SEMI E98-0302
PROVISIONAL STANDARD FOR THE OBJECT- BASED EQUIPMENT MODEL (OBEM)

This provisional standard was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published February 2000; previously published November 2001.

1 Purpose

1.1 Purposes of the Object-Based Equipment Model include the following:

- Define a standard model for interfacing to multi-process equipment and other complex equipment.
- Define standard equipment components so that communications can "discuss" component-related issues.
- Provide an equipment model that can be easily integrated with SEMI E81 CIM Framework systems by connecting an OBEM-compliant equipment to a Machine object.

1.2 The purpose of the Object-Based Equipment Model (OBEM) standard is to provide definitions, services, and behavior, as seen through communications with the factory, for the common types of physical and logical objects of which equipment is typically composed, including the equipment itself. The definition of standardized objects allows the equipment to describe its makeup to the factory and provides the factory visibility into the equipment.

2 Scope

2.1 This is a provisional standard that defines concepts, behavior, and services to support the integration of production equipment within a semiconductor factory. The scope of this standard includes all semiconductor manufacturing equipment that provides an interface to the factory host systems. Some services may not be applicable to some material handling systems.

2.2 Sections that must be completed in order for the provisional status of OBEM to be removed include the following:

1. Section 11.2 — Access Management
2. Section 14 — OBEM Compliance

2.3 Detail standards will also be added in the future to specify OBEM mappings to different protocols such as SECS-II, CORBA IDL, and DCOM.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard is not intended to define the attributes, behavior, or services of systems that are aggregates of equipment, such as cells.

3.2 The decomposition of equipment into different objects is chosen by the equipment supplier to map the physical equipment to the characteristics of the objects defined by this standard.

3.3 Object-oriented technology is not required for implementations of OBEM. However, object-oriented implementations should be compatible with OBEM.

4 Referenced Standards

4.1 This section lists documents referenced by this standard.

4.2 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Provisional Specification for 300 mm Tool Load Port

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E40 — Standard for Processing Management

SEMI E41 — Exception Management (EM) Standard

SEMI E42 — Recipe Management Standard: Concepts, Behavior, and Message Services

SEMI E53 — Event Reporting

SEMI E54 — Sensor/Actuator Network Standard

SEMI E58 — Automated Reliability, Availability, and Maintainability Standard (ARAMS): Concepts, Behavior, and Services

SEMI E81 — Provisional Specification for CIM Framework Domain Architecture

SEMI E87 — Provisional Specification for Carrier Management (CMS)

SEMI E90 — Specification for Substrate Tracking

SEMI E94 — Provisional Specification for Control Job Management

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AGV* — Automated Guided Vehicle

5.1.2 *AMHS* — Automated Material Handling System

5.1.3 *APC* — Advanced Process Control

5.1.4 *ARAMS* — Automated Reliability, Availability, and Maintainability Standard (SEMI E58)

5.1.5 *CIM* — Computer Integrated Manufacturing

5.1.6 *CJM* — Control Job Management

5.1.7 *CMS* — Carrier Management Standard

5.1.8 *FDC* — Fault Detection Control

5.1.9 *FIMS* — Front-Opening Interface Mechanical Standard (reference SEMI E62)

5.1.10 *FOUP* — Front-Opening Unified Pod

5.1.11 *FPD* — Flat Panel Display

5.1.12 *OBEM* — Object-Based Equipment Model

5.1.13 *OSS* — Object Services Standard (SEMI E39)

5.1.14 *PGV* — Personal Guided Vehicle

5.1.15 *R2R* — Run-to-Run Control

5.1.16 *RMS* — Recipe Management Standard (SEMI E42)

5.1.17 *SMIF* — Standard Mechanical Interface (SEMI E19)

5.1.18 *STS* — Specification for Substrate Tracking

5.2 *Definitions*

5.2.1 *abstract object type* — an object supertype that is not instantiated directly but only through one of its subtypes.

5.2.2 *actuator* — an analog or digital output device that is used to affect changes in the physical environment. Examples of actuators include mass flow controllers (MFCs) and open/closed valves.

5.2.3 *advanced process control (APC)* — techniques covering both feedforward and feedback control and automated fault detection, applied both by the equipment (in situ) and by the factory (ex situ).

5.2.4 *Automated Material Handling System (AMHS)* — a factory system used to transport and store carriers. AMHS has two major types of components: an automated transport system and one or more storage systems (stockers).

5.2.5 *automated transport system* — the component of AMHS used to transport carriers between stockers and/or production equipment.

5.2.6 *carrier* — a container with one or more fixed positions at which material may be held.

NOTE 2: Positions within a carrier may be considered as material locations owned by the carrier.

5.2.7 *clock* — a device that is used to provide real-time date and time information.

5.2.8 *container* — a durable that is used to hold other material, including other containers, for transport, storage, or shipping. Types of containers include carriers and boxes.

5.2.9 *dry run (mechanical dry run)* — a complete equipment cycle that allows the material handling and software capabilities of the equipment to be exercised without requiring full facilities hookups and without changing the physical state of the wafer. Environmental control subsystem (e.g., vacuum, nitrogen purge, particle detection) should not be affected by a dry run, and process consumables are not used.

5.2.10 *durable* — a type of material used to facilitate manufacturing but not normally consumed in the process that is removable, reusable, and trackable. Examples include containers, reticles, and pellicles.

5.2.11 *environmental subsystem* — a subsystem of equipment with the purpose of monitoring or maintaining one or more specific environmental conditions or used to handle product or durables. Environmental subsystems include vacuum systems, particle detection systems, and nitrogen purge systems.

5.2.12 *equipment* — equipment (manufacturing equipment) performs one or more of the following manufacturing functions in the factory: material process, material transport, or material storage. Equipment is made up of various parts: modules, subsystems and sensors/actuators. Equipment has at least one carrier port. Equipment communicates with the factory.

5.2.13 *equipment element* — a component of the equipment that behaves as a unit, performs work, and may or may not contain lower-level components.

5.2.14 *equipment module (module)* — a major component of equipment that contains at least one material location and performs some task on material. Equipment modules may be aggregates of equipment subsystems, i/o devices, and other modules.

5.2.15 *fault detection* — analysis of data for early detection of process faults before yield loss becomes significant.

5.2.16 *Front-Opening Unified Pod (FOUP)* — a front-opening pod with an integrated (non-removable) cassette.

5.2.17 *implementation* — the internal view of a type, class, or instance, including any non-public properties and behavior. The specific code and functionality that implements an interface. (See SEMI E81.)

5.2.18 *interface* — the external view of an object type, class, or object that defines its public properties and services without regard to the internal structure and internal behavior. (See also SEMI E81.)

5.2.19 *interface inheritance* — the construction of an interface by incremental modification of other interfaces (see implementation inheritance). (See SEMI E81.) OBEM specifies interface inheritance but not implementation inheritance.

5.2.20 *I/O device* — a general term for any type of sensor or actuator or aggregation of sensor and/or actuator.

5.2.21 *linked equipment* — two or more equipment that are physically and logically connected and function as a single installation of equipment. In this case, the individual component equipment are modeled as high-level modules of the linked equipment.

5.2.22 *load port* — The physical interface provided for the exchange of carriers with an agent of the factory (operator or automated material handling system). (Reference SEMI E15.)

5.2.23 *Manufacturing Execution System (MES)* — the factory system responsible for managing the manufacturing process, including logistics and process flow.

5.2.24 *material* — (1) any material used in, or required by, the manufacturing process. Material is classified as consumable, durable, or product. (2) an abstraction of the various types of things used during manufacturing, such as wafers, carriers, and chemicals, which require some management.

5.2.25 *material location* — a reference to a place within the equipment or an equipment component that can hold material, such as the top surface of an indexer or substrate chuck or the end effector of a substrate handler.

5.2.26 *measured value* — a value representing a measurement, with a numerical value, measurement units, and a valid range.

5.2.27 *measurement equipment* — equipment whose intended function is to measure or inspect the product and to report results. Measurement of the product is the factory's means of gaining feedback on the manufacturing process.

5.2.28 *Object-Based Equipment Model* — a model of equipment, its components, behaviors, attributes, and services, as defined by this document.

5.2.29 *object type* — a declaration (specification) that describes the common properties and behavior for a collection of objects. Types classify objects according to a common interface; classes classify objects according to a common implementation. (See also SEMI E39 and E81.)

5.2.30 *object specifier* — designates a logical path pointing to a specific instance of an object through a hierarchy of owners. See SEMI E39.

5.2.31 *Personal Guided Vehicle (PGV)* — a manually guided and operated vehicle capable of placing and removing carriers to and from a carrier port.

5.2.32 *pod* — as used in this document, a container providing environmental control, such as a SMIF or FIMS pod[1].

5.2.33 *production equipment* — process equipment and measurement equipment.

5.2.34 *process durable* — a specialized durable used by process equipment and specified by the user as part of the process, such as a reticle or burin-in board.

5.2.35 *process equipment* — equipment whose intended function is to process product, adding value to the product.

5.2.36 *product* — (1) from the equipment's perspective, product is a synonym for substrate, and includes

1 The term "pod" was originally defined as a bottom-opening pod with a SMIF interface.

non-product substrates such as test substrates and send-ahead substrates; (2) from the factory perspective, product is the material being processed and produced by the factory.

5.2.37 *run-to-run control* — techniques for varying settings in one run based on analysis of either incoming product (feed-forward) or product from an earlier run.

5.2.38 *sensor* — a component that responds to changes in the physical environment and provides an analog or digital input value.

5.2.39 *sensor/actuator device* — a device consisting of one or more sensors and/or actuators on the physical tool. See SEMI E54 for a precise definition of "sensor or actuator" and for a description of the internal structure of an sensor/actuator network Common Device Model definition.

5.2.40 *setup* — 1. (verb) the performance of one or more steps that puts the equipment into a known state in which it is ready to perform a specific process; 2. (noun) the state of the equipment once it has been setup.

5.2.41 *standardized object* — an object that is formally defined and compliant to SEMI E39, Object Services Standard (reference SEMI E42).

5.2.42 *storage equipment (stocker)* — equipment whose intended function is primarily to provide storage, either short-term or long-term, for carriers.

5.2.43 *subassembly* — a component of equipment that provides some limited functionality.

5.2.44 *substrate* — basic unit of material on which work is performed to create a product. Examples include wafers, die, plates used for masks, flat panels, circuit boards, and leadframes.

5.2.45 *subsystem* — a subsystem is an intelligent aggregate that behaves as a unit. A subsystem is made up of sensors and/or actuators and may contain mechanical assemblies. Subsystems may be shared by multiple modules.

5.2.46 *subtype* — an object type that is based on (derived from) another type and adds some specialization or overrides some properties or services. The type from which the subtype is derived is the supertype. For additional detail, see SEMI E39, Object Services Standard.

5.2.47 *supertype* — an object type which is used as a basis from which specializations are derived. The derived types are called subtypes. For additional detail, see SEMI E39.

5.2.48 *transport equipment* — equipment whose intended function is primarily to move material from one location in the factory to another location. Transport equipment may also provide short-term storage for material. (See also AMHS.)

5.2.49 *virtual sensor (synthetic sensor, derived sensor)* — one or more calculated measured values that are based on one or more sensor readings. This may include results based on neural nets, statistical analysis, etc. or may be based on a single sensor value.

5.2.50 *work* — a group of one or more substrates that undergo processing in a factory. Something that may be work in one kind of factory, such as reticles and leadframes, may have a different role in other types of factories. Work includes, but is not limited to, material intended as product. For example, it may include product substrates, test substrates, and filler substrates.

5.2.50.1 From the point of view of the equipment, work is either new (processing has not started), completed (all intended processing has been performed, terminated, or aborted, including rejected and resorted work, and no further processing is to be done) or incomplete (work in progress, on hold).

6 Conventions

6.1 This section defines the conventions followed by this document.

6.2 *Object Conventions* — This document conforms to the conventions for objects established by SEMI E39, including object diagrams, object terminology, and requirements for standardized objects. Accordingly, notation is based on Object Modeling Technique (OMT) as described in Object Oriented Modeling Design.[2]

6.2.1 *Formal Name of an Object* — The text capitalizes formal object name references. Similar to the way capitalization is normally used when discussing entities. When describing something in the general (like cities) lower case is used, but when a specific entity is of interest (New York City), then first letters are capitalized.

6.2.2 *Components of Complex Attributes* — The names of object attributes defined in tables are left-justified. The individual elements of complex attributes are right-justified in order of appearance below the complex attribute.

2 Rumbaugh, James, et al, Object Oriented Modeling Design, Prentice Hall, Englewood Cliffs, NJ, c1991.

6.2.3 *Names of OBEM Objects* — The names of abstract object types start with the word “Abstract” and are not intended to be directly implemented. All other objects defined in OBEM are concrete types that may be directly implemented.

6.3 *State Model Conventions*

6.3.1 This document uses the Harel state chart convention for describing dynamic operation of defined objects. The outline of this convention is described in an attachment of SEMI E30. The official definition of this convention is described in “State charts: A Visual Formalism for Complex Systems”[3].

6.3.2 The Harel convention has not the concept of state models of “creation” and “extinction” for expressing a temporary entity. The “job” described in this document is such an entity, and a copy of the same state model is used for an independent job newly created. In this document, a circle with a black circle inside is used for expressing extinction of an entity. A filled black circle denotes the entry to the state model (the entity creation).

6.3.3 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition table contains columns for Transition number, Previous State, Trigger, New State, Actions, and Comments. The “trigger” (column 3) for the transition occurs while in the “previous” state. The “actions” (column 5) includes a combination of:

1. Actions taken upon exit of the previous state.
2. Actions taken upon entry of the new state.
3. Actions taken which are most closely associated with the transition.

6.3.3.1 No differentiation is made between these cases.

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*

6.4 *Service Message Representation* — Services are functions or methods that may be provided by either the equipment or the host. A service message may be either a request message, which always requires a response, or a notification message, that does not require a response.

6.4.1 *Service Definition*

6.4.1.1 A service definition table defines the specific set of messages for a given service resource, as shown in the following table:

Message Service Name	*Type*	*Description*

6.4.1.2 Type can be either “N” = Notification or “R” = Request & Response.

6.4.1.3 Notification type messages are initiated by the service provider (e.g., the equipment) and the provider does not expect to get a response from the service user. Request messages are initiated by a service user (e.g., the host). Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

6.4.2 *Service Parameter Dictionary*

6.4.2.1 A service parameter dictionary table defines the description, format and its possible value for parameters used by services, as shown in the following table:

Parameter Name	*Description*	*Format: Possible Value*

6.4.2.2 A row is provided in the table for each parameter of a service.

3 D. Harel, “State charts: A Visual Formalism for Complex Systems”, Science of Computer Programming 8, 1987.

6.4.3 *Service Message Definition*

6.4.3.1 A service message definition table defines the parameters used in a service, as shown in the following table:

Parameter	*Req/Ind*	*Res/Cnf*	*Comment*

6.4.3.2 The columns labeled REQ/IND and RSP/CNF link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication" or the request. The receiver may then send a "Response" which the original sender terms the "Confirmation".

6.4.3.3 The following codes appear in the REQ/IND and RSP/CNF columns and are used in the definition of the parameters (eg., how each parameter is used in each direction):

M	Mandatory Parameter — Must be given a valid value.
C	Conditional Parameter — May be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the value of the other parameter.
U	User-Defined Parameter.
-	The parameter is not used.
=	(For response only.) Indicates that the value of this parameter in the response must match that in the primary (if defined).

6.5 *OBEM Standard Structure*

6.5.1 The remaining part of this document is organized as follows:

6.5.1.1 Section 7 contains background information to provide a context for the Object-Based Equipment Model.

6.5.1.2 Sections 8 provides an overview of two major views of the equipment: the functional view and the internal composition view.

6.5.1.3 Section 9 introduces the OBEM object model: the interface inheritance hierarchy and the rules of aggregation that together form the foundation of the OBEM model of equipment.

6.5.1.4 Section 11 defines the requirements for the component objects within the equipment interface hierarchy: and other related objects of significance not defined elsewhere.

6.5.1.5 Section 12 defines the message services used in OBEM that are not defined in other standards.

6.5.1.6 Section 13 defines the services that are required of the user (factory system, remote access, and operator).

6.5.1.7 Section 14 specifies the minimum requirements and optional capabilities for compliance to the OBEM standard.

6.5.1.8 Section 15 provides scenarios showing typical message flows during operation.

6.5.2 Additional sections are provided as related information: examples and additional material that are not part of the standard itself. These include models for linked litho, 300 mm equipment, the relationship of OBEM and the CIM Framework, and representations of date and time.

7 Background

7.1 Both modern manufacturing processes and modern manufacturing equipment are increasingly complex. A single installation of equipment may have hundreds or thousands of sensors and actuators. In order to manage this complexity, better methods of referencing the internal components of equipment are needed. Use of the object paradigm provides a means for the equipment to describe its internal composition to the factory in a natural way.

7.2 Definition of standardized objects allows the factory to be specific about its requirements and its need for information.

7.3 *Computer Manufacturing Integration Business Goals*

7.3.1 The intent of this section is to provide a context for, and insight into, those requirements of industries such as semiconductor and flat panel display (FPD) manufacturing businesses that affect the object-based equipment model.

7.3.2 The primary purpose of computer integrated manufacturing (CIM) technologies is to improve factory productivity.[4] Other inter-related secondary CIM business goals are listed below.

- Maximize product yields (line/mechanical yield).
- Maximize device yields (electrical/functional yield).
- Maximize total factory product substrate throughput.
- Increase individual equipment product substrate throughput.
- Reduce product variability.
- Reduce process variability.
- Optimize ability to center processes in a “sweet spot”.
- Reduce the use of non-product substrates.
- Reduced time to utilization for equipment (i.e., the time to install, qualify, characterize and ramp production).
- Increase the usability, accuracy, and reliability of data used for metrics.
- These business goals can be met by addressing certain concrete objectives, which are listed below.

7.4 *OBEM Functional Objectives*

7.4.1 OBEM will standardize specific functional capabilities to be implemented on semiconductor/FPD and other manufacturing equipment, providing a hierarchical view of equipment for effective factory integration.

7.4.2 The OBEM functional objectives are as follows:

- Manage material into and through the equipment.
- Manage the association of the process instructions with the material.
- Report data associated with the equipment, the process, and the material.
- Facilitate equipment performance monitoring.

7.4.3 These OBEM functional objectives, individually and collectively, can be shown to directly address the overall business goals:

7.4.4 The Object Based Model objective directly affects the ability to implement most of the other objectives, especially in the case of highly modular equipment.

7.4.5 Equipment performance monitoring has the effect of improving product variability, device yield and can reduce the need for non-product test substrates. It can also provide a means of targeting a specific process window to improve device characteristics such as speed.

7.4.6 Management of the association of process instructions with the material can reduce scrap due to misprocessing, thus improving product yield. The material management objectives impact on the throughput of individual equipment and the total factory throughput.

7.5 *Relevant Factory Environment* — Equipment must support a variety of different factory environments. This is necessary because factory business practices and factory configurations vary not only from company to company but also from one facility within a company to another. Items will be added to this section as their relevance becomes apparent.

7.5.1 *Material Handling Systems* — Material may be loaded and unloaded manually by a fab technician or it may be loaded and unloaded using semi-automated and automated transport systems. Types of systems include:

- Automated Guided Vehicles (AGV),
- Personal Guided Vehicles (PGV),
- Overhead Transport Systems (OTS), including Overhead Hoist Transport (OHT), and
- Fixed Arm Robots.

7.5.2 *Containers* — Containers may be open (e.g., cassettes) or closed (pods, including reticle pods). Pods may be bottom-opening (SMIF), with a removable cassette, or front-opening (FIMS), which may have either a removable cassette or an integrated (non-removable) cassette (FOUP).

7.5.3 *Factory Interface* — The equipment must be able to support different levels of automation, including:

4 For a more detailed discussion and list, see the Guidance and Guideline documents at http://www.sematech.org/public/docubase/abstract/tech-30.htm

- stand-alone (with no connection to the factory systems),
- fully on-line and operated locally (by the operator),
- fully on-line and operated remotely (by the factory systems), and
- fully on-line and able to support and coordinate interactions from multiple factory users and systems at the same time.

8 Equipment Overview

8.1 The Object-Based Equipment Model defines the objects that are generic components of equipment as well as the object representing the equipment itself. OBEM does not dictate the makeup of equipment. Through support of OBEM, the equipment is able to describe its own makeup to the factory. However, OBEM does require certain visibility and access to those parts of the equipment that control and/or monitor the environment or the location of the product.

8.2 Two view areas are of importance: the functional view of the equipment and the internal composition view of the equipment.

8.3 *Functional View of Equipment* — From a functional view, equipment is internally composed of logical subsystems with different areas of responsibility that are at different levels within a control hierarchy, as illustrated in Figure 1. There are three general levels. Equipment Control is at the highest level, both responsible for, and representing, the equipment as an integrated whole. The middle level provides management of specific areas, while the lowest level of functionality has specific time-critical responsibilities and handles all direct interaction with the equipment's I/O (sensors and actuators). The third level is below the factory level of visibility and is discussed here for completeness.

NOTE 3: This is not intended to represent the design of an actual implementation.

8.3.1 The functional areas are discussed below in alphabetical order.

8.3.2 *Access Management* — Access Management is responsible for communications with the factory, including factory computers, local and remote operators, third party systems, and alternate users (desktop access by process engineers, maintenance personnel, supplier remote diagnostics, etc.) Communications with the local operator include input devices (such as keyboards, wands, buttons, and optical character readers) and display devices (console, light pole, and LCD panel) as well as interpretation of operator requests.

8.3.3 *Communications Link* — Communications Link is responsible for low-level communications, including establishing a connection with a communications partner, sending messages, and receiving messages.

8.3.4 *Date/Time Management* — Date/Time Management is responsible for maintaining an accurate date and time-of-day, and for providing current date/time information to the rest of the system. This may include maintenance of regular time-based scheduling.

8.3.5 *Environment Control* — Environment Control is responsible for maintaining the internal environment according to the equipment's specifications. While Process Control is specific to a process and recipe, other monitoring activities may be required regardless of whether the equipment is processing or idle. Such activities include monitoring for particles, humidity, or temperature.

8.3.6 *Equipment Control* — Equipment Control is the supervisory level with overall high-level control. Equipment Control represents the entire equipment as an integrated whole to the factory and represents the decision-making authority within the equipment.

8.3.7 *Event Management* — Events continually occur in all equipment states. A variety of these events are of interest to the factory, including those events that generate a change of state in any standardized object. The factory requires notification when selected events occur, and in many cases, requires reports of the values of specified information at the time that the event occurred. Event Management is responsible for tracking those events and the reports associated with those events.

8.3.8 *Exception Management* — Exception Management is responsible for determining the proper response to an action or operation that the equipment was unable to perform which raised an exception condition. It prompts notification to all affected components, including internal components and currently connected users. In some cases, the proper action may have to be resolved by the user. Exception Management is a high level activity that is in addition to underlying hardware and software interlocks.

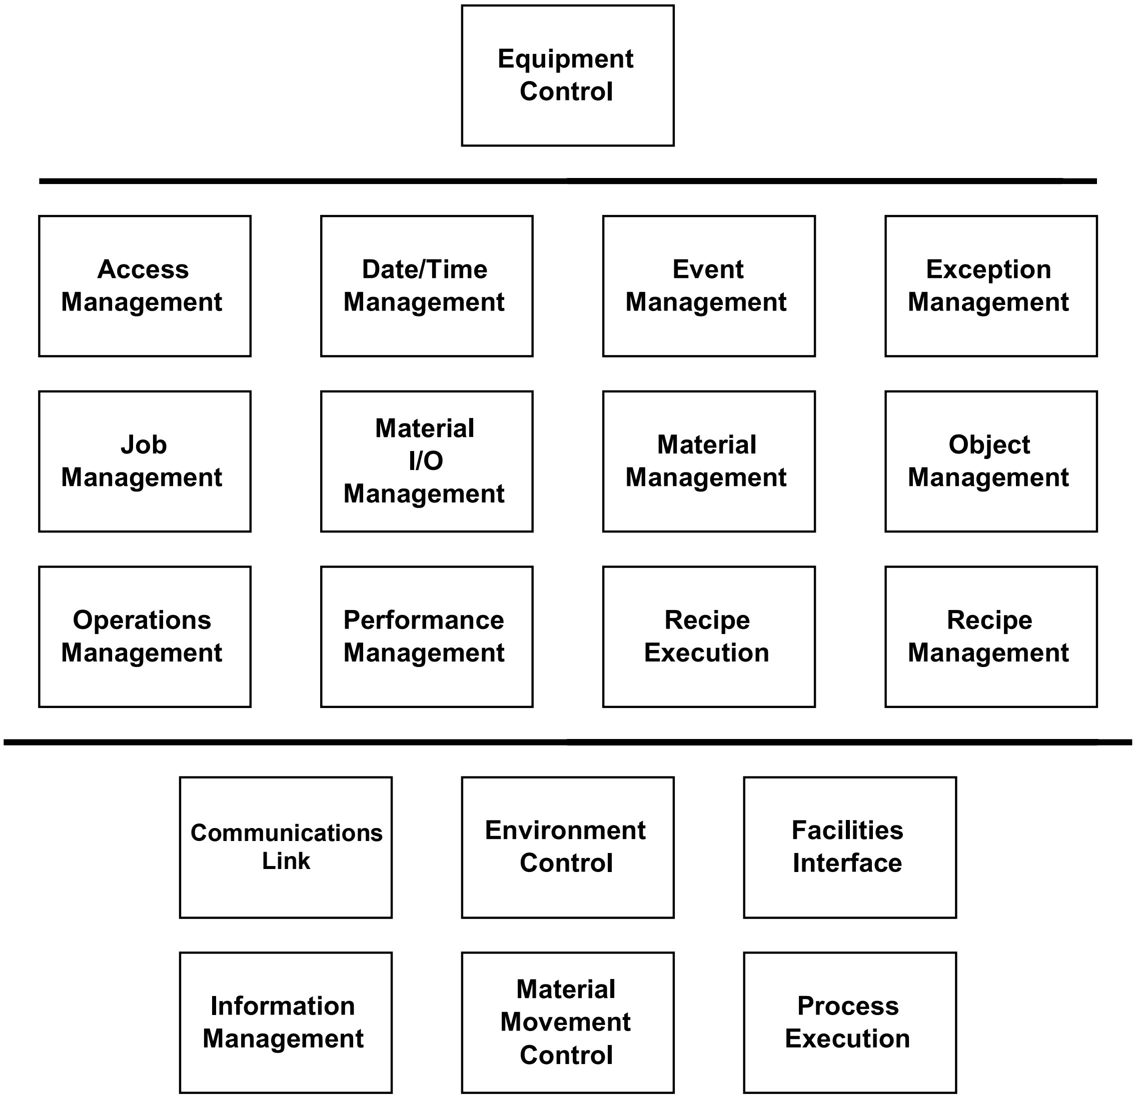

Figure 1
Functional View of Equipment

8.3.9 *Facilities Interface* — The Facilities Interface is responsible for managing the physical interfaces (hookups) to the factory. This includes bulk fill, continuous chemical services, factory vacuum, factory exhaust, and the electrical environment of the equipment.

8.3.10 *Information Management* — Information Management is responsible for the information and data stored by the equipment, including information required for the user as well as various internal event and data logs.

8.3.11 *Job Management* — Job Management is responsible for all jobs, including process jobs, job queues, and job execution.

8.3.12 *Material I/O Management* — The Material Input/Output (I/O) Management is responsible for loading and unloading material to and from the factory. This includes the AMHS interface (parallel I/O), pod interface, carrier management, and carrier-related services such as reading, writing, and slot mapping (identifying unoccupied, correctly occupied, and incorrectly occupied slots in a carrier).

8.3.13 *Material Management* — Material Management is responsible for tracking all material, including carriers, product, and consumables, within or used by the equipment. This includes providing historical information required for product history.

8.3.14 *Material Movement Control* — Material Movement Control consists of low-level control of internal subsystems, subassemblies, and i/o devices used in moving material within the equipment, such as robots, location sensors, proximity sensors, motors, centering and alignment systems, and material identifier readers.

8.3.15 *Object Management*

8.3.15.1 Object Management consists of management of OBEM objects, their attributes, and internal communications. It includes all elements of configuration definition, both fixed and user-configurable, that pertain to the equipment. Configuration settings consist of those attributes that affect the global behavior of the equipment and are generally static and change only on request. They are in effect at all times regardless of the current recipe(s) and/or processing states. They control activities that maintain the environment when “not processing”.

8.3.15.2 Configuration settings shall be retained in non-volatile storage. Some elements of configuration may be distributed. For example, individual process chambers may have their own configuration elements.

8.3.15.3 Elements of configuration management include:

- configuration of individual physical chambers, and
- configuration of individual logical objects.

8.3.16 *Operations Management* — Operations Management is responsible for the overall operation of the equipment in all operational modes: automatic, semi-automatic, and manual.

8.3.17 *Performance Management* — Performance Management is responsible for managing information and operations related to the performance of the equipment and equipment modules. This includes oversight for manual mode operations performed when the equipment and equipment modules are out of service. For implementations of ARAMS, this also includes ARAMS state changes and data as well as oversight for manual mode operations performed during downtime and non-scheduled time.

8.3.18 *Process Execution* — Process Execution covers those fixed algorithms and procedures that are not reachable or changeable by the user. This includes any embedded control and sequence algorithms not contained in recipes. It consists of low-level control of subsystems, sensors, and actuators not covered by Material Management Control, such as, chemical control (valves, exhaust), motion control (rotational, acceleration, positional) and the control of the environment during processing of the product (temperature, etc.). It also includes product environment control and any fixed embedded fault detection classification, and/or fixed low-level in-situ run-to-run control for advanced process control.

8.3.19 *Recipe Execution*

8.3.19.1 A recipe represents the pre-planned and reusable set of instructions, algorithms, and settings that are used by process execution to control process, including variable in situ process control algorithms. Recipes are created by the user, and in some cases by the equipment as well. Recipes may be of a variety of types, such as flow sequence, metrology, models, abort, and load maps, as well as etch, clean, etc.

8.3.19.2 Recipe Execution is responsible for the proper and safe execution of recipes, including loading the recipe into the execution area, verification of the recipe, validation of recipes (ensuring the recipe does not conflict with the current equipment configuration), and initiation of process execution based on recipe instructions (SEMI E42).

8.3.20 *Recipe Management* — Recipe Management consists of the management of stored recipes. This is differentiated from short-term storage of recipes and the selection and execution of recipes performed by Recipe Execution (SEMI E42). Recipes are classified (organized) according to their primary application function: process, environment, service (maintenance), etc.

8.4 *Relationships with Other Standards*

8.4.1 Only those functional areas in the middle in Figure 1 are of interest to the host. The top level of Equipment Control represents all of the functionality below it, while the functional areas at the bottom are considered to be low level and proprietary to the equipment supplier.

8.4.2 Table 1 shows those functional areas that are defined by OBEM and those that are defined by other SEMI standards. In some cases, OBEM may extend or limit the functionality defined elsewhere.

Table 1 Functional Area Definition

Functional Area	*Where Defined*	*Comments*
Access Management	SEMI E98 (OBEM)	Defines different kinds of user control.
Date/Time Management	SEMI E98 (OBEM)	Addresses timestamp, date/time synchronization.
Event Management	SEMI E53 (ERS)	SEMI E53 may be required for SECS-II implementations.
Exception Management	SEMI E41 (EMS)	Required for reporting alarms and exceptions.
Material I/O Management	SEMI E87 (CMS)	Required for Carrier Management.
Material Management	SEMI E90 (STS)	Required for Substrate Tracking.
Object Management	SEMI E39 (OSS)	Required
Operations Management	SEMI E98 (OBEM)	Overall coordination.
Performance Management	SEMI E58 (ARAMS)	Optional for EquipmentModule and Equipment. Not used for lower level components.
Job Management	SEMI E40 (PM), SEMI E94 (CJM)	Process Managment and Control Job Management
Recipe Execution	SEMI E42 (RMS)	Required for processing by EquipmentModule.
Recipe Management	SEMI E42 (RMS)	Required for long-term storage by Equipment.

8.5 *Internal Composition View of the Equipment* — The physical makeup of equipment is of interest to the factory, particularly for equipment that is complex, multi-module, and/or multi-process. Productivity and maintenance tracking, for example, requires that the factory be able to specify individual subsystems and/or modules for maintenance activities, where it is possible to do so without removing the entire equipment from manufacturing scheduling. For example, one or more baths in a wet bench may be down for maintenance even though the wet bench itself continues to process.

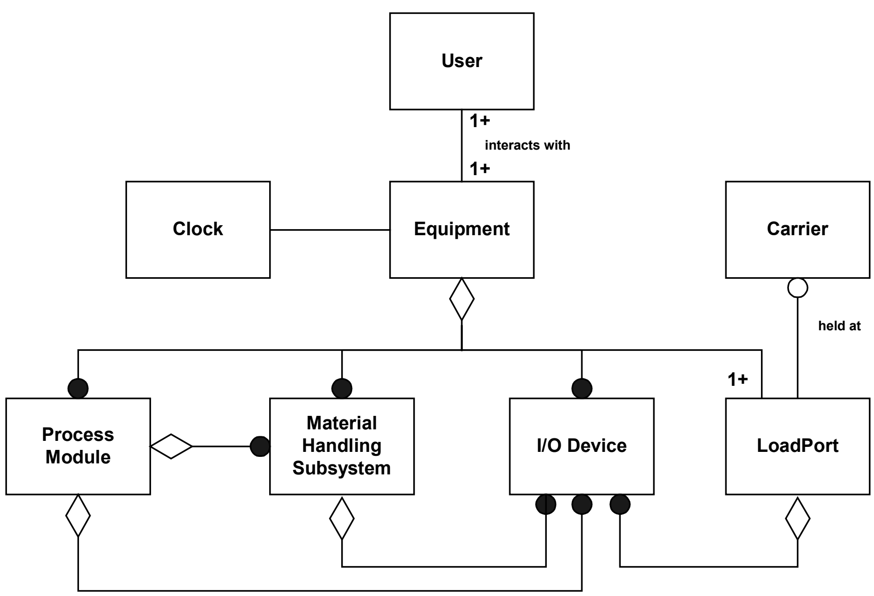

Figure 2
An Example of Equipment Internal Composition

9 OBEM Object Model

9.1 OBEM defines generic component objects of Equipment, and the Equipment object itself. Equipment is made up of elements (units or parts) of different levels of intelligence and complexity, such as modules, subsystems, and I/O devices. Each of these elements may itself be made up of several smaller elements, some of which may also be intelligent, and this allows the complexity of the equipment to be distributed to smaller functional units. Many of these elements may be of interest to the factory. In particular, process modules, which are intelligent and may be independently operable, are very interesting to the factory, since these are the units where the product is actually processed. The factory requires processing modules to be highly visible and individually addressable and to support certain of the same remote commands that are required of the equipment. Other elements of interest include subsystems for material handling, alignment, and measurement.

9.2 The equipment is responsible for all communications at all times, including messages directed to a specific part of the equipment. Service requests directed to components of the equipment shall be managed by the equipment to ensure equipment integrity.

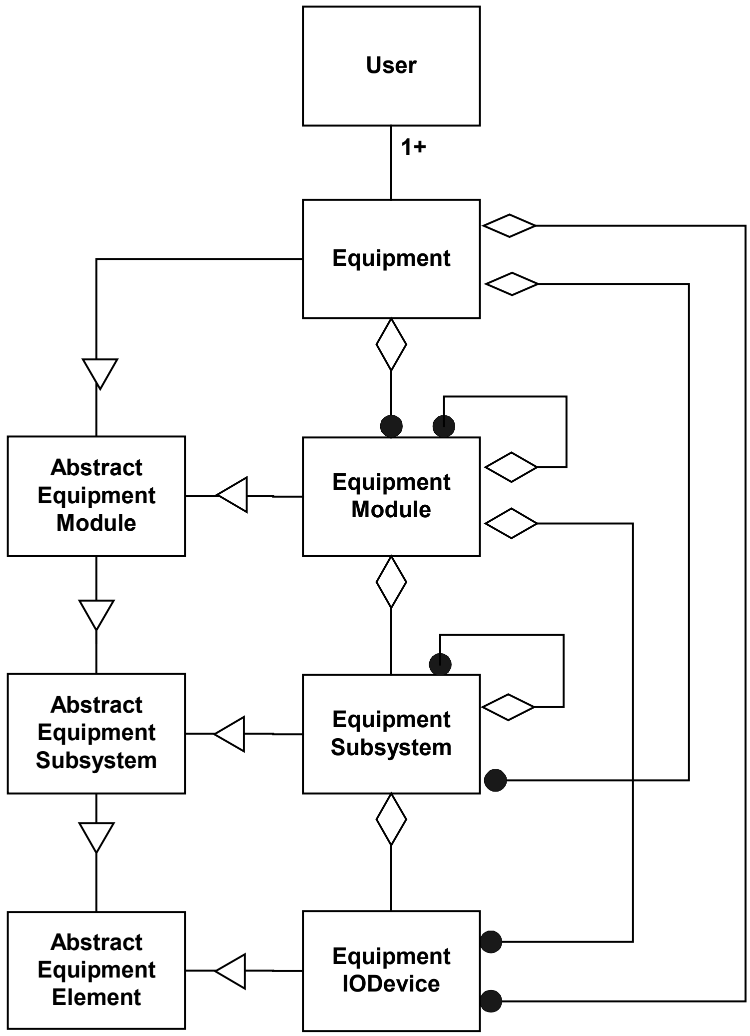

Figure 3
Equipment Object Model

9.3 In Figure 3, two hierarchies are shown. On the left is an inverted interface inheritance hierarchy, and on the right the concrete subtypes where rules of aggretation are shown. The interface inheritance shows the objects that define the attributes, state models, and services of the subtype objects as viewed externally. These are presented upside down from the usual presentation so that they may be directly related to the aggregation hierarchy on the right. In both cases, the simpler objects are below the more complex objects.

9.4 Those object types starting with the word "Abstract" are abstract objects not intended to be implemented directly. Their purpose is solely to define the inherited attributes, state models, and services for those objects used to build an OBEM model of equipment. The remaining objects shown in Figure 3 are concrete objects. All rules of aggregation are defined for concrete objects only.

9.5 *OBEM Object Requirements* — By definition, subtypes of objects inherit the properties (attributes, services, and relationships) of their supertypes. In some cases, properties of the subtype may be further specialized.

9.5.1 *Object Services Requirements* — All objects formally defined by this standard shall be compliant to the fundamental requirements of SEMI E39 (OSS). All OBEM-defined objects that are aggregates, containers, or managers of other objects shall comply with the additional OSS requirements for object owners. According to OSS, an owner is any aggregate, container, or manager of one or more other objects. An owner is required to respond to queries about the types of objects that it owns. Owners have additional responsibilities, as specified in OSS.

9.5.2 *Object Non-volatility*

9.5.2.1 All objects defined by OBEM shall be persistent. The individual object persists across powerdown and powerup conditions, and all current values of static attributes (attributes that do not change dynamically indicating the object's status) shall be maintained and restored upon powerup. It may be important to maintain other critical values as well, depending upon the object and the implementation. When the equipment is powdered on or reset[5], all state models are restored. Following initialization, the object is considered to be operational. Figure 4 shows this convention for a generic OBEM object. However, since the state model can not be accessed by the user until the object is operational, the default entry state for a specific state model is considered to be within the Operational state.

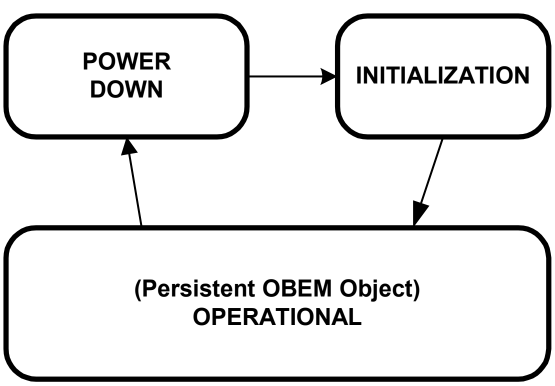

Figure 4
Persistence of OBEM Objects

5 For a more detailed discussion of powerdown, reset, and soft reset, see SEMI E58.

9.5.2.2 POWERDOWN and INITIALIZATION are common to all OBEM objects. Therefore, they are not specific to any object and are not generally shown. When operational, the OBEM object is capable of maintaining state information. From the user view, an instantiation of an OBEM object shall follow the behavior or state model as shown in Figure 4. The equipment representation, which consists of an aggregation of OBEM objects, shall also reflect the state model shown here.

9.5.2.3 The equipment is responsible for managing the exchange of any of its component parts, including parts exchanged during powerdown. This may be accomplished through use of intelligent components that are able to identify themselves or through the user interface.

9.5.3 *Shared Resources* — When two (or more) objects cooperate in using the services provided by a third object, then the third object should not be modeled as a component of either of the first two objects. If the two cooperating objects have a common owner, either logical or physical, then the shared resource object should belong to the common owner.

9.5.4 *Object Factory Communications* — OBEM objects other than the Equipment object are neither required nor expected to communicate directly with the factory. Factory communications are handled by the Equipment instantiation.

9.5.5 *Object Event Reporting*

9.5.5.1 Event reporting allows a user to receive notification of events together with related data of interest. OBEM compliance requires that the equipment provide a standard mechanism for reporting events of interest to the user, together with the current values of user-selectable data.

9.5.5.2 All transitions in state models are of interest to the user and reportable unless otherwise stated in the state model definition.

9.6 *OBEM Interface Inheritance Hierarchy*

9.6.1 An interface inheritance hierarchy begins with a simple interface at the highest (most abstract) level, and lower levels within the hierarchy represent added functionality (specialization). A subtype of an object inherits the attributes, behavior, relationships, and services of the supertype and adds to and/or modifies (overrides) them.

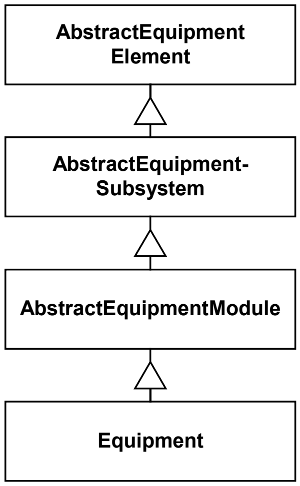

Figure 5
Object Interface Hierarchy Concept

9.6.1.1 The physical view shown in Figure 2 is concerned with the relationships between different objects. In that view, the equipment is at the highest level and owns (is responsible for) the lower level objects of which it is made up. A process chamber is considered to be at a higher level than subsystems such as substrate handlers.

9.6.1.2 From the view of the object interface hierarchy, this order is reversed, with AbstractEquipmentElement appearing at the top level as shown in Figure 5. From the view of an object interface — the interface to an object — the higher the level, the more simple the interface. This is because of inheritance, where the "child" object inherits all of the attributes, behavior, and services of the "parent" object and at the same time adds some degree of specialization that will be reflected in either additional attributes, behavior, or services, or in restrictions on the more general object.

9.6.1.3 All objects represent the view as seen by the factory, not the internal view of equipment control. From this view, the information and services required for an equipment part such as a pod door opener is relatively simple. The view of a module such as a process chamber is more complex but contains all the elements of the view provided for the simpler part (functional description, immutable id, etc.). The view of the equipment is the most complex and includes all of the attributes and services of the equipment element, equipment subsystem, equipment module, and the equipment itself.

9.6.1.4 The object model of equipment presented to the factory is based on SEMI E39 (OSS). OSS services allow the factory to "discover" the actual physical makeup and aggregation hierarchy of the physical view of equipment illustrated in Figures 2 and 3.

9.6.1.5 Each object is defined in terms of its requirements, attributes, behavior (state models), and the services that it is required to support. The equipment owns all of the objects that it is made of and is responsible for providing the required behavior.

9.6.1.6 All objects in OBEM inherit the attributes and services defined for the Top Object as specified in the Object Service Standard (OSS). This allows the factory to use object services to request the equipment to describe its physical view by reporting which objects that it owns.

9.6.1.7 Note that equipment support for an OBEM interface to the factory does not imply or require direct access from the factory to any equipment element.

10 OBEM Object Definitions

10.1 OBEM objects are defined in this section.

10.2 *AbstractEquipmentElement Object* — The supertype object of the interface hierarchy is AbstractEquipmentElement, which is an abstraction of any equipment component that can perform work. AbstractEquipmentElement is an abstract type that is not implemented directly. There are two subtypes of AbstractEquipmentElement: AbstractEquipmentSub-system, and EquipmentIODevice. AbstractEquipment-Element is an abstract type, so that implementations are of one of the subtypes.

10.2.1 *AbstractEquipmentElement Requirements*

10.2.1.1 *Object Exception Management*

10.2.1.1.1 SEMI E41 defines a model for Exception Conditions. An Exception Condition may be either an Alarm Condition or an Error Condition. Error Conditions may, in some cases, have a set of associated Recovery Actions that can be performed by the AbstractEquipmentElement to attempt to recover from the abnormal situation.

10.2.1.1.2 An OBEM object shall comply with the fundamental requirements of SEMI E41, Section 10.4. Exception Condition objects shall be provided in conformance with SEMI E41 and shall be accessible through services defined in SEMI E39. The AbstractEquipmentElement owns all exceptions that it generates. Therefore, it shall report all of its Exception Condition objects through OSS services.

10.2.2 *AbstractEquipmentElement Subtypes* — The AbstractEquipmentElement has two subtypes, the EquipmentIODevice and the AbstractEquipment-Subsystem.

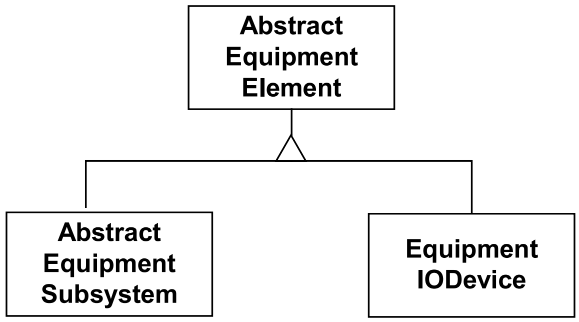

Figure 6
AbstractEquipmentElement Object Types

10.2.3 *AbstractEquipmentElement State Model*

10.2.3.1 The AbstractEquipmentElement is either IN SERVICE (available for work) or OUT OF SERVICE (unavailable for work). In some cases, the user may be able to set the AbstractEquipmentElement's operational state.

10.2.3.2 The state diagram for the AbstractEquipmentElement state model is shown in Figure 7.

10.2.3.3 The AbstractEquipmentElement shall be fault-free whenever it is in the IN SERVICE state.

10.2.3.4 An AbstractEquipmentElement in the OUT OF SERVICE state shall not be used by the equipment or the user for normal manufacturing purposes (while the Equipment or containing EquipmentModule is in the ARAMS superstate of MANUFACTURING).

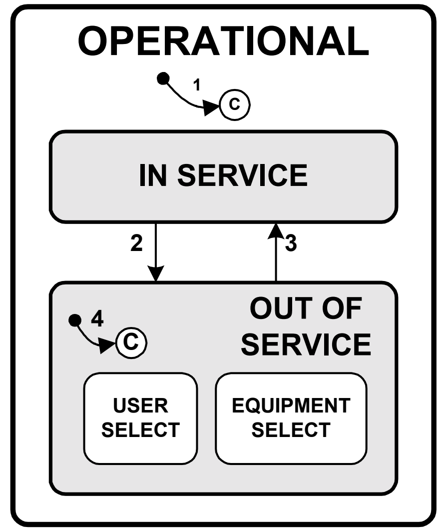

Figure 7
AbstractEquipmentElement State Model

10.2.3.5 The user may or may not be allowed to put a certain subtype of AbstractEquipmentElement out of service, depending upon the equipment design. This is optional for the equipment. In general, the user requires the ability to put major components into and out of service but does not require this for lower level components. In many cases, a component can not operate without some or all of its component elements.

10.2.3.6 Substates of OUT OF SERVICE are not required unless the user is able to put the AbstractEquipmentElement out of service. However, if a user places an AbstractEquipmentElement out of service, only a user shall be able to return it back in service. The substates are then required to retain the source of the out of service selection through the substates USER SELECT and EQUIPMENT SELECT.

10.2.3.7 *State Model Definitions* — Table 2 defines the states of the AbstractEquipmentElement object.

Table 2 AbstractEquipmentElement State Definitions

State Name	*Superstate*	*Definition*	*Comment*
IN SERVICE	OPERATIONAL	The AbstractEquipmentElement is error-free and may be used for work.	None
OUT OF SERVICE	OPERATIONAL	The AbstractEquipmentElement has one or more exceptions and/or has been made unavailable by the equipment or User.	None
USER SELECT	OUT OF SERVICE	The user requested the Abstract-Equipment-Element be put out of service.	Stays out of service until the user returns it to service. This substate may be omitted for low level elements.
EQUIPMENT SELECT	OUT OF SERVICE	The equipment determined that the AbstractEquipmentElement should be placed out of service.	Stays out of service until the equipment determines it is able to operate properly. This substate may be omitted for low level elements.

10.2.3.8 *State Transition Table* — Table 3 defines the state transitions of the AbstractEquipmentElement object.

Table 3 AbstractEquipmentElement State Transitions

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
1	INITIALIZATION	Initialization is complete.	Depends upon previous state and current condition	None	If the user made the element unavailable, it shall remain unavailable. If the element has a fault, it shall be made unavailable by the equipment.
2	IN SERVICE	The user has placed the element OUT OF SERVICE by the user or the equipment.	OUT OF SERVICE	None	The equipment should put the element out of service whenever a fault condition exists at the element.
3	OUT OF SERVICE	The element has been returned to service by the entity that placed it out of service. All exceptions and any user restriction have cleared.	IN SERVICE	None	The original out of service condition has cleared. The element may be used for work.
4	IN SERVICE or INITIALIZING	Default entry into OUT OF SERVICE	USER SELECT or EQUIPMENT SELECT	None	

10.2.4 *AbstractEquipmentElement Object* — Figure 8 represents the AbstractEquipmentElement object.

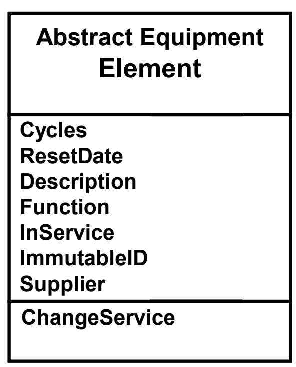

Figure 8
AbstractEquipmentElement Object Type

10.2.5 *AbstractEquipmentElement Attributes* — Table 4 defines the attributes of the AbstractEquipmentElement.

Table 4 AbstractEquipmentElement Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text="EqpElement"
ObjID	Object identifier	RO	Y	Text
Cycles	Number of cycles (or hours) since installation or last reset.	RO	Y	Unsigned long integer
ResetDate	Date cycles set to zero.	RO	Y	Text
Description	User-definable text	RW	Y	Text
Function	Describes function of object (e.g., substrate-chuck, apply/develop track).	RO	Y	Text
Supplier	Name of manufacturer or provider	RO	Y	Text
ImmutableID	An unchangeable identifier such as serial number.	RO	Y	Text
InService	Available for work.	RO	Y	Boolean

10.2.6 *AbstractEquipmentElement Services* — The user may be allowed to change the operational state of specific AbstractEquipmentElement objects that are of significance for preventive maintenance. This is particularly desirable for those subsystems for which preventive maintenance may be performed while the equipment is still assigned to manufacturing operations.

10.2.6.1 *ChangeService*

10.2.6.1.1 The user may request that an element currently in the IN SERVICE state be placed in the OUT OF SERVICE\ USER SELECT state. This request shall not affect any current activity for which the element is being used. However, an element in the OUT OF SERVICE state shall not be used for any new activities.

10.2.6.1.2 The user may request that an element currently in the OUT OF SERVICE/USER SELECT state be placed back into the IN SERVICE state.

10.3 *EquipmentIODevice Object*

10.3.1 An EquipmentIODevice object is a specialization of AbstractEquipmentElement used to represent the sensors, actuators, and intelligent sensor/actuator devices that provide most of the process data sought by manufacturing engineering. Individual I/O points are represented by individual Observables contained within the EquipmentIODevice object.

10.3.2 Observables are not formalized as standardized objects, as indicated by the thin line in Figure 9. The EquipmentIODevice may represent a single I/O point, an aggregation of I/O points, or a virtual sensor providing composite data.

10.3.3 Table 5 defines the attributes of the EquipmentIODevice. Attributes are in alphabetical order, with the exception of the Observables$_i$ attribute, which is placed at the end with its structure members for clarity.

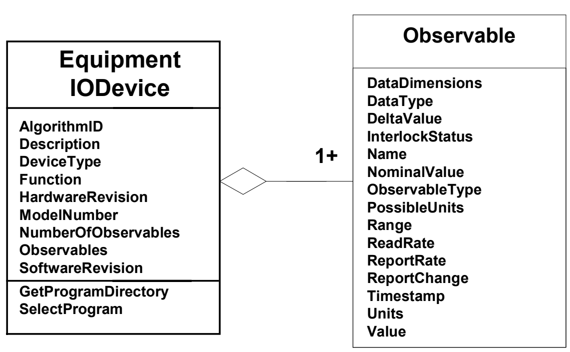

Figure 9
EquipmentIODevice and Observable Object Types

Table 5 EquipmentIODevice Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text = "EqpIODevice"
ObjID	Object identifier	RO	Y	Text
AlgorithmID	Identifier of any algorithm used to produce the set of observable values.	RO or RW	Y	Text
HardwareRevision	Revision level for hardware.	RO	Y	Text. 1–5 characters.
ModelNumber	Manufacturer model number.	RO	Y	Text. 1–20 characters.
Numberof-Observables	The number of data items provided	RO	Y	Integer
SoftwareRevision	Revision level for s/w or firmware	RO	Y	Text. 1–5 characters.
$Observables_I$	Information about the ith item of observable data values.	RO	Y	Structure comprised of Name, Value, Units, and Range, and Timestamp as follows.
Name	The name of the data, sensor, or actuator.	RO	Y	Text
DataDimension	Used for arrays to indicate the number and length of "rows" of data.	RO	N. Required for arrays.	List of unsigned integers.
Datatype	The form of the data.	RO	Y	Enumerated.
DeltaValue	Amount of change from the target for reporting. Zero value indicates it is not used.	RW	N	As indicated by Datatype.
InterlockStatus	Status of current interlock.	RO	N. Required for Actuator types.	Enumerated: None, Off, On
NominalValue	Target used for reporting change of DeltaValue.	RW	N	Numeric text string. If empty, is not used.
ObservableType	Type of Observable.	RO	Y	Enumerated
Possible Units	List of possible units	RO	N	List of text
Range	Valid interval or set of possible discrete values.	RO	Y	Text
ReadRate	Interval between sequential reads, in seconds.	RO	Y	Floating point
ReportChange	A user-settable switch to enable or disable reporting.	RW	N	Boolean. Set TRUE when enabled.
ReportRate	Interval between sequential reports, in seconds.	RW	N	Floating point. Zero indicates no time-based reporting.
Timestamp	The date and time when the value was last read or set.	RO	Y	Numeric. Specific form to be resolved.
Units	Units of measurement	RO or RW	Y if value is scalar.	Text. Conforms to units specified in SEMI E5 (SECS-II) Units of Measurement Identifiers.
Value	Current value.	RO	Y	Single item or array of numeric, or text
DeviceType	Defines the type of device (e.g., "MFC", "OES", FTIR", "CDG", etc.)	RO	Y	Text 1–8 characters

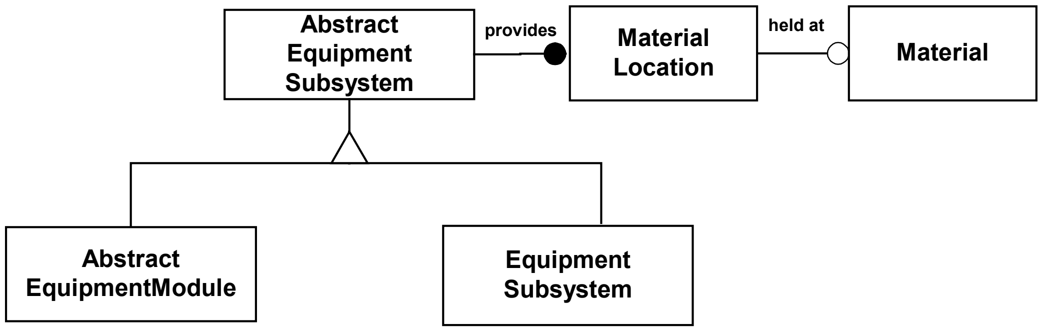

Figure 10
AbstractEquipmentSubsystem Subtypes

10.4 *AbstractEquipmentSubsystem Object*

10.4.1 The AbstractEquipmentSubsystem is a subtype of AbstractEquipmentElement and inherits all of its attributes and services. It may have associated MaterialLocations to hold Material. AbstractEquipmentSubsystem represents all subsystem and subassembly components of which the equipment is made up. The AbstractEquipmentSubsystem may or may not be capable of holding material and may or may not have recipe execution capability.

10.4.2 Figure 10 shows the relationships of the EquipmentSubsystem.

10.4.3 *Material Object*

10.4.3.1 An AbstractEquipmentSubsystem may or may not be able to hold material. Those that are able to hold material owns any material that it holds at any given point in time. They are expected to know the type of material that they hold, whether material is present, and the identifier of the material. In some cases, the AbstractEquipmentSubsystem may be able to hold multiple units of material or more than one type of material.

10.4.3.2 There are three major subtypes of material objects: consumables, durables, and substrates, where the major subtypes of durables are carriers and process durables.

10.4.3.3 Consumable materials, such as chemicals, are used up (as opposed to worn out) during the manufacturing process.

10.4.3.4 Durable material has a significant lifetime and is not part of the equipment (is removable). It includes material that some equipment may require to operate. The subtype of durable of common interest to almost all equipment is carrier. A carrier is a durable used to hold substrates. Process durables are of special interest to a limited subset of equipment. A process durable is an identifiable durable that is specified for a certain process step and recipe. For example, reticles are identified by product id and the mask level where used, and they are also identified by serial number. The factory is very interested in the management and tracking of process durables.

10.4.3.5 Product is typically a Substrate. In the semiconductor industry, Substrates include Wafer, Die, and Leadframe. Reticles are considered a Substrate by some equipment. In the semiconductor industry, reticles are considered as a process durable rather than a product. Specific reticles are specified in recipes for expose tools and modules. In other industries, substrates include flat panel (for flat panel displays) and discs (for hard disk drives).

10.4.3.6 Material objects are not formally defined in OBEM. Carrier objects are defined in SEMI E87 (CMS) and substrate objects are defined in SEMI E90 (STS).

10.4.4 *Material Locations*

10.4.4.1 A material location is a place that is capable of holding material.

10.4.4.2 A MaterialLocation is an abstraction used to facilitate the tracking of material without regard to the physical component associated with the tracking location. For example, a substrate chuck is a subsystem and can hold a single substrate on its surface. The entire subsystem consists of a stage that may or may not be able to move. It may use vacuum to hold the substrate in place, and it may have additional mechanisms and sensors. The MaterialLocation only represents the surface of the chuck. For this reason, the EquipmentSubsystem is said to *provide* a MaterialLocation rather than to be made up of MaterialLocations through aggregation.

10.4.4.3 This relationship is illustrated in Figure 11.

10.4.4.4 The MaterialLocation object is an abstract type. Figure 11 shows the subtypes of MaterialLocations of interest to OBEM.

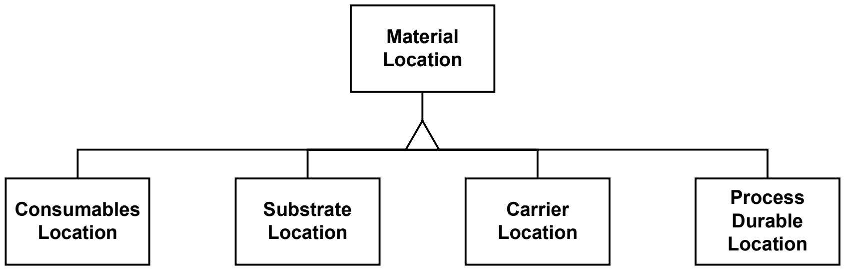

Figure 11
MaterialLocation Subtypes

10.4.4.5 *MaterialLocation Object* — Figure 12 shows the attributes of the MaterialLocation that are defined in Table 6. Every subtype of MaterialLocation shall have, at a minimum, attributes showing its current state and the ID of any material present.

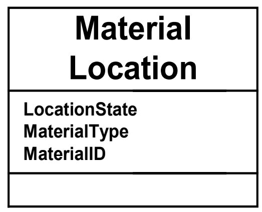

Figure 12
MaterialLocation Object Type

Table 6 MaterialLocation Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text="MatlLoc"
ObjID	Object identifier	RO	Y	Text
LocationState	Current state.	RO	Y	Enumerated: Occupied Unoccupied
MaterialType	Type of material held.	RO	Y	Enumerated: One of, or a subtype of, the following Consumable Carrier Substrate ProcessDurable
MaterialID	Identifier of any material that occupies the location.	RO	Y	Text. "Unknown" if identifier is not known. Null (empty) string if location is unoccupied.

10.4.4.6 *CarrierLocation Object* — The CarrierLocation attribute LocationState may allow an additional enumeration Not Aligned, as shown in Table 7.

Table 7 CarrierLocation Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text="CarrierLoc"
ObjID	Object identifier	RO	Y	Text
LocationState	Current state.	RO	Y	Enumerated: Occupied Unoccupied Not aligned

10.4.4.7 *SubstrateLocation Object* — The SubstrateLocation object is defined in SEMI E90 (STS). STS defines SubstID as an attribute of SubstrateLocation. Note this is identical to MaterialID in the general case for MaterialLocation.

10.4.5 *AbstractEquipmentSubsystem Requirements*

10.4.5.1 AbstractEquipmentSubsystems may or may not be able to hold material.

10.4.5.2 The AbstractEquipmentSubsystem owns all of the MaterialLocations that it provides or that are provided by one of its components. Similarly, it owns all of the Material at those MaterialLocations.

