service Message Representation*

5.3.1 *Service Resource Definition* — A service resource definition table defines the specific set of messages for a given service group, as shown in the following table:

Message Service Name	*Type*	*Description*
Message Name	N or R	The intent of the service.

5.3.1.1 Type can be either N = Notification or R = Request.

5.3.1.2 Notification type messages are initiated by the service provider, and the provider does not expect to get a response from the consumer/subscriber.

5.3.1.3 Request messages are initiated by a service consumer or subscriber. Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

5.3.2 *Service Parameter Dictionary* — A service parameter dictionary table defines the parameters used in a service, as shown in the following table:

Parameter	*Form*	*Description*
Parameter X	Data Type	A parameter called X is B in A.

5.3.2.1 A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and contents of the corresponding primitive.

5.3.2.2 The Form column is used to indicate the type of data contained in a parameter. (See Section 4.2 for definitions.)

5.3.2.3 The Description column in the Service Parameter Dictionary table describes the meaning of the parameter, the values it can take on, and any inter-relationships with other parameters.

5.3.2.4 To prevent the definition of numerous parameters named "XxxList," this document adopts the convention of referring to the list as "(List of) Xxx." In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type. Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element unless zero elements are specifically allowed.

5.3.3 *Service Message Definition* — A service message definition table defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Rsp/Cnf*	*Description*
Parameter X	(see below)	(see below)	A description of the service.

5.3.3.1 The columns labeled Req/Ind and Rsp/Cnf link the parameters to the direction of the message. The message sent by the initiator is called the "Request." The receiver terms this message the "Indication" or the request. The receiver may then send a "Response," which the original sender terms the "Confirmation."

5.3.3.2 The following codes appear in the Req/Ind and Rsp/Cnf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

M	**Mandatory Parameter** — Must be given a valid value.
C	**Conditional Parameter** — May be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of the other parameter.
U	**User-Defined Parameter**
-	The parameter is not used.
=	(for response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

6 Overview

6.1 Processing management is concerned with the processing of material by a processing resource. Its principle function is to ensure that material delivered to the processing resource is processed with the correct recipe. It defines the services needed by a supervisor (service-user) to initiate and track processing of a particular material. It also defines commands which affect the processing operation.

6.1.1 The processing resource is the entity which adds manufacturing value to the material. It may take several forms, including the processing element of a cluster tool process module or the entity managing processing for a complete stand-alone equipment. The processing agent is considered to be the provider of the processing services.

6.1.2 Process management allows for pre-conditioning before material arrival and post-conditioning after material departure. A simple tuning mechanism provides support for limited feedforward and feedback control. The tuning, applied at process initiation, sets recipe variable parameters.

6.1.3 The services are fully defined in terms of the functionality provided by the processing agent (service-provider) and, as such, do not dictate the architecture of the supervisor (service-user).

6.1.4 This standard describes the concepts and processing model on which the communications are based, followed by the detailed behavioral model used. It then describes the standard object attributes and message services in detail.

6.2 *Compliance* — Compliance to this standard includes adherence to all stated requirements in this document where implemented. Standard services are to be used where related functionality is required. This includes defined message services and state models.

6.2.1 Some capabilities are not required to be supported for compliance, such as queuing, multiple concurrent jobs, material groups, manual start, pause/ resume, and tuning. Required capabilities are indicated throughout the document and are also listed in the Fundamental Requirements section.

6.2.2 A processing agent shall provide the fundamental requirements, plus the set of optional services, appropriate to achieve effective processing management for the particular hardware architecture and automated processing requirements.

7 Concepts

7.1 *Material Processing Model* — Processing management ensures that the appropriate processing is applied to a particular material by a processing resource through the definition of a process job. The process job provides a widely applicable supervisory control capability for automated processing of material in equipment, irrespective of the particular process being used.

7.1.1 This standard assumes that, given the material and the recipe specification, the processing resource is capable of independently achieving the required processing objectives.

7.1.2 Processing management does not provide services for material movement, but the service-provider does need to coordinate its activities with regard to the receiving and sending of material, thereby maintaining system integrity.

7.2 *Process Job* — The process job is a dynamic object specified by the process supervisor (service-user) to effect material processing by the processing resource. The high-level job contains all the information required by the processing resource to achieve processing of the material, once it arrives, without further intervention by the supervisor.

7.2.1 The process job encompasses up to four sequential phases:

- processing resource pre-conditioning before material arrival,
- material and processing resource preparation for processing,
- material processing, and
- processing resource post-conditioning after material departure.

7.2.2 The material processing phase is the only phase in which the material is altered and is the only required phase.

7.2.3 This standard specifies services for the creation, control (pausing, aborting, etc.) and tracking of the process job. It does not define the low-level control of processing since this is application-dependent. The processing resource performing a process job is responsible for doing whatever is appropriate to achieve its processing objectives, as specified by the recipe and tuning parameters.

7.2.4 The material specified in a process job may be the actual single material elements to be processed or a container, such as in the case of a cassette of wafers.

7.2.5 The process job lifecycle may extend beyond the active processing of the material. It may exist from before material arrival, through setup and processing, and until after material departure. This allows for material processing-related pre-conditioning of the processing resource before the material is received and for processing resource post-conditioning (e.g., cleanup) after material is sent. Pre-conditioning and post-conditioning support is not a fundamental requirement.

7.2.6 The processing resource may provide process job queuing in order to offer flexibility in systems where work is pre-scheduled or the order of material arrival is unknown. Queuing is the acceptance of multiple process jobs in advance of performing the processing activities. Queuing is generally needed to support more complex systems requiring concurrent and consecutive jobs (see below). The jobs are listed in the queue in the order created. Execution order may be significant, such as consecutive jobs on the same material. Queuing is not a fundamental requirement.

7.3 *Relation to Material Movement* — Processing Management does not provide services for receiving material into the processing agent domain for processing or sending the material away after processing is complete.

7.3.1 Processing depends on the presence of the material, and material departure depends on process completion. There is also an interdependency requiring synchronization with material movement if processing resource pre-conditioning and post-conditioning are applied. The equipment is responsible for maintaining integrity between material transfer and processing.

7.3.2 Material movement management is outside the scope of this standard but may be achieved using applicable SEMI standards.

7.4 *Processing Description* — The description of the processing to be applied by the Process Job is crucial. The description may be supplied in the form of a Process Recipe (see SEMI E42) or a Process Program (see SEMI E30). This specification will define messages referencing only Process Recipes. Where there are special considerations for using Process Programs instead of a Process Recipe, they will be noted.

7.4.1 The process job includes a processing description (a recipe or process program) identifier that shall be unique within the domain of the processing agent. The type and content of the processing description must be appropriate for the processing resource and the type of material.

7.4.2 Creation and management of recipes and process programs is outside the scope of this standard.

7.5 *Process Tuning* — Feedforward and feedback control between process steps is becoming increasingly important for process tuning in stabilizing processes, such as those which lack in-situ metrology, and demand increasing yields (or performance). The process tuning requirements differ considerably with application, and there is little consensus on any particular method. It is not the intention of this standard to provide comprehensive support for process tuning, but rather to provide a simple mechanism which may be extended. Support for recipe tuning is not a fundamental requirement.

7.5.1 Processing management provides a mechanism for specification of the type of recipe method to be applied. Two methods are defined in the standard: RecipeID only, and RecipeID and Variables. User-defined methods may also be used, requiring all communicating entities to have a common understanding of the particular definition and application requirements.

7.5.2 The RecipeID only method accepts the identifier of the recipe to be applied but no additional tuning parameters. The application recipe body is not precluded from defining any application tuning, but there is no standardized support.

7.5.3 The RecipeID and Variables method provides a simple process tuning mechanism at process job creation to support limited run to run feedforward and feedback control. It defines the VariableTuning method, which supplies a list of variable names and values in the process job create. This sets variables defined in the recipe. Each variable name shall be one of the exposed variable definitions supported in recipe management, and its value shall fall within the range specified in the variable definition.

7.5.4 Recipe parameter names (RecipeVarName) shall be specified using the nomenclature defined for ‘Object Specification’ (ObjSpec) in SEMI E39 (Object Services Standard) within the scope of SEMI E40 (Note: see OBJSPEC in SEMI E5). This use of the ObjSpec nomenclature is required to unambiguously identify parameters within some complex recipes (e.g., cluster tool process recipes). If the specification of a recipe parameter is unambiguous, then the form of the ObjSpec may be simplified to just the parameter name. Using the ObjSpec nomenclature for SEMI E40 recipe parameter names requires an object model to describe equipment recipe structure.

7.5.5 Figure 1 shows an example of a typical set of cluster tool hierarchical recipe relationships. A processing parameter might be specified through Sequence Step AB, Process Recipe BB, Process Step CB, to Process Parameter DB. In this example, the object specifier for Process Parameter DB would be:

“Sequence:Erma>SequenceStep:AB>ProcessRecipe: BB>ProcessStep:CB>ProcessParameter:DB>”

or

“Erma>AB>BB>CB>DB>”

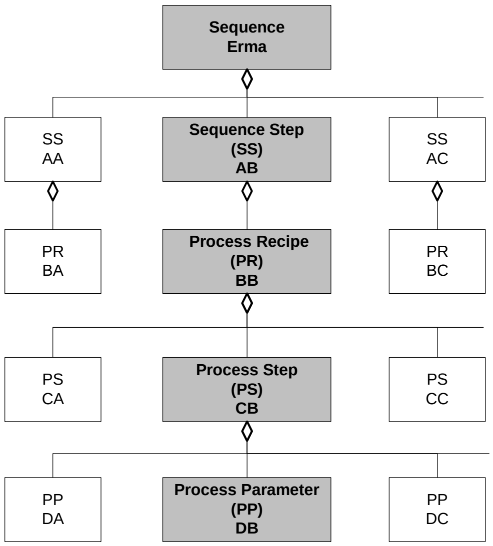

Figure 1
Cluster Tool Sequence Recipe Hierarchical Relationships

7.6 *Processing Material Groups* — Many equipment architectures require concurrent processing of groups of material. A single process job can control a group of material, with certain restrictions. All material in the group needs to be of the same type and processed identically. The processing of each material should be dependent on the arrival of the group. That is, the full material group shall be received by the equipment before processing begins and may not depart until all processing is complete. This ensures that the process job remains a simple logical control mechanism while maintaining robust control, good coordination with material movement, and effective material data tracking.

7.6.1 Two common examples of allowable material group processing are:

a) an equipment receiving a cassette of wafers to be processed identically. All the wafers in the group are received together, in the cassette. The processing of the wafers may or may not be simultaneous but can only proceed once the cassette has arrived. All wafer processing shall complete before the cassette may be removed. Note that this may alternatively be specified as a simple process job with the cassette as the material; and

b) a cluster tool batch process module processing wafers together. Wafers are received singly. Processing of the wafer group in the batch chamber begins when all the wafers specified in the process job have arrived. Wafers are sent after processing is complete.

7.7 *Concurrent Process Jobs* — Concurrent process jobs is the situation where multiple jobs are active (not queued) at the same time. A single process job is not always appropriate for concurrent processing of multiple material. In such cases, multiple concurrent jobs shall be supported by the processing resource. Support of concurrent process jobs is not a fundamental requirement.

7.7.1 An example of concurrent wafer processing which may not be achieved with a single process job is a carousel type cluster tool process module. The processing of a single wafer is not dependent on the arrival of the group. In this case, concurrent process jobs would be created, one for each wafer, even if they were to be processed identically. This allows effective control and tracking of the process jobs.

7.7.2 Processing management considers concurrent process jobs to be logically independent of one other. They are distinguished by unique job identifiers. Concurrent jobs may not apply to the same material because the processing resource may not have more than one active process job associated with a particular material.

7.7.3 There may be interdependencies between concurrent jobs due to resource availability and equipment hardware architecture.

7.8 *Consecutive Process Jobs* — Consecutive process jobs is a situation where multiple process jobs are applied to material while it is in the processing resource. The process jobs requested on the same material are maintained in the order received, and a subsequent job becomes active once the previous one has completed material processing.

7.8.1 A process job normally specifies all the processing to be applied to the material during a single visit to the processing resource. For example, a process job for a cluster tool would specify all the processing in the multiple sequential steps in the various process modules of the tool. Certain situations may require application of subsequent process jobs to material without it leaving the processing resource.

7.8.2 Processing management requires that a subsequent process job on the same material does not interrupt the previous process job processing. The previous process job terminates immediately once it completes active material processing, even though the material has not left the processing resource, and it is superceded by the subsequent job. The material becomes associated with the superceding process job. This allows sequential processing and maintains a single active association between material and process job.

7.9 *Process Job without Material* — This standard is primarily intended for the management of material processing. However, it permits application of a process job to a processing resource which contains no processing material. This may be used to achieve processing resource conditioning which is not related to a specific material.

7.9.1 The process job has the normal control characteristics, except that it has no dependency on material arrival and terminates at the end of active processing. Support of process jobs without material is not a fundamental requirement.

8 Behavior

8.1 This section provides a high-level definition of the communications between the supervisor and the processing resource needed to achieve material processing. It does not define the message detail, concentrating instead on the concepts. The message detail is addressed in Section 10, Messaging Services.

8.2 *Process Job Communications*

8.2.1 *Process Job Control Messaging* — The control message flow for normal operation is presented in Figure 1. The arrows represent significant information exchange.

8.2.1.1 A detailed description of each message used in normal operation follows.

8.2.1.2 *PR Job Create* — The supervisor requests that the processing resource perform the specified process job. This request may be acted upon immediately, or queued for later execution if the processing resource is busy or the order of material arrival unknown. If the processing resource does not support queuing or the queue is full, the request may be rejected. The request shall supply a process specification in which the supervisor supplies such information as:

- identification of the material to be processed,
- the recipe defining the processing, and
- whether processing will be started manually (optional, normal operation is automatic).

8.2.1.2.1 Upon receipt of the PR Job Create request and before acknowledging, the processing resource checks the process specifications to ensure that they are valid (i.e., that the specified parameters (recipe, material, manual start) are sufficient) and have legal values for the capabilities of the processing resource. Depending on its ability to queue jobs, it may also check such dynamic information as availability of the processing resource to receive the material or presence of correct material, etc., to determine whether to accept or reject.

8.2.1.2.2 The processing resource sets the process start attribute if automatic start is requested (normal operation).

8.2.1.3 *PR Job Create Acknowledge* — The processing resource informs the supervisor that the requested job is accepted or rejected, and if rejected, supplies error codes and textual reasons for the failure.

8.2.1.4 *PR Job Setup* — The processing resource reports that the process job is active and setting up for process. It may have been on the queue or have just been created. If the material is not already present, the processing resource performs any pre-conditioning required then awaits material arrival. Upon arrival of all the material, it prepares for processing and automatically initiates processing if the process start attribute is set.

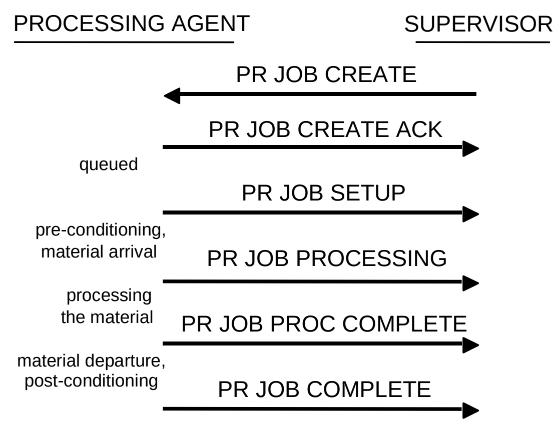

Figure 2
Process Job Message Flow

8.2.1.5 *PR Job Processing* — The processing resource reports that material processing has commenced.

8.2.1.6 *PR Job Processing Complete* — The processing resource reports that material processing is completed and that the material is available for removal.

8.2.1.7 *PR Job Complete* — The processing resource declares the process job to be complete once it has completed processing the material, the material has departed, and any required processing resource post-conditioning has completed. This message is also used when a process job ends abnormally. The message provides information on the success or failure of the processing and, if failed, supplies error codes and textual reasons for the failure.

8.2.2 *Process Job Informational Events* — There are process job related events which may be of significance to the service-user. These are designated as “collection events” and shall be available for event reporting. This section describes those collection events and shows how they fit into the chronology of a process job. These collection events, as specified by the PRJobEvent service, shall be implemented per definition of one of the following standards, SEMI E30, E40, E53 or similar style events, as required by the service-user. The equipment may also optionally implement the collection events per the remaining standards. However, the service-user shall only utilize one of the standards for collection event implementations. The selection mechanism by the service-user is equipment specific. For example, it may be part of an equipment power-on process or via an equipment specific equipment constant.

8.2.2.1 If SEMI E30, E53 or similar style collection events are used for PRJobEvent, the equipment must also implement events for the process job milestones as defined by the PRJobAlert service.

8.2.2.2 Collection event messages provide valuable information but are not strictly required to perform material processing. Therefore, it is expected that some message protocol implementations will provide a method by which the service-user may disable those events which are not needed in a particular implementation. For SEMI E40 style events, the activation for disabling the events is user specific. For SEMI E30, E53 or similar style events, the activation is as defined in those standards.

8.2.2.3 *PR Job Waiting for Material* — The processing resource reports that all required pre-conditioning has completed and that it cannot proceed until the process job material arrives. It is considered to be awaiting material arrival if it is not aware of activities in progress with the aim of receiving all or part of the material. This event may be generated only during process job setup. This event requires, at a minimum, PRJobID and Timestamp as its data.

8.2.2.4 *PR Job State Change* — The processing resource reports that it has changed state. All state transitions in the state model Figure 4 shall trigger this collection event. These events require, at a minimum, variables PRJobID, PRJobState, and TimeStamp (E30).

8.2.3 *Process Job Extended Messaging* — In this section, the extended messaging of Abort/Stop/Cancel, Pause/Resume and manual Start Process is added to the normal messaging described above. The only extended functionality required to be supported in processing management is Abort.

8.2.3.1 A detailed description of each message used in extended operation follows.

8.2.3.2 *PR Job Abort* — The supervisor may command the processing resource to abort a process job at any time. The goal of the abort command is to end the process job activities as quickly as possible. This includes halting all processing of material in progress, which may result in an unknown material condition. Abort is intended for use when serious problems are detected and further damage needs to be prevented. The abort command terminates the process job. In many cases, error recovery may be required before normal operation may continue and subsequent jobs can be executed. For processing equipment a part of the error recovery procedure may require the removal of substrates belonging to the aborted process job that still reside in the equipment. This is determined by the processing agent, which may use applicable service standards to handle the exception.

8.2.3.2.1 The abort command takes precedence over the stop, cancel, and pause commands. If the specified process job is queued, the abort command acts identically to a cancel command.

8.2.3.3 *PR Job Stop* — The supervisor may command the processing resource to stop a process job at any time. The stop command terminates the job in an orderly manner. The object of the stop command is to cease the current activity at the next safe, convenient point, preserving material integrity. In the situation of processing equipment, this convenient point may require that all related substrates are sent to their output destination. This implies that each material is either processed as specified in the recipe or not at all. As stop terminates the job, a new process job is needed to continue processing the material in the processing resource. If restart of the same job is needed, pause and resume should be used instead of stop. A new job is required if additional processing is needed after a job is stopped.

8.2.3.3.1 If the specified process job is queued, the stop command acts identically to a cancel command.

8.2.3.4 *PR Job Cancel* — The supervisor may cancel a process job which has not yet become active (e.g., a job which is queued). Cancel is used when the supervisor would like to remove a process job — to reschedule, for example — but does not want to affect process job activities already in-progress. A cancelled job is removed from the queue and ceases to exist. No physical action is associated with canceling a process job. If the specified process job is active, the processing resource shall reject this command.

8.2.3.5 *PR Job Pause* — The supervisor may issue a command to pause a process job at any time. A pause command shall cause the processing resource to continue to the first safe, continuable, pausing place and then cease activity. The activity may cease only at points that allow for resumption of the activity (see the resume command) such that material integrity is maintained and the processing goals are accomplished. Note that a paused process job may be aborted or stopped as an alternative to the resume command. In this case, the stop command may cause the equivalent of a resume in order to ensure material integrity (either fully processed or not processed at all) upon termination of the process job.

8.2.3.6 *PR Job Resume* — The resume command is used to continue a previously paused process job activity.

8.2.3.7 *PR Job Create* — The PR Job Create request as previously decribed is for normal automatic process job operation. If the process start attribute is not set, the processing resource waits for a manual start from the supervisor before processing the material. The control message flow for manual start is presented in Figure 3.

8.2.3.8 *PR Job Waiting for Start* — The processing resource is ready to process once the material has arrived and has been prepared for processing. The processing resource reports that it is ready to process and is waiting for start, if the process job PRProcessStart attribute is not set. The PRProcessStart attribute is not set if the job is defined to start manually and the start command has not yet been received. The WAITING FOR START state shall be a safe condition which maintains material integrity. If the process job is stopped or aborted while in this state, the material will not have been altered.

8.2.3.9 *PR Job Start Process* — The supervisor which has defined a process job to start manually issues a PR Job Start Process to allow processing of the material to proceed when the processing resource is ready. The start may be issued at any time after process job creation. On receiving the start command, the processing resource sets the process start attribute and starts processing if it is already in the WAITING FOR START state.

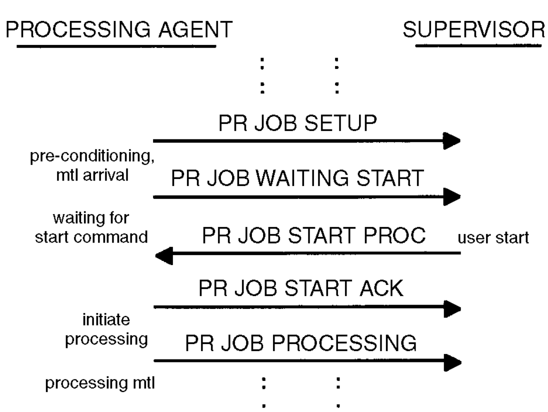

Figure 3
Manual Start Message Flow

8.2.3.10 *PR Job Start Acknowledge* — The processing resource responds to the supervisor that the requested start process is accepted or rejected and, if rejected, supplies errorcodes and textual reasons for failure.

8.3 *Process Job State Model* — The process job is a transient entity. It is created on request of the supervisor, executes, and then is deleted by the processing resource. The job usually spans the time period from shortly before material is physically delivered to the processing resource, through the processing, and until shortly after material is taken away.

8.3.1 *Process Job State Model Diagram* — Figure 4 shows the Process Job State Model diagram.

8.3.2 *Process Job State Descriptions* — The detailed state definitions follow.

8.3.2.1 *ABORTING (ACTIVE Substate)* — While the PR Job is in the ABORTING substate, the processing resource is performing an abort or an optional error recovery procedure. The abort procedure will cause immediate termination of the processing. It is the responsibility of the processing resource to cease physical activity as quickly as possible, having achieved a safe condition.

NOTE 2: For processing equipment the termination may have to be followed by an error recovery procedure with which remaining substrates can be brought to the output destination.

8.3.2.2 *ACTIVE* — ACTIVE is the parent state of all substates where the context of an active process job execution exists.

8.3.2.3 *EXECUTING (ACTIVE Substate)* — EXECUTING is the parent state of those substates that refer to the preparation and execution of a process job.

8.3.2.4 *SETTING UP (EXECUTING Substate)* — While the PR Job is in the SETTING UP substate, the processing resource performs pre-conditioning, awaits material arrival, and prepares for material processing. Pre-conditioning includes all operations in the processing resource, which are required by the recipe in advance of material arrival.

8.3.2.4.1 In cases where the material is already present, it is simply prepared for processing. If pre-conditioning (without material present) is required to achieve the processing goals specified by the recipe, the job fails and terminates.

8.3.2.5 *PAUSE (ACTIVE Substate)* — While the PR Job is in the PAUSE substate the processing resource is suspending or has suspended activity.

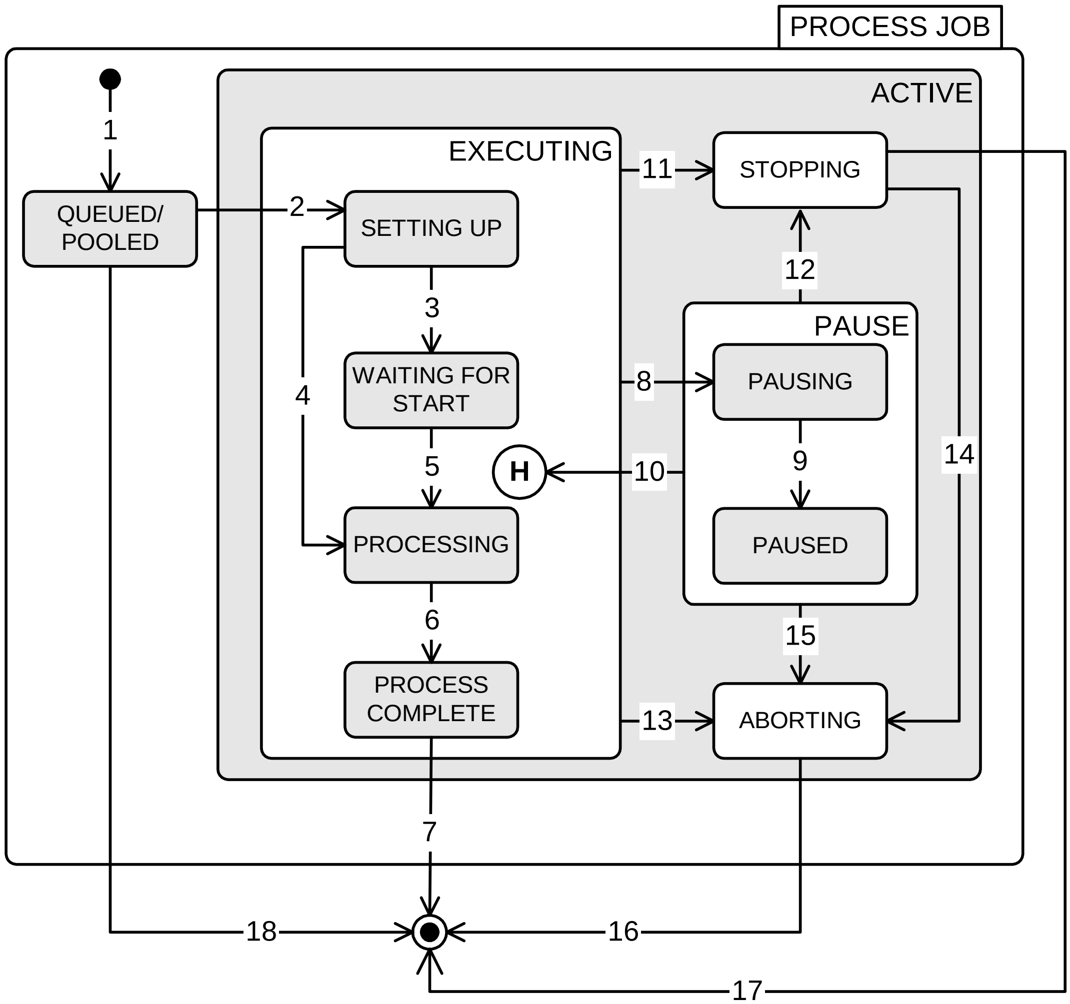

Figure 4
Process Job State Model

8.3.2.6 *PAUSED (PAUSE Substate)* — While the PR Job is in the PAUSED substate all processing resource activity has ceased. The PR Job is awaiting a RESUME (or STOP or ABORT) command.

8.3.2.7 *PAUSING (PAUSE Substate)* — While the PR Job is in the PAUSING substate, the processing resource continues to the first safe, continuable pausing place and then ceases activity. The activity may only cease at points that allow for resumption of the activity such that material integrity is maintained and the processing goals are accomplished.

8.3.2.8 *PROCESSING (EXECUTING Substate)* — While the PR Job is in the PROCESSING substate, the processing resource is doing the actual material processing using the equipment recipe(s) specified by the PR Job.

8.3.2.9 *PROCESS COMPLETE (EXECUTING Substate)* — While the PR Job is in the PROCESS COMPLETE substate the processing resource has completed processing all material specified by the PR Job. When all material removed from the processing resource, processing resource performs any required post-conditioning. Post-conditioning includes all operations in the processing resource after material departure, which are required by the recipe.

8.3.2.9.1 In cases where the process job is superseded by another process job on the same material and post-conditioning is not required, the first job terminates successfully while the material is still present. If post-conditioning is required, the second job may not supersede and remains on the queue.

8.3.2.10 *QUEUED/POOLED* — While the PR Job is in the QUEUED/POOLED substate, the process job has been accepted by the processing resource through a PR

Job Create/Acknowledge transaction (such as PRJobCreate, PRJobCreateEnh, PRJobDuplicateCreate, and PRJobMultiCreate) and is awaiting execution. One or more jobs may be in this state depending upon specific equipment capabilities. That is, if equipment does not support job queuing, then only one PR Job may be in this state at a time. If equipment does support job queuing, then the number of jobs that may be in this state must at least be equal to the number of load ports on the equipment. Advanced equipment job management capabilities require multiple jobs (greater than two) be in this state per load port.

8.3.2.10.1 The order that jobs become active is dependent upon whether the equipment supports job queuing and/or job pooling. Example methods for job activation include FIFO (first-in/first-out) order, material arrival order, and host ordering of jobs (provided by additional services). The equipment may support only one method of selecting jobs for activation, or more than one method allowing only one method to be used at a time or more than one method to be used at a time.

8.3.2.10.2 All process jobs pass through this state. If the processing resource supports queuing/pooling, jobs may remain in this state for prolonged periods. In any case, a process job remains queued/pooled until the material positions (of the processing resource) needed for the process are available or are already occupied by the material to be processed.

8.3.2.11 *STOPPING (ACTIVE Substate)* — While the PR Job is in the STOPPING substate, the processing resource is performing a stop procedure to terminate processing in an orderly manner. It is the responsibility of the processing resource to cease the current activity at the next safe, convenient point, preserving material integrity. For processing equipment this may require sending all related substrates to its output destination. This implies that each material is processed as specified in the recipe or not at all.

8.3.2.12 *WAITING FOR START (EXECUTING Substate)* — The substate WAITING FOR START is used only in manual start process jobs. It is entered once SETUP is complete and a PR Job Start Process has not yet been received by the processing resource. Manual start is defined by the supervisor in PR Job Create.

8.3.2.12.1 The job remains in this state, ready to process the material, until the PR Job Start Process is received or Abort or Stop terminates the job.

8.3.3 *Process Job State Transitions* — The detailed state definitions are defined in Table 1.

Table 1 Process Job State Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*
1	(no state)	The processing resource accepts a Process Job create request.	QUEUED/ POOLED	1. The job is placed the job queue/pool. 2. Acknowledge the Process Job creation.
2	QUEUED/ POOLED	The processing resource has been allocated to the Process Job.	SETTING UP	1. The job is removed from the queue/pool. 2. PR Job Setup event is triggered. 3. All required resource preconditioning is performed. 4. When job material arrives all material preparation is performed.
3	SETTING UP	Job material is present AND the processing resource is ready to start the process job AND PRProcessStart attribute is not set.	WAITING FOR START	PR Job Waiting for Start event is triggered.
4	SETTING UP	Material is present and ready for processing. PRProcessStart attribute is set.	PROCESSING	1. PR Job Processing event is triggered. 2. Material is processed.
5	WAITING FOR START	Job Start directive	PROCESSING	1. PR Job Processing event is triggered. 2. Material is processed.

#	*Current State*	*Trigger*	*New State*	*Action(s)*
6	PROCESSING	Material processing completed.	PROCESS COMPLETE	1. PR Job Processing Complete event is triggered. 2. The processing resource performs all required resource post-conditioning. 3. Await material departure.
7	PROCESS COMPLETE	Job material departed the processing resource AND resource post-conditioning completed, OR superceded by another process job on the same material.	(no state)	1. PR Job Complete event is triggered. 2. The process job is deleted.
8	EXECUTING	The processing resource initiated a process pause action. (it received a PAUSE command or initiated an internal pause)	PAUSING	The processing resource pauses at the first convenient time.
9	PAUSING	The processing resource paused the job.	PAUSED	None.
10	PAUSE	The processing resource resumed the job.	EXECUTING	The processing resource resumes the activity that was paused.
11	EXECUTING	The processing resource initiated a process stop action. (it received a STOP command or initiated an internal stop)	STOPPING	The processing resource stops the current execution activity at the first convenient time.
12	PAUSE	The processing resource initiated a process stop action. (it received a STOP command or initiated an internal stop)	STOPPING	The processing resource stops the current execution activity at the first convenient time.
13	EXECUTING	The processing resource initiated a process abort action. (it received an ABORT command or initiated an internal abort)	ABORTING	The processing resource terminates the current execution activity immediately.
14	STOPPING	The processing resource initiated a process abort action. (it received an ABORT command or initiated an internal abort)	ABORTING	The processing resource terminates the current execution activity immediately.
15	PAUSE	The processing resource initiated a process abort action. (it received an ABORT command or initiated an internal abort)	ABORTING	The processing resource terminates the current execution activity immediately.
16	ABORTING	The processing resource abort procedure is complete and for some processing equipment the related substrates are moved out as part of the error recovery.	(no state)	1. PR Job Complete event is triggered. 2. The process job is deleted.
17	STOPPING	The processing resources stop procedure completed.	(no state)	1. PR Job Complete event is triggered. 2. The process job is deleted.
18	QUEUED/ POOLED	"CANCEL," "ABORT," or "STOP" command received.	(no state)	1. Remove the process job from the queue/pool 2. PR Job Complete event is triggered. 3. Delete the process job.

9 Object Definitions

9.1 Processing management defines one standard object, the Process Job.

9.2 *Process Job Object Definition* — The process job is a dynamic object created by the processing resource as requested by the supervisor. It tracks progress of the operations required and is deleted by the processing resource automatically upon completion. The process job is uniquely identified by the PRJobID attribute. The object attribute notation used in the table below is described in Conventions, Section 5.2.

9.2.1 The attributes in Table 2 shall be accessible using Object Services Standard (SEMI E39).

Table 2 Process Job Attributes

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjID	An identifier for the service user. It is set when the process job is created.	Y	RO	Text
ObjType	The object type.	Y	RO	Text: "PROCESSJOB"
PauseEvent	List of event identifiers that cause the equipment to automatically transition to the PAUSING/PAUSED states when one of the listed events is triggered.	N	RO	List of: EventID
PRJobState	A unique sub-state of the job according to the process job state model in Figure 4.			Enumerated: QUEUED/POOLED SETTING UP WAITING FOR START PROCESSING PROCESS COMPLETED EXECUTING PAUSING PAUSE STOPPING ABORTING
PRMtlNameList	List of identifiers of the material being processed.	Y	RO	List of: PRMtlName
PRMtlType	Identifies the type of material being processed.	Y	RO	Enumerated
PRProcessStart	Indicates that the processing resource start processing immediately when ready.	N	RO	Boolean: TRUE — Automatic start FALSE — Manual start
PRRecipeMethod	Indication of recipe specification type, whether using is applied and which method is used.	Y	RO	Enumerated: Recipe only Recipe with Variable Tuning
RecID	Identifier of the recipe applied.	Y	RO	Text
RecVariableList	List of variables supporting a recipe method.	N	RO	List of: RecipeVariable

9.2.2 A number of the ProcessJob attributes are composite data types. The constituent data is defined in Table 3.

Table 3 Attribute Data Definitions

Data Itentifier	*Description*	*Form*
PRMtlName	Textual identifier of the material being processed.	Text
RecipeVariable	Variables supporting a recipe method.	Structure composed of: RecipeVarName RecipeVarValue
RecipeVarName	The name of the recipe variable.	Text
RecipeVarValue	Value of the recipe variable.	Depends on variable

10 Messaging Services Detail

10.1 This section defines the messaging services required to implement the processing management concepts. The messages were introduced in Section 8.1. These services are independent of the messaging protocol used. They may be mapped to SECS-II (SEMI E5) or to other comparable protocols.

10.1.1 These messaging services define the messages to be used, the nature of the parameters contained within the messages, and data type of the parameters. Not defined here is the internal structure of the actual messages as transferred, including order of the parameters and how various data structures and data types are represented.

10.1.2 The service message notation used in the tables below is described in Conventions, Section 5.3.

10.2 *Service List* — The following messages are exchanged between host and equipment for the purpose of accomplishing processing management tasks.

Table 4 Service List

Message Name	*Type*	*Description*
PRGetAllJobs	R	Get a list of the jobs and their states for all jobs which have not completed.
PRGetSpace	R	Get the number of jobs which can currently be created on the resource.
PRJobAlert	N	Notification by the processing resource that the process job is setting up, processing, completed process, or that the job is completed.
PRJobCommand	R	Command which affects the process job.
PRJobCreate	R	Supervisor (service-user) request that a process job be performed.
PRJobCreateEnh	R	User request for job to be done. User assigns a unique job identifier.
PRJobDequeue	R	Removes (deletes) process job(s) from the queue.
PRJobDuplicateCreate	R	Create a set of similar process jobs. User assigns unique job identifiers.
PRJobEvent	N	Notification by the processing resource that a process-related event has occurred.
PRJobMultiCreate	R	Create several jobs which may be dissimilar. User assigns unique job identifiers.
PRJobSetRecipeVariable	R	User request for setting a new value to one of more recipe variable parameters.
PRJobSetStartMethod	R	Create a set of similar process jobs. User assigns unique job identifiers.
PRSetMtrlOrder	R	Request the service to use a specific methodology for processing order.

10.3 *Parameter Dictionary*

Table 5 Parameter Dictionary, Part 1

Parameter Name	*Definition*	*Form: Possible Values*
CmdParameter	Parameter supporting a command type.	Structure composed of: CmdParmName CmdParmValue
CmdParmName	The name of the parameter.	Text
CmdParmValue	Value of the parameter.	Varies per parameter
ErrorCode	Contains the code for the specific error found.	Enumerated: *PRJobCreate, PRJobCreateEnh, PRDuplicateCreate, PRJobMultiCreate:* • Parameters improperly specified • Insufficient parameters specified • Unsupported option requested • Busy (no queueing or queue full) *PRJobCreateEnh, PRDuplicateCreate, PRJobMultiCreate:* • Object identifier in use *PRJobCommand:* • Parameters improperly specified • Insufficient parameters specified • Unsupported option requested

Parameter Name	*Definition*	*Form: Possible Values*
		• Command not valid for current state *PRJobComplete:* • No material altered • Material partially processed • All material processed • Recipe specification related error • Failed during processing • Failed while not processing • Failed due to lack of material • Job aborted • Job stopped • Job cancelled
ErrorText	Text in support of the error code.	Text
PRAck	Indicates whether the activity was successful.	Boolean: TRUE — Successful FALSE — Unsuccessful
PRCmdName	Indicates which process job command to perform.	Text: ABORT STOP CANCEL PAUSE RESUME STARTPROCESS
PREventData	Data related to the specific event.	Varies per parameter reported
PREventID	Identifier of the specific event which occurred.	Enumerated: Unique collection event ID for Waiting for Material and Process Job State Change events.

Table 6 Parameter Dictionary, Part 2

Parameter Name	*Definition*	*Form: Possible Values*
PRJobID	The unique identifier for a process job. It can be accessed as the ObjID attribute of the process job. The host may provide this identifier to the processing resource. In this case, the host must guarantee uniqueness of job identifiers for all the process jobs in the PROCESS JOB STATE in the equipment.	Text.
PRJobList	List of process job identifiers and their states.	List of Structure PRJobID PRJobState
PRJobMilestone	Process job milestone.	Enumerated: PR Job Setup PR Job Processing PR Job Processing Complete PR Job Complete PR Job Waiting for Start
PRJobSpace	Used to indicate the number of jobs that can currently be created for the processing resource.	Integer

Parameter Name	*Definition*	*Form: Possible Values*
PRJobState	A unique state of the process job according to the process job state model.	Enumerated: QUEUED/POOLED SETTING UP WAITING FOR START PROCESSING PROCESS COMPLETE PAUSING PAUSED STOPPING ABORTING
PRMtlName	Textual identifier of the material being processed.	Text: Unique for each material with respect to the processing agent.
PRMtlType	Identifies the type of material being processed.	Enumerated.
PRMtrlOrder	Defines the order by which material in the process jobs material list will be processed.	Enumeration: ARRIVAL – process whichever material first arrives. OPTIMIZE – process in an order that maximizes throughput. LIST – follow the order in the list.
PRPauseEvent	Variable containing information which is transferred to the corresponding PRJob attribute. Shall conform to event identifiers as defined in either SEMI E30 or E53.	(list of) text
PRProcessStart	Indicates that the processing resource start processing immediately when ready.	Boolean: TRUE — Automatic Start FALSE — Manual Start
PRRecipe	Specification of the process job recipe.	Structure composed of: PRRecipeMethod RecID (List of) RecipeVariable
PRRecipeMethod	Indication of recipe specification type, whether tuning is applied and which method is used.	Enumerated: Recipe only Recipe with VariableTuning
PRStatus	Reports the acceptance or rejection of a requested operation.	Structure composed of: PRAck (List of) Status
RecID	Identifier of the recipe applied.	Text: Unique with respect to the processing agent.
RecipeVariable	Variables supporting a recipe method.	Structure composed of: RecipeVarName RecipeVarValue
RecipeVarName	The name of the recipe variable.	Text: Depends on recipe
RecipeVarValue	Value of the recipe variable.	Depends on variable
Status	Reports any errors found.	Structure composed of: ErrorCode ErrorText
Timestamp	Event date and time.	Text: yyyymmddhhmmsscc

10.4 *Service Detail* — The tables below define the parameters for each service. In some cases, parameters have additional detail which is defined in the parameter definition section.

10.4.1 *PRJobCreate*

Table 7 PRJobCreate Service Detail

PRJobCreate Service Detail Section

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobID	-	M	The processing agent assigns the unique identifier which is used in all subsequent process job communications.
PRMtIType	M	-	
(List of) PRMtIName	M	-	All material shall be of the same material type. This is an ordered list and indicates the order in which the process job should process the material, if it is single wafer processing equipment.
PRRecipe	M	-	
PRProcessStart	M	-	Indicates auto or manual start.
PRStatus	-	M	

PRRecipe Parameter Detail Section

PRRecipeMethod	M	-	
RecID	M	-	The process job recipe identifier shall be unique within the domain of the processing agent.
(List of) Recipe Variable	C	-	Parameters required depend on the recipe method selected.

PRStatus Parameter Detail Section

PRAck	-	M	Indication of acceptance to perform the job.
(List of) Status	-	C	Error information, required if PRAck is unsuccessful.

10.4.2 *PRJobCreateEnh*

Table 8 PRJobCreateEnh Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobID	M	M	User supplied Job ID. Must be unique among jobs known by the processing resource or else the resource shall reject the create request.
PRMtlType	M	-	May be NULL when no material is processed.
(List of) PRMtlName	M	-	An ordered list that associates a set materials with process conditions (process programs or recipes).
PRRecipe	M	-	This is a structure.
PRProcessStart	M	-	Indicates auto or manual start.
PRPauseEvent	M	-	If null, then processing will not be automatically paused.
PRStatus	-	M	Indicates success or failure.

10.4.3 *PRJobDuplicateCreate* — This service creates multiple process jobs. Each job will be identical (a duplicate) in terms of doing the same processing on all the material that must be identical. This means the same values of PRRecipe and PRProcessStart are applied to each job that is created by this service. Creates a series of process jobs useful for single wafer processing.

Table 9 PRJobDuplicateCreate Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
(List of) PRJobDupSpec	M	C	Ordered list of user supplied Job ID's and material. Structure: PRJobID PRMtlName
PRMtlType	M	-	Enumeration that Indicates type of material.
PRRecipe	M	-	This is a structure.
PRProcessStart	M	-	Indicates auto or manual start.
PRPauseEvent	M	-	If null, then processing will not be automatically paused.
(list of) PRJobID	-	C	Shall be used if PRJobSpec is not returned.
PRStatus	-	M	Indicates success or failure.

10.4.4 *PRJobMultiCreate* — This service creates multiple process jobs. Each job can be created uniquely.

Table 10 PRJobMultiCreate Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
(List of) PRJobMultiSpec	M	C	An ordered list of job specifications as follows: (list of) Structure: PRJobID PRRecipe PRProcessStart (List of) PRMtlName
PRMtlType	M	-	Enumeration that indicates type of material.
(list of) PRJobID	-	C	Shall be used if PRJobSpec is not returned.
PRStatus	-	M	Indicates success or failure.

10.4.5 *PRJobDequeue* — Remove one or more jobs from the queue. PRStatus shall indicate any jobs which could not be removed because they either did not exist or were in the PR JOB ACTIVE state.

Table 11 PRJobDequeue Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobList	M	-	(List of) PRJobID
PRStatus	-	M	Indicates success or failure.

10.4.6 *PRJobCommand* — All of the process job commands described in Section 8.2.3 are communicated using the PRJobCommand service. The commands are Abort, Stop, Cancel, Pause, Resume, and Start Process. This standard does not specify any required parameters. Abort is the only command which is required to be supported.

Table 12 PRJobCommand Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobID	M	-	Identifies the process job on which to perform the command.
PRCmdName	M	-	
(List of) CmdParameter	C	-	Dependent on the command selected.
PRStatus	-	M	

10.4.7 *PRJobAlert* — Notification of process job milestones achieved by the processing resource are communicated using the PRJobAlert service. Process job milestones, which are described in Section 8.2.1, are events which are important to the control and tracking of the process job. The milestones required to be supported are PR Job Setup, PR Job Processing, PR Job Processing Complete, and PR Job Complete. An additional milestone, PR Job Waiting for Start, is used with the manual start option.

Table 13 PRJobAlert Service Detail

Parameter	*Req/Ind*	*Comment*
Timestamp	M	
PRJobID	M	Identifies the process job on which the milestone has been reached.
PRJobMilestone	M	
PRStatus	M	

10.4.8 *PRJobEvent* — Process job informational event notification, which is described in Section 8.2.2, is communicated using the PRJobEvent service. These are defined for Waiting for Material and Process Job State Change events. Support for informational events is not required.

Table 14 PRJobEvent Service Detail

Parameter	*Req/Ind*	*Comment*
PREventID	M	
Timestamp	M	
PRJobID	M	Identifies the process job which generated the event.
PREventData	C	

10.4.9 *PRJobSetRecipeVariable* — Sends a request to change the settings for a list of recipe variable parameters. Implementation of this service is optional.

Table 15 PRJobSetRecipeVariable Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobID	M	-	
RecVariableList	M	-	(list of) RecipeVariable
PRStatus	-	M	Indicates success or failure. Failure is if a variable can't be set. A List of variables which could not be set is returned in the status.

10.4.10 *PRJobSetStartMethod* — Sends a request to change the start method for job(s). This request will fail if a specified job is not in the QUEUED/POOLED state. Implementation of this service is optional.

Table 16 PRJobSetStartMethod Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobList	M	-	(List of) PRJobID
PRProcessStart	M	-	Indicates auto or manual start.
PRStatus	-	M	Indicates success or failure.

10.4.11 *PRGetAllJobs* — This message shall return a list containing job identifiers and the associated states of those jobs for all jobs which have not completed.

Table 17 PRGetAllJobs Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobList	-	M	

10.4.12 *PRGetSpace* — This message shall return the remaining number of jobs that can be created for the processing resource.

Table 18 PRGetSpace Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRJobSpace	-	M	

10.4.13 *PRSetMtrlOrder* — Request the Processing Management Service to use a specific strategy for the order in which materials are processed.

Table 19 PRSetMtrlOrder Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
PRMtrlOrder	M	-	Sets the value for the strategy the service will use.
PRAck	-	M	Indicates success or failure.

10.5 *Mapping of Semantics to Syntax* — Table 20 provides the correspondence between the message semantics defined in Section 8.2 and the syntax as defined in Section 10.4. The use of '.req', '.rsp', or '.nfy' suffixes shows the direction of message flow. '.req' is a message request from the service user to the service provider. '.rsp' is a response message from the service provider to the service user. '.nfy' is a notification from the service provider to the service user.

Table 20 Correspondence of Message Semantics to Syntax

Parameter	*Comment*
PR Job Create	PRJobCreate.req
PR Job Create Acknowledge	PRJobCreate.rsp
PR Job Setup	PRJobAlert.nfy (PRJobMilestone=PR Job Setup)
PR Job Processing	PRJobAlert.nfy (PRJobMilestone=PR Job Processing)
PR Job Processing Complete	PRJobAlert.nfy (PRJobMilestone=PR Job ProcessingComplete)
PR Job Complete	PRJobAlert.nfy (PRJobMilestone=PR Job Complete)
PR Job Waiting for Material	PRJobEvent.nfy (PREventID=Waiting for Material)
PR Job State Changes	PRJobEvent.nfy (PREventID=Process Job State Change)
PR Job Abort	PRJobCommand.req (PRCmdName=ABORT)
PR Job Stop	PRJobCommand.req (PRCmdName=STOP)
PR Job Cancel	PRJobCommand.req (PRCmdName=CANCEL)
PR Job Pause	PRJobCommand.req (PRCmdName=PAUSE)
PR Job Resume	PRJobCommand.req (PRCmdName=RESUME)
PR Job Waiting for Start	PRJobAlert.nfy (PRJobMilestone=PR Job Waiting for Start)
PR Job Start Process	PRJobCommand.req (PRCmdName=STARTPROCESS)
PR Job Start Acknowledge	PRJobCommand.rsp (PRSatus.PRAck=TRUE)

11 Variable Data

11.1 The purpose of this section is to define the list of variable data requirements for Processing Management compliant equipment. Values of these variables are available to the host via collection event reports.

11.2 *Variable Data Definitions* — The identifier and all other attributes of the ProcessJob object shall be available for inclusion in event reports associated with it. The following attributes are most likely to be used: PRJobID, PRJobState, RecID, RecVariableList and PRMtlNameLIst.

12 Compliance

12.1 Processing management defines the standard services available to achieve job-based material processing in equipment. The capabilities supported allow flexible management of automated processing encompassing many process types. Only a subset of these capabilities may be needed for a particular implementation.

12.2 *Fundamental Requirements* — All processing agent implementations shall support the fundamental requirements. These have been indicated in the appropriate sections of the document and are listed together below:

- Create and execute a single process job to completion, given:
  - a single material of the appropriate type, uniquely identified.
  - a unique recipe identifier for which the corresponding recipe can be found.
- Report the process job milestones: Setup, Processing, Processing Complete, and Job Complete.
- Detect and report the success or failure of the process job, indicating complete, partial, or non-processing of the material.
- Support Abort of the process job at all times, immediately ceasing activity and terminating the process job.
- Maintain the data of required process job attributes indicated in Table 2.
- Reject requests with incomplete or invalid parameters.
- Reject requests for capabilities not supported.
- Implement the services and messages with the exception of those required for the Optional capabilities.

12.2.1 Satisfying fundamental requirements may not provide sufficient flexibility or performance for some equipment. In such cases, fundamental functionality should be supplemented by optional capabilities as appropriate to the needs of the system.

12.3 *Additional Capabilities* — Optional capabilities defined or enabled in this standard include:

- Processing resource pre-conditioning and post-conditioning.
- Stop, Pause, and Resume of a process job.
- Manual process start.
- Process job queuing and Cancel on a queued job.
- Process tuning.
- Processing of material groups.
- Multiple concurrent process jobs.
- Multiple consecutive process jobs in a single visit.
- Process job with no material.
- Notification of waiting for material and of process job state changes.
- Implement PRJobCreateEnh, PRJobMultiCreate, and PRJobDuplicateCreate.

12.3.1 The services are defined with mechanisms to reject unsupported services and options should they be requested. This improves robustness and enables sophisticated service-users to adjust their requests to the capabilities of the particular processing agent.

12.4 Table 21 provides a checklist for Processing Management (PM) compliance.

Table 21 PM Compliance Statement

Fundamental PM Requirements	*PM Section*	*Implemented*	*PM Compliant*
Single Process Job Execution	8.2	☐ Yes ☐ No	☐ Yes ☐ No
Process Job Milestones	8.2.1 (except 8.2.1.2,3)	☐ Yes ☐ No	☐ Yes ☐ No
Process Job Failure Indication	8.2.1.7	☐ Yes ☐ No	☐ Yes ☐ No
Abort Command	8.2.3.2	☐ Yes ☐ No	☐ Yes ☐ No
Process Job Object Implementation	8.3, 9	☐ Yes ☐ No	☐ Yes ☐ No
Reject Invalid/Incomplete Parameters	8.2.1.2.1	☐ Yes ☐ No	☐ Yes ☐ No
Reject Unsupported Capabilities	11.2	☐ Yes ☐ No	☐ Yes ☐ No
Services Implementation (not per Additional)	10	☐ Yes ☐ No	☐ Yes ☐ No
Additional PM Capabilities	*PM Section*	*Implemented*	*PM Compliant*
Resource Pre/Post-conditioning		☐ Yes ☐ No	☐ Yes ☐ No
Stop, Pause and Resume Commands	8.2.3.3,4,5	☐ Yes ☐ No	☐ Yes ☐ No
Manual Process Start	8.2.3.9	☐ Yes ☐ No	☐ Yes ☐ No
Process Job Queuing	8.3	☐ Yes ☐ No	☐ Yes ☐ No
Process Tuning	7.5, 10.4.9	☐ Yes ☐ No	☐ Yes ☐ No
Processing of Material Groups	7.6	☐ Yes ☐ No	☐ Yes ☐ No
Multiple Concurrent Process Jobs	7.7	☐ Yes ☐ No	☐ Yes ☐ No
Multiple Consecutive Process Jobs	7.8	☐ Yes ☐ No	☐ Yes ☐ No
Process Job with No Material	7.9	☐ Yes ☐ No	☐ Yes ☐ No
Event Notification	8.2.2	☐ Yes ☐ No	☐ Yes ☐ No
Enhanced Job Creation	10.4.2	☐ Yes ☐ No	☐ Yes ☐ No
Multiple Job Creation	10.4.3	☐ Yes ☐ No	☐ Yes ☐ No
Duplicate Job Creation	10.4.4	☐ Yes ☐ No	☐ Yes ☐ No

SEMI E40.1-1101
SECS-II SUPPORT FOR PROCESSING MANAGEMENT STANDARD

This standard was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1996; previously published July 2001.

1 Purpose

1.1 This document maps the services and data of SEMI E40 to SECS-II streams and functions and data definitions.

2 Scope

2.1 This is the standard way to implement the Processing Management, which provides remote control of wafer processing, using the SECS-II message protocol.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E40 — Standard for Processing Management

4 Terminology

4.1 None.

5 Mapping of Processing Services

Table 1 Processing Management Messages Mapping

Service Message Name	*Stream, Function*	*SECS-II Name*
PRJobCreate request	S16F3,F4	Process Job Create Request/Acknowledge
PrJobCommand request	S16F5,F6	Process Job Command Request/Acknowledge
PRJobAlert notify	If E30 style events: S6F11,F12 If E40 style alerts: S16F7,F8 If E53 style events: S6F11,F12 S6F13,F14	If E30 style events: Event Report Send/Acknowledge If E40 style alerts: Process Job Alert Notify/Confirm If E53 style events: Event Report Send/Acknowledge Annotated Event Report Send/Ack
PRJobEvent notify	If E30 style events: S6F11,F12 If E40 style events: S16F9,F10 If E53 style events: S6F11,F12 S6F13,F14	If E30 style events: Event Report Send/Acknowledge If E40 style events: Process Job Event Notify/Confirm If E53 style events: Event Report Send/Acknowledge Annotated Event Report Send/Ack
PRSetMtrlOrder request	S16F29,30	Process Job Set Material Order
PRJobCreateEnh	S16F11/F12	PRJobCreateEnh
PRJobDuplicate-Create	S16F13/F14	PRJobDuplicateCreate
PRJobMultiCreate	S16F15/F16	PRJobMultiCreate
PRJobDequeue	S16F17/F18	PRJobDequeue
PRGetAllJobs	S16F19/F20	PRGetAllJobs
PRGetSpace	S16F21/F22	PRGetSpace
PRJobSetRecipe-Variable	S16F23/F24	PRJobSetRecipeVariable
PRJobSetStart-Method	S16F25/F26	PRJobSetStartMethod

6 Mapping of Processing Parameter

Table 2 Data Item Mapping

Service Parameter	*SECS-II Data Item*
PrJobID	PRJOBID
PRMtlType	MF
PRMtlName	MID
PRAck	ACKA
PRRecipeMethod	PRRECIPEMETHOD
RecID	RCPSPEC
RecipeVarName	RCPPARNM
RecipeVarValue	RCPPARVAL
PRProcessStart	PRPROCESSSTART
PRCmdName	PRCMDNAME
PRJobMilestone	If E30 style events: CEID If E40 style alerts: PRJOBMILESTONE If E53 style events: CEID
PRJobState	PRSTATE
Timestamp	TIMESTAMP
PREventID	If E30 style events: CEID If E40 style events: PREVENTID If E53 style events: CEID
CmdParmName	CPNAME
CmdParmVal	CPVAL
PRMtrlOrder	PRMTRLORDER
ErrorCode	ERRCODE
ErrorText	ERRTEXT
PREventData	V (SV, ECV, DVVAL)
PRJobSpace	PRJOBSPACE
PRPauseEvent	PRPAUSEEVENT

7 Variable Data Item Mapping

7.1 This section shows the specific SECS-II data classes, and formats needed for SECS-II implementations of SEMI E40 variable data. According to SEMI E40 section 11, all ProcessJob object attributes are to be available as variables for Process Job state transition events. These variables will be of SEMI E5 data item DVVAL.

8 Implementation Details

8.1 *Use of Object Services* — Several capabilities of the Processing Management Services are accessed through the Object Services Standard. Whan a Process Job has been created, (PRJOBID is valid), then its attributes can be read and written using the Object Services GetAttr and SetAttr messages.

8.1.1 E39 Object Services shall be used for access to ProcessJob attributes. The GetAttr service may be used for all ProcessJob attributes and the SetAttr service may be used on only those attributes whose Access is set to RW.

8.2 *Multi-Block Messages* — Processing Management Services is protocol independent and therefore, makes no mention of SECS-II multi-block access and grant messages. When these Service use the SECS-II protocol, then S16F3,F5 shall be preceded by an S16F1/S16F2 access request/grant message exchange when the message will be multi-block.

9 SECS-II Attribute Definitions

9.1 *Process Job Object SECS-II Attributes Definitions* — The following are the SECS-II structure definitions for the E40 ProcessJob object.

Table 3 Process Job SECS-II Attribute Definitions

Attribute Name	*Attribute Data Form: SECS-II Structure*
"ObjID"	<PRJOBID> (Conforms to the restrictions of ObjID as specified in SEMI E39.1, Section 6.)
"ObjType"	"ProcessJob"
"PauseEvent"	L,n n=number of collection events 1. <CEID$_1$> … n. <CEID$_n$> CEID restricted to format U()
"PRJobState"	<PRSTATE> PRJobState PRSTATE enumerated as follows: 51 (U1) Enumerations: 0 – QUEUED/POOLED 1 – SETTING UP 2 – WAITING FOR START 3 – PROCESSING 4 – PROCESS COMPLETE 5 – (Reserved) 6 – PAUSING 7 – PAUSED 8 – STOPPING 9 – ABORTING
"PRMtlNameList"	When MF = 13 (0x0d) (carriers) L,n n=number of carriers 1. L,2 1. <CARRIERID$_1$> 2. L,j j=number of slots 1. <SLOTID$_1$> : j. <SLOTID$_j$> : n. L,2 1. <CARRIERID$_n$> 2. L,k k=number of slots 1. <SLOTID$_1$> : k. <SLOTID$_k$> When MF = 14 (0x0e) (substrate) L,n n=number of material (substrate) 1. <MID$_1$> substrate ID … n. <MID$_n$> MID restricted to format A
"PRMtlType"	<MF> MF restricted to format B **MF Value** **Description** 13 (0x0d) carriers (e.g. FOUP, SMIF pod, cassette) 14 (0x0e) substrate (e.g. wafer, mask, flat panel) other not valid for E40 material

Attribute Name	*Attribute Data Form: SECS-II Structure*
"PRProcessStart"	<PRPROCESSSTART>
"PRRecipeMethod"	<PRRECIPEMETHOD>
"RecID"	<RCPSPEC>
"RecVariableList"	L,n n=number of recipe variables 1. L,2 1. <RCPPARNM$_1$> 2. <RCPPARVAL$_1$> … n. L,2 1. <RCPPARNM$_n$> 2. <RCPPARVAL$_n$>

SEMI E41-95
EXCEPTION MANAGEMENT (EM) STANDARD

1 Purpose

1.1 Interactive exception handling enhances the error recovery ability while maintaining automated control in the factory. This standard addresses the communications needs within the semiconductor manufacturing environment with respect to equipment exception handling.

1.2 This standard specifies capabilities to be provided by the exception agent for effective reporting and interaction with respect to abnormal situations in the equipment. It describes the *concept* of exception management, the *behavior* of the equipment in relation to interactive exception handling, and the *messaging services* which are needed to provide the functionality.

1.3 The communications services defined here will enable standards-based interoperability of independent systems. They shall allow application software to be developed which can assume the existence of these services and allow software products to be developed which offer them.

1.4 Implementation of automated exception management will help reduce error recovery time and avoid changing from automatic to manual equipment control in many situations. The adoption of the standards described will greatly reduce the effort required to integrate compliant equipment components. Compliance requires a specific set of standard services.

2 Scope

2.1 The current scope of this standard is interactive exception handling within a cluster tool.

2.2 While the functionality provided may be applied to other multi-resource equipment, it may not provide the flexibility required for automated management and command by the factory of all types of equipment. It is anticipated that this standard will be extended to accommodate management of exceptions in other types of multi-resource equipment and by the factory of all types of equipment.

2.3 This standard supports exception condition reporting, including alarms, by an exception agent to a decision authority. The exception agent also has the ability to enable and disable reporting on each exception condition.

2.4 Interactive exception handling is supported through selection by the decision authority of recovery actions in certain situations. The recovery actions are performed by the exception agent with the goal of resolving the abnormal situation and allowing normal equipment operation to continue.

2.5 This standard presents a solution from the concepts and behavior down to the messaging services. It does not define the messaging protocol.

2.6 A messaging service includes the identification that a message shall be exchanged and definition of the data which is contained in that message. It does not include information on the structure of the message, how the data is represented within the message, or how the message is exchanged. This additional information is contained within the *message protocol*.

2.7 The defined services may be applied to multiple protocols. Information on the mapping of exception management services to special protocols (e.g., SECS-II) are added as adjunct standards.