10.4.6 *AbstractEquipmentSubsystem Type* — Figure 13 shows the diagram for the AbstractEquipmentSubsystem object.

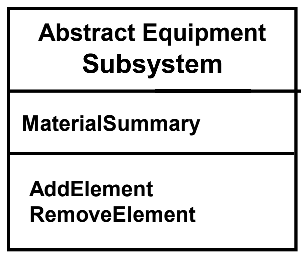

Figure 13
AbstractEquipmentSubsystem Object Type

10.4.7 *AbstractEquipmentSubsystem Attributes*

10.4.7.1 Table 8 defines the attributes of the AbstractEquipmentSubsystem.

Table 8 AbstractEquipmentSubsystem Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text="AbstractEqpSubsystem"
ObjID	Object identifier	RO	Y	Text
MaterialSummary	List of specifications of material capacity and current status for each type of material.	RO	N	List of structure composed of MaterialType, MaterialCapacity, and MaterialCount.

10.4.7.2 Table 9 defines individual elements of AbstractEquipmentSubsystem attributes.

Table 9 Definition of Elements of MaterialSummary Attribute

Element Name	*Definition*	*Access*	*Reqd*	*Form*
MaterialCapacity	Number of units of material that can be held at one time.	RO	Y	Unsigned integer.
MaterialCount	Current number of units of material present.	RO	Y	Unsigned integer.
MaterialType	Specifies the type of material held.	RO	Y	Text. Conforms to SEMI E5.

10.4.8 *AbstractEquipmentSubsystem Services*

10.4.8.1 *Add Element*

10.4.8.1.1 The user may be able to instruct the equipment to add a specific type of AbstractEquipmentElement. The supplier may restrict this service to specific AbstractEquipmentElement subtypes, both in destination (the AbstractEquipmentElement accepting the addition) and in the added element. This is an optional service.

10.4.8.1.2 A typical kind of AbstractEquipmentElement that the user may want to add is an "add-on sensor", a SensorActuatorDevice on a Sensor/Actuator Network. If the Equipment knows the properties, it is possible for it to read an added I/O device and to reference it within recipes.

10.4.8.2 *Remove Element* — The user may instruct the equipment to remove an AbstractEquipmentElement that was added earlier. This service is required wherever the Add Element service is supported.

10.4.9 *EquipmentSubsystem Object*

10.4.9.1 The EquipmentSubsystem is a concrete subtype of AbstractEquipmentSubsystem. It inherits all of the attributes, state models, and services of the AbstractEquipmentSubsystem and in addition defines the rules for aggregation. These rules are illustrated in Figure 14.

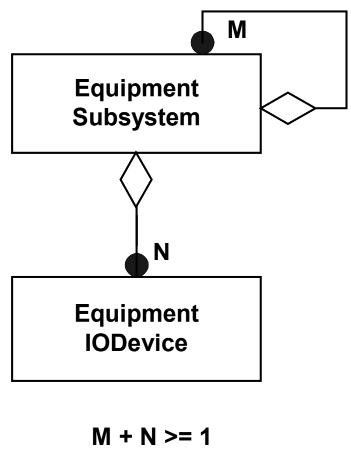

Figure 14
EquipmentSubsystem Aggregation

10.4.9.2 As shown in Figure 14, the EquipmentSubsystem may be made up of other, smaller EquipmentSubsystems and/or EquipmentIODevices. It is required to have at least one of these two components.

Table 10 EquipmentSubsystem Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text = "EqpSubsystem"
ObjID	Object identifier	RO	Y	Text.

10.5 *AbstractEquipmentModule Object*

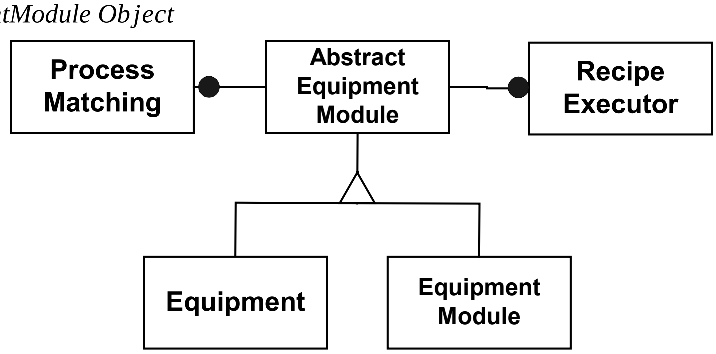

Figure 15
AbstractEquipmentModule Types

10.5.1 As shown in Figure 15, an *AbstractEquipment-Module* is a type of AbstractEquipmentSubsystem that represents a higher level of complexity and is of greater importance to the factory. It is mainly intended to represent process modules but may be used for other major intelligent subsystems capable of supporting the requirements for the AbstractEquipmentModule. It may be possible in some cases for the physical module to operate independently from the equipment.

10.5.2 The AbstractEquipmentModule has two subtypes, Equipment and EquipmentModule.

10.5.3 *ProcessMatching*

10.5.3.1 ProcessMatching provides one or more mechanisms for managing process differences between two or more identically configured subsystems of the same type to ensure that a generic recipe run on both subsystems will achieve the same process result. ProcessMatching may be either internal or external or both.

10.5.3.2 An example of an external method would be through provision of a ProcessMatching object that allows a user to manipulate offsets to process parameters. This can be done through setting parameter offsets for each subsystem so that, within specified constraints, all subsystems of the same type give the same process results. More sophisticated systems may use algorithms to determine process offsets based on mathematical models and module history.

10.5.3.3 As a simple example of process matching, three different individual hotplates may be matched for the temperature range 225–275°C by modifying their temperature offset by 1°C, 1.75°C, and –2.1°C respectively. This approach is illustrated in Figure 16.

10.5.3.4 The equipment supplier is responsible for determining the set of parameters to which offsets may be applied as well as the range of values that are valid.

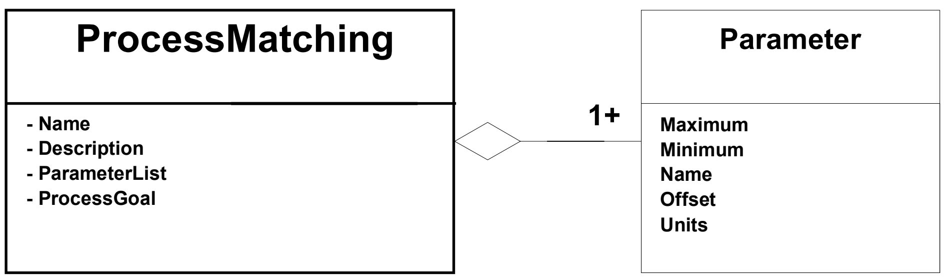

Figure 16
ProcessMatching and Parameter Objects

10.5.3.5 These parameters may be the same as those referenced within recipes for Recipe Variable Parameters.[6] In this case, Recipe Variable Parameters are given as setpoints that can be based on characteristics of the incoming substrate and are hardware independent, while Parameters used in Process-Matching are relative (applied to an existing setpoint) and are used to compensate for hardware differences. Support of both Recipe Variable Parameters and ProcessMatching parameters allows the user to compensate for hardware-specific differences separately from product-specific differences. The number of cycles since the last preventive maintenance performed on a process module affects its performance in a certain way, while the effect of too thin a film on the wafer will affect requirements in a different way.

10.5.3.6 The ProcessMatching object here is shown as an example. This is not a standardized object.

10.5.3.7 Internal methods of process matching may use other techniques, such as special types of recipes.

10.5.4 *AbstractEquipmentModule Requirements*

10.5.4.1 The AbstractEquipmentModule inherits the attributes, state models, and services of both the AbstractEquipmentElement and the AbstractEquipmentSubsystem. As a type of AbstractEquipmentSubsystem, the AbstractEquipmentModule is also able to hold one or more units of material.

10.5.4.2 The AbstractEquipmentModule represents major subsystems, such as process chambers. It supports basic operational commands: start, stop, pause, resume, and abort.

10.5.4.3 *ARAMS*

10.5.4.3.1 When implementing SEMI E58, the AbstractEquipmentModule shall provide compliance except as qualified in this section. The AbstractEquipmentModule is the smallest component of equipment for which SEMI E58 (ARAMS) states should be maintained.

10.5.4.3.2 An AbstractEquipmentModule that can not be powered off separately from Equipment is not required to provide its own powerdown estimate or time of last powerdown.

10.5.4.3.3 Otherwise, an AbstractEquipmentModule implementing SEMI E58 shall comply with the requirements of Section 13, Object Services Compliance, in SEMI E58, including all of the attributes defined in Table 6, ARAMS Object Attribute Definitions in that document. These attributes are not repeated in OBEM. The user may change the ARAMS state. In some cases, a change in the ARAMS state of a module may cause an ARAMS state change for the equipment. The supplier shall document any relationships between the ARAMS state of the Equipment and the ARAMS states of its modules.

10.5.4.4 *AbstractEquipmentModule Service States* — For implementations of ARAMS, to be consistent with SEMI E10, the AbstractEquip-mentModule is IN SERVICE whenever it is in an uptime state. Otherwise, it is OUT OF SERVICE, as it can not be scheduled for manufacturing. To change the service state of an AbstractEquipmentModule, the user must change its SEMI E10 (RAM) state. Note that the service state of some modules will affect the service state of Equipment as well.

10.5.4.5 *Clock* — For modules able to operate independently of the equipment (e.g., modules with a dedicated CPU), AbstractEquipmentModules are required to have individual clocks. It is the responsibility of the Equipment to synchronize multiple internal clocks.

10.5.4.6 *Process Type*

10.5.4.6.1 An AbstractEquipmentModule has a Process Type that indicates its primary functionality as one of the following: Process, Measurement, Transport, or Storage. This is represented as a text string that may specialized further as needed.

10.5.4.6.2 The AbstractEquipmentModule has one or more ProcessCapabilities. ProcessType and ProcessCapability are used for high-level and detailed process characterization. The user may add and remove ProcessCapability descriptions through operations Add Process Capability and Remove Process Capability.

10.5.4.7 *Process Matching*

10.5.4.7.1 All AbstractEquipmentModules supporting Recipe Execution shall provide one or more methods for process matching.

10.5.4.7.2 ProcessMatching allows the AbstractEquipmentModule to be tuned for a specific set of conditions in order to achieve the same results as other AbstractEquipmentModules with the same process capability.

10.5.4.8 *Process Setup*

10.5.4.8.1 AbstractEquipmentModules capable of performing different processes may need to be reconfigured following one process before a process of a different type can be executed. Examples of setup requirements include: a new reticle for a stepper, a source change for an ion implanter, or a significant change in temperature for a furnace.

6 Variable Parameters are defined in SEMI E42.

10.5.4.8.2 Both process recipes and service recipes may be associated with specific setups.

10.5.4.8.3 Recipes of the class "/SETUP/" may be used to put the AbstractEquipmentModule into a specific state. The user uses the name of the setup for scheduling work. This is captured in the attribute ProcessSetup.

10.5.4.9 *Recipes*

10.5.4.9.1 An AbstractEquipmentModule may provide recipe execution services and the ability to accept, store, verify, select, and run Execution Recipes (SEMI E42). This ability is required for AbstractEquipment-Modules with a ProcessType of "Process" or "Measure-ment". Where provided, recipes and recipe execution shall comply with the fundamental requirements for the Execution Recipe and Recipe Executor as specified in SEMI E42 (RMS).

10.5.4.9.2 Some equipment performs its process in three stages, which can be characterized as preamble, main process, and postamble, where the preamble is preparation for the stable part of the process, and the postamble takes care of the transition from the stable part of the process until it is ready to unload the material. In a furnace, for example, the preamble could include both the period where it is ramping to attain the setpoint temperature and the gas flow setpoints. A fourth stage is sometimes defined to handle abnormal terminations.

10.5.4.9.3 From a recipe standpoint, these different stages can be represented as different sections of a single recipe or as separate recipes linked to a main recipe.

10.5.4.10 *Mechanical Dry Run*

10.5.4.10.1 The AbstractEquipmentModule shall support the capability to do a mechanical dry run. This allows the material handling subsystems and software functions to be exercised and tested without requiring full process hookups and without using process consumables. Typically this is done through a specially designated recipe that allows time settings and does not use settings for temperature, gases, plasmas, water, etc. In some cases, it may require a recipe of a special class, such as "/DRYRUN/". Environmental subsystems such as vacuum, nitrogen purge, particle detection subsystems, etc. must be allowed to function normally during a mechanical dry run.

10.5.4.10.2 Dry runs shall be prohibited during the ARAMS Manufacturing state.

10.5.4.10.3 Certain types of tools may need to modify the definition of the mechanical dry run to address special issues in a way that still satisfies the objectives. Equipment documentation shall specify the method used to satisfy this requirement.

10.5.5 *AbstractEquipmentModule State Model*

10.5.5.1 The AbstractEquipmentModule inherits the Operational State Model of the AbstractEquipment-Subsystem. In addition to the concurrent substates of SERVICE, the AbstractEquipmentModule adds the BEHAVIOR state. Figure 17 shows the Operational State Model with its two concurrent substates.

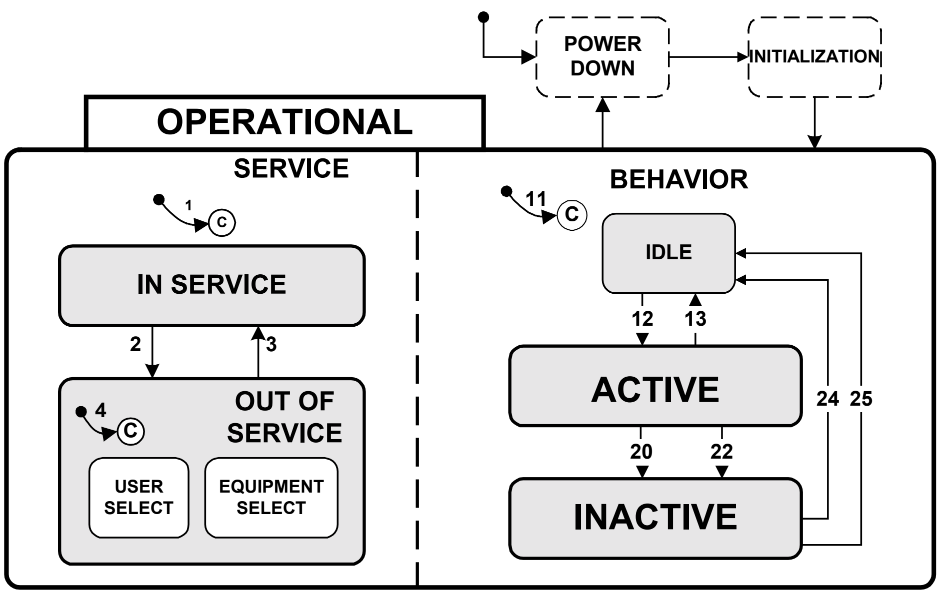

Figure 17
AbstractEquipmentModule Operational State Model

10.5.5.2 Additional details of the BEHAVIOR state are shown in Figure 18.

10.5.5.3 In addition to the states shown above, the AbstractEquipmentModule has an ARAMS state model, defined in SEMI E58. The diagram for the ARAMS state model for modules is shown in Figure 6 in that document.

10.5.5.4 *AbstractEquipmentModule Behavior State*

10.5.5.4.1 The details of the BEHAVIOR state are shown in Table 11. POWERDOWN and INITIALIZING states are included in the table to simplify comparisons with the ARAMS State Model and the Operational State Model defined in SEMI E58. State models are initialized during the INITIALIZATION state. Communications shall be initialized before the ARAMS state model is initialized in order to allow reporting of power down events.

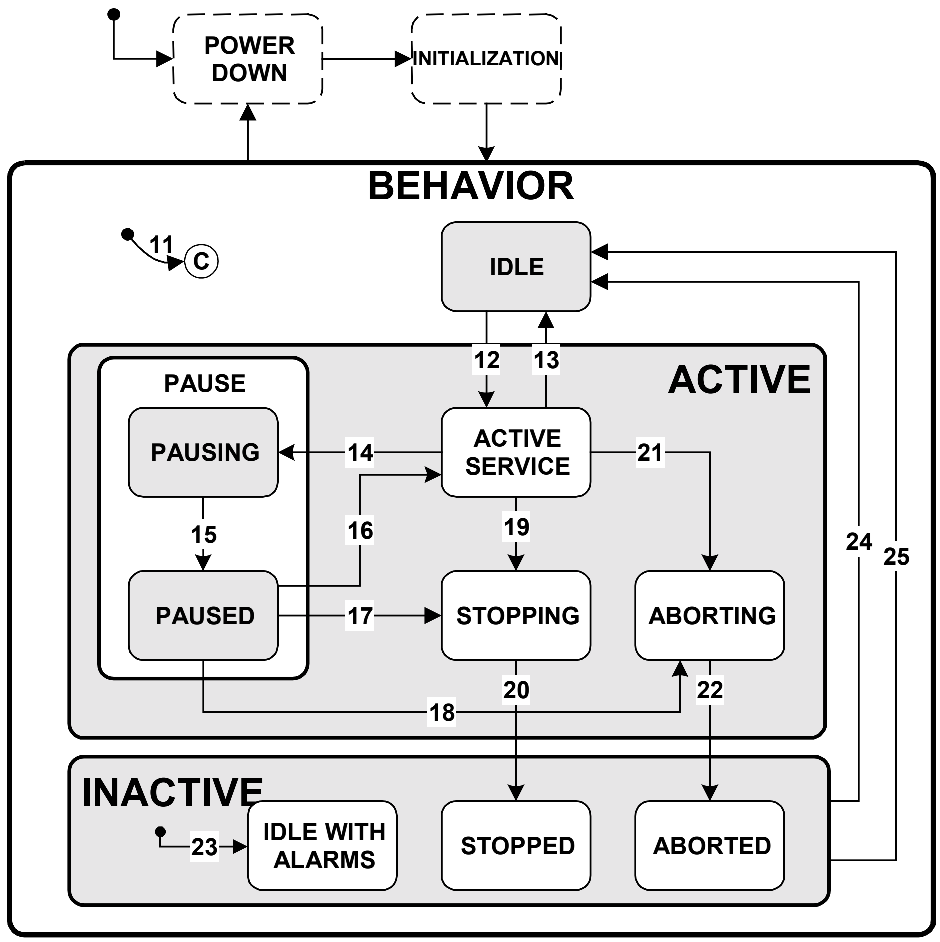

Figure 18
Behavior State

10.5.5.4.2 Table 11 defines the substates of the BEHAVIOR state.

Table 11 AbstractEquipmentModule Behavior State Definitions

State Name	*Superstate*	*Definition*
POWERDOWN	None	The AbstractEquipmentModule is powered off.
INITIALIZING	None	The AbstractEquipmentModule system, including hardware and software, is being initialized. It is not ready to accept instructions.
IDLE	IN SERVICE	The AbstractEquipmentModule is fault free and able to accept instructions to perform a manual or automated procedure that may change its physical state.

State Name	*Superstate*	*Definition*
ACTIVE	IN SERVICE	The AbstractEquipmentModule is performing activities that change its physical state.
ACTIVE SERVICE	ACTIVE	While assigned to manufacturing, the AbstractEquipmentModule may only perform its normal process.
PAUSE	ACTIVE	The AbstractEquipmentModule has received instructions to pause its activity.
PAUSING	PAUSE	The AbstractEquipmentModule is in the process of putting itself into a safe state.
PAUSED	PAUSE	The AbstractEquipmentModule is in a safe state.
STOPPING	ACTIVE	The AbstractEquipmentModule has begun the stop operation.
ABORTING	ACTIVE	The AbstractEquipmentModule has started the abort operation.
INACTIVE	IN SERVICE	The AbstractEquipmentModule has completed its stop or abort operation.
IDLE WITH ALARMS	INACTIVE	The AbstractEquipmentModule is idle but has a fault condition.
STOPPED	INACTIVE	The AbstractEquipmentModule has completed the stop operation.
ABORTED	INACTIVE	The AbstractEquipmentModule has completed the abort operation.

10.5.5.5 *AbstractEquipment Module State Transition Table* — Table 12 defines the state transitions for the AbstractEquipmentModule Operations state model.

Table 12 AbstractEquipmentModule Behavior State Transitions

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
11	Any	State model is initialized.	depends on previous state and current condition	None	See Section 9.5.2.2.
12	IDLE	An activity changing the physical state of the module is started.	ACTIVE SERVICE	None	Substates of ACTIVE SERVICE are module dependent.
13	ACTIVE SERVICE	All activities changing the physical state are completed without fault.	IDLE	None	IDLE is fault-free.
14	ACTIVE SERVICE	The module received instructions to pause its activity.	PAUSING	None	The module is responsible for reaching a safe state.
15	PAUSING	All activity is paused.	PAUSED	None	
16	PAUSED	The module has received instructions to resume its activity.	ACTIVE SERVICE	None	
17	PAUSED	The module has received instructions to stop its activity.	STOPPING	None	The module is responsible for reaching a safe state.
18	PAUSED	The module has received instructions to abort its activity.	ABORTING	None	
19	ACTIVE SERVICE	The module has received instructions to stop its activity.	STOPPING	None	
20	STOPPING	The Stop operation has completed and all material started has been returned to its proper destination.	STOPPED	None	
21	ACTIVE SERVICE	The module has received instructions to abort its activity.	ABORTING	None	The module is responsible for reaching a safe state.
22	ABORTING	Completion of aborting activity.	ABORTED	None	
23	Any	Default entry into INACTIVE	IDLE WITH ALARMS	None	One or more exceptions detected during initialization.
24	INACTIVE	The module received instructions to return to IDLE.	IDLE	None	IDLE is fault-free.
25	INACTIVE	The module returns to IDLE automatically.	IDLE	None	IDLE is fault-free.

10.5.6 *AbstractEquipmentModule Attributes*

10.5.6.1 The AbstractEquipmentModule Object is shown in Figure 19.

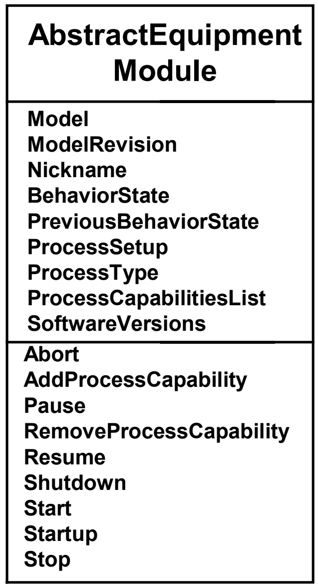

Figure 19
AbstractEquipmentModule Object Type

10.5.6.2 Attributes of the AbstractEquipmentModule are defined in Table 13.

Table 13 AbstractEquipmentModule Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text="AbstractEquipmentModule"
ObjID	Object identifier	RO	Y	Text
Nickname	User-assigned name	RW	Y	Text
Model	Model designator	RO	Y	Text
ModelRevision	Model Revision	RO	Y	Text
BehaviorState	Current substate of BEHAVIOR	RO	Y	Enumerated
ProcessType	Characterization of processes for user	RW	Y	Text
ProcessCapabilityList	One or more specific process capabilities	RO	Y	List of text
PreviousBehaviorState	The previous operations state	RO	Y	Enumerated
ProcessSetup	Name of current setup.	RW	Y	Text
SoftwareVersions	The set of software versions installed	RO	Y	Ordered list of text
Units	Type of material held	RO	Y	Text

NOTE 1: Required if the AbstractEquipmentModule provides recipe execution services.

10.5.7 *AbstractEquipmentModule Services* — The AbstractEquipmentModule has one or more automated activities, including its normal process (its intended function). The user shall be able to start, stop, abort, and resume the activities of the module.

NOTE 4: Changing the operational state of an individual AbstractEquipmentModule within a multi-process Equipment during automatic processing will affect both upstream and downstream operations. The Equipment is responsible for determining the impact on other AbstractEquipmentModules.

NOTE 5: Directly changing the operational state of the AbstractEquipmentModule is not the same as changing the state of a job or as changing the operational state of the Equipment. The equipment supplier shall document the relationships between the operational state of the Equipment, the AbstractEquipmentModule, and the different job types that it supports.

10.5.7.1 *Abort*

10.5.7.1.1 On receipt of an Abort request from the user, the module shall stop all of its current activity as soon as it is safe to do so. It should remove any material in process within the module whenever possible to do so safely.

10.5.7.1.2 A module may also self-abort when it detects a dangerous condition.

10.5.7.1.3 In the Behavior State Model, the module shall transition from ACTIVE SERVICE to ABORTING when an abort occurs. When all activity has ceased other than normal background activities for environmental control, the module transitions to ABORTED. The module shall not start a new activity until it is instructed to do so by the user or the user instructs it to return to IDLE.

10.5.7.2 *Add Process Capability* — ProcessCapabilityList is an attribute of the equipment module and consists of a list of text strings representing process capabilities that are meaningful to the user. Individual capabilities are added by the factory to recognize the type of processes the equipment module may be able to run.

10.5.7.3 *Pause*

10.5.7.3.1 On receipt of a Pause request from the user, the module shall suspend its activity at the next logical point in the process from which it will be able to resume activities at a later time and which will prevent unintended change to the product. It shall not accept new work while it is in this state.

10.5.7.3.2 In many cases, to avoid unintended change to the product, the AbstractEquipmentModule should wait until the current product has been removed and then pause, preventing new product from entering.

10.5.7.4 *Remove Process Capability* — This allows the factory to remove from the ProcessCapabilityList a capability that is no longer required or one that can not be performed by the equipment due to environment or actual physical changes in the equipment.

10.5.7.5 *Resume* — When a Resume request is received during a PAUSE state, the module shall resume its activity from the point where it was paused.

10.5.7.6 *Shutdown* — The Shutdown request is used to put an AbstractEquipmentModule in a state where it is safe to turn off its power and remove it from the equipment. The specific operations shall be documented by the supplier.

10.5.7.7 *Start*

10.5.7.7.1 Some activities may require specific Start instructions.

10.5.7.7.2 The user may issue a Start Activity request to a specific AbstractEquipmentModule.

10.5.7.8 *Startup* — The Startup request is used when an AbstractEquipmentModule has been shutdown. The specific activities that result shall be documented by the supplier.

10.5.7.9 *Stop*

10.5.7.9.1 On receipt of a Stop request from the user, the module shall stop its current activity in an orderly fashion as soon as it is safe to do so, with all product material returned as would be expected had the activity completed normally.

10.5.7.9.2 In the Behavior State Model, the module shall transition from ACTIVE SERVICE to STOPPING when a stop operation begins. When all activity has ceased other than normal background activities for environmental control, the module transitions to STOPPED. The module shall not start a new activity until it is instructed to do so by the user.

10.5.8 *EquipmentModule Object* — The EquipmentModule is a type of AbstractEquipmentModule and inherits all of its attributes, state models, relations, and services. As shown in Figure 20, the EquipmentModule may be an aggregate of EquipmentIODevice, EquipmentSubsystem, and other EquipmentModule objects.

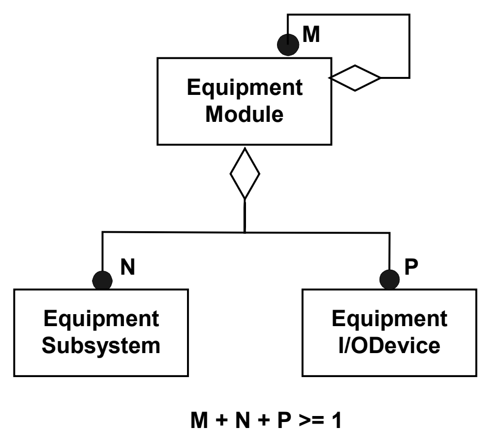

Figure 20
EquipmentModule Aggregation

10.6 *Equipment Object*

10.6.1 The Equipment is a type of AbstractEquipmentModule and supports all of the attributes, state models, and services defined for the AbstractEquipmentModule.

10.6.2 Equipment is an aggregation of EquipmentModules, EquipmentSubsystems, and EquipmentIODevices objects and owns all the objects of which it is made. Figure 21 shows the relationships of the Equipment.

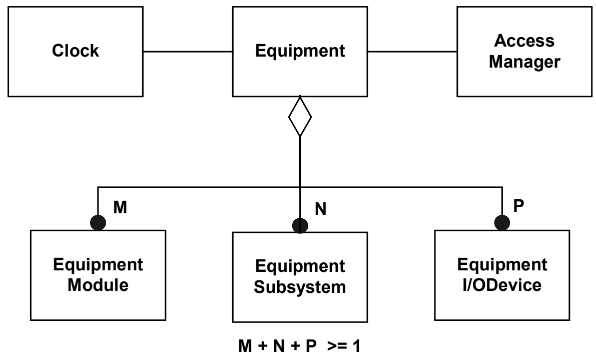

Figure 21
Equipment Object Relationships

10.6.3 *Equipment Requirements* — All equipment shall satisfy the following requirements:

- The Equipment provides the interface to the factory and shall not be made up of other Equipment.
- Equipment is the root object within the equipment hierarchy.
- Equipment may not be a component of any other AbstractEquipmentElement or any of its subtypes.
- Equipment may be made up of any standardized objects except for other Equipment objects.
- Equipment is required to have a Clock.
- Equipment is required to have at least one CarrierPort. Exceptions to this requirement may be made for testers and for exposure equipment in a linked litho cell that have separate communications with the factory systems.
- Equipment is responsible for (owns) all of its components

10.6.4 *Clock Object*

10.6.4.1 Clock represents current real-time date and time of day information. This information may be provided by a physical real-time clock or by other methods of calculating time. The Clock is used to timestamp data and events.

10.6.4.2 Requirements include:

- The user shall be able to read the current date and time at any time.
- Equipment shall be capable of using both factory network time services and user interface services to set current date and time.
- Clock resolution shall be 0.01 seconds or smaller.
- Date shall maintain a four-digit year.

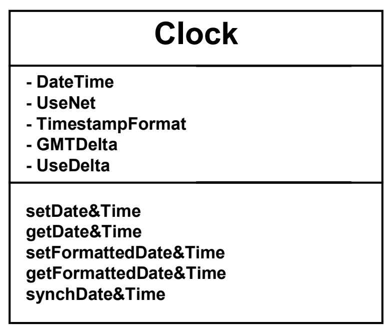

Figure 22
Clock Object

10.6.4.3 All calculations based on, or related to, date and time shall be fault-free in both the twentieth and twenty-first centuries.

10.6.4.4 Table 14 defines the attributes of Clock.

Table 14 Clock Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text = “Clock”
ObjID	Object identifier	RO	Y	Text
DateTime	Current date and time	RO	Y	Protocol specific
UseNet	Enable/disable network time synchronization	RW	Y	Boolean
TimestampFormat	Date and time format used to timestamp events	RW	Y	Enumerated
GMTDelta	Difference, in minutes, between the current time and Greenwich Mean Time (GMT)	RO	Y	Integer
UseDelta	Enable/disable showing current GMTDelta on timestamps	RW	Y	Boolean

10.6.4.5 *Network Time*

10.6.4.5.1 It shall be possible to set current date and time by using time services provided by the network in the factory. Use of network time allows the different systems within the factory to remain closely synchronized with a high degree of accuracy, and it relieves the factory host from explicitly setting the equipment's clock. The attribute UseNet allows the user to enable and disable use of network time services.

10.6.4.5.2 When enabled, the equipment shall be responsible for ensuring that any change in time does not result in discontinuities in date/timestamp reporting. For example, if the time changes in the middle of a process, applying the time change to current process events can cause later events to appear earlier than previous events, or they can give the appearance of large pause in activities during processing. Both of these cases can cause time-based analysis of data to give wrong results and must be prevented.

10.6.4.6 *Timestamp Data*

10.6.4.6.1 Date/time information is used by the factory for a variety of purposes, including analysis of historical data. Typically a factory keeps local time. GMTDelta, the offset between local time and Greenwich Mean Time, is provided to allow time values to be compared outside of the local time zone. GMTDelta may also be added to the timestamp to clarify time data when local time changes within a process.

10.6.4.6.2 The attribute TimestampFormat allows the user to select the format used for timestamping events. Possible formats include: formatted time, a text string of the form YYYYMMDDhhmmsscc, long signed integer, and floating point.

10.6.5 *Equipment Attributes*

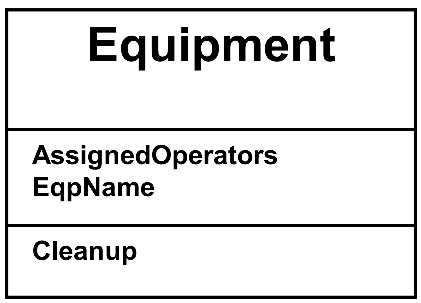

Figure 23
Equipment Object

10.6.5.1 Table 15 defines the attributes of the Equipment object, as shown in Figure 23.

Table 15 Equipment Attribute Definitions

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text="Equipment"
ObjID	Object identifier	RO	Y	Text
AssignedOperators	Currently assigned operators.	RO	Y	List of text
Nickname	User-assigned name.	RW	Y	Text

10.6.6 *Equipment Services*

10.6.6.1 Basic operational commands may be directed to an EquipmentModule, the Equipment as a whole, or to an individual Process Job.

10.6.6.2 For multi-module or multi-process Equipment, the effect of an operational command varies depending upon the level of the target object and the configuration of the Equipment. Given the number of Process Jobs that are defined during the course of a work shift and their temporary nature; it is unlikely that an operator will differentiate easily between one Process Job and another. Whereas they will be able to more quickly identify an individual module or the Equipment when time is a critical factor.

10.6.6.3 *Operational Services*

10.6.6.3.1 *Abort* — The user may direct the Equipment to abort its operations at any time. The Equipment shall stop all activity as soon as possible while maintaining the safety of the product, the Equipment itself, and people. Product is not returned to the carriers.

10.6.6.3.2 *Cleanup* — When product is left in the Equipment following an abort operation, it may be necessary to request the Equipment to return all substrates to their carriers.

10.6.6.3.3 *Pause* — The user may request the Equipment to pause its operations. The Equipment is responsible for determining the appropriate points within its process where it is safe to temporarily stop. As with the Stop command above, the multi-module Equipment may direct individual EquipmentModules to Pause one at a time.

10.6.6.3.4 *Resume* — This command directs the Equipment to resume normal operations from the PAUSED state.

10.6.6.3.5 *Start* — The Start command directs the Equipment to begin an activity that is already setup and ready. Its use is not intended for automatic processing by Equipment providing Process Job capabilities.

10.6.6.3.6 *Stop* — The user may direct the Equipment to stop activity at any time. The Equipment shall be responsible for ensuring that all of its components stop their activities in an orderly fashion at the first opportunity. Processing shall be completed for all work in process (e.g., substrates that have already been removed from their input carrier), but no processing shall be started for remaining work.

For Equipment with multiple EquipmentModules performing individual process steps in a sequence of steps, a Stop command to the Equipment is equivalent to issuing a Stop command to the first EquipmentModule in the sequence, followed by subsequent Stop commands to each EquipmentModule once it has accepted the substrate last started.

10.6.6.4 *Time Services* — This section describes the services provided by the clock.

10.6.6.4.1 *Request Date and Time* — The user shall be able to read the equipment's current date and time as a numeric value.

10.6.6.4.2 *Set Date and Time*

10.6.6.4.2.1 If UseNet is disabled, the user shall be able to set the current date and time as a numeric value. Note that this method does not generally give good synchronization results.

10.6.6.4.2.2 Set Date and Time shall not cause a discontinuity in timestamps for data associated with an individual substrate in process.

10.6.6.4.3 *Request Formatted Date and Time* — The user shall be able to read the equipment's current date and time as a formatted text string.

10.6.6.4.4 *Set Formatted Date and Time* — If UseNet is disabled, the user shall be able to set the current date and time as a formatted text string. Note that this method does not generally give good synchronization results.

10.6.6.4.5 *Synchronize Date and Time* — The user may request the equipment to synchronize date and time from the network as soon as it can do so without disrupting the timestamp series for any work in process.

11 OBEM Equipment Functional Requirements

11.1 The functional areas of the equipment are described in the Functional View in Section 8.3. Section 11 defines the requirements for each of these functional areas. These are requirements at the level of the Equipment object, in addition to those specified in Section 10.

11.2 *Access Management*

11.2.1 Access Management is responsible for all communications with the user, including local operators, factory systems, and remote users. As illustrated in Figure 24, the equipment may be required to support multiple users, with at least one connection to the factory and at least one interface to the local operator. Where automation is used for material handling, more than one human interface will be required.

11.2.2 Objects shown in Figure 24 are not standardized objects. Further work is required to determine requirements for standardized objects to support access management.

11.2.3 *Arbitration* — This section is reserved.

11.2.4 *Authorization* — This section is reserved.

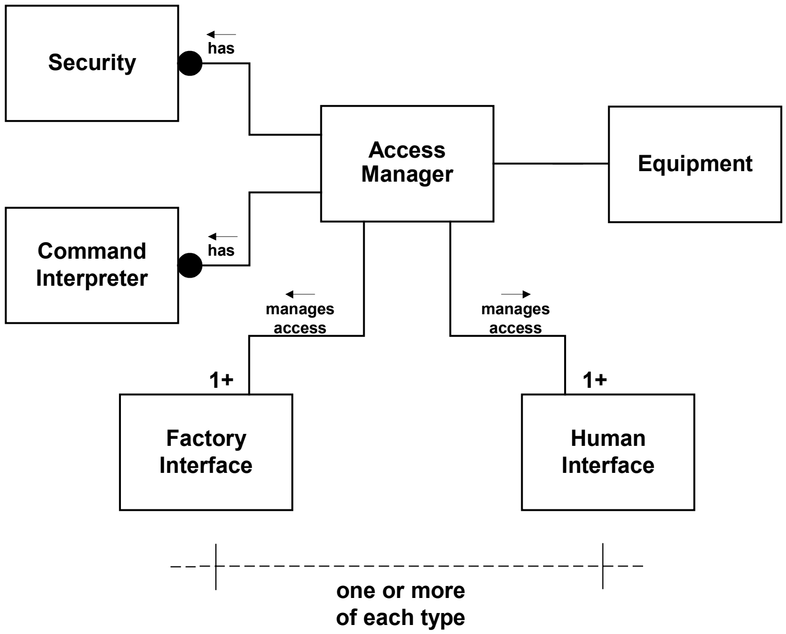

Figure 24
Access Management Model

11.2.5 *Multiple Operator Interfaces*

11.2.5.1 The equipment shall support a minimum of two user interfaces, one that is dedicated to factory system communications and one that is dedicated for local operations.

11.2.5.2 Equipment may support additional interfaces as well. Equipment handling large wafers (300 mm diameter or more) may be required to provide a second operator interface away from the traditional interface at the front. The factory may require separate connections for direct communications with AMHS and/or advanced process control. The equipment supplier's customer service may need remote access for diagnostics.

11.2.6 *Remote Dial-in* — This section is reserved for requirements for remote dial-in using a modem.

11.2.7 *Access Attributes* — Table 16 defines the attributes of the Access Object.

Table 16 Access Session Configuration Data

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
Authorization	Level of authorization specifies user access.	RO	Y	Equipment-specific
FDControl	User may detect a probable fault and instruct that no new work be started.	RO	Y	Boolean
FormatCode	Indicates the code used for interpretation of text.	RW	Y	Enumerated
Language	Indicates the preferred language for text.	RW	Y	Enumerated
Recipe Access	The user may request recipe upload, download, and other recipe-access requests.	RW	Y	Enumerated
R2Rcontrol	User may issue instructions for run-to-run control.	RO	Y	Boolean
MaterialControl	User may issue instructions related to loading and unloading carriers.	RO	Y	Boolean
OperationsControl	User may issue operational instructions.	RO	Y	Boolean
UserID	Identification of the user	RO	Y	Text

11.3 *Date/Time Management* — Equipment shall have an OBEM-compliant Clock with sufficient resolution to differentiate the order in which events occur. (See Section 12.)

11.3.1 *Timestamp Data* — Date/time information is used by the factory for a variety of purposes, including analysis of historical data. Should time change significantly during processing, the assumed ordering of events can be affected so that later events appear earlier, large unexplained gaps can appear in a sequence of events, or data can seem to appear from the past. For these reasons, any change in current time shall not be applied to material in the middle of a process.

11.3.2 *Date/Time Values* — Date and Time information shall be expressed as a numeric value.

11.3.3 *Local Time Change* — Where local time changes automatically, the equipment is responsible for maintaining the correct difference between local time and Greenwich Mean Time (GMT) in the Clock attribute GMTDelta.

11.3.4 *Optional Timestamp Format* — The equipment shall provide an option for the user to include the value of GMTDelta as an additional field in timestamps. The user may enable and disable use of GMTDelta by setting and clearing the Boolean Clock attribute UseDelta.

11.4 *Equipment Control* — Control is divided into several areas: Fault Detection Control, Run to Run Control, Material-Control, and Operational Control. Control of each of these four areas shall be assigned to exactly one user at any point in time. However, that user may be the same for one or more of these areas.

11.4.1 *Advanced Process Control (APC)* — Two categories of APC are described herein: run-to-run control (between lots, carriers, or substrates), and fault-detection control. Support for APC may be required at the EquipmentModule level.

11.4.2 *Run-to-Run Control (R2R)* — The factory may dedicate a separate session for Run-to-Run Control. Run-to-run control consists of adjusting Variable Parameter settings of Process Recipes within a process job.

11.4.3 *Fault Detection Control (FDC)*

11.4.3.1 Fault detection is able to detect a probable fault before it can be detected by SPC, equipment failure, or product failure. The user may provide fault detection through analysis of process data in conjunction with data from external sensors.

11.4.3.2 A separate dedicated session may be used for fault detection control because of its need for large amounts of data. FDC may instruct the Equipment to put itself into a downtime state as soon as it completes work currently in process.

11.5 *Event Management* — Equipment shall provide standard mechanisms for notifying the user of events of interest to the user, together with any data the user has associated with specific events.

11.6 *Exception Management* — The equipment shall comply with SEMI E41 (EMS).

11.7 *Job Management* — This section is reserved for requirements related to specifications for managing jobs. Jobs are defined by SEMI E94 Control Job Management and by SEMI E40 Process Management.

11.8 *Material I/O Management* — Material I/O Management allows the user to request services related to management of the carrier ports and internal buffers required for managing the movement of product through the factory (material logistics). Equipment shall comply with the fundamental requirements of SEMI E87 (CMS).

11.9 *Material Management*

11.9.1 Material Management is responsible for all material present at the equipment from the time it is loaded from the factory until it is unloaded. This includes tracking of all material that is identifiable.

11.9.2 The location of all material that is mobile, such as product, shall be known at all times. The factory may inquire about what material is currently present and where (at what MaterialLocation) that material is placed.

11.9.3 Consumables that are not mobile; such as gold wire on a wire-bonder, may be identified by lot number. The equipment may be required to store current lot numbers for non-mobile material when that information is provided by the factory.

11.9.4 Equipment shall comply with the fundamental requirements for SEMI E90 (STS).

11.10 *Operational Control* — The user with Operation Control may issue operational commands related to starting, stopping, process job management, and recipe access, including upload, download, and recipe selection.

11.11 *Object Management*

11.11.1 This section is reserved for requirements concerning data and information.

11.11.2 Object Management is responsible for providing all data and information required by the factory through Object Services.

11.12 *Performance Management* — As a type of AbstractEquipmentModule, the equipment shall con-form to the Operational State Model defined in Section 10.5.5 and compliance to SEMI E58 (ARAMS).

11.13 *Operations Management* — This section specifies the requirements related to operations, including processing.

11.14 *Recipe Execution* — As a type of EquipmentModule, Equipment providing temporary recipe storage and recipe execution capabilities shall comply to the fundamental requirements for the Execution Recipe and Recipe Executor as specified in SEMI E42.

11.15 *Recipe Management* — Equipment providing long-term storage of recipes shall comply with the fundamental requirements for the Managed Recipe and either the Recipe Namespace with its Recipe Namespace Manager, or the Distributed Recipe Namespace Segment, for all recipes stored, as specified in SEMI E42.

12 OBEM Service Definitions

12.1 This section defines the content of service messages specified in this document and provided by OBEM objects. The services are described in previous sections. This section details the parameters for each message.

12.2 Table 17 lists the services defined in this section. Services of Type "R" are asynchronous requests that require a response. Services of Type N are notifications and do not require a response.

12.3 OBEM compliant equipment is required to understand all service requests. However, if the service is not marked as required, then support for the service itself (the operations) is optional for the equipment, and a response of "request denied" may be returned.

12.4 Services are listed in alphabetical order.

Table 17 List of Services

Operation	*Description*	*Type*	*Reqd*
Abort	Directs an object to immediately stop all activity as soon as it is safe to do so.	R	Y
AddElement	Add a type of AbstractEquipmentElement.	R	N
AddProcessCapability	Add a process capability.	R	Y
ChangeService	Set an AbstractEquipmentElement in service or out of service.	R	N
Cleanup	Directs Equipment to return all substrates to their carriers.	R	N
GetDateTime	Returns the current date and time.	R	Y
GetProgramDirectory	Returns the list of identifiers of Sensor Programs stored by the specified Sensor/ActuatorDevice.	R	N
Pause	Directs an object to temporarily stop its activity as soon as it is at a point where it is safe to the process to do so.	R	Y
RemoveProcessCapability	Remove a process capability from the list.	R	Y
RemoveElement	Remove an element added by the user.	R	Y
Resume	Directs a paused object to resume its activity.	R	Y
SelectProgram	Provides an EquipmentIODevice Program identifier to be selected and executed.	R	N
SetDateTime	Provides current date and time for setting the equipment Clock.	R	Y
Shutdown	Prepare for powerdown.	R	N
Start	Directs an object to begin an activity that has been set up.	R	N
Startup	Prepare for standby for processing.	R	N
Stop	Directs an object to stop an activity in progress by completing work already started and not beginning new work.	R	Y

12.5 *Service Parameter Definitions* — Table 18 defines the parameters for OBEM services.

Table 18 Service Parameter Definitions

Parameter	*Definition*	*Form*
DateTime	Date and time setting.	To be resolved.
DeviceProgramID	Identifier for EquipmentIODevice program.	Integer
ErrorCode	Contains the code for the specific error found.	Enumerated
ErrorText	Text in support of the error code.	Text

Parameter	*Definition*	*Form*
ObjSpec	Object specifier of target object. An empty string implies Equipment is the target.	Formatted text. See SEMI E39 for restrictions.
ProcessCapability	User-defined description	Text
Property	An attribute name and value.	Structure of attribute name, attribute value
RequestAcknowledge	Acknowledgement of request.	Enumerated: Request performed Cannot perform now Invalid request Already in requested state Will perform when able and report results when complete
RequestStatus	Result of request	Structure consisting of RequestAcknowledge and Status
Service	New substate of SERVICE	Enumerated: IN SERVICE, OUT OF SERVICE
Status	Reports any errors found.	List of ErrorCode, ErrorText pairs

12.6 *Abort* — Table 19 defines the Abort service. The Abort request may be directed to the Equipment or to an EquiipmentModule.

Table 19 Abort Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for EquipmentModule.
RequestStatus	-	M	Result status

12.7 *AddProcessCapability* — Table 20 defines the service to add a ProcessCapability. This request may be directed to the Equipment or to an EquipmentModule.

Table 20 AddProcessCapability Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M		Object specifier for owner of capability
ProcessCapability	M	-	User description of a process objective.
RequestStatus	-	M	Result status

12.8 *AddElement* — Table 21 defines the service to add an AbstractEquipmentElement. This request may be directed to the Equipment or to an EquipmentModule. Properties needed for the AbstractEquipmentElement must be included in the list of properties.

Table 21 AddElement Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for new owner
(list of) Property	M	-	Properties of new element
RequestStatus	-	M	Result status

12.9 *Cleanup* — This service directs the equipment to return all substrates that have been removed from their carriers to their appropriate destinations. Table 22 defines the Cleanup service.

Table 22 Cleanup Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RequestStatus	-	M	Result status

12.10 *GetDateTime* — Table 23 defines the GetDateTime service.

Table 23 GetDateTime Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
DateTime	-	M	Date and time.
RequestStatus	-	M	Result status

12.11 *ChangeService* — Table 24 defines the ChangeService service. This service requests that the target object be placed either in service or out of service. The user shall only be allowed to place an object back into service if it was originally put out of service by a user.

Table 24 ChangeService Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target
Service	M	-	New substate for SERVICE.
RequestStatus	-	M	Result status

12.12 *Pause* — Table 25 defines the Pause service.

Table 25 Pause Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target object.
RequestStatus	-	M	Result status

12.13 *RemoveProcessCapability* — Table 26 defines the service to remove a process capability from the ProcessCapabilityList.

Table 26 RemoveProcessCapability Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target object.
ProcessCapability	M	-	Capability to be removed
RequestStatus	-	M	Result status

12.14 *RemoveElement* — Table 27 defines the service to remove an element previously added by a user.

Table 27 RemoveElement Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for element to be removed
RequestStatus	-	M	Result status

12.15 *Resume* — Table 28 defines the service for starting an activity at a designated EquipmentModule or at the Equipment.

Table 28 ResumeService Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target object.
RequestStatus	-	M	Result status

12.16 *SelectProgram* — Table 29 defines the service to select a program for an EquipmentIODevice.

Table 29 SelectProgram Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target object.
DeviceProgramID	M	-	Text
RequestStatus	-	M	Result status

12.17 *SetDateTime* — Table 30 defines the service for setting the equipment's date and time.

Table 30 SetDateTime Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
DateTime	M	-	Date and time
RequestStatus	-	M	Result status

12.18 *Shutdown* — Table 31 defines the service to shut down the equipment or one of its modules.

Table 31 Shutdown Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target
RequestStatus	-	M	Result status

12.19 *Start* — Table 32 defines the service for starting an activity at a designated EquipmentModule or at the Equipment.

Table 32 Start Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for EquipmentModule or Equipment.
RequestStatus	-	M	Result status

12.20 *Startup* — Table 33 defines the service to start up the equipment or one of its modules.

Table 33 Shutdown Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for target
RequestStatus	-	M	Result status

12.21 *Stop* — Table 34 defines the service for stopping an activity at the equipment or one of its modules.

Table 34 Stop Service Definition

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
ObjSpec	M	-	Object specifier for EquipmentModule or Equipment.
RequestStatus	-	M	Result status

12.22 *SynchDate&Time* — The SynchDate&Time service instructs the equipment to synchronize date and time with the network at its next opportunity to do so at a time where a timestamp series for work in process will not be compromised by a change in date or time. This service is defined in Table 35.

Table 35 SynchDate&Time Service

Parameter	*Req/Ind*	*Rsp/Conf*	*Description*
RequestStatus	-	M	Result status

13 Services Provided by Factory Systems

13.1 This section describes the services provided by the factory system. These are messages sent by the equipment to the factory system.

13.2 *Date and Time Request* — The equipment may request the current date and time from the factory system. This message service is identical to the GetDateTime service defined in Section 12.6 and Table 23.

13.3 *Event Notification* — The factory system will receive standard event notifications from the equipment. Event notifications used will depend upon the protocol used.

13.4 *Alarm and Error Notifications* — The factory system will receive notifications of errors and alarms. Errors may be recoverable. Equipment shall comply to SEMI E41.

14 OBEM Compliance

NOTE 6: Section must be completed in order for the provisional status of OBEM to be removed.

15 Scenarios

NOTE 7: Section must be completed in order for the provisional status of OBEM to be removed.

15.1 This section contains scenarios showing typical interactions between factory and equipment, including interactions defined by other standards.

RELATED INFORMATION 1
MODELS

NOTE: This related information is not an official part of SEMI E98. This is Related Information for the provisional specification and is not intended to modify or supersede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

This section provides examples of equipment models to clarify the standard.

R1-1 Linked Litho Model

R1-1.1 This section describes the application of OBEM objects to a linked litho as illustrated in Figure R1-1.

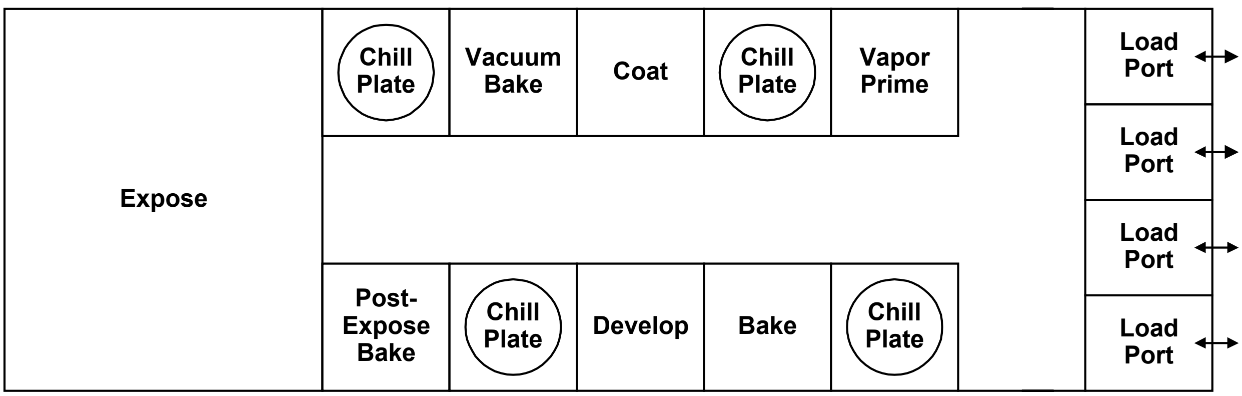

Figure R1-1
Illustration of Linked Litho

R1-1.2 A linked litho is an aggregate created by physically connecting an apply/develop track to a lithography equipment. Work enters through the track where it goes through a set of initial processing steps. Individual substrates are passed to the lithography equipment where they are exposed and returned to another part of the track, where they complete another set of processing steps. Both the track and the lithography equipment are capable of acting independently. However, in the linked-litho configuration, they must perform together as a single system and are treated as a single Equipment by the factory.

R1-1.3 *Apply/Develop Track Equipment*

R1-1.3.1 Before considering the object model for a linked litho, it is helpful to examine the model for an apply/develop track as a type of stand-alone equipment. This is illustrated in Figure R1-2.

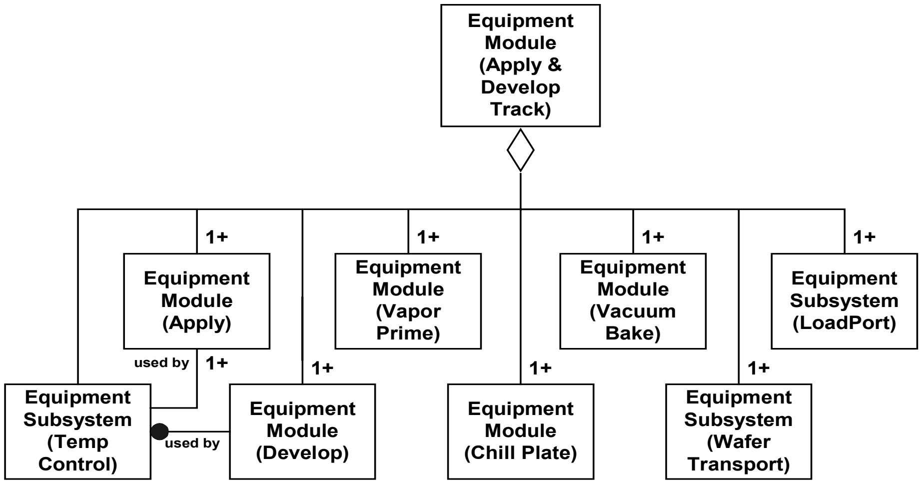

Figure R1-2
Apply and Develop Track Equipment

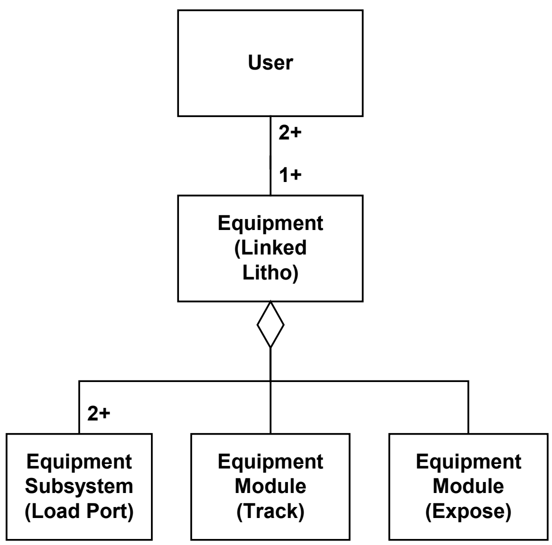

Figure R1-3
Object Model for Linked Litho Equipment

R1-1.4 *Combined Linked Litho*

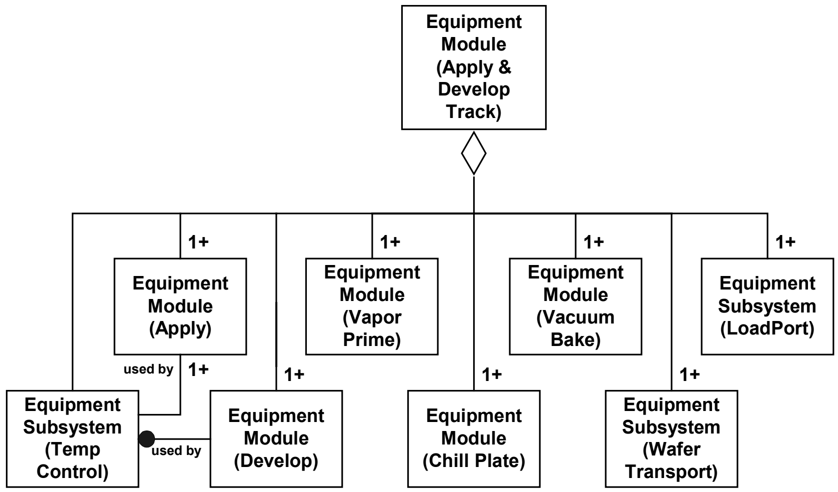

Figure R1-4
Linked Litho Track Module

R1-1.4.1 The Linked Litho Equipment has two major EquipmentModules, the track module and the expose module in this model. The track, in turn, is composed of various types of Sub-modules, such as the Vapor Prime module, the Spin module, and so forth.

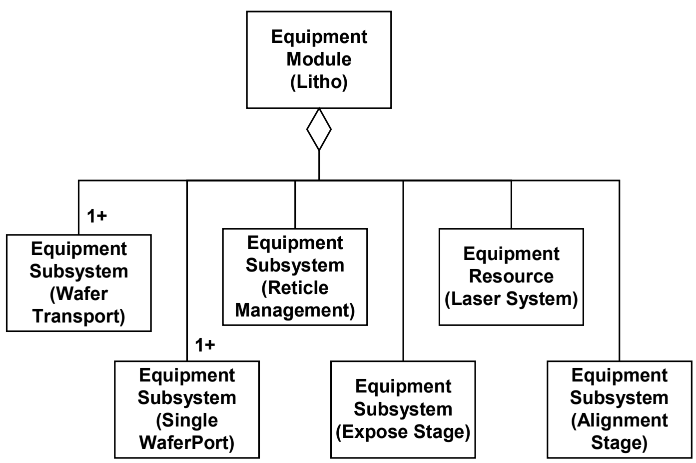

Figure R1-5
Linked Litho Expose Module Object Model

R1-1.4.2 Figure R1-6 shows the makeup of another track module. This process may be extended as many times as is required by the particular installation.

R1-2 300 mm Equipment

R1-2.1 Because of the size and the weight of wafers with a diameter of 300 mm or greater, a 25-wafer cassette is too heavy for repetitive lifting by people. 300 mm factories must be able to integrate automated material handling systems and production equipment. To achieve this, equipment loadports must be standardized for access by different material handling technologies such as overhead tracks and rail-guided vehicles in addition to personal-guided vehicles (PGVs) used by operators.

R1-2.2 In addition to issues regarding access, users require that equipment be capable of continuous processing. To meet this requirement, certain types of equipment need to provide intermediate storage for carriers to prevent starvation, running out of work before new work is delivered.