2.8 The services assume a communications environment in which a reliable connection has been established between the user of the services and the provider of the services. Establishing, maintaining, releasing a connection, and handling communication failures is beyond the scope of this standard.

3 Referenced Standards

3.1 *SEMI Standards*

3.2 The following SEMI[1] standard is related to the Exception Management standard:

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

4 Definitions

The following definitions are arranged in alphabetical order. Some are defined using terms defined elsewhere within this section. No references beyond this section should be necessary for a basic understanding of these terms.

agent — an intelligent system within a factory that provides one or more service resources and uses the services of other agents. A generalization of host, equipment, cell, cluster, cluster module, station controller, work station. Agents are associated with a physical system or a collection of physical systems, including computer platforms.

1 These documents can be obtained from Semiconductor Equipment and Materials International, 3081 Zanker Road, San Jose, CA 95134, 408.943.6900.

alarm — an alarm is related to any abnormal situation of the equipment that may endanger people, equipment, or material being processed.

clearing — exception agent to decision authority reporting that an abnormal situation related to an exception condition is no longer apparent or relevant.

decision authority — an entity requiring to be notified of significant exception condition changes and which decides how to proceed to resolve abnormal situations related to recoverable error conditions. The decision authority may be represented by a supervisory controller interacting with an operator who may ultimately choose the recovery action.

error condition — an exception condition which is not an alarm and which may support recovery actions requested by a decision authority.

exception agent — the entity which manages access to and reporting of information on abnormal situations in equipment. It achieves this by defining exception conditions, each related to a significant abnormal situation. It may provide services for a decision authority to direct the recovery from certain situations.

exception condition — a condition managed by an exception agent for reporting on and recovery from an abnormal situation in the equipment.

form — type of data representing information contained in an object attribute or service message parameter. The data types are detailed in Section 4.1.

fundamental requirements — the requirements for information and behavior that must be satisfied for compliance with a standard. Fundamental requirements apply to specific areas of application, objects, or services.

posting — all exception agent to decision authority reporting associated with an exception condition while the related abnormal situation is apparent and relevant.

recovery action — an operation associated with an error condition with the aim of resolving the abnormal situation detected. It may supply information to the exception agent or request the exception agent to perform some activity.

service — the set of messages and definition of the behavior of a service provider that enables remote access to a particular functionality.

service-provider — the software control entity that is the provider of any of the related services.

service-user — the software control entity that is the user of any of the related services.

4.1 *Data Type*

form — type of data: positive integer, unsigned integer, integer, enumerated, boolean, text, formatted text, structure, list, ordered list.

positive integer — may take the value of any positive whole number. Messaging protocol may impose a limit on the range of possible values.

unsigned integer — may take the value of any positive integer or zero. Messaging protocol may impose a limit on the range of possible values.

integer — may take on the value of any negative or unsigned integer. Messaging protocol may impose a limit on the range of possible values.

enumerated — may take on one of a limited set of possible values. These values may be given logical names, but they may be represented by any single-item data type.

boolean — may take on one of two possible values, equating to TRUE or FALSE.

text — a text string. Messaging protocol may impose restrictions, such as length or ASCII representation.

formatted text — a text string with an imposed format. This could be by position, by use of special characters, or both.

structure — a complex structure consisting of a specific set of items, of possibly mixed data types, in a specified arrangement.

list — a set of one or more items that are all of the same form (one of the above forms).

ordered list — a list for which the order in which items appear is significant.

5 Conventions

5.1 *Harel State Model* — This document uses the Harel State Chart notation to describe the dynamic behavior of the objects defined. An overview of this notation is presented in an Appendix of SEMI E30. The formal definition of this notation is presented in Science of Computer Programming 8, “Statecharts: A Visual Formalism for Complex Systems,” by D. Harel, 1987.

Transition tables are provided in conjunction with the state diagrams to describe explicitly the nature of each state transition. A transition contains columns for Transition #, Current State, Trigger, New State, Action(s). The “trigger” (column 3) for the transition occurs while in the “current” state. The “actions” (column 5) include a combination of (1) actions taken upon exit of the current state, (2) actions taken upon entry of the new state, and (3) actions taken which are most closely associated with the transition. No differentiation is made.

5.2 *Object Attribute Representation* — The object information models for standardized objects will be supported by an attribute definition table with the following column headings:

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
The formal text name of the attribute	Description of the information contained	RO or RW	Y or N	(see below)

The Access column uses RO (Read Only) or RW (Read and Write) to indicate the access that service-users have to the attribute.

A 'Y' or 'N' in the requirement (Rqmt) column indicates whether or not this attribute must be supported in order to meet fundamental compliance for the service.

The Form column is used to indicates the format of the attribute. (See Section 4.1 for definitions.)

5.3 *Service Message Representation*

5.3.1 *Service Resource Definition* — A service resource definition table defines the specific set of messages for a given service group, as shown in the following table:

Message Service Name	*Type*	*Description*
Message Name	N or R	The intent of the service.

Type can be either N = Notification or R = Request.

Notification type messages are initiated by the service provider, and the provider does not expect to get a response from the consumer/subscriber.

Request messages are initiated by a service consumer or subscriber. Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

5.3.2 *Service Parameter Dictionary* — A service parameter dictionary table defines the parameters used in a service, as shown in the following table:

Parameter	*Form*	*Description*
Parameter X	Data type	A parameter called X is B in A.

A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and contents of the corresponding primitive.

The Form column is used to indicate the type of data contained in a parameter. (See Section 4.1 for definitions.)

The Description column in the Service Parameter Dictionary table describes the meaning of the parameter, the values it can assume, and any interrelationships with other parameters.

To prevent the definition of numerous parameters named "XxxList," this document adopts the convention of referring to the list as "(List of) Xxx." In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type. Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element unless zero elements are specifically allowed.

5.3.3 *Service Message Definition* — A service message definition table defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Rsp/Cnf*	*Description*
Parameter X	(see below)	(see below)	A description of the service.

The columns labeled Req/Ind and Rsp/Cnf link the parameters to the direction of the message. The message sent by the initiator is called the "Request." The receiver terms this message the "Indication" or the request. The receiver may then send a "Response," which the original sender terms the "Confirmation."

The following codes appear in the Req/Ind and Rsp/Cnf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M" — *Mandatory parameter* — must be given a valid value.

"C" — *Conditional parameter* — may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of another parameter.

"U" — *User-defined parameter*.

"-" — The parameter is not used.

"=" — (for Response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

6 Overview

Exception management is concerned with the interactive handling of equipment exception conditions. This standard defines the services provided by which abnormal situations are reported by an exception agent (service-provider) to a decision authority (service-user). In the case of recoverable situations, services are provided for a decision authority to choose how to proceed to resolve the abnormal situation.

The exception agent is the equipment entity which manages access to and reporting of information on abnormal situations. It achieves this by defining exception conditions, each related to a significant abnormal situation. All services are defined in terms of these exception conditions.

Exception management allows for the decision authority to direct the resolution of an abnormal situation. The decision authority selects a recovery action to be performed to resolve the situation from among the options supplied with the exception condition. The exception agent performs the requested recovery action, which may or may not resolve the situation.

The services are fully defined in terms of the functionality provided by the exception agent (service-provider) and as such do not dictate the architecture of the decision authority (service-user).

This standard describes the concepts and exception condition model on which the communications are based, followed by the detailed behavioral model used. It then describes the standard object attributes and message services in detail.

6.1 *Compliance* — Compliance with this standard includes adherence to all stated requirements in this document where implemented. This includes defined message services and state models.

There are two levels of compliance defined. The first is alarm reporting support. The second extends support to include interactive handling of recoverable exception conditions. Required capabilities are listed in Fundamental Requirements, Section 10.4.

7 Concepts

7.1 *Exception Management Model* — The exception management model describes the mechanism for interactive handling of equipment exception conditions.

An exception condition is a condition monitored in equipment by an exception agent (service-provider) for detecting an abnormal situation. Exception conditions are limited in this standard to those accessible by a remote decision authority (service-user).

An exception condition is persistent, existing whether or not the abnormal situation currently exists. The abnormal situation is indicated by the exception condition state becoming SET. An exception agent is an entity which manages remote decision authority access to any number of exception conditions. Each exception condition is identified by a name which is unique for the exception agent.

A decision authority is a remote entity requiring to be notified of exception condition information and which decides appropriate actions to take to resolve abnormal situations. The decision authority may be represented by a supervisory controller interacting with an operator who may ultimately choose the recovery action.

The exception agent notifies the decision authority on detection of an abnormal situation related to an exception condition (i.e., state is SET) and again when it is no longer apparent. It also provides access to exception condition attribute data and for the execution of recovery actions requested by the decision authority.

Exception management defines two types of exception conditions: alarms and error conditions.

An alarm is related to any abnormal situation on the equipment that may endanger people, equipment, or material being processed. Alarms do not provide for decision authority involvement in the resolution of the abnormal situation.

An error condition is related to any abnormal situation detected which is made accessible to a decision authority. An error condition may supply a list of possible recovery actions from which the decision authority can select to attempt to resolve the abnormal situation, thereby resulting in the error condition state becoming CLEARED.

Being persistent, exception condition attributes may be queried at any time, and reporting of changes, such as state SET/CLEARED, can be disabled by the decision authority.

7.2 *Posting and Clearing* — Significant changes in an exception condition are reported to the decision authority if enabled. The major significant events are the transitioning of the exception condition state to SET or CLEARED, which indicate that the abnormal situation has been detected or is no longer apparent, respectively.

All significant information is sent when reporting that the exception condition state is SET. This includes the unique identifier, type, a message describing the abnormal situation, time and a list of possible recovery actions where appropriate. It is important to keep the decision authority updated on exception condition information while the abnormal situation exists, especially with respect to valid recovery actions. All changes in the list of possible recovery actions are reported to the decision authority while the exception condition state is SET.

The term posting is used to describe all reporting the transition to the SET state and while an exception condition state is SET.

Clearing is the reporting of the occurrence of an exception condition state transition to CLEARED. Note that the exception agent, not the decision authority, transitions the state to CLEARED. Any acknowledgment at the decision authority of exception condition posting (e.g., by the operator) is not relevant to the exception agent.

Exception condition changes while its state is CLEARED are not reported to the decision authority.

7.3 *Enable/Disable Reporting* — The decision authority may enable and disable posting and clearing for a particular exception condition by setting and resetting its enabled attribute, respectively. Reporting on an exception condition is enabled by default.

Note that the exception condition itself is not being enabled or disabled, but the reporting of its state is being enabled or disabled.

Posting of an exception condition shall occur upon being enabled if the exception condition state is SET.

7.4 *Recovery Actions* — Recovery actions provide a mechanism for a decision authority to assist in resolving an abnormal situation detected in the equipment. This is generally needed to resolve failure or conflict where information is required beyond the capabilities of the system. By supplying options related to each error condition, error recovery is directed to the problem area.

One or more recovery actions may be associated with an error condition. A recovery action is any operation with the aim of resolving the abnormal situation detected. It may supply information to the exception agent or request it to perform some activity.

A recovery action may be requested by the decision authority only when the error condition state is SET. Only recovery actions currently valid for the error condition are accepted by the exception agent.

The list of valid recovery actions is supplied in the posting of an error condition. Changes in this list are notified by re-posting. A decision authority may request any of the supplied recovery actions to be performed and is notified of acceptance to perform the recovery and, some time later, its completion. No more than one recovery action may be in progress on a particular error condition and it may be aborted by the decision authority at any time.

A recovery action does not directly change the error condition state to CLEARED. It performs activities or provides information with the object of removing the abnormal situation which in turn changes the state to CLEARED. A recovery action may continue after the state has transitioned to CLEARED, until the activity initiated has completed. A recovery action is rejected if received when the error condition state is CLEARED.

Since the exception agent must maintain system integrity by ensuring that incompatible operations are not performed concurrently, it may reject any recovery action requested.

8 Behavior

This section provides a high-level definition of the communications between the decision authority and the exception agent used in exception management. It does not define the message detail, concentrating on the concepts. The message detail is addressed in the Messaging Services section.

8.1 *Exception Condition Communication*

8.1.1 *Exception Report Messaging* — The message flow for exception reporting is shown in Figure 1. The arrows represent significant information exchange.

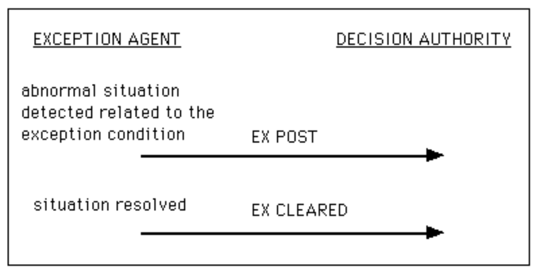

Figure 1
Exception Reporting Message Flow

A detailed description of each message used in exception reporting follows:

EX Post — The exception agent has detected an abnormal situation which is monitored by an exception condition. It changes the exception condition state attribute to SET. The exception agent notifies the decision authority using the EX Post notification, supplying the following information:

- identification of the exception condition,
- type of exception,
- time,
- a message explaining the abnormal situation,
- a list of possible recovery actions (where available with error conditions).

EX Post is re-sent every time the message or recovery action information changes as long as the exception condition state remains SET.

The EX Post notification is not sent if reporting on the exception condition is disabled, that is, if the enabled attribute is false. The EX Post notification is sent when an exception condition becomes enabled if the exception condition state is SET.

Upon receipt of the EX Post, the decision authority has the information needed to take the appropriate action. This may include requesting the exception agent to perform one of the supplied recovery actions.

EX Cleared — The abnormal situation detected by the exception agent is no longer apparent or relevant. The exception agent changes the exception condition state attribute to CLEARED. It notifies the decision authority using the EX Cleared notification, supplying the following information:

- identification of the exception condition,
- type of exception,
- time,
- a message.

The EX Cleared message is not sent if reporting on the exception condition is disabled. That is, the enabled attribute is false.

Upon receipt of the EX Cleared, the decision authority knows that the abnormal situation related to the exception condition is no longer apparent or relevant.

8.1.2 *Recovery Action Messaging* — In this section, the extended messaging of the recovery action is added to the reporting messaging described above. Recovery actions are not available for alarms. The message flow for recovery actions is shown in Figure 2.

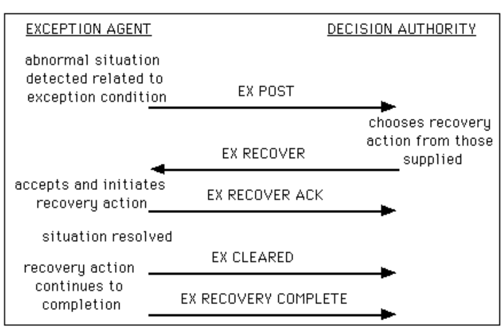

Figure 2
Recovery Action Message Flow

A detailed description of each message used in recovery actions follows:

EX Recover — The decision authority requests that the exception agent perform a recovery action. The particular recovery action selected is identified in the EX Recover request together with the related exception condition identifier. It shall be one of the recovery actions supplied for the exception condition in the EX Post notification.

Upon receipt of the EX Recover request and before acknowledging, the exception agent checks that the specified recovery action is currently valid. The request shall be accepted and initiated immediately or rejected by the exception agent.

The exception agent rejects a recovery action request if there is already a recovery action in progress on that exception condition.

EX Recover Acknowledge — The exception agent responds to the decision authority that the requested recovery action is accepted or rejected, and if rejected, supplies text reasons for failure.

Acceptance of a recovery action indicates that the exception agent has initiated the operation. The operation continues to completion without further intervention by the decision authority. The recovery action may or may not result in the exception condition state changing to CLEARED and the recovery action may continue after the state becomes CLEARED.

The exception agent may reject a requested recovery action for a number of reasons, including:

- unknown recovery for the exception condition,
- recovery currently invalid,
- busy with recovery for this exception condition,
- currently unable to perform the recovery (e.g., other conflicting activity or failure).

EX Recovery Complete — The exception agent declares the recovery action to be complete once it has completed the associated operation. This message is also used when a recovery action ends abnormally. The message indicates whether the operation completed normally and, if not, supplies text reasons for the failure.

Note that normal completion of a recovery action does not indicate that the abnormal situation has been resolved. That is indicated by the EX Cleared notification.

EX Recovery Abort — The decision authority may command the exception agent to abort a recovery action at any time. The goal of the abort command is to end the recovery action activities as quickly as possible. The abort command terminates the recovery action.

8.2 *Exception Condition State Model* — The behavior required for exception management is fully specified by the exception agent (service-provider) behavior. This is described by the exception agent exception condition state model. All required decision authority (service-user) behavior is inferred by this model.

Message flow diagrams presented in the previous section are useful to show simple situations. The exception condition state model presented in this section provides the information necessary to extrapolate the message flow diagrams for all situations within the scope of this standard.

The exception condition provides for exception agent reporting on an abnormal situation in the equipment and management of a recovery action requested by the decision authority to resolve the situation. Recovery is requested in the context of a particular exception condition so the recovery action behavior forms a part of the exception condition behavior.

Figure 3 shows the state diagram for an exception condition. The Harel state model notation used is described in Conventions, Section 5.1. The corresponding state transition table is shown in Table 1 on the following page.

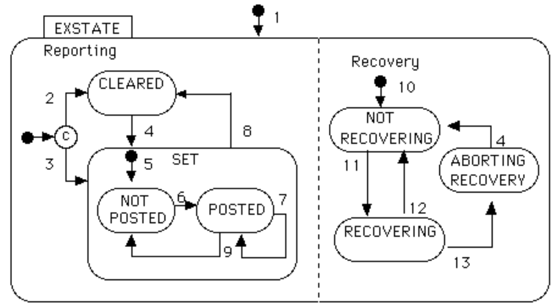

Figure 3
Exception Condition State Model

The detailed state definitions follow:

EXSTATE — When created by the exception agent, an exception condition enters the EXSTATE. It is in this state as long as it is in existence, irrespective of association to the decision authority. The exception condition has two concurrent subsets, which together fully describe its state. These subsets are Reporting and Recovery.

The exception condition initializes to the SET state if the abnormal situation related to the exception condition is apparent and relevant; otherwise, it initializes to the CLEARED state.

Reporting — Reporting is one concurrent subset of EXSTATE. It includes the substates describing whether the abnormal situation related to the exception condition is apparent and relevant, and whether the latest information on the situation has been reported.

Table 1 Exception Condition Transition Table

#	*Current State*	*Trigger*	*New State*	*Action(s)*
1	not EXSTATE	The exception agent creates the exception condition.	EXSTATE	
2	not EXSTATE	Initial creation and the abnormal situation is either not apparent or irrelevant.	CLEARED	
3	not EXSTATE	Initial creation and the abnormal situation is both apparent and relevant.	SET	
4	CLEARED	The abnormal situation is detected.	SET	
5	not SET	Default entry into SET state.	NOT POSTED	
6	NOT POSTED	Reporting enabled.	POSTED	Send “EX Post” message.
7	POSTED	Change in the list of possible recovery actions.	POSTED	Send “EX Post” message.
8	SET	The abnormal situation is either no longer apparent or has become irrelevant.	CLEARED	Send “EX Cleared” message.

9	POSTED	Reporting disabled.	NOT POSTED	
10	not EXSTATE	Default entry into recovery concurrent state at initial exception condition creation.	NOTRECOVERING	
11	NOTRECOVERING	“EXRecover” message received while in the SET state and accepted.	RECOVERING	Initiate requested recovery action and execute to completion.
12	RECOVERING	Recovery action completed.	NOTRECOVERING	Send “EX Recovery Complete” message.
13	RECOVERING	“EXRecoveryAbort” message received.	ABORTING-RECOVERY	Perform the abort procedure to terminate the recovery action in progress.
14	ABORTING-RECOVERY	Abort procedure is complete.	NOTRECOVERING	Send “EX Recovery Complete” message.

CLEARED — The abnormal situation related to the exception condition is either not apparent or not relevant.

SET — The abnormal situation related to the exception condition is apparent and relevant.

The exception agent should generate a collection event each time an exception condition transitions from CLEARED to SET and another from SET to CLEARED.

NOT POSTED — The latest information on the detected abnormal situation has not yet been reported by the exception agent. This may be transient on entering the SET state or may be because reporting is disabled. NOT POSTED is the default state when entering the SET state.

POSTED — The latest information on the detected abnormal situation has been reported by the exception agent to the decision authority.

Recovery — Recovery is one concurrent subset of EXSTATE. It includes the substates describing the behavior in relation to exception condition recovery actions.

NOTRECOVERING — In the NOTRECOVERING substate, there is no recovery action in progress directly related to the exception condition. NOTRECOVERING is the default state when an exception condition is initially created.

Recovery actions may only be initiated when the exception condition is in the SET state.

RECOVERING — A recovery action related to the exception condition is in progress when in the RECOVERING state.

ABORTINGRECOVERY — In the ABORTINGRECOVERY substate, the abort procedure is performed to immediately terminate the recovery action. It is the responsibility of the exception agent to cease physical activity as quickly as possible, having achieved a safe condition.

9 Object Definitions

Exception management defines one standard object, the Exception Condition.

9.1 *Exception Condition Object Definition* — The exception condition is a persistent object created by the exception agent. It provides the decision authority with reporting on, access to, and the possibility to direct resolution of an abnormal situation detected. It also tracks progress of a requested recovery action. The exception condition is uniquely identified by the EXID attribute.

The object attribute notation used in Table 2 is described in Conventions, Section 5.2.

Table 2 Exception Condition Attributes

Attribute Name	*Definition*	*Rqmt*	*Access*	*Form*
ObjType	The object type.	Y	RO	Text: “EXCEPTION”
ObjID	Exception agent unique identifier for the exception condition.	Y	RO	Text: Unique with respect to the exception agent.

EXType	Identifies the type of exception condition.	Y	RO	Enumerated: AlarmError
EXMessage	Text message describing the abnormal situation monitored.	Y	RO	Text
EXEnabled	Indicates that reporting to the decision authority on the exception condition is enabled.	Y	RW	Boolean: TRUE – Enabled FALSE - Disabled
EXRecActList	List of possible recovery actions.	N	RO	List of: Text
EXStateList	All concurrent sub-states of the exception condition according to the state model in Figure 3.	Y	RO	List of: Text
EXRecoveryAction	Recovery action which may be requested to resolve the abnormal situation.	N	RO	Text
EXState	A unique sub-state of the exception condition according to the state model in Figure 3.	Y	RO	Text: EXSTATE/CLEARED EXSTATE/SET/NOTPOSTED EXSTATE/SET/POSTED EXSTATE/NOTRECOVERING EXSTATE/RECOVERING EXSTATE/ABORTINGRECOVERY

10 Messaging Services Detail

This section defines the messaging services required to implement the exception management concepts. The messages were introduced in Section 8.1. These services are independent of the messaging protocol used. They may be mapped to SECS-II (SEMI-E5) or to other comparable protocols.

These messaging services define the messages to be used, the nature of the parameters contained within the messages, and data type of the parameters. Not defined here is the internal structure of the actual messages as transferred, including order of the parameters and how various data structures and data types are represented.

The service message notation used in the tables below is described in Conventions, Section 5.3.

10.1 *Service List* — The messages shown in Table 3 are exchanged between service-provider and service-user for the purpose of accomplishing exception management tasks.

Table 3 Service List

Message Name	*Type*	*Description*
EXPost	N	Notification by the exception agent that the abnormal situation related to the exception condition has been detected or significant information has changed while the situation exists.
EXCleared	N	Notification by the exception agent that the abnormal situation related to the exception condition is no longer apparent or relevant.
EXRecover	R	Decision authority request that a particular recovery action be performed.
EXRecoveryComplete	N	Notification by the exception agent that a recovery action has completed.
EXRecoveryAbort	R	Decision authority request that a recovery action be terminated immediately.

10.2 *Parameter Dictionary*

Table 4 Parameter Dictionary

Parameter Name	*Definition*	*Form: Possible Values*
ErrorCode	Contains the code for the specific error found.	Enumerated: EXRecover: Parameters improperly specified Insufficient parameters specified Recovery action currently invalid Busy with another recovery Currently unable to perform the recovery EXRecoveryAbort: Parameters improperly specified Insufficient parameters specified No active recovery action EXRecoveryComplete: FailedRecovery aborted
ErrorText	Text in support of the error code.	Text
EXAck	Indicates whether the request was successful or the activity completed normally.	Boolean: TRUE – Successful FALSE – Unsuccessful
EXID	Persistent exception condition identifier.	Text: Unique with respect to the exception agent.
EXMessage	Message describing the situation related to an exception condition.	Text
EXRecovery	Identifies a recovery action associated with an exception condition.	Text
EXRecoveryStatus	Reports the acceptance or rejection of a requested recovery action and whether completion was normal.	Structure composed of: EXAck (List of) Status
EXType	Identifies the type of exception condition.	Enumerated: Alarm Error
Status	Reports any errors found.	Structure composed of: ErrorCode ErrorText
Timestamp	Event date and time.	Text yyyymmddhhmmsscc

10.3 *Service Detail* — Tables 5 through 9 define the parameters for each service. Parameters have additional detail which is defined in the parameter dictionary, Table 4.

10.3.1 *EXPost* — Detection of abnormal situations by the exception agent is communicated using the EXPost service, as described in Section 8.1. This notification is also used to communicate any significant changes in exception condition information while its state is SET.

Table 5 EXPost Service Detail

Parameter	*Req/Ind*	*Comment*
Timestamp	M	
EXID	M	Identifies the exception condition which has detected the abnormal situation.
EXType	M	
EXMessage	M	
(List of) EXRecovery	C	List of possible recovery actions. Not available for alarms.

10.3.2 *EXCleared* — Notification that an abnormal situation is no longer apparent or relevant, as is described in Section 8.1, is communicated using the EXCleared service.

Table 6 EXCleared Service Detail

Parameter	*Req/Ind*	*Comment*
Timestamp	M	
EXID	M	Identifies the exception condition which has detected the abnormal situation.
EXType	M	
EXMessage	M	

10.3.3 *EXRecover* — Recovery action requests, described in Section 8.1, are communicated using the EXRecover service. The recovery action services are not available for alarms.

Table 7 EXRecover Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
EXID	M	-	Identifies the exception condition on which to perform the recovery action.
EXRecovery	M	-	The particular recovery action being requested.
EXRecoveryStatus	-	M	

10.3.4 *EXRecoveryComplete* — Notification of recovery action completion by the exception agent is communicated using the EXRecoveryComplete service. Recovery action completion, which is described in Section 8.1, is not directly linked to clearing the exception condition state, and successful completion indicates only that the operation performed completed normally.

Table 8 EXRecoveryComplete Service Detail

Parameter	*Req/Ind*	*Comment*
Timestamp	M	
EXID	M	Identifies the exception condition on which the recovery action was performed.
EXRecoveryStatus	M	

10.3.5 *EXRecoveryAbort* — Recovery action abort, described in Section 8.1 is communicated using the EXRecoveryAbort service.

Table 9 EXRecoveryAbort Service Detail

Parameter	*Req/Ind*	*Rsp/Cnf*	*Comment*
EXID	M	-	Identifies the exception condition on which the recovery action is being performed.
EXRecoveryStatus	-	M	

10.4 *Fundamental Requirements* — Exception management defines the standard services available to achieve exception condition-based exception handling and error recovery in equipment.

All exception agent implementations shall support the fundamental requirements. This standard provides for two aspects of fundamental requirements: exception reporting and interactive exception handling. It is possible to support only exception reporting in systems which do not require interactive exception handling. Interactive exception handling requires that exception reporting be supported.

10.4.1 *Exception Reporting* — The fundamental requirements of the exception agent for exception reporting are based on maintaining the decision authority updated on the exception conditions it is interested in. These are listed below.

- Detect and report the occurrence of significant abnormal situations by setting the related exception condition, and posting it if reporting is enabled.

- Detect and report that an abnormal situation is no longer apparent or relevant by clearing the related exception condition and reporting it if enabled.
- Provide for enabling and disabling reporting on each exception condition.
- Maintain the data of exception condition attributes indicated in Table 2.
- Reject requests for capabilities not supported (such as recovery actions).

10.4.2 *Interactive Exception Handling* — The fundamental requirements of the exception agent for interactive exception handling extend the exception reporting to allow the decision authority to request recovery actions to be performed to resolve abnormal situations. These are listed below.

- Support all exception reporting fundamental requirements specified above.
- Supply a list of valid recovery actions for an exception condition when posting.
- Execute a requested recovery action for an exception condition if the requested recovery action is currently valid. The exception agent may support only a single recovery action to be in progress at a time and reject all other recovery action requests for other exception conditions while it is busy.
- Report the completion of the recovery action.
- Support Abort of the recovery action at all times, immediately ceasing recovery activity and terminating the recovery action.
- Reject requests with incomplete or invalid parameters.
- Reject requests for capabilities not supported.

Optional capabilities defined or enabled in this standard include the following:

- Support for multiple concurrent recovery actions. The standard allows only one recovery action in progress for each exception condition.
- Adjust the exception condition message and the valid recovery action list as appropriate during the error recovery, and post the changes if reporting is enabled.

The services are defined with mechanisms to reject unsupported services and options should they be requested. This improves robustness and enables sophisticated service-users to adjust its requests to the capabilities of the particular exception agent.

SEMI E41.1-0996
SECS-II SUPPORT FOR EXCEPTION MANAGEMENT STANDARD

1 Purpose

This document maps the services and data of its prime document, SEMI E41, to SECS-II streams and functions and data definitions.

2 Scope

This is the standard way to implement the Exception Management Standard, which provides remote control communication of exceptions and recovery, using the SECS-II message format.

SEMI E42-0299[E]
RECIPE MANAGEMENT STANDARD: CONCEPTS, BEHAVIOR, AND MESSAGE SERVICES

[E] This standard was editorially modified in September 1999 to conform to its non-provisional status. Changes were made to Section 1.2.

1 Introduction

This standard defines the concepts required for management of recipes, the operations or behavior provided by the Recipe Management Standard (RMS), and the messages through which services are provided through an interface between the provider and the user of these services.

1.1 *Purpose* — The purpose of this standard is twofold:

- *To enable applications software to be developed that can assume the existence of standard concepts, behaviors, and message services that collectively form Recipe Management and that take advantage of them.*
- *To enable software to be developed to offer the Recipe Management capabilities.*

1.2 *Scope* — This is a standard that defines concepts, behavior, and services to support the integration of automated recipe management within a semiconductor factory. These services are applicable to a variety of relationships, including both traditional **host/equipment** and cluster tool controller/attached module communications and control.

The standard provides a set of communications services which allows such systems to transfer and manage recipes to ensure the correct processing of material within semiconductor manufacturing *equipment* and systems. RMS also requires compliance to SEMI E39 (Object Services Standard (OSS): Concepts, Behavior, and Services) for completeness.

This document describes several different hierarchical relationships: supervisory agents and their supervised agents, recipes and their subrecipes, and recipe classes and their subclasses. Such hierarchical relationships provide a natural organizational and classification structure that is reflected in many different kinds of systems, such as telephone switching systems and directory trees. It is the intent of this standard to support logical hierarchical relationships rather than to require that strict hierarchical relationships be implemented in systems architecture.

RMS places no restriction on where the set of defined services is implemented.

1.4 *Definitions* — Basic definitions for objects, services, and form are provided in SEMI E39, Sections 4.1 through 4.4. This section provides additional definitions.

Definitions in Section 1.4.3 are specific to RMS.

1.4.1 *Services*

service provider — An application (a component of an *agent*) responsible for providing services to the service user.

service user — (service consumer) An application that uses the services provided.

1 Semiconductor Equipment and Materials International (SEMI), 805 East Middlefield Road, Mountain View, CA 94043, 650.964.5111, FAX 650.967.5375

1.4.2 *Form*

binary — A string of bit values (zeroes and ones), with a format that is either left unspecified or specified by bit position, with the most significant bit first. The total length of the string is a multiple of eight. Messaging protocol may impose restrictions on length.

1.4.3 *Recipe Management* — This section introduces basic terminology used in RMS. Entries are in alphabetical order. Additional definitions and specifications are provided in later sections.

agent — An intelligent system within a factory that provides one or more service resources and uses the services of other agents. This is a generalization that includes host, equipment, cell, cluster, cluster module, station controller, and work station. *Agents* are associated with a physical system or a collection of physical systems, such as computer platforms.

authorized user — A user who can be identified to an *agent* as having the level of authority required for a particular activity, such as *certifying* a recipe for that equipment.

collection event — A detectable occurrence of interest to a service user.

component agent — A subordinate *agent* that provides services to a *supervisory* agent.

download — An operation that transfers a recipe (down) to an execution storage area.

edit — An operation which creates a new recipe body or changes the body of an existing recipe.

editor — A service which allows a *user* to edit a recipe. *Editors* are not specified in RMS.

equipment[2] — An *agent* with associated hardware that provides, at a minimum, recipe **execution** services.

event — A detectable occurrence significant to an object.

execution (recipe execution) — The process of reading the recipe contents and implementing its instructions, process parameters, or other information required for its own processing.

executing agent — An *agent* that provides *recipe execution* capabilities.

execution area — The storage location of the recipe(s) currently *selected* (ready) for *execution*.

host — A *supervisory agent* that represents the factory to its subordinates.

logical recipe — A recipe with a particular set of *attributes* and a particular *body,* considered independently from its physical location. A *logical recipe* may have multiple instances or copies.

name — A text-based *attribute* of an object that may be used as all or part of its *identifier*.

namespace — In general, a domain within which object identifiers are unique. In RMS, the term *namespace* is used as a synonym for *recipe namespace*, unless otherwise stated.

operator — The user who interacts locally with *agent* through the *agent's* interface.

recipe — The pre-planned and reusable portion of the set of instructions, *settings*, and parameters under control of an *agent* that determines the processing environment seen by the manufactured object and that may be subject to change between runs or processing cycles.

recipe class — A formal grouping of recipes with a common language syntax and functionality.

recipe executor — The component of an *executing agent* that executes recipes.

recipe namespace — A logical management domain with the responsibility for the storage and management of recipes, the ensurance of the uniqueness of recipe **identifiers** within that domain, and the provision of services pertaining to recipes stored within that domain.

recipe parameter — A control value that affects the *agent's* process.

select — The act of preparing a recipe for execution.

setting — A static value accessible to the *user*, through one or more methods, that is used by equipment to control its process. *Settings* include, but are not limited to, setpoint values. *Settings* typically may be specified within a recipe.

storage area — An area where objects and data are stored.

subordinate agent — An *agent* that is a component of, or managed by, another *agent*.

supervisory agent — An *agent* with supervisory responsibilities for one or more subordinate *agents*.

timestamp — The notation of the date and time of the occurrence of an event.

upload — An operation that transfers a recipe (up) from an execution storage area.

user — A person interacting with an *agent* directly through the *agent's* human interface or indirectly through the *agent's supervisor*.

---

2 The term "equipment" is restricted in RMS to "intelligent equipment."

validate — The action of checking recipe contents to ensure that parameter type and range are valid for the equipment configuration prior to execution. [Note that *validation* and *verification* are used in different ways.]

variable parameter — A formally defined variable (*setting*) defined in the body of a recipe permitting the actual value to be supplied externally.

verify — The operation of reading a recipe's contents to ensure that it is syntactically correct and identifying elements that must be made public.

version — Part of a recipe's *identifier* that is used to show its heritage.

1.5 *Conventions* — The following conventions are used in this document:

- *To highlight terms specific to RMS (excluding terms defined in Sections 1.4.1 through 1.4.3 that are common to multiple standards), a defined term appears in* **boldface** *wherever it first appears and wherever it is defined. This alerts the reader to those terms with specific meanings. Except for terms that are very common, such as recipe, host, and equipment, defined terms otherwise are in* italics *wherever they appear.*
- *Terms related to objects and object services are in conformance with SEMI E39 (Object Services Standard: Concepts, Behavior, and Services). A brief discussion of objects is provided in the Appendix of that document.*
- *Attribute names are underlined.*
- *Attributes called "names" in RMS are generally intended to be used for the ObjID attribute of a* standardized object.
- *To prevent the definition of numerous message parameters named "XxxList," this document adopts the convention of referring to the list as "(List of) Xxx". In this case, the definition of the parameter Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type.*

For attributes that are lists, this convention is not followed, as the entire attribute, as a list, must be assigned a specific name.

1.5.1 *Text String Restrictions* — Text strings used in attribute names, attribute values, or message parameters, are subject to the restrictions defined by OSS: Text in ASCII is restricted to the characters between 20_{16} and $7D_{16}$, excluding the question mark "?" ($3F_{16}$), the asterisk "*" ($2A_{16}$), and the tilde "~" ($7E_{16}$). Text strings used as, or within, the object identifier ObjID are additionally restricted to exclude the "greater than" symbol ">" ($2E_{16}$) and the colon character ":" ($3A_{16}$) to conform with OSS requirements.

1.5.2 *Harel State Model* — This document uses the Harel State Chart notation to describe the dynamic behavior of the objects defined. An overview of this notation is presented in an Appendix of SEMI E30. The formal definition of this notation is presented in Science of Computer Programming 8, "Statecharts: A Visual Formalism for Complex Systems," by D. Harel, 1987.

This document also adopts the extension of Harel notation to show the deletion of an object as used by Rumbaugh, et al. (see Section 1.5.2.1).

1.5.3 *Objects — Standardized objects* defined by RMS conform to the requirements of SEMI E39 (Object Services Standard: Concepts, Behavior, and Services). RMS adopts the convention of showing *standardized objects* as drawn with a heavy line in object models. *Non-standardized objects* are used to illustrate concepts and relationships but are not formally defined and cannot be accessed through Object Services. A list of *standardized objects* defined by RMS is included in Related Information 1.

1.5.3.1 *OMT Object Information Model* — The object models are presented using the Object Modeling Technique, developed by Rumbaugh et al., in *Object-Oriented Modeling and Design,* Prentice-Hall, Englewood Cliffs, NJ, 1991. Overviews of this notation are provided in an appendix of SEMI E39 (Object Services Standard: Concepts, Behavior, and Services).

1.5.3.2 *Object Attribute Representation* — The object information models for *standardized* objects will be supported by an **attribute definition** table with the following column headings:

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
The formal text name of the attribute.	Description of the information contained.	RO or RW	Y or N	(see below)

The Access column uses RO (Read Only) or RW (Read and Write) to indicate the access that users of the service have to the attribute.

A 'Y' or 'N' in the Requirement (Rqmt) column indicates if this attribute must be supported in order to meet fundamental compliance for the service.

The Form column is used to indicate the format of the attribute. (See Section 1.4 for definitions.)

1.5.4 *Service Message Representation*

Service Resource Definition

A **service definition table** defines the specific set of messages for a given *service resource*, as shown in the following table:

Message Service Name	*Type*	*Description*
Message name	N or R	The intent of the service.

Type can be either N = Notification or R = Request.

Notification type messages are initiated by the service provider, and the provider does not expect to get a response from the user.

Request messages are initiated by a service user. Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

Service Parameter Dictionary

A **service parameter dictionary** table defines the parameters for one or more services, as shown in the following table:

Parameter	*Form*	*Description*
Parameter X	Data type	A parameter called X is B in A.

A row is provided in the table for each parameter of the service. The first column contains the name of the parameter. This is followed by columns describing the form and contents of the corresponding primitive.

The Form column is used to indicate the type of data contained in a parameter. (See Section 1.4 for definitions.)

The Description column in the Service Parameter Dictionary table describes the meaning of the parameter, the values it can take on, and any interrelationships with other parameters.

To prevent the definition of numerous parameters named "XxxList", this document adopts the convention of referring to the list as "(List of)Xxx". In this case, the definition of the variable Xxx will be given, not of the list. The term "list" indicates a collection (or set) of zero or more items of the same data type. Where a list is used in both the request and the response, the list order in the request is retained in the response. A list must contain at least one element, unless zero elements are specifically allowed.

Service Message Definition

A **service message definition** table defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
Parameter X	(see below)	(see below)	A description of the service.

The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message. The message sent by the initiator is called the "Request". When receiver terms this message the "Indication" or the "Request", the receiver may then send a "Response", which the original sender terms the "Confirmation".

The following codes appear in the Req/Ind and Rsp/Conf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M" — **Mandatory parameter** — must be given a valid value.

"C" — **Conditional parameter** — may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of the other parameter.

"U" — **User-defined parameter**.

"-" — The parameter is not used.

"=" — (for Response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

1.6 *Requirements* — Requirements for recipe management are varied. For example, there is a fundamental need to retain information about each recipe, to provide that information upon request, and to transfer it with the recipe so that it remains available. There is a need to classify recipes, to reuse them, and to share them with multiple installations of *equipment*. The need for sharing recipes introduces a new requirement for safeguarding the relationship between a recipe's **identifier** and its contents, to be able to protect a recipe from unauthorized changes, and to ensure that the *identifier* for a recipe that is used by multiple *equipment* is in fact the same recipe.

The requirements for managing recipes in a factory are given in tabular form in Table 1.1, which presents them according to their functional areas and the specific issues involved. Table R1-1, in Related Information, shows the specific concepts defined in RMS to address each of these requirements.

Table 1.1 Requirements

Functional Areas	*Issue*	*Requirements*
Management of Recipes	Identification	Uniquely store, identify, and select recipes in a system.
		Easy and clear identification of a recipe.
	Multiple Access	Share recipes among *equipment*.
		Enable synchronized change of shared recipes among *equipment*.
	History and Traceability	Capture the history of recipe usage.
		Capture the history of recipe changes.
	Life Cycle Management	Manage approval of recipes for process development and production.
Operations	Protection	Protect recipes from unexpected changes.
		Protect recipes from mistakes in operations.
	Portability	Create, edit, and change recipes outside the *equipment* which execute them.
	Reusability	Change recipes for a specific piece of *equipment*.
		Use recipes developed on one piece of *equipment* for other *equipment*.
		Share recipes among the same kind of *equipment* by adjusting for individual differences.
Execution	Safety	Do not execute recipes that are not syntactically correct.
		Execute the specified (selected) recipes without errors.
		Protect recipes being executed from inadvertent change caused by other activities.
	Flexibility	Change a recipe's **parameters** during or between runs in a systematic way.
System Operation	System Node Operation	Dynamically connect and disconnect *equipment* to/from the communications network.
	Stand-Alone Operation	Execute recipes with no communications link.
		Create and change recipes with no communications link.
		Manage recipes moved between *equipment* or from off-line storage through removable media.
		Enable smooth integration of stand-alone *equipment* into on-line factory systems.

1.7 *Document Structure* — Figure 1.1 depicts the domain of the Recipe Management Standard as consisting of Purpose, Concepts, Behavior, and Message Services. This also reflects an underlying structure of the document.

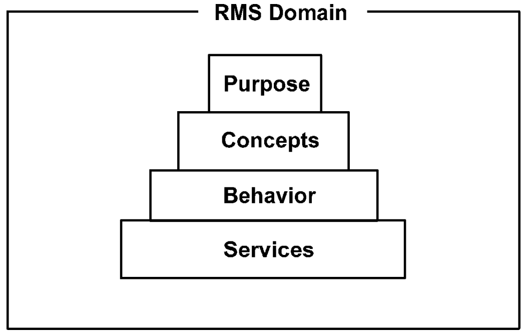

Figure 1.1
Recipe Management Domain

Purpose provides the motivation for Recipe Management capabilities and is addressed in Section 1.6. Concepts provide a detailed introduction to the *standardized objects* of RMS, their attributes, and their relationships with other objects. Behavior describes the operations that are performed by, or on, these objects. Finally, message services define the messages and their parameters independently of the protocol in which they are implemented. Both concepts and behavior represent an "inside view" of an RMS application, while services provide an interface from an external view.

- *Section 1: the formal introduction to RMS.*
- *Section 2: an overview of the major objects of RMS and their relationships, to provide a general context for the technical detail that follows.*
- *Sections 3-6: concepts for recipes, recipe namespace, distributed recipe namespace, and recipe executor.*
- *Section 7: the concept of the* agent *and of* service resources*, to provide a more complete context for RMS implementations.*
- *Sections 8-11: behavior (operations) for recipe management, namespace management, distributed recipe namespace management, and the* recipe executor.
- *Sections 12-14: definitions of message services for the* recipe namespace, distributed recipe namespace, *and* recipe executor ***service resources****.*
- *Section 15: RMS compliance.*
- *Section 16: a glossary of terms, provided as a convenient reference.*
- *Related Information: provides background information on the requirements behind RMS and examples of applications.*

1.8 *Applicable Documents*

ISO/TR 8509:1987, Information Processing Systems, Open Systems Interconnection — Service Conventions.

2 Overview of RMS

This section provides an introduction to, and overview of, the major objects of RMS.

2.1 *Recipe Management Models* — To provide a clearer understanding of the major entities or areas of functionality specified by RMS, they are portrayed as objects in RMS models, using OMT notation.

Relationship lines in the object-based models do not represent a direct communication link between objects, but rather the knowledge and association that one object has with respect to another.

The models do not indicate the relative location of two objects.

2.2 *Major Objects in RMS* — Recipe Management is concerned with the major areas of functionality illustrated in Figure 2.1: recipes[3], **recipe namespaces** providing persistent recipe storage, **recipe namespace managers** that provide management of the *namespace* and access to its recipes, and the **recipe executor** that executes recipes.

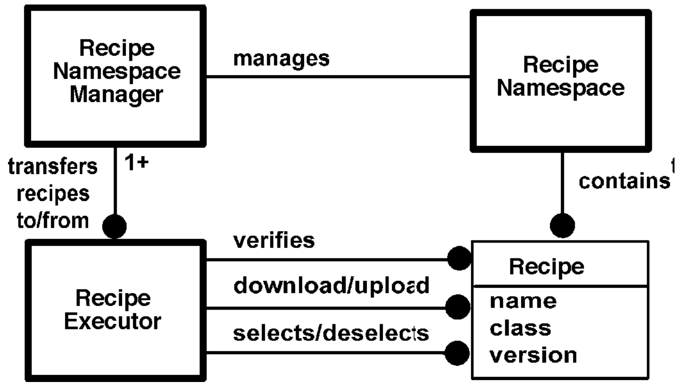

Figure 2.1
Major Objects of RMS

2.2.1 *Recipes* — Recipes provide a flexible, manipulatable, and re-usable form for users to select sequencing and settings to effect a particular result. Equipment uses recipes in a variety of ways to control the processing environment, sometimes using several types of recipes together. Recipes may also be used for maintenance activities, such as calibration or cleaning.

Recipes can be modified and copied from one environment to another. Their inherent flexibility as a form also becomes an endless source of problems unless they can be managed. Misprocessing, unintentionally running the wrong recipe for a given product, is prohibitively expensive for factories.

RMS defines a recipe as an object with attributes — information about the recipe — as well as content. It is the attributes of the recipe that allow true management of recipes, throughout their lifecycles, to occur.

2.2.2 *Recipe Namespace* — A *recipe namespace* in RMS is analogous to a smart file directory. The *namespace* provides long-term recipe storage capability.

Basic operations are part of the *namespace* specification. For example, recipes can be copied from one *namespace* to another, copied within a *namespace*, renamed, created, updated, and deleted. They can be downloaded to, and uploaded from, an application called a *recipe executor*. Several recipes can be *linked* together to form a set.

The *namespace* also can serve as a recipe pool that can be shared by a group of equipment of a common type. The *distributed recipe namespace* is a *namespace* able to utilize and manage recipe storage provided by such an equipment group.

2.2.3 *Recipe Namespace Manager* — The *recipe namespace* itself is passive, a container for recipes. The **recipe namespace manager (manager)** provides the dynamic element that manages the *namespace*. The *manager* represents the interface for the *namespace* to the external world and the internal decision authority within the *namespace*.

---

3 The recipe object in Figure 2.1 is not itself a standardized object. However, two recipe subtypes defined in Section 3 are standardized objects.

2.2.4 *Recipe Executor* — The **recipe executor (executor)** is the component of an *agent* that understands the contents of a recipe and is able to **verify** their syntactical correctness and to **validate** that it can be executed under the current configuration. It **executes** a recipe by reading its contents and applying them appropriately in order to achieve a desired result.

The *recipe executor* also may provide additional limited storage capability, but it is restricted from modifying existing recipes, except under special conditions, to prevent unexpected and/or unwanted change.

2.3 *Agent* — As used in RMS, an **agent** is a system, or subsystem, in a factory, that has a physical aspect. It consists of one or more applications that provide and/or use *service resources*, such as a *recipe namespace manager* and/or a *recipe executor*, as illustrated in Figure 2.2.

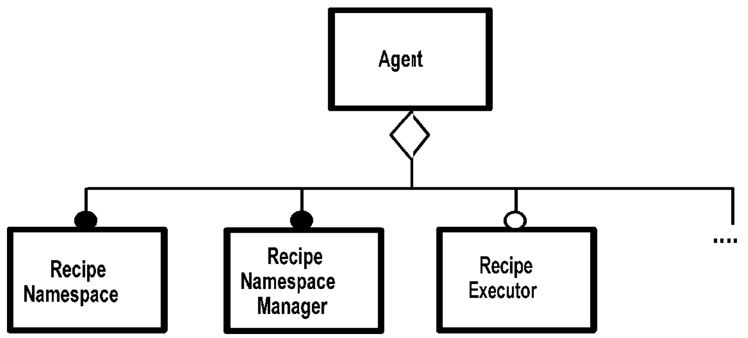

Figure 2.2
An Example of an Agent and Component Applications

Agent is a generalization that covers traditional *equipment*, supervisory or aggregate systems such as stations, cells, and clusters, and intelligent subsystems within *equipment*, such as process modules within a cluster. Other types of *agents* may also be implemented, such as those dedicated to *recipe namespace management*.

An *agent* that provides a *recipe executor* is called an **executing agent**. **Equipment** is an *executing agent* with associated hardware to which the recipe applies and which it uses to do work.

2.4 *Implementations* — RMS can be implemented on different platforms within a factory. A host controller may only provide *recipe namespace management*, while a diskless cluster module may provide only *recipe execution*. Traditional *equipment* capable of operating in stand-alone mode is required to provide a *recipe namespace* that is available on powerup as well as a *recipe executor* component. Additional examples of implementations of RMS are provided in Related Information 1.

RMS defines the services provided through an external interface. Communications between or within applications that are internal to an *agent* are not covered by RMS, so long as the attributes and operations comply with RMS requirements.

3 Recipes

This section describes the concepts concerning recipes.

3.1 *Motivations* — Definitions of recipe structure, attributes, and operations address the following issues:

- *maintenance of recipe attributes for management and traceability,*
- *provision of a standard method for transferring attributes separately, as well as with the recipe body,*
- *reduction or elimination of the need for dedicated recipe editors,*
- *support for applications requiring multiple recipe types, such as formats or language syntaxes,*
- *run-to-run control,*

- *support for sorting by factory approval and* ***certification levels****,*
- *the ability to tune a generic recipe for a specific installation of agent as well as the same agent over time, and*
- *the ability to share recipes across* executing agents *supporting the same recipe syntax or language(s).*

3.2 *Basic Concepts* — There are two types of recipes addressed by RMS, the **managed recipe** that is stored in a *recipe namespace* and the **execution recipe** that is stored in **recipe execution storage**. This section describes the basic concepts concerning both types of recipes.

3.2.1 *Types of Recipes* — There are three types of recipe objects shown in Figure 3.1. Most of Recipe Management is concerned with the management of recipes stored in a ***recipe namespace***. These recipes are called **managed recipes**. Recipes are also stored by the *recipe executor* in the **recipe execution storage**, and these are called **execution recipes**.

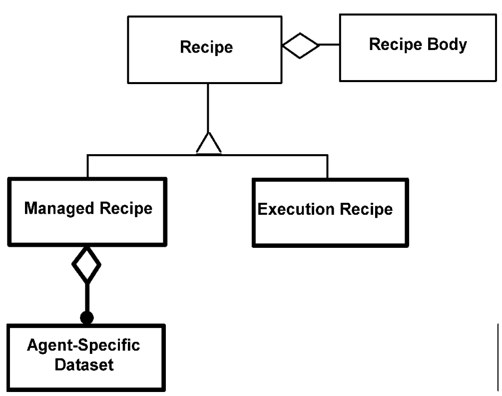

Figure 3.1

Recipe Types

The recipe supertype is an abstract type that shows the common elements and attributes of the *managed recipe* and the *execution recipe* and their differences. The recipe supertype is not itself intended to be implemented. That is, recipe object types formally defined in RMS are either *managed recipes* or *execution recipes*. As indicated by the light lines, the supertype is not a *standardized object*.

3.2.2 *Recipe Structure* — Both the *managed* and the *execution* recipe have a **body**[4] and a set of attributes. The *body* (contents) of the recipe contains the data used by the *recipe executor* for its execution process. The *body* is also not a *standardized object* and may not be accessed through Object Services.

Figure 3.2 illustrates all of the attributes defined by RMS that are common to both the *managed recipe* and the *execution recipe*. Not all of these attributes are required for a minimum implementation of RMS. The rules for setting the values of certain attributes, however, are different for the *managed recipe* and the *execution recipe*.

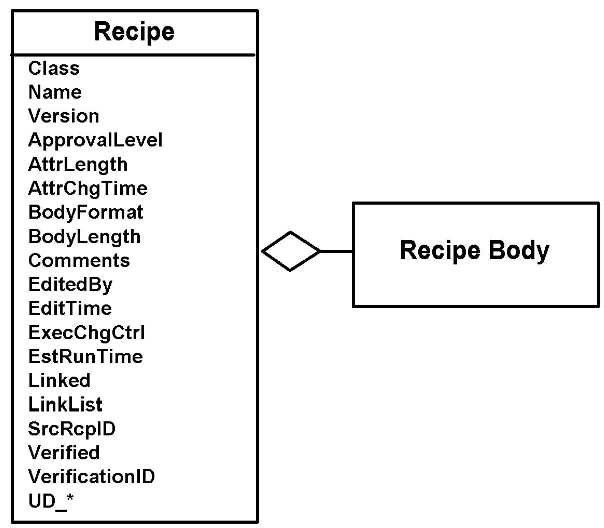

Figure 3.2

Recipe Supertype

The **identification attributes**, those attributes used for purposes of identification, are discussed in Section 3.3. The other attributes are discussed in later sections specific to each recipe type.

The *managed recipe* also may maintain a set of attributes that are specific to a single *executing agent*. The **agent-specific** attributes are technically attributes of the association between the recipe and the *executing agent*. In RMS, however, these attributes are treated as attributes of a component of the recipe called the **agent-specific dataset**, in order to allow them to be managed within the *namespace* along with the other attributes of the recipe. *Agent-specific* attributes allow the recipe to be personalized for particular *executing agents* (i.e., particular *recipe executors*).

4 The recipe's body corresponds to a "process program" in SEMI E5 and SEMI E30.

Because the *managed* recipe may be applied to multiple *agents*, it may have multiple *agent-specific datasets*. When a *recipe* is downloaded from a *recipe namespace* to a *recipe executor*, the *managed recipe* is transformed into an *execution recipe* by taking the *agent-specific* attributes of the *agent-specific dataset* for that *agent* (its *recipe executor*) and merging them into the attributes of the *execution recipe*.

Methods of storing a recipe or the components of a recipe are not dictated by RMS. However, the association between a recipe's *body* and its attributes shall be carefully maintained.

3.2.2.1 *Recipe Body* — The recipe **body** contains the reusable instructions, *settings*, *parameters*, and other data that the *recipe executor* reads to *execute* the recipe and control its operation.

A recipe *body* may be in one of two basic forms: **source** (text) or **object**. The purpose of the *source form* is to encourage the use of human-readable and human-editable text. The *object form* supports the types intended only to be read and applied by machines and other automated systems, such as those produced by vision systems or CAD programs, as well as proprietary formats created and used by the *recipe executor*.

3.2.2.1.1 *Source Form* — Recipes that are created and modified by a form of editor should be available in *source form*. The **source form** of a recipe *body* is equivalent to a text file, such as ASCII or JIS-8, that can be created, read, printed, or modified with any "standard" text editor[5]. The *executing agent* is not required to supply such a text editor, but its *recipe executor* should be able both to read and write recipes in *source form*. Editing is not covered by RMS.

The *source form* of a recipe may be copied from one *namespace* to another *namespace* and from a *namespace* to a *recipe executor's recipe execution storage*, and all *recipe executors* with access to a given *namespace* are assumed to use the same recipe language and the same functionality.

Two restrictions are placed on the interpretation of the text transferred between agents:

- *In ASCII, the valid characters are from space* (20_{16}) *through "~"* ($7D_{16}$)*, plus the tab* (09_{16})*, linefeed* ($0A_{16}$)*, carriage return* ($0D_{16}$)*, and form feed* ($0C_{16}$) *characters. The space and tab are considered as* ***horizontal whitespace*** *characters, and the carriage return and form feed characters are considered* ***vertical whitespace*** *characters. The line-feed character is used to define the end of a line of text (eol).*

- *The meaning of a recipe should not depend on embedded control characters, or specific* whitespace *characters, or the existence of* whitespace *at the end of a line.* Horizontal whitespace *characters should be treated alike for purposes of interpretation, as should* vertical whitespace *characters. All other characters, aside from those specified here, are discouraged and, if found, should be removed from the text prior to transfer.*

In general, the recipe language and syntax used within a recipe *body* are beyond the scope of recipe management. However, to reduce arbitrary variability for the *user*, the following "rules" are recommended:

- *Case is not significant for the purpose of comparison or meaning but should be retained as encountered, since it is often used to enhance readability. For example, the tokens alarmlevel, ALARMLEVEL, and AlarmLevel should all have the same meaning.*

- *Comments may be included in the text and are ignored in recipe interpretation. Two types of comments are defined: comments that begin with the character pair "//" continue to the end of the line, while comments that begin with the character pair "/*" are terminated only by the character pair "*/". A comment of the second type is terminated by the first character pair "*/" that follows. Comments may not be nested. Nested comments are not honored and may generate a syntax error.*

- *The minimum line consists of a single line-feed character.*

In addition, recipe languages that support **external references** to other recipes should use the text form defined for the recipe *identifier* (Section 3.2.3.4) and for the recipe **specifier** (Section 3.2.4.1.2).

The supplier of the *recipe executor* shall provide documentation that formally defines each recipe language that the *agent* supports. Two forms are required, one for the *user*, who must be able to write correct recipes, and one that covers both the syntactical and lexical structures of the language using a formal descriptive protocol such as the Backus-Naur Form (BNF). The second form of documentation allows parsers to be built that are capable of pre-checking a recipe for syntactic and lexical correctness prior to downloading it. Pre-checking improves efficiency and

---

5 The intent is not to specify the text editor, but rather to allow a user to modify text on the basis of clear guidelines and restrictions that may apply. Source form recipes are highly desirable to reduce the proliferation of, and need for, proprietary editors that are dedicated and language-specific.

performance by reducing the demand for recipe checking by the *recipe executor*.

The final responsibility for determining the correctness of a recipe shall belong to the *recipe executor*.

3.2.2.1.2 *Object Form* — Recipes that cannot be translated into a meaningful *source form* include datasets derived from vision systems or mechanical systems through a special hardware-dependent "teach" operation. Such recipes may remain in a proprietary *object form* and may or may not be applicable to other *recipe executors* because of their hardware dependencies.

For greater efficiency, *recipe executors* may rewrite (e.g., **tokenize**) a *source* recipe to generate a proprietary *object form* of the recipe. This is called the **derived object form**, to distinguish it from *object form* recipes that never exist in *source form*. The *agent's* manufacturer may choose to make this form available for transfer as well. From the point of view of the *supervisor*, the *body* of a recipe that is in *object form* is an unstructured binary vector or string. In general, it cannot be edited on a *supervisor*, and the *source form* of the recipe is still required. *Derived object form* recipes that cannot be used by multiple *recipe executors* should not be stored in *recipe namespaces* that are shared.

Where both the *source form* and the *derived object form* exist, the *identifier* for the *object form* of the recipe shall be different from that of the *source form* in some recognizable way. The supplier of the *recipe executor* shall provide a documented method for distinguishing one from the other within the *identifier*. This method must be such that the relationship of the *derived object form* recipe from the original source recipe is obvious to the user. (See Section 3.2.3.4 for examples.) An attribute of the recipe, SrcRcpID, is provided to retain the relationship between the *source form* recipe and the *derived object form* recipe.

3.2.3 *Recipe Identification* — The ability to properly and unambiguously identify a recipe is critical to both recipe management and processing. It is also important for the user that identification be logical. RMS defines three elements used to uniquely identify a recipe within any *recipe namespace*. These three elements are the recipe's **class**, **name**, and version. Each element is expressed as a text string, and they are concatenated together to form the **recipe identifier** (see Section 3.2.3.4).

3.2.3.1 *Recipe Name* — The **recipe name** is a user-defined text string that may be used to encode the technology, layer, manufacturing area, and other characteristics. The *recipe name* alone is not necessarily unique within either a given class or a given *namespace*.

The *recipe name* is subject to the conventions for text as defined in Section 1.5.1.

3.2.3.2 *Recipe Class* — A **recipe class** is a formal grouping of recipes that have a common syntax. A class may contain **subclasses** where the recipes within the *subclasses* operate in different environments or have different syntaxes from the parent *class* and/or from one another. A *subclass* is itself a *class* and may contain further *subclasses*.

The overall model for recipes is a set of *class* hierarchies or "*class* trees" defined by the supplier of the *recipe executor*. The major *classes* of recipes are the **PROCESS** *class*, the **SERVICE** *class*, and possibly other *agent-specific classes*. These are called **primary classes**. A **primary class** is a *class* that is not a *subclass* of another *class*.

The PROCESS *class* is a required *primary class* and is composed of recipes whose primary purpose is to increase the manufactured value of the production material[6].

The SERVICE class is an optional *primary class* used for recipes whose purpose is to maintain, prepare, calibrate, or test the operation of *equipment*. Typical *subclasses* of the SERVICE *class* might be CALIBRATION and CLEANING. SERVICE recipes that use the same recipe language as normal process recipes are not required to be placed into a separate *primary* class. The SERVICE class allows separation and use of a different syntax for special non-process purposes.

Other *primary classes* that do not fit the PROCESS or SERVICE may be provided by the supplier of the *recipe executor*. Such additional *classes*, and their function, shall be documented.

Recipes that are not in the PROCESS *class* or one of its *subclasses* shall not be used for production purposes. However, recipes within the PROCESS class may be used for purposes other than production.

Figures 3.3 and 3.4 show examples of object models of possible *classes* and *subclasses* for a wire-bonder and for a furnace with an automatic boat-loader subsystem.