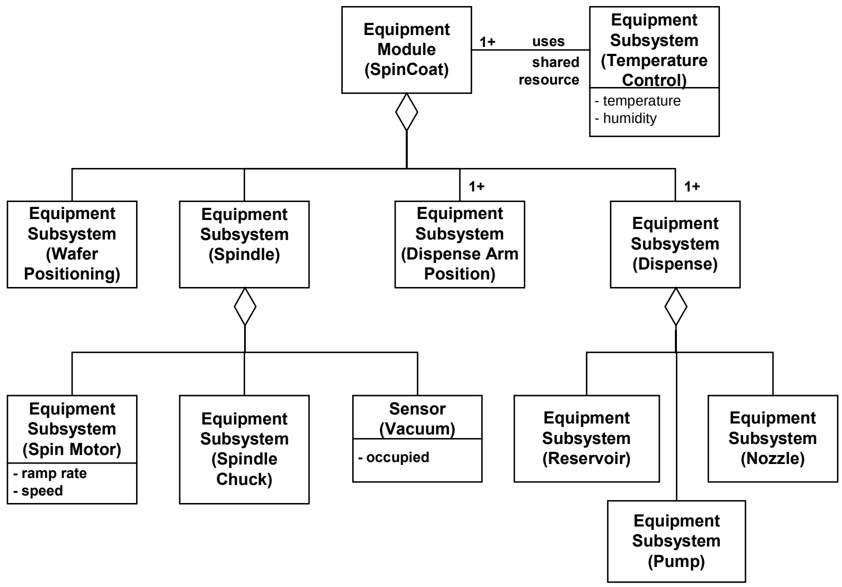

Figure R1-6
Spin/Coat Track Module Object Model

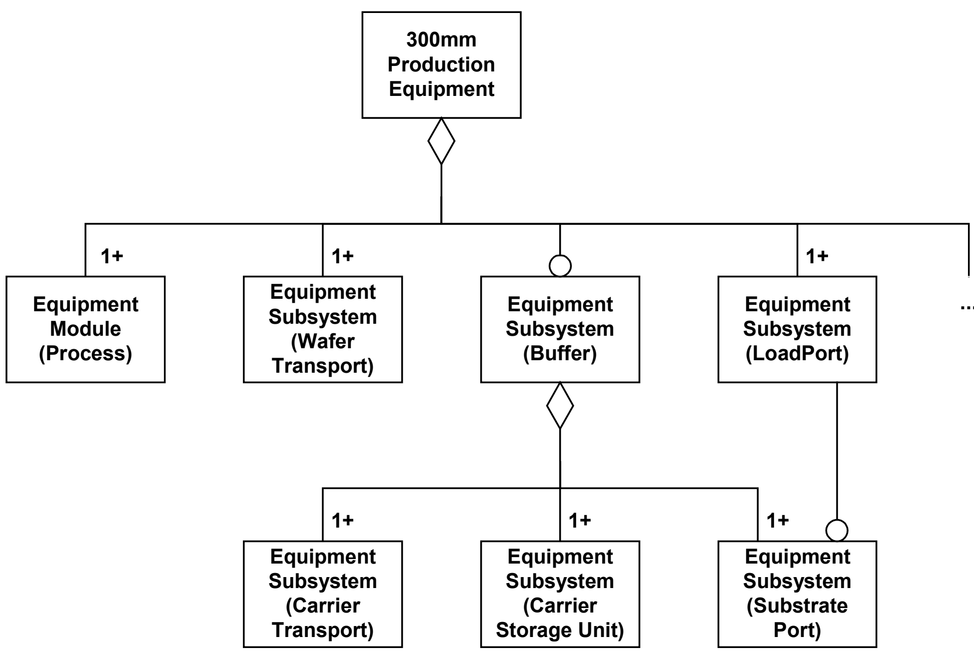

Figure R1-7
Example of Object Model for 300 mm Equipment

R1-2.3 The term “Equipment Front End Module” (EFEM) refers to the aggregation shown in Figure R1-8 consisting of all the components handling carriers, i.e., the loadport and buffer subsystems. An EFEM would not typically provide ARAMS capability and therefore would be considered as an EquipmentSubsystem and not considered as an OBEM EquipmentModule.

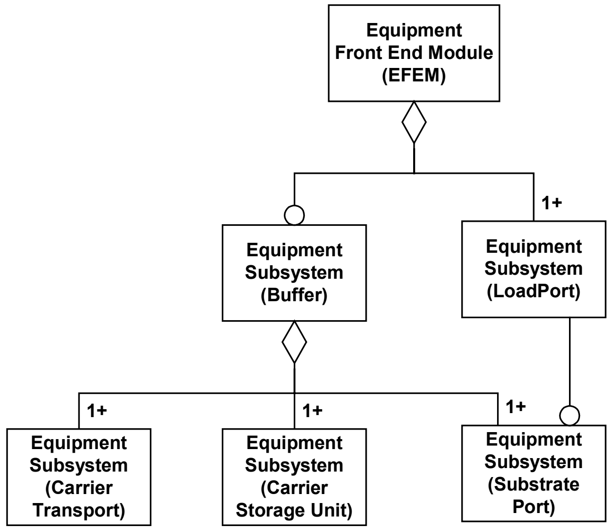

Figure R1-8
Equipment Front End Module (EFEM)

RELATED INFORMATION 2
RELATIONSHIP TO THE CIM FRAMEWORK

NOTE: This related information is not an official part of SEMI E98. This is Related Information for the provisional specification and is not intended to modify or supersede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

This section discusses the relationship of OBEM and the OBEM objects to the objects defined in SEMI E81. It uses terms both from the CIM Framework and from OBEM. It is not part of the OBEM standard.

Additional documentation should be provided in this section as the CIM Framework develops.

R2-1 Equipment and Machine

R2-1.1 The interface to Equipment defined in OBEM is provided for the physical equipment on the manufacturing floor. From time to time, the Equipment will be powered off for maintenance and at these times is unable to communicate. In contrast, the Machine object, defined in the CIM Framework, is part of the manufacturing execution system and is always available, even when the Equipment is powered off or otherwise unable to communicate.

R2-1.2 The Machine provides a generic interface for factory logistics and is able to provide some services without relying on the Equipment itself. The Machine is responsible for communications with the Equipment and for representing the Equipment to the Factory and representing the Factory to the Equipment.

R2-2 EquipmentModule and MachineResource

R2-2.1 The EquipmentModule defined in OBEM corresponds to the MachineResource interface defined in the CIM Framework. The MachineResource is a type of Resource and therefore can respond to requests to start up and shut down. These services are provided for the EquipmentModule but not for its supertypes.

R2-3 Location Tracking

R2-3.1 The CIM Framework defines an interface for a MaterialTrackingLocation. The MaterialTrackingLocation differs from the OBEM MaterialLocation. MaterialLocations represent places within the equipment itself where carriers and substrates can be placed, including wafer chucks, carrier slots, and robot end effectors. A MaterialTrackingLocation, in contrast, is at a higher level of granularity and provides the ability to locate material associated with a Machine. MaterialTrackingLocation does not track material locations down to the level of specific places within the equipment.

RELATED INFORMATION 3
ADDITIONAL DATA

NOTE: This related information is not an official part of SEMI E98. This is Related Information for the provisional specification and is not intended to modify or supersede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

This section provides examples of equipment models to clarify the standard.

This section contains additional information that is not part of the standard.

R3-1 Representations of Date and Time

R3-1.1 This section discusses several date and time representations, and provides background information in support of the OBEM adoption of an IEEE floating point representation of date and time values.

R3-1.2 In this section, the term "date value" means an encoding of a date and time value, such as 12/25/1997 11:04:56.

R3-1.3 *ASCII Digit Representation*

R3-1.3.1 The standard date and time format in SECS communication is the ASCII representation "YYYYMMDDhhmmsscc". In this representation, date and time are represented as a fixed length sequence of ASCII digit characters, grouped into fields as indicated.

Advantages	*Disadvantages*
Very simple conversion to display format.	Date computations difficult. For example, adding two date values is not a trivial operation.
Simple to extract date and time from date value.	Many digit sequences are not valid date values.
	The format does not lend itself to expressions of time intervals. The representation of "ten minutes" might be "00000000001000", but the job of adding this interval to a date value is not simple.
	The resolution of the representation is fixed at seconds.

R3-1.4 *Long Signed Integer Representation*

R3-1.4.1 UNIX represents date and time as the number of ticks since Epoch. Typically the time interval of a tick is one second. Date values are expressed as the number of ticks since a certain instant, called the Epoch.

R3-1.4.2 There are 31,536,000 seconds in a 365 day year. If stored as a four byte signed integer, with ticks in seconds, this representation will overflow after approximately 68 years. Eight byte integers provide sufficient range for dates spanning human history many times. Unfortunately, eight byte integers are inconvenient on many computer platforms.

Advantages	*Disadvantages*
All bit sequences are valid date values.	Difficult to separate date and time from date value.
Intervals are simple to express.	Eight byte representation required for sufficient range, but inconvenient on many computer platforms.
Date value arithmetic is simple.	No simple way to convert date value to display format.
	The resolution of the representation is fixed at the tick value, typically seconds.

R3-1.5 *Floating Point Representation*

R3-1.5.1 This representation is used in many applications. It represents date values as floating point numbers, with units of days past 12/30/1899. It is very similar to the "Ticks since the Epoch" representation, except that the tick values are days.

R3-1.5.2 This representation has the advantages of the "Tick since Epoch" representation for date value arithmetic. Second, the separation of the date and time from a date value is simple. The date is the whole value, the time is the fractional value. Third, the minimum time resolution is very small, and is not fixed by the representation.

R3-1.5.3 The following calculation is used to determine roughly the minimum time resolution that can be expressed:

R3-1.5.4 The IEEE 8 byte floating point representation uses an excess 128 notation. This means 7 bits of exponent and one bit of sign. This leaves 7 bytes of significant. On November 18, 1997 the day number is 35752. This is hex 8BA8, and requires two bytes. This leaves 5 bytes of significant to represent the fractional day, or the time portion of the date value. These 5 bytes of significant contain 40 bits, and can represent values to 2^40, or one part in 1,099,511,627,776. There are 86,400 seconds in one day, so this representation is accurate to approximately 7.86E-08 seconds, or about 1/10 of a microsecond. In about a hundred years the day number will have doubled, and this resolution will have shrunk by a factor of 2. For practical purposes the resolution is no worse than one microsecond resolution.

Advantages	*Disadvantages*
All legal float values are valid date values.	Minimum resolution changes over time.
Simple to separate date and time from a date value.	No simple way to convert date value to display format (but simpler than the "Tick since the Epoch" representation).
Intervals are simple to express.	
Date value arithmetic is simple.	
The eight byte floating point representation used is supported on most computer platforms.	
The time resolution is not implied by the representation, but is valid to very small intervals.	

R3-1.6 *Examples*

11/18/1997	35752
11/18/97 1:03:13 PM	35752.543912037
One second	1.15740740740741E-05
One day	1
One microsecond	1.15740740740741E-11
1/1/1000	-328716
12/30/1899	0

RELATED INFORMATION 4
OBEM EQUIPMENTIODEVICE AND SENSOR/ACTUATOR NETWORK COMMON DEVICE MODEL

NOTE: This related information is not an official part of SEMI E98 and was derived from work developed in the Object-Based Model Task Force in North America, and the Sunsor/Actuator Bus subcommittee. This related information was approved for publication by full letter ballot on April 30, 2001.

R4-1 Relationship between OBEM EquipmentIODevice and Sensor/Actuator Network Common Device Model

R4-1.1 This section describes the relationship between the EquipmentIODevice defined in Section 10.3 and the Common Device Model defined in SEMI E54.1 Standard for Sensor/Actuator Network Common Device Model.

R4-1.2 SEMI E54.1 defines in detail the internal structure of a sensor/actuator device on an E54-compliant sensor/actuator network. That is, it defines the possible internal components of such a device and the relationships between these components. To ensure proper behavior, it was necessary to give sufficient guidance to implementers using an E54 network communication protocol. E54.1 defines sensor (input) objects, actuator (output) objects, controller objects, a sensor/actuator controller object (SAC), and a device manager object (DM) as individual components of a sensor/actuator device aggregation as components of an aggregate Common Device Model (CDM). The device aggregation must have at least one sensor or actuator or controller (combined) and exactly one SAC and one DM. In addition, the CDM defines additional classes to further classify components, such as the ActiveElement, Sensor, and Sensor-Analog Input classes, which should be considered. Some attributes of the EquipmentIODevice Observables only apply to elements of certain classes.

R4-1.3 E54.1 does not define the CDM, which is the aggregation of these elements, as an object in its own right,. Such an aggregation might have the sum of all of the attributes of its components.

R4-1.4 OBEM defines a high-level device, the EquipmentIODevice, that is of interest to factory system applications such as Advanced Process Control (APC) and Fault Detection Classification (FDC). These systems are seldom interested in all of the low-level details. Actual raw data as read directly by an analog sensor may not be desired but rather a calculated value that has been converted into some specified units, such as degrees Celsius. OBEM can support either.

R4-1.5 Some of the attributes of the EquipmentIODevice are maintained only by the equipment. Most of the attributes must come directly from the attributes read from the CDM components for E54.1 compliant devices. The following sections suggest a way to relate attributes of the EquipmentIODevice and attributes of the elements from the CDM in a consistent manner.

R4-1.6 Each individual sensor or actuator or controller element within the CDM corresponds to one Observable in the EquipmentIOElement model. Observables were not made into formal objects, as they could be, but rather are included as one set of data within the EquipmentIODevice. Each EquipmentIODevice may have multiple sets of Observables data.

R4-1.7 Table R4-1 lists all of the attributes of an EquipmentIODevice, including those it inherits from the AbstractEquipmentElement (marked with asterisks) and shows the object and attribute in the General Device Model hierarchy to which it corresponds, where a correspondence exists.

R4-1.7.1 The “em dash” character “—”is used where no correspondence exists.

R4-1.7.2 This table is intended for equipment implementers of E98 and not for the suppliers of E54-compliant devices.

Table R4-1 Relationships between EquipmentIOElement and Generic Device Model

EquipmentIODevice Attribute Name	*Generic Device Model Object Name*	*Corresponding Attribute Name*

NOTICE: SEMI makes no warranties or representations as to the suitability of the provisional standards set forth herein for any particular application. The determination of the suitability of the provisional standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These provisional standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this provisional standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this provisional standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this provisional standard. Users of this provisional standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E98.1-0302
PROVISIONAL SPECIFICATION FOR SECS-II PROTOCOL FOR THE OBJECT-BASED EQUIPMENT MODEL

This specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002.

1 Purpose

1.1 This document maps the services and data of SEMI E98 Object-Based Equipment Model (OBEM) to SECS-II streams and functions and data definitions.

2 Scope

2.1 This document applies to all implementations of OBEM that use the SECS-II message protocol (SEMI E5).

2.2 This specification is provisional. To remove the provisional status, the SECS-II format for the attributes of the remaining object defined in OBEM must be included in Section 6:

- EquipmentIODevice

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Documents

SEMI E39 — Object Services Standard: Concepts, Behavior, and Services

SEMI E39.1 — SECS-II Protocol for Object Services Standard (OSS)

SEMI E98 — Provisional Standard for the Object-Based Equipment Model (OBEM)

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Services Mapping

4.1 Table 1 shows the specific SECS-II streams and functions that shall be used for SECS-II implementations of the services defined in OBEM.

Table 1 Services Mapping Table

Message Name	*Stream, Function*	*SECS-II Message Name*
Abort	S14,F19/ 20	Generic Service Request/Acknowledge
AddElement	S14,F19/ 20	Generic Service Request/Acknowledge
AddProcessCapability	S14,F19/ 20	Generic Service Request/Acknowledge
ChangeService	S14,F19/ 20	Generic Service Request/Acknowledge
Cleanup	S14,F19/ 20	Generic Service Request/Acknowledge
GetDateTime	S14,F19/ 20	Generic Service Request/Acknowledge
GetProgramDirectory	S14,F19/ 20	Generic Service Request/Acknowledge
Pause	S14,F19/ 20	Generic Service Request/Acknowledge
RemoveProcessCapability	S14,F19/ 20	Generic Service Request/Acknowledge
RemoveElement	S14,F19/ 20	Generic Service Request/Acknowledge
Resume	S14,F19/ 20	Generic Service Request/Acknowledge
SelectProgram	S14,F19/ 20	Generic Service Request/Acknowledge
SetDateTime	S14,F19/ 20	Generic Service Request/Acknowledge
Shutdown	S14,F19/ 20	Generic Service Request/Acknowledge
Start	S14,F19/ 20	Generic Service Request/Acknowledge
Startup	S14,F19/ 20	Generic Service Request/Acknowledge
Stop	S14,F19/ 20	Generic Service Request/Acknowledge

5 Service Parameter Mapping

5.1 Table 2 shows the mapping between service parameters defined by OBEM and the data items defined by SEMI E5. All OBEM messages map to Stream 14 Functions 19 and 20. The data item SVCNAME is the text string representation of the service name found in Table 1 and should be assumed as case-sensitive. The name of each parameter is the text string representation of the parameter name as it appears in Table 2. The SECS-II Data Item Reference, where different from SPVAL, provides additional information and restrictions for the value.

Table 2 Service Parameter Mapping Table

Parameter Name (SPNAME)	*Parameter Range (SPVAL)*	*SECS-II Data Item Reference*	*SECS-II Format*
"DateTime"	A valid date and time.	SPVAL	20,34,30
"DeviceProgramID"	0–65,535	SPVAL	51,52
"ErrorCode"	Enumerated as defined in SEMI E5 or by supplier.	ERRCODE	5()
"ErrorText"	1–80 characters	ERRTEXT	20
"ObjSpec"	0–80 characters	OBJSPEC	20
"ProcessCapability"	1–80 characters	SPVAL	20
"Property"	See Table 4.	SPVAL	—
"RequestAcknowledge"	Enumerated: 0 = Request performed 1 = Invalid request 2 = Can not perform now 4 = Will perform when able and report results when complete.	SVCACK	10
"Service"	Enumerated: 0 = OUT OF SERVICE 1 = IN SERVICE	SPVAL	51
"Status"	See Table 4.		

5.2 Table 3 shows the data items in SECS II messages that do not have a corresponding service parameter.

Table 3 Additional Data Item Requirement Table

Function	*SECS-II Data Item*
Used to satisfy SECS-II conventions for linking a multi-block inquiry with subsequent multi-block message.	DATAID
Name of OBEM service. Enumerated: "Abort" "Add Element" "AddProcessCapability" "ChangeService" "Cleanup" "GetDateTime" "GetProgramDirectory" "Pause" "RemoveProcessCapability" "RemoveElement" "Resume" "SelectProgram" "SetDateTime" "Shutdown" "Start" "Startup" "Stop"	SVCNAME

Function	*SECS-II Data Item*
A unique number generated by the service requestor to identify a specific operation and connect it to a later completion confirmation.	OPID

NOTE 1: The text strings specified in Table 3 for SVCNAME shall be recognized by the equipment as vaild, whether the equipment is or is not case-sensitive.

5.3 Table 4 provides the parameter mapping for OBEM parameters not specified in Tables 2 or 3.

Table 4 Mapping for Elements of Service Parameters

Parameter Name	*Mapping*	*SPVAL Format*
Property	Each property is an attribute name/value pair for some object indicated in ObjSpec. Each attribute name maps directly to SPNAME, and each attribute value maps directly to SPVAL.	The format of SPVAL is dictated by the format used for the specific attribute.
Status	Each ErrorCode/ErrorText pair maps directly to an SPNAME/SPVAL name pair:	--
ErrorCode	SPNAME = "ErrorCode"	52. Enumerated per ERRORCODE. Implementers may add documented values above 63 as needed.
ErrorText	SPNAME = "ErrorText"	20. I-80 characters. May not be blank.

6 Object Attribute Form

6.1 Section 6 defines the SECS-II form of the attributes of objects defined in OBEM, presented in alphabetical order. Note that attribute names in this section indicate the literal text string that shall be accepted in string comparisons for attribute names in Stream 14 messages.

6.1.1 By convention, all tables include ObjID as well as ObjType as the two attributes required by SEMI E39.

6.2 *AbstractEquipmentElement*

6.2.1 Table 5 specifies the attributes of the AbstractEquipmentElement.

Table 5 AbstractEquipmentElement Object Attribute Specification

Attribute Name	*Range/Value*	*SECS-II Format*
"Cycles"	0+.	54
"Description"		20
"Function"		20
"ImmutableID"		20
"InService "	Enumerated: 0 = OUT OF SERVICE 1 = IN SERVICE	51
"ObjID"	Conforms to OBJID restrictions in SEMI E39.1, Section 6.	20
"ObjType"	"EqpElement"	20
"ResetDate"	Conforms to DateTime attribute of Clock	20,30,34
"Supplier"		20

6.3 *AbstractEquipmentModule*

6.3.1 Table 6 specifies the elements of the AbstractEquipmentModule object.

Table 6 AbstractEquipmentModule Object Attribute Specification

Attribute Name	*Range/Value*	*SECS-II Format*
"BehaviorState"	Enumerated: 0 = IDLE 1 = ACTIVE SERVICE 2 = PAUSING 3 = PAUSED 4 = STOPPING 5 = STOPPED 6 = ABORTING 7 = ABORTED 8 = IDLE WITH ALARMS

MaterialID	Conforms to OBJID restrictions in SEMI E39.1, Section 6.	20

SEMI E102-0600
PROVISIONAL SPECIFICATION FOR CIM FRAMEWORK MATERIAL TRANSPORT AND STORAGE COMPONENT

This provisional specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the Japanese Information and Control Committee. Current edition approved by the Japanese Regional Standards Committee on March 14, 2000 and by the North American Regional Standards Committee on March 2, 2000. Initially available at www.semi.org March 2000; to be published June 2000.

1 Purpose

1.1 Wafer fabrication factories will require the baseline capabilities of stocker storage and interbay transport. In addition to these baseline capabilities, intrabay transport will be added as a result of ergonomic and safety requirements brought about by the increased size and weight of 300 mm wafer carriers. These stocker, interbay transport, and intrabay transport systems will be required to be fully integrated with each other and the factory Manufacturing Execution System (MES) in order to realize the full vision of cost effective automated material transport to and from production equipment.

1.2 A baseline requirement of Automated Material Handling System (AMHS) equipment is efficient integration with the factory MES. Therefore, the purpose of this specification is to enable cost effective integration of interoperable AMHS systems, as illustrated in Figure 1. Manufacturers require a SEMI standard which specifies the visible behavior of the AMHS Integration system and its interface to the factory MES. The purpose of this standard is to specify these interfaces and the interactions between MES and AMHS systems as a part of the CIM Framework. While the term AMHS is commonly used to refer to a wide range of equipment and systems that support automated material handling, the CIM Framework specifies a software component called “Material Transport and Storage Component (MTSC)” which represents the standard interface of the MES to the complete suite of AMHS capabilities.

2 Scope

2.1 This specification provides the common interfaces required by Manufacturing Execution Systems for runtime interactions between the factory (as represented by other CIM Framework components) and the Material Tracking and Storage Component. Some interfaces supporting configuration and tracking of the material transport and storage equipment are the responsibility of the Equipment Tracking and Maintenance component of the CIM Framework. These interfaces are complementary to the interfaces of Transport Machines and Storage Machines presented in this specification.

2.2 The responsibilities of the Material Transport and Storage Component include interfaces that

- Support scheduling of material transport and processing by predicting time for material delivery to specific locations. NOTE: The interfaces for delivery time prediction are deferred as one of the deficiencies noted in this provisional specification.
- Execute and monitor transport jobs to move material to specific locations.
  - Validate that the job can be done: the material is available, the destination is reachable and has available storage or loadport capacity, and there are sufficient material movement resources (cars, storage space, etc.) to implement the job.
  - Request operations from AMHS equipment controllers to enact internal material movement and storage actions. Implementations of the Material Transport and Storage Component will use lower level standards such as IBSEM and StockerSEM for communication with equipment that performs the physical movement and storage actions.
  - Collect and record data on transport job execution and history.
  - Capture, record, interpret, and respond to equipment events and fault detection.
  - Generate MES-level job status events and material location change events.
- Record and report on material locations and material transport histories for material in the system.
- Interact with machine and port interfaces for material hand-off handshake protocols.

2.3 Automated Material Handling Systems (AMHS’s) are an important part of any semiconductor factory and have, typically, been implemented and integrated with a

Manufacturing Execution System (MES) as a separate logical software entity. An AMHS is made up of the AMHS Framework, the system controllers for AMHS equipment (the software) and the transport and storage machines (the hardware). In keeping with this tradition, the CIM Framework views the AMHS as a "black box" where the interface into that system is visible, but the inner workings and control of that system is the responsibility of the AMHS supplier and not in the domain of the MES. The CIM Framework specifies the Material Transport and Storage Component (MTSC) as the MES level interface to AMHS capabilities.

2.4 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

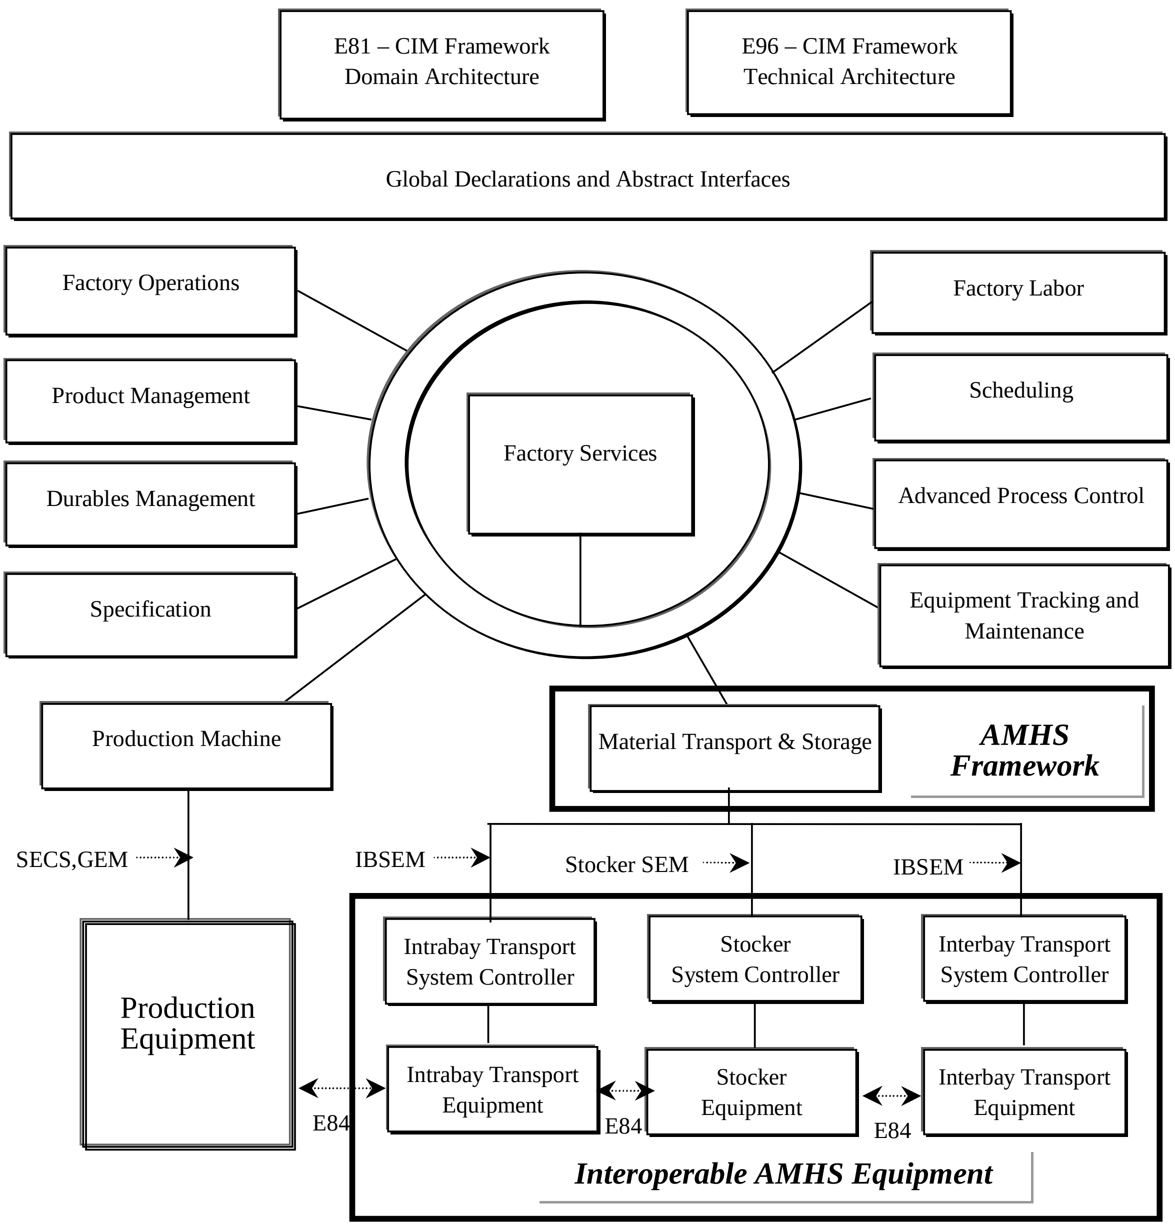

Figure 1
AMHS Environment

3 Limitations

3.1 The Material Transport and Storage Component provides AMHS Framework level interfaces to interoperable AMHS Equipment. This level of material transport is factory level movement, i.e., the transport of product and durables between machines, areas or material tracking locations. The Material Tracking and Storage Component does not provide interfaces that make material movement within machines visible.

3.2 *Provisional Status* — This specification is designated as provisional due to known areas that need to be completed. The following items summarize the deficiencies of the provisional specification to be addressed before a subsequent ballot to upgrade it to full standard status.

3.2.1 *Dependence on Global Declarations and Abstract Interfaces* — Components of this document reference global declarations and specialize abstract interfaces for material, resource and job concepts. The provisional specification for these declarations and interfaces was balloted and recommended by the SEMI Information and Control Committee in July, 1999. When this specification is published a revision will be undertaken to clearly define the relationship of this specification to those common elements of the CIM Framework.

3.2.2 *Dependence on Durables Management Component* — The Material Transport and Storage Component depends upon interfaces specified as part of the Durables Management Component of the CIM Framework. This document includes only the required interfaces from Durables Management. Those interfaces, found in Section 6.2.3, will be removed from this document when the Durables Management Component of the CIM Framework is adopted in a future ballot.

3.2.3 *Dependence on Machine Abstract Interface Group* — The Material Transport and Storage Component depends upon interfaces specified as part of the Machine Abstract Interface Group (Machine AIG) of the CIM Framework. This document includes only the required interfaces from the Machine AIG. Those interfaces, found in Section 6.2.4, will be removed from this document when the Machine AIG of the CIM Framework is adopted in a future ballot.

3.2.4 *Dependence on Factory Operations Component* — The Material Transport and Storage Component depends upon interfaces specified as part of the Factory Operations Component of the CIM Framework. This document includes only the required interfaces from the Factory Operations Component. Those interfaces, found in Section 6.2.5, will be removed from this document when the Factory Operations Component of the CIM Framework is adopted in a future ballot.

3.2.5 *Deterministic Prediction of Transport Time* — The responsibility for providing estimates of predicted transport time of future TransportJobs in a deterministic way is beyond the scope of the Provisional Specification. This capability may be offered in future upgrades of this specification based on added experience with such predictions. It may be found that heuristic methods for transport time prediction are the most practical way to provide such estimates.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AMHS* — Automated Material Handling System

5.1.2 *MTSC* — Material Transport and Storage Component

6 Requirements

6.1 The following sections specify the interfaces that comprise the Material Transport and Storage Component of the CIM Framework. Additionally, the subsets of interfaces from Durables Management, Machine Abstract Interface Group, and Factory Operations required to support Material Transport and Storage are included here pending future ballots that will address the full scope of these other specifications.

6.1.1 Figure 2 illustrates the context of the Material Transport and Storage Component within the CIM Framework. The Factory Operation component requests the transport of material by the Material Transport Manager which provides services for creation

1 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland

2 UML Notation Guide v1.1 is available to the general public at http://www.omg.org/cgi-bin/doclist.pl, +1-508-820 4300, Object Management Group, Inc. , Framingham Corporate Center, 492 Old Connecticut Path, Framingham, MA 01701.

of Transport Jobs. The Material Transport and Storage Component uses services provided by the Machine AIG to access interfaces of Machines and Ports that serve as the source or destination of Transport Jobs. The MES Factory defines areas within a factory which represent groups of machines. Finally, Durables Management provides the services needed to manage the material containers that are moved.

6.1.2 Figure 3 shows the Material Transport and Storage Component information model, including the inherited interfaces and the associations between interfaces. These interfaces are fully defined in Sections 6.3 and 6.4. The interfaces associated with the Material Transport and Storage are as follows:

1. TransportJobSupervisor – abstract interface,
2. MaterialTransportManager,
3. MaterialTransportController, and
4. TransportJob.

6.2 *Required Subsets of Future CIM Framework Specifications*

6.2.1 This specification depends on interfaces from Durables Management Component, the Machine Abstract Interface Group and the Factory Operations Component that will eventually be contained in future CIM Framework component specifications. They are included with this document to support a complete specification for AMHS support within the CIM Framework. When these items are balloted as separate documents, they will be removed from this specification and referenced in their full form.

6.2.2 Figure 4 illustrates the dependencies of the Material Transport and Storage Component.

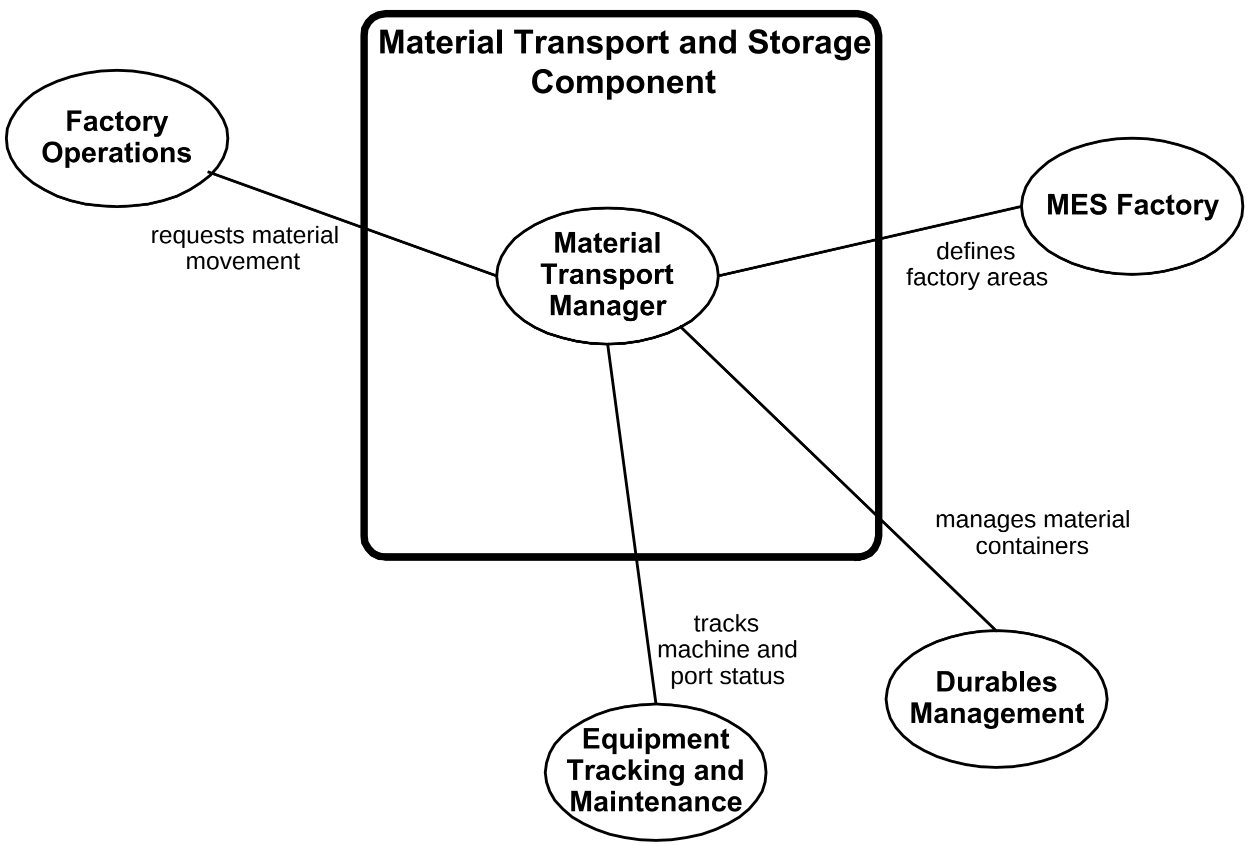

Figure 2
Material Transport and Storage Component Context

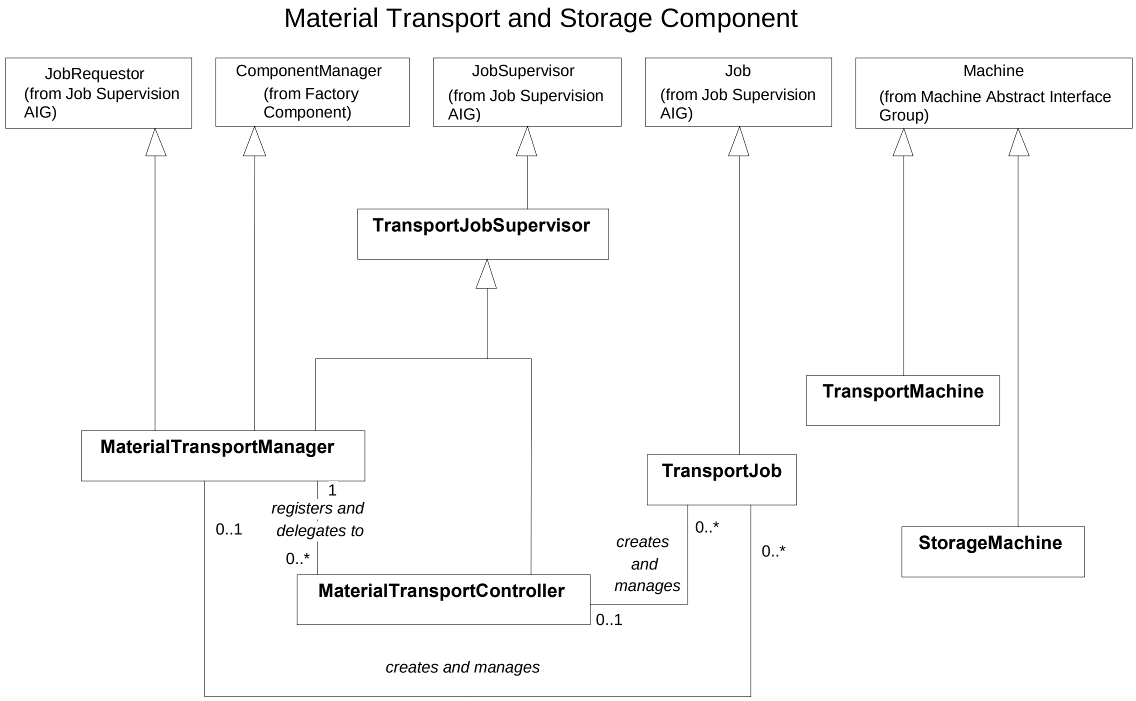

Figure 3
Material Transport and Storage Information Model

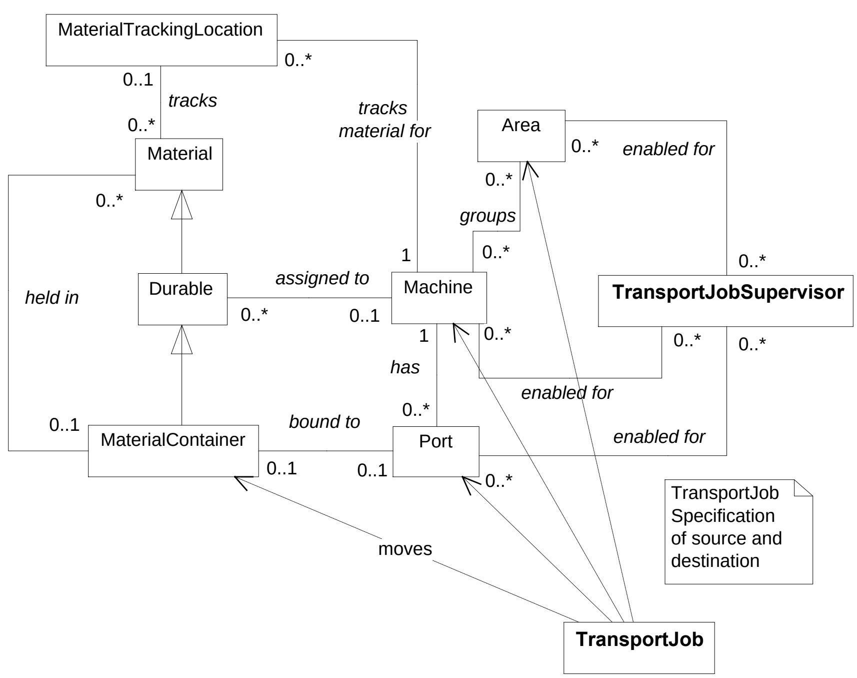

Figure 4
Material Transport and Storage Dependencies

6.2.3 *Durables Management Component (subset)* — This section includes only those interfaces and specific operations from the Durables Management Component that are referenced within this component specification. These interfaces are provided here for the referential integrity of this specification and are not included as part of this component. Further, this is not intended to be a comprehensive treatment of the required interfaces, but only the subset needed here for reference prior to the full specification of Durables Management being adopted through a subsequent ballot. When that occurs, this specification can be updated by a follow-on ballot to reference the interfaces directly rather than replicate them here.

6.2.3.1 *Durable Interface (subset)*

Module:	DurablesManagement
Interface:	Durable
Inherited Interface:	Material

```
interface Durable : AbstractIF::Material {
```

Description: The Durable interface represents any Material in the Factory used to facilitate manufacturing but not normally consumed in the process. It is capable of relocation within the Factory and requires dynamic tracking. This includes containers used to transport the Material, fixtures (attachments for holding material in a fixed position), and tools (such as reticles, load boards, workholders) used by equipment or personnel in the manufacturing process. Grouping of Durables (such as all reticles that are usable for a given process) can be achieved by creating MaterialGroups for the specific categorizations required.

Exceptions:

Published Events:

/* Notifies subscribers of a change in the MaterialTrackingLocation that is tracking the Durable. */

```
DurableLocationChangedEvent
```

Provided Services:

/* Set and get the location of the durable. If the MaterialTrackingLocation is set to NULL, the durable is not in any MaterialTrackingLocation and may be under manual control within the factory. */

```
void setMaterialTrackingLocation (
      in MachineAIG::MaterialTrackingLocation
            aMaterialTrackingLocation)
      raises (Global::FrameworkErrorSignal,
            MachineAIG::MaterialTrackingLocation::MaterialTrackingLocationFullSignal);

MachineAIG::MaterialTrackingLocation getMaterialTrackingLocation ( )
      raises (Global::FrameworkErrorSignal);
```

/* Set and get the Unit that determines which MaterialTrackingLocation this Durable will be tracked through for a given Machine. The Unit is a string value that maps to the Unit attribute of the MaterialTrackingLocation. */

```
void setUnit(
      in string aUnit)
      raises (Global::FrameworkErrorSignal,
            MachineAIG:: MaterialTrackingLocation::InvalidUnitSignal);

string getUnit( )
      raises (Global::FrameworkErrorSignal);

}; // Durable
```

Dynamic Model: None

6.2.3.2 *MaterialContainer Interface (subset)*

Module: DurablesManagement

Interface: MaterialContainer

Inherited Interface: Durable

```
interface MaterialContainer : Durable {
```

Description: A MaterialContainer interface represents any receptacle for holding Material for transport, processing or storage. Examples of MaterialContainers are shipping boxes, tubes, standard mechanical interface (SMIF) pods, etc.

Exceptions: None.

Published Events:

/* Notifies subscribers of a state change in the MaterialContainer. */

MaterialContainerStateChangeEvent

Provided Services:

/* The following operations are provided to trigger MaterialContainer state transitions. */

```
void makeManualControl ( )
     raises (Global::FrameworkErrorSignal,
          Global::InvalidStateTransitionSignal);

void makeStored ( )
     raises (Global::FrameworkErrorSignal,
          Global::InvalidStateTransitionSignal);

void makeInTransit ( )
     raises (Global::FrameworkErrorSignal,
          Global::InvalidStateTransitionSignal);

void makeProcessing ( )
     raises (Global::FrameworkErrorSignal,
          Global::InvalidStateTransitionSignal);

}; // MaterialContainer

typedef sequence <MaterialContainer> MaterialContainerSequence;
```

Dynamic Model:

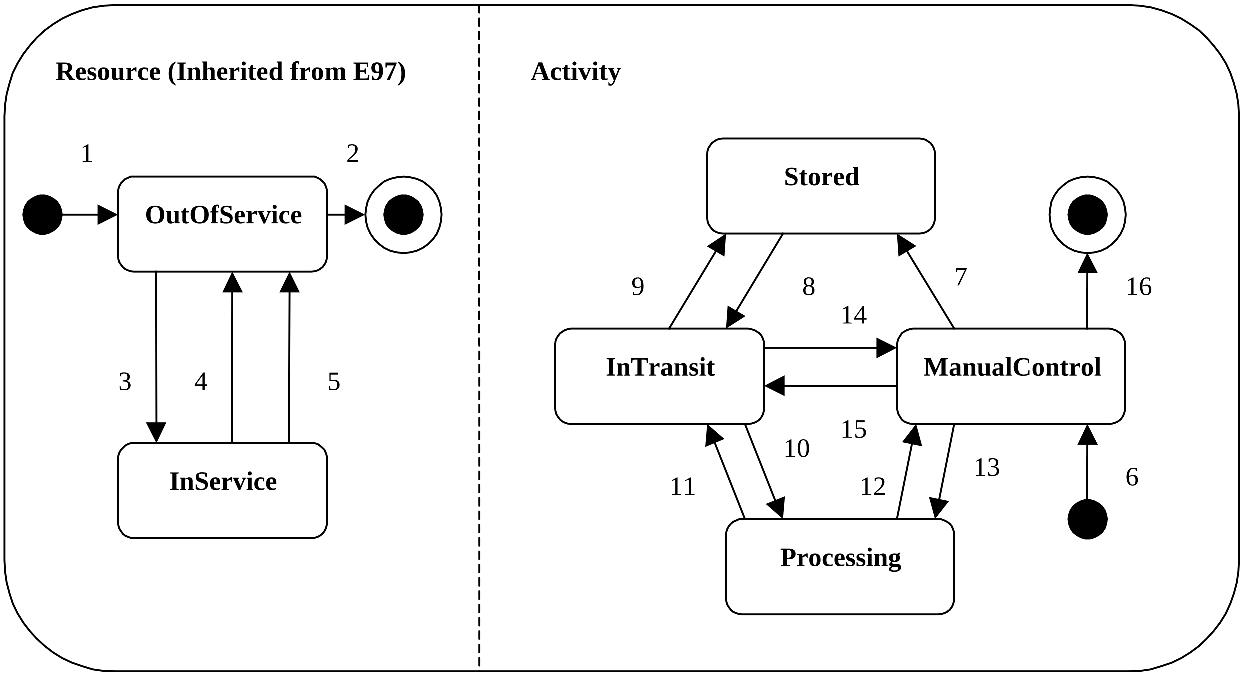

Figure 5
MaterialContainer Dynamic Model

Table 1 MaterialContainer State Definitions

State	*State Definition*	*Example*
InService	Inherited from Resource State Model	
OutOfService	Inherited from Resource State Model	
InTransit	Container is en route as the subject of a Transport Job.	Container is on an OHT transport vehicle.
Stored	Container is stored in a Storage Machine and not subject to a Transport Job.	Container is on a stocker shelf.
ManualControl	Container is outside of the control of the Material Transport and Storage Component.	Container is on a PGV.
Processing	Container is at process equipment.	Container is on a lithography tool.

Table 2 MaterialContainer State Transitions

#	*Current State*	*Trigger*	*Next State*	*Action*	*Comment*
1–5	NOTE: Transitions 1–5 are defined in the dynamic model inherited from Resource.				
6	N/A	makeManual Control()	ManualControl	MaterialContainer instance is created.	Initial state
7	ManualControl	makeStored()	Stored	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container is placed on input port of a Storage Machine without a TransportJob assigned to it.
8	Stored	makeInTransit()	InTransit	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has started to move. TransportJob state transitions to Executing.
9	InTransit	makeStored()	Stored	DurableLocation ChangedEvent Published	Container stored. TransportJob state

#	*Current State*	*Trigger*	*Next State*	*Action*	*Comment*
				by the instance of MaterialContainer	transitions to Completed.
10	InTransit	makeProcessing()	Processing	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has reached destination at process equipment. TransportJob state transitions to Completed.
11	Processing	makeInTransit()	InTransit	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has left process equipment. TransportJob state transitions to Executing.
12	Processing	makeManual Control()	ManualControl	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has left control of process equipment (not via TransportJob).
13	ManualControl	makeProcessing()	Processing	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has entered control of process equipment (not via TransportJob).
14	InTransit	makeManual Control()	ManualControl	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has left the control of the TransportJob via a manual output port. TransportJob state transitions to Aborted.
15	ManualControl	makeInTransit()	InTransit	DurableLocation ChangedEvent Published by the instance of MaterialContainer	Container has entered the AMHS via a manual input port. TransportJob state transitions to Executing.
16	ManualControl	none	N/A	none	MaterialContainer instance has been removed.

6.2.4 *Machine Abstract Interface Group (subset)*

This section includes only those interfaces and specific operations from the Machine Abstract Interface Group that are referenced within this component specification. These interfaces are provided here for referential integrity of this specification and are not intended to remain as part of this component. Further, this is not intended to be a comprehensive treatment of the required interfaces, but only the subset needed for reference until the full specification is adopted through a subsequent ballot. When that occurs, this specification can be updated to reference the interfaces directly rather than replicate them here.

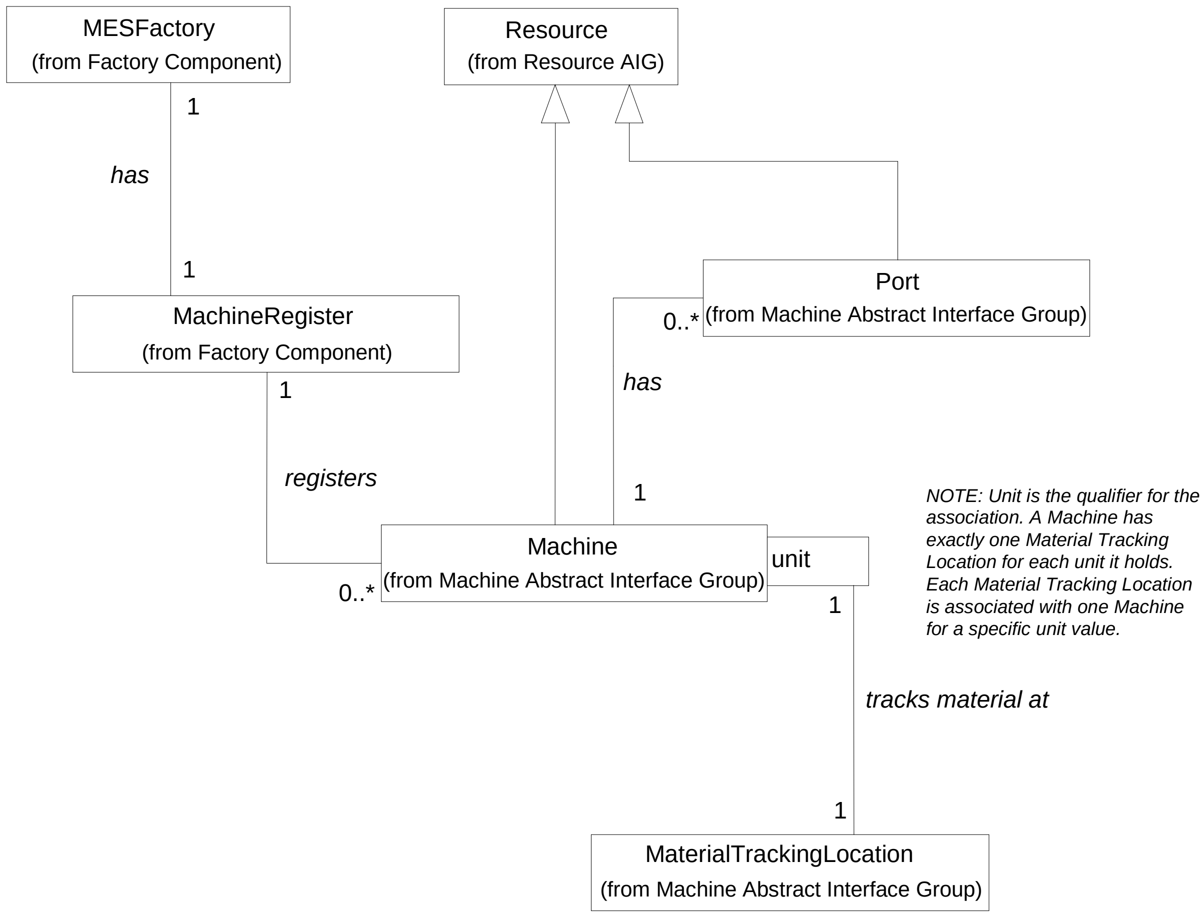

Figure 6
Machine Abstract Interface Group (subset) Information Model

6.2.4.1 *Machine Interface (subset)*

Module: MachineAIG

Interface: Machine

Inherited Interface: Resource

```
interface Machine : AbstractIF::Resource {
```

Description: This abstract interface representing the concept of a piece of equipment in the factory. A Machine establishes the identity of the physical equipment existing in the factory for reference within an MES context. The Machine also maintains one MaterialTrackingLocation for each Unit defined to classify the Material processed, used, or stored by the Machine.

Type Definitions:

```
typedef sequence <Machine> MachineSequence;

typedef sequence <MaterialTrackingLocation> MaterialTrackingLocationSequence;
```

```
typedef sequence <Port> PortSequence;

enum MachineType {
      FixedBufferProductionMachine,
      InternalBufferProductionMachine,
      StorageMachine,
      TransportMachine };
```

Exceptions:

/* Port indicated for receiving material was invalid. */

```
exception InvalidPortSignal { };
```

/* Material specified for unloading was invalid. */

```
exception InvalidMaterialSignal { };
```

Published Events:

/* An E10 State change has occurred in the Machine that the Factory needs to know. */

MachineResourceE10StateChangedEvent

Provided Services:

/* Set the MachineType for this machine. */

```
void setMachineType (
      in MachineType aMachineType )
      raises (Global::FrameworkErrorSignal);
```

/* Return the MachineType for this machine. */

```
MachineType getMachineType ( )
      raises (Global::FrameworkErrorSignal);
```

/* Set up a MaterialTrackingLocation for this Machine to track a particular material Unit characterizing its contents. A Machine may have more than one MaterialTrackingLocation as long as each is tracking a different Unit. The value of Unit is used with corresponding attributes of the material to allocate the tracked material to the correct MaterialTrackingLocation for a Machine. */

```
void setMaterialTrackingLocation (
      in MaterialTrackingLocation aMaterialTrackingLocation,
      in string aUnitToTrack)
      raises (Global::FrameworkErrorSignal);
```

/* Get all MaterialTrackingLocations for this Machine. There is one and only one MaterialTrackingLocation per Unit used in the Machine. */

```
MaterialTrackingLocationSequence getAllMaterialTrackingLocations ( )
      raises (Global::FrameworkErrorSignal);
```

/* Get the MaterialTrackingLocation for the Unit specified. */

```
MaterialTrackingLocation getMaterialTrackingLocation (
      in string aUnit)
      raises (Global::FrameworkErrorSignal);
```

/* Request a Machine to reserve a port to load material. This may involve communication between the Port and the Machine Objects, but these need not be public (or may involve communication between the Machine and the Equipment). If requestedPort parameter left null, machine chooses the requestedPort. Returns Null if Machine cannot or refuses to comply. */

```
Port reservePortForTransferTo (
     in DurablesManagement::MaterialContainer aContainer,
     in Port requestedPort )
     raises (Global::FrameworkErrorSignal,
          InvalidPortSignal);
```

/* Request a Machine to reserve a port to load two or more MaterialContainers. All MaterialContainers in the sequence must be loaded before the Machine can accept another port reservation request. The MaterialContainers specified in the MaterialContainerSequence may be loaded in any order. If requestedPort parameter left null, machine chooses the requestedPort. Returns Null if Machine cannot or refuses to comply. */

```
Port reservePortForBatchTransferTo (
     in DurablesManagement::MaterialContainerSequence aContainerGroup,
     in Port requestedPort )
     raises (Global::FrameworkErrorSignal,
          InvalidPortSignal);
```

/* Request a Machine to cancel a reservation previously established for a transfer to a port. */

```
void cancelPortReservationForTransferTo (
     in DurablesManagement::MaterialContainer aContainer,
     in Port requestedPort )
     raises (Global::FrameworkErrorSignal,
          InvalidPortSignal);
```

/* Inform a Machine that a transfer to or from a port has been completed. This may involve communication between the Port and the Machine Objects, but these need not be public (or may involve communication between the Machine and the Equipment). */

```
void transferComplete (in DurablesManagement::MaterialContainer aContainer,
     in Port reservedPort )
     raises (Global::FrameworkErrorSignal,
          InvalidPortSignal);
```

/* Request a Machine to prepare to unload material. Returns the Port on which the material will be unloaded or Null if the Machine cannot or refuses to comply. */

```
Port containerOut (
     in DurablesManagement::MaterialContainer aContainer,
     in Port requestedPort )
     raises (Global::FrameworkErrorSignal,
          InvalidMaterialSignal);
```

/* Returns a list of all Ports for the machine. */

```
PortSequence allPorts ( )
     raises (Global::FrameworkErrorSignal);
```

/* Returns the list of all Areas that this Machine is in. */

```
AreaSequence allAreas( )
     raises (Global::FrameworkErrorSignal);

}; // Machine
```

6.2.4.2 *MaterialTrackingLocation Interface*

Module: MachineAIG

Interface: MaterialTrackingLocation

Inherited Interface: OwnedEntity

```
interface MaterialTrackingLocation : AbstractIF::OwnedEntity {
```

Description: A MaterialTrackingLocation is a place where Material may be held. The "type" of the location is based on the classification Unit of Material that the location can hold (e.g., locations to hold wafers have a "Wafer" Unit and can only hold this Material type). Each machine has one MaterialTrackingLocation for each material Unit. The MaterialTrackingLocation also maintains a capacity.

Exceptions:

/* Material specified in the call is not a valid Material for this MaterialTrackingLocation. */

```
exception InvalidMaterialSignal { };
```

/* Intent to assign more Material to the MaterialTrackingLocation failed because it is full. */

```
exception MaterialTrackingLocationFullSignal { };
```

/* Unit value is not valid for the MaterialTrackingLocation. */

```
exception InvalidUnitSignal { };
```

Published Events:

/* A Material Tracking Location has reached its capacity. */

MaterialTrackingLocationFullEvent

/* A Material Tracking Location that was previously Full now has available capacity. */

MaterialTrackingLocationNotFullEvent

Provided Services:

/* Return the Material at the MaterialTrackingLocation, return nil if the location is empty. */

```
AbstractIF::MaterialSequence allMaterialHeld ( )
     raises (Global::FrameworkErrorSignal);
```

/* Get and set the unique identifier for the MaterialTrackingLocation. */

```
string getIdentifier ( )
     raises (Global::FrameworkErrorSignal);

void setIdentifier (
     in string identifier)
     raises (Global::FrameworkErrorSignal,
          Global::SetValueOutOfRangeSignal,
          Global::DuplicateIdentifierSignal);
```

/* Return the Machine that holds this MaterialTrackingLocation. */

```

     raises (Global::FrameworkErrorSignal);

}; // MaterialTrackingLocation
```

6.2.4.3 *Port Interface (subset)*

Module:	MachineAIG
Interface:	Port
Inherited Interface:	Resource

```
interface Port : AbstractIF::Resource {
```

Description:	The Port represents the point at which a “change of ownership” occurs during a material transfer. Each Port has at least one associated Machine and the Port may be thought of as an “access point” to the Machine.
Exceptions:	None.
Events:	None.

Provided Services:

/* Returns the machine to which this port belongs. */

```
Machine getMachine ( )
     raises (Global::FrameworkErrorSignal);

}; // Port
```

6.2.5 *Factory Operations Component (subset)* — This section includes only those interfaces and specific operations from the Factory Component that are referenced within this component specification. These interfaces are provided here for referential integrity of this specification and are not intended to remain as part of this component. Further, this is not intended to be a comprehensive treatment of the required interfaces, but only the subset needed for reference until the full specification is adopted through a subsequent ballot for the full Factory Operations component. When that occurs, this specification can be updated to reference the interfaces directly rather than replicate them here.

6.2.5.1 *MachineRegister Interface*

Module:	FactoryOperations
Interface:	MachineRegister
Inherited Interface:	Resource

```
interface MachineRegister : AbstractIF::Resource {
```

Description:	The MachineRegister maintains a list of known machines for the factory and supplies related information on demand. There is only one MachineRegister per factory. NOTE: this interface may eventually be replaced by the trader service.

Exceptions:

/* An attempt was made to locate an unknown Machine. */

```
exception MachineNotFoundSignal {string machineName;};
```

```
exception MachineRemovalFailedSignal { };
```

Published Events:

/* Event indicating that a Machine has been added or removed from the Factory. */

MachineListChangedEvent

Provided Services:

/* Add a Machine to the set of machine(s) managed by the MachineRegister. */

```
void addMachine (in Machine aMachine)
     raises (Global::FrameworkErrorSignal);
```

/* Remove a Machine from the set of machine(s) managed by the MachineRegister. */

```
void removeMachine (in Machine aMachine)
     raises (Global::FrameworkErrorSignal,
          MachineRemovalFailedSignal);
```

/* Return a sequence of all machines managed by the MachineRegister. */

```
MachineSequence allMachines ( )
     raises (Global::FrameworkErrorSignal);
```

/* Return the Machine corresponding to the given name. */

```
Machine findMachineNamed (in string identifier)
     raises (Global::FrameworkErrorSignal,
          MachineNotFoundSignal) ;
```

Contracted Services: None.

Dynamic Model: None.

```
}; // MachineRegister
```

6.3 *Material Transport Abstract Interfaces* — The Material Transport Abstract Interfaces are defined to perform material transport at the factory level. The TransportJobSupervisor interface must be specialized by the users of the Material Transport Manager Interface. These interfaces provide a way to track the job through the factory.

6.3.1 *TransportJobSupervisor Interface*

Module: MaterialTransport

Interface: TransportJobSupervisor

Inherited Interface: JobSupervisor

```
interface TransportJobSupervisor : AbstractIF::JobSupervisor {
```

Description: TransportJobSupervisor is an abstract interface which provides the operations needed by clients to request, track, and control material transport within the domain of the specific TransportJobSupervisor. Any entity which is responsible for moving material will inherit and implement TransportJobSupervisor.

Type Definitions:

```
typedef sequence <Global::Properties> JobSpecSequence;
```

Exceptions:

```
exception UnsupportedDestinationTypeSignal { };
```

Published Events: None.

Provided Services:

The Creation of TransportJobs is accomplished by use of the requestJob operation from the inherited JobSupervisor interface. The “JobType” property specified in the inherited interface should be set to “TransportJobType” for all TransportJob requests. The additional Job Specification properties required for the creation of Transport jobs are defined in Table 3. The types of machines specified in the TransportJob are AMHS Storage Machines, Fixed Buffer Production Equipment, or Internal Buffer Production Equipment. Each machine type represents a separate case used in defining the Job Specification for a Transport Job, and these cases are also defined in Table 3.

For transportJobs, the inherited ABORTING and ABORTED states may not always result in an immediate termination of the job and associated activities. For example, transportJobs may involve autonomous transport equipment that operate without persistent communication links to the TransportJob and TransportJobSupervisor objects. In these cases there may be a time delay before the results of a transportJob makeAborted request can be enacted to allow the transport equipment to reach a known location. In other cases a movement activity must reach a stable condition before it can be interrupted. The location of the MaterialContainer associated with the aborted TransportJob is the nearest location where movement can be safely and reliably interrupted.

By contrast, if a transportJob is transitioned to the inherited STOPPING state, the location of the MaterialContainer associated with the stopped TransportJob must be a legal Source for issuing a new TransportJob.

Table 3 Additional Required Properties for Transport Jobs

Name	*Value Type*	*Description*
“Container”	MaterialContainer	Container being transported.
“SourceMachine”	Machine	The source production machine for the transport job. AMHS Storage Equipment: SourceMachine is Optional. Fixed Buffer Production Equipment: SourceMachine is Required. Internal Buffer Production Equipment: SourceMachine is Required.
“SourcePort”	Port	The source production machine port for the transport job. AMHS Storage Equipment: SourcePort is Optional. Fixed Buffer Production Equipment: SourcePort is Required. Internal Buffer Production Equipment: SourcePort is optional. Port may be obtained dynamically with the containerOut operation or it may be predefined in the TransportJob specification.
“DestinationArea”	Area	The destination area for the transport job. DestinationArea shall contain only StorageMachines. The implementation shall determine the specific machine to which the MaterialContainer is delivered. AMHS Storage Equipment: DestinationArea is optional. Fixed Buffer Production Equipment: DestinationArea is not allowed. Internal Buffer Production Equipment: DestinationArea is not allowed.
“DestinationMachine”	Machine	The destination machine for the transport job. AMHS Storage Equipment: DestinationMachine is required if DestinationArea is not specified. Fixed Buffer Production Equipment: DestinationMachine is required. Internal Buffer Production Equipment: DestinationMachine is required.

Name	Value Type	Description
"DestinationPort"	Port	The destination port for the transport job. AMHS Storage Equipment: DestinationPort is required for Manual output port destinations. Fixed Buffer Production Equipment: DestinationPort is required. Internal Buffer Production Equipment: DestinationPort is NULL.

/* The requestBatchTransportJob operation will provide two or more job specifications for transport jobs that share a dependency on completion. All job specifications must have the same priority. In the normal case, the TransportJobSupervisor will create simple transport jobs for each job specification and return the jobs as a sequence. Subsequently, if one of the simple jobs cannot complete, the other subordinate jobs must be reassessed by the JobRequestor to determine the appropriate corrective action. In this case, the TransportJobSupervisor will notify the JobRequestor of the job failure with the informJobTerminated message and pause the other jobs of the batch-job to allow the JobRequestor to determine its response. Implementations may implement the TransportJobSupervisor with more complex default actions in response to a partial failure of a batch-transport-job, but these more complex scenarios are not part of the standard behavior for this operation. */

```
AbstractIF::JobSequence requestBatchTransportJob (
     in JobSpecSequence jobSpecs,
     in AbstractIF::JobRequestor aJobRequestor)
     raises (Global::FrameworkErrorSignal,
          AbstractIF::JobSupervisor::JobRejectedSignal);
```

Contracted Services: None

Dynamic Model: None

```
}; // TransportJobSupervisor
```

6.4 *Material Transport and Storage Component*

6.4.1 This component is concerned only with factory-wide material transport and not the movement of material within a piece of equipment. Also note that material can be either product, durables, or consumables. The CIM Framework recognizes the potential for multiple AMHS's within a single factory (e.g., one supplier of interbay movement and another supplier of intrabay movement). The MES, however, wants to only have to issue a move request ("move this material from here to there") without regard to whether that transport spans one or more AMHS's. Therefore, the component supporting material transport requires a single entry point for initiating material transport which will be through the Material Transport Manager (MTM).

6.4.2 The Material Transport Manager must be able manage transport jobs carried out by many different AMHS's. To accomplish this, a separate interface for a Material Transport Controller (MTC) is specified. In the simplest implementations, a single MTM may manage all TransportJobs directly. In this case no separate Material Transport Controller implementation is needed. If there is a need for delegation to one or more Material Transport Controllers, the Material Transport Manager can register any conformant MTC implementation which supports the specified interface. The low-level interaction of the material movement controllers with the physical equipment (transport machines, storage machines and ports) is encapsulated within the scope of this component. Note that the component manager does not provide lifecycle services for its managed material movement controllers, but instead uses the registration interfaces.

6.4.3 *MaterialTransportManager Interface*

Module: MaterialTransport

Interface: MaterialTransportManager

Inherited Interface: ComponentManager, TransportJobSupervisor, JobRequestor

```
interface MaterialTransportManager : FactoryOperations::ComponentManager,
     TransportJobSupervisor, AbstractIF::JobRequestor {
```

Description: A MaterialTransportManager (MTM) operates on requests to move material in the factory. It returns a TransportJob to the requestor, allowing the requestor to track the status and progress of the move. The MTM may perform these TransportJobs by breaking them into separate tasks to be performed by MaterialTransportControllers (MTC). If TransportJobs are decomposed, the MaterialTransportManager then tracks the MTC TransportJobs to fulfill its commitment.

Exceptions:

```
exception MaterialTransportControllerNotRegisteredSignal { };
```

Published Events: None.

Provided Services:

/* Add a MaterialTransportController to the collection of MaterialTransportControllers which the MaterialTransportManager can use to carry out jobs. */

```
void registerMaterialTransportController (
     in MaterialTransportController aMaterialTransportController)
     raises (Global::FrameworkErrorSignal);
```

/* Remove a MaterialTransportController from the list of resources available to the MaterialTransportManager. No new jobs will be issued but existing jobs will be unaffected. */

```
void unregisterMaterialTransportController (
     in MaterialTransportController aMaterialTransportController)
     raises (Global::FrameworkErrorSignal,
          MaterialTransportControllerNotRegisteredSignal);
```

/* Return a list of all MaterialTransportControllers managed by the MaterialTransportManager. */

```
MaterialTransportControllerSequence allMaterialTransportControllers ( )
     raises (Global::FrameworkErrorSignal);
```

/* Returns a list of all material in the material transport system. */

```
AbstractIF::MaterialSequence allMaterial ( )
     raises (Global::FrameworkErrorSignal);
```

/* Returns a list of all material in transit in the material transport system. */

```
AbstractIF::MaterialSequence allMaterialInTransit ( )
     raises (Global::FrameworkErrorSignal);
```

/* Returns a list of all material in storage in the material transport system. */

```
AbstractIF::MaterialSequence allMaterialInStorage ( )
     raises (Global::FrameworkErrorSignal);
```

Contracted Services: None

Dynamic Model: None

```
}; // MaterialTransportManager
```

6.4.4 *MaterialTransportController Interface*

Module: MaterialTransport

Interface: MaterialTransportController

Inherited Interface: TransportJobSupervisor

```
interface MaterialTransportController : TransportJobSupervisor {
```

Description: A MaterialTransportController accepts transport job requests, schedules them, and executes them in order to move material around the factory or a part of the factory.

Exceptions: None.

Published Events: None.

Provided Services:

```
typedef sequence <MaterialTransportController> MaterialTransportControllerSequence;
```

/* Returns a list of all material in the domain of this material transport controller. */

```
AbstractIF::MaterialSequence allMaterial ( )
     raises (Global::FrameworkErrorSignal);
```

/* Returns a list of all material in transit in the domain of this material transport controller. */

```
AbstractIF::MaterialSequence allMaterialInTransit ( )
     raises (Global::FrameworkErrorSignal);
```

/* Returns a list of all material in storage in the domain of this material transport controller. */

```
AbstractIF::MaterialSequence allMaterialInStorage ( )
     raises (Global::FrameworkErrorSignal);
```

Contracted Services: None

Dynamic Model: None

```
}; // MaterialTransportController
```

6.4.5 *TransportJob Interface*

Module: MaterialTransport

Interface: TransportJob

Inherited Interface: Job

```
interface TransportJob : AbstractIF::Job {
```

Description: This type of Job performs a specific transport of material. The ongoing status of the move can be monitored by subscribing to the appropriate Job events.

Exceptions:

```
exception TimeUndeterminableSignal { };
```

Published Events: Same as Job

Provided Services:

/* Determine if the move can be completed by the specified time. */

```
boolean canCompleteBy (
     in Global::TimeStamp whenNeeded)
     raises (Global::FrameworkErrorSignal,
          TimeUndeterminableSignal);
```

/* Estimate how long this job will take once it begins. */

```
Global::Duration transportTime ( )
     raises (Global::FrameworkErrorSignal,
          TimeUndeterminableSignal);
```

Contracted Services: None

Dynamic Model: None

```
}; // TransportJob
```

6.4.6 *TransportMachine Interface*

Module: MaterialTransport

Interface: TransportMachine

Inherited Interface: Machine

```
interface TransportMachine : MachineAIG::Machine {
```

Description: This concrete specialization of Machine represents the equipment used to transport material within the factory. Implementations of the Material Transport and Storage Component would provide implementations supporting this interface for each TransportMachine registered with the factory.

Exceptions: None

Published Events: Same as Machine

Provided Services: None

Contracted Services: None

Dynamic Model: None

```
}; // TransportMachine
```

6.4.7 *StorageMachine Interface*

Module: MaterialTransport

Interface: StorageMachine

Inherited Interface: Machine

```
interface StorageMachine : MachineAIG::Machine {
```

Description: This concrete specialization of Machine represents the equipment used to store material within the factory. Implementations of the Material Transport and Storage Component would provide implementations supporting this interface for each StorageMachine registered with the factory.

Exceptions: None

Published Events:

*/ Notifies subscribers that a MaterialContainer arrived on a manual input port may require further action (e.g., creation of a TransportJob or transfer to a particular logical partition). */

```
const string MaterialContainerArrivedAtManualInputPortSubject =
      "/MaterialTransport/StorageMachine/MaterialContainerArrivedAtManualInputPort";

struct MaterialContainerArrivedAtManualInputPortFilters {
      Global::Property Port;
      Global::Property MaterialContainer;
};
```

Table 4 MaterialContainerArrivedAtManualInputPortFilters Properties:

Name	*Value Type*	*Description*
"Port"	MachineAIG::Port	The port where the MaterialContainer was placed.
"MaterialContainer"	DurablesManagement::Material Container	The carrier that arrived at the manual input port.

```
struct MaterialContainerArrivedAtManualInputPortEvent {
     string eventSubject;
     Global::TimeStamp eventTimeStamp;
     MaterialContainerArrivedAtManualInputPortFilters eventFilterData;
     Global::Properties eventNews;

RELATED INFORMATION 1
SCENARIOS FOR MATERIAL TRANSPORT AND STORAGE

NOTE: This related information is not an official part of SEMI E10# and was derived from the work of the I300I/J300E AMHS workgroup accomplished during development of the proposed standard. This related information is included with the Material Transport and Storage Component specification to aid the readers in understanding the intent and use of the standard. This related information was approved for publication by full letter ballot procedures on January 14, 2000.

R1-1 Introduction

R1-1.1 *Scenario Assumptions* — These scenarios show possible implementations of the SEMI standard. The information shown here is intended to be a guide rather than describe rigid implementation rules. Some of the message sequences and implied functionality included in these scenarios will vary across different implementations.

R1-1.2 *Scenario Configuration* — There are thirteen scenarios included in this section. The first and last scenarios show all interactions at an individual interface level. For simplicity, the remaining scenarios show interactions abstracted up to the Component level. Background information related to the scenarios is shown in Figure R1-1. Table R1-1 outlines the thirteen scenario case conditions.

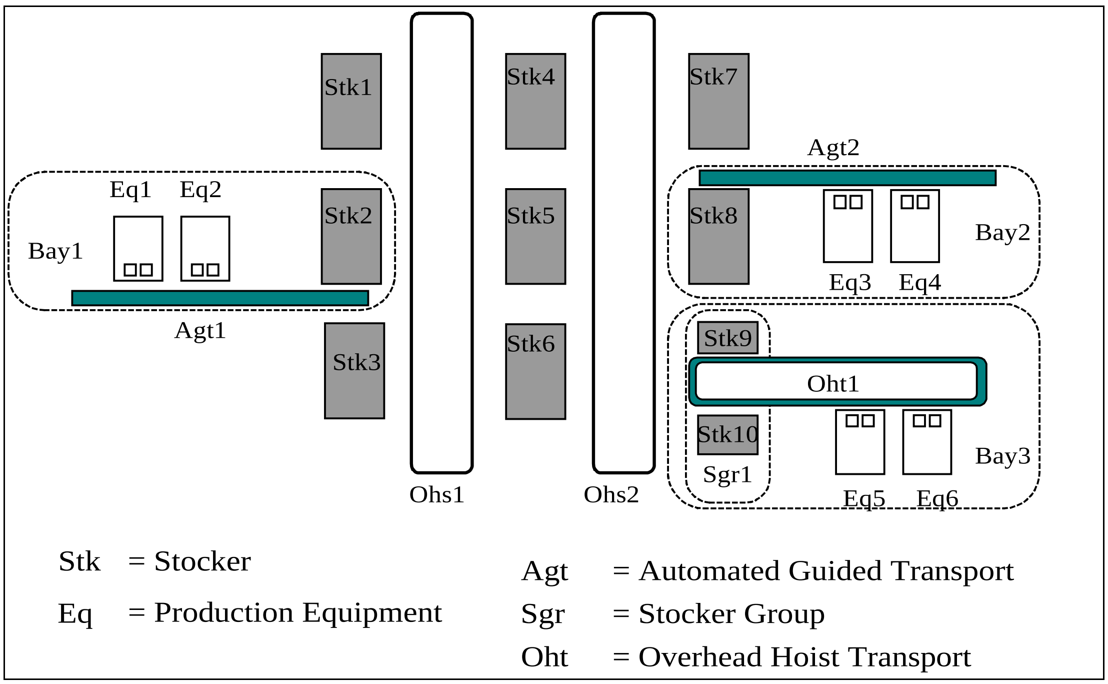

Figure R1-1
Scenario System Layout Configuration

Table R-1 Material Transport and Storage Scenario Definitions

Case	*Source*	*Destination*	*Batch Size*	*Route/Condition*	*Comments*
1	Stk4	Stk9 Manual Output Port	1 Carrier	Stk4>Ohs2>Stk9	Interactions at an individual interface level.
2	Eq1	Stk7	1 Carrier	Eq1>Agt1>Stk2>Ohs1>Stk(Relay)>Ohs2>Stk7 Stk(Relay) priority = Stk4, Stk5, Stk6	Base Scenario: Delivery from Production Equipment to Stocker.
3	Stk7	Eq3	2 Carriers	Stk7>Ohs2>Stk8>Agt2>Eq3 Eq3 batch size = 2 Carrier Ohs2 batch size = 1 Carrier Agt2 batch size = 2 Carrier	Base Scenario: Batch delivery from Stocker to Production Equipment.
4	Eq1	Stk7	1 Carrier	Eq1>Agt1>Stk2>Ohs1>Stk (Relay)>Ohs2>Stk8 (Temp)>Stk7 Stk(Relay) priority = Stk4, Stk5, Stk6 Stk4 Status = Down Stk7 logical partition = Full	Includes AMHS equipment (Storage Device) monitoring and stocker logical partition overflow control.
5	Stk6	Stk4	1 Carrier	Operator>Stk6	Manual Carrier Input handling.
6	Stk4	Stk9	1 Carrier	Stk4>Ohs2>Stk9 - Ohs2 Status = Down	Includes AMHS equipment (transport device) monitoring.
7	Stk7	Eq6	4 Carriers	Stk7>Ohs2>Sgr1>Oht1>Eq6 Eq6 has internal buffer, batch size = 4 carriers Ohs2 batch size = 1 carrier, Oht1 batch size = 1 carrier	Base scenario: Batch delivery to internal buffer equipment.
8	Stk5	Eq5	1 Carrier	Stk5>Ohs2>Sgr1>Oht1>Eq5 Macro command is aborted with carrier on Ohs2.	Includes abort job handling.
9	Stk5	Eq5	1 Carrier	Stk5>Ohs2>Sgr1>Oht1>Eq5 Macro command is modified to final destination Sgr1.	Includes modify job handling.
10	-	-	-	Startup - Material Transport and Storage Component is registered and starts up.	Base scenario: MTSC startup.
11	Stk6	Stk4	1 Carrier	Stk6>Ohs2>Stk4 - Operator removes carrier while on Ohs2.	Includes handling of manual interruption of delivery.
12	Eq3	Eq5	1 Carrier	Eq3>Agt2>Stk8>Ohs2>Sgr1>Oht1>Eq5	Base scenario: tool-to-tool delivery.
13	Stk4	Stk9	1 Carrier	Stk4>Ohs2>Stk9	Interactions at an individual interface level (including capacity reservation).

RELATED INFORMATION 2
LOGICAL PARTITION STORAGE

NOTE: This related information is not an official part of SEMI E10# and was derived from the work of the I300I/J300E AMHS workgroup accomplished during development of the proposed standard. This related information is included with the Material Transport and Storage Component specification to aid the readers in understanding the intent and use of the standard. This related information was approved for publication by full letter ballot procedures on January 14, 2000.

R2-1 The concept of Stocker storage via logical partitions has been implemented through the use of the MaterialTrackingLocation concept and interfaces. In the example below, the correlation between Durables and MaterialTrackingLocations are each object's unit attribute. First, the Factory Supervisor sets the Durable unit to a particular value based on user specifications. The MTSC then maps the Durable Unit to the appropriate MaterialTrackingLocation unit for the destination Storage Machine in order to determine the appropriate logical partition for that particular durable. It is not required that the Durable unit and MaterialTrackingLocation unit be identical in order for a mapping to occur, the MTSC may implement mapping logic in order to obtain various relationships between Durable units and MaterialTrackingLocation units.

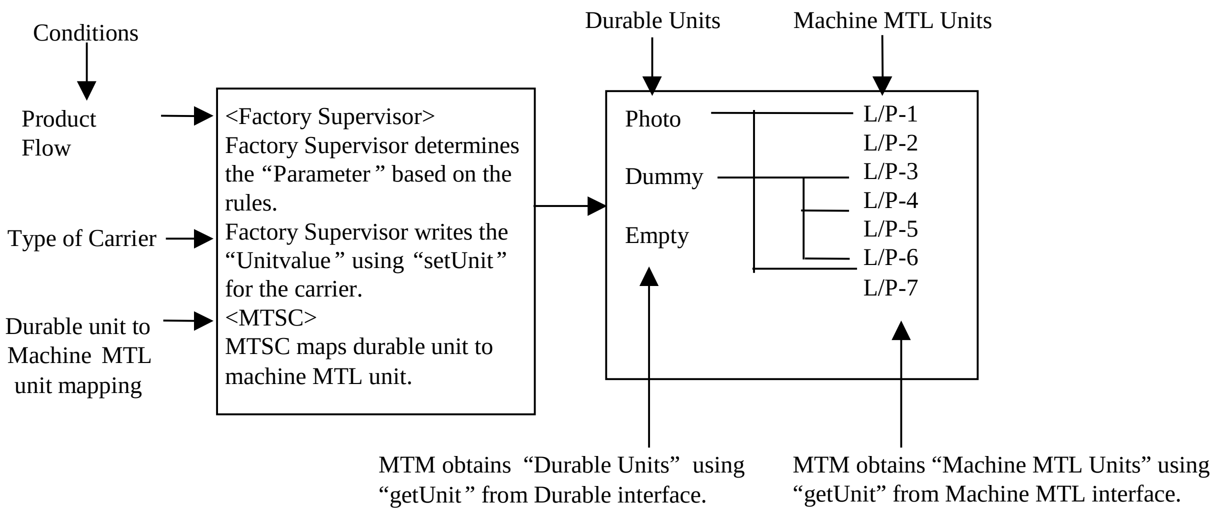

Figure R2-1
Storage in Logical Partitions

NOTICE: SEMI makes no warranties or representations as to the suitability of the specification set forth herein for any particular application. The determination of the suitability of the specification is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These specifications are subject to change without notice.

The user's attention is called to the possibility that compliance with this specification may require use of copyrighted material or of an invention covered by patent rights. By publication of this specification, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E105-0701
PROVISIONAL SPECIFICATION FOR CIM FRAMEWORK SCHEDULING COMPONENT

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the Japanese Regional Standards Committee on February 1, 2001. Initially available at www.semi.org April 2001; to be published July 2001. Originally published October 2000.

1 Purpose

1.1 The Scheduling Component supports Factory Operations, Material Transport and Storage, Production Machine, and Equipment Tracking and Maintenance components by ordering, in time, jobs that process material on equipment, move material, and maintain equipment. The scheduler uses knowledge of product demand, equipment and material state, process flows, throughput bottlenecks, operational policy and constraints, and other information to recommend jobs that maximize effective utilization of factory resources to satisfy product demand and planned objectives.

1.2 Increased control over operations requires an active Scheduling Component that can respond to factory events and changes in state and dynamically adjust the schedules for material processing, material transport and equipment maintenance. The Scheduling Component can react to inventory levels of material in the factory to adjust priorities to minimize queue sizes and ensure that use of bottleneck equipment is optimized to keep WIP inventory levels at desired levels.

1.3 The Scheduling Component can minimize turn around time (TAT) by coordinating material transport (for substrates and durables) with processing to reduce equipment idle time. The Scheduling Component can sequence activities to minimize setup time. It can also respond to scheduled and unscheduled equipment down-time to minimize impact on turn around time. In addition to minimizing overall TAT, it can react to the priorities for urgent lots to move them through the process flow in the minimum possible time while adjusting the schedules of lower-priority lots that are impacted.

2 Scope

2.1 The primary run-time responsibilities of the Scheduling Component are to monitor resource and material state and apply scheduling and dispatching decision mechanisms to identify the next activity (dispatching) or sequence of activities (scheduling) for factory resources. The Scheduling Component includes an interface that supports both scheduling and dispatching. Figure 1 illustrates the interactions between the Scheduling Component and other components of the CIM Framework. This illustration does not reflect all of the many inputs to the Scheduling Component that are required to provide it with the current status of the factory resources.

2.2 As described in this standard, the Scheduling Component produces activity option and activity forecast lists. These lists are produced by combining the factory model and status information from other components with scheduling policies in the Scheduling Component. For example, the Scheduling Component combines data from the Specification Component on how products are made with status data from the Equipment and Product Management Components to give activity options for a machine.

2.3 The Factory Operations Component uses the Scheduling Component services to orchestrate the management of machines and production of lots. For example, when a tool becomes available, Factory Operations uses the Activity Options list to select the next lot to process on the tool. Factory Operations then works with other components to execute the production job for the lot on the machine. Executing the production job changes the state of lot and tool in other components. These status changes are then used by the Scheduling Component when it produces new activity lists.

2.4 The Scheduling Manager supports Factory Operations by providing an answer to questions like, “What is next for this material or resource?” The answer may be based on evaluation of current or future constraints and objectives. Although the dispatcher's output takes the form of a decision for the next activity for the target resource, the interface may also support manual scenarios by providing a list of prioritized activities from which the decision is selected.

2.5 The Scheduling Manager interface also provides forecasts of future activities projected to occur after the next activity. By simulating anticipated future activity sequencing and execution timing the scheduler can generate forecasts that predict future responses from the dispatcher for subsequent requests. These forecasts are subject to change as factory conditions change, but they offer the best current projection of future activity decisions.

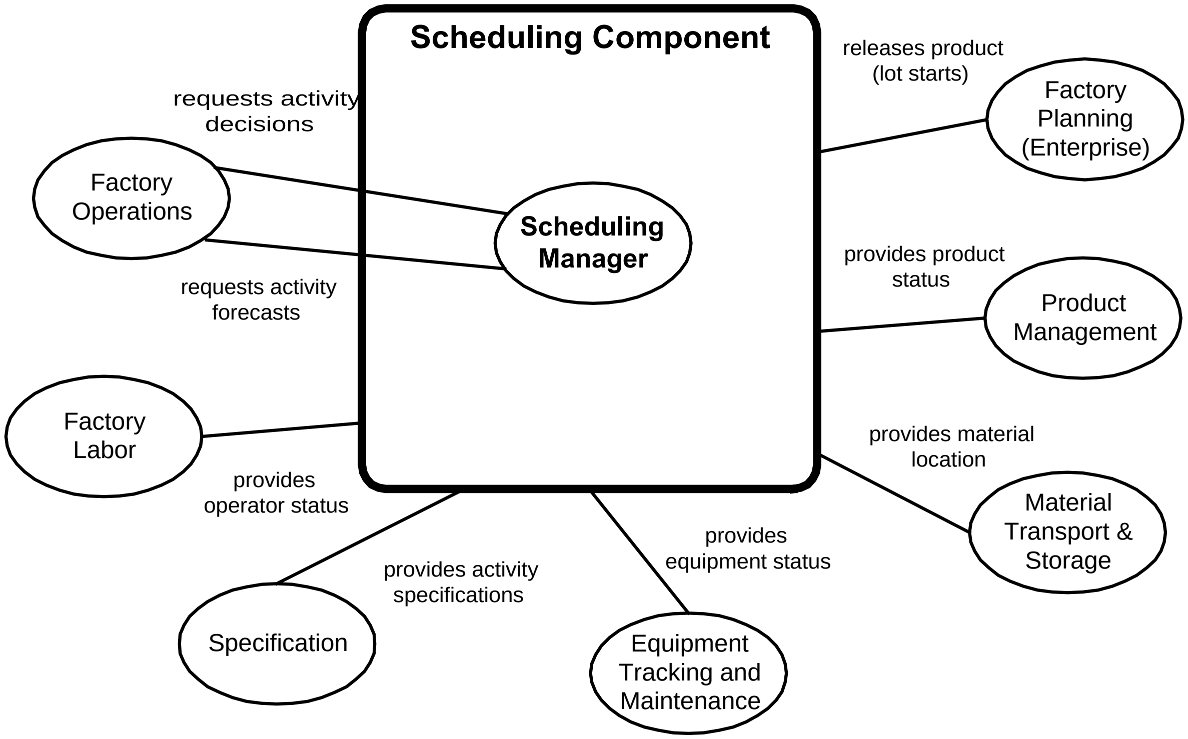

Figure 1
Scheduling Component Interactions

2.6 This specification does not describe the definition of the policies used by the Scheduling Component to produce activity lists. This is left to component implementors.

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 *Provisional Status* — This specification is designated as provisional due to known areas that need to be completed. The following items summarize the deficiencies of the provisional specification to be addressed before a subsequent ballot to upgrade it to full standard status.

3.1.1 *Dependence on Factory Operations Component* — The Scheduling Component provides specifications of activities that are executed by the Factory Operations Component in the form of production jobs, transport jobs and maintenance jobs. The specification of Factory Operations may require changes to the activity specification properties of the Scheduling Component. When the Specification for CIM Framework Factory Operations Component is complete, this dependency can be resolved.

3.1.2 *Specification of Event Subscriptions* — The Scheduling Component maintains a current status of the factory resources and material by receiving event notifications of occurrences that indicate changes in other components. Events are specified with the component responsible for publishing the event notifications. Until all of the required event formats are defined as part of the publishing component specification, the inputs to the Scheduling Component will be defined only in general terms. When event specifications are complete, these event subscriptions can be specified.

3.1.3 *Initialization* — The Scheduling Component does not currently provide interfaces that allow the representation of factory conditions to be initialized for the start-up of dispatching and scheduling. The addition of initialization interfaces will be added or deemed out of scope prior to upgrade to full standard status.

SEMI E102 — Provisional Specification for CIM Framework Material Transport and Storage Component

4.2 *Other Documents*

UML Notation Guide, Version 1.1, document number ad/97-08-05, Object Management Group.[1]

ISO/IEC International Standard 14750 (also ITU-T Recommendation X.920): Information Technology – Open Distributed Processing – Interface Definition Language [2]

5 Terminology

5.1 *Definitions*

5.1.1 *activity* — work performed as part of the manufacturing operations of a factory. Activities may be specified formally by a predefined type of job specification (for example, Production Job, Transport Job or PM Job), or they may be represented by identifying the minimal set of resources and material needed to allow subsequent completion of the job specification. An activity is the result of dispatching or scheduling.

5.1.2 *dispatching* — generation of a decision or option for the next activity involving a particular factory resource or material. The dispatch result is determined by evaluating the current state of the factory, the priorities and requirements for the activities, and the relationship of the activities to one another. Dispatching returns only the immediately applicable part of a schedule.

5.1.3 *factory planning* — recommendation of lot starts for a particular production facility over an extended period of time. The factory plan is determined by predicting future changes in factory state and available capacity as lots progress through production. This prediction is used to determine the optimum sequence of lot starts to best achieve the production goals of the facility. Factory planning is typically the responsibility of enterprise systems.

5.1.4 *scheduling* — generation of a forecast of future time sequenced activities involving factory resources or material. The schedule is based on the current state of the factory, the priorities and requirements for the activities, the relationship of the activities to one another and knowledge of factory level goals and capacity. Scheduling covers activities projected to occur over a longer future time interval than dispatching.

6 Requirements

6.1 *Scheduling Component* — The Scheduling Component provides a single interface called the SchedulingManager with operations for both dispatching and scheduling.

6.1.1 Any resource or material within the factory may have a next activity defined for it. The SchedulingManager interface is responsible for identifying activities that answer questions such as:

- What's next for this Machine?
- Where next for this Lot?
- What's next for this Operator?

6.1.2 The SchedulingManager interface is also responsible for generating a time-sequenced forecast of future activities for a resource or for material within the factory. This forecast is based on projections from the current factory state and may be updated as actual activities are dispatched and executed.

6.1.3 The Scheduling Component Information Model is shown in Figure 2.

6.1.4 *Scheduling Component Declarations*

/* The ActivityType enumerated value will determine which kind of activity is represented and the appropriate properties present in the activitySpec. */

```
enum ActivityType {
     ProductionActivity,
     TransportActivity,
     MaintenanceActivity,
     DoNothing };
```

/* ActivityOption represents a single activity that is eligible to be dispatched for execution. The prioritySequenceNumber represents the priority ordering of a list of ActivityOptions in the case where a manual process includes selection of one ActivityOption from the list. The deadline is a timestamp that is used to convey start time constraints for activities. It may also be used in a DoNothing activity to specify the timeout for a retry of the dispatch request. */

```
struct ActivityOption {
     ActivityType activityType;
     short prioritySequenceNumber;
     Global::TimeStamp deadline;
     AbstractIF::ResourceSequence resources;
     AbstractIF::MaterialGroupSequence materialGroups;
     DurablesManagement::DurableSequence durables;
     Global::Properties activitySpec;
}; // ActivityOption
```

/* ActivityForecast represents a single Activity that may be dispatched and executed in the future. An ActivityForecast includes information that is equivalent to an ActivityOption, but with added start and finish time projections. The timeSequenceNumber represents the time ordering of activities consistent with the projectedStart and projectedFinish. */

```
struct ActivityForecast {
     ActivityType activityType;
     short timeSequenceNumber;
     AbstractIF::ResourceSequence resources;
     AbstractIF::MaterialGroupSequence materialGroups;
     DurablesManagement::DurableSequence durables;
     Global::TimeStamp projectedStart;
     Global::TimeStamp projectedFinish;
     Global::Properties activitySpec;
}; // ActivityForecast
```

/* An ActivityList contains one or more ActivityOptions for a Resource, MaterialGroup or Durable which are all eligible for immediate execution. A list of one ActivityOption represents a decision from the SchedulingComponent. A list of more than one ActivityOption represents recommendations from the SchedulingComponent which require some external interaction for a decision to be reached. */

```
typedef sequence <ActivityOption> ActivityList;
```

/* A ForecastList contains one or more ActivityForecasts for a Resource or MaterialGroup which are not yet dispatched for execution. */

```
typedef sequence <ActivityForecast> ForecastList;
```

6.1.5 *Use of ActivitySpec Properties*— The ActivitySpec part of the ActivityOption and ActivityForecast are provided to allow implementations to extend the specifications of activities for specific implementations. The names and value types of properties included in these ActivitySpec structure are not part of the standard.

6.1.6 *SchedulingManager Interface*

Module: Scheduling

Interface: SchedulingManager

Inherited Interface: ComponentManager

```
interface SchedulingManager : FactoryOperations::ComponentManager {
```

Description: The SchedulingManager provides the concrete interfaces that support the registration and control of the Scheduling Component and enable access to the Dispatcher and Scheduler interfaces.

Exceptions:

/* An attempt was made to request an activity for a resource that is not found within the factory data available to this SchedulingManager. */

```
exception ResourceNotFound {
      AbstractIF::Resource requestedObject;};
```

/* An attempt was made to request an activity for a material group that is not found within the factory data available to this SchedulingManager. */

```
exception MaterialGroupNotFound {
      AbstractIF::MaterialGroup requestedObject;};
```

/* An attempt was made to request an activity for a durable that is not found within the factory data available to this SchedulingManager. */

```
exception DurableNotFound {
      DurablesManagement::Durable requestedObject;};
```

Published Events:.

/* The ActivityListAvailable event is published by the Scheduling Component to notify event subscribers that a new ActivityList containing changes is available. The generation of ActivityListAvailable events is controlled as an implementation specific configuration choice. */

ActivityListAvailable

/* The ForecastListAvailable event is published by the Scheduling Component to notify event subscribers that a new Forecast is available. ForecastList generation is potentially a compute-intensive operation which may benefit from event notification when an updated forecast is available. The generation of ForecastListAvailable events is controlled as an implementation specific configuration choice. */

ForecastListAvailable

Provided Services:

/* Return an activity list for this resource. The activity list will contain the number of existing activities requested in listCount in maximum. If “listCount” is blank, the activity list shall contain all existing activities. A decision will be represented by an activity list with only one activity option. The ActivityOptions returned by this operation may be ProductionActivity, MaintenanceActivity or DoNothing ActivityTypes. Although Resources are typically immobile (such a Equipment), some Resources may also be subject to TransportActivities. */

```
ActivityList whatNextForResourceByCount (
       in AbstractIF::Resource aResource)
       in short listCount)
       raises (Global::FrameworkErrorSignal,
                    ResourceNotFound);
```

/* Return an activity list for this material group. The activity list will contain the number of existing activities requested in listCount in maximum. If “listCount” is blank, the activity list shall contain all existing activities. A decision will be represented by an activity list with only one activity option. The ActivityOptions returned by this operation may be ProductionActivity, TransportActivity or DoNothing ActivityTypes. */

```
ActivityList whatNextForMaterialGroupByCount (
     in AbstractIF::MaterialGroup aMaterialGroup,
     in short listCount)
     raises (Global::FrameworkErrorSignal,
          MaterialGroupNotFound);
```

/* Return an activity list for this durable. The activity list will contain the number of existing activities requested in listCount in maximum. If “listCount” is blank, the activity list shall contain all existing activities. A decision will be represented by an activity list with only one activity option. The ActivityOptions returned by this operation may be ProductionActivity, MaintenanceActivity, TransportActivity or DoNothing ActivityTypes. */

```
ActivityList whatNextForDurableByCount (
       in DurablesManagement::Durable aDurable)
       in short listCount)
       raises (Global::FrameworkErrorSignal,
            DurableNotFound);
```

/* Return an activity list containing the next TransportActivity for this material group. A decision will be represented by an activity list with only one activity option. The ActivityOptions returned by this operation may be TransportActivity or DoNothing ActivityTypes. This operation is defined to support a factory operating with a “push” model that pushes material to the next storage or production machine. */

```
ActivityList whereNextForMaterialGroup (in AbstractIF::MaterialGroup aMaterialGroup)
     raises (Global::FrameworkErrorSignal,
          MaterialGroupNotFound);
```

/* Return an activity list containing the next TransportActivity for this durable. A decision will be represented by an activity list with only one activity option. The ActivityOptions returned by this operation may be TransportActivity or DoNothing ActivityTypes. This operation is defined to support a factory operating with a “push” model that pushes material to the next storage or production machine. */

```
ActivityList whereNextForDurable (in DurablesManagement::Durable aDurable)
     raises (Global::FrameworkErrorSignal,
          DurableNotFound);
```

/* Return a forecast list containing future activities for this resource. The forecast list will contain all activities projected to start before the lookAheadTime, but which have not yet been started. The forecast list may include a mix of different activity types. */

```
ForecastList forecastForResourceByTime (
     in AbstractIF::Resource aResource,
     in Global::TimeStamp lookAheadTime)
     raises (Global::FrameworkErrorSignal,
          ResourceNotFound);
```

/* Return a forecast list containing future activities for this material group. The forecast list will contain all activities projected to start before the lookAheadTime, but which have not yet been started. The forecast list may include a mix of different activity types. */

```
ForecastList forecastForMaterialGroupByTime (
     in AbstractIF::MaterialGroup aMaterialGroup,
     in Global::TimeStamp lookAheadTime)
     raises (Global::FrameworkErrorSignal,
          MaterialGroupNotFound);
```

/* Return a forecast list containing future activities for this durable. The forecast list will contain all activities projected to start before the lookAheadTime, but which have not yet been started. The forecast list may include a mix of different activity types. */

```
ForecastList forecastForDurableByTime (
      in DurablesManagement::Durable aDurable,
      in Global::TimeStamp lookAheadTime)
      raises (Global::FrameworkErrorSignal,
            DurableNotFound);
```

/* Return a forecast list containing future activities for this resource. The forecast list will contain the number of upcoming activities requested in lookAheadCount. The forecast list may include a mix of different activity types. */

```
ForecastList forecastForResourceByCount (
      in AbstractIF::Resource aResource,
      in short lookAheadCount)
      raises (Global::FrameworkErrorSignal,
            ResourceNotFound);
```

/* Return a forecast list containing future activities for this material group. The forecast list will contain the number of upcoming activities requested in lookAheadCount. The forecast list may include a mix of different activity types. */

```
ForecastList forecastForMaterialGroupByCount (
      in AbstractIF::MaterialGroup aMaterialGroup,
      in short lookAheadCount)
      raises (Global::FrameworkErrorSignal,
            MaterialGroupNotFound);
```

/* Return a forecast list containing future activities for this durable. The forecast list will contain the number of upcoming activities requested in lookAheadCount. The forecast list may include a mix of different activity types. */

```
ForecastList forecastForDurableByCount (
      in DurablesManagement::Durable aDurable,
      in short lookAheadCount)
      raises (Global::FrameworkErrorSignal,
            DurableNotFound);
```

Contracted Services: None.

Dynamic Model: Inherited from ComponentManager.