6 Material handling systems, wafer metrology, wafer measurement, wafer inspection systems, as well as process equipment which directly changes the characteristics of the material, increase the value of the material in some way.

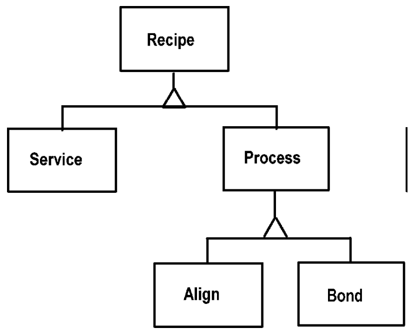

Figure 3.3

Wire-Bonder Recipe Classes

The text form of a recipe *class* shall conform to the convention for text (Section 1.5.1). Within the text form of a recipe *identifier*, a class is delimited on both ends by the forward slash character "/". The complete *class* specification within recipe *identifier* is formed by the concatenation of *classes* and *subclasses*, starting with the *primary class* and ending with the particular *class* of the recipe in question:

"/PRIMARY CLASS/SUBCLASS$_1$/SUBCLASS$_2$/…".

For example, a recipe named DryOx, version 4, within the NORMAL CYCLE *class* in Figure 3.4., has an *identifier* of

"/PROCESS/FURNACE/DIFFUSION/NORMAL CYCLE/DryOx;4".

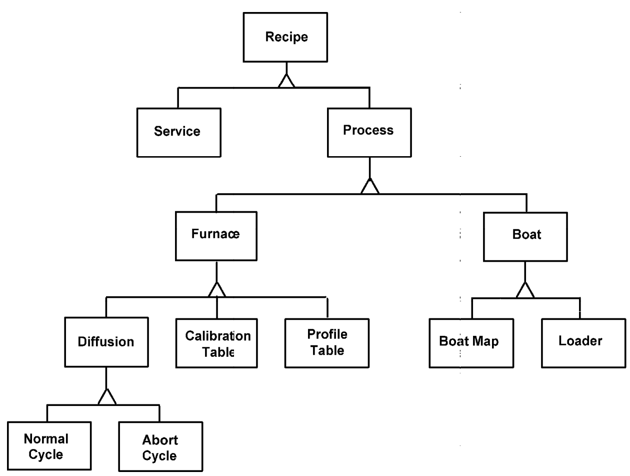

Figure 3.4

Recipe Classes for Furnace

The complete *class* specification, which always starts with the *primary class*, shall always be accepted. If *class names* within a *namespace* are all unique, however, the *service* provider may also accept a *class* designator consisting of a single *class*. The *identifier* in the example above then becomes

"/NORMAL CYCLE/DryOx;4".

3.2.3.3 *Version* — A recipe may evolve over time and exist in several versions. This allows the user to retain a recipe *name* over multiple versions and show the recipe's heritage. Different versions are identified by the **version** portion of the recipe's *identifier*. NOTE: More than one version of a recipe may be in use for production at the same time, not only within the factory, but also within a single equipment.

A **version** is a text string consisting of at least one character. A new *version* is either generated automatically by the *recipe namespace* or is assigned by the *user*. A *user* may assign any combination of text characters and punctuation marks to the *version*, except for:

- *the characters prohibited by the convention for text usage and the object identifier (Section 1.5.1),*
- *whitespace characters.*

It is recommended, but not required, that only upper case be used.

Numeric versions (**version numbers**) consist only of the digits "0" through "9" and one decimal point character "." and can be translated to a pure number. To avoid confusion and multiple *versions* with the same numeric value, *numeric versions* are further restricted as follows:

- *whole numbers (with no decimal point) may not start with a zero "0" followed by another digit, and*
- *decimal numbers (with a decimal point) may not start or end with the decimal point or end with a zero following the decimal point.*

For example, *version numbers* "09", "1.", ".5", and "1.670" are prohibited. The proper forms with the same numeric values are "9", "1", "0.5", and "1.67". The *user* may assign a *version* of "0" but not of "00".

Versions that are assigned automatically have additional restrictions:

- *They shall be* numeric versions*, excluding the decimal point and with a minimum value of "1".*
- Versions *shall be assigned incrementally. When assigning a* version *for a recipe with a given* class *and* name*, if no other recipe exists within the* namespace *with that* class *and* name*, then a* version *of "1" is assigned. Otherwise, the highest* existing version *already in use for that* class *and* name *is determined, and the new* version *is assigned a value equal to that value plus 1. For example, if the highest* version *in use has a numeric value of 5, then the next* version *assigned would be "6". To compare* two versions*, they are converted to upper-case and compared character by character.*

3.2.3.4 *Recipe Identifiers* — The **recipe identifier** is formed from the concatenation of the recipe's *class*, *name*, and *version*, in that order:

"/$CLASS_1$/$CLASS_2$/…/$CLASS_n$/NAME;VERSION"

where $CLASS_1$ is a *primary class* and $CLASS_{i+1}$ is a *subclass* of $CLASS_i$. The recipe *name* follows *class*. *Name* and *version* are always separated by a semicolon ";" ($3B_{16}$).

Where $CLASS_n$ is a unique class name, the form becomes

"/CLASS/NAME;VERSION".

The recipe *identifier* is used for the OSS-required attribute ObjID and shall conform to restrictions imposed on ObjID (see SEMI E39). The total length of ObjID may have additional restrictions imposed by the protocol.

NOTE: There is no necessary relationship between a recipe's *identifier* or *name* and any file name(s) under which the *body* and attributes may be stored internally. The recipe *identifier* is a logical reference to the recipe that is independent of specific platforms and implementations. In particular, file services provided by operating systems may have naming restrictions, such as length, that are incompatible with the requirements of RMS. A recipe may be stored internally in different ways, such as in a single flat file, a set of related files, or a database. Actual storage methods shall be invisible to RMS.

Where suppliers supporting recipes in *source form* also rewrite them, as discussed in Section 3.2.2.1.2, a method based on the recipe *identifier* (ObjID) is required to both distinguish between the two *forms* and to recognize the relationship between the original *source form* recipe and the derived *object form* recipe. The method may use any of the three elements of the *identifier* for this purpose. For example, recipes in *object form* may be placed in a separate *subclass* called "/OBJ/", or a suffix such as ".obj" might be appended to the user-defined *name* of the original recipe.

3.2.3.4.1 *Default Recipe Identifiers* — It is always possible to reference a recipe by specifying its *full identifier* (*class*, *name*, and *version number*). In certain cases, described in Section 3.2.4.1.1, it may also be necessary to specify the *namespace* of a recipe. However, it is not always necessary to specify all components of the *identifier*. Specifically, *class* and/or *version* may be omitted when a recipe is *selected* for execution and within an *external reference*. *Namespace* is not normally specified. Rules define default values for *namespace* and *class*, and there are rules for determining the appropriate *version*.

The recipe *name* must always be specified.

For *external references* within a recipe, the default *class* is the *class* of the recipe making the reference. The proper *class* is determined when the recipe is *linked* (see Section 3.2.4.1.3).

Where a recipe *version* is unspecified, the recipe of that *class* and *name* having the highest *approval level* will be used. Where several recipes are found with the same *approval level*, the one with the highest *version* will be used. Where the *version* is unspecified in an *external reference*, the correct *version* is determined when a **linked recipe set** is built by the **link** operation.

For references with *managed recipes*, if no *namespace* is specified, the default is *namespace* of the referring recipe.

3.2.4 *Advanced Recipe Capabilities*

3.2.4.1 *Multi-Part Recipes* — Use of multi-part recipes is often dictated by the *recipe executor*, which may require a set of recipes of different *classes* for its process. In addition, support for multi-part recipes can be helpful for the user, in particular where recipes are otherwise long. The recipe language may define use of subrecipes analogous to that of subroutines in ordinary programming languages. This enables better re-use where a high degree of similarity exists between different recipes.

Where recipes of more than one *class* are required, it is convenient to allow one recipe to reference another. A recipe in the PROCESS *class*, for example, may refer to recipes in other *classes* to ensure that an entire set of recipes is *executed* together.

It is also convenient to allow one recipe to reference other recipes within the same *class*, where a substantial set of instructions and/or *settings* are common to a variety of other recipes.

A reference within the *body* of one recipe to a different recipe is called an **external reference.** The exact syntax in which this is done is determined by the recipe language used. An *external reference* may also specify values for *variable parameters* defined in the referenced recipe or in one of its *subrecipes*.

3.2.4.1.1 *Subrecipes* — When one recipe references another recipe, both recipes are required for *execution*. The starting recipe is called the **main** recipe.

Subrecipes are those recipes that are referenced by the *main* recipe, or by another *subrecipe* of the main recipe. A recipe that references other recipes is a **parent** recipe to the referenced *subrecipes*. A parent recipe is not necessarily a *main* recipe. A main recipe must not be referenced by any of its *subrecipes*.

External references to recipes within the same *namespace* may or may not be explicit. That is, references to the current *class* (i.e., the *class* of the recipe being *verified*) may be implicit, and *versions* may be left to the rules for determining the default *version* at *link-time*.

A recipe may also reference recipes in another *namespace*. This occurs either when a recipe is to be **delegated** or when a recipe in a *namespace* accessed by multiple *agents* must reference a hardware-dependent or other *agent-specific* recipe kept in a **default namespace**. The *default namespace* of a *recipe executor* is always referenced within a recipe as the namespace named "Default". This name is interpreted by the *recipe executor* at execution time, based on its attribute DefaultNamespace (see Section 6.3).

When specified in a text string within a recipe with the subrecipe's *identifier*, the *identifier* is preceded by the value of the *namespace's* identifier, followed by a greater-than symbol ">". This is called the **recipe specifier**. For a recipe ETCH version 5 in a *namespace* named "NS-MOM", this would be specified as

“NS-MOM>/PROCESS/ETCH;5”.

According to the rules of OSS, object type may be omitted when it may be otherwise determined. In RMS, determination is made according to order.

3.2.4.1.2 *Delegated Recipes* — A recipe may reference recipes in another *namespace* that are to be executed by a *component agent* and are termed **delegated recipes**. Although referenced by another recipe, *delegated recipes* are not considered as *subrecipes* of the *parent* (referencing) recipe as they are to be *executed* by a difference *agent* and are themselves required to be a *main* recipe. A reference to a *delegated recipe* is the equivalent to an automated "select" and "start" sequence of commands from the *supervisor*. As such, they are generally subject to the constraints of a *select* operation.

Delegated recipes may or may not require the *name* of the *executing agent* (*recipe executor*), depending on the rules of the particular implementation. For example, a *supervisor* may be able to determine the appropriate *executing agent* at run-time, based on the *namespace* specified. However, the ability to specify a particular *executing agent* is important to the user, as process results may be sensitive to a particular equipment installation. Therefore, recipe languages that support delegation shall allow specification of the particular *executing agent* to be used. The text format of the full **recipe specifier** in this case is:

"Agent-Name>Namespace-Name>CLASS/Name;Version".

The required order of *identifiers* within the *specifier* is: agent, *namespace*, recipe.

3.2.4.1.3 *Linked Recipe Sets* — Where one recipe references another, a set of recipes to be executed together is formed by starting at the *main* recipe and collecting the *external references* to identify all the members of the set. This set is called a **linked recipe set**, and the operation of collecting the references is the **link** operation.

3.2.4.2 *Variable Parameters* — **Variable parameters** are variables that can be assigned values from outside the recipe itself. *Variable parameters* allow recipes to use variables rather than constants for such actions as setting temperature setpoints, time delay intervals, and data-set names. This capability greatly extends the re-usability of a recipe.

A *parameter* first is formally **defined** within a recipe body and given a unique **parameter name**, a **parameter initial value** (default value) for use when the recipe is *selected* for execution, unless overridden. Where applicable, the *definition* also includes a **parameter restriction** that represents one or more conditions that any *value* assigned to that *parameter* is required to satisfy to be valid.

The syntax for *parameter definitions* in recipe *bodies* remains unspecified, so long as it conforms to the syntax of the recipe language and contains the required elements. Other restrictions concerning the use of *variable parameters* may be imposed by the *recipe executor's* supplier through the specification of the recipe language.

The **parameter domain** is the set of all possible values of a given *form* (see Section 1.4.3) that fulfill the conditions of the **parameter restriction** (if any).

The form need not be included in the *parameter definition* declared within the recipe *body*, but rather may be derived by the *recipe executor* during the *verification* process from the way in which the *parameter* is applied within the recipe. If temperature is maintained internally as an unsigned integer, for example, those *parameters* that are used in the recipe to assign temperature setpoints and ranges would typically be required by the supplier of the *executing agent* to represent unsigned integers as well. The supplier shall document the forms and valid *domains* for each of the *parameters* that may be used as a *variable parameter*.

NOTE: The *parameter's value* may be changed from its *initial* (default) *value* within the text of a recipe, and it may also be set as an "argument" passed to a *subrecipe*. These capabilities are a function of the recipe language and are beyond the scope of RMS.

Two categories of *parameters* are defined: **numeric** and **non-numeric**.

3.2.4.2.1 *Numeric Parameters* — *Numeric parameters* include all *parameters* that can take on *any numeric value* for its *format type* between a **parameter low limit** and **parameter high limit**.

The *parameter restriction* for a *numeric parameter* in any of the attributes that store *parameter definitions* shall be a text string that conforms to one of the following:

- *"(a,b)└┘UNITS" the* domain *of numbers x such that* $a<x<b$
- *"(a,)└┘UNITS" the* domain *of numbers x such that* $a<x<+\infty$
- *"(,b)└┘UNITS" the* domain *of numbers x such that* $-\infty<x<b$
- *"UNITS" the* domain *of numbers x such that* $-\infty<x<+\infty$.

where:

1. a and b are *numeric values* formed from the digits "0" through "9", the plus and minus signs "+" and "-", the period ".", and the letters "E" or "e" for floating point numbers,
2. └┘ represents optional *whitespace*, and
3. UNITS is a valid case-sensitive string conforming to the Units of Measure Identifiers (see SEMI E5, Section 9).

For example, both of the following strings are valid: "(500,2000)└┘degC" and "(0,100)".

To include equality, parentheses are replaced by the square brace "[" and/or "]" on the left or right end, respectively. For example, "[a,b)" represents the domain of numbers x such that $a \le x < b$.

To specify units only, with no restriction on range, the *low limit* may be set to $-\infty$ and the *high limit* to $+\infty$. However, the *low* and *high* limit shall not exceed absolute minimum and maximum limits set for that *parameter* by the *recipe executor's* supplier.

Numeric parameters with no *parameter restriction* are pure numbers (with no units) with a domain of $(-\infty,\infty)$.

A *numeric parameter* shall have a *format type* of one of the following:

- *text string of a length of no more than 80 characters,*
- *signed or unsigned integer of an even length,*
- *floating point number of an even length.*

Text strings are restricted to the character set defined above to represent the *low* and *high limits* of the *domain* and shall convert to a *numeric value* within that *domain*.

3.2.4.2.2 *Non-Numeric Parameters* — A **non-numeric parameter** is any parameter other than a *numeric parameter*, including *parameters* whose *domains* are sets of discrete numbers that cannot be represented by a single mathematical interval, and strings that represent names. *Non-numeric values* may or may not place restrictions on the replacement *value*. A *parameter* that contains the name of a wafer map, for example, cannot be easily restricted by a general rule[7], whereas a *parameter* that contains a string identifying thermocouple type can be restricted to one of a defined, unordered set of valid strings. Restrictions for *non-numeric parameters* might also consist of, or include, logical expressions that shall evaluate to TRUE before a value may be used.

If a recipe language has been defined for the corresponding *class* of recipes, the syntax for the *restriction* is taken directly from the formal *definition* of that *parameter* within the body of a *source form* recipe (and therefore conforms to the specification for that recipe language). Otherwise, the restriction is expressed in a syntax defined by the *recipe executor's* supplier specifically for *parameter* attributes.

For example, the *parameter* for a furnace recipe may specify which set of PID *values* should be used, where sets A-F exist on the *equipment*. The automatic *restriction* on the *value* for such a parameter, as specified by the *recipe executor's* supplier, might be "{A,B,C,D,E,F}" with the default for the *value* specified as the character "C" with a *format type* of "ASCII string of length 1".

In another example, a *restriction* might be that the *value* be taken from the enumerated set

"{cassette, lot , batch }".

3.2.4.2.3 *Agent-Specific Parameters* — In order to "tune" a recipe so that it produces the same result on all *recipe executors* of the same type, it may be necessary to provide a different *initial value* for the *parameter* or a different *parameter restriction* for individual *executing agents*. A special editing facility may be provided by the *recipe manager* to allow the original *value* and/or *restriction* of a *parameter* to be modified for a specific *executing agent*.

NOTE: *Agent-specific parameter definitions* replace the corresponding original *definitions* in the recipe that is *downloaded* to the *recipe executor*. At run-time, they are superseded by *parameter values* specified for the *recipe executor's select* operation.

3.2.5 *Attributes* — The name of an attribute is a text string required to be unique for its object. The names of the attributes defined in this document are reserved for their standard use.

Identification attributes are those used to identify the object in OSS. These attributes are available through OSS, but in RMS, services are handled separately from the other attributes and are not transferred in parameters for "recipe attributes".

Attributes other than *identification* attributes and **mandatory** attributes discussed below always have a defined **default value**. Attributes with a *default value* not otherwise specified are considered to have a **null value** corresponding to their form as their *default value*. The *null value* for a text string is a zero-length string. The *null value* for a numeric form is zero. The *null value* for a boolean form is FALSE. The null value for an empty list or structure is an empty (zero-length) list. The manner of representing *null values* is left to the protocol.

An attribute is **cleared** or **reset** by setting its value to the *default value*.

Mandatory attributes are attributes that are required to always have a *non-default value*.

Certain attributes are **required**, including all *mandatory attributes*. A **required** attribute is one that shall be supported with a *non-default value*. For example, the BodyFormat attribute is *required*. This means that *object form* recipes (for which BodyFormat has a *non-default value*) shall be supported by a *namespace*.

Any attribute defined in this standard shall only be modified according to the rules specified for that attribute.

Attributes of the *managed recipe* and the *execution recipe* may be accessed through Object Services. However, only certain of the attributes may be set through Object Services.

For purposes of OSS, all attributes defined in RMS shall be *recognized*. That is, a response to a GetAttr service request that references any attribute of an object defined in RMS for that object shall not return an "invalid attribute" error. If the attribute is not supported by the application, then it shall show the value of that attribute as having the null value appropriate for its form, and it shall deny attempts to set its value through the SetAttr service.

7 Typically, the validity of parameters which are unrestricted names can only be established at run-time.

3.2.5.1 *Descriptors* — Two types of *mandatory* attributes of particular importance are the **timestamp** and **length** attributes. These are provided for the *body*, for each *agent-specific dataset*, and for the set of attributes of the recipe object itself, including the *timestamp* and length attributes of the *body*.

A **descriptor** contains the *length* and *timestamp* attributes (in that order) of one or more of the aspects of a recipe: its attributes, its *body*, or an *agent-specific dataset*. *Descriptors* are used to compare two recipes stored in different *namespaces* or in a *namespace* and in the *recipe execution area* of a *recipe executor*.

NOTE: Provision of a real-time clock or other device capable of counting time in centiseconds greatly improves the value of the *timestamps* for this comparison.

3.3 *Full and Minimal Recipe Models* — Figure 3.5 contains an object model for the *managed* and *execution* recipes supporting all of the standard *attributes* defined in RMS. *Non-identifier* attributes are shown in alphabetical order. Many of these attributes are not required for minimal applications. Minimal models for the *managed* and *execution* recipes are shown in Sections 3.4.2.3 and 3.5.2, respectively.

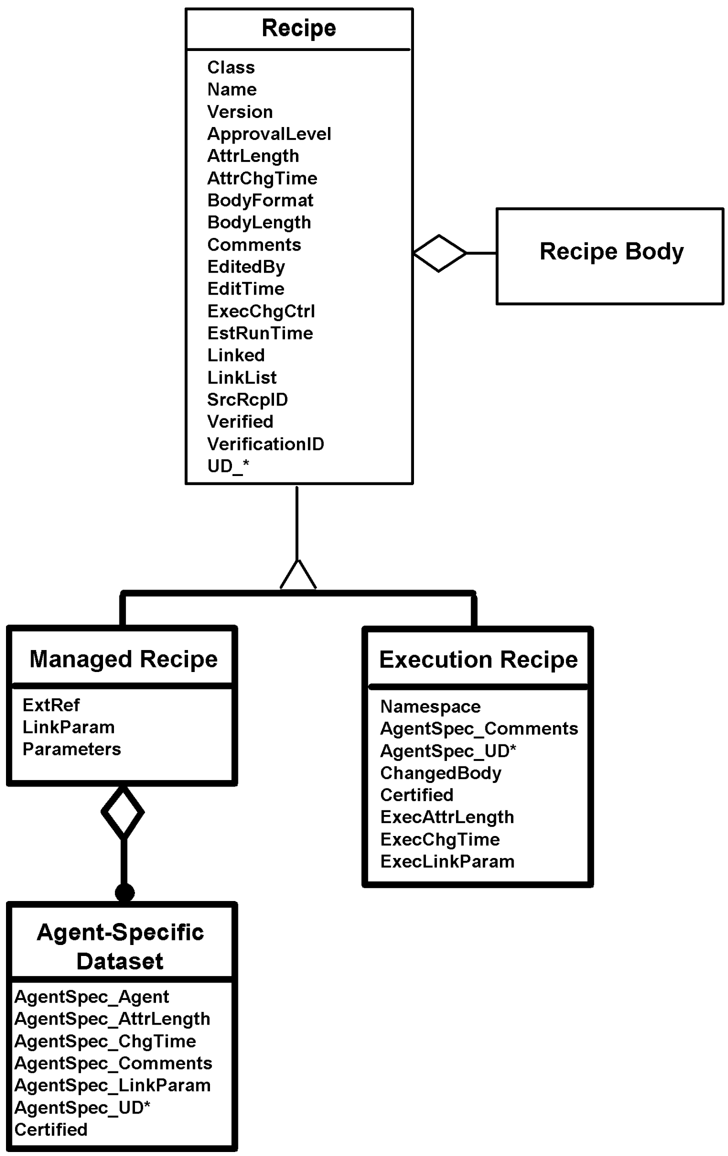

Figure 3.5
Full Recipe Object Model

3.4 *Managed Recipes* — This section defines the *managed recipe* and its attributes.

3.4.1 *Generic Attributes* — For clarity, the attributes of the *managed recipe* are sometimes called **generic** attributes to distinguish them from *agent-specific* attributes or attributes of the *execution recipe*.

Attributes that are not specifically defined in this standard may be defined by an application or by the user. Attributes that are defined by a *namespace* or by a *recipe executor* for its own use shall be changed only by rules specified and documented by the originator of the attribute.

To prevent conflict between non-standard attribute names and names which may become standard in the future, non-standard attribute names shall start with the prefix "UD_" (the two characters "U" and "D" followed by the underline character). It is the responsibility of the originator to provide unique attribute names. When using other RMS services, non-standard attributes shall follow all standard attributes.

It is desirable that a method be provided for the user to define new attributes.

3.4.1.1 *Timestamp Attributes* — **Timestamp** information (date and time of the last change) is important to recipe management. *Timestamp* attributes are maintained by the *recipe namespace* and may not be changed otherwise.

A **timestamp** attribute shall always contain the date and time that the particular aspect of the recipe was last changed. This attribute is a text string of the form "yyyymmddhhmmsscc" for the year yyyy, the month mm, the day dd, the hour hh, the minutes mm, the seconds ss, and the centiseconds cc.

The *timestamp* of the *body* is called EditTime and is set when a recipe is first **created** and updated whenever the *body* is modified in any way.

Because a recipe's attributes may be changed without changing the body, both the recipe's *generic* attributes and each set of *agent-specific* attributes themselves each have a *timestamp* attribute. For the *generic* attributes, the *timestamp* attribute is called AttrChgTime. The set of *agent-specific* attributes (of an *agent-specific dataset*) has its own *timestamp* attribute, called AgentSpec_ChgTime.

3.4.1.2 *Length Attributes* — There are three **length attributes**, one which contains the length of body, one that contains the length of the *generic* attributes, and one that contains the length of the *agent-specific* attributes. *Length* attributes are calculated without regard to either protocol overhead or storage overhead, such as proprietary formats used for internal storage that may change from one implementation to another. This preserves the length across different conventions used for recipe storage and different communications protocol.

The *length attribute* of the *body*, BodyLength, contains the length of the *body* in bytes. The *length* of the *body* is calculated as the number of bytes it will require when transferred, excluding any overhead, such as that which might be required for protocol format information.

The length of an individual attribute is calculated as the sum of the lengths of the attribute name and the attribute value.

The length of a set of attributes shall be calculated as the sum of the lengths of the individual attributes that are set to a *non-default value* at the time the calculation is performed, including the *length attribute* itself. All attributes set to their *default value*, at the time the *length* is calculated, are excluded from the calculation. This is because only the attributes with a *non-default* value are transferred when a recipe is moved into or out of a *namespace*. It also results in a more significant change to value of the *length* attribute when an attribute is set to a non-default value.

3.4.1.3 *Descriptors* — The *descriptors* of the *managed recipe* are the **body descriptor** (BodyLength and EditTime), the *generic* **attribute descriptor** (AttrLength and AttrChgTime), and the *agent-specific descriptor* (AgentSpec_AttrLength and AgentSpec_ChgTime). The **recipe descriptor** for a *managed recipe* consists of the *attribute descriptor*, the *body descriptor* (in that order), followed by *descriptors* of any existing *agent-specific datasets*.

3.4.2 *Managed Recipe Object Attribute Definitions* — This section provides the formal definitions for the recipe's *generic* attributes. For Object Services, a recipe is considered as the owner of its *components*, any *agent-specific datasets*. The *body* may not be accessed through Object Services.

Attributes in Tables 3.1 and 3.2 are presented in the following order:

- identification *attributes, including object type and identifier, appearing above the heavy line in Tables 3.1 and 3.2,*
- mandatory *attributes and the other required attributes, in the order in which they are to appear when a recipe is transferred,*
- *optional attributes in alphabetical order, and*
- *non-standard attributes, which are transferred last.*

When transferring a recipe with RMS services, *identification* attributes are not included in the list of attributes, and required attributes are sent, in order, before optional attributes. *Non-mandatory* attributes having their *default value* are not transferred, since their absence indicates their value, but they are always available through Object Services. Order of optional attributes is not dictated.

3.4.2.1 *Generic Attribute Definitions* — Table 3.1 provides the formal definition of the *generic* attributes of the *managed recipe*.

Table 3.1 Managed Recipe Attribute Definition

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
Identification Attributes				
ObjType	The object type.	RO	Y	Text: "MRcp"
ObjID	An identifier derived from Class, Name, and Version. No part of a recipe's identifier shall be changed except through *renaming*.	RO	Y	Formatted text.
Name	A logical name assigned by the user when the recipe is *created* or *renamed*.	RO	Y	Text.
Class	The recipe's class (e.g., "/PROCESS/" or "/PROCESS/LOADER/").	RO	Y	Formatted text: "CLASS/CLASS/../CLASS/"
Version	The version of the recipe.	RO	Y	Text.
Mandatory Attributes				
AttrLength	The total length of the *generic* attributes, in bytes. *Mandatory*.	RO	Y	Unsigned integer.
AttrChgTime	Timestamp of the last change to a *generic* attribute. *Mandatory*.	RO	Y	Formatted text.
BodyLength	Length of the recipe's body, in bytes. *Mandatory*.	RO	Y	Unsigned integer.
EditTime	Timestamp of when the *body* was *created* or last *updated*. *Mandatory*.	RO	Y	Formatted text. *Timestamp* format.
Required Attributes				
BodyFormat	Indicates the form and format of the recipe's *body*. *Default* is zero.	RO	Y	Enumerated unsigned integer: 0 = *source*, 1 = *object*, > 1 reserved.
Verified	Indicates whether the recipe's body is syntactically correct. Reset when the recipe is *created* or *updated*. Default is FALSE.	RO	Y	Boolean.
Linked	Indicates whether the recipe is linked. Reset when the recipe is *originated*, *verified*, or *unlinked*. Default is FALSE.	RO	Y	Boolean.
Optional Attributes				
ApprovalLevel	Indicates the level of approval assigned by an *authorized user*. Default is zero. Reset when the recipe is *originated* or *linked*. For a *linked* recipe, may not be higher than any of its *subrecipes*.	RW	N	Unsigned integer.
Comments	User comments.	RW	N	Text. Maximum length is 80 characters.
EditedBy	The name of the person who last edited the recipe.	RO	N	Text. Maximum length is 40 characters.
EstRunTime	The nominal or estimated execution (run) time of the recipe, in seconds. Reset when the recipe is *created* or *updated*. Set when the recipe is *verified*. May be	RW	N	Unsigned integer.

Attribute Name	Definition	Access	Rqmt	Form
	recalculated to total time for a main recipe when *linked*. Used for scheduling purposes. Algorithm for calculation shall be documented. Default is 0.			
ExecChgCtrl	Specifies change control requirements for recipe. (See Section 6.5.)	RW	N	Binary. Bitwise (MSB = 8**). 1 - The recipe body may be changed, 2 - Change notification is required, 3 - Recipe may be selected after change, 4 - Most recent parameter settings shall be saved.
ExtRef	A list of all recipe *specifiers* as referenced within the recipe. Explicit *versions* not required. Reset when the recipe is *created*, *updated*, and *verified*.	RO	N	List of formatted text.
LinkList	A complete list of recipe *specifiers* found in the ExtRef attribute of a *main* recipe and all of its *sub-recipes*, with duplicates removed and all *versions* explicitly determined. Set for the *main* recipe when linked. Reset when the recipe is *originated* or *verified*. Required for multi-part recipe support.	RO	N	List of formatted text.
LinkParam	A list of all variable parameter definitions contained in the Parameters attribute of a *main* recipe and all of its *subrecipes*, with duplicates removed. Reset when the recipe is *created*, *updated*, or *verified*. Set when the recipe is *linked*. Required for *variable parameter* support.	RO	N	Structure composed of parameter name, initial value, and restrictions.
Parameters	A list of variable parameter definitions contained in the recipe. Reset when the recipe is *created*, *updated*, and *verified*. Set when the recipe is *verified*. Required only for *variable parameter* support.	RO	N	Structure composed of parameter name, initial value, and restrictions.
SrcRcpID	*Identifier* of the *source form* recipe from which a *derived object form* recipe is derived. Value determined by the *verifier* of the recipe. Required only for support of *derived object form* recipes.	RO	N	Formatted text.
VerificationID	Identification code set by the *verifier* of the recipe. May be used to determine out-of-date formats that need to be *reverified*.	RO	N	Text. Maximum length is 40 characters.
UD_*	Non-standard attribute defined by supplier or *user*. Asterisk indicates the part of the attribute name that is provided in this definition. Shall be preserved exactly except by the entity that defined it.	RO	N	Varies with definition. Text form is limited to 80 characters.

** NOTE: SEMI E4 and E5 number bits 1–8, where Bit 8 = MSB (most significant bit).

3.4.2.2 *Agent-Specific Attribute Definitions* — The names of user-defined attributes shall start with the prefix "AgentSpec_UD_" and shall be preserved without modification from transferred recipes. These attributes follow all standard attributes when transferred.

An *agent-specific dataset* exists only if an *agent-specific* attribute other than the *timestamp* and *attribute-length attributes* of the *dataset* itself have been set.