```
}; // SchedulingManager
```

RELATED INFORMATION 1
IMPLEMENTATION GUIDANCE FOR INPUT OF FACTORY STATE INFORMATION TO THE SCHEDULING COMPONENT

NOTE: This related information is not an official part of SEMI E105. This related information was approved for publication by full letter ballot procedures on August 28, 2000.

NOTE: This related information is included with the Scheduling Component specification to aid the readers in understanding the intent and use of the standard.

R1-1 The Scheduling Component has two types of interfaces:

A. Scheduling and Dispatching Service Interface - this is the interface for services provided by the Scheduling Component in response to requests from the Factory Operations Component or some other client. It also includes interfaces to support asynchronous actions for an active scheduler or dispatcher which provides the same information content on an event driven basis rather than requiring a client request.

This is included within the scope of the current standard.

B. Scheduling and Dispatching Factory Input Interface - this is the interface used by other components to provide updated information on factory state used by the Scheduling Component in making scheduling and dispatching decisions. The updates are typically provided by other CIM Framework components to the Scheduling Component asynchronously.

This is NOT included within the scope of the current standard.

R1-2 The goal for CIM Framework standards is to eventually standardize both of these types of interface. However, at this time there are two major issues that prevent inclusion of the Factory Input Interface to the Scheduling Component.

1. There is inadequate consensus on the technical maturity of the currently available asynchronous input mechanisms. While the CIM Framework specifies events for delivery via an Event Broker mechanism, it is not assumed that the quality of service for events will include guaranteed delivery and performance adequate for keeping a Scheduling Component current with real-time factory state changes. For a more complete discussion of the CIM Framework technical architecture issues, see SEMI E96.

2. Some key components of the CIM Framework needed to provide factory state to the Scheduling Component have not yet been approved as SEMI standards.

R1-3 The following approach is suggested as a possible way to address Scheduling Component Input in the future:

1. Identify the most important inputs required by the Scheduling Component in a follow-on ballot for the Scheduling Component to be used during the interim period until the full component specifications containing those events are approved as SEMI standards.

2. Suppliers who implement the Scheduling Component should take advantage of existing standard interfaces defined in adopted CIM framework standards and use this experience as expert input on future updates to this standard.

3. Encourage technical studies to provide added understanding of the tradeoffs and limitations that impact standardization of this interface in the future.

RELATED INFORMATION 2
SCENARIOS FOR SCHEDULING AND DISPATCHING.

NOTE: This related information is not an official part of SEMI E105. This related information was approved for publication by full letter ballot procedures on August 28, 2000.

These scenarios show possible implementations of the SEMI Scheduling Component. The information shown here is intended to be a guide rather than describe prescriptive implementation rules. Some of the message sequences and implied functionality included in these scenarios will vary across different implementations.

This section focuses primarily on the interface between the Scheduling Component and factory operations component. The messaging between the lower level components is for informational purposes, and may not actually reflect what is developed in the future when standards for those components have been completed.

R2-1 *Scenario 1* — Simulator Based Scheduler/Dispatcher, Stocker is Not Managed by Scheduling Component

R2-1.1 Lot 1 is scheduled for equipment 2 at 10:00. Lot is held in stocker until ready to start on equipment 2. Factory operations makes the carrier delivery decisions.

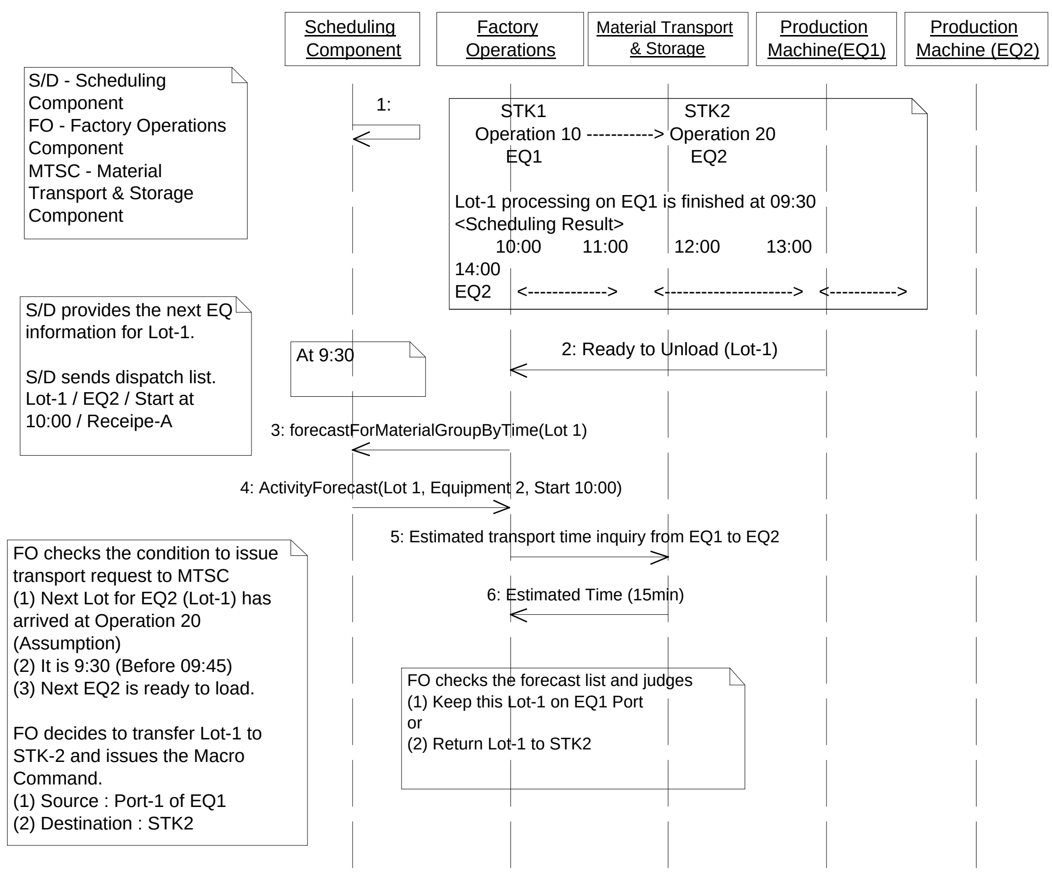

Figure R2-1
Scenario Case 1

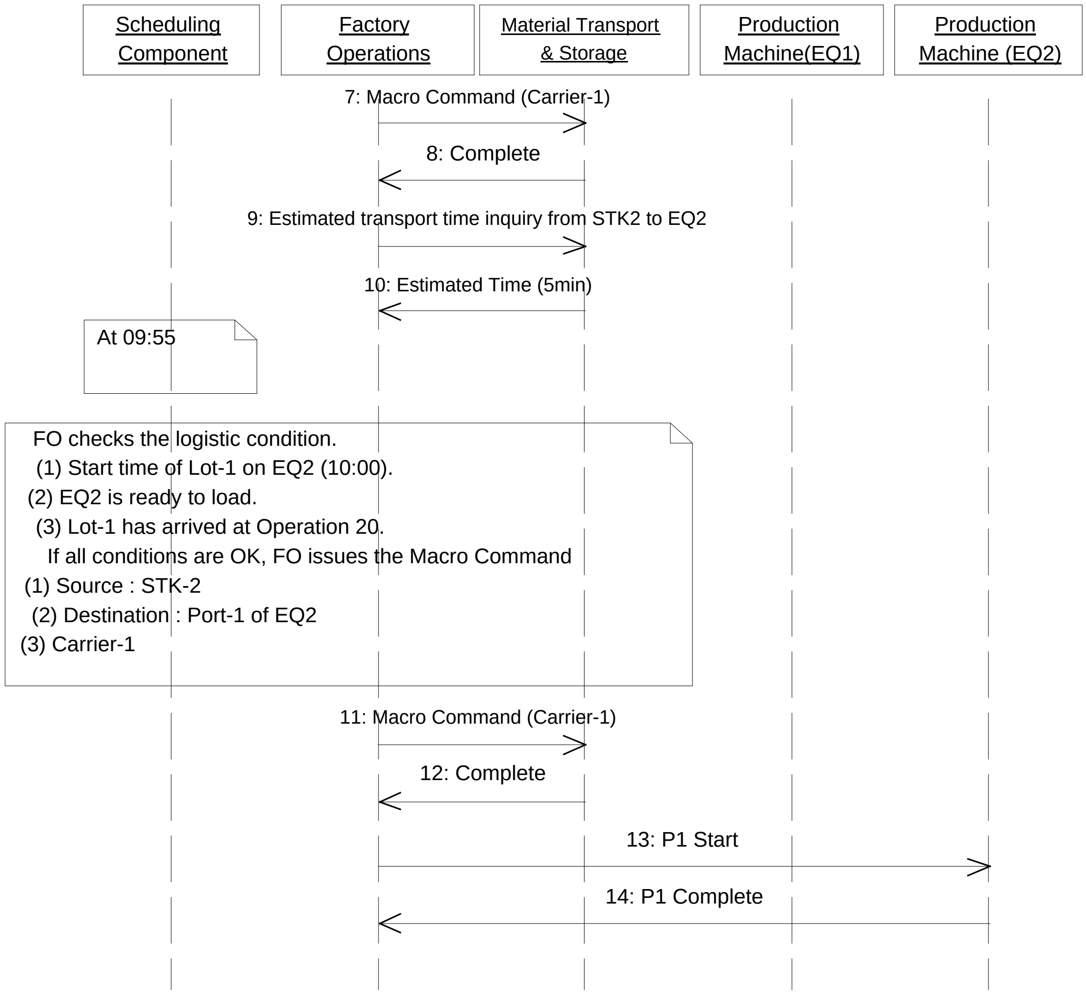

Figure R2-2
Scenario Case 1 Continued

R2-2 *Scenario 2* — Simulator Based Scheduler/Dispatcher, Stocker is Not Managed by Scheduling Component

R2-2.1 Lot 1 is scheduled for equipment 2. Lot is transported directly from Eqp1 to Eqp 2. Factory Operations makes the carrier delivery decisions.

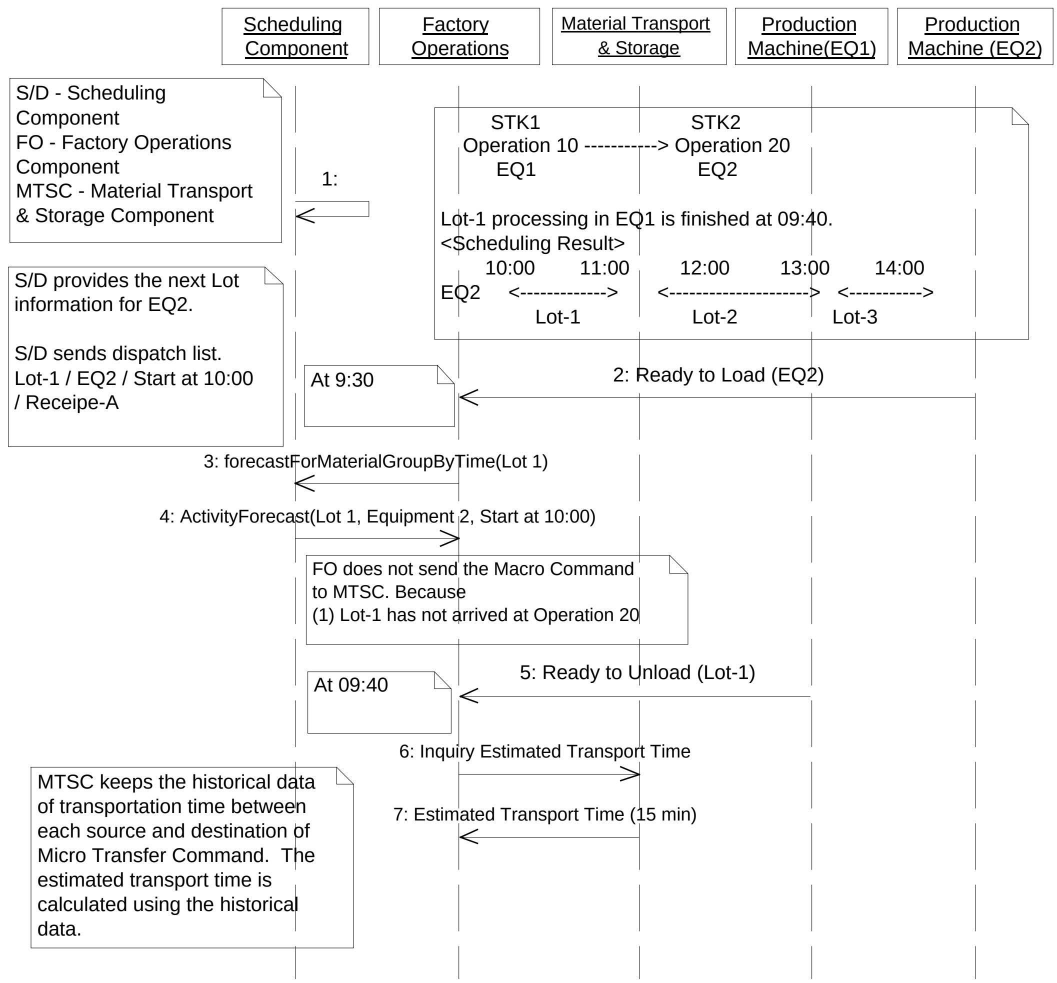

Figure R2-3
Scenario Case 2

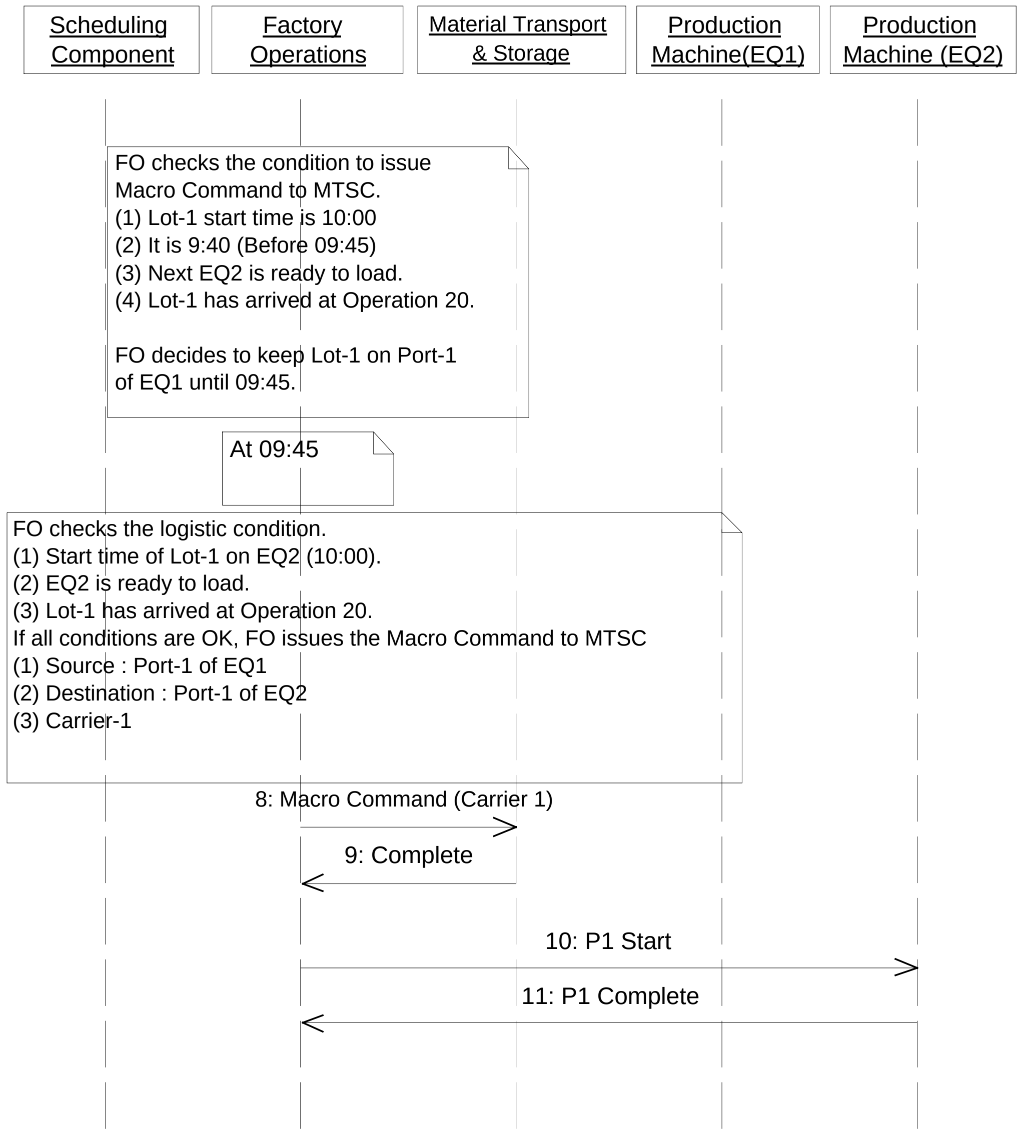

Figure R2-4
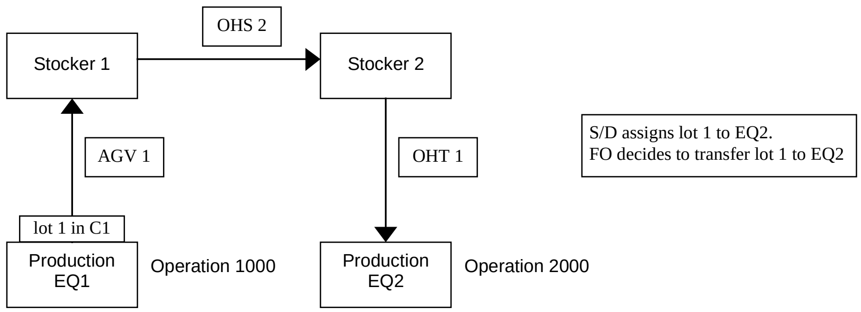
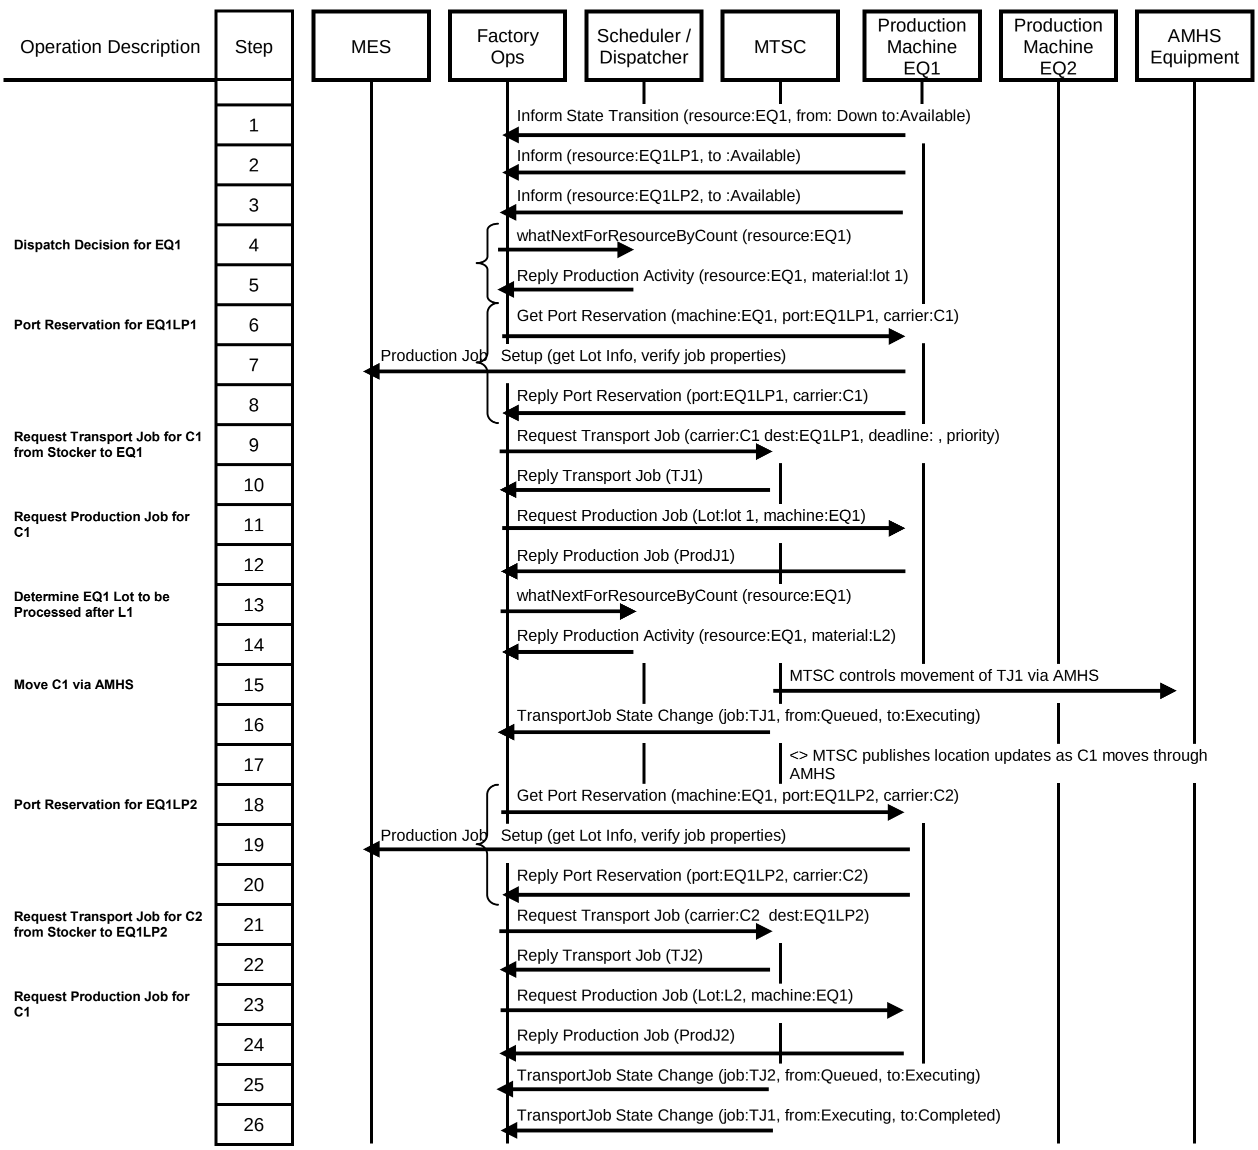
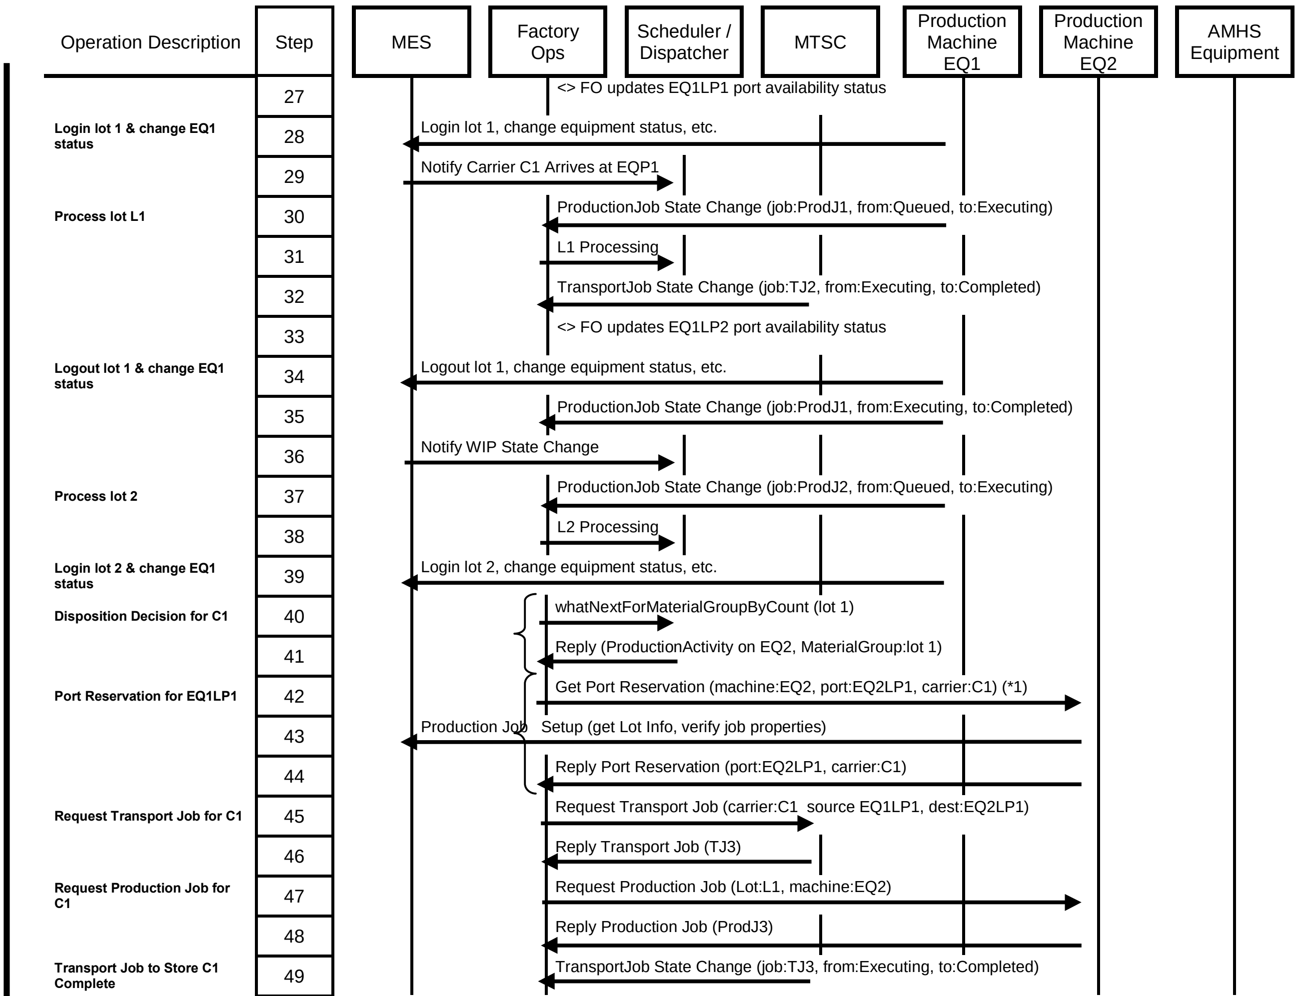
Scenario Case 2 Continued

R2-3 *Scenario 3* — Dispatch List Based Scheduler/Dispatcher, Stocker is Not managed by Scheduling Component

R2-3.1 Dispatch list based. EQ1->EQ2. After lot 1 processing on EQ1 is finished, Scheduler assigns lot 1 to EQ2. FO checks the EQ2 port status and finds the available port. FO makes the logistic decision to transfer lot 1 from EQ1 to EQ2 directly. Scheduler does not assign lots to Stocker. In this scenario 3, the direct transfer "from EQ1 to EQ2" is described.



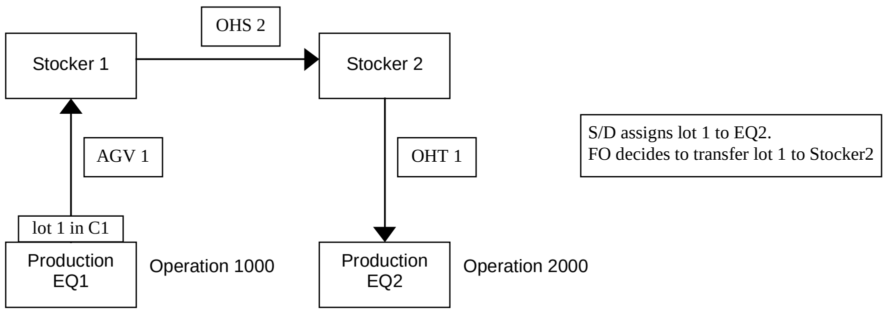


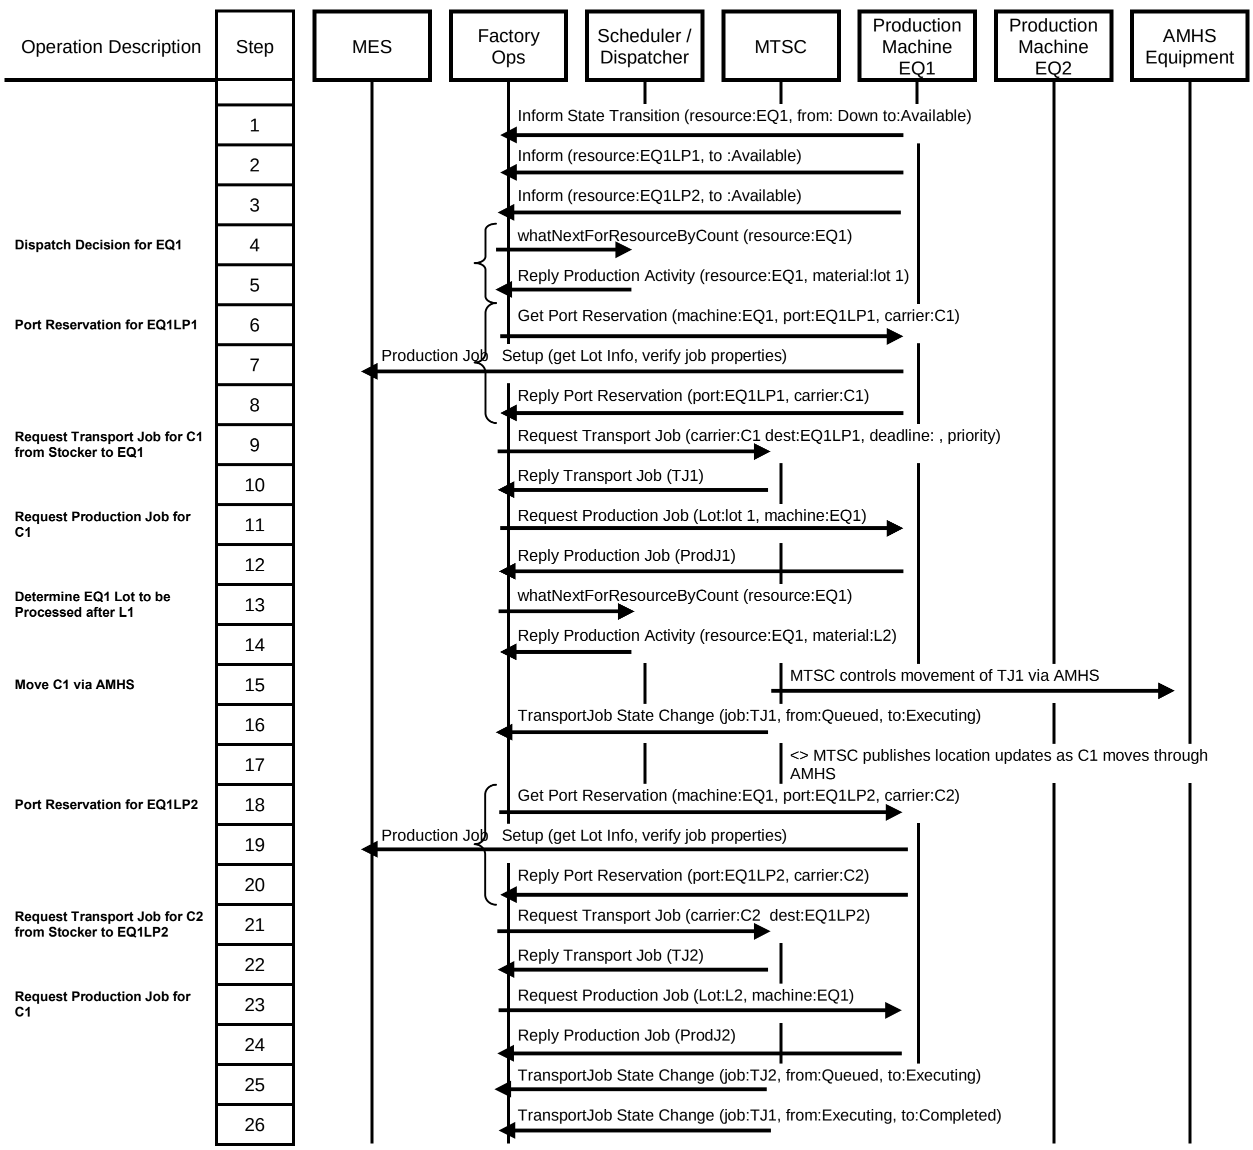


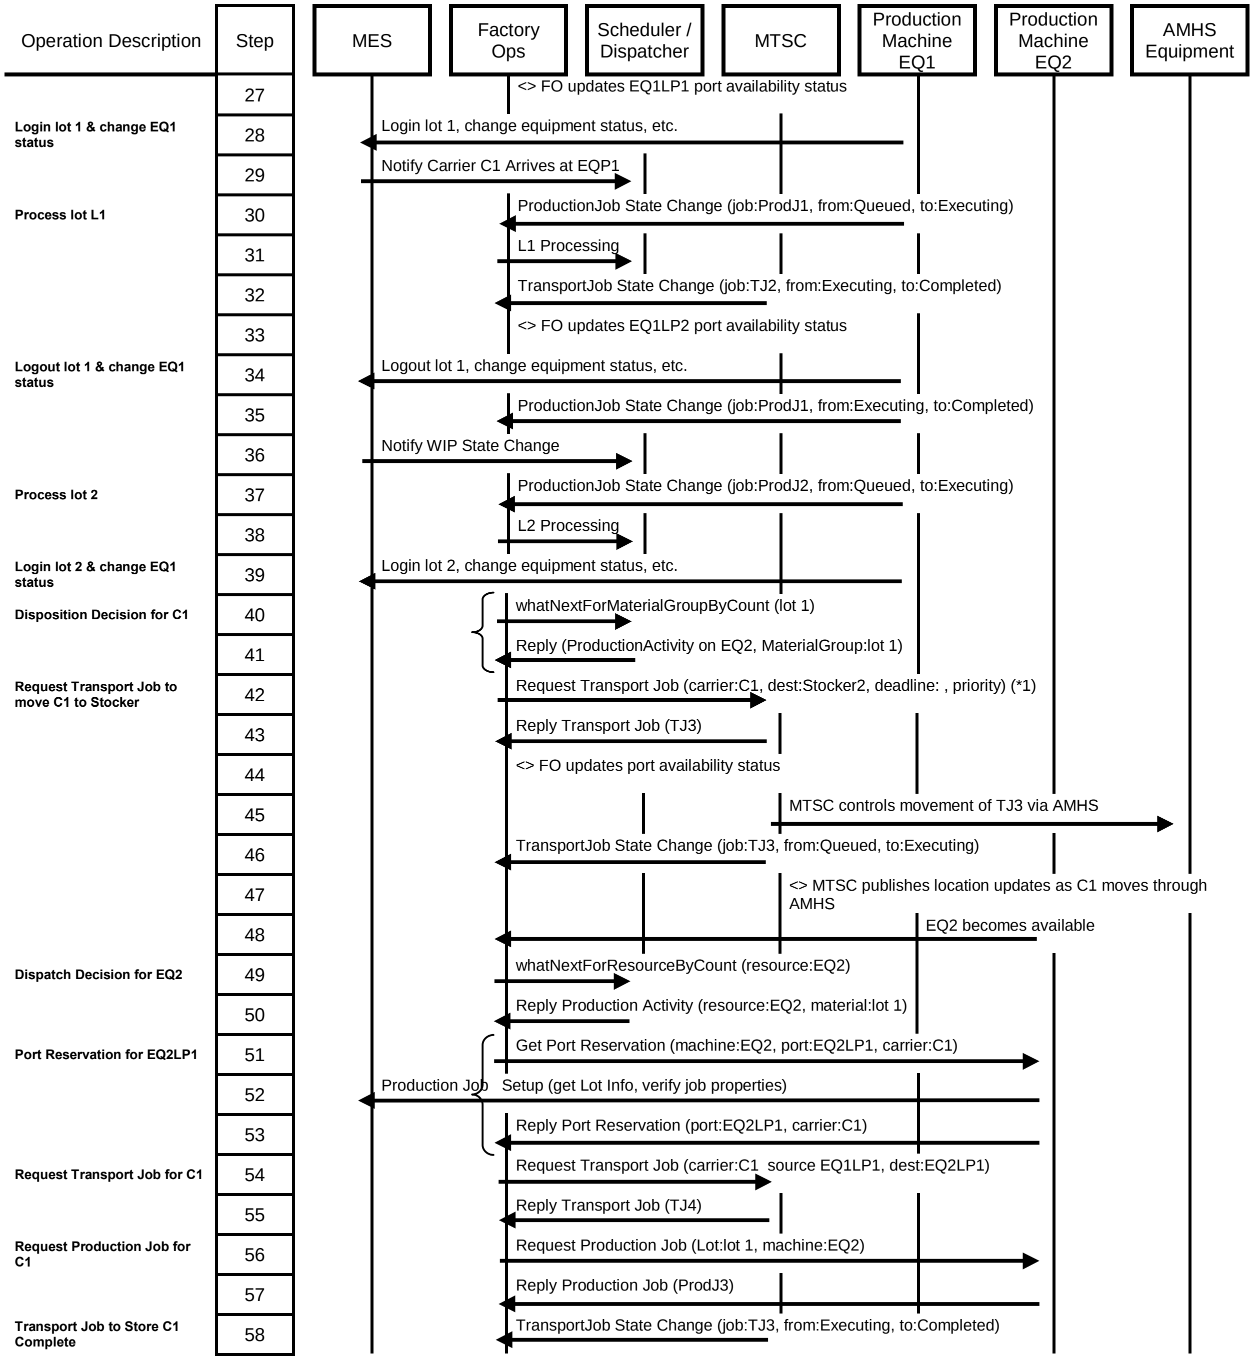
(*1) FO checks port status on tool. Finds port available. Delivers lot directly to EQ2.

R2-4 *Scenario 4* — Dispatch List Based Scheduler/Dispatcher, Stocker is Not managed by Scheduling Component

R2-4.1 Dispatch list based. EQ1->Stocker->EQ2. After lot 1 processing on EQ1 is finished, Scheduler assigns lot 1 to EQ2. FO checks the EQ2 port status and finds No available port. FO makes the logistic decision to transfer lot 1 from "EQ1 to Stocker 2" instead of "from EQ1 to EQ2". Scheduler does not assign lots to Stocker. In this scenario 4, the separate transfers "from EQ1 to Stocker 2" and "from Stocker 2 to EQ2" are described.







(*1) FO checks port status on tool. Finds no ports available. Delivers lot to stocker close to tool.

R2-5 *Scenario 5* — Dispatch List Based Scheduler/Dispatcher, Stocker is managed by Scheduling Component

R2-5.1 Dispatch list based. EQ1->EQ2. After lot 1 processing on EQ1 is finished, Scheduler assigns lot 1 to EQ2. Scheduler additionally checks the EQ2 port status and finds the available port. Scheduler makes the logistic decision to transfer lot 1 from EQ1 to EQ2 directly. Scheduler assigns lots to Stocker when the next assigned equipment is not available. In this scenario 5, the direct transfer "from EQ1 to EQ2" is described.

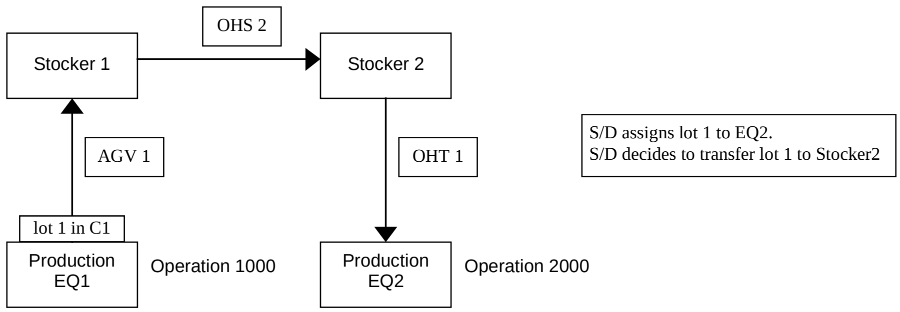
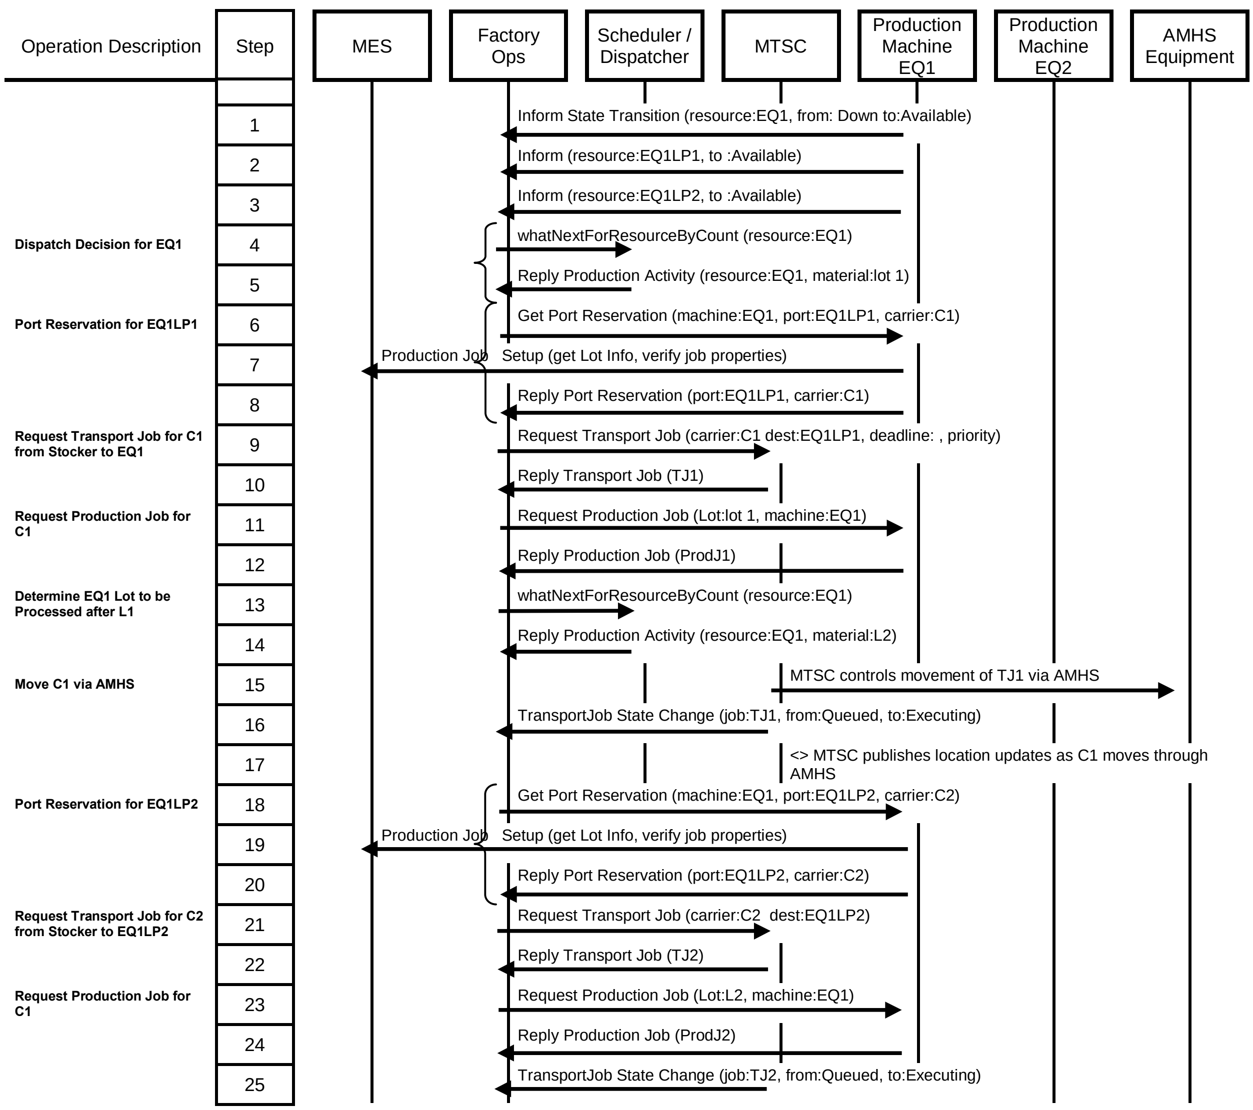
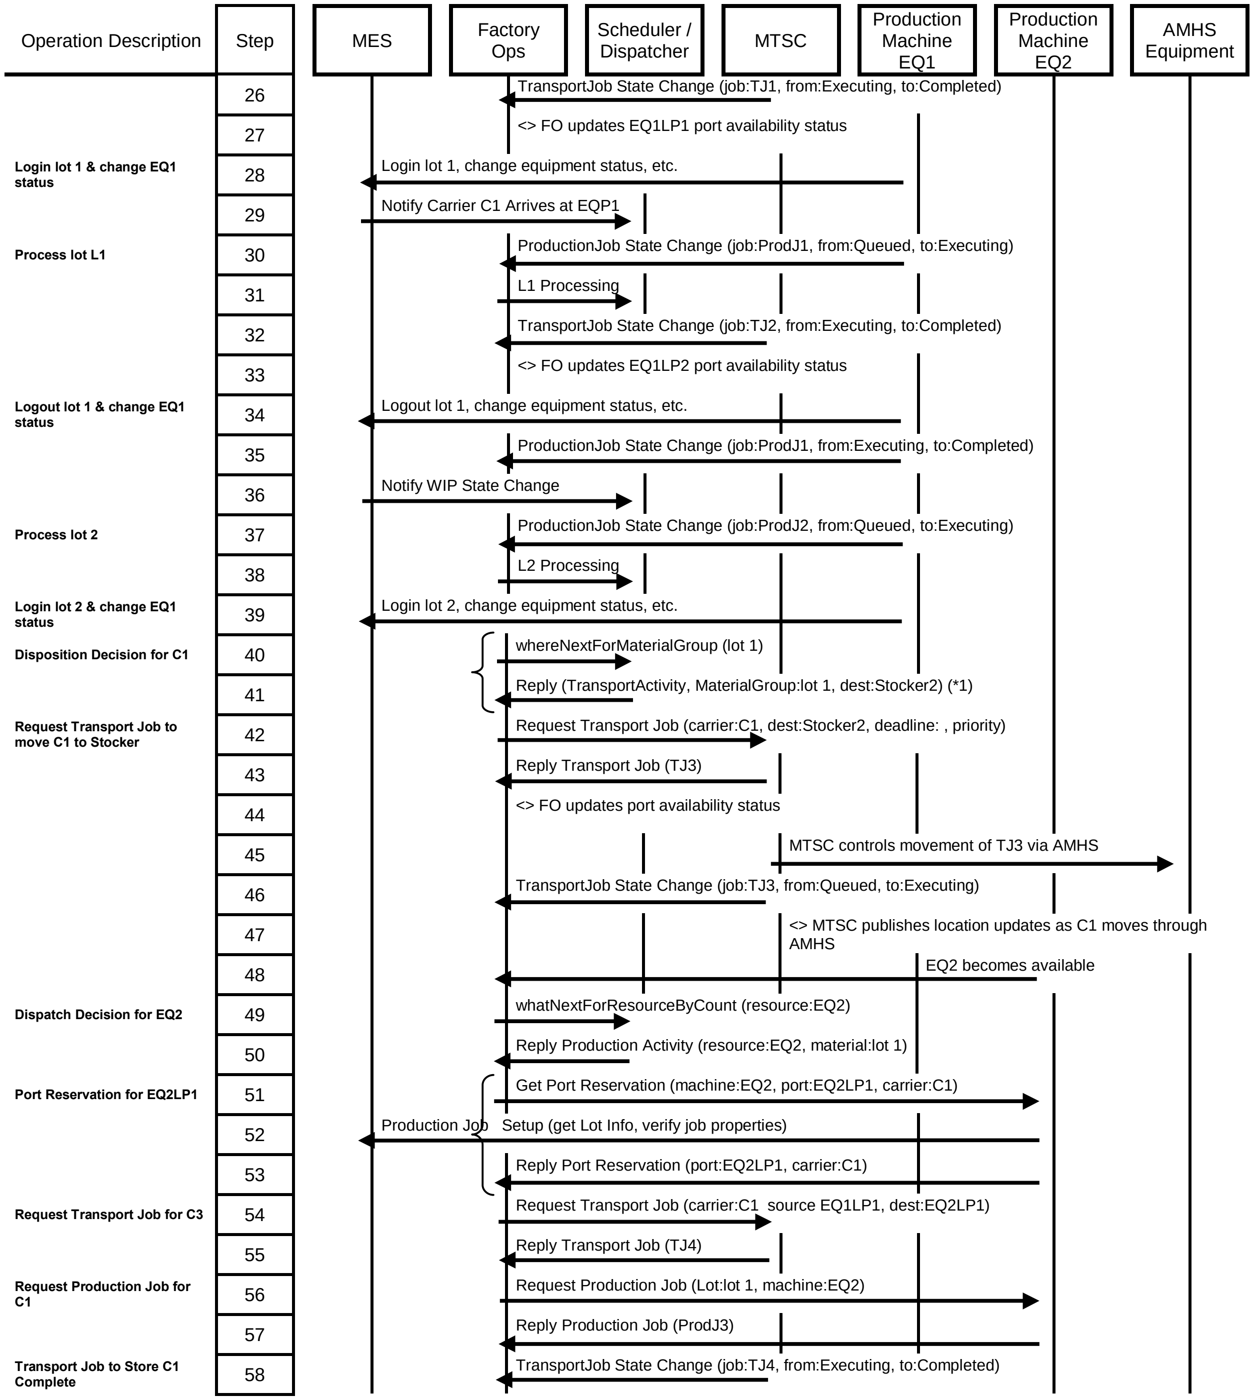
TransportJob State Change (job:TJ3, from:Executing, to:Completed)

R2-6 *Scenario 6* — Dispatch List Based Scheduler/Dispatcher, Stocker is managed by Scheduling Component

R2-6.1 Dispatch list based. EQ1->Stocker->EQ2. After lot 1 processing on EQ1 is finished, Scheduler assigns lot 1 to EQ2. FO checks the EQ2 port status and finds the available port. Scheduler makes the logistic decision to transfer lot 1 "from EQ1 to Stocker 2" instead of "from EQ1 to EQ2". Scheduler assigns lots to Stocker when the next equipment is not available. In this scenario 6, the separate transfers "from EQ1 to Stocker 2" and "from Stocker 2 to EQ2" are described.







(*1) Scheduler/Dispatcher checks the next equipment EQ2 status and port availability. EQ2 Status: Processing, Available Ports: No vacant port. Scheduler/Dispatcher decides to transfer lot 1 to Stocker 2.

RELATED INFORMATION 3
ASSUMED CASE OF SCHEDULER/DISPATCHER

NOTE: This related information is not an official part of SEMI E105. This related information was approved for publication by full letter ballot procedures on February 1, 2001.

The assumed two cases of scheduler/dispatcher were used to have an analysis and to make scenarios when the interfaces defined in SEMI E105 ware developed. This related information describes the assumed two case of scheduler/dispatcher to make easier for the standard user to understand SEMI E105. SEMI E105 does not limit the case of Scheduler/Dispatcher to these two assumed scheduler/dispatcher.

R3-1 *Dispatch List Based Scheduler/Dispatcher*

R3-1.1 *Basic Functions*

Dispatch List Based Scheduler/Dispatcher has a waiting lots list in each operation and has a capability to prioritize the existing lots.

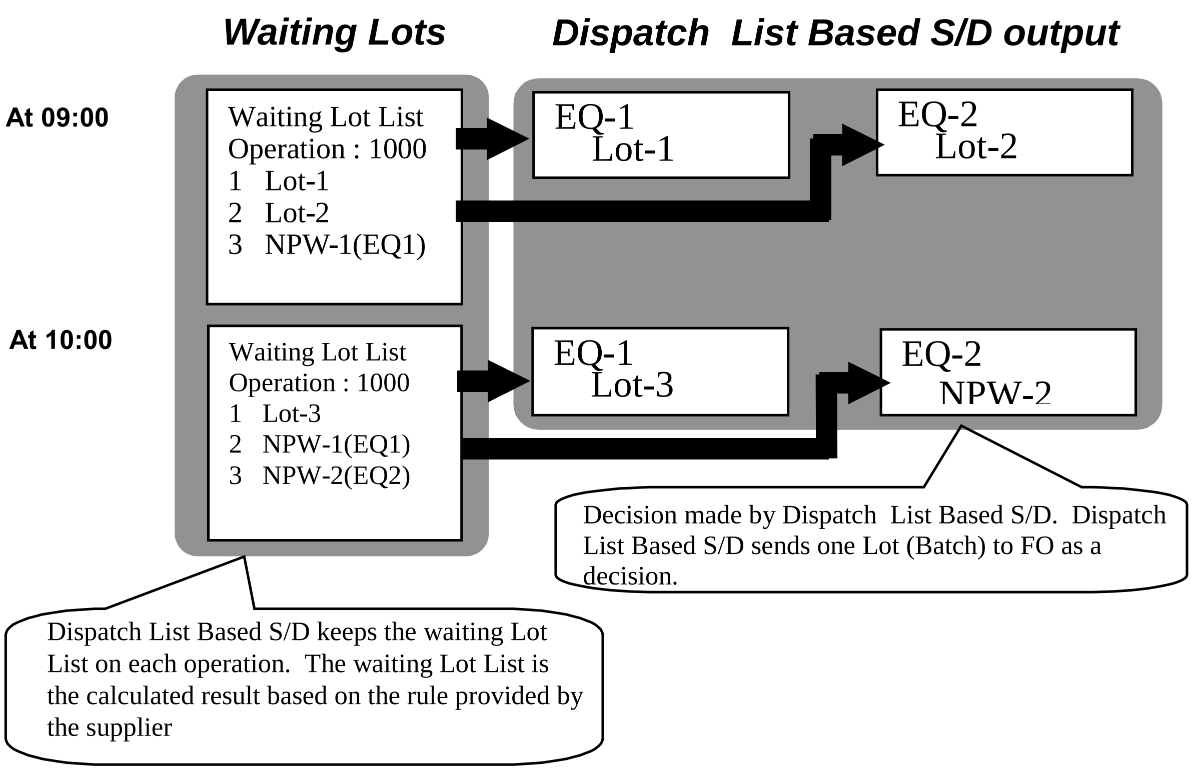


Figure R3-1

R3-1.2 *Case 1* – Factory Operation decides storage machine (Refer to Scenarios R2-3 and R2-4)

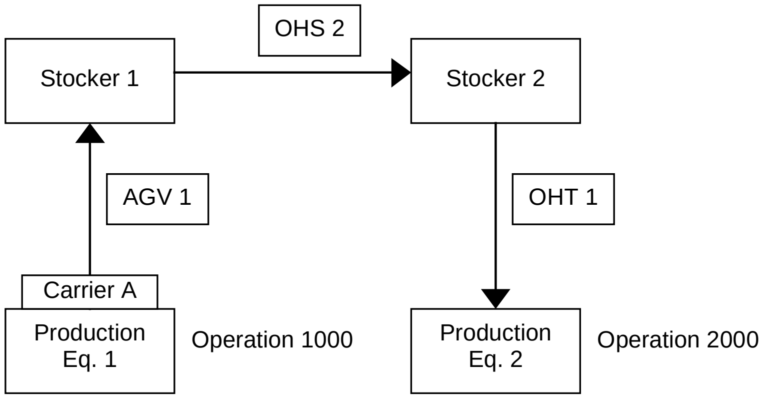

Figure R3-2

1. Carrier A processing on Eq.1 (Operation 1000) is finished.
2. Next operation for Carrier A is “2000” and the production equipment in operation “2000”is Eq.2 only.
3. Factory Operation makes the logistic decision .

(1) Transfer Carrier A from Eq.1 to Eq.2

or

(2) Transfer Carrier A from Eq.1 to Stocker 2.

4. Factory Operation uses the following interfaces defined in section 6.1.6. (*1)

- whatNextForResourceByCount
- whatNextForMaterialGroupByCount
- whatNextForDurableByCount

5. Factory Operation dose not use the following interfaces defined in section 6.1.6. (*1)

- whereNextForMaterialGroup
- whereNextForDurable

6. Scheduler / Dispatcher shows the waiting Lot list in operation “2000” (Eq.2) to Factory Operation

R3-1.2 *Case 2* – Scheduler / Dispatcher decides storage machine (Refer to Scenarios R2-5 and R2-6)

1. Carrier A processing on Eq.1 (Operation 1000) is finished.
2. Next operation for Carrier A is “2000” and the production equipment in operation “2000”is Eq.2 only.
3. Scheduler / Dispatcher checks the port status of Eq.2 and makes the logistic decision .

(1) Transfer Carrier A from Eq.1 to Eq.2

or

(2) Transfer Carrier A from Eq.1 to Stocker 2.

4. Factory Operation uses the following interfaces defined in section 6.1.6. (*1)

- whatNextForResourceByCount
- whereNextForMaterialGroup
- whereNextForDurable

5. Factory Operation dose not use the following interfaces defined in section 6.1.6. (*1)

- whatNextForMaterialGroupByCount
- whatNextForDurableByCount

R3-2 *Simulator Based Scheduler/Dispatcher (Refer to Scenarios R2-1 and R2-2)*

R3-2.1 *Basic Functions*

Simulator Based Scheduler / Dispatcher has a forecast list for each production equipment and provides the lot list with forecast time stamp to Factory Operation.

Factory Operation uses “forecastFor…” interfaces defined in section 6.1.6. (*1)

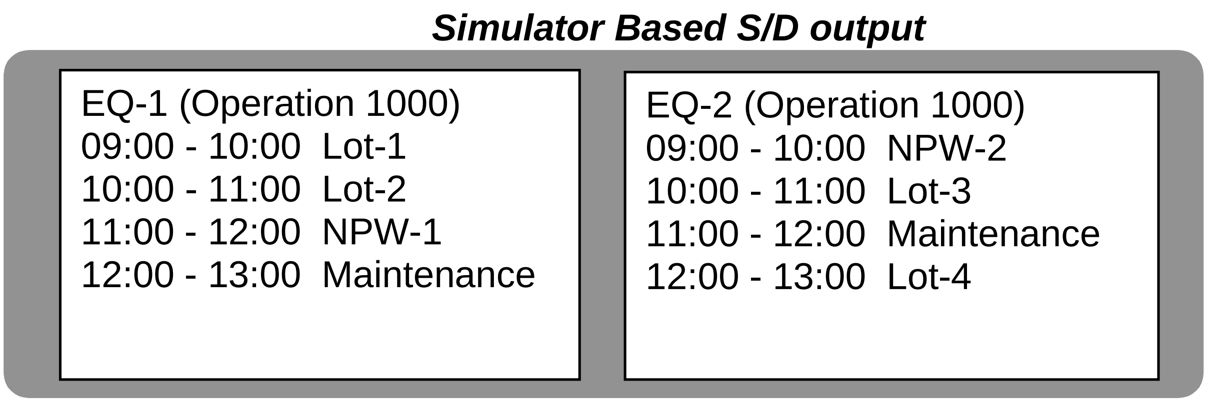

Figure R3-3

Remarks

In (*1), the conformance of each interfaces to each case of Scheduler/Dispatcher are described. These are only for reference and are not the requirement to the Scheduler/Dispatcher product. For example, Simulator Based Scheduler / Dispatcher may support “whatNextFor…” interfaces.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer’s instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user’s attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI E107-1101
PROVISIONAL SPECIFICATION OF ELECTRIC FAILURE LINK DATA FORMAT FOR YIELD MANAGEMENT SYSTEM

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the Japanese Information & Control Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published March 2001.

1 Purpose

1.1 The objective of this document is standardization of the specific data format passed from the test equipment to the Yield Management System. The Yield Management System is a kind of data server for detail test data and geometrical defect data of patterns on a wafer as described in the Terminology section of this document.

1.2 This document assumes a Yield Management System in which test equipment electrical failure information is managed and analyzed in an integrated manner. Examples of test equipment failure information include bit map data, bin data, and inpsection information obtained by devices such as wafer inspection equipment and review tools. Standardization of the data file format helps to reduce the development burden on customers and related vendors.

2 Scope

2.1 This document specifies the data file format for transferring from test equipment to a Yield Management System.

2.2 This document is an extension of the general map data item standard, i.e. SEMI G81, and the general map data format document, currently under development. This document does not redefine the general specification.

2.3 The scope of this document is just defining data items and their formats. Data file creation methods, data creating environments and file naming conventions are outside of the scope of this document. Also, communication protocols to transfer the data are beyond the scope of this document.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This document has provisional status because the common Specification for Map Data Format and a general map data format document are currently under development. Data format is related to YMS Link and this needs to be completed in Section 8.1.6, Map Data Format for YMS Link to be in conformance. In addition, the example of data file in Related Information must be revised and the idea of Map Data Format for YMS Link Data should be removed.

NOTE 1: A standard for Map Data Format is currently under development.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communication Standard 2 Message Content (SECS-II).

SEMI E30.1 — Inspection and Review Specific Equipment Model (ISEM).

SEMI G81 — Specification for Map Data Items

NOTE 2: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *analog data* — One of three categories of data: measured values such as voltage or current obtained when test equipment measures a semiconductor device's electrical characteristics, parameter values which are test parameters when measuring, and limit values which are decision parameters if test results are pass or fail.

5.2 *bin data* — same as Category below.

5.3 *fail bit map data* — data representing memory cell electrical failure information according to its location information, in units of the die or wafer.

5.4 *category* — data indicating the type of electric failure or rank of characteristics of die tested by the test equipment. Used in the same manner as Bin Data in this standard.

5.5 *cell-logical-address* — gives the electrical location of a memory cell in a die.

5.6 *cell-logical-io-number* — number identifying the IO data which can be simultaneously electrically accessed within a memory device.

5.7 *cell-physical-address* — gives location of a memory cell in a die on two-dimensional plane.

5.8 *die* — a unit equivalent to one die on a wafer. Also known as Chip.

5.9 *electrical failure information* — failure information generated by test equipment; e.g. Bit Map Data, Bin Data and Analog Data.

5.10 *error class* — specifies the type of electrical failure configuration in a memory cell group. Bit-fail, line-fail and block-fail are examples.

5.11 *inspection information* — inspection results for a wafer, indicating defect location and defect details obtained as the result of inspection used in wafer fabrication and the inspection process, such as appearance inspection, contaminant inspection, etc.

5.12 *test equipment* — equipment which tests the electrical characteristics and functions of semiconductor devices.

5.13 *test program name* — name of program used on test equipment when testing a die electrically.

5.14 *yield management system (YMS)* — a system that stores visual inspection data of geometrical defects on wafer and electrical test data of each die. The system processes those data statistically to discover correlation between them. Correlation leads to discovery the cause of failures and understanding of production situation in order to help improve yield. Defect data is standardized in SEMI E30.1 (ISEM).

6 Requirements

6.1 *Map Data Item* — All map data items appear in map data except those standardized in this document shall be specified in the common map data item document, SEMI G81.

6.2 *Map Data Format* — All map data formats appear in map data except those standardized in this document shall be specified in a common map data format document currently under development.

7 General

7.1 *General File Format*

NOTE 3: A standard for Data representation is currently under development.

8 Description

8.1 The fail-bit map data item specifications defined in this document are shown in Table 2. The columns in this table are described in the following sections.

8.1.1 *Item Name Column* — The name by which the data item is referenced.

8.1.2 *Data Type Column* — The type of the data as defined in Table 1.

Table 1 Data Types and Sizes

Type	*Definition*
String	A string of ASCII characters from zero to “Size” characters in length.
Integer	A string of numeric characters (0..9) that represent an integer value.
Float	A string representing a floating point value in exponent format.

8.1.3 *Size Column* — See SEMI G81.

8.1.4 *Description Column* — See SEMI G81.

8.1.5 *Coordinate System Conventions* — See SEMI G81.

Table 2 Data Items for YMS Link

Item Name	*Data Type*	*Size*	*Description*
Comment	String	256	Comment Area. [Comment] = ‘Engineering Test’
TestProgramName	String	256	Name of test program when test equipment obtains test data. [TestProgramName] = ‘pro123a’
TestEquipmentId	String	256	Test equipment identification code. [TestEquipmentId] = ‘tester1’
DieCoordinate	String	13	The die coordinates’ origin location and coordinate axis direction for expressing location coordinates within a die. See Figure 2 and Table 7. [DieCoordinate] = ‘TopLeftXY’ [DieCoordinate] = ‘BottomLeftXY’ [DieCoordinate] = ‘TopLeftYX’

Item Name	*Data Type*	*Size*	*Description*
			[DieCoordinate] = 'BottomLeftYX' [DieCoordinate] = 'TopRightXY' [DieCoordinate] = 'BottomRightXY' [DieCoordinate] = 'TopRightYX' [DieCoordinate] = 'BottomRightYX'
ErrorClassList	String	---	Error type category list, per error class definition. See Figure 2.
ErrorClassNumber	String	3	Error class number from 0 to 255.
ErrorQuality	String	16	Describes the quality of the specified [ErrorClassNumber]. This may be "bit-fail" or "line-fail" or some other value defined by an application.
ErrorDescription	String	256	A description of the specified [ErrorClassNumber], e.g. "100MHz".
FailBitDataTemplate	String	---	Defines the data items and order for expressing the fail bit error class data analyzed within a die by die address and coordinate values within the die. See Figure 2. Defines the items and order for outputting the following fail bit data. See Table 3.
FailBitData	String	---	The list of data expressing the fail bit error class. Data analyzed within a die in accordance with the fail bit data definition. Expresses it as die address and coordinates within a die. See Figure 2.
AnalogDataTemplate	String	---	Defines analog data items and order. These are measured values such as voltage, current, etc. on measuring semiconductor device's electrical characteristics by the test equipment, setting values which are test parameters when measuring, and limit values which are decision parameters if test results are pass or fail. See Table 4.
Invalid	String	14	Defined to indicate invalid data for Analog Data field.
AnalogData	String	---	List of analog data, per analog data definition. These are the semiconductor device's electrical characteristics measured by the test equipment.
ErrorTotal	Integer	10	Total number of electrical errors in the tested/analyzed substrate, by error class type.
TestDie	Integer	10	Total number of dies which were tested/analyzed on the substrate.

Table 3 Data Items for FailBitDataTemplate

Item Name	*Data Type*	*Size*	*Description*
Seq	Integer	10	Sequential number assigned in ascending order, starting with 1.
XAddress	Integer	5	X address of defective die with fail bit data.
YAddress	Integer	5	Y address of defective die with fail bit data.
XMin	Float	14	X minimum coordinate value of fail bit data's error range. Unit 'um'.
XMax	Float	14	X maximum coordinate value of fail bit data's error range. Unit 'um'.
YMin	Float	14	Y minimum coordinate value of fail bit data's error range. Unit 'um'.
YMax	Float	14	Y maximum coordinate value of fail bit data's error range. Unit 'um'.
XCenter	Float	14	X-direction center point coordinate value of fail bit data's error range. Unit 'um'.
YCenter	Float	14	Y-direction center point coordinate value of fail bit data's error range. Unit 'um'.
XSize	Float	14	X-direction size of fail bit data's error range. Unit 'um'.
YSize	Float	14	Y-direction size of fail bit data's error range. Unit 'um'.
Area	Float	14	Area of fail bit data's error range. Unit 'um'.
DefectCate	String	16	Category name of fail bit data.
XMinPhysic	Integer	10	X minimum cell physical address of fail bit data's error range.
XMaxPhysic	Integer	10	X maximum cell physical address of fail bit data's error range.
YMinPhysic	Integer	10	Y minimum cell physical address of fail bit data's error range.

Item Name	*Data Type*	*Size*	*Description*
YMaxPhysic	Integer	10	Y maximum cell physical address of fail bit data's error range.
IoNumber	Integer	10	Cell logical IO number of fail bit data's error range.
XMinLogic	Integer	10	X minimum cell logical address of fail bit data's error range.
XMaxLogic	Integer	10	X maximum cell logical address of fail bit data's error range.
YMinLogic	Integer	10	Y minimum cell logical address of fail bit data's error range.
YMaxLogic	Integer	10	Y maximum cell logical address of fail bit data's error range.

Table 4 Data Items for AnalogDataTemplate

Item Name	*Data Type*	*Size*	*Description*
XAddress	Integer	5	X address of die with analog data.
YAddress	Integer	5	Y address of die with analog data.
TestNumber	Integer	7	Test number corresponding to analog data.
Note	String	256	Note
Measure	Float	14	Analog data measured value.
MeasureUnit	String	4	Unit of above. See Tables 5 and 6.
Std	Float	14	Standard deviation, etc., for measuring analog data.
Parameter	Float	14	Analog data measurement parameter value.
ParameterUnit	String	4	Unit of above. See Tables 5 and 6.
UpperLimitData	Float	14	Upper limit of first type of parameter for judging analog data.
LowerLimitData	Float	14	Lower limit of first type of parameter for judging analog data.
TestResult	String	256	Analog data PASS/FAIL or decision result such as category type number, etc.

Table 5 Unit Table

Unit Code	*Description*
s	Seconds
Hz	Hertz
A	Amperes
V	Volts
Ohm	Ohms
W	Watts
F	Farad
H	Henry
%	Percent
dB	Decibel
lsb	Least Significant Bit
rad	Radian
deg	Degree

Table 6 Prefix Symbol Table

Prefix Symbol	*Multiplicative*
T	10^{12}
G	10^{9}
M	10^{6}
k	10^{3}
m	10^{-3}
u (micro)	10^{-6}
n	10^{-9}
p	10^{-12}

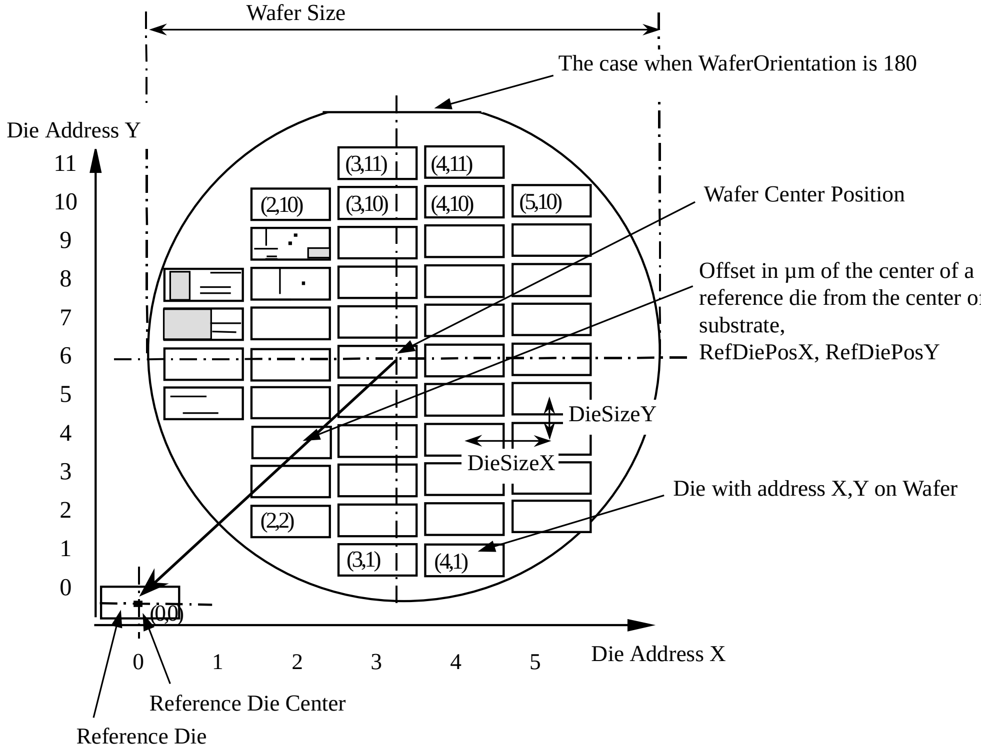
Example:

[MeasureUnit] = 'V' or 'mV'

[ParameterUnit] = 'A' or 'uA'

The units above are a subset of those in Section 9 ("Units of Measure") of SEMI E5 (SECS-II).

8.1.6 *Map Data Format of YMS Link* — This section is reserved for data format of above items.



(The case of BottomLeft)

R1-3 An Example of Format in XML

R1-3.1 Following format definitions are potential map data formats in XML. Because basic map data format specification is standardization process, this document reserves data format until the basic format is standardized, to keep consistent with the document. Following descriptions are just examples to help understanding.

R1-3.2 The first example result in longer file but more descriptive. Templates for Fail-bit Data and Analog Data are eliminated and components of each data unit expressed as attributes rather than data elements.

```

SEMI E109-0302
PROVISIONAL SPECIFICATION FOR RETICLE AND POD MANAGEMENT (RPMS)

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Facilities Committee on October 14, 2001. Initially available at www.semi.org Decemeber 2001; to be published March 2002. Originally published July 2001.

1 Purpose

1.1 This document provides standardized behavior for lithography, reticle inspection, and bare reticle stocker equipment. It also provides for standardized communication with lithography, reticle inspection, and bare reticle stocker equipment. This includes the coordination, execution, and completion of automated and manual reticle pod transfers to and from the equipment, transfer of reticles to and from the reticle pods, movement of the reticles within the equipment, identification and verification of both reticle pods and reticles, inspection and qualification of reticles, and other relevant information such as tracking reticle usage.

2 Scope

2.1 This is a provisional standard that covers host and equipment communication for equipment that handle reticles. This only includes equipment that handle reticles both in and outside of a reticle pod. The provisional status is required because of the immaturity of implementations of integrated equipment with Automated Material Handling Systems (AMHS) or Automated Reticle Handling Systems (ARHS), and additional specifications may yet be defined to add further functionality. Also, further exception handling and error recovery scenarios need to be defined.

2.2 The scope of this document is to define standards that facilitate the host's knowledge and role in automated and manual reticle pod transfers, reticle transfers to and from the reticle pod, internal reticle movement, identification and verification of ReticleID, inspection and qualification of reticles, and tracking reticle usage. Specifically, this document provides state models and scenarios that define the host interaction with the equipment for the following:

- Reticle pod transfer between AMHS vehicles and production equipment, bare reticle stockers, and reticle inspection equipment reticle load ports.
- Reticle transfers to/from lithography production equipment internal reticle library space.
- Equipment and reticle load port access mode switching.
- Reticle Pod to load port association.
- Reticle Pod ID verification and Reticle Pod slot map verification.

2.3 In order for the provisional status to be removed, the following issues must be resolved:

- Linkage to process job management standard.
- Implementations of this standard must prove validity of the standard before the provisional status can be removed.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard applies to semiconductor equipment that handles reticles and reticle carriers. This standard is intended to be used for lithography production, bare reticle storage, and reticle inspection equipment. It may or may not be applied to other types of equipment.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load port

SEMI E30 — Generic Model for Communications and Control of SEMI Equipment (GEM)

SEMI E39 — Object Services Standard: Concept, Behavior, and Services

SEMI E41 — Exception Management (EM) Standard

SEMI E53 — Event Reporting

SEMI E84 — Specification for Enhanced Carrier Handoff Parallel I/O interface

SEMI E99 — Carrier ID Read/Write Functional Standard

SEMI E100 — Specification for a Reticle SMIF Pod (RSP) Used to Transport and Store 6 inch or 230 mm Reticles

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *AGT* — Automated Guided Transport

5.1.2 *AGV*— Automated Guided Vehicle

5.1.3 *AMHS* — Automated Material Handling System

5.1.4 *ARHS* — Automated Reticle Handling System

5.1.5 *GEM* — Generic Equipment Model

5.1.6 *IRL* — Internal Reticle Library

5.1.7 *OHT* — Overhead Hoist Transport

5.1.8 *PGV* — Person Guided Vehicle

5.1.9 *PIO* — Parallel Input/Output Interface

5.1.10 *RGT* — Rail Guided Transport

5.1.11 *RGV* — Rail Guided Vehicle

5.1.12 *RSP* – Reticle SMIF Pod

5.2 *Definitions*

5.2.1 *Automated Material Handling System* — an automated system to store and transport materials within the factory.

5.2.2 *Automated Reticle Handling System* — a specific type of Automated Material Handling System to store and transport reticles and reticle pods within the factory.

5.2.3 *automation* — the degree to which activities of machines or production systems are self-acting. In this standard automation provides methods that will reduce the amount of operator intervention required.

5.2.4 *buffer* — a set of one or more locations for holding reticles at/inside the production equipment.

5.2.5 *collection event* — a collection event is an event (or grouping of related events) on the equipment that is considered to be significant to the host.

5.2.6 *content map* — Ordered list of reticle identifiers corresponding to slot 1,2,3…n. (Note that this is redundant with the definition in Table 6).

5.2.7 *host* — the factory computer system or an intermediate system that represents the factory and the user to the equipment.

5.2.8 *internal reticle library* — a set of locations within the equipment to store reticles. These locations exclude load ports.

5.2.9 *Internal Pod Buffer* — storage area for reticle pod that is internal to the equipment.

5.2.10 *load* — the operation of placing a pod on a load port.

5.2.11 *load port* — the interface location on the equipment where pods are loaded and unloaded.

5.2.12 *Multi-Reticle Pod* — TBD

5.2.13 *object instantiation* — the act of storing of information related to a physical or logical entity so that it can be recalled on demand based on its public identifier.

5.2.14 *on-line equipment* — equipment that is connected to, and able to communicate fully with, the host.

5.2.15 *pod* — in this document pod refers to an RSP or a Multi Reticle SMIF Pod.

5.2.16 *PodID* — a readable and unique identifier for the pod.

5.2.17 *PodID read* — the process of the equipment reading the PodID from the carrier.

5.2.18 *PodID tag (tag, ID tag)* — a physical device for storing PodID and other information. There are two basic types of tags, read-only tags and read/write tags. [SEMI E99]

5.2.19 *process equipment* — equipment used to produce product, such as semiconductor devices. This excludes metrology and material handling equipment.

5.2.20 *production equipment* — equipment used to produce product, such as semiconductor devices, including substrate sorting, process, and metrology equipment and excluding material handling equipment.

5.2.21 *properties* — a set of name value pairs assigned to an object or used in a service message to include additional information about the object (i.e., pod, port, etc.).

5.2.22 *re-initialization* — a process where production equipment is either powered off then on or when some kind of hardware or software reset is initiated to cause the equipment to reset and possibly reload its software. On production equipment that contains some kind of mass storage device this can also be called a "reboot".

5.2.23 *read position* — any position where the tag on a pod can be read.

5.2.24 *reticle* — a mask that contains the patterns to be reproduced on a substrate; the image may be equal to or larger than the final projected image.

5.2.25 *Reticle SMIF Pod (RSP)* — minienvironment compatible carrier capable of holding one 6 inch or one

230 mm reticle in a horizontal orientation during transport and storage and is compatible with a Standard Mechanical Interface (SMIF) per SEMI E19.4.

5.2.26 *single communication connection* — exactly one physical connection using exactly one logical session and a standard set of messages.

5.2.27 *slot map* — the information that relates which slots in a reticle pod hold reticles, both correctly and incorrectly.

5.2.28 *slot map read* — the process of the equipment reading the slot map for substrate position and placement within the pod.

5.2.29 *standard message set* — messages conforming to standard message specifications.

5.2.30 *transfer unit* — maximum number of pods allowed in a specific transfer service:

- AA is the maximum number of pods allowed for acquisition at the transfer source.
- BB is the maximum number of pods allowed for deposit at the transfer destination.
- CC is the maximum number of carrier pods allowed for transfer in one transport vehicle.

The transfer unit is the minimum of AA, BB, and CC.

NOTE 2: At the time this document was originally written, December 2000, transfer unit for reticle transfer to process equipment is expected to be equal to one. Transfer unit to other equipment may be greater than one.

5.2.31 *unload* — the operation of removing a pod from a load port.

5.2.32 *write position* — any position on a load port or in an internal buffer from which the tag on a pod can be written to. This position may vary on any particular equipment depending on the write technology selected by the end user. The read position and the write position may or may not be the same position.

6 Requirements

6.1 Reticle and Pod Management compliant equipment is required to provide certain capabilities defined by other standards: accessibility to status information, event reporting, alarm management, and equipment control. These requirements shall be satisfied through compliance to the following sets of standards:

6.2 *Generic Equipment Model Standard (GEM) SEMI E30*

- Event Notification
- Status Data Collection
- Equipment Constants
- Alarm Management
- Equipment Control
- Remote Control
- Error Messages
- Dynamic Event Report Configuration

6.3 *Object-Based Standards*

- Object Services Standard (SEMI E39)
- Event Reporting (SEMI E53)
- Exception Management (SEMI E41)

7 Conventions

7.1 *Objects*

7.1.1 Whenever the equipment is required to know about specific kinds of entities, and required to manage information concerning these entities, it is useful to treat these entities as objects that comply with the basic requirements of SEMI E39 (OSS). This is especially true whenever there are a large number of objects of a given type or when the entities are transient rather than permanent. In both cases, it is difficult to describe a general way for the host and equipment to specify which particular entity is referenced and to get information related only to a specific one out of many.

7.1.2 By defining these entities as objects that comply with SEMI E39, it is only necessary for the host to specify the type of object and its specific identifier in order to inquire about one or more properties of the specific entity of interest.

7.1.3 *Object Properties*

7.1.3.1 A property (attribute) is information about an individual object that is presented as a name/value pair. The name is a formally reserved text string that represents the property, and the value is the current setting for that property.

7.1.3.2 Properties shall be accessible to the host via the service GetAttr and SetAttr for the Reticle Pod object. Reticle object, and Reticle location object.

- get the list of IDs for the current reticle pods at the equipment, and
- get the specified properties for one or more individual reticle pods.

7.1.4 *Rules for Object Properties*

- Attributes with RO access can not be changed using SetAttr service as defined in OSS.

- Attributes with RW access can be changed using SetAttr service as defined in OSS.
- Additional attributes may be specified by the user or the equipment supplier by using an attribute name starting with "UD" (User Defined). Care should be taken to ensure the name of the attribute is unique.

7.1.5 *Object Attribute Table*

7.1.5.1 The object attribute table is used to list all the attributes related to the defined object as shown below the access is defined as Read only (RO) or Read/Write (RW). The REQD column is used to specify whether the attribute is required for implementation. Finally, the Form column is used to specify the format of that particular attribute.

Table 1 Object Attribute Table

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type	RO	Y	Text = "Carrier"

7.2 *State Model Methodology*

7.2.1 A state model has three elements: definitions of each state and sub-state, a diagram of the states and the transitions between states, and a state transition table. The diagram of the state model uses the Harel State Chart notation. An overview of this notation is presented in an Appendix of SEMI E30. The definition of this notation is presented in Science of Computer Programming 8, "Statecharts: A Visual Formalism for Complex Systems", by D. Harel, 1987.[1]

7.2.2 *State Model Requirements*

7.2.2.1 The state models included in this standard are a requirement for RPMS compliance. A state model consists of a state model diagram, state definitions, and a state transition table. All state transitions in this standard, unless otherwise specified, shall correspond to collection events.

7.2.2.2 A state model represents the host's view of the equipment, and does not necessarily describe the internal equipment operation. All Reticle and Pod Management state model transitions shall be mapped sequentially into the appropriate internal equipment collection events that satisfy the requirements of those transitions. In certain implementations, the equipment may enter a state and have already satisfied all of the conditions required by the RPMS state model for transition to another state. In this case, the equipment makes the required transition without any additional actions in this situation.

7.2.2.3 Some equipment may need to include additional sub-states other than those in this standard. Additional sub-states may be added, but shall not change the Reticle and Pod Management defined state transitions. All expected transitions between Reticle and Pod Management states shall occur.

7.2.2.4 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition table contains columns for Transition number, Previous State, Trigger, New State, Actions, and Comments. The "trigger" (column 3) for the transition occurs while in the "previous" state. The "actions" (column 5) includes a combination of:

- Actions taken upon exit of the previous state.
- Actions taken upon entry of the new state.
- Actions taken which are most closely associated with the transition.

Table 2 State Transition Table

Num	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*

1 Elsevier Science, P. O. Box 945, New York, NY 10159-0945, http://www.elsevier.nl/homepage/browse.html

7.3 *Services*

7.3.1 Services are functions or methods that may be provided by either the equipment or the host. A service message may be either a request message, which always requires a response, or a notification message that does not require a response.

7.3.2 *Service Message Description*

7.3.2.1 A service message description table defines the parameters used in a service, as shown in the following table:

Table 3 Service Message Description Table

Service Name	*Type*	*Description*

NOTE 1: Type can be either "N" = Notification or "R" = Request & Response.

7.3.2.2 Notification type messages are initiated by the service provider (e.g., the equipment) and the provider does not expect to get a response from the service user. Request messages are initiated by a service user (e.g., the host). Request messages ask for data or an activity from the provider. Request messages expect a specific response message (no presumption on the message content).

7.3.3 *Service Message Parameter Definition*

7.3.3.1 A service parameter dictionary table defines the description, range, and type for parameters used by services, as shown in the following table:

Table 4 Service Message Parameter Definition Table

Parameter Name	*Form*	*Description*

NOTE 1: A row is provided in the table for each parameter used on a service.

7.3.4 *Service Message Definition*

7.3.4.1 A service message description table defines the parameters used in a service message. It also describes each message and its cause/effect to the equipment. The columns labeled Req/Ind and Resp/Conf link the parameters to the direction of the message.

Service Parameter	*Req/Ind*	*Resp/Conf*	*Description*

7.3.4.2 The columns labeled Req/Ind and Rsp/Conf link the parameters to the direction of the message. The message sent by the initiator is called the "Request". The receiver terms this message the "Indication". The receiver may then send a "Response", which the original sender terms the "Confirmation".