Table 3.2 defines the attributes of the *agent-specific dataset object*.

Table 3.2 Agent-Specific Dataset Object Attribute Definition

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "MRcpASDS"
ObjID	The object's identifier. Contains the value in AgentSpec_Agent.	RO	Y	Text.
AgentSpec_Agent	The name of the *executing agent* to which the other attributes in the *dataset* apply. *Mandatory*.	RO	Y	Text.
AgentSpec_AttrLength	The length of the *agent-specific* attributes, in bytes. *Mandatory*.	RO	Y	Unsigned integer.
AgentSpec_ChgTime	Timestamp of when an *agent-specific* attribute was last changed. *Mandatory*.	RO	Y	Formatted text.
AgentSpec_Comments	Comments specific to the *agent* entered by the author.	RW	N	Text. Maximum length is 80 characters.
AgentSpec_LinkParam	A list of *variable parameter definitions* modified from the list in LinkParam. Valid only for a *linked main* recipe. *Parameter name* and form may not be changed.	RO	N	List of Structure composed parameter name, value, and restrictions.
Certified	The certification-level for the specific *agent*, assigned by an *authorized user*. Reset when AgentSpec_LinkParam is modified. Required for *certification* support.	RW	N	Unsigned integer.
AgentSpec_UD_*	Non-standard attribute defined by the supplier or user. Asterisk indicates the part of the attribute name that is provided in this definition. Must be preserved exactly except by the defining entity.	RO	N	Varies with definition. Text form is limited to 80 characters.

3.4.2.3 *Minimal Managed Recipe* — The minimal model for a *managed recipe* is shown in Figure 3.6. Only required attributes are supported in this model. This model can only be used for single-part recipes in the dedicated *namespace,* such as the *default namespace* required for stand-alone *equipment*. There are no *agent-specific datasets*.

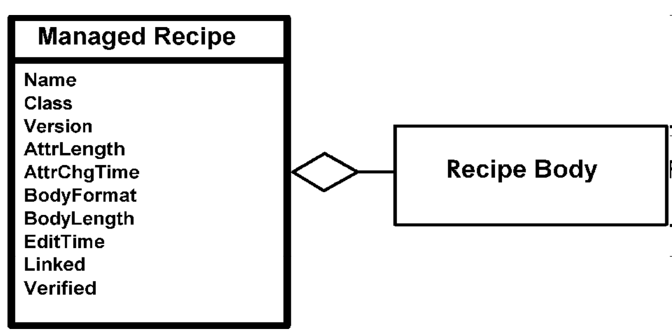

Figure 3.6
Object Model for Minimal *Managed* Recipe

3.5 *Execution Recipes* — The type of recipe handled by a *recipe executor* is called an *execution recipe*. This type of recipe has attributes and a *body* but does not have an *agent-specific dataset*. Most of the *generic* attributes of the *managed recipe*, and certain of the *agent-specific* attributes, are also attributes of the *execution recipe*, while in other cases, a *generic* attribute and an *agent-specific* attribute are merged and placed in a new *execution recipe* attribute.

A *managed recipe* is converted to an *execution recipe* when the recipe is *downloaded* to the *recipe executor*, and correspondingly, an *execution recipe* is converted to a *managed recipe* when *uploaded* from the *recipe executor*.

The *execution recipe* is defined in detail in Section 6.3.

4 Recipe Namespace

This section defines the basic conceptual model for the **recipe namespace**, a logical domain for recipe storage and management, within which the *identifier* of a recipe is guaranteed to be unique. The model in the current section is applicable to implementations with centralized storage. Section 5 defines an extension of the basic model for a distributed recipe namespace.

In general, the term "namespace" refers to a domain of unique *identifiers*. The issue of *namespace* boundaries exists for all object types, particularly in a distributed environment, and is not unique to recipes. However, within the context of RMS, **namespace** is used as a synonym for *recipe namespace*.

4.1 *Motivations* — A recipe's *identifier* may not be unique across different *namespaces* or throughout a factory. (That is, a given identifier may be used by internally different recipes except within a single *namespace*.) A primary role of a *namespace* is to define an area within which the uniqueness of any given recipe *identifier* may be guaranteed.

The requirements for Recipe Management that are addressed in this section include:

- *to define the boundaries of specific areas where recipes may be uniquely identified, stored, and retrieved,*
- *to define the* attributes *and operations for the management domain of recipes, including recipe protection and recipe operations,*
- *to allow control of removable media,*
- *to allow stand-alone* equipment *to* execute *recipes,*
- *to facilitate smooth integration of stand-alone* equipment *into on-line factory systems,*
- *to allow integrated* equipment *to continue to execute recipes when communications have been lost, and*
- *to provide the basis for the* **distributed** *model in Section 5, which allows a* supervisor *to use and manage the storage capacity of its* subordinate agents.

4.2 *Namespace Model* — The *namespace* model serves two major purposes. First, it provides a common set of management rules. Second, it allows a set of recipes to be shared among a group of *executing agents* that have a common process type, common functionality, and a common recipe language.

Figure 4.1 shows the basic *namespace* model with four objects: the recipe, the *namespace* itself, a *namespace* component called **recipe namespace segment**, and a **recipe namespace manager**.

The **recipe namespace manager** (or **manager**) represents the interface for the *namespace* to the external world and the internal decision authority within the *namespace*. All services for the *namespace* and its recipes are provided by the *manager*. The *namespace* itself is passive. While it has important *attributes*, the *namespace* has no operations, and it provides no services.

The **recipe namespace segment** (or **segment**) represents both the internal storage element and the actual manipulation of recipes within the *namespace*, under the supervision of the *manager*. In the basic model, it also provides no public services. The relationship between the *segment* and the *manager* in this model is presumed to be internal to an application.

Figure 4.1 represents a *namespace* with centralized storage. However, it can easily be extended to the **distributed recipe namespace**, which may have multiple *segments*, each provided by a different external *agent*. For that case, the *manager* and *segment* must provide public services for one another.

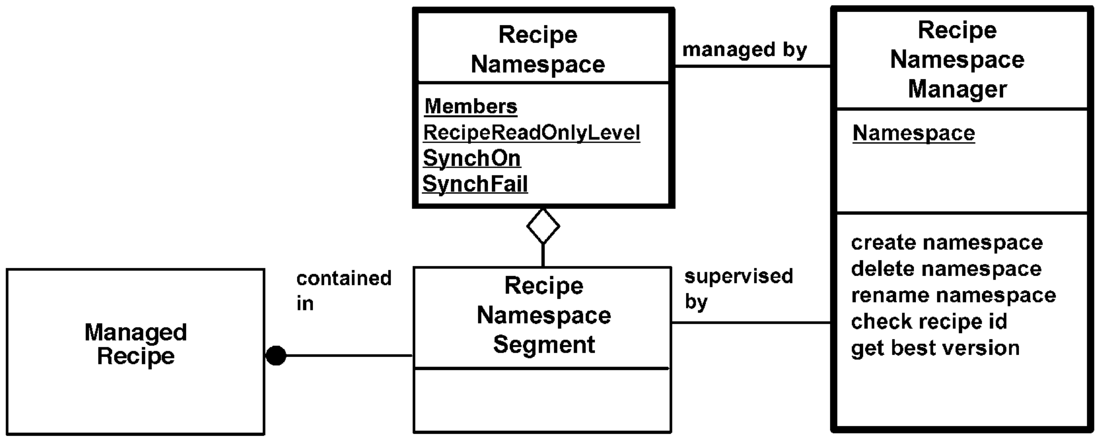

Figure 4.1

Recipe Namespace Model

All operations performed on a recipe through Recipe Management *services* are performed within the *namespace* by, or under the supervision of, the **namespace manager**, with two exceptions. A *namespace manager* is not required to understand the syntax of the recipe languages. For this reason, recipe **editing** (modifying a recipe's *body*) is not part of the *namespace* definition, and *verification* shall be provided by a **recipe executor** of an appropriate *executing agent* (see Section 6). These two activities require an in-depth understanding of the particular recipe languages used. Their separation from the other activities allows generic *namespace* capabilities to be provided.

4.3 *Namespace Specifications* — The combination of the *recipe namespace*, its *segment* component, and its *manager* provides storage, retrieval, and management of recipes conforming to RMS.

A *namespace manager* is responsible for maintaining the integrity of the *namespace*, the integrity of the recipes within the *namespace*, and the integrity of the recipe *identifiers*. It understands the rules regarding recipes, their *attributes*, and their components, and it is responsible for enforcing those rules. It will not allow a *read-only* recipe to be changed or deleted, for example. Therefore, it will not accept a recipe with an *identifier* already used by a *read-only* recipe.

A *namespace* has no restrictions on the **read access** of a recipe as a whole or of its *attributes*, nor is it concerned with the uses to which they might be put outside the *namespace*. The ability for multiple *agents* to share the same recipes is determined solely by the ability of the *agents* to access the same *namespace*. Issues of security and authentication are beyond the scope of RMS.

The term *recipe namespace*, or *namespace*, is used inclusively to refer to those *attributes*, operations, and other requirements common to both the *namespace* described in this section and to its *distributed* subtype. The term **centralized namespace** is used in references to an instance (implementation) of the basic model and to clarify statements that do not apply to instances of the *distributed* subtype.

A *centralized namespace* is analogous to a single directory of files, where duplicate file names are not allowed. It may exist in several different configurations that are incidental to *namespace* requirements.

It is possible to provide a *namespace* that uses removable media for its physical storage. Recipes may then be transferred to and from this *namespace* to any other *namespace*.

In no case shall it be possible to transfer recipes into a *namespace* except according to the requirements for *namespace management*. For example, a *read-only* recipe may not be replaced.

The *centralized namespace* may be applied several ways. An *agent* with *execution* capabilities that may be operated in stand-alone mode shall provide itself with a *centralized namespace* to be used when operating in stand-alone mode. Other *agents*, such as diskless process modules in a cluster, may expect to rely upon the *namespace* capabilities provided by the cluster *supervisor*.

4.4 *Member Agents* — A *namespace* that contains recipes used by multiple *agents* is called **shared**. Otherwise, it is called **dedicated** or **non-shared**. Figure 4.2 illustrates two *dedicated namespaces*, one provided by an etcher and one by its host. This terminology is introduced for clarification and descriptive purposes only.

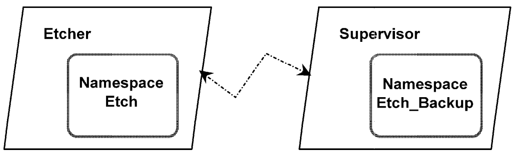

Figure 4.2

Host Backup of Equipment Namespace

The Members attribute of the *namespace* contains the names (object identifiers) of the *agents* that use the recipes in the *namespace*, and these *agents* are called **member agents** (**members**) of the *namespace*. The *namespace manager* uses this information as it may require assistance from a *member agent* to *verify* a recipe.

If the Members attribute of the *namespace* contains multiple *agent* names, then the *namespace* is *shared*. Otherwise, it may be *non-shared* or not yet completely set up. If it is empty (null), the *namespace* has not been completely set up and is not fully functional, as certain operations, including recipe *verification*, require it to have content.

4.5 *Illustrations* — This section provides illustrations of several possible configurations of a *centralized namespace*.

Figure 4.2 illustrates an etcher that has its own local *namespace* and that communicates with its *supervisor* over an RS-232 line. The *supervisor* in this example maintains a separate *namespace*, providing backup for recipes of particular significance.

Figure 4.3 illustrates a *supervisor* with four diskless subordinates. In this configuration, the *supervisor* provides recipes for all four subordinates from a *centralized namespace*.

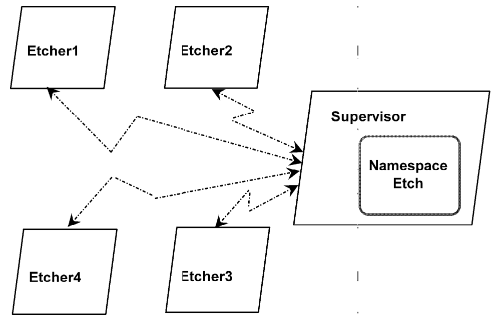

Figure 4.3

Namespace Provided by Supervisor

Figure 4.4 illustrates four *executing agents* on a common network with a *supervisory agent* and a sixth *agent* providing a *centralized namespace*. Each *executing agent* is able to access the *namespace* independently of the *supervisor*.

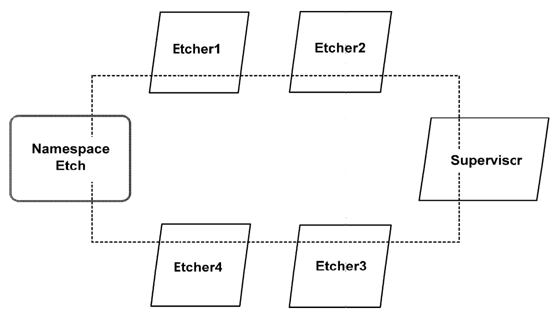

Figure 4.4

Shared Network Access

Figures 4.3 and 4.4 both represent examples of *shared centralized namespaces*.

4.6 *Attribute Definition Tables* — Table 4.1 defines the attributes of the recipe namespace.

Table 4.1 Recipe Namespace Attribute Definition

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RNS"
ObjID	The *name* of the *namespace*.	RO	Y	Text. A name of "Default" is prohibited.
RecipeReadOnly-Level	The level of *approval* at which recipes are *read-only*.	RW	Y	Unsigned integer.
Members	The *names* of *agents* capable of *verifying* and *executing* the recipes in the *namespace*.	RW	Y	List of *agent names* (identifiers).
SynchOn	Level of synchronization (see Section 9.5). Required if synchronization is supported.	RW	N	Unsigned integer: Either 0 = Disabled, or any combination (sum) of: 1 = changes in body 2 = new *execution recipe* 8 = changes in *last value* 16 = new *derived object form execution recipe*
SynchFail	Specifiers for *execution recipes* for which an attempt to *synchronize* failed. Required if *synchronization* is supported.	RW	N	List of formatted text.

Table 4.2 defines the attributes of the *recipe namespace manager* objects. The *name (identifier)* of the *manager* is not generally of interest, as the *namespace specifier* is more commonly used. However, it is important for the *manager* to be accessible through Object Services.

Table 4.2 Recipe Namespace Manager Attribute Definition

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RNS_Mgr"
ObjID	The *manager's* name.	RO	Y	Text.
NamespaceName	The *name* of the *namespace* managed.	RO	Y	Text.

5 Distributed Recipe Namespace

A **distributed recipe namespace** is a *recipe namespace* that utilizes the storage capacity of multiple *agents* for recipe storage. Recipes are stored in special **recipe namespace segments** provided by the different *agents*. These *segments* are **distributed recipe namespace segments** and are supervised by the **distributed recipe namespace manager**.

This section defines the different objects that together provide the *distributed recipe namespace* capability: the *distributed recipe namespace*, the *distributed recipe namespace manager,* the *distributed recipe namespace segment*, and the **distributed recipe namespace recorder**. Detailed descriptions of operations are contained in Section 10.

Throughout this document, the acronym **DRNS** refers to the term "distributed recipe namespace" and is used primarily to differentiate a *DRNS* subtype object from its supertype.

5.1 *Motivations* — The *distributed recipe namespace* capability provides a method for using the storage capacity of multiple *agents*, as illustrated in Figure 5.1. This reduces the storage requirements of a centralized factory system, improves performance by allowing recipes to be used by those *agents*, and provides a centralized management of the *namespace* to ensure that the uniqueness of the recipe *identifier* is properly maintained.

Figure 5.1 illustrates a *distributed recipe namespace* with four *segments*, each provided by a different *agent*, and each *agent* also having a local *namespace*.

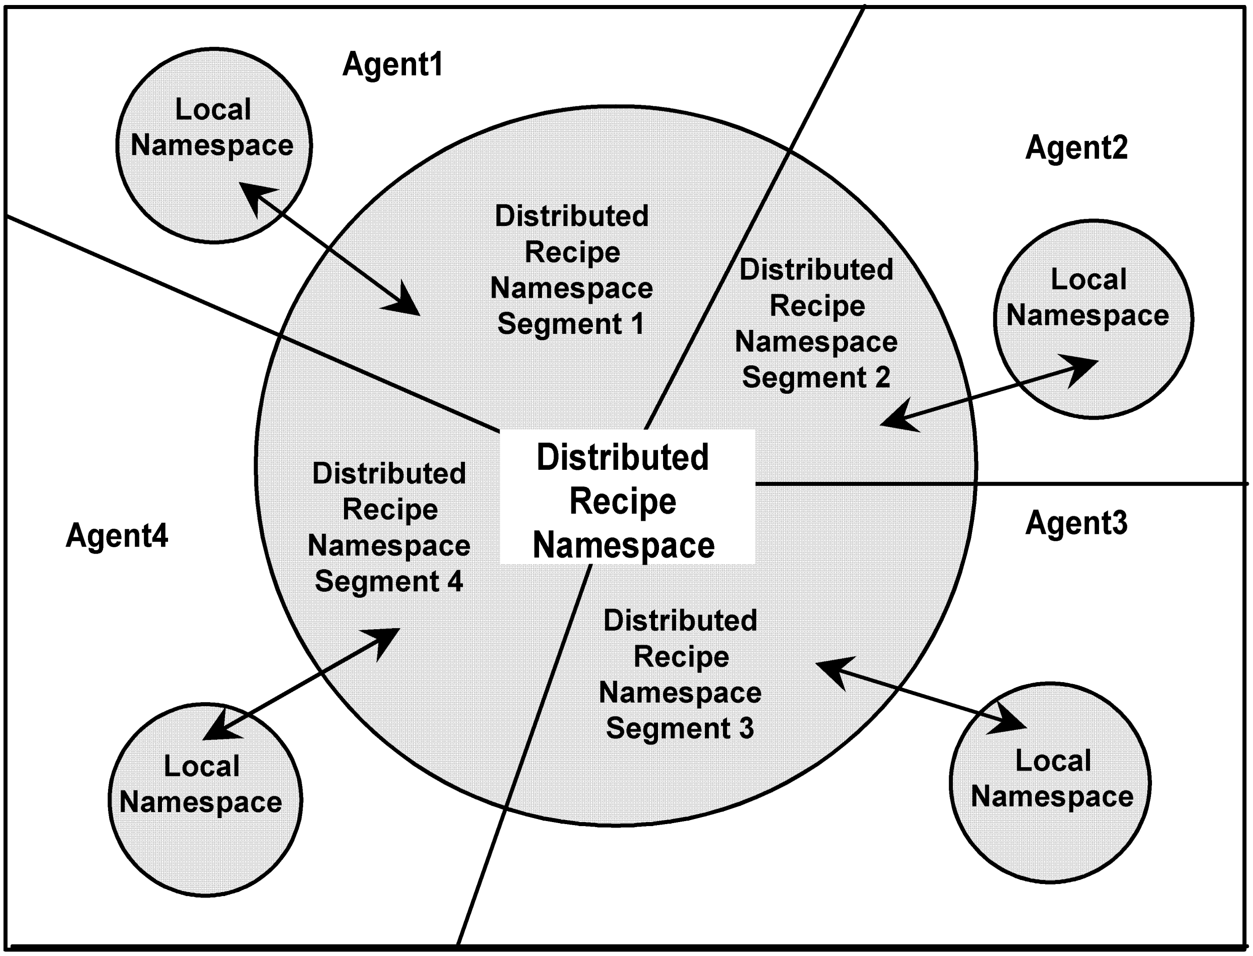

Figure 5.1
Illustration of Agents, Segments, and Local Namespaces

5.2 *Overview* — The *DRNS* object model (Figure 5.2) is a specialization of the model introduced in Section 4. The *distributed recipe namespace*, the *DRNS* segment, and the *DRNS* manager are subtypes of the *recipe namespace*, the *recipe namespace segment*, and the *recipe namespace manager* respectively. Each inherits the *attributes* and *operations* of its corresponding *supertype*. Only those attributes and operations that are specific to the *DRNS* types are shown in object representations.

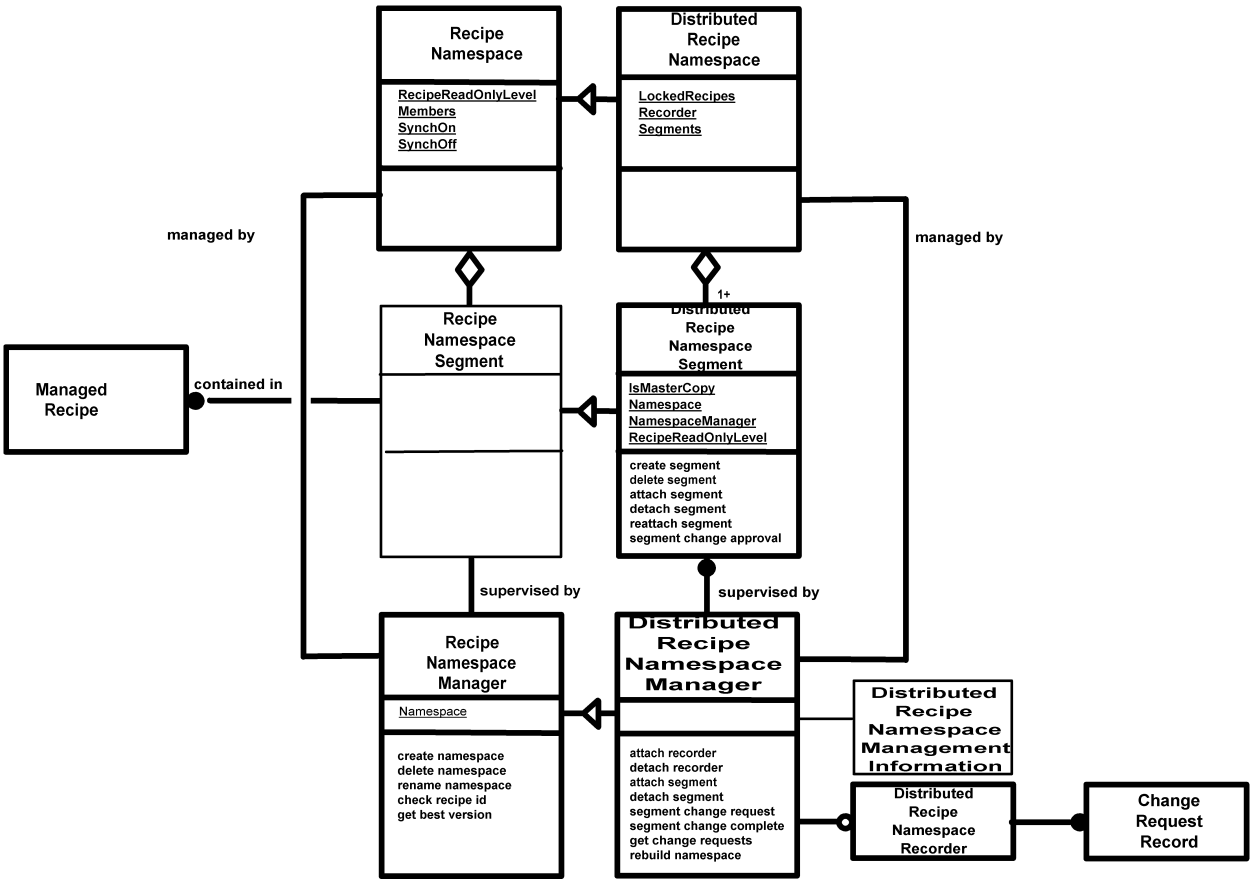

Figure 5.2

Distributed Recipe Namespace Model

The *namespace* supertype has exactly one *segment* of storage. Where storage is *centralized*, the *segment* is internal and private to the *namespace*. However, in the case of the *distributed recipe namespace*, there may be multiple *DRNS segments*, each provided by a separate *agent*. For this reason, the *DRNS segment* is a *standardized object*.

The *distributed recipe namespace* separates the management of recipes within a specific recipe storage area from the management of the entire *namespace*. The management of individual recipes within a specific storage area is delegated to the *distributed recipe namespace segment*. The *distributed recipe namespace manager* manages the various *segments* and the *namespace* itself. The *manager* is responsible for knowing the *identifiers* of all recipes stored in the entire *namespace*. It requires a knowledge of the structure of the recipe's *identifier* and the significance of the *version* in differentiating between recipes of the same name and different *versions*.

The *DRNS recorder* provides a backup facility for information required to automate the rebuilding of a *distributed recipe namespace*. It is external to the *DRNS namespace* and to its *DRNS manager*.

5.3 *Distributed Recipe Namespace Issues* — This section introduces issues that are applied to more than one object within the *distributed recipe namespace* capability.

5.3.1 *Object Services* — Attachment is a relationship between a managed object and its manager that is defined in OSS (SEMI E39). One object may be attached, detached, and reattached to a manager. When attached, the managed object is able to recognize that certain critical services have been requested by its manager. The *segment* and *recorder* objects shall comply with requirements for the operations and services defined in SEMI E39 (OSS) to attach, detach, and reattach to and from a *DRNS manager*. They shall also allow their *manager* to modify specified attributes that are otherwise read-only.

The ability to create and delete a *segment* or *recorder* is optional.

The *authorized user* may request a *DRNS manager* to attach or detach a specified *segment* or *recorder*.

5.3.2 *Logical Recipe* — A **logical recipe** is defined as a recipe with a specific *body* and a specific set of *generic attribute values*. Every *managed* recipe stored is an instance of a *logical recipe*.

In a *distributed recipe namespace*, it is normal for instances (copies) of a given *logical recipe* to exist in more than one *DRNS segment* at any time. In other words, multiple duplicate copies of a recipe with the same *identifier* may co-exist within the *distributed recipe namespace*. To retain the integrity of the *namespace*, this can be allowed if, and only if, each copy of a recipe with a given *identifier* is an instance of the same *logical recipe*. It is the responsibility of the *DRNS manager* to ensure this logical identity is maintained.

Agent-specific datasets are not included in the definition of the *logical recipe* because multiple *agent-specific datasets* may exist independently of one another, and only the *dataset* specific to the *agent* providing the *DRNS segment* is normally kept in that *segment*.

5.3.3 *Change Requests* — A **change request** occurs whenever a *user*, an external application, or an attached *DRNS segment* requests the *DRNS manager* to make, or permit, any change in a recipe. Information concerning *change requests* is kept in the form of logical **change request records**. Once a *change request* is made, a *change request record* is created and maintained until the change has been either completed or discarded. Because the information represented by *change request records* is publicly available, they provide a degree of diagnostic capability.

The *change request record* is not a formal or standardized object, but it represents the information that is available through services.

Change management is the most critical issue of the *DRNS* capability and is discussed in detail in different sections below.

5.4 *Distributed Recipe Namespace Segment* — The **distributed recipe namespace segment** (Figure 5.3) is responsible for all of the activities that directly manipulate recipes, including storage, retrieval, deletion, and operations that change a recipe's *attributes* or *body*. This requires a micro-level knowledge of the recipe's *identifier*, its structure, the inter-relationships between the various recipe *attributes*, how the recipe is stored, and how it is transferred. It also includes a macro-level knowledge of all of the *identifiers* of the recipes that it has stored. The *DRNS segment* shall ensure that only one recipe with a given *identifier* exists within that *DRNS segment*. The contents of an unattached *DRNS segment* shall be *read-only*.

A *DRNS segment* and its storage are provided by an *agent*, which could be equipment, an independent "recipe server", or other factory systems.

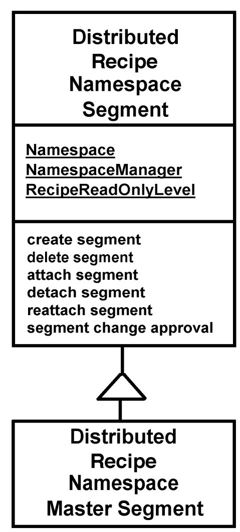

Figure 5.3

Distributed Recipe Namespace Segment

5.4.1 *Master and Dedicated Segments* — A **master segment** is a specialization of a *DRNS segment* that is capable of storing multiple *agent-specific datasets* per recipe. *Master segments* are not dedicated to a single equipment and are used to store a **full copy** (including all existing *agent-specific datasets*) of all *logical* recipes within the *namespace*. It is required that every *distributed recipe namespace manager* be capable of supporting at least one attached *master segment*. Additional *master segments* may be desirable for further backup protection.

The term **dedicated segment** is used to refer to *segments* that are not *master segments*. *Dedicated segments* store at most one *agent-specific dataset* per recipe. Because a *DRNS segment* provided by equipment would not expect to keep *agent-specific datasets* for other *equipment*, equipment normally does not provide *master segment* capability.

Master and *dedicated* segments have the same attributes and support the same message services, but they respond differently to *agent-specific datasets* and are used for different purposes. A *master segment* requires approval prior to changing an *agent-specific dataset*.

5.4.2 *Change Restrictions* — The *DRNS segment* may provide access to recipes within its storage to the other *components* of the *agent* providing the storage. However, neither the generic attributes nor the body of recipes stored by the *segment* shall be changed except with the explicit approval of the *distributed recipe namespace manager*.

Dedicated DRNS segments that are attached to a *DRNS manager* may change the contents of an *agent-specific dataset* without first asking permission. However, they are required to notify the *manager* of any change as soon as it occurs.

The attribute RecipeReadOnlyLevel is set by the *DRNS manager* to the value of the corresponding *namespace* RecipeReadOnlyLevel attribute when the *segment* is first attached and whenever the *namespace* attribute is changed. This attribute has the same function as the *namespace* attribute and allows the *segment* to prohibit changes based on a recipe's *approval level* as defined in Section 8.2.5. For example, the *segment* shall deny requests to *modify a write-protected* recipe.

The *DRNS segment* is prohibited from changing its contents whenever it is unattached. However, recipes and recipe *attributes* may be read at any time by other entities, including other *components* of the owner *agent*.

Any changes to a logical recipe stored by the *DRNS segment* shall first be approved by the *DRNS manager* before the change is made. This includes any changes to the body or to any generic attribute. This is required for two reasons. First, two different *DRNS segments* may attempt to change a recipe at the same time, and this activity must be coordinated. Second, to protect the integrity of the recipe *identifier* where multiple instances of a recipe exist, the *distributed recipe namespace* is required to ensure that all such instances have been updated appropriately with that change before other changes to the same recipe are allowed.

NOTE: The prohibition against unauthorized change does not preclude the saving of such changes external to the *DRNS segment* while waiting for authorization. However, changes made by other *DRNS segments*, subsequent to such changes and prior to authorization, may invalidate these changes.

Communications between the different *components* of an *agent* that do not require or use the formal *services* defined by RMS are considered as proprietary to the *agent* and are neither covered nor excluded by RMS, subject to the above restrictions against change.

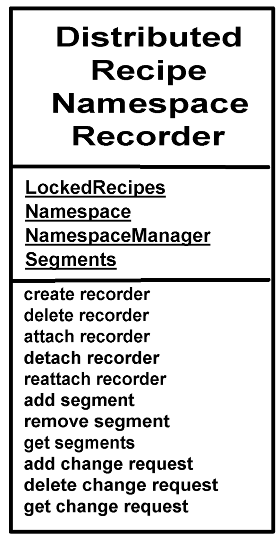

Figure 5.4

Distributed Recipe Namespace Recorder

5.5 *Distributed Recipe Namespace Recorder* — The **distributed recipe namespace recorder** provides a method of externally storing and retrieving information critical to automated rebuilding of a damaged *distributed recipe namespace*. It contains two types of information: a list of the *DRNS segments* that are attached to the *DRNS manager* and the current *change request record* in process per recipe.

A *DRNS recorder* may be attached and detached from a *DRNS manager*, and reattached to that *manager*. Information that it contains is available to anyone but may only be changed by its *manager*.

The *DRNS recorder* is able to store the *DRNS* **segment specifiers** (the *object specifiers*) of the attached *DRNS segments* in its Segments attribute. This information allows a *distributed recipe namespace* to be automatically rebuilt in the event that the *namespace*, or the *DRNS manager*, is damaged and its information becomes lost or unavailable.

The *DRNS recorder* is also used to store the current *change request* per recipe, to delete a *change request*, and to return the set of *change requests* for one or more recipes. The attribute LockedRecipes provides a list of *identifiers* for recipes with *change requests*.

The *DRNS manager* shall use the services of a *DRNS recorder* when one is attached to the *namespace* by a service user. However, use (attachment) of a *recorder* is optional for the user. The *DRNS recorder* is provided for remote storage of critical information and is not intended as a general source of information for the user. It is not able to provide *inactive change request* information.

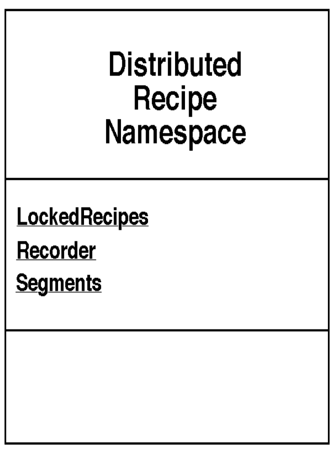

Figure 5.5

Distributed Recipe Namespace

5.6 *Distributed Recipe Namespace Management Information* — The *DRNS* **management information** object is private and proprietary to the *DRNS manager*. It is included in Figure 5.2 as an emphasis on the importance of the information that a *DRNS manager* requires for management. This includes, but is not limited to, the recipe *identifiers* stored in each attached *segment* and all existing *change request records*.

The *DRNS manager* is required to know the contents of all of its attached *segments* at all times. It shall be able to uniquely identify each instance of a recipe within the *distributed recipe namespace*. It is responsible for tracking the current status of each instance of a logical recipe within the *distributed recipe namespace* when a change to a recipe within one *segment* is being updated to other *segments*. The *DRNS management information* is important for these purposes.

5.7 *Distributed Recipe Namespace* — The *distributed recipe namespace* has three additional attributes, as shown in Figure 5.5, that are read-only, set by the *DRNS manager*. The attribute Segments contains a list of the *object specifiers* of the *DRNS segments* currently attached. The attribute Recorder contains the object specifier of an assigned *DRNS recorder*. The attribute LockedRecipes contains a list of recipe *identifiers* of recipes with existing *change request records*.

5.8 *Distributed Recipe Namespace Manager* — The *distributed recipe namespace manager* (Figure 5.6) is responsible for ensuring that the *distributed recipe namespace* and *DRNS segments* operate together and for maintaining *namespace* integrity as a whole. It is required to know the identities of its attached *DRNS recorder* and *DRNS segments* and the contents (*recipe identifiers*) of each attached *DRNS segment* at all times.

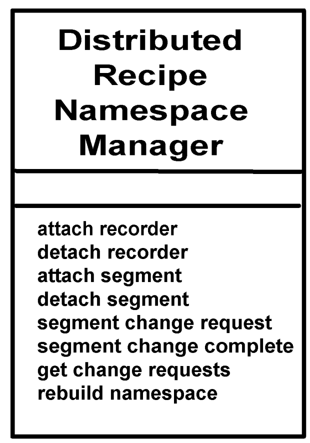

Figure 5.6

Distributed Recipe Namespace Manager

The current attachments of the *DRNS manager* are maintained in the *DRNS namespace* attributes Recorder and Segments and through the services of the *DRNS recorder* described in Section 5.5. Whenever a *DRNS segment* is attached, the *DRNS manager* shall add the *segment specifier* to the *namespace* attribute Segments and to the current list maintained by the *DRNS recorder*. Whenever a *DRNS segment* is detached, the *DRNS manager* shall remove its *specifier* from the Segments attribute and from the *DRNS recorder's* list.

The *DRNS manager* is able to know which recipes are stored in each *DRNS segment* through use of Object Services provided for or by the individual *DRNS segments*. It shall maintain the integrity of the *namespace* through ensuring that an *identifier* of any recipe stored within the *namespace* represents exactly one *logical recipe*. This is achievable because the *manager* must give explicit approval of any change of *logical recipes* (generic attributes or body) stored by the *DRNS segments*.

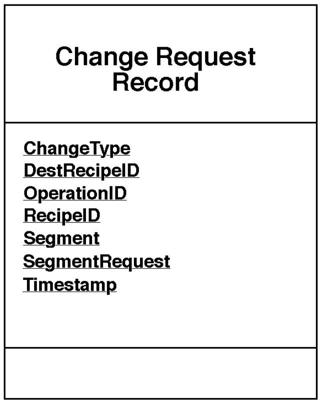

Figure 5.7

Change Request Record

5.8.1 *Change Management* — A *change request* occurs whenever a *user* or an attached *segment* requests the *distributed recipe namespace manager* to make, or permit, a specific type of change. A change request record (Figure 5.7) contains information about who requested what type of change. This allows later diagnostics when necessary.

A *change request record* is created for a recipe whenever an attached *DRNS segment* requests a change and is deleted when the requested change has been completed or discarded. A *change request* is either **inactive** or **active**. Once a *change request* is made, it is considered as inactive until the change has been approved by the *DRNS manager*. Once approved, it is considered as **active**.

The *change request record* is not a standardized object and is not accessed directly through public services. However, the information represented by the *change request record* shall be available, upon request, from the *DRNS manager* for all *inactive* and *active change requests*. For this reason, it is convenient to model the *change request record* as an object.

A recipe for which a *change request* exists is called **locked**. Otherwise, it is **unlocked**.

The *DRNS manager* is responsible for ensuring that only one *change request* per recipe is *active* at any time. The results of each approved *change request* shall be updated appropriately to each of the other *DRNS segments* with a copy of the same *logical recipe* before a subsequent change to the recipe is approved.

5.9 *Building a Distributed Recipe Namespace* — A *distributed recipe namespace* is built up in several stages. The *distributed recipe namespace* and its associated *DRNS manager* are created separately in the first stage. The individual *DRNS segments* are first *created* and then attached to the *DRNS manager*. At least one *DRNS segment* must be attached to the *DRNS manager* before it can accept recipes, as the *distributed recipe namespace* has no other means of storage. Figure 5.8 illustrates the attachment relationship.

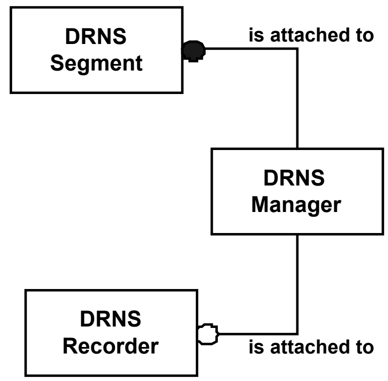

Figure 5.8

The Attachment Relationship

The attached *DRNS segments* may later be detached from the *namespace* and then either attached again to the same *namespace* or to a different *namespace* without affecting the recipes stored within the *DRNS segment*.

NOTE: When a *DRNS segment* with existing recipes is detached and then attached to a different *namespace*, its recipe *identifiers* fall within the domain of the new *namespace*. This may require some recipes to be *renamed* before the attach process is complete.

5.10 *Rebuilding a Damaged Distributed Recipe Namespace* — A *distributed recipe namespace*, or its *manager*, may become damaged or unavailable. If a *DRNS recorder* was attached to the *damaged* name-space, then rebuilding the *namespace* can be automated.

A new *distributed recipe namespace* and new *DRNS manager* are created, assigning the old *namespace* name as the object identifier ObjID for the new *namespace*. The new *DRNS manager* should be assigned a different *identifier*, however, as a security measure. The *user* may then request the new *DRNS manager* to rebuild the *namespace* with the old *DRNS recorder*. A *namespace* may also be rebuilt without a *recorder* if the list of *segment specifiers* can be provided by the user. However, the user is not expected to provide the information retained through *change request records*.

5.11 *Object Attribute Definition Tables* — This section contains the formal attribute definitions for the *distributed recipe namespace* capability. Except for the *object identifier* attributes, attributes are listed alphabetically.

Objects that are subtypes of objects introduced in Section 4 inherit the attributes of the supertype objects. These attributes are not repeated in this section.

5.11.1 *Distributed Recipe Namespace Segment Attribute Definition* — Table 5.1 defines the attributes required for a *distributed recipe namespace segment*, and Table 5.2 defines the attributes of the subtype *master segment*.

Table 5.1 Distributed Recipe Namespace Segment Attribute Definition

Attribute Name	*Description*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RNSDSegment"
ObjID	The object name (identifier).	RO	Y	Text.
Namespace	The name (ObjID) of the *namespace* to which the *segment* belongs. May be set by the manager.	RO	Y	Text.
NamespaceManager	Identifies the *distributed recipe namespace manager*. May be set by the manager.	RO	Y	Text.
RecipeReadOnlyLevel	Used to track the corresponding attribute of the *namespace* to which the *segment* belongs. May be set by the manager.	RO	Y	Unsigned integer.

Table 5.2 Distributed Recipe Namespace Master Segment Attribute Definition

Attribute Name	*Description*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RNSDMaster"
ObjID	The object name (identifier).	RO	Y	Text.

5.11.2 *Distributed Recipe Namespace Recorder Attribute Definition* — Table 5.3 defines the attributes required for a *distributed recipe namespace recorder*.

Table 5.3 Distributed Recipe Namespace Recorder Attribute Definition

Attribute Name	*Description*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RNSDRecorder"
ObjID	Text.	RO	Y	Text.
LockedRecipes	List of *identifiers* of recipes with existing *change request records*.	RO	Y	List of formatted text.
Namespace	Identifies the *namespace* to which the recorder is attached. May be set by the manager.	RO	Y	Text.
NamespaceManager	Identifies the *distributed recipe namespace manager*. May be set by the manager.	RO	Y	Text.
Segments	List of *specifiers* of currently attached *segments*.	RO	Y	List of formatted text.

5.11.3 *Distributed Recipe Namespace Attribute Definition* — Table 5.4 defines the attributes required for a distributed recipe namespace.

Table 5.4 Distributed Recipe Namespace Attribute Definition

Attribute Name	*Description*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RNSD"

ObjID	The *manager's* name.	RO	Y	Text.

6 Recipe Executor

This section describes the basic concepts for the *recipe executor* and the *execution recipe* that it stores.

The **recipe executor** is the component of an *executing agent* that reads and comprehends the contents of a recipe (its *body*) and puts into effect its instructions, settings, and/or other data. The object model of the *recipe executor* is shown in Figure 6.1.

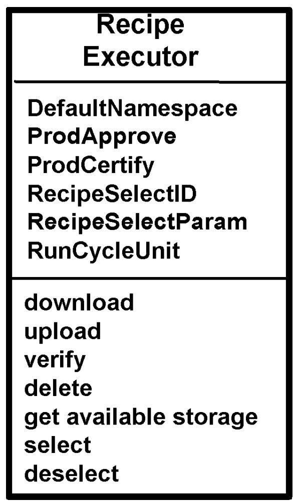

Figure 6.1
Recipe Executor

The *recipe executor* is able to temporarily store recipes for execution purposes, and it may also be able to store *execution recipes* for later execution.

The execution process is beyond the scope of RMS.

6.1 *Motivations* — Specification of the *recipe executor* and the *execution recipe* that it stores is necessary to complete the management of recipes in the factory. The *recipe executor* provides limited storage for recipes and minimum capability to manage them. The storage provided is intended to be temporary only.

Some *recipe executors* have the ability to purposefully change a recipe's body or create new recipes. To ensure that *execution* recipes remain synchronized with the *managed* recipes in a *recipe namespace*, additional rules are required for such cases.

The requirements for RMS that are addressed by the *recipe executor* include the following:

- *The ability to create, edit, and change recipes outside the* executing agents *that execute them,*
- *The ability for* executing agents *to use recipes developed externally,*
- *The ability to share recipes among equipment of the same type,*
- *Protection of stored* execution recipes *and of currently* selected *recipes from unexpected or unauthorized change,*

- *Execution of recipes without errors, including errors detected during* verification *and* ***validation*** *errors caused by improper settings or parameters or incompatibility with the current configuration,*

- *The ability to change a recipe's* parameters *between runs in a systematic way without changing the recipe itself,*

- *The ability to dynamically connect and disconnect the* executing agent *from the communications environment, and*

- *The ability of standalone equipment to execute recipes without a communications link.*

6.2 *Description* — The *recipe executor* is able to receive a downloaded *execution recipe* and temporarily store it. The *executor* can *verify* the recipe *body* (Section 11.2.2) both at the time of the download and after the recipe has been stored. It is able to store at least as many recipes as it requires for a single process cycle, which is determined by its own requirements.

Recipes stored by the *recipe executor* may be downloaded from more than one *namespace*. To prevent ambiguity or conflict between recipe *identifiers* from different *namespaces*, the name of the namespace from which the recipe was originally downloaded is retained in the *identifier* of the *execution recipe*.

The *recipe executor* **selects** one or more specified recipes by *validating* them and preparing them for execution. This may include moving the recipes into a separate **recipe execution area** to create an **executable copy** recipe. The *executable copy* recipe, if it exists separately, shall be protected from inadvertent change caused by other activities, such as downloading a new recipe. The *executable copy* recipe is not otherwise addressed by RMS. If a separate *copy* is *selected*, the stored *execution recipe* shall be protected from change. Protection from change and permission to change are discussed in Section 6.6.

Validation of a recipe consists of checking the values of its settings and variable parameters against existing supplier-defined and/or user-defined restrictions, and ensuring the recipe, or the *linked recipe set*, is valid for the current configuration of the *executor* (e.g. equipment or attached module).

Additionally, the *recipe executor* is able to calculate the amount of available storage, to delete recipes from its storage to make room for new recipes, to **de-select** recipes by preventing them from being re-executed without another explicit *select*, to **rename** an *execution recipe*, and to provide requested information about itself and its stored *execution recipes*, in conformance with OSS.[8]

The *recipe executor* may wish to rewrite *source form* recipes into a proprietary *derived object form* that is more efficient for execution or storage purposes. Where this type of recipe is to be stored for re-use, a new *identifier* is required for the *object form*, as described in Section 3.2.2.1.2. *Derived object form* recipes are discussed in detail in Section 11.2.2.1.

6.3 *The Execution Recipe* — An *execution recipe* is a type of recipe, as shown in Section 3, Figure 3.5. The *recipe executor* stores recipes as *execution* recipes. *Execution* recipes are created in one of two ways: they are either **downloaded** from a *recipe namespace*, or they are **created** by the *recipe executor*.

6.3.1 *Comparison of Managed and Execution Recipes* — An *execution recipe* differs from a *managed recipe* in two ways: its attributes and its lack of *agent-specific datasets*.

The differences in attributes between a *managed recipe* and an *execution recipe* consist of:

- *The addition of* <u>*Namespace*</u> *as an* identification *attribute of the* execution recipe*,*

- *The intermediate parameters,* <u>*ExtRef*</u> *and* <u>*Parameters*</u>*, of a* verified managed *recipe, required for the* namespace link *operation, are not used by the* recipe executor *and are not retained in the* execution recipe*,*

- *The attributes* <u>*LinkParam*</u> *and* <u>*AgentSpec LinkParam*</u> *of the* managed recipe *are merged into the single attribute* <u>*ExecLinkParam*</u>*,*

- *The attributes of the remaining* agent-specific dataset *are absorbed into the attributes of the* execution *recipe, and*

- *The addition of the attribute* length <u>*ExecAttrLength*</u> *and attribute* timestamp <u>*ExecAttrChgTime*</u> *attributes, and*

- *The additional attribute* <u>*ChangedBody*</u>*, which is required for* execution recipes *where the* recipe executor *is capable of changing the recipe* body *or of creating new recipes and is not otherwise used.*

The conversion of a *managed recipe* to and from an *execution recipe* is the responsibility of the *namespace manager* and is discussed in Sections 9.4.8 and 9.4.9.

Most of these differences are invisible for an *unverified* recipe or minimal recipe implementations. For an

---

8 SEMI E39 (Object Services Standard)

unverified recipe, all of the above attributes are *cleared* to their *default value* and are not transferred with the recipe. Attributes needed for multi-part recipes and *variable parameters* are not required for minimal implementations. Figure 6.2 provides a model of the minimal implementation of an *execution recipe* to meet RMS requirements.

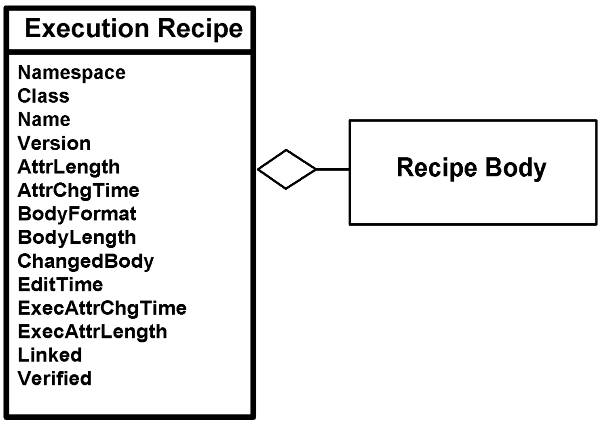

Figure 6.2

Object Model for Minimal *Execution* Recipe

6.3.2 *Downloaded Recipes* — To *download* a recipe from a *namespace*, the *namespace manager* is responsible for first converting the attributes of the specified *managed recipe* into those of the *execution recipe*. The *recipe executor* stores the downloaded recipe as an *execution* recipe. The body of the recipe is unchanged by the download operation and may be in *source form* or *object form*, including the *derived object form*. (See Section 11.2.2.1.)

The *namespace manager* may optionally request that the recipe being downloaded replace any pre-existing recipe with the same *identifier*. Otherwise, if such a recipe exists, the download request is denied.

Upon request, the *recipe executor* shall *verify* a recipe that it has previously stored and return to the requestor the information required for recipe management.

Attributes of the *execution* recipe that have the same attribute *name* as either a *generic* attribute or an *agent-specific* attribute of the *managed recipe* are not changed except in specific cases.

The attributes giving the *timestamp* and *length* of the attributes of the *execution recipe* are different from those of the *managed recipe*. This allows the *generic* and *body descriptors* of a *managed recipe* to be compared with the corresponding attributes of an *execution recipe* for traceability. The *timestamp* of the *execution recipe's* attributes is ExecChgTime, and the *length* of its attributes is ExecAttrLength. These are calculated by the *recipe executor* at the time the *execution recipe* is stored and updated whenever other attributes of the recipe change.

6.3.3 *Execution Recipe Identifier* — The *identifier* of an *execution recipe*, in addition to the recipe *name, class,* and *version* of the *managed* recipe, also contains the name of the **originating namespace**. The **originating namespace** is the namespace from which the recipe was originally downloaded. For recipes newly created within the storage of the *recipe executor*, this is the namespace to which the recipe will be *uploaded*.

The full *identifier* of an *execution recipe* is identical to that used within recipes to indicate the recipe is external to that of the referencing recipe (see Section 3.2.4.1.1) and has the form:

"Namespace Name>/CLASS/.../CLASS/name; version".

6.3.4 *Execution Recipe Descriptor* — The *descriptors* of the *execution recipe* consist of the *execution attribute descriptor* (ExecAttrLength and Exec-AttrChgTime), the *generic attribute descriptor* (AttrLength and AttrChgTime), and the *body descriptor* (BodyLength and EditTime). The **execution recipe descriptor** consists of the *execution attribute descriptor*, the *generic attribute descriptor*, and the *body descriptor*, in that order.

6.3.5 *Execution Recipe Attribute Definitions* — Table 6.1 provides the formal definition of the attributes of the *execution recipe*. Attributes in Table 6.1 are classified as identification attributes, mandatory and other required attributes, optional attributes, and non-standard attributes. Identification attributes are not used in RMS services as "recipe attributes" and are used solely to specify one or more execution recipes. Support for all required attributes is necessary for RMS compliance. Support for the remaining attributes is not required.

The *execution* recipe's attribute *length* and *timestamp* attributes are transferred first when a recipe **attribute section** (Section 14.1) is **uploaded**.

Attributes that are described as "preserved" are maintained without change from a *downloaded* recipe. For recipes that are first created by the *recipe executor*, such as hardware-specific recipes, they are set to their appropriate values. Default values have been added for attributes that cannot be determined.

Attributes in Table 6.1 are presented in the following order:

- *Identification attributes, including object type and identifier, the first six listed in the table,*

- *Mandatory attributes and the other required attributes, in the order in which they are to appear when a recipe is transferred.*
- *Optional attributes in alphabetical order, and*
- *Non-standard attributes, transferred last.*

Default values for *non-mandatory* attributes are shown in the last column. Null values (indicated by "NULL") are dependent upon the particular form (see Section 3.2.5).

Table 6.1 Execution Recipe Attribute Definition

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*	*Default Value*
Identification Attributes					
ObjType	The object type.	RO	Y	Text: "ERcp"	"ERcp"
ObjID	An identifier derived from Namespace, Class, Name, and Version	RO	Y	Formatted text.	-
Namespace	The name of the *originating namespace.*	RO	Y	Text.	NULL
Name	A logical name assigned by the user when the recipe is *created*.	RO	Y	Text.	-
Class	The recipe's class (e.g., "/PROCESS/" or "/PROCESS/LOADER/").	RO	Y	Formatted text: "CLASS/CLASS/../ CLASS/"	-
Version	The version of the recipe.	RO	Y	Text.	-
Mandatory Attributes					
ExecAttrLength	The *length attribute* for the attributes of the *execution recipe*. Calculated when the recipe is *downloaded* and whenever an attribute changes.	RO	Y	List of formatted text.	-
ExecChgTime	The *timestamp* of a change to the attributes of the *execution recipe*.	RO	Y	Formatted text, *timestamp* format.	-
AttrLength	Preserved.	RO	Y	Unsigned integer.	0
AttrChgTime	Preserved.	RO	Y	Formatted text.	NULL
Required Attributes					
BodyLength	Preserved unless recipe is modified. Length of the recipe's body, in bytes.	RO	Y	Unsigned integer.	-
EditTime	Preserved unless recipe is modified. *Timestamp* of when the *body* was *created* or modified.	RO	Y	Formatted text. *Timestamp* format.	-
BodyFormat	Indicates the form and format of the recipe's *body.*	RO	Y	Enumerated unsigned integer: 0 = *source*, 1 = *object*, > 1 reserved.	0
Verified	Indicates whether the recipe's body is syntactically correct.	RO	Y	Boolean.	FALSE
Linked	Indicates whether the recipe is *linked*.	RO	Y	Boolean.	FALSE
ChangedBody	Set to TRUE if the recipe body has changed without a subsequent upload to the originating namespace. NOTE: This attribute is never uploaded to a namespace. Required only if recipe can be changed or created.	RO	Y	Boolean.	FALSE

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*	*Default Value*
ExecChgCtrl	Preserved. Specifies change control requirements for recipe.	RO	Y	Binary. Bitwise (MSB=8): 1 - The recipe body may be changed, 2 – Change notification required, 4 - Recipe may be selected after change, 8 - Most recent parameter setting shall be saved.	0
Optional Attributes					
AgentSpecComments	Copied from the original *agent-specific* attribute when downloaded. Set by the user.	RO	N	Text. Maximum length is 80 characters.	-
ApprovalLevel	Indicates the level of approval assigned by an *authorized user*.	RW	N	Unsigned integer.	0
Certified	Preserved from the *agent-specific* attribute as downloaded. May be used as control for production-worthy recipes.	RO	N	Unsigned integer.	0
Comments	User comments. Preserved from the *generic* attribute as downloaded.	RO	N	Text. Maximum length is 80 characters.	-
EditedBy	Preserved unless recipe is modified. The name of the person or *executing agent* who last modified the recipe.	RO	N	Text. Maximum length is 80 characters.	-
EstRunTime	The nominal or estimated execution (run) time of the recipe, in seconds. Used for scheduling purposes. Preserved from the *generic* attribute as downloaded.	RO	N	Unsigned integer.	0
ExecLinkParam	Preserved unless *last value* is changed (Section 6.6.4). Contains the list of *parameter definitions*, including any *agent-specific* modifications. Required for *variable parameter* support.	RO	N	Structure composed of parameter name, initial value, and restrictions.	NULL
LinkList	Preserved. A complete list of recipe *specifiers* for a *linked recipe set*. Required for multipart recipe support.	RO	N	List of formatted text.	NULL
SrcRcpID	For a *derived object form* recipe, contains the recipe *identifier* of the original *source form* recipe. Required only for *derived object form* recipes.	RO	N	Formatted text.	NULL
VerificationID	Identifier code used by the *verifier* of the recipe. May be used to determine out-of-date formats that need to be *reverified*.	RO	N	Text. Maximum length is 40 characters.	NULL
Non-Standard Attributes					
AgentSpec- UD *	Preserved from the original *agent-specific* attributes as downloaded.	RO	N	Defined by supplier or user. Text limited to 80 characters.	-

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*	*Default Value*
UD *	Non-standard attribute defined by supplier or *user*. Asterisk indicates the part of the attribute name that is provided in this definition. Shall be preserved exactly, except by the entity that defined it.	RO	N	Varies with definition. Text form is limited to 80 characters.	-

6.4 *Default Namespace* — The **default namespace** is a *dedicated centralized namespace* (see Section 4.4) that is used for all *agent-specific* recipes. A *recipe executor* that uses *agent-specific* recipes, such as thermocouple calibration tables, shall be provided with a *namespace* for such recipes. *Equipment* that may be operated in a stand-alone mode, and that requires *agent-specific* recipes, shall also provide a local *namespace* to be used for this purpose. A single *namespace* shall be used to satisfy both requirements.

The *recipe executor* shall provide a user-settable *attribute* DefaultNamespace that contains the name of the *default namespace*. The *default namespace* shall be available on power-up for stand-alone operation. For *executing agents* intended to operate only in a *supervised* configuration, such as cluster process modules, the *default namespace* may be provided by the *supervisor*.

A recipe in a *default namespace* is referenced within a recipe *body* by specifying a *namespace* named "Default". This allows controlled specification by *namespace* role for hardware-specific recipes.

6.5 *Recipe Storage* — Discussion of types of storage used by the *recipe executor* is provided to clarify terminology.

Storage is generally assumed to consume space in some form, and the amount of space available for recipes is assumed to be finite, so that adding recipes reduces the amount of space available and deleting recipes increases the amount of space available. These assumptions are based on current technologies and are not requirements.

The *recipe executor* may have one or more types of storage area for recipes, shown in Figure 6.3. The storage area used for the current process cycle is called the **recipe execution area**. This is the minimum storage capacity required. *Executable copy* recipes in the *recipe execution area* may or may not be transformed for execution purposes but shall retain the attributes of the *execution recipe*. The *recipe execution area* shall be protected from all inadvertent and unintentional change, including change resulting from transferring a recipe to or from a *recipe namespace* or from *editing* a recipe.

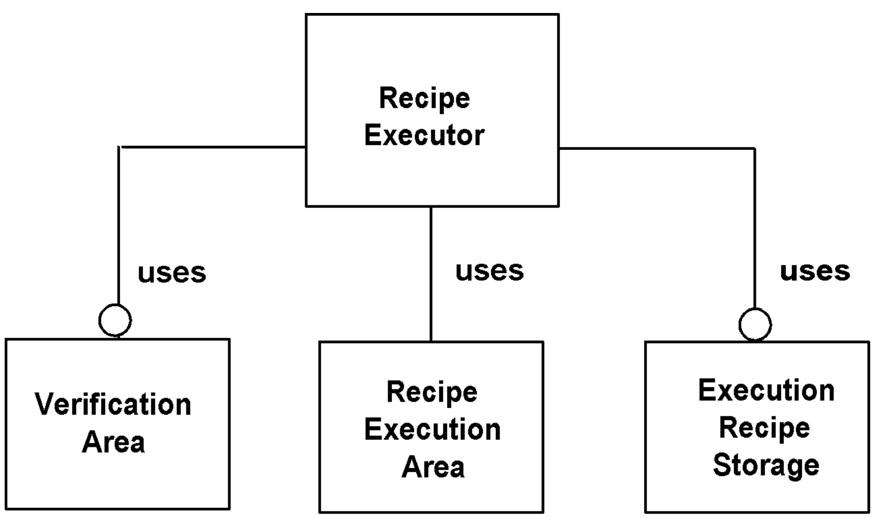

Figure 6.3

Object Model for Recipe Executor

Extra storage area, for additional recipes that are not currently *selected*, when provided, is called the **execution recipe storage**.

A separate intermediate area for temporary storage of *unverified* downloaded recipes may also be provided. This area is the **verification area**. The separation of this area provides protection for the *executable copy* recipes and the *execution recipes*. Recipes that fail *verification*, or that have been requested to be discarded without storage after *verification*, may be removed from this area more easily when it is separate.

A recipe temporarily placed in a *verification area* shall be immediately either discarded or else moved to *execution recipe storage* following a successful *verification*.

The term **stored recipes** in this section refers to recipes in *execution recipe storage*.

The storage areas of the *recipe executor* may or may not be volatile. The *verification area*, *recipe execution area*, and the *execution recipe storage* are not required to be physically separate, so long as recipes in each logical area are protected from change caused by activities in the other areas.

6.6 *Change Control* — Storage provided by the *recipe executor* is intended as temporary, and only minimum management capability is required, such as the ability to rename or delete recipes.

Some *recipe executors* may choose to provide additional capabilities, such as the ability to *create* new recipes, to *edit* existing recipes, to build a compressed *derived object form* recipe, to modify existing recipes through the execution process itself, and/or to save the **last value** used for *variable parameter settings*. Certain restrictions apply to these activities. Each different capability provided for creating and changing recipes shall be explicitly documented by the supplier.

In general, change is controlled by the *user* through the attribute ExecChgCtrl. ExecChgCtrl specified four separate types of control related to change, including permission to subsequently *select* or *re-select* a changed recipe and a requirement that the *originating recipe* be notified of all protected changes to the recipe.

The *recipe executor* is prohibited from setting the Linked attribute of any recipe to TRUE.

The *recipe executor* is responsible for ensuring the uniqueness of the *identifiers* of the recipes that it stores.

Detailed requirements governing the creation of new recipes and the changes protected by ExecChgCtrl are defined in Section 11.

6.6.1 *Recipe Creation* — Certain *recipe executors* may be able to *create* recipes. This capability is allowed to cover the hardware-dependent recipes and the provision of editing services. Mechanisms for creating and changing recipes are beyond the scope of RMS. *Change notification* is required for all newly *created* recipes.

6.6.2 *Recipe Compression* — A *source form* recipe may be *compressed* to obtain a *derived object form* recipe, described in Section 3.2.2.1.2. This is not considered as a *newly created* recipe, as the *source form* and *derived object form* recipes achieve the identical process results. For this reason, most of the attributes of the *source form* recipe, including the Linked and ExecChgCtrl attributes, are passed to the *derived object form*. A *change notification* requirement for the *source form* recipe extends to the *derived object form* as well, including notification when the *derived object form* is built. Requirements for the *derived object form* recipe are defined in detail in Section 11.2.2.1.