7.3.4.3 The following codes appear in the Req/Ind and Rsp/Conf columns and are used in the definition of the parameters (e.g., how each parameter is used in each direction):

"M"	Mandatory Parameter – must be given a valid value.
"C"	Conditional Parameter – may be defined in some circumstances and undefined in others. Whether a value is given may be completely optional or may depend on the values of other parameters.
"U"	User-Defined Parameter.
"-"	The parameter is not used.
"="	(for response only) Indicates that the value of this parameter in the response must match that in the primary (if defined).

7.4 *Alarm Requirements Definition*

7.4.1 An alarm requirements definition table defines the specific set of alarms required by RPMS. The table is divided up by equipment configuration, and then by alarm. The danger and affected columns are marked with "X" characters to show each alarm and its possible impact to operators, equipment, and material. The table format is shown in the following example:

Equipment		*Danger*		*Affected*		
Configuration	*Alarm Text*	*Potential*	*Imminent*	*Operator*	*Equipment*	*Material*
Configuration 1	Alarm 1	X		X	X	X
	Alarm 2		X			X
Configuration 2	Alarm 3	X		X	X	
	Alarm 4	X			X	X

8 Overview

8.1 The Reticle and Pod Management standard defines the behavior, data, and services required for equipment supporting automated reticle pod transfer, reticle pod management, and reticle management. This document provides a standard interface for host/equipment communications regarding the transfer of reticle pods, reticle pod identification and verification, transfer of reticles to and from equipment, reticle identification and verification, reticle inspection and qualification, and tracking of reticles. The standardized reticle pod transfer host interface include transfers to and from the external reticle load ports and internal reticle pod locations, the standardized reticle host interface include transfers to and from the reticle pod, transfers to and from the internal reticle library positions, and reticle identification, inspection, verification, qualification and tracking of reticles.

8.2 *Single Connection Requirement*

8.2.1 The expectation of the production and storage equipment supplier is that this standard be implemented in conjunction with the GEM interface to their production equipment and without the use of a separate communication connection.

9 Load Port

9.1 A reticle pod load port (port) is used by the factory to load and unload reticle pods to and from Lithography, reticle inspection, and bare reticle storage equipment. A reticle pod load port may be used as a reticle pod input load port, a reticle pod output load port, or as a reticle pod input/output load port, depending upon equipment type, configuration and/or factory practices. This classification may be fixed or it may be programmable by the user. A reticle pod load port is generally designed to handle one specific carrier type, reticle SMIF pods (RSP).

9.1.1 The equipment supplier is free to implement Load Ports as objects, but this is not a requirement for compliance to this standard.

9.2 *Load Port Numbering*

9.2.1 The reticle pod load port number shall be assigned incrementally from the bottom left to bottom right, then top left to top right when facing the reticle load ports. The numbering system should start with 101 to differentiate from FOUP load ports. The reticle pod load port-numbering requirement is to provide a common reference base to external entities, such as humans.

9.3 *Reticle Pod Slot Numbering*

9.3.1 The slot numbers for a reticle pod shall be assigned incrementally from the bottom, starting with "1."

9.4 *Reticle Pod Load Port Resource Sharing*

9.4.1 A model of a reticle pod load port must account for any mechanical assemblies that are either active during reticle pod transfer or are capable of interacting with the transfer. The reticle pod load port is responsible for such mechanisms when the reticle pod load port is in the TRANSFER READY state. If these mechanisms are shared with other reticle pod load ports, then the sharing must be coordinated.

9.5 *Reticle Pod Load Port Transfer State Model*

9.5.1 The purpose of the Reticle Pod Load Port Transfer State Model is to define the host view of a reticle pod transfer, which includes the host interactions with the equipment necessary to transfer reticle pods to and from equipment reticle pod load ports. Each reticle pod load port on the equipment shall maintain an independent instance of this state model.

9.5.2 *Reticle Pod Load Port Transfer State Model Diagram*

9.5.2.1 Figure 1 is the diagram for the Reticle Pod Load Port Transfer State Model.

9.5.3 *Reticle Pod Load Port Transfer State Definitions*

9.5.3.1 RETICLE POD LOAD PORT TRANSFER — The super state for the IN SERVICE and OUT OF SERVICE states.

9.5.3.2 OUT OF SERVICE — Transfer to/from this reticle pod load port is disabled. A transition to IN SERVICE is required to continue using this reticle pod load port for transfers.

9.5.3.3 IN SERVICE — Transfer to/from this reticle pod load port is enabled. A transition to OUT OF SERVICE disables the reticle pod load port for transfer use.

9.5.3.4 TRANSFER READY — A sub-state of IN SERVICE. The reticle pod load port is available for pod transfer. The transfer can either be manual or automated, and can be a load or an unload. This state contains two sub-states, which are used depending on whether or not a reticle pod is present on the load port (READY TO LOAD and READY TO UNLOAD).

9.5.3.5 READY TO LOAD — A sub-state of TRANSFER READY. When transitioning to the TRANSFER READY state, if a reticle pod is not present on the specified reticle pod load port, this is the active sub-state. In this state, the reticle pod load port is available to be loaded with an external reticle pod.

9.5.3.6 READY TO UNLOAD — A sub-state of TRANSFER READY. When transitioning to the TRANSFER READY state, if a reticle pod is present on the specified reticle pod load port, this is the active sub-state. In this state, the reticle pod load port is available for unloading of a reticle pod from the reticle pod load port to material handling equipment. When the reticle pod load port is being used by the equipment, the state shall transition to TRANSFER BLOCKED.

9.5.3.7 TRANSFER BLOCKED — The reticle pod transfer state is neither READY TO LOAD nor READY TO UNLOAD. Because of reticle pod load port related activity being performed, transfer is not available to/from this reticle pod load port at this time.

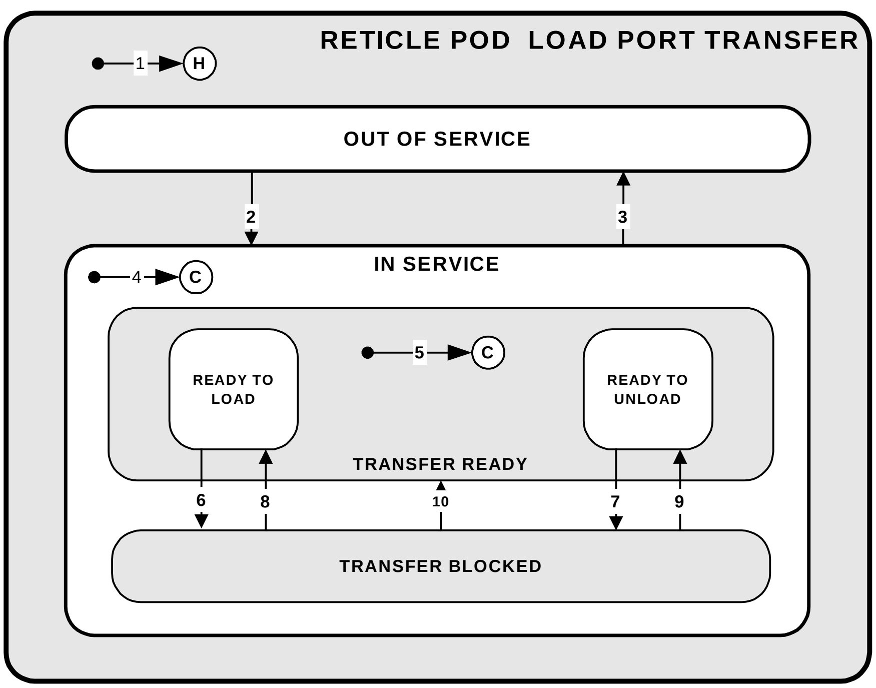

Figure 1
Reticle Pod Load Port Transfer State Model Diagram

9.5.4 *Reticle Pod Load Port Transfer State Transition Table*

Table 5 Reticle Pod Load Port Transfer State Transition Definition

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(no state)	System reset.	OUT OF SERVICE or IN SERVICE (History)		This transition is based on what the current transfer status was prior to system reset. Data required to be available for this event report: PortID
2	OUT OF SERVICE	The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of IN SERVICE.	IN SERVICE		Reticle Pod Load port is now usable for transfer. Data required to be available for this event report: PortID
3	IN SERVICE	The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of OUT OF SERVICE.	OUT OF SERVICE		Reticle Pod Load port is now rendered unusable for transfer. Attempted usage of the reticle pod load port for reticle pod transfer after the state transition results in an alarm. Data required to be available for this event report: PortID
4	IN SERVICE	*Service:* The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of IN SERVICE. *System Reset:* This transition can be activated by an equipment re-initialization.	TRANSFER READY or TRANSFER BLOCKED		This is the default entry into IN SERVICE. The state is TRANSFER BLOCKED if the reticle pod, or reticle pod load port, is not available for pod transfer. Otherwise, the state is TRANSFER READY. Data required to be available for this event report: PortID
5	TRANSFER READY	*Service:* The host or an operator has invoked the ChangeServiceStatus service for this load port with a value of IN SERVICE. *System Reset:* This transition can be activated by an equipment re-initialization. *Failed Transfer:* If a transfer fails, this transition is activated by transition #10.	READY TO LOAD or READY TO UNLOAD		When entering the TRANSFER READY state, if a reticle pod is present, the sub-state is READY TO UNLOAD, else the sub-state is READY TO LOAD. If the state is READY TO LOAD, data required to be available for this event report: PortID If the state is READY TO UNLOAD, data required to be available for this event report: PortID PodID
6	READY TO LOAD	*Manual*: "The equipment recognizes the logical indication of the start of a manual load transfer. This trigger is configurable by the user, examples are included in table 8." *Automated*: The PIO load transfer is beginning and the PIO ready signal is activated.	TRANSFER BLOCKED		Data required to be available for this event report: PortID

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
7	READY TO UNLOAD	*Manual*: The equipment recognizes a logical indication of the start of an unload transfer. *Automated*: The PIO unload transfer is beginning and the PIO ready signal is activated.	TRANSFER BLOCKED		Data required to be available for this event report: PortID
8	TRANSFER BLOCKED	*Manual:* The reticle pod unload transfer has completed, and the reticle load port is now empty and ready for load transfer. *Automated:* The PIO unload transfer ends with a PIO complete signal.	READY TO LOAD		Data required to be available for this event report: PortID
9	TRANSFER BLOCKED	*Manual: Activities using reticles contained within the pod have completed* the reticle pod is ready to be removed. *Automated:* Handling for reticles destined for the reticle pod has completed, or a CancelPod/ CancelPodAtPort service has been issued, and the reticle pod is ready to be removed. This is indicated by a PIO unload request signal.	READY TO UNLOAD		The reticle pod on the reticle pod load port can now be unloaded from the reticle load port to an external entity. Data required to be available for this event report: PortID PodID
10	TRANSFER BLOCKED	The transfer was unsuccessful, and the reticle pod was not loaded or unloaded.	TRANSFER READY		The sub-state of TRANSFER READY, which is decided by transition #5. Data required to be available for this event report: PortID

10 Reticle Pod Object

10.1 Information about a reticle pod is encapsulated as an object. This allows the host to exchange information with the equipment about one or more specific reticle pods using services defined in SEMI E39, Object Services Standard. A reticle pod has properties (attributes) that are defined in Table 6, Pod Attribute Definition.

10.2 *Object Instantiation*

10.2.1 The reticle pod object is a software representation of the reticle pod in the equipment. Under normal circumstances this object is instantiated by the equipment when the host uses the Bind, ReticleTransferJob, or PodNotification service or when the equipment successfully reads the PodID from the reticle pod. A reticle pod object is instantiated by PodID read only if there are no currently existing objects of the same object type with the PodID just read. A reticle pod object can also be instantiated by either the ProceedWithPod or CancelPod Services on an UNASSOCIATED port. (This implies a failed PodID read event.) The ContentMap attribute will be an empty list (a list of zero) when the instantiation is done by PodID read. The SlotMap attribute should be a list consisting of all slots enumerated as “UNDEFINED” when the reticle pod object is instantiated by PodID read.

10.2.2 From the host point of view, an object is instantiated if the host is able to query the equipment about that object, it' s current state, and other attributes. Once instantiated, the object is considered destroyed (no longer instantiated) if the response to such queries is “unknown object”.

10.2.3 Summary of reticle pod object instantiation:

1. Bind, ReticleTransferJob, or PodNotification Service;
2. PodID read with no currently existing pod objects having the PodID just read; and
3. ProceedWithPod or CancelPod Service on an UNASSOCIATED port with a pod.

10.2.4 *Reticle Pod Object Identifier (ObjID)*

10.2.4.1 The purpose of an Object Identifier is to allow references to an object within the system. The object identifier is created when an object is instantiated and should be unchanged or persistent until the end of the object lifecycle. The Object Identifier shall be unique at the equipment during lifecycle of the object. The PodID is the Reticle Pod Object Identifier. The equipment is responsible for ensuring uniqueness of the PodID prior to instantiation by the bind, pod notification, or ReticleTransferJob service.

10.2.5 *Reticle Pod Object Destruction*

10.2.5.1 Normally, the Reticle Pod Object reaches the end of its lifecycle when the reticle pod is unloaded from the equipment. Abnormally, the Reticle Pod Object reaches the end of it's lifecycle when a CancelBind, CancelReticleTransferJob, or CancelPodNotification service is executed prior to the reticle pod being loaded, or when an equipment based pod verification fails following pod instantiation by the bind service.

10.2.5.2 Summary of reticle pod object destruction:

1. A reticle pod is unloaded from the equipment;
2. A CancelBind, CancelReticleTransferJob or CancelPodNotification service is received; and
3. An equipment based verification fails (after the object has been instantiated via the bind services).

10.3 *Reticle Pod Attribute Definitions*

10.3.1 The following table contains the attributes that are of importance to the host and/or the equipment in order to manage the history and the reports about the reticle carrierpod object.

10.3.2 *REQD Column*

10.3.2.1 All attributes in the following table are required to be associated with the reticle pod object. However only the attributes marked with a "Y" in the REQD column are always required to be maintained and updated by the equipment. The attributes marked with an "N" in the REQD column are only required to be maintained if they are provided by the host by either the Bind, PodNotification, ReticleTransferJob or ProceedWithPod Services or if the equipment has means of determining the attribute values. (For example, if the equipment has a ReticleID reader, the equipment can determine the ContentMap).

10.3.3 *ACCESS Column*

10.3.3.1 Even though a value may be marked as RO (read only), the initial value for the attribute may be provided by the host when attached to either the Bind, PodNotification, ReticleTransferJob or ProceedWithPod services. The only other time the PodCapacityStatus attributes are updated is at the first ProceedWithPod service.

10.3.4 *Pod Attribute Definition Table*

Table 6 Pod Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type.	RO	Y	Text equal to "Reticle Pod".
ObjID	Object identifier.	RO	Y	Text 1 to 80 characters equal to the PodID.
Capacity	Maximum number of reticles in pod.	RO	Y	Positive integer. If a pod arrives at a load port with no warning the default value is one.
PodIDStatus	Current state of the PodID verification.	RO	Y	Enumerated: ID NOT READ, WAITING FOR HOST ON ID STATUS, ID VERIFICATION OK, ID VERIFICATION FAILED.
ReticlePodAccessing-Status	The current accessing state of the reticle pod by the equipment. The current substate of the ReticlePodAccessingStatus state model.	RO	Y	Enumerated: NOT AVAILABLE, AVAILABLE, IN ACCESS, COMPLETE
ContentMap	Ordered list of reticle identifiers corresponding to slot 1,2,3….n	RO	Y	Ordered list of n elements, where n is equal to the value of "Capacity" above, and each element consists of a ReticleID. When a slot has no reticle, the ReticleID value should be null.
ReticlePodLocationID	Identifier of current location of the reticle pod.	RO	Y	Text 1 to 80 characters.

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ReticlePodLocking-Status	The current state of pod locking by the equipment. The current substate of the ReticlePodLockingStatus.	RO	Y	Enumerated: NOT LOCKED, RELEASED AND LOCKED, HOLD
SlotMap	Ordered List of slot status as provided by the host until a successful slot map read, then as read by the equipment.	RO	Y	Ordered List of n elements where n is equal to the value of "Capacity" above. 1. Enumerated $_1$. n. Enumerated$_n$ Enumerated: UNDEFINED, EMPTY, CORRECTLY OCCUPIED. The number shown above is the slot number.
SlotMapStatus	Current state of slot map verification.	RO	Y	Enumerated: SLOT MAP NOT READ, WAITING FOR HOST ON SLOT STATUS, SLOT MAP VERIFICATION OK, SLOT MAP VERIFICATION FAILED.

10.3.5 *Rules for Reticle Pod Attributes*

- The equipment shall change object attributes, ContentMap, SlotMap, and Reticle count, provided by the host. All other attributes, such as LocationID, shall be set and maintained by the equipment.
- The attributes, Capacity, ContentMap, Reticle count, shall be provided with Bind, PodNotification, ReticleTransferJob, or ProceedWithPod service before or when SlotMap is provided.
- The SlotMap shall be provided with Bind, PodNotification, ReticleTransferJob or ProceedWithPod to verify PodID, when the SlotMap verification is equipment based. And it shall not be provided when the SlotMap verification is host based.
- Reticle pod properties may be provided before the reticle pod arrives as part of the Bind, PodNotification, or ReticleTransferJob service and should be retained until either a CancelBind, CancelPodNotification, or CancelReticleTransfer-Job service is received or the reticle pod is removed.
- Reticle pod properties may also be provided by the ProceedWithPod service. The reticle pod properties that are provided by the ProceedWithPod service may differ based whether or not the object is instantiated by the service.
- Reticle pod properties that are required shall be actively updated by the equipment.

10.3.6 *Reticle Pod Location*

10.3.6.1 A reticle pod location, signified by LocationID, is used for tracking. A reticle pod location is any physical area that is capable of holding a pod. It is not intended to represent entire mechanisms, which may have a variety of other properties of interest, but only that portion where a reticle pod may rest.

10.3.7 *Reticle Pod Location Examples*

10.3.7.1 Reticle Pod Locations include reticle pod load port locations, internal pod buffer locations, as well as grippers, conveyors, and elevators that are used internally for moving the pod from one fixed location to another.

10.3.8 *Slot Map Relation to Content Map* — The slot map attribute and content map attribute hold similar information. The purpose of these attributes differs. The slot map is provided so that the equipment or host can quickly verify that the pod has reticles correctly placed in the correct slot (as provided by the host). This verification is based on a slot map read. The content map is provided so that the host can communicate the specific ReticleID in a specific slot as delivered and that the equipment can communicate the specific ReticleID that it places in a specific slot.

10.3.9 *Reticle Pod Location Naming* — All locations shall be assigned a unique name. Information about the reticle pod location can be obtained by querying the Pod Object for the ReticlePodLocationID or by asking the equipment for the PodLocationMatrix. The text form of the ReticlePodLocationID shall be descriptive of the location.

10.3.10 *Capacity*

10.3.10.1 The Capacity parameter can be sent to the equipment by the host in either the PodNotification, Bind, ReticleTransferJob, or the ProceedWithPod service. However the equipment shall update this *10.3.10.2* parameter based on the results of the read slot map operation. Furthermore, the equipment shall update the parameter based on it's own actions. . If the equipment does not know the value of Capacity prior to instantiation, the equipment shall instantiate the reticle pod object with the value of one for Capacity.

10.3.11 *Reticle Pod Accessing Status*

10.3.11.1 The ReticlePodAccessingStatus is used by the host to know whether or not the reticle pod owned by the equipment can be transferred from the equipment.

10.3.11.2 Enumerated values of ReticlePodAccessing-Status correspond to the substates of ReticlePodAccessingStatus (see Figure 2).

10.4 *Reticle Pod State Model*

10.4.1 The purpose of the Reticle Pod State Model is to define the host's view of a reticle pod. The equipment shall maintain a separate and independent state model for each reticle pod in/at the equipment.

10.4.2 *Reticle Pod State Model Diagram*

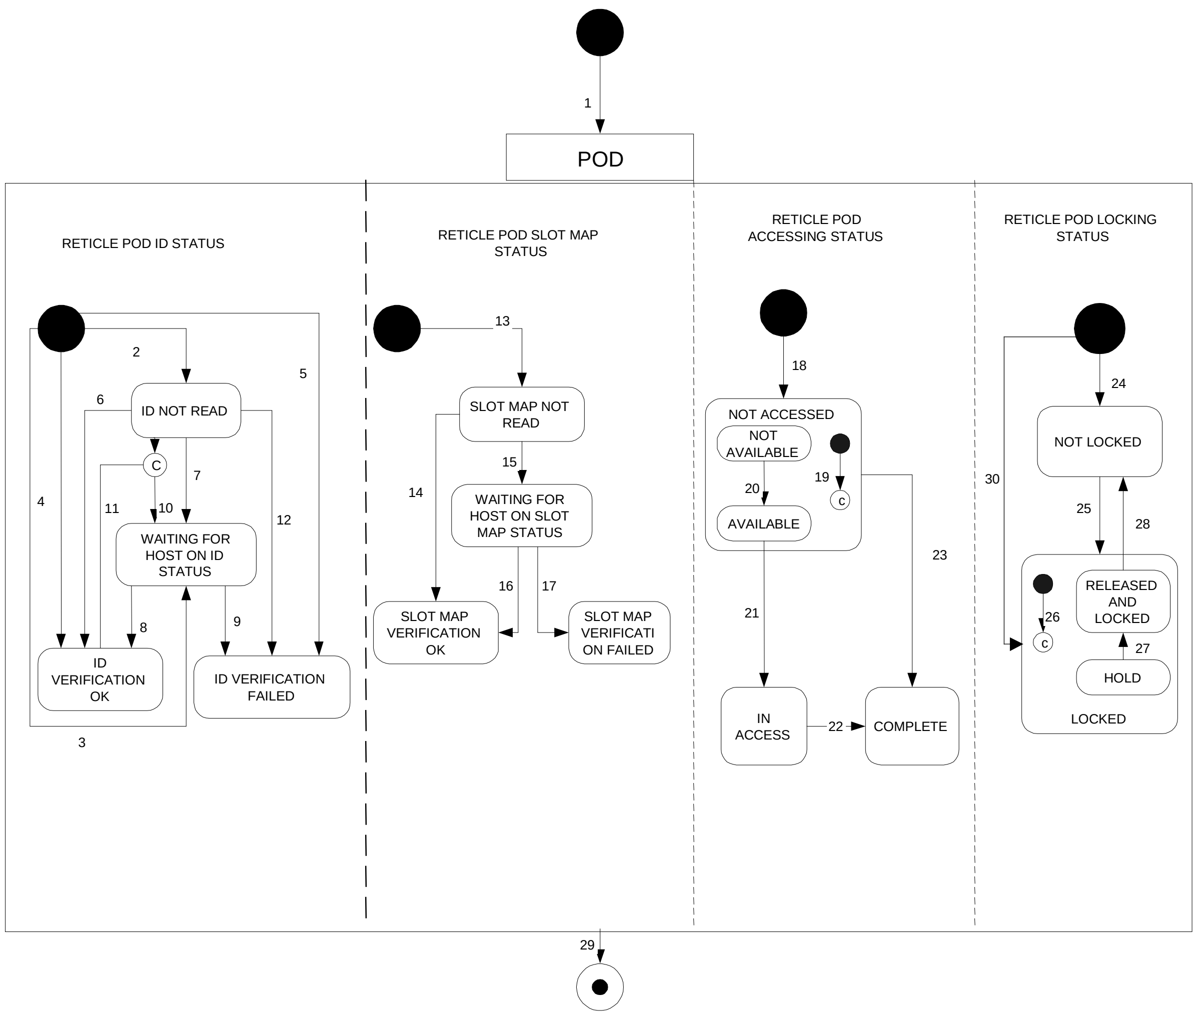

Figure 2
Reticle Pod State Model Diagram

10.4.3 *Reticle Pod State Definitions*

10.4.3.1 *RETICLE POD* — The RETICLE POD state has four ANDed (orthogonal) substates: RETICLE POD ID STATUS, RETICLE POD SLOT MAP STATUS, RETICLE POD ACCESSING STATUS, AND RETICLE POD CLAMPING STATUS.

10.4.3.1.1 *RETICLE POD ACCESSING STATUS* — This is a substate of RETICLE POD and indicates the current accessing status of the pod. It has three substates, NOT ACCESSED, IN ACCESS, and COMPLETE. The initial default entry substate is NOT ACCESSED.

10.4.3.1.1.1 *NOT ACCESSED* — This is a substate of RETICLE POD ACCESSING STATUS and is active when the reticle pod has not been opened. It has two substates NOT AVAILABLE and AVAILABLE.

10.4.3.1.1.1.1 *NOT AVAILABLE* — This is a substate of NOT ACCESSED and is active when the reticle pod has been instantiated via service but has not been received by the equipment.

10.4.3.1.1.1.2 *AVAILABLE* — This is a substate of NOT ACCESSED and is active when the reticle pod has been received by the equipment but not opened.

10.4.3.1.1.2 *IN ACCESS* — This is a substate of RETICLE POD ACCESSING STATUS and is active when reticle pod has been opened once, and the reticle pod should not be unloaded from the equipment. In this state the slot map is read and reticles may be moved in and out of the reticle pod.

10.4.3.1.1.3 *COMPLETE* — This is a substate of RETICLE POD ACCESSING STATUS and is active when all known activity, as defined by the ReticleTransferJob service, for the reticle pod has completed, or the PodComplete service has been received, and the reticle pod has been closed. The reticle pod may be unloaded from the equipment.

10.4.3.1.2 *RETICLE POD LOCKING STATUS* — This is a substate of RETICLE POD and indicates the current status of the pod with respect to removability.

10.4.3.1.2.1 *NOT LOCKED* — This is a substate of RETICLE POD LOCKING STATUS and is active when there are no physical or logical mechanisms that prevent removal of the reticle pod by an external entity.

10.4.3.1.2.2 *LOCKED* — This is a substate of RETICLE POD LOCKING STATUS and is active when there are physical mechanisms that prevent removal of the reticle pod by an external entity. It has two substates RELEASED AND LOCKED and HOLD.

10.4.3.1.2.2.1 *RELEASED AND LOCKED* — This is a substate of LOCKED and is active when the pod may be released by the equipment.

10.4.3.1.2.2.2 *HOLD* — This is a substate of LOCKED and is active when there are physical or logical mechanisms that prevent removal of the pod engaged and the pod release flag is set to host release and the PodRelease service has not been received.

10.4.3.1.3 *RETICLE POD ID STATUS* — This is a substate of RETICLE POD and indicates the current status of the pod with respect to its identifier. It has four substates, ID NOT READ, WAITING FOR HOST ON ID STATUS, ID VERIFICATION FAILED, ID VERIFICATION OK. The initial substate is conditional based on information the equipment has about the reticle pod. When the PodID is provided by the Bind, ReticleTransferJob, or the PodNotification service, the reticle pod object shall be instantiated in the ID NOT READ substate. When the PodID is provided by the PodID read, the reticle pod shall be instantiated in the WAITING FOR HOST ON ID STATUS substate. When the Reticle Pod is instantiated by the ProceedWithPod service, the reticle pod shall be instantiated in the ID VERIFICATION OK substate. Finally when the reticle pod is instantiated by the CancelPod service, the pod will be instantiated in the ID VERIFICATION FAILED substate.

10.4.3.1.3.1 *ID NOT READ* — This is a substate of RETICLE POD ID STATUS. This state is active whenever the PodID has not been read by the equipment.

10.4.3.1.3.2 *ID VERIFICATION FAILED* — This is a substate of RETICLE POD ID STATUS and is active when the PodID has verification by the host with the CancelPod service. This is a final state.

10.4.3.1.3.3 *ID VERIFICATION OK* — This is a substate of RETICLE POD ID STATUS and is active as soon as the PodID has been accepted. The ID is determined to be accepted by either successful verification by the equipment or the host, or by bypassing ID read because a PodID reader is not available and the BypassReadID variable is set to true. This is a final state.

10.4.3.1.3.4 *WAITING FOR HOST ON ID STATUS* — This is a substate of RETICLE POD ID STATUS and is active during the period of time when the PodID has been read by the equipment successfully or unsuccessfully and has not yet been verified.

10.4.3.1.4 *RETICLE POD SLOT MAP STATUS* — This is a substate of RETICLE POD and indicates the current status of the reticle pod with respect to its slot map. It has four substates, SLOT MAP NOT READ,

WAITING FOR HOST ON SLOT MAP STATUS, SLOT MAP VERIFICATION FAILED, SLOT MAP VERIFICATION OK. The initial default entry sub-state is SLOT MAP NOT READ.

10.4.3.1.4.1 *SLOT MAP NOT READ* — This is a substate of RETICLE POD SLOT MAP STATUS and is the default entry state. It is active when the Reticle Pod is first loaded at the equipment until the Slot Map has been read successfully by the equipment.

10.4.3.1.4.2 *SLOT MAP VERIFICATION FAIL* — This is a substate of RETICLE POD SLOT MAP STATUS and is active when the Slot Map has been read by the equipment and has failed verification by the host. This is a final state.

10.4.3.1.4.3 *SLOT MAP VERIFICATION OK* — This is a substate of RETICLE POD SLOT MAP STATUS and is active as soon as the slot map has been verified. This is a final state.

10.4.3.1.4.4 *WAITING FOR HOST ON SLOT MAP STATUS* — This is a substate of RETICLE POD SLOT MAP STATUS and is active when the equipment is waiting for input from the host.

10.4.4 *Reticle Pod State Transition Table*

10.4.4.1 Table 7 indicates the triggers and the expected behavior of the instantiated reticle pod object.

Table 7 Reticle Pod State Transition Definition

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
1	(no state)	A reticle pod is instantiated.	RETICLE POD	None.	Data required to be available for this event report: PodID
2	(no state)	*Normal:* A Bind, ReticleTransferJob or PodNotification service is received.	ID NOT READ	None.	Data required to be available for this event report: PodID
3	(no state)	*Normal:* A PodID not currently existing at the equipment is successfully read. *Abnormal:* A PodID is read successfully but an equipment based verification failed.	WAITING FOR HOST ON ID STATUS	None.	Data required to be available for this event report: PodID PortID Normally, this transition will happen after a successful ID read if a bind or ReticleTransferJob service has not been issued (host based verification) or abnormally if a bind or ReticleTransferJob service is followed by a successful ID read and an unsuccessful equipment based verification.
4	(no state)	*ID Read fail*: A ProceedWithPod service is received.	ID VERIFICATION OK	A reticle pod is instantiated having the PodID provided by the ProceedWithPod service.	Data required to be available for this event report: PodID This transition can happen only if a bind or ReticleTransferJob, service has not been received.
5	(no state)	*ID Read fail:* A CancelPod service is received.	ID VERIFICATION FAIL	A reticle pod is instantiated having the PodID provided by the Cancel Pod service.	Data required to be available for this event report: PodID This transition can happen only if a bind or ReticleTransferJob service has not been received.

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
6	ID NOT READ	PodID is read successfully and the equipment has verified the PodID successfully.	ID VERIFICATION OK	None.	Data required to be available for this event report: PortID PodID
7	ID NOT READ	PodID is read unsuccessfully.	WAITING FOR HOST ON ID STATUS	None.	Data required to be available for this event report: PortID PodID
8	WAITING FOR HOST ON ID STATUS	A ProceedWithPod service is received.	ID VERIFICATION OK	None.	Data required to be available for this event report: PortID PodID
9	WAITING FOR HOST ON ID STATUS	A Cancel Pod Service is received.	ID VERIFICATION FAILED	None.	Data required to be available for this event report: PortID PodID
10	ID NOT READ	$BypassReadID_i$ variable is set to FALSE, and a reticle pod is received when the id reader is not in service or not installed.	WAITING FOR HOST ON ID STATUS	Wait for ProceedWithPod.	Data required to be available for this event report: PortID PodID
11	ID NOT READ	$BypassReadID_i$ variable is set to TRUE, and a reticle pod is received when the id reader is not in service or not installed.	ID VERIFICATION OK	None.	Data required to be available for this event report: PortID PodID
12	ID NOT READ	The equipment successfully reads, but unsuccessfully verifies a reticle PodID.	ID VERIFICATION FAILED	None.	This transition should be followed by the equipment performing a self initiated CancelBind service (see transition 29) Data required to be available for this event report: PodID (of the pod instantiated in the Bind service) Data required to be available for this event report: PortID PodID
13	(no state)	A reticle pod is instantiated.	SLOT MAP NOT READ	None.	No event is required for this transition.
14	SLOT MAP NOT READ	Slot Map is read and verified successfully by the equipment.	SLOT MAP VERIFICATION OK	None.	Data required to be available for this event report: PortID (if valid) PodID LocationID

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
15	SLOT MAP NOT READ	*Normal host based verification:* Slot Map is read successfully and the equipment is waiting for host verification. *Equipment based verification:* Slot map is read successfully but equipment based verification has failed. *Slot map read fail:* Slot Map cannot be read.	WAITING FOR HOST ON SLOT MAP STATUS	Save new slot map in the SlotMap attribute.	Data required to be available for this event report: PortID (if valid) PodID LocationID SlotMap (if valid) Reason
16	WAITING FOR HOST	A ProceedWithPod service is received.	SLOT MAP VERIFICATION OK	Proceed with the Reticle Pod as instructed.	Data required to be available for this event report: PortID (if valid) PodID LocationID
17	WAITING FOR HOST	A CancelPod service is received.	SLOT MAP VERIFICATION FAIL	Prepare the Reticle Pod for Unload.	Data required to be available for this event report: PortID (if valid) PodID LocationID
18	(no state)	A reticle pod object is instantiated.	NOT ACCESSED	None.	Data required to be available for this event report: PodID
19	(no state)	A reticle pod object is instantiated.	NOT AVAILABLE or AVAILABLE	None.	This is the default entry into NOT ACCESSED. If the reticle is instantiated by service, the state is NOT AVAILABLE. If instantiated by PodID read the state is AVAILALBLE Data required to be available for this event report: PodID
20	NOT AVAILABLE	The reticle pod is received by the equipment.	AVAILABLE	None.	Data required to be available for this event report: PodID PortID
21	AVAILABLE	The equipment opens the reticle pod.	IN ACCESS	None.	Data required to be available for this event report: PodID

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comment*
22	IN ACCESS	*Normal with ReticleTransfer-Job service for pod with OutputPortID not equal to zero:* The actions defined in the reticle transfer job have completed and the equipment closes the reticle pod. *PodComplete service:* The host sends the PodComplete service and the equipment closes the reticle pod. *Internal Pod Buffer:* The PodOut service has been received. *Abnormal:* The pod has failed slot map verification and / or a CancelPod service is received and the pod is ready for unload.	COMPLETE	None.	Data required to be available for this event report: PodID
23	NOT ACCESSED	*Via ID verification failure:* The pod has failed ID verification and the carrier is ready for unload. *Via Service:* A CancelBind, CancelPodNotification, CancelPod, or CancelReticleTransferJob has been received prior to pod arrival.	COMPLETE	None.	Data required to be available for this event report: PodID
24	(no state)	A reticle pod is instantiated.	NOT LOCKED	None.	Data required to be available for this event report: PodID PortID
25	NOT LOCKED	A reticle pod is clamped or otherwise physically restrained from removal by an entity external to equipment.	LOCKED	None.	Data required to be available for this event report: PortID PodID
26	NOT LOCKED	A reticle pod is clamped or otherwise physically restrained from removal by an entity external to equipment.	RELEASED AND LOCKED or HOLD	None.	This is the default entry into LOCKED. If the PodRelease flag is set to Equipment Release the state is RELEASED AND LOCKED. If the PodRelease flag is set to Host Release the state is HOLD. Data required to be available for this event report: PortID PodID
27	HOLD	A PodRelease service has been received by the equipment.	RELEASED AND LOCKED		

#	Previous State	Trigger	New State	Actions	Comment
28	RELEASED AND LOCKED	*MANUAL Access Mode:* The POD ACCESSING state enters COMPLETE and a reticle pod is unclamped or has had any restraints preventing removal by an external entity removed. *AUTO Access Mode and Unclamp control trigger set to Pod Closed:* The POD ACCESSING state enters COMPLETE and a reticle pod is unclamped or has had any restraints preventing removal by an external entity removed. *AUTO Access Mode and Unclamp control trigger set to AMHS Triggered Unclamp:* The POD ACCESSING state is COMPLETE and the AMHS arrives and starts a PIO sequence.	NOT LOCKED	None.	Data required to be available for this event report: PortID PodID
29	POD	*Normal:* The reticle pod is unloaded from the equipment. *Abnormal by service:* CancelBind, CancelPodNotification, or CancelReticleTransferJob service is received prior to pod load. *Abnormal by equipment:* An equipment-based verification fails and the equipment performs a self-initiated CancelBind service.	(no state)	The equipment destroys the instance of this reticle pod object.	Data required to be available for this event report: PodID
30	(no state)	A Reticle Pod is loaded, locked, and the id is read on a load port for which no previous reticle pod has been instantiated	LOCKED		Data required to be available for this event report: PodID PortID

NOTE 1: Only one collection event report is required when entering the Reticle Pod State Model (instantiating a reticle pod object). This event report shall include the entry state of the all the substates of Reticle Pod State Model, (including RETICLE POD ID STATUS substate, the RETICLE POD SLOT MAP STATUS substate, the RETICLE POD ACCESSING STATUS, and the RETICLE POD LOCKING STATUS).

10.4.5 *Slot Map Read Details*

10.4.5.1 The Slot Map shall be read on all production equipment prior to removal of reticles from the reticle pod.

10.4.6 *Pod Read Failure* — A pod read failure occurs when the PodID reader is present, in service, and reports that it is unable to read the ID of a pod. This represents a transient random failure rather than a steady condition.

10.4.7 *Bypass Read ID* — A PodID reader may be unavailable: either out of service, not installed, or otherwise malfunctioning and unable to execute a read operation. This represents a steady condition that often is known in advance. The equipment shall provide a user-configurable variable BypassReadID that the user is able to set to specify the action to take when a pod is received to an ASSOCIATED load port. In this case, the reticle pod object is instantiated in the ID NOT READ state, and when the reticle pod is received, the state model transitions to either WAITING FOR HOST or ID VERIFICATION OK, depending upon whether BypassReadID is FALSE (the default value) or TRUE. When TRUE, then the PodID received in the Bind is used automatically. Otherwise, the pod transitions to WAITING FOR HOST and waits for the host to send a ProceedWithPod. The ID used will be the ID included with the ProceedWithPod.

11 Access Mode

11.1 *Access Mode State Model*

11.1.1 The Access Mode State Model defines the host view of equipment access mode, as well as the host interactions with the equipment necessary to switch the access mode. Each Reticle Load Port has its own Access Mode State Model. There are two access mode states. These are defined in Section 11.3.3.

11.1.2 The access mode for a reticle pod load port may be switched at anytime by the host or the operator, except when the Reticle Load Port Reservation State Model for that Reticle Pod Load Port is in the RESERVED state or during reticle pod transfer. Reticle pod transfer boundaries, for determining when access mode may be changed, are designated by Table 8, Reticle Pod Transfer Boundaries.

Table 8 Reticle Pod Transfer Boundaries

Transfer Type	*Transfer Method*	*Starting Boundary*	*Ending Boundary*
LOAD	MANUAL	This starting boundary is specified by the user. Known examples of the starting boundary include but are not limited to; the presence sensor detecting a pod, a pod load port operator access door opening, input to the equipment by the operator through a switch at the load port or the equipment console.	This ending boundary is specified by the user. Known examples of the ending boundary include but are not limited to; a preset configurable time following presence and placement sensor detecting a pod, a pod load port operator access door closing, or input to the equipment by the operator through a switch at the load port or the equipment console or a service message.
	AUTO	The PIO Ready signal is active for load.	The PIO signals a transfer complete.
UNLOAD	MANUAL	This starting boundary is specified by the user. Examples of the starting boundary include but are not limited to presence and placement sensor no longer detecting a pod, a pod load port operator access door opening, or input to the equipment by the operator through a switch at the load port or the equipment console or a service message.	This ending boundary is specified by the user. Examples of the ending boundary include but are not limited to a preset configurable time following presence and placement sensor no longer detecting a pod, a pod load port operator access door closing, or input to the equipment by the operator through a switch at the load port or the equipment console or a service message.
	AUTO	The PIO Ready signal is active for unload.	The PIO signals a transfer complete.

11.2 *Manual Pod Transfer Confirmation Trigger*

11.2.1 For a manual transfer completion confirmation, the production equipment supplier must implement a software or hardware mechanism for an operator to inform the equipment that the pod transfer is complete, but also support methods such as timers that allow equipment to consider a manual transfer complete without operator input.

11.3 *Access Mode Initial Value*

11.3.1 Also, when equipment re-initialization occurs, the access mode(s) must be remembered, and used as the initial value when initializing. Since the access mode is remembered through re-initializations, the initial value that is used the very first time the software is ever loaded is not important. The equipment supplier is free to set this default value.

11.3.2 *Access Mode State Model Diagram*

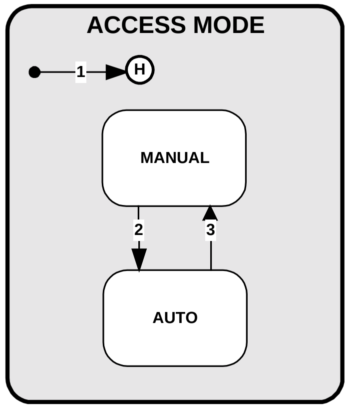

Figure 3
Access Mode State Model Diagram

11.3.3 *Access Mode State Definitions*

11.3.3.1 *ACCESS MODE* — The parent state for the MANUAL and AUTO sub-states.

11.3.3.2 *MANUAL* — A sub-state of ACCESS MODE. When the production equipment or specified reticle pod load port is in this mode, only manual (non-AMHS) pod transfers are allowed. The production equipment shall have the capability of generating an alarm if an automated (AMHS) delivery is attempted.

11.3.3.3 *AUTO* — A sub-state of ACCESS MODE. When the production equipment or specified reticle pod load ports are in this mode, only automated (AMHS) pod transfers are allowed. The production equipment shall have the capability of generating an alarm if a manual delivery is attempted.

11.3.4 *Access Mode State Transition Table*

11.3.4.1 Table 9 defines the transitions for the Access Mode State Model.

Table 9 Access Mode State Transition Definitions

#	*Previous State*	*Trigger*	*New state*	*Actions*	*Comments*
1	(no state)	System restart.	MANUAL or AUTO (History)	The access mode returns to the mode it was previous to the system reset.	Data required to be available for this event report: PortID
2	MANUAL	The host or operator has executed a Change-Access service with the value of AUTO. This trigger can happen at anytime, except during a reticle pod transfer.	AUTO		Manual deliveries are not allowed after this state transition. The operator may also trigger this transaction from the production equipment console. Data required to be available for this event report: PortID
3	AUTO	The host or operator has executed a ChangeAccess service with the value of MANUAL. This trigger can happen at anytime, except during pod transfer.	MANUAL		The operator may also trigger this transaction from the production equipment console or a manual switch at the reticle load port. Automated transfers are not allowed after this state transition. Data required to be available for this event report: PortID

12 Reservation State Model

12.1 The purpose of the Reticle Load Port Reservation State Model is to define the host view of future activity at a specific reticle load port.

12.1.1 The Reticle Load Port Reservation State Model, the ReserveAtPort service and CancelReserveAtPort enable the following items:

1. They enable the host to inform the equipment of a future reticle pod delivery without specifying the reticle PodID and at the same time allow host based verification. (Equipment based verification is enabled via the Load Port/Pod Association State Model, the Bind service, ReticleTransferJob, and the PodNotification service detailed in Sections 13, 18.4.2, 18.5.15, and 18.4.11 of SEMI E109.)
2. They enable the equipment to send a state change event to the host if the operator (either local or remote) informs the equipment of a future pod delivery to a reticle load port without specifying the reticle PodID. Thus the host knows that the operator expects to use that reticle load port for something the host did not request for AMHS based delivery.
3. The Bind, ReticleTransferJob, and CancelBind, CancelReticleTransferJob services also trigger changes in the Reticle Load Port Reservation State Model. If the Reticle Load Port Reservation state model is in the NOT RESERVED state, the Bind or ReticleTransferJob service triggers a transition to the RESERVED state. If the Reticle Load Port Reservation is in the RESERVED State, the CancelBind or CancelReticleTranserJob service triggers a transition to NOT RESERVED.

12.1.2 For Lithography, reticle inspection, and bare reticle stocker equipment, the Reservation State Model, the ReserveAtPort service, the CancelReserveAtPort service, and all other associated functionality is a user option and not necessary for fundamental compliance.

12.1.3 For equipment implementing the reservation state model, the equipment shall provide a reticle load port reservation state model for each load port.

12.2 *Reservation Visible Signal*

12.2.1 When a port reservation has taken place, the equipment shall display a visible signal indicating that the designated load port is in the Reserved State. Examples of visible signals for the associated load port are: Blinking LEDs, flags, color indicators, or other methods that allow easy recognition that the load port is reserved; proximity to or location on the load port is recommended. The visible signal shall remain present as long as the load port state remains RESERVED. When the state changes to NOT RESERVED the visible indicator shall cease. This capability is not required for fundamental compliance to RPMS.

12.3 *Load Port Reservation State Model Diagram*

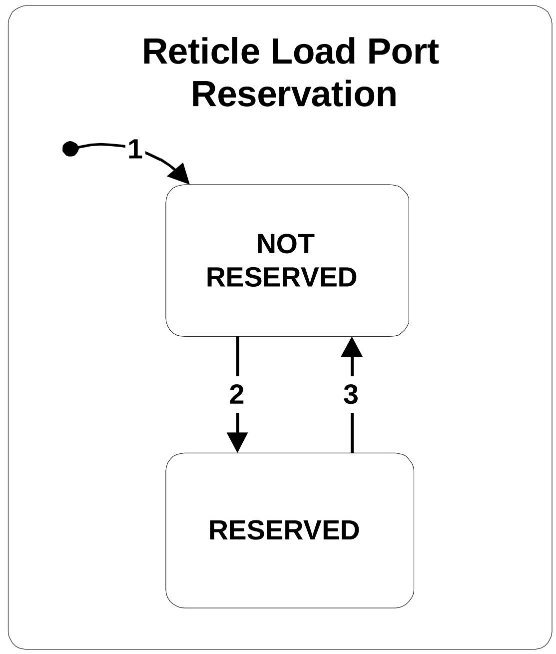

Figure 4
Reticle Load Port Reservation State Model Diagram

12.4 *Reticle Load Port Reservation State Definitions*

12.4.1 *RETICLE LOAD PORT RESERVATION* — The super state of the substates NOT RESERVED and RESERVED.

12.4.2 *NOT RESERVED* — A substate of LOAD PORT RESERVATION, this state is active when there is no reservation existing at the load port.

12.4.3 *RESERVED* — A substate of LOADPORT RESERVATION, this state is active when there is a reservation for future activity at the load port. When in this state, the access mode for a load port may not be changed.

12.5 *Reticle Load Port Reservation State Transition Table*

Table 10 Reticle Load Port Reservation State Transition Table

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(no state)	System reset.	NOT RESERVED		No event report is required for this transition.
2	NOT RESERVED	*Service:* If reserved by service, the host or operator sends a ReserveAtPort, ReticleTransferJob, or a Bind service to the production equipment. *PodOut:* This happens when the equipment physically initiates a PodOut operation.	RESERVED	If the user has configured the equipment to use the reservation visible signal indicator, it is activated for this load port.	Data required to be available for this event report: PortID PodID may be included when a pod out, ReticleTransferJob or a bind service triggers this transition.
3	RESERVED	*Service:* If a reservation is cancelled by service, the host or operator sends a CancelBind, CancelReticleTransferJob, or a CancelReservationAtPort. *Pod arrival:* A pod arrives at the reserved port.	NOT RESERVED	If the user has configured the equipment to use the reservation visible signal, the indicator is deactivated for this load port.	Data required to be available for this event report: PortID

12.6 *Relation of Reservation to Association*

12.6.1 The following figure indicates the relationship of Association to Reservation.

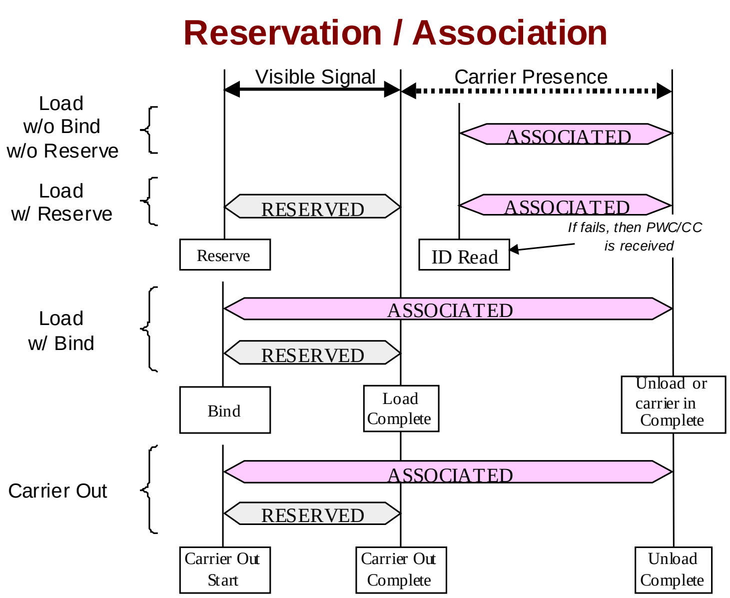

Figure 5
Relation of Reservation to Association

13 Reticle Pod Load Port/Pod Association State Model

13.1 The purpose of the Reticle Pod Association State Model is to define the host view of pod to reticle load port association of the production equipment, as well as the host interactions with the production equipment necessary to associate a reticle pod to a reticle load port, and to perform equipment based pod verification. Each reticle load port shall maintain an independent instance of the Pod Association State Model. Each instance of this state model must not influence the state of the same state model for a different reticle load port.

13.1.1 This state model provides the ability to perform PodID verification with two different methods. If the PodID is provided before the equipment reads the PodID, the PodID that becomes associated with the reticle load port can be used later for equipment based pod verification. If the association happens by PodID read (not by a service execution), then the production equipment shall report the PodID information in a data collection event.

13.2 *Reticle Pod Load Port/Pod Association State Model Diagram*

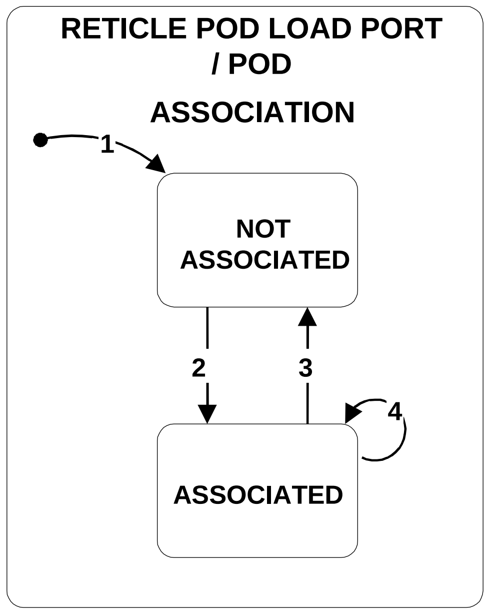

Figure 6
Reticle Pod Load Port/Pod Association State Model Diagram

13.2.1 *Reticle Pod Load Port/Pod Association State Definitions*

13.2.1.1 *RETICLE POD LOAD PORT/POD ASSOCIATION* — The parent state of the NOT ASSOCIATED and ASSOCIATED sub-states.

13.2.1.2 *NOT ASSOCIATED* — A sub-state of RETICLE POD LOAD PORT/POD ASSOCIATION. There is no pod association present for this load port.

13.2.1.3 *ASSOCIATED* — A sub-state of RETICLE POD LOAD PORT/POD ASSOCIATION. A PodID has been associated with this reticle load port. The reticle pod load port is not available for a new pod association.

13.2.2 *Reticle Pod Load Port/Pod Association State Transition Table*

13.2.2.1 Table 11 defines the transitions of the Reticle Pod Load Port/Pod Association State Model.

Table 11 Reticle Pod Load Port/Pod Association State Transition Definitions

#	*Previous State*	*Trigger*	*New State*	*Actions*	*Comments*
1	(no state)	System reset.	NOT ASSOCIATED		No pod associations exist for reset/re-initialized equipment. Data required to be available for this event report: PortID
2	NOT ASSOCIATED	*Service:* If associated by service, the host sends a Bind or ReticleTransferJob service to the production equipment. *PodID Read:* If associated by a PodID read, the production equipment creates the association at the time the PodID read is performed.	ASSOCIATED	The association visible signal indicator is activated for this reticle pod load port.	If the Bind or ReticleTransferJob service is performed before the PodID is read by the production equipment, the production equipment can perform the PodID verification. Once the PodID to reticle pod load port association is complete, the reticle pod load port is not available for association until the state returns to NOT ASSOCIATED again. Data required to be available for this event report: PortID PodID
3	ASSOCIATED	*Service:* If an association cancellation is desired, this can be done by the host sending a CancelBind or CancelReticleTransfer-Job service to the production equipment. *Reticle Pod Unload:* An association cancellation may also be performed by removing the reticle pod from the reticle pod load port.	NOT ASSOCIATED	The association visible signal indicator is deactivated for this reticle pod load port.	A reticle pod unload may happen before or after processing occurs. The reticle pod load port is available for another association. Data required to be available for this event report: PortID
4	ASSOCIATED	Production equipment based pod verification fails, and the pod assumes the ID value from the reticle pod that is on the reticle pod load port.	ASSOCIATED	The existing PodID that was associated by a Bind or ReticleTransferJob service is unassociated by the production equipment and the new PodID is now associated to the Reticle Pod Load Port. The production equipment shall delay further action until receiving either a CancelPod or a ProceedWithPod command from the host.	This transition only occurs when the Bind or ReticleTransferJob command has been used. Data required to be available for this event report: PortID PodID

14 Reticle Object

14.1 Information about a reticle is encapsulated as an object. This allows the host to exchange information with the equipment about one or more specific reticle using services defined in SEMI E39, Object Services Standard. A reticle has properties (attributes) that are defined in Table 12, Reticle Attribute Definition.

14.2 *Object Instantiation*

14.2.1 The reticle object is a software representation of the reticle in the equipment. Under normal circumstances this object is instantiated by the equipment when the host uses the Bind, ReticleTransferJob, PodNotification, ProceedWithPod service (when it included the content map attribute), MoveReticle service, when the equipment successfully reads the ReticleID from the reticle pod tag, or when the equipment successfully reads the ReticleID from the reticle itself. A reticle is instantiated by reticle pod tag read or ReticleID read only if there are no currently existing objects with the ReticleID just read. A reticle object can also be instantiated by either the ProceedWithPod or CancelPod Services when these services contain the content map. A Reticle can be instantiated by the MoveReticle Service if the ReticleID(s) provided by the service have not been previously instantiated.

14.2.2 From the host point of view, an object is instantiated if the host is able to query the equipment about that object, it' s current state, and other attributes. Once instantiated, the object is considered destroyed (no longer instantiated) if the response to such queries is “unknown object”.

14.2.3 Summary of possible reticle object instantiation methods:

1. Bind, ReticleTransferJob, or PodNotification Service that contains the content map attribute;
2. PodID tag read containing the content map with no currently existing reticle objects having the ReticleID just read from the pod tag;
3. ReticleID read with no currently existing reticle objects having the ReticleID just read from the ReticleID read;
4. ProceedWithPod or CancelPod Service containing the content map attribute;
5. MoveReticle Service when the reticle is not previously instantiated.

14.2.4 *Reticle Object Identifier (ObjID)*

14.2.4.1 The purpose of an Object Identifier is to allow references to an object within the system. The object identifier is created when an object is instantiated and should be unchanged or persistent until the end of the object lifecycle. The Object Identifier shall be unique at the equipment during lifecycle of the object. The ReticleID is the Reticle Object Identifier. The equipment is responsible for ensuring uniqueness of the ReticleID prior to instantiation by the bind, PodNotification, ReticleTransferJob, or MoveReticle service.

14.2.5 *Reticle Object Destruction*

14.2.5.1 Normally, the Reticle Pod Object reaches the end of its lifecycle when the reticle pod containing the reticle is unloaded from the equipment. Abnormally, the Reticle Object reaches the end of its lifecycle when a CancelBind, CancelReticleTransferJob, or CancelPodNotification service (if the original Bind, ReticleTransferJob, or PodNotification service contained the contentmap) is executed prior to the reticle pod being loaded, when a CancelMoveReticle service is executed prior to reticle removal from the reticle pod (if the reticle was instantiated using the MoveReticle command), when an equipment based pod verification fails following reticle pod and reticle instantiation by the bind service, ReticleTransferJob, or reticle pod tag read.

14.2.5.2 Summary of reticle object destruction:

1. A reticle pod is unloaded from the equipment;
2. A CancelBind, CancelReticleTransferJob, or CancelPodNotification service that contained the content map is received; and
3. An equipment based verification fails (after the object has been instantiated via the bind, ReticleTransferJob service, or reticle pod tag read).
4. A CancelMoveReticle service is executed prior to reticle removal from the reticle pod (when the content map has not been provided by other service or reticle pod tag read).
5. Manual removal of the physical reticle.

14.3 *Reticle Attribute Definitions*

14.3.1 The following table contains the attributes that are of importance to the host and/or the equipment in order to manage the history and the reports about the reticle object.

14.3.2 *REQD Column*

14.3.2.1 All attributes in the following table are required to be associated with the reticle object. However only the attributes marked with a “Y” in the REQD column are always required to be maintained and updated by the equipment. The attributes marked with an “N” in the REQD column are only required to be maintained if they are provided by the host by either the Bind, PodNotification, ReticleTransferJob, ProceedWithPod, or MoveReticle Services or if the equipment has means of determining the attribute values. (for example, if the equipment has a ReticleID reader, the equipment can determine the ContentMap).

14.3.3 *ACCESS Column*

14.3.3.1 Even though a value may be marked as RO (read only), the initial value for the attribute may be provided by the host when attached to either the Bind, PodNotification, ReticleTransferJob or ProceedWithPod services. The only other time the PodCapacityStatus attributes are updated is at the first ProceedWithPod service.

Table 12 Reticle Attribute Definition

Attribute Name	*Definition*	*Access*	*Reqd*	*Form*
ObjType	Object type.	RO	Y	Text equal to “Reticle”
ObjID	Object identifier.	RO	Y	Text 1 to 80 characters equal to the ReticleID.
# of Exposures	Count of the number of exposures since the reticle was loaded to the equipment.	RO	Y	Non negative integer
QualificationInterval-Time	The amount of time (in minutes) allowed between equipment inspections of a reticle. If this time is exceeded, the reticle state must transition to REJECTED.	RO	Y	52
Qualification-TerminationTime	The actual time if when a qualified reticle will expire and the reticle state must transition to rejected.	RO	Y	20
ReticleStatus	Current state of the Reticle.	RO	Y	Enumerated: RETICLE NOT PRESENT, QUALIFIED, IN USE, RETICLE PRESENT, RETICLE QUALIFICATION, REJECTED
ReticleAllocationStatus	The current allocation state of the reticle by the equipment. The current substate of the Allocation state model.	RO	Y	Enumerated: NOT ALLOCATED, ALLOCATED
ReticleLocationID	The specific location of the reticle.	RO	Y	Enumerated: Equipment dependent text Example locations: Inspection position, ReticleID read position, storage location 1.
Reticle type	The type of reticle.	RO	Y	Enumerated: Equipment dependent text Example subtypes: phase shift, binary

14.4 *Reticle State Model*

14.4.1 The purpose of the Reticle State Model is to define the host’s view of a reticle. The equipment shall maintain a separate and independent state model for each reticle pod in/at the equipment.

14.4.2 *Reticle State Model Diagram*

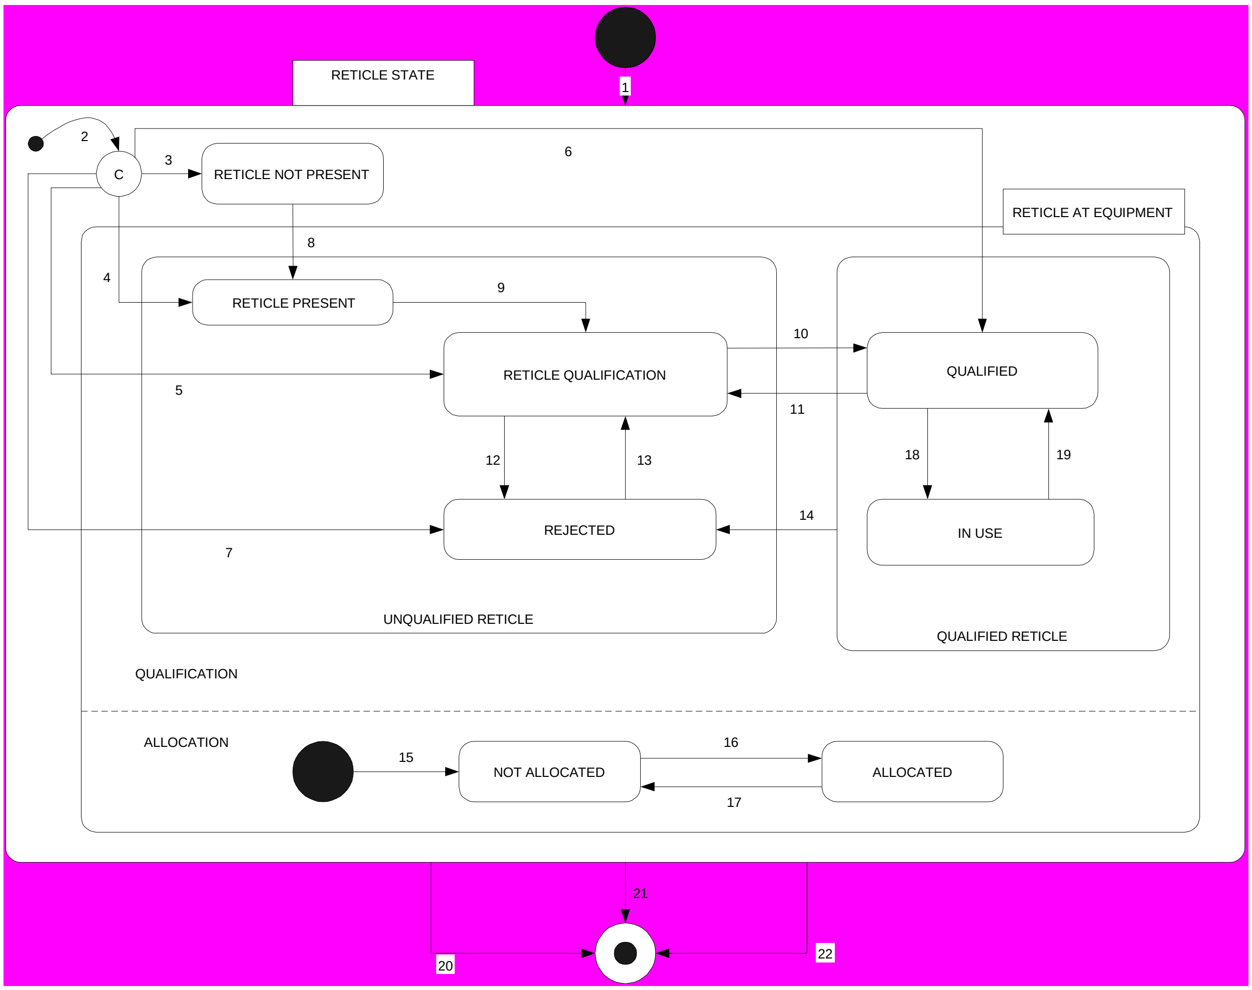

Figure 7
Reticle State Model Diagram

14.4.3 *Reticle State Definition*

14.4.3.1 *RETICLE NOT PRESENT* — This is a subset of RETICLE STATE and is active when the reticle is not present on the Equipment. The reticle has been instantiated with a Bind, PodNotification, ReticleTransferJob, or MoveReticle service.