6.6.3 *Changes to Stored Recipes* — The *recipe executors* may be able to **change** *an existing recipe by changing its body*. Certain hardware-dependent recipes may sometimes be *changed* by, or as a result of, the execution process itself. Recipes also may be *changed* through an **editing** activity, including interactive “teach” and automated “self-teach” operations provided by some systems. Except where expressly granted permission to change an existing recipe through the ExecChgCtrl attribute, the bodies of all recipes in storage shall be *protected from change*. This is not the same as the *write-protection* of the *namespace* in that *execution recipes* may be *deleted* and *renamed* by an *authorized user* and by the manager of the *originating namespace*.

Depending upon the value of the ExecChgCtrl attribute of the recipe, permission to **change** the *execution recipe* (stored in the *execution recipe storage*) is granted or denied in advance and allows case-by-case granularity. Unless explicitly granted permission, a *changed* recipe may not be subsequently *selected* or *re-selected*.

Purposeful change during the *execution* process for hardware-dependent recipes is included in the ExecChgCtrl attribute permission to change the recipe body. For example, furnaces may be able to update a “profile recipe” during a normal process cycle. Recipes changed purposefully by the execution process are assumed to represent the best, most up-to-date, and most valid version of a hardware-dependent *class* of recipe. Suppliers of *recipe executors* with this capability shall provide complete documentation of the *class* of recipe changed and the circumstances under which it is changed.

The ExecChgCtrl attribute of a recipe may require that the *originating namespace* be notified of change. **Change notification** consists of a *notification message* sent to the *originating namespace* that alerts the *namespace manager* that a recipe has been changed or *originated*. Where *change notification* is required through ExecChgCtrl, the *namespace manager* is responsible for subsequently uploading the recipe, assigning it a new *identifier* if necessary, and requesting the renaming of the *execution recipe* as necessary to remain *synchronized*.

6.6.4 *Last Value* — Some *recipe executors* may also want to save the **last value** set by the user for each *variable parameter* and use it as the new *initial value* of that *parameter* when the same recipe is rerun.

This is useful when internal conditions drift in a consistent manner over time, the parameters are occasionally modified to compensate for such drift, and the last *setting* used is, therefore, a better "default" than the one specified in the recipe itself.

Permission to save the *last value* may be expressly granted by the user in the recipe attribute ExecChgCtrl.

Care should be taken to prevent unintentional modifications.

6.7 *Production* — Equipment utilizations states are defined by SEMI E10 (Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)). These states include the PRODUCTIVE and STANDBY states used by the factory for normal production work. The attributes ProdApprove and ProdCertify are defined as required only for equipment supporting states defined in this document.

To ensure that only recipes authorized for production are executed while the *executing agent* is in the PRODUCTIVE state, or are *selected* while in the STANDBY state, the *authorized user* may set the values of the attributes ProdApprove and/or ProdCertify to non-zero values. Non-zero values in ProdApprove or ProdCertify represent minimums for a recipe's ApprovalLevel and Certified attributes, respectively.

The *recipe executor* is responsible for comparing the corresponding recipe attributes ApprovalLevel and Certified. When a recipe is *selected* for execution (implicitly or explicitly) while either of the PRODUCTIVE or STANDBY states is active, the value of ApprovalLevel is required to be equal to or greater than the value in ProdApprove, and the value in Certified is required to be equal to or greater than the value in ProdCertify. Otherwise, the *select* shall fail.

6.8 *Recipe Executor Attributes* — The *recipe executor* is owned by the *agent* that provides a *recipe execution resource*. The *recipe executor* in turn owns the recipes that it has stored. It shall support Object Services for its owned object types and for itself.

Table 6.2 defines the *attributes* of the *recipe executor* in alphabetical order.

Table 6.2 Recipe Executor Attribute Definition

Attribute Name	*Definition*	*Access*	*Rqmt*	*Form*
ObjType	The object type.	RO	Y	Text = "RcpExec"
ObjID	Text.	RO	Y	Text.
DefaultNamespace	The name of an *executing agent's namespace* used for all hardware-dependent and other *agent-specific* recipes.	RW	Y	Text.
ProdApprove	The minimum value of a recipe's *approval level* accepted during productive and standby states. Required for SEMI E10 support only.	RW	N	Unsigned integer.
ProdCertify	The minimum value of a recipe's *certification level* accepted during productive and standby states. Required for SEMI E10 support only.	RW	N	Unsigned integer.
RunCycleUnit	The process unit on which the calculation of the estimated value of the recipe *generic attribute* EstRunTime is based.	RO	N	Case-sensitive formatted text composed of a unit of measure and an optional numeric suffix. Compliant with SEMI E5, Section 9.
RecipeSelectID	A list of recipe *identifiers* for the currently selected recipes.	RO	Y	List of formatted text.
RecipeSelect-Parameters	A list of all *parameter definitions* in effect for the i^{th} recipe *identifier* in RecipeSelectID. The maximum value for i is determined by the equipment supplier as the maximum number of recipes which may be *selected* at the same time. Required if variable parameters are supported.	RO	N	List of structures composed of parameter name, parameter value, parameter restriction.

7 Agents

This section describes the *agent* and **resources** as they are used in Recipe Management. The concept of *agent* is introduced to cover the different types of RMS implementations and to provide a context for the other specific object types introduced in RMS.

7.1 *Definitions* — A **resource** is an owned entity that has an active role in factory operations. A factory has many different kinds of *resources*. Some *resources*, such as valves, may be primarily physical. A software application is a type of *resource* not generally considered as physical. The factory itself is a *resource* for the corporation.

An **agent** is a system in a factory — a type of *resource* that includes both hardware and software components, at least some of which are also *resources*. Intelligent equipment that provides recipe namespace capability, for example, would be an *agent* with a recipe namespace *resource*, as well as a computer platform, operating system, and electro-mechanical components, some or all of which represent other types of *resources*. An *agent* may be a component of another *agent*, and it may also contain other *agents* as components. For example, a cluster module is a component of a cluster and may itself contain intelligent subsystems as components.

Agents may, in some cases, share certain *resources* with other *agents*. An example is a docking station that connects two clusters.

Services defined by RMS may be provided at various levels within the factory. The generic term *agent* may be applied at any of these levels as appropriate. Typical *agents* that use and provide Recipe Management services include *equipment*, clusters, cluster modules, cells, and independent *recipe namespace* servers[9] . The term *agent* applies equally well to each of these.

A **service resource** is a set of services within a particular area of specialization. *Service* resources of interest to RMS are the **recipe namespace resource**, the **recipe execution resource**, and the Object Services Resource. The *service resource* object, illustrated in Figure 7.1, allows a group of message services defined by a service standard (such as RMS) to be represented by a single object, one of the subtypes of the *service resource*. However, this concept is introduced for clarification only. The *service resource* object is not a *standardized object*.

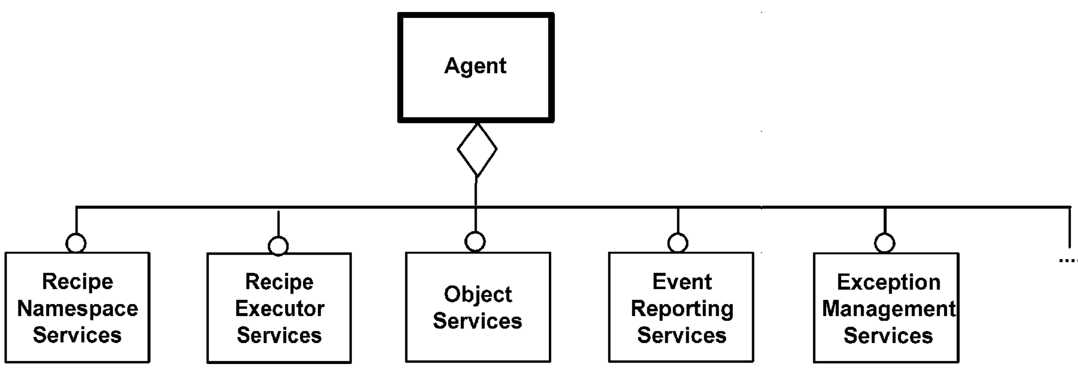

Figure 7.1
Examples of Service Resource Subtypes

An **agent** is introduced as a *standardized object* that provides one or more *service resources*. Figure 7.1 shows an example of an *agent* composed of different *service resources*. Also, an *agent* may *supervise subordinate agents* or be *supervised by a superior agent*, each of which in turn will possess their own *service resources*.

---

9 A recipe namespace server is an agent whose primary function is to provide recipe namespace capabilities.

Agents interact with one another collaboratively and/or hierarchically, through the *service resources* that they provide, to perform work in the factory.

7.2 *RMS Resources* — The service resources defined by RMS are the **recipe namespace resource** and the **recipe execution resource**.

A *recipe namespace resource* consists of the set of message services defined in Section 12, corresponding to the *namespace* operations defined in Sections 8 and 9. All services required for operations designated as required are *fundamental* and shall be provided for an RMS-compliant *recipe namespace resource*.

A **recipe execution resource** consists of the set of messages defined in Section 14 corresponding to the *recipe executor* operations defined in Section 11. All services required for operations designated as required are *fundamental* and shall be provided for an RMS-compliant *recipe execution resource*.

7.3 *Agent Attributes* — Table 7.1 defines the *public attributes* of *agents* that are required for recipe management.

Table 7.1 Agent Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqt*	*Form*
ObjType	Agent object type.	RO	Y	Text: "Agent"
ObjID	The agent's name, assigned by an *authorized user.*	RO	Y	Text.

8 Recipe Management Operations

There are two important kinds of operations involving recipes within a *namespace*. Those that change a recipe's attributes or body are called **recipe management** operations. Those that affect the set of recipe *identifiers* within a *namespace* are part of **recipe namespace management** operations. A few operations qualify as both *recipe management* and *namespace management* and are discussed in their different aspects under both topics.

A third type of operation is informational only and requires reading but not changing recipe attributes. Operations of this type that require knowledge of the attributes of the *namespace* or of more than one recipe are discussed in Section 9.

This section describes **recipe management** operations.

Requests for *recipe operations* are always directed to the *namespace* where the recipe is stored. *Recipe management* operations are delegated by the *namespace manager* to the *namespace segment*, which is considered as the **recipe manager**. This is invisible for a *centralized namespace* and explicit for a *distributed recipe namespace*.

Operations may be invoked by the *operator* or through *namespace* services defined in Section 12. In many cases, service scenarios consist of a single message request from the service user and a corresponding response from the *namespace manager*. This case is illustrated in Section 12.2, Figure 12.1. Operations requiring additional messages are discussed in Section 8.2.

The service user is responsible for proper authorization of the user prior to requesting an operation that is restricted to authorized users through RMS services.

8.1 *Recipe Lifecycle* — A typical production recipe goes through various stages in its development within a *namespace*. These stages are shown below in a typical order through their associated operations. The attributes concerning the body are provided by the initiator of the operation.

create — The **create** operation enters a recipe *body* into the *namespace*.

Editing is expected, but not required, to be performed outside the *namespace.* Where provided by the *manager*, the same requirements concerning *creating* or *updating* a recipe are to be followed.

update — A recipe is **updated** when a body (typically, a modification of the original body) is entered into the *namespace* to replace the *body* of an existing recipe that is not **write-protected**. The attributes concerning the body are provided by the initiator of the operation.

verify — The **verify** operation is used to build a recipe. Checks for semantic correctness may also be performed at this time but are not required. The recipe *body* is read and checked for syntactical correctness, and all *external references* and *variable parameter definitions* are collected. The *verification* operation may be delegated to a *recipe executor*, which returns the required information.

write-protect — At some point during its development, an *authorized user* needs to be able to prevent the accidental deletion or modification of a recipe and requests to have it be **write-protected**. A **write-protected (read-only)** recipe may not be *updated*, **renamed, deleted, unlinked,** or **relinked**.

link — The **link** operation is used to signify that the recipe is ready for *execution*. If the recipe has *external references*, *linking* also builds a *linked recipe set* by collecting the *external references* and *variable parameter definitions* and saving them for quick access in the *main* recipe's attributes. *Linking* resolves all *identifiers* explicitly for recipes that are within the *namespace*.

unlink — At times it may be desirable to undo the *link* operation. The **unlink** operation *clears* those attributes set by the last *link* operation. A *write-protected* recipe may not be *unlinked*.

approve — The factory uses the recipe's *approval level* to indicate the level of its authorization. For example, *approval levels* of 1, 2, and 3 may indicate "write-protected," "authorized for engineering," and "authorized for production," respectively.

modify variable parameters — The *variable parameter definitions* of a *linked* recipe may be adjusted for a specific *executing agent* to achieve the desired result. For example, a *generic* parameter for time may be incremented repeatedly for a specific furnace until it goes out of range, which indicates that it needs to be cleaned. If the recipe did not previously have an *agent-specific dataset* for this *agent*, this operation causes one to be created.

certify — An *authorized user* (typically by the process engineer who developed the recipe) assigns it a **certification-level** to indicate that it achieves the desired result on a specific *executing agent*. The factory may require certain **certification levels** for production.

de-certify — the *certification level* of the recipe is reset to zero.

unprotect — Before a recipe can be *updated, deleted, renamed, re-linked,* or *unlinked*, the recipe must be *unprotected*.

delete — **Deleting** a recipe causes it to be removed from the *namespace*.

8.2 *Description of Operations* — Operations that require additional messages are of two types: operations that may be performed on more than one recipe (such as **certify recipe**) and operations that may require interactions with a *recipe executor* to complete (**verify recipe**). The scenario for *verify recipe* is shown in Section 9.4.7.

The remaining operations that require additional messages are invoked with the *namespace* service RMNAction, where multiple recipes are specified for the operation. Operations such as these may require more time to complete. The initial response to the message service request only indicates the intent to perform the operation. In this case, the scenario is illustrated by Figure 8.1 and Figure 12.2, Section 12.2. The *namespace manager* performs the operation for each recipe, in the order specified, and upon the completion of each operation, sends the notification message RMNComplete with the results for that operation. (See Sections 12.15 and 12.17 for additional details.)

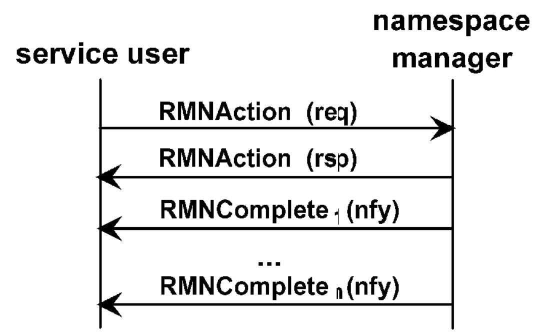

Figure 8.1

Message Flow with Completion Notification

Recipe management operations are categorized into three types: **recipe origination, recipe building,** and **recipe authorization**.

Recipe origination includes those operations that create or modify an entire recipe. **Recipe building** includes the *verification, link, unlink,* and *modify variable parameter* operations. **Recipe authorization** includes the *write-protect,* **unprotect, approve,** and **certify** operations.

Except for those operations that only provide information, *recipe management* operations change the state of the recipe. Section 8.3 contains the complete state model, and a table of transitions is given in Table 3.1. Substates of this model are provided for illustration in sections defining the operations that affect these substates.

8.2.1 *General Requirements* — The *generic length* and *timestamp* attributes AttrLength and AttrChgTime shall be updated whenever any other *generic* attribute changes value.

An *agent-specific dataset* for a specific *agent* exists only when a non-required attribute is given a *non-default value*, such as whenever a recipe is *certified* for a given *agent*. If the non-required attributes are all *cleared*, the *agent-specific dataset* is **removed** and no longer exists. Otherwise, the *agent-specific length* and *timestamp* attributes for an *agent-specific dataset* shall be updated whenever one of its attributes changes value.

8.2.2 *Recipe Origination* — A recipe may be originated by the *create recipe* operation and by the *copy recipe* operation. The *copy recipe* operation creates a duplicate of an original recipe and assigns it a new *identifier*. All of the attributes of the original are copied directly. These operations are included in *Namespace Management* in Section 9.4.1.

8.2.2.1 *Create Recipe* — A recipe is **created** when a recipe *body* is first entered into a *namespace* and assigned a new *identifier*. The recipe's *mandatory attributes* are set. All other *attributes* take on their default values. The values for the *attributes* BodyLength, *EditTime*, and EditedBy are required to be provided by the initiator of the *create* operation. The attribute BodyFormat is also provided at this time if it is not in source form (i.e., if BodyFormat has a *non-default* value).

A newly *created* recipe has an active state model (Figure 8.7). The recipe is in the UNVERIFIED, UNLINKED, UNAPPROVED, UNPROTECTED, and UNCERTIFIED states.

The *create recipe* operation is invoked with the RMNCreate service.

8.2.2.2 *Update Recipe* — The **update** operation is identical to that of *create* except that an *unprotected* recipe with the specified *identifier* already exists, and the new *body* replaces the existing *body*. Attributes concerning the *body* are provided by the initiator of the request, as for the *create* operation. All *non-mandatory attributes* are *cleared* (reset to their *default values*). Any existing *agent-specific datasets* are discarded.

The *update recipe* operation is invoked with the RMNUpdate service.

8.2.3 *Recipe Building* — Building a recipe is a two-step process. First the recipe is *verified* and then *linked*.

8.2.3.1 *Verify Recipe* — The **verify operation** is the only time it is necessary to parse the contents of the recipe *body* until the recipe is *executed*. The primary purpose of this process is to ensure that the syntactical and lexical structure of the *body* is correct. One or more checks for semantic correctness may also be performed as part of the *verification* operation, but this is not required.

Actual *verification* is performed by a member agent's **recipe executor** at the request of a *namespace manager*. For this reason, this operation is also discussed under *namespace management* in Section 9.4.7.

Recipes may be stored in a *namespace* in an incomplete or unfinished form. For recipes in *source form*, the *verification* procedure shall be performed only at the request of the *user*. It shall not be performed automatically.

There are four attributes affected by the *verification* operation: Verified, EstRunTime, ExtRef, and Parameters.

The boolean *generic attribute* Verified is used to indicate the recipe's state with respect to this procedure. Verified is *cleared* when a recipe is first created and whenever it is updated. Verified is set TRUE only when the recipe passes the *verification* by a *recipe executor*. A recipe is considered to be **verified** if, and only if, the Verified *attribute* is TRUE. Figure 8.2 illustrates the recipe's VERIFICATION state. For a description of the transitions, see Table 8.1 in Section 8.3.

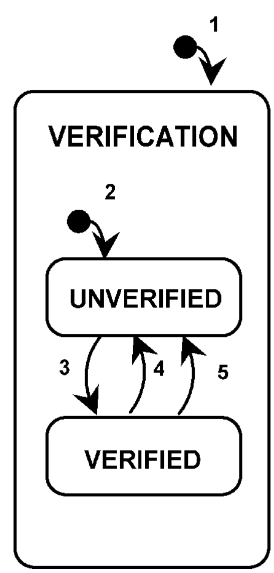

Figure 8.2
Verification State Model

The values for the attributes EstRunTime, ExtRef, Parameters, and VerificationID are returned (where set) by the *recipe executor* when the *verification* has been successful. If the operation is unsuccessful, they shall be *cleared*.

ExtRef contains a list of all *external references* found within the *body* of the recipe by the *recipe executor*. These references may be explicit or implicit, leaving the *class* and/or *version* unspecified.

The *verify recipe* operation is invoked with the RMNAction service.

8.2.3.2 *Link Recipe* — The **link operation** is a required *operation* that may be requested at any time by the *operator* or *supervisor*. Successful completion of the *link operation* indicates that the recipe is ready for *execution*. For single-part recipes without *variable parameters*, *linking* consists only of *setting* the *generic attribute* Linked to TRUE. Figure 8.3 illustrates the LINKAGE state of the recipe. For a description of the transitions, see Table 8.1 in Section 8.3.

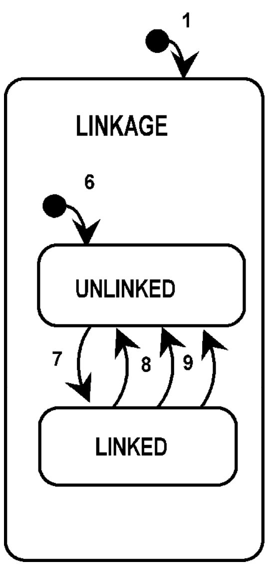

Figure 8.3
Link State Model

For multi-part recipes, this *operation* also collects *external references* and *variable parameter definitions* into the LinkList and LinkParam attributes, to be used by the *recipe executor* at run-time.

External references contained within multi-part recipes are not required to specify the *class* of the *subrecipe* when the *class* is the same as that of the *parent* recipe. Where *class* is omitted in a recipe *identifier* in the ExtRef attribute, the *link* operation is responsible for adding the *class* of the *parent recipe* in the *identifier* added to the LinkList parameter, as the *parent/child* relationship cannot be derived from the final contents of LinkList.

External references are assumed to refer to recipes within the same *namespace* and are not required to give explicit *versions* unless they specify a different *namespace*. This ensures that the *user* will be able to *link* together the "best choice" *subrecipes*. The exact value of *versions* of such references is determined only at the time the *main* recipe is *linked*.

The **link** operation is performed on a *main* recipe. That is, it only modifies *attributes* of the *main* recipe. It resolves all *external references* within that recipe and within any of its *subrecipes* according to well-defined rules for determining default *versions* at the time of the *link*. At the same time, *variable parameter definitions* are collected. The resulting explicit references are placed in the LinkList *attribute*, *variable parameter definitions* are placed in LinkParam, the ApprovalLevel attribute is *cleared*, the Linked attribute is set to TRUE, and the *main* recipe is then said to be **linked**.

Subrecipes are not affected by this operation. *Subrecipes* of a *main* recipe have no knowledge of parents or of linkages. As a result, it is possible to *delete* or change a *subrecipe* with an unintended detrimental impact on a *linked recipe set*. Factory policy may designate certain levels of *approval* to mean "this recipe is used by (*linked* into) one or more *protected* recipes."

For multi-part recipes, *linking* starts at the *main recipe* and works through all chains of referenced *subrecipes* to determine the complete set of *identifiers* that will comprise the recipe as a whole. The *link* operation is a mechanical procedure that may be performed at any time.

Successful *linking* implies that all referenced *subrecipes* have been located and parsed for further references until all references are exhausted. The *link* operation shall fail when any recipe or *subrecipe* within the namespace either is *unverified* or cannot be located.

If the same *parameter name* is used to *define* a *parameter* in more than one recipe of a set of recipes that are *linked* together, the *name* shall represent the same *parameter* and have the same *parameter definition* in all recipes in the set, to avoid ambiguity. *Parameters* with the same *parameter name* and differing *definitions* shall cause, at a minimum, a warning to the user when the *link operation* completes.

For purposes of comparison of results, the order of references in LinkList and LinkParam at the completion of the *link* operation shall conform to the results when the following sequence is used:

1. Copy the contents of ExtRef from the *main* recipe to LinkList, resolving *class* and *version* to each recipe *identifier* as needed. For support of *variable parameters*, also copy the contents of

Parameters to LinkParam. If ExtRef is *empty*, then LinkList is also *empty* and the parsing process is complete.

2. If LinkList is not *empty*, begin with the first reference in LinkList as the **link target reference**.
3. If the *link target reference* lies within the same *namespace*, resolve the *class* and *version* if necessary. (Note: the referenced recipe must be already present within the *namespace* at the time the *link* is performed, or else the *link* fails.) If the *link target reference* specifies a different *namespace*, go to Step (6) — the *link* operation of this chain terminates (without error) without an attempt to locate the actual recipe or its ExtRef *attribute*. If the recipe is located, then it is called the **link target recipe**.
4. Determine the contents of the Verified attribute of the *link target recipe*. If Verified is FALSE, the *link* operation fails immediately.
5. Determine the contents of the ExtRef *attribute* of the *link target recipe*. Remove any references that duplicate those already contained in LinkList, resolve *class* and *version* as needed, and append the result to LinkList. If *variable parameters* are supported, also determine the contents of Parameters in the *link target recipe*, remove *parameters* already defined in LinkParam, and append the result to LinkParam.
6. Set the *link target reference* to the next reference in LinkList and repeat steps (3) through (6) until all references in LinkList have been processed.

For recipes with no *external references*, the LinkList list will be *empty*. Similarly, for recipes with no *variable parameters*, the LinkParam list will be empty.

The effect of allowing incomplete recipe *versions* to be specified within a recipe *body*, and determined only when the *main* recipe is *linked*, means that a *linked recipe set* (the set of recipes *linked* together) produced on one occasion may not be the same as those produced on a different occasion. Therefore, it is necessary to protect the contents of the LinkList *attribute* from inadvertent change.

For this reason, the *link* operation cannot be performed on a *read-only* recipe with the Linked *attribute* already set from a previous *link*. Any attempt to *link* an already *linked read-only* recipe either shall be denied or a new copy of that recipe shall be generated with a new *identifier*, which may then be automatically *approved* and *linked*.

The *link recipe* operation is invoked with the RMNAction service.

8.2.3.3 *Unlink Recipe* — A *linked* recipe that is not *write-protected* may also be *unlinked*. The *unlink* operation *clears* the *generic attributes* Linked, LinkList, and LinkParam. If the recipe has *agent-specific datasets*, the attributes Certified and AgentSpec_LinkParam are *cleared*. If no other non-required *agent-specific* attributes have a *non-default value*, the *agent-specific dataset* is removed.

The *unlink recipe* operation is invoked with the RMNAction service.

8.2.3.4 *Modify Variable Parameters* — The recipe *attributes* Parameters, LinkParam, and AgentSpec_LinkParam each consist of a list of **parameter definitions**. Each *parameter definition* contains the *parameter name, parameter initial value,* and the *parameter restriction* (if any) specified for that *parameter* by a formal definition within the recipe body.

In order to "tune" a recipe so that it produces the same result on all *executing agents* of the same type, it may be necessary to provide a different *initial value* or a different *parameter restriction* for one or more *parameters* for individual *executing agents*. The *agent-specific* attribute AgentSpec_LinkParam is used to provide this capability.

AgentSpec_LinkParam is an optional *agent-specific attribute* that contains a list of alternate *parameter definitions* for one or more of the *variable parameters* included in the *definitions* in the *generic attribute* LinkParam of a *linked* recipe. A special editing facility may be provided to allow an *authorized user* to **add**, **delete**, or **modify** *parameter definitions* to AgentSpec_LinkParam.

Parameter definitions initially are added individually to AgentSpec_LinkParam by copying the *definition* for that *parameter* from LinkParam. The *initial value* or *restriction* then may be modified by the user, subject to the absolute restrictions, such as minima and maxima, imposed by the *executing agent's* supplier. The *initial value* may be changed to any value within the *parameter domain*.

Any modification of the *restriction* shall cause the *certification level* to be *cleared* in the Certified *attribute*. This is required because of the potential impact on fab operations of a change in the *restriction*.

The UNITS in the *restriction* of a *numeric parameter* may be modified within constraints imposed by the use of the *parameter* and the *executing agent's* supplier. For example, a two-byte unsigned integer named WaitTime that is used to set a variable time delay period may permit units of either “min” (minutes) or “s” (seconds). It is desirable, but not required, that suppliers of *executing agents* support different options for specifications of UNITS. The possible options for each potential *variable parameter* shall be documented by the supplier.

The **modify variable parameter** operation consists of **adding**, **deleting**, or **modifying** a specific *parameter definition* to a list of *definitions* in AgentSpec_LinkParam for a specific *agent*.

A *definition* is **added** when it is copied directly from the LinkParam *attribute* to the AgentSpec_ LinkParam *attribute* without modification. A *definition* shall only be *added* if there is currently no *definition* for a *parameter* with the same *parameter name* in the AgentSpec_LinkParam *attribute*.

A *definition* is **deleted** when it is completely removed from the list of *definitions* in AgentSpec_ LinkParam.

A *definition* is **modified** when the *value* or *restriction* of an existing *definition* is replaced in AgentSpec_LinkParam.

The *modify variable parameters* operation is invoked with the RMNVarPar service.

8.2.4 *Recipe Authorization* — Recipe authorization operations include those that allow an *authorized user* to change the value in the *generic* attribute Approval-Level or the *agent-specific* attribute Certified.

The *de-certify* operation is invoked with the service RMNAction.

8.2.4.1 *Approve Recipe* — Recipe management provides two different methods of controlling how a recipe is applied: through the *generic* attribute ApprovalLevel and through the *agent-specific* attribute Certified. The recipe's **approval level** (the value contained in ApprovalLevel) is also used to protect it from change.

A recipe goes through different stages during its lifecycle. After a recipe has been initially created, it will typically go through a dynamic period while it is tested and adjusted until it produces the desired results.

ApprovalLevel is an unsigned integer used to designate the different stages in a recipe's life cycle. It is set to zero (its *default value*) whenever a recipe is *created*, *updated*, or *linked*.

The **approval** operation allows an *authorized user* to set ApprovalLevel to a non-zero value. Otherwise, it may not be set externally.

A recipe is said to be **approved** whenever Approval-Level is non-zero. An example of a factory's implementation of *approval levels* is given in the appendix, Section 8.3. Figure 8.4 illustrates the recipe's APPROVAL state. For a description of the transitions, see Table 8.1 in Section 8.3.

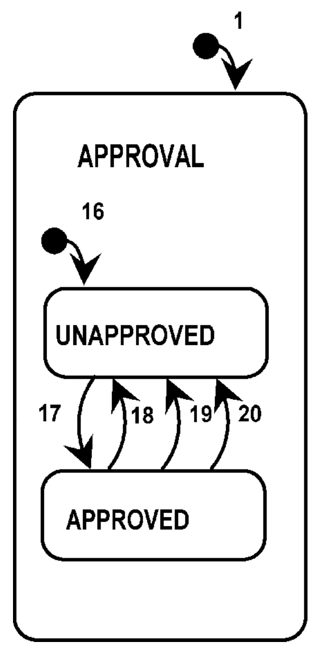

Figure 8.4
Approval State Model

A *subrecipe* may be *approved* independently from any recipes which reference it.

A *linked* recipe may not be *approved* to a level higher than the lowest *approval level* of any of its *subrecipes*. Therefore, all *subrecipes* referenced in the *attribute* LinkList of a *linked* recipe must be located prior to granting an *approval level* other than zero. The ApprovalLevel *attribute* of the *subrecipes* must be increased to a value equal to, or greater than, the required *level* by an *authorized user* before the higher *approval level* of the *linked recipe* is accepted.

The restriction on the *approval level* of the *linked* recipe requires the *user* to purposefully change the *approval level* in order to protect the entire *linked recipe set* as a unit from unexpected change, as it is by the *main recipe identifier* that the recipe as a whole will be known. It should be noted that *approval* of a *linked* recipe is not the same as approval of the individual parts, as a *subrecipe* which is appropriate in one recipe may be inappropriate in another.

The *approve recipe* operation is invoked with the RMNAction service.

8.2.4.2 *Certify* — The **certify** operation sets the value of Certified for a specific *executing agent* to a non-zero value specified by an *authorized user*. This operation affects no other attributes (except the *length* and *timestamp* attributes of the affected *agent-specific dataset*).

A recipe may be syntactically and procedurally correct but, due to the differences between different installations of *agents* with access to a *namespace*, may give different results on these different installations. Recipe **certification** signifies that a *linked* recipe produces the desired results on a specific installation.