14.4.3.2 *RETICLE AT EQUIPMENT* — This is a subset of RETICLE STATE and is active when the reticle is present. The reticle is physically present on the Equipment. **There are two ANDed states: Qualification (indicating if the reticle may be used) and Allocation (shows if the reticle is allocated to a lot inside the lot queue) .** There is very little relation between the ANDed state.

14.4.3.2.1 *QUALIFICATION* — This is a substate of the RETICLE AT EQUIPMENT and is active when the reticle is physically present. There are two substates UNQUALIFIED RETICLE and QUALIFIED RETICLE.

14.4.3.2.1.1 *UNQUALIFIED RETICLE* — This is a substate of QUALIFICATION and is active when the reticle is physically present but not QUALIFIED. There are three substates, RECTICLE PRESENT, RETICLE QUALIFICATION, AND REJECTED.

14.4.3.2.1.1.1 *RECTICLE PRESENT* — This is a substate of UNQUALIFED RETICLE and is active when the reticle is waiting to be selected for qualification. The physical ReticleID is not read in this state

14.4.3.2.1.1.2 *REJECTED* — This is a substate of UNQUALIFIED RETICLE and is active when the reticle did not pass the qualification(s) due to an unexpected ReticleID or poor inspection results. The operator or the host (depending on the control mode) will have to decide if the reticle must be re-qualified or removed from the equipment.

14.4.3.2.1.1.3 *RETICLE QUALIFICATION* — This is a substate of UNQUALIFIED RETICLE and is active when the reticle is being qualified for production. The ReticleID is being read from the ReticleID and / or a reticle inspection for particles is being performed.

14.4.3.2.1.2 *QUALIFIED RETICLE* — This is a substate of QUALIFICATON and is active when the reticle may be used for production. It has two substates QUALIFIED and IN USE.

14.4.3.2.1.2.1 *IN USE* — This is a substate of QUALIFIED RETICLE and is active when any kind of processing on the reticle is being done (i.e. the reticle is not at an inventory position).

14.4.3.2.1.2.2 *QUALIFIED* — This is a substate of QUALIFIED RETICLE and is active when the reticle is at an inventory position, including either the internal reticle buffer or a reticle pod.

14.4.3.2.2 *ALLOCATION* — This is a substate of RETICLE AT EQUIPMENT, and is active when the reticle is physically present.

14.4.3.2.2.1 *NOTALLOCATED* — This is a substate of ALLOCATION and the reticle is not allocated to a lot in the queue.

14.4.3.2.2.2 *ALLOCATED* — This is a substate of ALLOCATION and the reticle is allocated to one or more lots in the queue.

14.4.4 *Reticle State Transition Table* — Table 13 indicates the triggers and the expected behavior of the instantiated reticle object.

Table 13 Reticle State Transition Definition

#	*Current State*	*Trigger*	*New (Sub-)State*	*Action*	*Comment*
1	-	A reticle is instantiated.	RETICLE NOT PRESENT or RETICLE AT EQUIPMENT	None.	If the reticle is instantiated via the ReticleTransferJob it must be moved from the pod into the internal reticle library according to the ' ReticleTransferJob' instructions.
2	-	*By Service:* A reticle is instantiated via the Bind, PodNotification, or ReticleTransferJob, message in which the content map is provided, or the reticle is instantiated via a MoveReticle service for which the Reticle Pod has not been received by the equipment. *By Reticle Pod Tag Read:* A reticle is instantiated after placing a reticle pod on a load port via a reticle PodID tag read. that provided the content map. *By ReticleID read:* A reticle is instantiated via a ReticleID read.	RETICLE NOT PRESENT or RECTICLE PRESENT or RETICLE QUALIFICA-TION		Data required to be available for this event report: PodID

#	*Current State*	*Trigger*	*New (Sub-)State*	*Action*	*Comment*
3	-	A reticle is instantiated via the Bind, PodNotification, or ReticleTransferJob, message in which the content map is provided, or the reticle is instantiated via a MoveReticle service for which the Reticle Pod has not been received by the equipment.	RETICLE NOT PRESENT		Data required to be available for this event report: PodID
4	-	A reticle is instantiated after placing a reticle pod on a load port via a reticle PodID tag read that provided the content map or via a MoveReticle service for which the Reticle Pod has been received by the equipment.	RECTICLE PRESENT	None.	This transition happens only if the content map has not been provided to the equipment prior to reticle pod load port receiving a reticle pod.
5	-	A reticle is instantiated via a ReticleID read and a particle inspection is still required.	RETICLE QUALIFICA-TION		Data required to be available for this event report: PodID PortID
6	-	A reticle is instantiated via a ReticleID read and no particle inspection is required.	QUALIFIED		Data required to be available for this event report: PodID PortID
7	-	A reticle is instantiated via a read and has been found to be the incorrect ID.	REJECTED		Data required to be available for this event report: PodID PortID
8	RETICLE NOT PRESENT	A Reticle Pod load port receives a previously instantiated reticle pod for which the equipment holds the content map attribute.	RECTICLE PRESENT		
9	RECTICLE PRESENT	The equipment has begun to qualify a previously instantiated reticle.	RETICLE QUALIFICA-TION		
10	RETICLE QUALIFICA-TION	*Equipment based* – Equipment decides based on preset criteria that a reticle is suited for use. *Host based* – The equipment receives the OktoUseReticle Service.	QUALIFIED		Reticle qualification includes both ID verification and quality verification. Reticle is able to be used.
11	QUALIFIED	Host based – The equipment receives a Re-qualify service.	RETICLE QUALIFICA-TION	Start reticle inspection.	
12	RETICLE QUALIFICA-TION	*Equipment based* – Equipment determines that an incorrect reticle has been delivered or that a reticle inspection failed. *Host based* – The equipment receives a RejectReticle service from the host. *Operator based* – An operator issues a RejectReticle command from the equipment operator interface.	REJECTED		Data required to be available for this event report: PodID PortID Reject Reason
13	REJECTED	*Host based* – The equipment receives a Re-qualify service. *Equipment based* – A re-inspection is automatically triggered by the Equipment.	RETICLE QUALIFICA-TION	Start reticle inspection.	

#	*Current State*	*Trigger*	*New (Sub-)State*	*Action*	*Comment*
14	QUALIFIED RETICLE	*Host based* - The equipment receives a RejectReticle service from the host. *Equipment based* -Inspection results of the reticle are expired. *Operator based* – An operator issues a RejectReticle command from the equipment operator interface.	REJECTED		
15	-	A reticle is instantiated.	NOT ALLOCATED		
16	NOT ALLOCATED	*Production Equipment:* The reticle becomes allocated to a pre-processing or processing lot. Inspection Equipment: The reticle becomes allocated to an inspection. Bare Reticle Stockers: The reticle is selected for kitting.	ALLOCATED		
17	ALLOCATED	The last lot allocation to the reticle by a pre-processing or processing lot is removed because this lot has moved to an other state OR the equipment has been restarted.	NOT ALLOCATED		
18	QUALIFIED	*For Exposure Equipment:* An-exposure process has started. *For Reticle Inspection Equipment:* A Reticle Inspection has started. *For Bare Reticle Stockers:* A reticle kitting has started.	IN USE		This transition should take place as soon as the needed physical movement of a reticle for processing or inspection has begun.
19	IN USE	*For Exposure Equipment:* A reticle exposure process has finished. *For Reticle Inspection Equipment:* An inspection process has finished.	QUALIFIED		
20	RETICLE AT EQUIPMENT	Reticle pod containing the reticle is removed from the machine.	-	Delete reticle object.	
21	RETICLE AT EQUIPMENT	Reticle has been manually removed from the equipment.	-	Delete reticle object.	Abnormal situation
22	RETICLE AT EQUIPMENT	*Via service:* Reticle object has been destroyed via a CancelBind, CancelReticleTransferJob, CancelPodNotification, or CancelMoveReticle service from the host prior to the Reticle being physically read. *Via equipment based verification failure:* A reticle instantiated via Bind, ReticleTransferJob, PodNotification, Pod Tag read (for a pod tag that holds the contentmap attribute of the pod) or MoveReticle service failed equipment based verification and the equipment destroys the reticle object.	-	Delete reticle object.	Abnormal situation

15 Verification

15.1 Verification is the operation of comparing an actual value with an expected value. Verification may be performed by either the host or the equipment, depending upon whether the host is using the Bind, ReticleTransferJob, or PodNotification service or not.

15.1.1 If the host provides the expected value before the actual value is obtained by the production equipment, then the production equipment shall perform the verification.

15.1.2 If the host does not provide the expected value before the actual value is read, then the production equipment shall provide to the host, the information necessary for host based verification.

15.1.3 There are three values that are defined by Reticle and Pod Management that require verification: PodID, Pod Slot Map, and ReticleID.

15.2 *PodID Verification*

15.2.1 Table 14 defines the methods for verifying the PodID.

Table 14 PodID Verification Methods

Verification Method Desired	*Host Actions before Load*	*Equipment Action When Reticle Pod Is Loaded*	*Host Actions after Load*
Production Equipment Based	*Bind or ReticleTransferJob Service:* The host executes the Bind or ReticleTransferJob service to associate a reticle pod load port and a PodID.	*Bind or ReticleTransferJob Service:* The production equipment reads the PodID from the reticle pod, compares it to the podID supplied with the Bind or ReticleTransferJob service.	
		Verification Passed: Transition 6 of the Reticle Pod State Model occurs. The production equipment proceeds with processing.	*Verification Passed:* None.
		Verification Failed: The equipment initiates Transition 12 of the reticle pod state model then Transition 29 and the reticle pod object created via the bind or ReticleTransferJob service is destroyed. The equipment also initiates Transition 3 of the reticle pod state model and a reticle pod object with the PodID equal to the one determined by the PodID read is instantiated. The reticle pod shall not be opened by the equipment until and unless the ProceedWithPod service is received from the host.	*Verification Failed:* The host uses either the CancelPod service to force the reticle pod to be readied for unload, or indicates to the production equipment that it may proceed with the unexpected reticle pod, by sending the ProceedWithPod service. In both cases the PodID specified in the service is equal to the one determined by the PodID read.
	PodNotification Service: The host executes the PodNotification service to inform the equipment of the future arrival of a pod to an unspecified reticle pod load port.	*PodNotification Service:* The production equipment reads the PodID from the reticle pod, compares it to the PodID supplied with a PodNotification service.	
		Verification Passed: Transition 6 of the Reticle Pod State Model occurs. The production equipment proceeds with processing.	*Verification Passed:* None.

Verification Method Desired	*Host Actions before Load*	*Equipment Action When Reticle Pod Is Loaded*	*Host Actions after Load*
		Verification Failed: Not Applicable; because there is no association between a reticle pod load port and a reticle pod, equipment based verification failure is not possible. If a reticle pod that has not been instantiated arrives at a load port, the equipment shall consider this as host based verification.	*Verification Failed:* Not Applicable, because there is no association between a reticle pod load port and a reticle pod, equipment based verification failed is not possible. If a reticle pod that has not been instantiated arrives at a reticle pod load port, the equipment shall consider this as host based verification." The host will respond with either a ProceedWithPod or a CancelPod Service. (See Host Based verification method).
Host Based	None required, the host may issue a ReserveAtPort service.	The production equipment reads the PodID and reports it to the host in an event report. Following PodID read the equipment initiates Transition 3 of the Reticle Pod State Model and a reticle pod object with the PodID equal to the one determined by the PodID read is instantiated. The reticle pod shall not be opened the equipment until and unless the ProceedWithPod service is received from the host.	*Verification Passed:* The host sends a ProceedWithPod service indicating the verification passed.
			Verification Failed: The host uses the CancelPod or CancelPodAtPort service to force the equipment to prepare the pod for unload.

15.3 *Slot Map Verification*

15.3.1 Table 15 defines the methods for verification of the Reticle Pod Slot Map. Some user's factory operations may not require strict management of the slot map. In this case the user may use the host based verification method.

Table 15 Slot Map Verification Methods

Verification Method Desired	*Host Actions Before Verification*	*Equipment Action When Pod is Loaded*	*Host Actions After Load*
Production Equipment Based	The host provides a Slot Map with the Bind, PodNotification, ReticleTransfer-Job, or the ProceedWithPod service.	The production equipment checks the reticle pod slot map and compares it to the slot map supplied by the host. Either transition 14, or 15 of the Pod State Model occurs.	*Verification Passed:* None, the production equipment proceeds with the pod. *Verification Failed:* If the host decides to cancel processing, the host issues the CancelPod service. If the host decides to continue processing, the host issues the ProceedWithPod service.
Host Based	None.	The production equipment checks the reticle pod slot map and reports it to the host in an event report. The host has the responsibility for verifying the slot map.	*Verification Passed:* The host sends a ProceedWithPod indicating the verification passed. *Verification Failed:* If the host decides to cancel processing, the host issues the CancelPod service. If the host decides to continue processing, the host issues the ProceedWithPod service.

15.4 *ReticleID Verification*

15.4.1 Table 16 below defines the Optional methods for ReticleID verification.

Table 16 ReticleID Verification Methods

Verification Method Desired	*Host Actions before Load*	*Equipment Action When Reticle Pod Is Loaded*	*Equipment Action when Reticle is removed from cassette*	*Host Actions after Load*
Production Equipment Based	*Bind, PodNotification, ReticleTransferJob, or MoveReticle Service prior to Pod Arrival:* The host executes a Bind, PodNotification or ReticleTransferJob service that includes the ContentMap and the ReticleIDs.	*Bind, PodNotification, ReticleTransferJob Service, or MoveReticle Service prior to Pod Arrival:* Transition 8 of the Reticle State Model Occurs (from RETICLE NOT PRESENT to RETICLE PRESENT (E.Ch). The equipment must verify the ReticleID successfully.	Transition 9 of the Reticle State Model occurs. The ReticleID is read.	
			Verification Passed: The equipment may proceed with reticle qualification.	*Verification Passed:* None.
			Verification Failed: The equipment initiates Transition 12, then Transition 22 of the reticle state model the reticle object created via the service is destroyed. The equipment also initiates Transition 5 (if a particle inspection is required) or Transition 6 (if a particle inspection is not required) of the model and a reticle object with the ReticleID equal to the one determined by the ReticleID read is instantiated (if not currently instantiated)	*Verification Failed:* The host uses either the RejectReticle service to indicate that the equipment should not use the reticle for processing, or indicates to the production equipment that it may proceed with the unexpected reticle, by sending the OKtoUseReticle service. In both cases the ReticleID specified in the service is equal to the one determined by the ReticleID read.
	MoveReticle Service after Pod Arrival prior to reticle instantiation: The host executes a MoveReticle service.	Transition 4 of the Reticle State Model Occurs (from no state to RECTICLE PRESENT).	Transition 9 of the Reticle State Model occurs. The ReticleID is read.	
			Verification Passed: The equipment may proceed with reticle qualification.	*Verification Passed:* None.
			Verification Failed: The equipment initiates Transition 12, then Transition 22 of the reticle state model the reticle object created via the service is destroyed. The equipment also initiates Transition 5 (if a particle inspection is required) or Transition 6 (if a particle inspection is not required) of the reticle state model and a reticle object with the ReticleID	*Verification Failed:* The host uses either the RejectReticle service to indicate that the equipment should not use the reticle for processing, or indicates to the production equipment that it may proceed with the unexpected reticle, by sending the OKtoUseReticle service.

Verification Method Desired	*Host Actions before Load*	*Equipment Action When Reticle Pod Is Loaded*	*Equipment Action when Reticle is removed from cassette*	*Host Actions after Load*
			equal to the one determined by the ReticleID read is instantiated.	In both cases the ReticleID specified in the service is equal to the one determined by the ReticleID read.
	MoveReticle after pod arrival and reticle instantiation via pod tag read: None	Equipment reads the pod tag and instantiates the reticle object via transition 4.	Transition 9 of the Reticle State Model occurs. The ReticleID is read.	
			Verification Passed: The equipment may proceed with reticle qualification.	*Verification Passed:* None.
			Verification Failed: The equipment initiates Transition 12, the Transition 22 of the reticle state model the reticle object created via the service is destroyed. The equipment also initiates Transition 5 (if a particle inspection is required) or Transition 6 (if a particle inspection is not required) of the reticle state model and a reticle object with the ReticleID equal to the one determined by the ReticleID read is instantiated.	*Verification Failed:* The host uses either the RejectReticle service to indicate that the equipment should not use the reticle for processing, or indicates to the production equipment that it may proceed with the unexpected reticle, by sending the OKtoUseReticle service. In both cases the ReticleID specified in the service is equal to the one determined by the ReticleID read.
Host Based	None required, the host may issue a ReserveAtPort service.	The production equipment reads the PodID and reports it to the host in an event report. Following PodID read the equipment initiates Transition 3 of the Reticle Pod State Model and a reticle pod object with the PodID equal to the one determined by the PodID read is instantiated. The reticle pod shall not be opened by the equipment until and unless the ProceedWithPod service is received from the host.	The production equipment reads the ReticleID and reports it to the host in an event report. Following the ReticleID read the equipment initiates Transition 5 (if a particle inspection is required) or Transition 6 (if a particle inspection is not required) of the Reticle State Model and a reticle object determined by the ReticleID read is instantiated.	*Verification Passed:* The host sends a OKtoUseReticle service indicating the verification passed. The equipment may proceed with reticle qualification.
				Verification Failed: The host uses the RejectReticle service to indicate that the equipment should not use the reticle for processing.

15.5 Table 17 clarifies the relation of the reservation and verification to the related services.

Table 17 Reservation and Verification Relation to Service

	Reser-vation	*PodID Verification*	*Cassette SlotMap Verification*	*ReticleID Verification*	*Service Used*	*Information Provided with Service*			
						Port ID	*Pod ID*	*Slot Map*	*Content Map and ReticleID*
1	Yes	Equipment based	Equipment based	Equipment based	Bind, or ReticleTransferJob	Yes	Yes	Yes	Yes
2	Yes	Equipment based	Host based	Host based	Bind,	Yes	Yes	No	No
3	Yes	Host based	Host based	Host based	ReserveAtPort	Yes	No	No	No
					ProceedWithPod (following ID read and host verification)	No	Yes	No	No
4	Yes	Host based	Equipment based	Host based	ReserveAtPort	Yes	No	No	No
					ProceedWithPod to provide slotmap (following ID read and host verification)	No	Yes	Yes	No
5	No	Equipment based	Equipment based	Equipment based	PodNotification	No	Yes	Yes	Yes
6	No	Equipment based	Host based	Host based	PodNotification	No	Yes	No	No
7	No	Host based	Equipment based	Host based	ProceedWithPod to provide slotmap (following ID read and host verification)	No	Yes	Yes	No
8	No	Host based	Host based		ProceedWithPod (following ID read and host verification)	No	Yes	No	

16 Reticle Pod Release Control

16.1 For equipment, where Pod Read/Write technology is used and the Host initiates writing, the reticle pod or reticle cassette must remain at the write position where the tag may be accurately written on until the Host has completed all of its read and write operations. For this purpose, a variable that affects the equipment releasing a pod is defined.

16.2 *Pod Hold Trigger* — Equipment shall allow the user to select a trigger to release the carrier pod when reading/writing is complete. Release does not mean the equipment must move the pod from the location it currently occupies, only that it is permissible to do so.

16.2.1 *Pod Hold Trigger set to Host Release* — If the Pod Hold trigger is set to Host Release, equipment shall hold the pod at the write position until the PodRelease service is received.

16.2.2 *PodHold Trigger set to Equipment Release* — If the Pod Hold trigger is set to Equipment Release, the equipment shall release the reticle pod based on the when the equipment has finished removing all reticles from the pod, finished placing all reticles in the pod, and in the case where the equipment initiates writing until the equipment has finished writing.

16.3 Fixed Buffer Equipment shall allow the user to select a trigger to unclamp the reticle pod based on AMHS arrival at the equipment. If the access mode is MANUAL, the unclamp control trigger has no effect.

16.3.1 *UnclampControl trigger set to* *PODCOMPLETE Triggered Unclamp* — The equipment automatically unclamps the reticle pod when the reticle pod status is COMPLETE.

16.3.2 *UnclampControl trigger set to AMHS Triggered Unclamp* — The equipment behavior depends upon the Reticle Load Port Access State. If the Reticle Pod Load port Access State is AUTO, the reticle pod remains clamped until AMHS has arrived. The AMHS arrives and begins a PIO unload sequence.

17 Reticle Location Object Definition

17.1 A Reticle Location Object (RLO) provides a model for identifying reticle locations. Each RLO on an equipment is assigned a reticle location ID to uniquely identify it. The assignment shall be documented by the equipment supplier. There are two types of substrate locations: reticle pod reticle location, which is the location or position (e.g., slot) in the reticle pod, and equipment reticle location, which is on the equipment resource. The equipment reticle location is a persistent object, while the reticle pod reticle locations are dynamic objects that shall be created or deleted by the placement or removal of reticle pods on the equipment. The intent is to follow E90 in regards to location object management. The reticle location object is a subtype of the substrate location object.

17.1.1 Source reticle locations and Destination reticle locations are the points at which reticles transfer to/from the equipment's internal reticle locations (often locations at which processing occurs). A reticle pod reticle location is the Source or Destination reticle location when a pod is used to transfer the reticle. An equipment reticle location can be the Source or Destination reticle location when the reticle is transferred directly (without a pod).

17.2 *Reticle Location State Model* — Figure below shows the dynamic behavior of the reticle location using the Harel state chart representation.

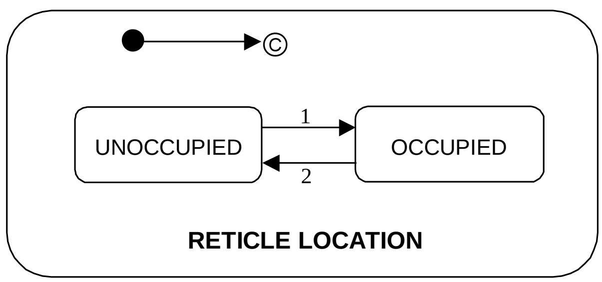

Figure 8
Reticle Location State Model Diagram

17.3 *Reticle Location State Definitions*

17.3.1 *RETICLE LOCATION* — the superstate of UNOCCUPIED and OCCUPIED.

17.3.2 *UNOCCUPIED* — the state in which the reticle location does not hold or have a reticle.

17.3.3 *OCCUPIED* — the state in which the reticle location holds a reticle.

17.4 *Substrate Location State Transition*

Table 18 Reticle Location State Model Transition Table

#	*Current State*	*Trigger*	*New State*	*Action*	*Comment*
1	UNOCCUPIED	Reticle moves onto the substrate location.	OCCUPIED	None.	Data required to be available for this event: ReticleID
2	OCCUPIED	Reticle moves off the location.	UNOCCUPIED	Update reticle tracking history.	Data required to be available for this event: ReticleID

17.5 *Reticle Location Object Attributes*

17.5.1 Table 19 defines attributes for Reticle location objects. These attributes can be accessed by using GetAttr and SetAttr messages as defined in SEMI E39 (OSS).

Table 19 Reticle Location Object Attribute Table

Attribute Name	*Definition*	*Access*	*Reqmt*	*Format*
ObjID	Object Identifier	RO	Y	Text equal to the Reticle Location ID
ObjType	Object type	RO	Y	Text = "ReticleLoc"
ReticleID	Reticle IDentifier relevant to the location	RO	Y	Text
ReticleLocation-State	Reticle Location state	RO	Y	Enumerated: UNOCCUPIED OCCUPIED

18 Services

18.1 The purpose of this section is to define the message services required to support Reticle Management functionality.

18.1.1 This message service definition has four parts:

- A service description table.
- A service parameter table.
- A service parameter value table that specifies the type and range of the parameters.
- A service state mapping table that defines the states in which each service is valid.

18.2 *Service Message Description*

18.2.1 There are two types of services:

- An initial message and response between the service user and the service provider.
- A notification message from the service provider to the service user that does not require a response.

18.2.2 The "TYPE" column in the following table is used to indicate whether the service consists of a request/response message pair, "R", or a single notification message, "N".

18.2.3 The "Requirement" level column in the following table is used to indicate whether the service is a fundamental requirement, "F", or an additional capability "A" for RPMS.

Table 20 Service Message Description

Service Name	*Type*	*Requirement level*	*Description*
Bind	R	F	This service shall associate a PodID to a load port and shall cause the load port to transition to the RESERVED state.
CancelAllPodOut	R	A	This service shall cause all PodOut services to be removed from the queue.
CancelBind	R	F	This service cancels a PodID to load port association and shall cause the load port to transition to the NOT RESERVED state.
CancelMoveReticle	R	A	This service cancels a prior MoveReticle service provided that MoveReticle service has not been started.
CancelPod	R	F	This service shall Cancel the current pod related action, and the production equipment shall return the pod to the unload position of the load port, or an internal buffer position, depending on the pod's position in the production equipment.
CancelPodAtPort	R	F	This service shall Cancel the current pod related action, and the production equipment shall return the pod to the unload position of the load port.
CancelPod-Notification	R	F	This service shall cause the equipment to destroy a pod object instantiated through a prior PodNotification.
CancelPodOut	R	A	This service shall cause a specified PodOut service to be removed from the queue by the production equipment.

Service Name	*Type*	*Requirement level*	*Description*
CancelReservation-AtPort	R	F	This service shall cause the equipment to remove the reservation at the specified Port and to deactivate the visible signal.
CancelReticle-TransferJob	R	A	The service cancels a reticle PodID to load port associations and shall cause the load port to transition to the NOT RESERVED state. Also it shall cause the equipment to refrain from removing the reticles from the reticle pod specified in a previous ReticleTransferJob service. Finally it shall cause the equipment to refrain from removing the reticles from the equipment specified in the same previous ReticleTransferJob service.
ChangeAccess	R	F	This service shall change the access mode of the specified Ports at the production equipment. If a load port is dedicated to either Automated delivery or Manual delivery, the access mode cannot be changed.
ChangeServiceStatus	R	F	This service shall change the transfer status of a specified load port at the production equipment.
Clamp	R	A	This service shall cause the equipment to engage any clamping mechanisms that are independent of opening the pod.
ClosePod	R	A	This service shall cause the equipment to close the pod.
IndexDown	R	A	This service shall cause the equipment to index the cassette down when it is safe for equipment, operators, and reticles to do so.
IndexUp	R	A	This service shall cause the equipment to index the cassette up when it is safe for equipment, operators, and reticles to do so.
MoveReticle	R	A	This service shall cause the equipment to move a reticle from one position to another either internal to internal, internal to external, external to internal, or external to external.
OktoUseReticle	R	F	This service shall change the qualification status of the specified reticle to QUALIFIED.
OpenPod	R	A	This service shall cause the equipment to open the pod.
PodComplete	R	F	This service shall change the reticle pod accessing status to COMPLETE.
PodIn	R	A	This service shall cause a pod to be moved from a load port to an internal buffer location. Used in anomaly situations.
PodNotification	R	F	This service shall cause the equipment to instantiate a pod object.
PodOut	R	A	This service shall cause a pod to be moved from the internal buffer to a load port. This service can be queued by the production equipment.
PodRelease	R	A	Release the pod from Pod Hold.
PodTagReadData	R	A	Read data from PodID tag.
PodTagWriteData	R	A	Write data to the PodID tag.
ProceedWithPod	R	F	This service shall instruct the production equipment to proceed with using the specified pod.
RejectReticle	R	F	This service shall cause the equipment to change the qualification state to REJECTED.
Re-qualifyReticle	R	A	This service shall cause the equipment to reinspect the reticle.
ReserveAtPort	R	F	This service shall cause the equipment to reserve the specified Port and activate a visible signal. This service is a possible transfer boundary.
ReticleTransferJob	R	A	This service shall associate a PodID to a load port and shall cause the load port to transition to the RESERVED state. It will also cause the equipment to begin removal, identification, and qualification of specific reticles in the pod as well as placement of specific reticles into the pod upon pod arrival and verification.
SetQualification-IntervalTime	R	A	This service shall set the maximum interval time between reticle inspections.
Unclamp	R	A	This service This service shall cause the equipment to release any clamping mechanisms that prevent removal of the pod. The pod must be closed prior to execution of this service.

18.3 *Service Message Parameter Definition*

18.3.1 The following is a list of required parameters used in conjunction with service messages.

Table 21 Service Message Parameter Definition

Parameter Name	*Form*	*Description*
AccessMode	Enumerated AUTO, MANUAL	The desired access mode of the ports specified.
ArrivingReticleList	Ordered list of ReticleID, ReticlePropertiesList, and removal instructions corresponding to the slot number.	Ordered List of n structures where n is equal to the value of the pod attribute “Capacity,” and each structure consists of a ReticleID, a ReticlePropertiesList, and an enumerated removal instruction. List of structure ReticleID ReticlePropertiesList Enumerated Enumerated: REMOVE PASS BY
AttributeData	Could be several different data types.	The data value associated with AttributeID.
AttributeID	Text 1 to 40 characters	The ID of the object attribute in a PropertiesList.
PodID	Text 1 to 64 characters	ID number of a pod.
Qualification-IntervalTime	U2	The time in minutes allowed between equipment inspections of a reticle.
RPMAcknowledge	Enumerated: • Acknowledge, service has been performed • Service does not exist • Cannot perform now • At least parameter is invalid • Acknowledge, service will be performed with completion notified later with parameters for response • No such object exists	Acknowledgement of request.
RPMStatus	A structure consisting of RPMAcknowledge and Status.	Return information for a service.
Data	Text	User data.
DataSeg	Protocol-specific	Indicates specific section of data to read or write.
DataSize	Unsigned integer	Indicates the number of bytes of data to read or write.

Parameter Name	*Form*	*Description*
DepartingReticle-List	Ordered list of ReticleID and instructions to remove from the equipment and place in the reticle cassette corresponding to the slot number of the cassette to which the reticle will be placed.	Ordered List of n structures where n is equal to the value of the pod attribute "Capacity," and each structure consists of a ReticleID and an enumerated instruction. List of structure ReticleID Enumerated Enumerated: CURRENTLY OCCUPIED PLACE PASS BY When no reticle is targeted to be placed in a slot, the ReticleID should be null. When the enumeration is equal to CURRENTLY OCCUPIED or PASS BY the ReticleID should be null.
DestinationLocation	LocationID	The location for which a reticle is to be moved.

Parameter Name	*Form*	*Description*
ErrorCode	Enumerated: *Valid for all services listed below* Unsupported option [service] requested Command not valid for current state Insufficient parameters specified Parameters improperly specified *Bind* Load port does not exist Object identifier already in use Invalid attribute value Unknown attribute name *CancelAllPodOut* (none) *CancelBind* Load port does not exist Unknown object instance *CancelPod* Load port does not exist Unknown object instance *CancelPodAtPort* Load port does not exist *CancelPodNotification* Unknown object instance *CancelPodOut* Unknown object instance *CancelReservationAtPort* Load port does not exist *PodIn* Unknown object instance *PodNotification* Object identifier already in use Invalid attribute value Unknown attribute name *PodOut* Load port does not exist Unknown object instance *ChangeAccess* Load port does not exist *ChangeServiceStatus* Load port does not exist *ProceedWithPod* Load port does not exist Unknown object instance Invalid attribute value Unknown attribute name *ReserveAtPort* Load port does not exist	Contains the code for the specific error found.
ErrorText	Text	Text in support of the error code.
InputPortID	Integer 0, 101 to 255	ID number of the load port where the Pod will be delivered. The InputPortID number should be the same as the load port number. When the value of the InputPortID = zero, the Pod will be picked up from the internal buffer.

Parameter Name	*Form*	*Description*
OutputPortID	Integer 0, 101 to 255	ID number of a load port where the Pod will be presented for removal. The OutputPortID number should be the same as the load port number. When the value of the OutputPortID = zero, the Pod will be delivered to the internal buffer.
PortID	Integer 1 to n.	ID number of a load port. The PortID number should be the same as the load port number.
PortList	List 1 to n items.	List of n items $PortID_1$ . . n $PortID_n$
PodPropertiesList	List 1 to n name/value pairs.	List of n items 1. $AttributeID_1$ $AttributeData_1$ . . n. $AttributeID_n$ $AttributeData_n$
ReticlePlacement-Instruction	Enumerated: 0=PLACE 1=PASS BY 2=CURRENTLY OCCUPIED	The instructions for placing reticles in pod slot.
ReticleProperties-List	List 1 to n name/value pairs.	List of n items 1. $AttributeID_1$ $AttributeData_1$ . . n. $AttributeID_n$ $AttributeData_n$
ReticleLocation-PropertiesList	List 1 to n name/value pairs.	List of n items 1. $AttributeID_1$ $AttributeData_1$ . . n. $AttributeID_n$ $AttributeData_n$
ReticleRemoval-Instruction	Enumerated: 0=REMOVE 1=PASS BY	The instructions for removing reticles from a pod slot.
ServiceStatus	Enumerated: IN SERVICE, or OUT OF SERVICE.	The desired transfer service status of the specified list of load ports.
SourceLocation	LocationID	The source location from which to move a reticle.
Status	A list of ErrorCode/ErrorText pairs.	Reports any errors found.

18.4 *Fundamental Service Message Definitions*

18.4.1 The following tables specify the allowable/required parameters for each service. The column marked "REQ/OPT", specifies which parameters are required to be supported for RPMS compliance ("R"=Required, "O"=Optional).

18.4.2 *Bind*

18.4.2.1 The Bind service is used to associate a PodID with a load port. The Bind can contain a PropertiesList of pod object attributes that are supplied by the host. A pod object is instantiated when this service is used successfully. The Bind service will be rejected if the pod specified has already been instantiated through the Bind or

PodNotification service, or a PodID read. The Bind service also triggers a transition in the Load Port Reservation state model from NOT RESERVED to RESERVED.

Table 22 Bind Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	The PortID where a pod is expected.
PodID	M	—	The expected PodID.
PodPropertiesList	C	—	A list of name value pairs providing attributes for the pod object being instantiated with the Bind service.
CMStatus	—	M	Information concerning the result of the service.

18.4.3 *CancelBind*

18.4.3.1 The CancelBind request is used to cancel the association between a port and a PodID. The pod object is destroyed when this service is used successfully. The CancelBind service also triggers a transition in the Load Port Reservation state model from RESERVED to NOT RESERVED.

Table 23 CancelBind Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	C	—	The PortID for which to cancel the load port to pod association. Either PortID or PodID must be specified.
PodID	C	—	The PodID for which to cancel the load port to pod association. Either PortID or PodID must be specified.
CMStatus	—	M	Information concerning the result of the service.

18.4.4 *CancelPod*

18.4.4.1 The CancelPod request is used to stop a reticle pod. If the reticle pod is at a reticle pod load port, then it shall be made ready for unload. The production equipment shall reject this service if issued after reticles have been removed for processing.

Table 24 CancelPod Service Parameters

Parameter Name	*Req/Opt*	*Rsp/Conf*	*Description*
PodID	M	—	The PodID to cancel.
CMStatus	—	M	Information concerning the result of the service.
PortID	C	—	The PortID where the pod object is located. This parameter is not required if the pod object has been previously instantiated.

18.4.5 *CancelPodAtPort*

18.4.5.1 CancelPodAtPort is used to abort any pod at a designated port. This service can be used when the podID of the pod at the designated port is unknown.

Table 25 CancelPodAtPort Service Parameters

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	Any pod that exists on the load port specified shall be made ready for unloading.
CMStatus	—	M	Information concerning the result of the service.

18.4.6 *CancelPodNotification*

18.4.6.1 The CancelPodNotification is used by the host to request the equipment cancel a previous PodNotification service. This service shall cause the equipment to destroy the pod object specified.

Table 26 CancelPodNotification Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	The PodID of the pod object to destroy.
CMStatus	—	M	Information concerning the result of the service.

18.4.7 *ChangeAccess*

18.4.7.1 The ChangeAccess message requests a change of access mode for the load ports specified in the PortList.

Table 27 ChangeAccess Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
AccessMode	M	—	The new desired access mode.
PortID	M	—	The port to use the new access mode.
CMStatus	—	M	Information concerning the result of the service.

18.4.8 *ChangeServiceStatus*

18.4.8.1 The ChangeServiceStatus service is used to request the production equipment change a load port service state.

Table 28 ChangeServiceStatus Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	PortID to designate the new service status.
ServiceStatus	M	—	The new service state.
CMStatus	—	M	Information concerning the result of the service.

18.4.9 *OktoUseReticle*

18.4.9.1 The OktoUseReticle service is sent by the host to indicate that the reticle may be used for processing. The equipment should change the reticle state model qualification status to QUALIFIED.

Table 29 OktoUseReticle Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
ReticleID	M	—	ReticleID to designate the new qualification status.
RPMStatus	—	M	Information concerning the result of the service.

18.4.10 *PodComplete*

18.4.10.1 The PodComplete service is used by the host to inform the equipment that all actions for transferring reticles in and out of the pod are complete. This service is used when the equipment has not previously received a ReticleTransferJob service for the pod.

Table 30 PodComplete Parameters

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	The PodID of the Pod that is complete.
PortID	C	—	The Port ID the Pod currently occupies.
CMStatus	—	M	Information concerning the result of the service.

18.4.11 *PodNotification*

18.4.11.1 The PodNotification service is used by the host to inform the equipment that a Pod with the ID specified will be arriving at the equipment. The load port is not specified; therefore no pod to load port association takes place. A pod object with the ObjID equal to the PodID specified in the service is instantiated. The PodNotification service will be rejected if the pod specified has already been instantiated through the Bind or PodNotification service, or a PodID read.

Table 31 PodNotification Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	The PodID of the pod object to instantiate.
PodPropertiesList	C		The PropertiesList of the pod to instantiate.
CMStatus	—	M	Information concerning the result of the service.

18.4.12 *ProceedWithPod*

18.4.12.1 The ProceedWithPod service is sent by the host to indicate that the pod operations may continue. When using host based verification it is used by the host to indicate to the production equipment that the verification of PodID and/or the Cassette Slot Map is correct. For successful production equipment based verification the production equipment shall not require this message before proceeding with the pod. For failed production equipment based verification the production equipment shall require either a CancelPod or ProceedWithPod service.

18.4.12.2 Using Table 30, for the Host based PodID verification case, the ProceedWithPod service sent by the host after the first PodID read is referred to as ProceedWithPod #1, the ProceedWithPod service sent after slot map read is referred to as ProceedWithPod #2.

Table 32 ProceedWithPod Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	C	—	The PortID for which processing may proceed.
PodID	M	—	The PodID for which processing may proceed.
PodPropertiesList	C	—	A list of name value pairs providing attributes for the pod object.
CMStatus	—	M	Information concerning the result of the service.

18.4.13 *RejectReticle*

18.4.13.1 The RejectReticle service is sent by the host to indicate that the reticle may no longer be used for processing, unless it is requalified. The equipment shall change the reticle state model qualification status to REJECTED.

Table 33 RejectReticle Service Parameter Definition

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
ReticleID	M	—	ReticleID to be removed.
RPMStatus	—	M	Information concerning the result of the service.

18.4.14 *SetQualificationIntervalTime*

18.4.14.1 The SetQualifiactionIntervalTime service is sent by the host to change the time between inspection for a specific or a list of specific reticles. This service uses SETATTR as defined in SEMI E39.

Table 34 SetQualificationIntervalTime Service Parameter Definition

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
ReticleID	M	M	The reticleID for which to change the time between reticle inspections.
Qualification-IntervalTime	M	M	The time in minutes allowed between equipment inspections of the reticle.

18.5 *Additional Service Message Definitions*

18.5.1 *CancelAllPodOut*

18.5.1.1 The CancelAllPodOut service is sent to internal buffer production equipment to cancel all PodOut services in queue.

Table 35 CancelAllPodOut Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
CMStatus	—	M	Information concerning the result of the service.

18.5.2 *CancelMoveReticle*

18.4.4.1 The CancelMoveReticle service is sent by the host to cancel a MoveReticle service. The equipment shall refrain from removing the reticle specified. This shall apply on if the move has not been started.

Table 36 CancelMoveReticle

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
ReticleID	M	—	The ReticleID which should not be removed.
RPMStatus	—	M	Information concerning the result of the service.

18.5.3 *CancelPodOut*

18.5.3.1 The CancelPodOut service is sent to internal buffer production equipment to cancel a queued PodOut.

Table 37 CancelPodOut Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	PodID for the PodOut service that is being cancelled.
CMStatus	—	M	Information concerning the result of the service.

18.5.4 *CancelReservationAtPort*

18.5.4.1 The CancelReservationAtPort service is sent by the host to cancel a reservation at the load port. The load port will enter the UNRESERVED State after receiving this service. A Port reserved by the physical initiation of a pod out operation may not be cancelled by this service.

Table 38 CancelReservationAtPort Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	The Port ID to reserve.
CMStatus	—	M	Information concerning the result of the service.

18.5.5 *CancelReticleTransferJob*

18.5.5.1 The CancelReticleTransferJob is sent by the host to cancel a previous ReticleTransferJob service.

Table 39 CancelReticleTransferJob Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	The PodID of the pod for which to cancel the load port to pod association.
PortID	M	—	The Port ID for which to cancel the load port to pod association.
RPMStatus	—	M	Information concerning the result of the service.

18.5.6 *Clamp*

18.5.6.1 The Clamp service is used by the host if the equipment has separate mechanisms for clamping the carrier that are independent of opening the carrier. It is used to instruct equipment to engage the independent clamping mechanism. It is used by the host when “macro” instructions such as provided by Bind, PodNotification, ProceedWithPod and ReticleTransferJob have not been provided.

Table 40 Clamp Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	C	—	The PodID of the pod to clamp. Either the PodID or the PortID must be specified.
PortID	C	—	The PortID for which to clamp a carrier. Either the PodID or the PortID must be specified.
CMStatus	—	M	Information concerning the result of the service.

18.5.7 *Close Pod*

18.5.7.1 The ClosePod service is used by the host to request the equipment close a pod.

Table 41 ClosePod Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	C	-	The PortID where a pod is to be closed. Either PortID or PodID must be specified.
PodID	C	-	The PodID for which the door should be closed. Either PortID or PodID must be specified.
CMStatus	—	M	Information concerning the result of the service.

18.5.8 *IndexDown*

18.5.8.1 The IndexDown service is sent by the host to indicate that the equipment should index the reticle cassette to the position where reticle may be removed from the cassette when it is safe for equipment, personnel, and reticles to do so.

Table 42 IndexDown Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	PortID to designate the new service status.
PodID	C	—	The ID of the pod to index down.
CMStatus	—	M	Information concerning the result of the service.

18.5.9 *IndexUp*

18.5.9.1 The IndexUp service is sent by the host to indicate that the equipment should index the reticle cassette to the position where the reticle pod may be removed from the equipment when it is safe for equipment, personnel, and reticles to do so. This service is optional.

Table 43 IndexUp Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	PortID to designate the new service status.
PodID	C	—	The ID of the pod to index up.
CMStatus	—	M	Information concerning the result of the service.

18.5.10 *MoveReticle*

18.5.9.1 The MoveReticle service is used to move reticles from one reticle location to another. This can include moving a reticle from a reticle pod location (external to a tool) to an internal reticle library, ReticleID read location, process location, or a different reticle pod location or from an internal location to another internal location or to a reticle pod location.

Table 44 MoveReticle Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	PortID to designate the new service status.
ReticleID	C	—	The ID of the Reticle to move, either the ReticleID or the SourceLocation must be used.
SourceLocation	C	—	The ReticleLocationID of the location from which to move the reticle, either the SourceLocation or the ReticleID must be used.
Destination-Location	M	—	The ReticleLocationID of the location to which the reticle shall move.
CMStatus	—	M	Information concerning the result of the service.

18.5.11 *OpenPod*

18.5.11.1 The OpenPod service is used by the host to request the equipment open a pod

Table 45 OpenPod Service Parameter Definitions

Paramter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	C	-	The PortID where a pod is to be opened. Either PortID or PodID must be specified.
PodID	C	-	The PodID for which the door should be opened. Either PortID or PodID must be specified.
CMStatus	—	M	Information concerning the result of the service.

18.5.12 *PodIn*

18.5.12.1 The PodIn service is only used to request the internal buffer equipment internalize a carrier that has been moved to the load port via a previous PodOut service. When using host based verification, the production equipment shall move the pod in to the internal buffer for the first time after receiving the ProceedWithPod request. If the PodIn service is received by the production equipment without previously having received a PodOut service for the carrier, the service will be refused.

Table 46 PodIn Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	The CarrierID for the carrier to internalize.
CMStatus	—	M	Information concerning the result of the service.

18.5.13 *PodOut* — The PodOut service is sent to internal buffer production equipment, to request that the equipment move the specified carrier to a load port, as soon as the carrier is completed. When the CarrierOut service is started, the destination load port state becomes TRANSFER BLOCKED, and the load port's association state becomes ASSOCIATED.

18.5.13.1 *PodOut Queuing*

18.5.13.1.1 This service request can be queued by the production equipment. The production equipment is required to support a queue of n size, where n is equal to the sum of the number of internal buffer locations and the number of internal FIMS ports. The order of the queue is FIFO for each load port. If the load port is not specified in service request, the equipment chooses which load port queue to place the PodOut service. The queued service does not take effect until the current substrate handling action is complete (i.e., filling, emptying of the pod) and the load port is in the NOT ASSOCIATED state. When a PodOut service is queued and the production equipment load port is currently in the TRANSFER BLOCKED state, the production equipment shall keep the load port in the TRANSFER BLOCKED state. Then, after the port is cleared, the PodOut service shall begin.

Table 47 PodOut Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	PodID for the carrier to be moved out.
PortID	C	—	If omitted, the production equipment shall select an appropriate port at the time the pod is ready to be moved.
CMStatus	—	M	Information concerning the result of the service.

18.5.14 *PodRelease*

18.5.14.1 PodRelease request is used to tell the equipment that the pod is ready to be moved away from the read or write position. Equipment shall deny the request if LocationID and PodID are mismatched.

Table 48 PodRelease Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
LocationID	C	—	The ID for the location of the pod. Either LocationID or PodID must be used.
PodID	C	—	The PodID of the pod. Either LocationID or PodID must be used.
CMStatus	—	M	Information concerning the result of the service.

18.5.15 *PodTagReadData*

18.5.15.1 PodTagReadData is used to request a block of data from the PodID tag. Equipment shall deny the request if LocationID and PodID are mismatched.

Table 49 PodTagReadData Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
LocationID	C	—	The ID for the location of the pod. Either LocationID or PodID must be used.
PodID	C	—	The PodID of the pod. Either LocationID or PodID must be used.
DataSeg	C	—	Indicates a specific section of data.
DataSize	C	—	Indicates the number of bytes to read.
Data	—	C	Data from the PodID tag. May be NULL if no data exists for the given section.
CMStatus	—	M	Information concerning the result of the service.

18.5.16 *PodTagWriteData*

18.5.16.1 PodTagWriteData is used to request that a block of data be written to the PodID tag. Equipment shall deny the request if LocationID and PodID are mismatched.

Table 50 PodTagWriteData Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
LocationID	C	—	The ID for the location of the pod. Either LocationID or PodID must be used.
PodID	C	—	The PodID of the pod. Either LocationID or PodID must be used.
DataSeg	C	—	Indicates a specific section of data.
DataSize	C	—	Indicates the number of bytes to read.
Data	M	—	Data from the PodID tag. May be NULL if no data exists for the given section.
CMStatus	—	M	Information concerning the result of the service.

18.5.17 *Re-QualifyReticle*

18.5.17.1 The Re-QualifyReticle service is sent by the host to indicate that a reticle should be re-qualified.

Table 51 Re-QualifyReticle Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
ReticleID	M	—	ReticleID to remove from equipment.
CMStatus	—	M	Information concerning the result of the service.

18.5.18 *ReserveAtPort*

18.5.18.1 The ReserveAtPort service is sent by the host to indicate future activity at the load port. This allows for reserving the port but doing host based ID verification. The load port will enter the RESERVED State after receiving this service.

Table 52 ReserveAtPort Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PortID	M	—	The Port ID to reserve.
CMStatus	—	M	Information concerning the result of the service.

18.5.19 *ReticleTransferJob*

18.5.19.1 The ReticleTransferJob service is sent by the host to inform the equipment of the expected arrival of a reticle pod to a reticle pod load port and/or the expected departure of a reticle pod. The equipment should create an association between the reticle pod and reticle load port. The equipment should transition the load port reservation state model to RESERVED. The ReticleTransferJob service is also used by the host to inform the equipment which reticles contained in the reticle pod should be removed and placed in the equipment. Lastly the ReticleTransferJob service is used by the host to inform the equipment which reticles contained in the equipment should be removed from the equipment and placed in the reticle pod. This service is optional.

Table 53 ReticleTransferJob Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	M	—	The PodID of the pod which will delivered to the equipment.
InputPortID	M	—	The Port ID where the pod will be received. If zero: The pod must be picked from the tool's internal buffer (for internal buffer equipment only). Either InputPortID or OutputPortID must be used (both may be specified as well).
OutputPortID	M	—	The Port ID to which the pod will be delivered after having executed all related reticle actions. If zero: The pod will remain in the tool's internal buffer (for internal buffer equipment only). Either InputPortID or OutputPortID must be used (both may be specified as well).
PodPropertiesList	C	—	A list of name value pairs providing attributes for the pod object being instantiated with the ReticleTransferJob service.
ArrivingReticleList	C	—	The list of reticles to remove from the reticle pod and place in the equipment. Either ArrivingReticleList or DepartingReticleList must be used.
DepartingReticleList	C	—	The list of reticle to remove from the equipment and place in the reticle pod. Either ArrivingReticleList or DepartingReticleList must be used.
RPMStatus	—	M	Information concerning the result of the service.

18.5.20 *Unclamp*

18.5.13 The Unclamp service is used by the host if the equipment has separate mechanisms for unclamping the carrier that are independent of opening the carrier. It is used to instruct equipment to disengage the independent clamping mechanism. It is used by the host when “macro” instructions such as provided by Bind, PodNotification, ProceedWithPod and ReticleTransferJob have not been provided by the host.

Table 54 Unclamp Service Parameter Definitions

Parameter Name	*Req/Ind*	*Rsp/Conf*	*Description*
PodID	C	—	The PodID of the pod to unclamp. Either the PodID or the PortID must be specified.
PortID	C	—	The PortID for which to unclamp a carrier. Either the PodID or the PortID must be specified.
CMStatus	—	M	Information concerning the result of the service.

19 Pod Tag Read/Write

19.1 Some technologies allow data to be stored on a PodID tag where it can be subsequently read and/or modified. In one case the equipment can write information to the PodID tag. For example, the equipment will have knowledge of the ReticleID of a reticle placed in a pod. At this time the equipment may write the ReticleID on the PodID tag. In another case, it is the host that specifies when this data is written and read, because the equipment has no knowledge of the contents of the data. The read operations shall be performed only when the pod is at the read position. The write operations shall be performed only when the pod is at the write position.

NOTE 3: The read and write positions may be the same position. The host shall be able to both read and write whenever PodHold switch is set to Host Release and the pod is at the respective read or write position. Once the host has completed all of its read and write operations for that pod, then the host sends the PodRelease request to the equipment. The PodRelease service informs the equipment that pod read or pod write is complete. The PodRelease service has a different purpose from the PodOut service. The intent of the PodOut service request is to move the pod to a load port, while the intent of the PodRelease service request is to inform equipment that it may move the pod away from the read or write position. Therefore, PodOut may also be used with the PodRelease command. If PodHold is Host Release, then the pod shall be kept at the write position until an PodRelease service request is received, regardless of when a PodOut is sent. If PodHold is set to Equipment Release, then the PodRelease request has no effect.

20 Additional Events

20.1 This section identifies data collection events that are not related to State transitions for variable data items. The intent of this section is to ensure certain data is available for specific events that are not related to state transitions, not to define all the additional collection events for RPMS. Also, all state transitions in RPMS state models are required to have associated event reports.

20.2 *Buffer Capacity Changed Event*

20.2.1 An event shall be generated whenever Buffer Capacity changes. This applies to all internal buffers and internal buffer partitions.

20.2.2 Data required to be available for this event report:

- BufferPartitionInfo.

20.3 *Pod Closed Event*

20.3.1 If the pod is equipped with a door, an event shall be generated when a pod door has been closed.

20.3.2 Data required to be available for this event report:

- PodID,
- LocationID, and
- PortID (if valid)

20.4 *Pod Location Change Event*

20.4.1 An event shall be generated whenever a pod has changed location. This applies to both load ports, substrate ports, and internal buffer locations.

20.4.2 Data required to be available for this event report:

- PodID,
- LocationID (new destination location), and
- PodLocationMatrix.

20.5 *Pod Opened Event*

20.5.1 If the pod is equipped with a door, an event shall be generated when a pod door has been opened.

20.5.2 Data required to be available for this event report:

- PodID,
- LocationID and
- PortID (if valid).

20.6 *PodID Read Fail Event*

20.6.1 An event shall be generated when the equipment attempts to read a PodID and fails at a port in the NOT ASSOCIATED STATE.

20.6.2 Data required to be available for this event report:

- PortID

20.7 *ID Reader Unavailable Event*

20.7.1 An event shall be generated whenever an id reader becomes unavailable for any reason. This applies to all load ports.

20.7.2 Data required to be available for this event report:

- Port ID

20.8 *ID Reader Available Event*

20.8.1 An event shall be generated whenever an id reader becomes available. This applies to all load ports.

20.8.2 Data required to be available for this event report:

- Port ID

20.9 *Reticle Usage Warning Limit Event*

20.9.1 An Event shall be generated whenever a reticle is nearing the configurable limits of usage

20.9.2 Data required to be available for this event

- ReticleID

20.10 *ReticleTransferJob Complete Event*

20.10.1 An event shall be generated whenever a ReticleTransferJob completes.

20.10.2 Data required to available for this event:

- PodID

21 Variable Data

21.1 The purpose of this section is to define the list of variable data requirements for RPMS equipment. Values of these variables are available to the host via collection event reports and host status queries. Some of the data items listed are valid for internal buffer production equipment only, and are marked as such.

21.2 *Variable Data Definitions*

21.2.1 The following table defines variable data that shall be provided by the production equipment. Also, for the objects defined by Reticle and Pod Management, the identifier of that object and all of the attributes of that object shall be available for inclusion in event reports associated with that object. Subscripted variables are used either as items within a list or to differentiate data representing different entities. Subscripted variables are always valid.

Table 55 Variable Data Definitions

Variable Name	*Description*	*Type*	*Access*	*Comment*
$AccessMode_i$	The access mode for the i^{th} load port.	Enumerated: MANUAL, AUTO	RO	
AvailPartitionCapacity	The current available buffer capacity for a logical partition inside internal buffer equipment (PartitionCapacity - # of pods in partition).	Positive integer	RO	Only applicable to internal buffer production equipment.
$AvailPartitionCapacity_i$	The AvailPartitionCapacity for the i^{th} PartitionID within the internal buffer.	Positive integer	RO	Only applicable to internal buffer production equipment.
BufferCapacityList	The current PartitionType, AvailPartitionCapacity, and PartitionCapacity for all logical buffer partitions.	List of n groups of items 1. $BufferPartitionInfo_1$ . . n. $BufferPartitionInfo_n$	RO	Only applicable to internal buffer production equipment.
BufferPartitionInfo	The related information for a logical buffer partition.	Structure of 4 items PartitionID PartitionType AvailPartitionCapacity PartitionCapacity	RO	Only applicable to internal buffer production equipment.
$BufferPartitionInfo_i$	The related information for the i^{th} buffer partition.	Structure of 4 items $PartitionID_i$ $PartitionType_i$ $AvailPartitionCapacity_i$ $PartitionCapacity_i$	RO	Only applicable to internal buffer production equipment.
BypassReadID	Enables or disables automatic ID acceptance when the PodID reader is unavailable.	Boolean	RW	If TRUE, the ID provided with Bind is used automatically.
PodID	The ID of the pod.	Text	RO	
$PodID_I$	The PodID at the i^{th} locationID.	Text	RO	
PodLocationMatrix	A list all the pods at/in the equipment. Both internal to the equipment, and on equipment load ports.	List of n pairs of items 1. $LocationID_1$ $PodID_1$ . . n. $LocationID_n$ $PodID_n$	RO	The $PodID_i$ shall be null if there is no pod at the $locationID_i$. If a pod is at $LocationID_i$, but the $PodID_i$ is not known, the value of $PodID_i$ shall be “UNKNOWN”.
LocationID	The ID of a pod location.	Text	RO	Pod locations are any location at/in the production equipment where a pod may rest.
$LocationID_i$	The LocationID of the i^{th} pod location.	Text	RO	Pod locations are any location at/in the production equipment where a pod may rest.
PartitionCapacity	The total PartitionCapacity for a logical internal buffer partition.	Positive integer	RO	Only applicable to internal buffer production equipment.
$PartitionCapacity_i$	The PartitionCapacity for the i^{th} PartitionID of the internal buffer.	Positive integer	RO	Only applicable to internal buffer production equipment.

Variable Name	*Description*	*Type*	*Access*	*Comment*
PartitionID	The ID of a logical internal buffer partition.	Text	RO	Used to identify separate material types in an internal buffer.
$PartitionID_i$	The ID of the i^{th} logical partition of the internal buffer.	Text	RO	Used to identify separate material types in an internal buffer.
PartitionType	The type of a logical partition within an internal buffer.	Text	RO	Only applicable to internal buffer production equipment. Some examples of logical buffer PartitionType are Product, Dummy, Substrate, and Seed.
$PartitionType_i$	The PartitionType corresponding with the i^{th} PartitionID.	Text	RO	Only applicable to internal buffer production equipment. Some examples of logical buffer PartitionType are Product, Dummy, Substrate, and Seed.
PortAssociationState	The association state of a load port.	Enumerated: ASSOCIATED, NOT ASSOCIATED	RO	
$PortAssociationState_i$	The association state of the i^{th} load port.	Enumerated: ASSOCIATED, NOT ASSOCIATED	RO	
PortAssociationState-List	The current association state for all load ports.	A list of n items 1. $PortAssociationState_1$ . . n. $PortAssociationState_n$	RO	This can be used to re-synchronize the host.
PortID	ID of a load port.	Positive integer	RO	
$PortID_I$	ID of the load port where the pod transfer is taking place. One PortID exists for each load port.	Positive integer	RO	
PortStateInfo	The PortAssociationState combined with the PortTransferState.	List of 2 items PortAssociationState PortTransferState	RO	A combination of both port states.
$PortStateInfo_i$	The PortAssociationState combined with the PortTransferState for the i^{th} load port.	List of 2 items $PortAssociationState_i$ $PortTransferState_i$	RO	A combination of both port states.
PortStateInfoList	List of PortStateInfo for all load ports.	List of n items 1. $PortStateInfo_1$ . . n $PortStateInfo_n$	RO	A list of all the port states for all the ports.
PortTransferState	The current transfer state of a load port.	Enumerated: OUT OF SERVICE, TRANSFER BLOCKED, READY TO LOAD, READY TO UNLOAD	RO	Super states are not included, only sub states.
$PortTransferState_i$	The current transfer state of the i^{th} load port.	Enumerated: OUT OF SERVICE, TRANSFER BLOCKED, READY TO LOAD, READY TO UNLOAD	RO	Super states are not included, only sub states.

Variable Name	*Description*	*Type*	*Access*	*Comment*
PortTransferStateList	The current Load Port Transfer State for all load ports.	A list of n items 1. $PortTransferState_1$ . . n. $PortTransferState_n$	RO	This can be used to re-synchronize the host.
Reason	The reason for transition 14, SLOT MAP NOT READ to WAITING FOR HOST.	Enumerated: VERIFICATION NEEDED, VERIFICATION BY EQUIPMENT UNSUCCESSFUL, READ FAIL, IMPROPER WAFER POSITION	RO	Information to aid host in deciding appropriate action.
Reject Reason	The reason a reticle is rejected.	Enumerated: ID Verification failedParticle qualification failed Rejected By Host Rejected By Operator Inspection Results Expired	RO	Information to aid the host in understanding why a reticle is rejected.

22 Alarms

22.1 This section includes specific alarms that are required to be implemented by RPMS compliant equipment.

22.2 *Alarm List Table*

22.2.1 Table 55 is a listing of required alarms for both fixed buffer and internal buffer equipment. This list is only a subset of the pod transfer alarms. There may be more pod transfer related alarms that are not listed here.

Table 56 Alarm List

Equipment		*Danger*		*Affected*		
Configuration	*Alarm Text*	*Potential*	*Imminent*	*Operator*	*Equipment*	*Material*
Fixed & Internal Pod Buffer Equipment	PIO Failure	X		X	X	X
	Access Mode Violation	X		X	X	X
	Attempt To Use Out Of Service Load Port	X			X	X
	Pod Presence Error	X		X	X	X
	Pod Placement Error	X		X	X	X
	Pod Open/Close Failure	X			X	X
Fixed and Internal Pod Buffer Equipment	Duplicate PodID	X				X
Fixed & Internal Pod Buffer Equipment	Pod Removal Error	X		X	X	X
Duplicate Reticle ID	A duplicate reticle is detected.	X				X
Pod Pick/Place error	The internal robot that moves the Pods failed to pick or place a pod. Can be triggered if the state of the system after a pick or place is inconsistent (i.e., both robot and pod think they are empty).	X			X	X

Equipment		Danger		Affected		
Configuration	Alarm Text	Potential	Imminent	Operator	Equipment	Material
Reticle Pick/Place error	The internal robot that moves the reticles failed to pick or place a reticle. Can be triggered if the state of the system after a pick or place is inconsistent (i.e. both robot and pod think they are empty).	X			X	X
Automation Error	Automation errors that do not fit other categories have been detected.	X		X	X	X

22.3 *Alarm Usage*

22.3.1 Reticle and Pod Management requires standardization on the alarm codes. Many errors may be mapped to a sinlge "generic" alarm code. In this case, the recovery scenario would be the same but the alarm text shall contain a more descriptive explanation of the error. For example, the Pod Open/Close alarm can be caused by many different opener errors.

22.3.2 This alarm applies to both Fixed and Internal Pod Buffer Equipment.

22.3.3 For any load port Alarm condition, process equipment should not stop processing current jobs.

Table 57 Alarm Information

Alarm Description	*Alarm Code*	*Auto Clear*	*Set trigger*	*Clear Trigger*
PIO Failure	1	NO	E84 error	Manual intervention
Access Mode Violation (unexpected load)	2	NO	Operator places pod on load port with access mode set to auto.	Operator switches to manual Operator removes the pod Operator switches to auto Operator clears alarm at UI
Access Mode Violation (unexpected unload)		NO	Operator takes a pod off load port with access mode set to auto.	Operator clears alarm at UI
Attempt to use out of service load port	3	YES	Pod placed on load port with transfer state set to out-of-service.	Pod is removed
Pod placement/placement error	4	YES	Sensors detect pod is not properly placed at pod opener.	Sensors detect pod is properly placed at pod opener or no pod present
Pod Open/Close error	5	NO	Opener errors while opening or closing.	Manual intervention
Duplicate Pod ID	6	Yes	A duplicate pod is detected.	Methods vary by equipment type
Pod Removal Error	7	NO	Pod removed before the Pod is in the READY TO UNLOAD state.	Operator clears alarm at UI
Duplicate Reticle ID	8	YES	A duplicate reticle is detected.	Methods vary by equipment type
Pod Pick/Place error	9	NO	The internal robot that moves the Pods failed to pick or place a pod. Can be triggered if the state of the system after a pick or place is inconsistent (i.e. both robot and pod think they are empty).	Manual intervention
Reticle Pick / Place error	10	NO	The internal robot that moves the reticles failed to pick or place a reticle. Can be triggered if the state of the system after a pick or place is inconsistent (i.e. both robot and pod think they are empty).	Manual intervention

Alarm Description	Alarm Code	Auto Clear	Set trigger	Clear Trigger
Automation Error	11	NO	Equipment and Alarm dependent, alarms that do not fit other categories.	Manual intervention

22.4 *Duplicate PodID at Production Equipment*

22.4.1 If the equipment receives a pod with a PodID that is the same as that of another pod present at the equipment, the following rules shall apply:

1. The second pod with a PodID shall not be processed.
2. If processing on the first pod with the PodID has not begun, it should not be processed.
3. If processing on the first pod has begun a Duplicate PodID In Process event shall be issued to notify the host.

23 Requirements for Compliance

23.1 Table 56 provides a checklist for RPMS compliance.

Table 58 RPMS Compliance Statement

Fundamental RPMS Requirements	*RPMS Section*	*Implemented*	*RPMS Compliant*
Load Port Numbering	9.2	☐ Yes ☐ No	☐ Yes ☐ No

APPENDIX 1
APPLICATION NOTES

NOTE: The material in this appendix is an official part of SEMI E109 and was approved by full letter ballot procedures on April 30, 2001 by the North American Regional Standards Committee.

A1-1 This is a place holder for the description of when the Alarms can be cleared.

SEMI E109.1-0302
PROVISIONAL SPECIFICATION FOR SEC-II PROTOCOL FOR RETICLE AND POD MANAGEMENT (RPMS)

This specification was technically approved by the Global Information and Control Committee and is the direct responsibility of the North American Information and Control Committee. Current edition approved by the North American Facilities Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002.

1 Purpose

1.1 This document maps the services of SEMI E109 to SECS-II streams and functions. This document also maps the data of SEMI E109 to E5 data definitions

2 Scope

2.1 This is a provisional standard that covers host and equipment communication for equipment that handle reticles. This includes equipment that handle reticles both inside and outside of a reticle pod. The provisional status is required because of the immaturity of implementations of integrated equipment with Automated Material Handling Systems (AMHS) or Automated Reticle Handling Systems (ARHS). Additional specifications may be defined to add further functionality. Also, further exception handling and error recovery scenarios need to be defined.

2.2 This document applies to all implementations of SEMI E109 that use SECS-II message protocol (SEMI E5). Compliance to this standard requires compliance to both SEMI E109 and SEMI E5.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard applies to semiconductor equipment that handles reticles and reticle carriers. This standard is intended to be used for lithography production, bare reticle storage, and reticle inspection equipment. It may or may not be applied to other types of equipment

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of the standards.

5 Services Mapping

5.1 This sections shows the specific SECS-II streams and functions that shall be used for SECS-II implementations of the services defined in SEMI E109, as well as the parameter mapping for data attached to services.

5.2 *Services Message Mapping*

5.2.1 Table 1 defines the relationships between SEMI E109 services and SECS-II messages.

Table 1 Service Message Mapping

Service Name	*Stream/Function*	*SECS-II Message Name*
Bind	S3F17/F18	Carrier Action Request/Acknowledge
CancelAllPodOut	S3F33/F34	Cancel All Pod Out Request/Acknowledge
CancelBind	S3F17/F18	Carrier Action Request/Acknowledge
CancelMoveReticle	S14F19/20	Generic Service Request/Acknowledge
CancelPod	S3F17/F18	Carrier Action Request/Acknowledge
CancelPodAtPort	S3F17/F18	Carrier Action Request/Acknowledge

SEMI E116-0702
PROVISIONAL SPECIFICATION FOR EQUIPMENT PERFORMANCE TRACKING

This specification was technically approved by the Global Information & Control Committee and is the direct responsibility of the North American Information & Control Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002.

1 Purpose

1.1 This document provides specification for implementing basic equipment performance tracking for production equipment. Provisions in this document enable the host computer to track basic equipment performance in an automated and consistent matter, without operator or host input. This document provides specification for equipment suppliers to:

- Track basic equipment states (no operator or host input required).
- Track basic equipment states in a modular manner, for both major modules and the overall equipment.
- Report basic equipment state changes to a host computer, at both module and equipment level.
- Report equipment's time in state to a host computer, at both module and equipment level.
- Report reasons to a host computer for why equipment is blocked from performing its task, at both module and equipment level.
- Report information to a host computer to allow computation of equipment run rate, at both module and equipment level.

1.2 Equipment users require the ability to track equipment performance without dependence on user input to eliminate inaccuracies due to incorrect or untimely input from the user. The ability to track equipment performance without user input is essential in 300 mm wafer factories where operational scenarios require minimal manual interaction. EPT defines concepts, behavior, and message services that enable the host computer to obtain the equipment data required for equipment performance tracking in an automated and consistent matter without operator or host input.

1.3 EPT enables factory managers to identify the current states of factory equipment, both at the equipment level and at the module level (e.g. processing chambers), without dependence on user input. EPT enables factory engineers to evaluate the time that equipment and modules spent in different states and identify areas for improvement. EPT enables factory engineers to obtain directly from the equipment the reasons why the equipment or module is prevented from performing. EPT provides industrial engineers the equipment data which, when combined with external data from the Manufacturing Execution System (MES), will enable accurate calculation of SEMI E10 states and SEMI E79 metrics at the equipment-level and the module-level. EPT allows capital equipment managers to obtain run-rate information at the equipment-level and module-level to identify requirements for new equipment purchases. EPT enables automation engineers to develop reusable host interfaces by using a standardized collection event and data variables to collect equipment state data.

2 Scope

2.1 The Scope of this standard is to define equipment behavior states and the data required to track basic equipment performance for production equipment. These requirements are intended to facilitate equipment-level and module-level state tracking and to communicate state information to the host for simple equipment performance tracking, without requiring host or operator input.

2.2 Specifically, this document provides:

- An Equipment Performance Tracking (EPT) state model that defines triggers for state changes.
- Specification of data variables required to communicate basic equipment performance data to the host computer.
- Specification of event messages used to communicate basic equipment performance data to the host computer.
- Specification of requirements for run rate information.
- Requirements for EPT compliance.

2.3 This standard specifies the concepts, behavior, and message services that enable the host computer to obtain the equipment data required for equipment performance tracking in an automated and consistent manner, without operator or host input. It does not specify the report of E10 states from the equipment to a host computer, as this information requires user input and is already specified by SEMI E58.

2.4 This standard does not conflict with SEMI E58 nor does it inhibit the equipment's ability to report out SEMI E10 states via SEMI E58.

2.5 This standard is a building block towards SEMI E10 and SEMI E79 by providing accurate equipment information required for SEMI E10 and SEMI E79 metrics, without dependence on operator or host input, eliminating inaccuracies due to incorrect or untimely input from the user. EPT assists both SEMI E10 and SEMI E79 by providing a modular approach to equipment performance tracking, allowing the state of the equipment to be determined by the states of its major modules. EPT assists SEMI E79 by providing task-level detail of the equipment or module's current activity, allowing performance metrics to be tracked at the task level.

2.6 This is a provisional standard. In order to have the provisional status removed, the following areas must be completed:

- Equipment Interlock Information
- Equipment Process Monitoring Information
- Equipment Maintenance Trigger Information
- Application of EPT State Model to load ports and internal buffers

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This standard applies to semiconductor production equipment. Other types of equipment have not been examined. However, it may be used for other types of equipment when applicable.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E10 — Specification for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI E30 — Generic Model for Communications and Control of Manufacturing Equipment (GEM)

SEMI E79 — Standard for Definition and Measurement of Equipment Productivity

SEMI E90 — Specification for Substrate Tracking

SEMI E98 — Provisional Standard for the Object-Based Equipment Modeling (OBEM)

SEMI 101 — Provisional Guide for EFEM Functional Structure Model

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *EFEM* — Equipment Front End Module

5.1.2 *EPT* — Equipment Performance Tracking

5.1.3 *GEM* — Generic Equipment Model [SEMI E30]

5.2 *Definitions*

5.2.1 *EPT module* — a major component of the equipment that affects processing or throughput.

For purposes of simplification, an EPT module executes one and only one task at a time. Each EPT Module has an EPT state model that is maintained by the equipment.

5.2.2 *EPT state* — the state of IDLE, BUSY, or BLOCKED within EPT state model.

5.2.3 *event report* — a message the equipment sends to the host on the occurrence of a collection event.

5.2.4 *fault* — an exception.

5.2.5 *host* — the factory computer system or an intermediate system that represents the factory and the operator to the equipment.

5.2.6 *intended function* — a manufacturing function that the equipment was built to perform. This includes transport functions for transport equipment, measurement functions for metrology equipment, as well as process functions such as physical vapor deposition and wire bonding. Complete equipment may have more than one intended function. [SEMI E58]

5.2.7 *material* — the basic unit of process. For the purposes of this standard, material is a set of one or more substrates.

5.2.8 *module* — a major component of equipment that contains at least one material location and performs some task on material. Equipment modules may be aggregates of equipment subsystems, I/O devices, and other modules. [SEMI E98]

5.2.9 *substrate* — the basic unit of material on which work is performed to create a product. Examples include wafers, die, plates used for masks, flat panels, circuit boards, and leadframes. [SEMI E90]

5.2.10 *task* — a planned and repeatable activity with an expected duration and a definite beginning and end (e.g. Move wafer from cassette to stage, Pre-align wafer, Align reticle, Preheat chamber, Increase vacuum). NOTE: Actual durations may vary.

5.2.11 *trigger* — an event that causes a change in the state of the equipment. Examples are changes in sensor readings, alarms, and messages received from the host, and operator commands.

5.2.12 *unit* — any wafer, die, packaged device, or piece thereof (included product and non-product units). [SEMI E10]

5.2.13 *user* — any entity interacting with the equipment, either locally as an operator or remotely via the host. From the equipment's viewpoint, both the operator and the host represent the user. [SEMI E58]

6 Requirements

6.1 An EPT compliant implementation requires provision of certain capabilities defined by other standards: accessibility to status information, event reporting, alarm management, and provision of an internal time-and-date clock. These requirements may be satisfied through compliance to SEMI E30 for the following sets of requirements:

- Clock Services
- Event Notification
- Status Data Collection
- Equipment Constants
- Alarm Management

6.2 An EPT compliant implementation requires support of SEMI E90.

6.3 An EPT compliant implementation requires a documented list of all EPT modules contained within the equipment.

6.4 An EPT compliant implementation requires an EPT state model for the equipment and for each EPT module.

6.5 Each EPT module shall have a documented list of tasks that the module may perform.

7 Conventions

7.1 This document follows the conventions for state model methodology and service definitions used by the SEMI standards referenced in Section 4.

7.2 *State Model Methodology*

7.2.1 A state model has three elements: definitions of each state and sub-state, a diagram of the states showing the valid transitions between states, and a corresponding state transition table that defines the triggers for each transition. The diagram of the state model uses the Harel State Chart notation. An overview of this notation is presented in an Appendix of SEMI E30. The definition of this notation is presented in Science of Computer Programming 8, "Statecharts: A Visual Formalism for Complex Systems", by D. Harel, 1987.

7.2.2 Transition tables are provided in conjunction with the state diagrams to explicitly describe the nature of each state transition. A transition table contains columns for Transition number, Previous State, Trigger, New State, Actions, and Comments. The "trigger" (column 3) for the transition occurs while in the "previous" state. The "actions" (column 5) includes a combination of:

1) Actions taken upon exit of the previous state.
2) Actions taken upon entry of the new state.
3) Actions taken that are most closely associated with the transition.

7.2.3 No differentiation is made between these cases.

#	*PREVIOUS STATE*	*TRIGGER*	*NEW STATE*	*ACTIONS*	*COMMENTS*
Transition #					

7.3 *Variable Data Item Definition*

7.3.1 The variable item dictionary contained in this document defines the variable name, description, type (format), access (read/write or read only), and comments about the variable. This is depicted in the format of the following table:

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*

7.4 *Event Description*

7.4.1 The collection event description table contained in this document includes the event name, the state model transition, the description, and the data required for the event. This is depicted in the format of the following table:

EVENT NAME	*STATE MODEL TRANSITION NUMBER*	*DESCRIPTION*	*REQUIRED DATA*

8 Overview

8.1 This section defines the concepts that enable EPT to provide information required for determining equipment performance.

8.2 Equipment processing times, including throughput and cycle times, are determined by two factors: (1) the sequence of tasks performed by the equipment, including the number of each task performed, as well as the series and parallel relationships between tasks, and (2) the execution time of each individual task. By tracking equipment systems in terms of modules that perform tasks, it will be possible to precisely identify the affect of both factors toward overall system performance.

8.3 EPT enables tracking to this level of detail by introducing the concept of an EPT module and the concept of a task. EPT-compliant equipment are required to report events according to a breakdown of equipment operations into tasks and EPT modules. An EPT module is an equipment component that affects processing or throughput, and is capable of executing only one task at a time. Examples of EPT modules include process stations, process chambers, wafer handling systems, etc. A task is a planned and repeatable activity with an expected duration and a definite beginning and end. Examples of tasks include the following:

- Move wafer from cassette to stage
- Pre-align wafer
- Align reticle
- Preheat chamber
- Increase vacuum etc.

8.4 EPT-compliant equipment consist of EPT modules that perform tasks. Thus, the state of the equipment can be effectively modeled as a composition of the states of the EPT modules. In addition, EPT provides detailed information required for performance tracking by providing the task-level details and run-rate information for each EPT module.

8.5 EPT modules and tasks are to be defined such that each EPT module executes only one task at a time. An example is given in Related Information Section R1-7. Each equipment system must have defined at least as many EPT modules as tasks that may be performed simultaneously by that system.

8.6 Each task should be defined such that the units involved (e.g., wafers, substrates, reticles), the EPT modules involved (e.g., process station, robot, etc.), and the task type (e.g., "process", "support", etc.) are constant throughout the duration of the task. A change in any of the following items should result in the start of a new task or completion of current task:

- Change in material involved (e.g. arrival of wafer, removal of wafer)
- Change of EPT modules involved (e.g. robot moves wafer, chamber processes wafer)
- Change in task type (e.g. purge recipe followed by production recipe)

NOTE 2: It is not practical for equipment to define tasks or modules at an indefinite level of detail. It is therefore recommended that in each instance for which the material involved, the EPT modules involved, and the task types are all constant, events for only one task should be reported. Any further breakdown is not required for EPT compliance. EPT places no limitations on supplemental event reporting within any task. However, these supplemental events should not be reported as EPT events.

9 EPT State Model

9.1 This section defines the basic Equipment Performance Tracking State Model, which is applied to the equipment and its EPT modules.

9.2 *EPT State Model Requirements*

9.2.1 The EPT state model is intended to capture the different states of the equipment and its EPT modules from an operational point of view:

- Busy executing a task
- Blocked from executing a task
- Idle (no tasks executing)

9.2.2 The equipment shall maintain an EPT state model for each major module (e.g. process stations and chambers, wafer handling systems, etc.) through which a unit passes throughout the entire equipment from removal of units from the carrier to the return of units to the carrier.

9.2.3 The equipment shall maintain an EPT state model for any major component of the equipment that impacts processing and throughput.

9.2.4 The equipment shall maintain its own EPT state model for the overall equipment.

9.2.5 The equipment is responsible for communicating all EPT state transitions.

9.2.6 The EPT state model can be applied to the Equipment Front-End Module (EFEM).

9.2.7 The state of the EFEM/carrier/load port related modules shall not impact the overall equipment state.

9.3 *EPT State Model Diagram*

9.3.1 Figure 1 shows the EPT state module diagram.

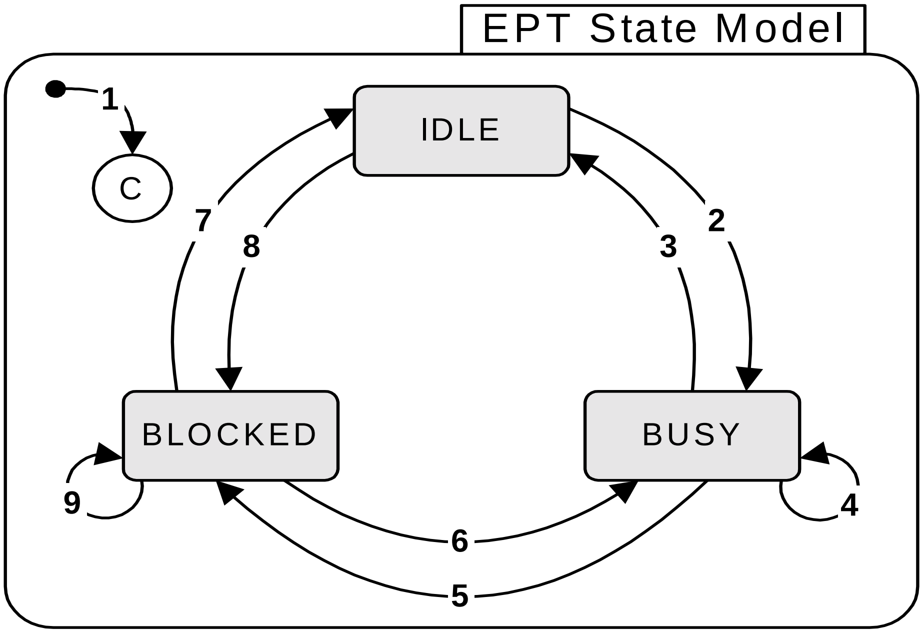

Figure 1
Equipment Performance Tracking State Model

9.4 *EPT State Definitions*

This section describes the EPT states.

9.4.1 IDLE

9.4.1.1 *EPT Module* — The following conditions are required for the module to be in the IDLE state:

- No material is present in the module and
- The module is not executing a task and
- No fault condition exists in the module that prevents it from starting a new task.

9.4.1.2 *Equipment* — The following condition is required for the equipment to be in the IDLE state:

- All of the equipment's EPT modules are in the IDLE state (excluding EFEM/carrier/load port related modules)

9.4.1.3 For both the equipment and modules the following conditions may exist in the IDLE State:

- The equipment or module is maintaining and monitoring environmental requirements (e.g. background temperature, particle monitoring, etc).

9.4.2 BUSY

9.4.2.1 *EPT Module* — The following conditions are required for the module to be in the BUSY state:

- The module is executing a task and
- No fault condition exists in the module that prevents the execution of a task.

9.4.2.2 *Equipment* — The following condition is required for the equipment to be in the BUSY state:

- At least one EPT module is BUSY (excluding EFEM/carrier/load port related modules).

9.4.2.3 For both the equipment and modules the following conditions may exist in the BUSY State:

- Material is present.

9.4.3 BLOCKED

9.4.3.1 *EPT Module* — One or more of the following conditions are required for the module to be in the BLOCKED state:

- Conditions exist that do not allow the EPT module to continue or start execution of a task (excluding EFEM/carrier/load port related modules):
- A fault condition(s) exists that prevents the EPT module from completing its task.
- A fault condition(s) exists that prevents the EPT module from starting a new task.
- The EPT module is pausing (or aborting) as the result of a pause (or abort) directive.
- The EPT module has paused its task and is awaiting a resume directive.
- The EPT module fails to initialize upon start-up.

9.4.3.2 *Equipment* — All of the following conditions are required for the EPT equipment to be in the BLOCKED state:

- At least one EPT module is BLOCKED (excluding EFEM/carrier/load port related modules) and
- No EPT modules are BUSY (excluding EFEM/carrier/load port related modules)

9.4.3.3 For both the EPT equipment and modules the following conditions may exist in the BLOCKED State:

- Material is present.

9.5 *EPT State Transition Table – Module Level*

9.5.1 This section defines the state transitions for the EPT modules within the equipment.

9.5.2 For each status variable updated with the event change, the corresponding event variable shall also be updated (see Table 5).

Table 1 Basic EPT State Transitions – Module Level

#	*PREVIOUS STATE*	*TRIGGER*	*NEW STATE*	*ACTIONS*	*COMMENTS*
1	(No state)	EPT module initialization completed.	IDLE [OR] BLOCKED	• No EPT event is triggered • $EPTState_i$ = IDLE or BLOCKED • $PreviousEPTState_i$ = NoState • $NumIdle_0$ is set • $NumBlocked_0$ is set • $PreviousTaskName_i$ = “No Task” • $PreviousTaskType_i$ = 0 • $EPTStateTime_i = 0$	• If no Fault conditions exist and no material is present, transition to IDLE • If Fault conditions exist, or EPT module cannot be initialized, then transition to BLOCKED • If Material is present, then transition to BLOCKED

#	PREVIOUS STATE	TRIGGER	NEW STATE	ACTIONS	COMMENTS
2	IDLE	EPT module starts execution of a new task.	BUSY	• *EPTStateChange$_i$* event is triggered • *EPTStateTime$_i$* is calculated • *EPTState$_i$* = BUSY • *PreviousEPTState$_i$* =IDLE • *TaskName$_i$* is set • *TaskType$_i$* is set • *NumBusy$_0$* incremented • *NumIdle$_0$* decremented	
3	BUSY	EPT module completes execution of task. [AND] Material is removed from the EPT module.	IDLE	• *EPTStateChange$_i$* event is triggered • *EPTStateTime$_i$* is calculated • *EPTState$_i$* = IDLE • *PreviousEPTState$_i$*=BUSY • *TaskName$_i$* = “No Task” • *TaskType$_i$* = 0 • *PreviousTaskName$_i$* is set • *PrevoiusTaskType$_i$* is set • *NumIdle$_0$* incremented • *NumBusy$_0$* decremented	
4	BUSY	EPT module starts execution of a new task upon the normal completion of the previous task.	BUSY	• *EPTStateChange$_i$* event is triggered • *TaskName$_i$* is set • *TaskType$_i$* is set	EPTStateTime$_i$ does not change. Thus when the module transitions out of BUSY state, the value of EPTStateTime$_i$ will reflect the total time the module was BUSY. PreviousEPTState$_i$ does not change. Thus, PreviousEPTState$_i$ will continue to reflect the state of the module before it was BUSY.
5	BUSY	A pause command is received that pauses the EPT module. [OR] An abort command is received that aborts the EPT module. [OR] A Fault condition occurs that prevents the EPT module from executing its task.	BLOCKED	• *EPTStateChange$_i$* event is triggered • *EPTStateTime$_i$* is calculated • *BlockedReason$_i$ is* set • *BlockedReasonText$_i$* is set • *EPTState$_i$* =BLOCKED • *PreviousEPTState$_i$* =BUSY • *NumBlocked$_0$* incremented • *NumBusy$_0$* decremented	TaskName$_i$ and TaskType$_i$ do not change. The variables continue to reflect the information of the task that is currently blocked from executing.

#	PREVIOUS STATE	TRIGGER	NEW STATE	ACTIONS	COMMENTS
6	BLOCKED	All fault conditions that prevented task execution are cleared and the EPT module resumes execution of its task or starts execution of a new task. [OR] A resume command is received that enables the EPT module to resume its task.	BUSY	• *EPTStateChange*$_i$ event is triggered • *EPTStateTime*$_i$ is calculated • *EPTState*$_i$ = BUSY • *PreviousEPTState*$_i$ =BLOCKED • *TaskName*$_i$ is set • *TaskType*$_i$ is set • *BlockedReason*$_i$ = 0 • *BlockedReasonText*$_i$ = "Not Blocked" • *NumBusy*$_0$ incremented • *NumBlocked*$_0$ decremented	
7	BLOCKED	All fault conditions that prevented task execution are cleared. [AND] All material is removed from the EPT module. [AND] EPT module can begin a new task.	IDLE	• *EPTStateChange*$_i$ event is triggered • *EPTStateTime* $_i$ is calculated • *EPTState*$_i$ =IDLE • *PreviousEPTState*$_i$ =BLOCKED • *TaskName*$_i$ = "No Task" • *TaskType*$_i$ = 0 • *PreviousTaskName*$_i$ is set • *PrevoiusTaskType*$_i$ is set • *BlockedReason*$_i$ = 0 • *BlockedReasonText*$_i$ = "Not Blocked" • *NumIdle*$_0$ incremented • *NumBlocked*$_0$ decremented	
8	IDLE	Material arrives at the EPT module and the EPT module cannot begin executing a task on the material. [OR] A fault condition occurs which prevents the EPT module from starting a new task.	BLOCKED	• *EPTStateChange*$_i$ event is triggered • *EPTStateTime*$_i$ is calculated • *BlockedReason*$_i$ is set • *BlockedReasonText*$_i$ is set • *EPTState*$_i$ = BLOCKED • *PreviousEPTState*$_i$ = IDLE • *NumBlocked*$_0$ incremented • *NumIdle*$_0$ decremented	

#	PREVIOUS STATE	TRIGGER	NEW STATE	ACTIONS	COMMENTS
9	BLOCKED	Fault conditions occur that prevent the EPT module from resuming a blocked task, or starting a new task.	BLOCKED	• *$EPTStateChange_i$* event is triggered • *$BlockedReason_i$* is set • *$BlockedReasonText_i$* is set	$EPTStateTime_i$ does not change. Thus when the module transitions out of BLOCKED state, the value of $EPTStateTime_i$ will reflect the total time the module was BLOCKED from processing. $PreviousEPTState_i$ does not change. Thus, $PreviousEPTState_i$ will continue to reflect the state of the module before it was BLOCKED from processing.

9.6 *EPT State Transition Table for Equipment*

9.6.1 This section defines the State Transitions for the Equipment, in terms of its EPT modules.

Table 2 Basic EPT State Transitions – Equipment Level

#	PREVIOUS STATE	TRIGGER	NEW STATE	ACTIONS	COMMENTS
1	(No state)	Equipment initiation completed (includes initialization of EPT modules).	IDLE [OR] BLOCKED	• *$EPTStateChange_0$* event is triggered • *$EPTState_0$* = IDLE or BLOCKED • *$PreviousEPTState_0$* = NoState • *$EPTStateTime_0$* = 0	• If any EPT module transitions to BLOCKED, then transition to BLOCKED • If all EPT modules transition to IDLE, then transition to IDLE
2	IDLE	Any EPT module transitions to BUSY.	BUSY	• *$EPTStateChange_0$* event is triggered • *$EPTStateTime_0$* is calculated • *$EPTState_0$* = BUSY • *$PreviousEPTState_0$* =IDLE	
3	BUSY	All EPT modules have transitioned to IDLE. [AND] All material is removed from Equipment.	IDLE	• *$EPTStateChange_0$* event is triggered • *$EPTStateTime_0$* is calculated • *$EPTState_0$*= IDLE • *$PreviousEPTState_0$* =BUSY	

#	*PREVIOUS STATE*	*TRIGGER*	*NEW STATE*	*ACTIONS*	*COMMENTS*
4	BUSY	Any EPT module transitions to BUSY from BUSY. [OR] Any EPT module transitions to BUSY when at least one other EPT module was already BUSY.	BUSY	• No event required	This event parallels the module-level BUSY events, and thus is not required
5	BUSY	At least one EPT module transitions from BUSY to BLOCKED when no other EPT modules are BUSY. [OR] At least one EPT module transitions from BUSY to IDLE when at least one EPT module is already BLOCKED and no other EPT modules are BUSY.	BLOCKED	• $EPTStateChange_0$ event is triggered • $EPTStateTime_0$ is calculated • $BlockedReason_0$ is set • $BlockedReasonText_0$ is set • $EPTState_0$=BLOCKED • $PreviousEPTState_0$ =BUSY	
6	BLOCKED	At least one EPT module that was BLOCKED transitions to BUSY. [OR] At least one EPT module that was IDLE transitions to BUSY.	BUSY	• $EPTStateChange_0$ event is triggered • $EPTStateTime_0$ is calculated • $EPTState_0$= BUSY • *PreviousEPT* $State_0$ =BLOCKED	
7	BLOCKED	All EPT modules that were BLOCKED have transitioned to IDLE. [AND] No EPT modules are BUSY.	IDLE	• $EPTStateChange_0$ event is triggered • $EPTStateTime_0$ is calculated • $EPTState_0$=IDLE • $PreviousEPTState_0$ =BLOCKED	
8	IDLE	Any EPT module that was IDLE transitions to BLOCKED.	BLOCKED	• $EPTStateChange_0$ event is triggered • $EPTStateTime_0$ is calculated • $BlockedReason_0$ is set • $BlockedReasonText_0$ is set • $EPTState_0$= BLOCKED • $PreviousEPTState_0$ = IDLE	

#	PREVIOUS STATE	TRIGGER	NEW STATE	ACTIONS	COMMENTS
9	BLOCKED	An EPT module that was already BLOCKED transitions again to BLOCKED. [OR] Any EPT module transitions to BLOCKED when at least one other EPT module was already BLOCKED. [OR] Any EPT module transitions to IDLE when at least one other EPT module was already BLOCKED.	BLOCKED	• *$EPTStateChange_0$* event is triggered • *$BlockedReason_0$* is set • *$BlockedReasonText_0$* is set	$EPTStateTime_0$ does not change. Thus when the equipment transitions out of BLOCKED state, the value of $EPTStateTime_0$ will reflect the total time the equipment was BLOCKED from processing. $PreviousEPTState_0$ does not change. Thus, $PreviousEPTState_0$ will continue to reflect the state of the equipment before it was BLOCKED from processing.

10 EPT Variable Data Definitions – Module Level and Equipment Level

10.1 The purpose of this section is to define variable data requirements for EPT events. The variable data is updated by the equipment at the time an EPTStateChange event occurs in the corresponding EPT state model. These variables are reported to the host via collection events reports and/or status queries from the host. Table 3 defines the EPT status variables required at the EPT module level. Table 4 defines the EPT status variables required at the equipment level. Table 5 defines the EPT event variables required at both the EPT module and equipment level.

10.2 *Variable Data Dictionary – Module Level*

10.2.1 This section defines the EPT module data variables that must be kept valid at all times. When queried for these data variables, the equipment shall send the current value of the data variable.

Table 3 Variable Data Definitions – Module Level

VARIABLE NAME	DESCRIPTION	TYPE	ACCESS	COMMENT
$ModuleName_i$	The name of the EPT module.	Text, 0 to 80 characters	RW	There exist i ModuleName variables, where i is the number of EPT modules. $ModuleName_0$ is unused. $ModuleName_1$ contains name of 1^{st} EPT module, $ModuleName_2$ contains name of 2^{nd} EPT module, etc.
$EPTState_i$	The current EPT state of the EPT module.	Enumerated	RO	0 = IDLE 1 = BUSY 2 = BLOCKED There exist i+1 EPTState variables, where i is the number of EPT modules. $EPTState_1$ contains state of 1^{st} EPT module, $EPTState_2$ contains state of 2^{nd} EPT module, etc.

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*
$PreviousEPTState_i$	The previous EPT State of the EPT module.	Enumerated	RO	0 = IDLE 1 = BUSY 2 = BLOCKED 3 = No State There exist i+1 PreviousEPTState variables, where i is the number of EPT modules. $EPTState_1$ contains previous state of 1st EPT module, $EPTState_2$ contains previous state of 2nd EPT module, etc.
$EPTStateTime_i$	Time spent in previous EPT state.	Unsigned Double	RO	Seconds This is the time period between the entry into the previous EPT state and the entry into the current EPT State There exist i+1 EPTStateTime variables, where i is the number of EPT modules. $EPTStateTime_1$ contains time in EPT state for 1st EPT module, $EPTStateTime_2$ contains time in EPT state for 2nd EPT module, etc.
$TaskName_i$	Name of the task that was started.	Text, 0 to 80 characters	RO	There exist i+1 TaskName variables, where i is the number of EPT modules. $TaskName_1$ contains task name for 1st EPT module, $TaskName_2$ contains task name for 2nd EPT module, etc. TaskName is defined by the equipment supplier.
$TaskType_i$	The type of task that module i is currently executing.	Enumerated	RO	No Task Process – adding value (e.g. exposing) Support – incapable of adding value (e.g. Handling/Transport) Equipment Maintenance (e.g. equipment initiated clean cycle) Equipment Diagnostics (e.g. equipment-initiated health check) Unspecified There exist i+1 TaskType variables, where i is the number of EPT modules. $TaskType_1$ contains type of task for 1st EPT module, $TaskType_2$ contains type of task for 2nd EPT module, etc.

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*
$PreviousTaskName_i$	The name of task that module i was previously executing.	Text	RO	There exist i+1 PreviousTaskName variables, where i is the number of EPT modules. $PreviousTaskName_1$ contains previous task name for 1st EPT module, $PreviousTaskName_2$ contains time previous task name for 2nd EPT module, etc.
$PreviousTaskType_i$	The type of task that module i was previously executing.	Enumerated	RO	No Task Process – adding value (e.g. exposing) Support – incapable of adding value (e.g. Handling/Transport) Equipment Maintenance (e.g. equipment initiated clean cycle) Equipment Diagnostics (e.g. equipment-initiated health check) Unspecified There exist i+1 TaskType variables, where i is the number of EPT modules. $TaskType_1$ contains type of task for 1st EPT module, $TaskType_2$ contains type of task for 2nd EPT module, etc.
$BlockedReason_i$	A numeric code that identifies the most recent block condition of a module.	Enumerated	RO	$BlockedReason_i$ shall have one of the following values: 0 – Not Blocked 1 – Unknown 2 – Safety Threshold 3 – Error Condition 4 – Parametric Exception 5 – Aborting, Aborted 6 – Pausing, Paused 7 – Reserved 8 – Reserved 9 – Reserved There exist i+1 BlockedReason variables, where i is the number of EPT modules. $BlockedReason_1$ contains Blocked Reason for 1st EPT module, $BlockedReason_2$ contains Blocked Reason for 2nd EPT module, etc.
$BlockedReasonText_i$	A description of the current block condition of a module. The reason why the transition was made to the BLOCKED state.	Text, 0 to 80 characters	RO	There exist i+1 BlockedReasonText variables, where i is the number of EPT modules. $BlockedReason_1$ contains Blocked Reason text for 1st EPT module, $BlockedReason_2$ contains Blocked Reason text for 2nd EPT module, etc.

10.3 *Variable Data Dictionary – Equipment Level*

10.3.1 This section defines the Equipment data variables that must be kept valid at all times. When queried for these data variables, the equipment shall send the current value of the data variable.

Table 4 Variable Data Definitions – Equipment Level

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*
EqpName	The name of the equipment.	Text, 0 to 80 characters	RW	
$EPTState_0$	The current EPT state of the equipment.	Enumerated	RO	0 = IDLE 1 = BUSY 2 = BLOCKED
$PreviousEPTState_0$	The previous EPT State of the equipment.	Enumerated	RO	0 = IDLE 1 = BUSY 2 = BLOCKED 3 = No State
$EPTStateTime_0$	Time spent in previous EPT state for the equipment.	Unsigned Double	RO	Seconds This is the time period between the entry into the previous EPT state and the entry into the current EPT State
$NumModules_0$	Total Number of EPT modules on the equipment.	Unsigned integer	RO	$NumModules_0$ = $NumBusy_0$ + $NumBlocked_0$ + $NumIdle_0$
$NumBusy_0$	Number of BUSY EPT modules on the equipment.	Unsigned integer	RO	$NumBusy_0$ = $NumModules_0$ - $NumBlocked_0$ - $NumIdle_0$
$NumBlocked_0$	Number of BLOCKED EPT modules on the equipment.	Unsigned integer	RO	$NumBlocked_0$ = $NumModules_0$ - $NumBusy_0$ - $NumIdle_0$

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*
$NumIdle_0$	Number of IDLE EPT modules on the equipment.	Unsigned integer	RO	$NumIdle_0 = NumModules_0 - NumBusy_0 - NumBlocked_0$
$BlockedReason_0$	The number of the block condition that initiated the transition to the BLOCKED state for the equipment.	Enumerated	RO	0 – Not Blocked 1 – Unknown 2 – Safety Threshold 3 – Error Condition 4 – Parametric Exception 5 – Aborting, Aborted 6 – Pausing, Paused 7 – Reserved 8 – Reserved 9 – Reserved
$BlockedReasonText_0$	The reason why the transition was made to the BLOCKED state for the equipment.	Text, 0 to 80 characters	RO	Description of the Blocked reason

10.4 The data items *TaskType* and *PreviousTaskType* may take on one of the following values:

0. No Task — Value for *TaskType* when the EPT module is IDLE , and value for the *PreviousTaskType* when the EPT module transitions out of the IDLE state or initial state (no state).
1. Process — Tasks expected under normal or desired manufacturing operations that are capable of adding value by either (1) a physical-chemical change or (2) providing critical process information (e.g., inspection or metrology). This includes tasks that are dependent on a recipe ID, dependent on parameters (e.g., target etch thickness), or recipe and parameter independent (e.g., fixed purge time for all recipes or regardless target etch thickness).
2. Support — Tasks expected under normal or desired manufacturing operations that are incapable of adding value according to the criteria for a process task. These include alignment, handling and other transport, and environmental changes by supporting EPT modules (e.g., pumpdown and vent operations in a load lock).
3. Maintenance — Any equipment-initiated task that is intended to change the state of the equipment for the purpose of maintaining equipment functionality or performance. This includes clean cycles, purges not expected under normal or desired manufacturing operations, and certain reset operations that do not put the EPT module or equipment in a non-operational state.
4. Diagnostics — Any equipment-initiated task that obtains information about the status of the equipment for the purpose of determining the equipment's health or identifying an equipment problem(s). This excludes any task that is intended to change the status of the equipment, as in a maintenance task. This also excludes metrology and inspection tasks that provide critical information about the process even if those tasks also provide equipment diagnostic information as a byproduct.
5. Unspecified — A placeholder for unspecified task types.

10.4.1 NOTES: The following notes resolve ambiguities that arise from limitations of the equipment or EPT module point of view. From the equipment or EPT module point of view:

- process maintenance activities (e.g., monitor wafers) and engineering activities (e.g., new process qualification runs) may be indistinguishable from normal or desired manufacturing operations. These operations shall be reported as either process or support operations.
- equipment maintenance activities (e.g., equipment qualification runs monitor wafers) may be indistinguishable from normal or desired manufacturing operations. These operations shall be reported as either process or support operations.

- activities executed for exception handling (e.g., pausing, aborting, stopping, or otherwise moving to a safe state) may be indistinguishable from support tasks. Examples include handling/transporting wafers to safe locations, pumping, venting, purging, etc. If the equipment or module implementing EPT does not have *reasonable inherent knowledge of purpose* regarding these activities, the tasks should be always declared as support tasks. If the equipment or module implementing EPT does have reasonable inherent knowledge of purpose regarding these activities, these activities shall be either (1) modeled as task faults or otherwise blocked conditions, or (2) exempted entirely from treatment under EPT. In case 2, the affected EPT module or modules must be in a BLOCKED state due to related conditions reported to the EPT state model(s).

10.5 Blocked Reason Text Requirements:

- Fault Condition: Blocked reason text should begin with "Fault: - 'appropriate text'"
- Pause Condition: Blocked reason text should begin with "Pause: - 'appropriate text'"

11 EPT Events

11.1 This section defines the required events and variable data associated with transitions in the EPT state model.

11.2 Table 5 defines the data variables that are valid at the time of an EPT State Change event. When the equipment or EPT module triggers an EPTStateChange event, the value of the data variable shall be updated to reflect the data valid at the time the event occurred.

Table 5 Variable Data Definitions – Event Variables

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*
EPTState	The new (resulting) EPT state of the module or equipment at the end of an EPT state transition.	Enumerated	RO	0 = IDLE 1 = BUSY 2 = BLOCKED
PreviousEPTState	The previous EPT state of the module or equipment of an end of an EPT state transition.	Enumerated	RO	0 = IDLE 1 = BUSY 2 = BLOCKED 3 = No State
EPTStateTime	Time spent in previous EPT state for the equipment or module.	Unsigned Double	RO	Seconds This is the time period between the entry into the previous EPT state and the entry into the current EPT State
Clock	The time and date at the end of an EPT state transition.	Formatted numeric text: timestamp format	RO	When included in an event report, Clock represents the timestamp for the occurrence of the event
TaskName	Name of the task that was started by the module or equipment at the occurrence of an EPT state transition.	Text, 0 to 80 characters	RO	TaskName is defined by the equipment supplier.

VARIABLE NAME	*DESCRIPTION*	*TYPE*	*ACCESS*	*COMMENT*
TaskType	The type of task that was started by the module or equipment at the occurrence of an EPT state transition.	Enumerated	RO	No Task Process – adding value (e.g. exposing) Support – incapable of adding value (e.g. Handling/Transport) Maintenance (e.g. equipment initiated clean cycle) Diagnostics (e.g. equipment-initiated health check) Unspecified
PreviousTaskName	Name of the task that was completed by the module or equipment at the occurrence of an EPT state transition.	Text, 0 to 80 characters	RO	
PreviousTaskType	The type of the task that was completed by the module or equipment at the occurrence of an EPT state transition.	Enumerated	RO	No Task Process – adding value (e.g. exposing) Support – incapable of adding value (e.g. Handling/Transport) Maintenance (e.g. equipment initiated clean cycle) Diagnostics (e.g. equipment-initiated health check) Unspecified
NumBusy	Number of BUSY EPT modules on the equipment at the end of an EPT state transition.	Unsigned integer	RO	NumBusy = i - NumBlocked - NumIdle where i is the number of EPT modules
NumBlocked	Number of BLOCKED EPT modules on the equipment at the end of an EPT state transition.	Unsigned integer	RO	NumBlocked = i - NumBusy - NumIdle where i is the number of EPT modules
NumIdle	Number of IDLE EPT modules on the equipment at the end of an EPT state transition.	Unsigned integer	RO	NumIdle = i - NumBusy - NumBlocked where i is the number of EPT modules
BlockedReason	The number of the block condition that initiated the transition to the BLOCKED state for the module or equipment.	Enumerated	RO	0 – Not Blocked 1 – Unknown 2 – Safety Threshold 3 – Error Condition 4 – Parametric Exception 5 – Aborting, Aborted 6 – Pausing, Paused 7 – Reserved 8 – Reserved 9 – Reserved

VARIABLE NAME	DESCRIPTION	TYPE	ACCESS	COMMENT
BlockedReasonText	The reason why the transition was made to the BLOCKED state for the module or equipment.	Text, 0 to 80 characters	RO	Description of the Blocked reason

11.3 All events require the following data variables to be available:

< Clock > *(Clock* represents the timestamp for the occurrence of the event*)*
< EPTState >
<PreviousEPTState>
< EPTStateTime >
<TaskName>
<TaskType>
<PreviousTaskName>
<PreviousTaskType>
<NumBusy>
<NumIdle>
<NumBlocked>
Additional data required for specific transitions are shown in Table 6.

Table 6 Events

EVENT NAME	***STATE MODEL TRANSITION NUMBER***	***DESCRIPTION***	*REQUIRED DATA*
EPTStateChange$_0$	1, 2, 3, 4, 5, 6, 7, 8, 9	Triggered by a EPT State change at the equipment-level.	<EqpName > The following additional data is required for Transitions 5, 8 and 9: < Blocked Reason> < BlockedReasonText>
EPTStateChange$_i$	1, 2, 3, 4, 5,6, 7, 8, 9	Triggered by an EPT State change at the EPT module-level. There exist i+1 EPTStateChange events, where i is the number of EPT modules. EPTStateChange$_1$ is triggered by a state change at the 1st EPT module, EPTStateChange$_2$ is triggered by a state change at the 2nd EPT module, etc.	<ModuleName> The following additional data is required for Transitions 5, 8 and 9: < Blocked Reason> < BlockedReasonText>

12 Run Rate Information

12.1 This section defines the EPT requirements for Run Rate Information. Run Rate is calculated as the number of units processed divided by the amount of time used to process those units. Equipment is not required by EPT to report its own run rate since the period of time may vary according to user requirements. However, EPT does require that the equipment provide sufficient information for the user to calculate run rate.

12.2 *Support for Run Rate (Throughput) Calculations*

12.2.1 The equipment shall report E90 events to provide data for the user to calculate Run Rate. These events must be generated at both the module-level and the equipment-level in order for an equipment to be EPT-compliant. The equipment must provide E90 events for each EPT module through which the wafer moves throughout the entire equipment.

12.2.2 At the equipment level, run rate information can be calculated by the user by using the total time from the point of time the first substrate in a run is removed from its carrier and the point in time the final substrate is returned to its destination carrier. The equipment is required to provide a method for tracking substrates as they move from position to position within it. This requirement is satisfied through compliance to SEMI E90 Specification for Substrate Tracking.

12.2.3 Each EPT module that contains a material location shall provide E90 events that can be used by the user to calculate the number of units processed and the time used for processing. Time for processing can be calculated by the user as the time between the arrival of the substrate in the EPT module and the departure of the substrate from the EPT module. Each EPT module shall provide events for the arrival and departure of the substrate. This requirement is satisfied through compliance of the EPT modules to the SEMI E90 state model for substrates and substrate locations.

13 Requirements for Compliance

13.1 Table 7 provides a checklist for EPT compliance.

Table 7 EPT Compliance Statement

Fundamental EPT Requirements	*EPT Section*	*Implemented*	*EPT Compliant*
EPT State Model for Equipment	9	☐ Yes ☐ No	☐ Yes ☐ No
EPT State model for each EPT module	9	☐ Yes ☐ No	☐ Yes ☐ No
EPT Variable Data	10	☐ Yes ☐ No	☐ Yes ☐ No
EPT Events	11	☐ Yes ☐ No	☐ Yes ☐ No
EPT Run Rate Information	12	☐ Yes ☐ No	☐ Yes ☐ No

R1-1 An Example of Equipment Performance Tracking on a Carrier Handling Module

R1-1.1 This section provides examples of equipment performance tracking to clarify the application of the standard to modules that are part of the Equipment Front-End Module (EFEM).

R1-2 Carrier Handling Module (CHM)

R1-2.1 The Carrier Handler is a part of EFEM, excluding any Substrate Handler, which is defined in SEMI E101. A Carrier Handling Module is similar but different from the definition. It is a more general subsystem to handle carriers without handling substrates in EFEM that is applicable to various analyses and applications. The Carrier Handling Module is a logical module that may or may not represent an existing physical module.

R1-2.2 The advantages of applying Equipment Performance Tracking to the Carrier Handling Module are as follows:

- Any equipment, except certain specific ones such as an expose tool within a linked litho tool in the lithography process, has one or more Carrier Handling Modules.

The state of the Carrier Handling Module leads to whole input and output of material to and from an equipment.

- Monitoring the Equipment Performance Tracking state of the Carrier Handling Module helps control loading to or unloading from equipment on appropriate time.
- The state can reveal what related SEMI standards, i.e. SEMI E87 and SEMI E90, may not address.
- Estimation of capabilities about sub-components on a Carrier Handling Module is available with tracking the state.
- Each component that makes up the Carrier Handling Module may experience mechanical failure. This can cause the entire Carrier Handling Module to be in an out of service state. Tracking time between failures would be valuable.

R1-3 Components to track performance of Carrier Handling Module

R1-3.1 Generally, a Carrier Handling Module has the following components.

- Carrier Handoff PIO (SEMI E84) Port
- Carrier Transfer Mechanism
- Carrier ID Reader
- Carrier ID Writer
- FOUP Opener
- Carrier Slot Mapper

R1-3.2 This section investigates the following composition to represent examples for Fixed Buffer type and Internal Buffer type equipment. An example of a Carrier Handling Module is illustrated in Figure R1-1. Number of installed components are listed in the Table 1.

Table R1-1 Typical Composition of Carrier Handoff Module

Number Installed	*Carrier Handoff PIO*	*Carrier Transfer Mechanism*	*Carrier ID Reader*	*Carrier ID Writer*	*FOUP Opener*	*Slot Mapper*
Internal Buffer Type	2	4	2	1	1	1
Fixed Buffer Type	2	2	2	2	2	2

Note: Several Carrier Transfer Mechanisms are usually docking mechanism for Fixed Buffer type. For Internal Buffer type, one of them is a Carrier Transfer Robot in internal buffer, one is a Docking Mechanism inside the internal buffer and the other one is Carrier Transfer Mechanism to pass carrier between Load Port and the Internal Buffer.

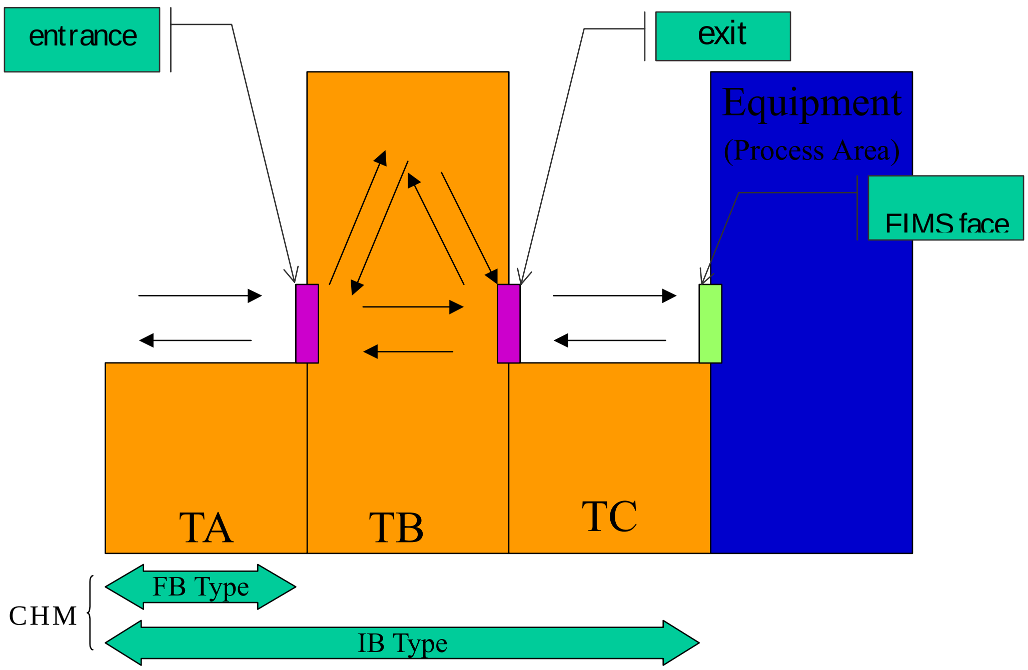

Figure R 1-1 Carrier Handling Module

<u>In Diagram R1-1, the following translation applies</u>
FB Type = Fixed Buffer Type
IB Type = Internal Buffer Type
TA = Transport A
TB = Transport B
TC = Transport C

R1-4 Triggers of Transition for each Components of Carrier Handling Module

The following tables describe triggers to change the state of components for specific tasks.

Table R1-2 Triggers of Transitions for specific tasks of Carrier Handoff PIO

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Receiving VALID signal in E84.	BUSY	Set off handoff sequence	Loading or Unloading sequence. Processing or moving wafers between carrier and process container before Unloading.
3	BUSY	Receiving COMPT signal in E84 or Timeout in handoff sequence.	IDLE	Waiting disconnected	Loading or Unloading sequence is completed or terminated. Processing or moving wafers between carrier and process container after Loading.

Table R1-3 Triggers of Transitions for specific tasks of Carrier Transfer Mechanism on Loadport of Fixed Buffer Type or FIMS port of IB

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Docking or Undocking Started	BUSY	None	Carrier moving sequence before docking. Processing or moving wafers between carrier and process container before undocking.
3	BUSY	Docking or Undocking Complete	IDLE	None	Processing or moving wafers between carrier and process container after docking.

Table R1-4 Triggers of Transitions for specific tasks of Carrier Transfer Mechanism in Internal Buffer Unit

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Transfer Started	BUSY	Moves carrier to destination	
3	BUSY	Transfer Complete	IDLE	None	Ready to unload or remove from port.

Table R1-5 Triggers of Transitions for specific tasks of Carrier ID Reader

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Reading Started	BUSY	None	Carrier moving sequence before reading.
3	BUSY	Reading Complete	IDLE	Verification	Processing or moving wafers between carrier and process container after opening.

Table R1-6 Triggers of Transitions for specific tasks of Carrier ID Writer

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Writing Started	BUSY	None	Processing wafers before writing.
3	BUSY	Writing Complete	IDLE	Waiting next writing or any post writing action	Carrier moving sequence after writing.

Table R1-7 Triggers of Transitions for specific tasks of FOUP Opener

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Opening or Closing Started	BUSY	None	Carrier moving sequence before opening.
3	BUSY	Opening or Closing Complete	IDLE	None	Processing or moving wafers between carrier and process container after opening.

Table R1-8 Triggers of Transitions for specific tasks of Slot Mapper

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
2	IDLE	Scanning Started	BUSY	None	Carrier moving sequence before mapping.
3	BUSY	Scanning Complete	IDLE	Waiting next scan	Processing or moving wafers between carrier and process container after mapping.

Table R1-9 Triggers of Transitions Common for all Components of Carrier Handling Module

#	*Previous State*	*Trigger*	*New State*	*Action(s)*	*Comment*
1	(no state)	Initialization is complete	IDLE	None	
7	BLOCKED	Get Recovered	IDLE	None	
8	IDLE	Unable to do task	BLOCKED	None	
9	BLOCKED	Get another Fault	BLOCKED	None	

R1-5 Operation Scenarios for Carrier Handling Module

R1-5.1 A couple of following scenarios are typical for different type of Carrier Handling Module.

R1-5.2 *Carrier Handling Module for Fixed Buffer Type*

R1-5.2.1 Beside the number of Loadports, following table shows just one set of components out of them.

R1-5.2.2 Indicated subsystems: PIO = Carrier Handoff PIO Port, CID-R = Carrier ID Reader, X'fer Transfer Mechanism = Carrier Transfer Mechanism (Docking Mechanism), CID-W = Carrier ID Writer, Opener = FOUP Opener, Mapper = Carrier Slot Mapper

Table R1-10 Scenario of Fixed type Carrier Handling Module

Event #	*Description*	*Time*	*PIO*	*CID-R.*	*X'fer Mech*	*CID-W*	*Opener*	*Mapper*
0	Carrier Handling Module and all components starting in "IDLE"	0:00	IDLE	IDLE	IDLE	IDLE	IDLE	IDLE
1	Loading Started	0:30	BUSY	↑	↑	↑	↑	↑
2	Loading Completed	1:00	IDLE	↑	↑	↑	↑	↑
3	ID Reading Started	1:05	↑	BUSY	↑	↑	↑	↑
4	ID Reading Complete	1:10	↑	IDLE	↑	↑	↑	↑
5	ID Verification	-	↑	↑	↑	↑	↑	↑
6	Docking Started	1:20	↑	↑	BUSY	↑	↑	↑
7	Docking Complete	1:50	↑	↑	IDLE	↑	↑	↑
8	Opening Start	1:55	↑	↑	↑	↑	BUSY	↑
9	Opening Complete	2:25	↑	↑	↑	↑	IDLE	↑
10	Mapping Started	2:30	↑	↑	↑	↑	↑	BUSY
11	Mapping Complete	2:15	↑	↑	↑	↑	↑	IDLE
12	Slotmap Verification	-	↑	↑	↑	↑	↑	↑
13	Process Started	12:15	↑	↑	↑	↑	↑	↑
14	Process Completed	47:15	↑	↑	↑	↑	↑	↑
15	Writing Started	47:20	↑	↑	↑	BUSY	↑	↑
16	Writing Complete	48:10	↑	↑	↑	IDLE	↑	↑
17	Closing Start	48:10	↑	↑	↑	↑	BUSY	↑
18	Closing Complete	48:40	↑	↑	↑	↑	IDLE	↑
19	Undocking Started	48:45	↑	↑	BUSY	↑	↑	↑
20	Undocking Complete	49:15	↑	↑	IDLE	↑	↑	↑
21	Unloading Started	52:25	BUSY	↑	↑	↑	↑	↑
22	Unloading Complete	52:55	IDLE	↑	↑	↑	↑	↑
23	Carrier Handling Module and all components returning in "IDLE"	52:55	↑	↑	↑	↑	↑	↑

R1-5.3 *Carrier Handling Module for Internal Buffer Type*

R1-5.3.1 It is assumed that Carrier Slot Mapper and Carrier ID Writer are mounted at an FIMS port next to Internal Buffer located inside of the equipment. The following table shows the set of components of a single Loadport.

R1-5.3.2 Indicated subsystems: PIO = Carrier Handoff PIO Port, CID-R = Carrier ID Reader, X'fer A = Carrier Transfer Mechanism from Handoff position to Carrier In/Out position, X'fer B = Carrier Transfer Mechanism of Internal Buffer, X'fer C = Carrier Transfer Mechanism (Docking Mechanism) for internal FIMS port, CID-W = Carrier ID Writer, Opener = FOUP Opener, Map = Carrier Slot Mapper

Table R1-11 Scenario of Fixed type Carrier Handling Module

Event #	*Description*	*Time*	*PIO*	*CID-R.*	*X'fer A*	*X'fer B*	*X'fer C*	*CID-W*	*Opener*	*Map*
0	Carrier Handling Module and all components starting in "IDLE"	0:00	IDLE	IDLE	IDLE	IDLE	IDLE	IDLE	IDLE	IDLE
1	Loading Started	0:30	BUSY	↑	↑	↑	↑	↑	↑	↑

R1-6 Tracking Performance for Whole Carrier Handling Module

R1-6.1 Even composition and property of equipment are dependent on equipment type, operation and usage depends on equipment user. Because actual usage deeply affects the whole performance of the Carrier Handling Module and/or Equipment, the user is responsible for reconstructing the performance from performance tracking events for each component.

R1-7 EPT Module / Task Definition Example

R1-7.1 Figure R1-2 shows a simple module and the associated actions/tasks that correspond. The EPT Tasks have been diluted to the level that will allow a serial chain of tasks to occur. The Internal Tasks column is present to show that the equipment may have much more happening concurrently at a more detailed level. Table R1-12 shows a possible task-based process flow in this module.

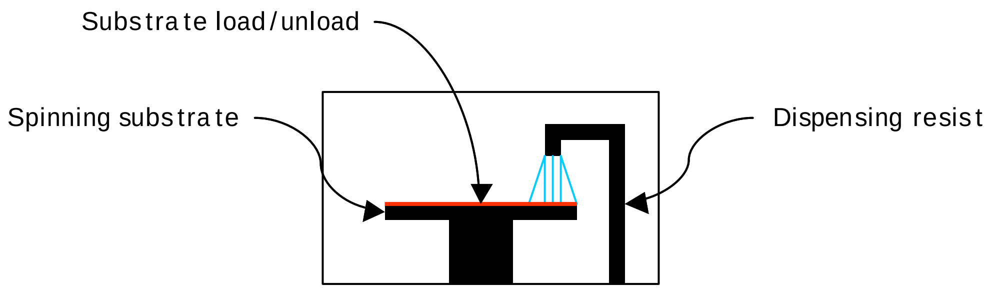

Figure R1-2
Example EPT Module

Table R1-12 Example EPT Tasks

Step	*Action*	*Possible Internal Tasks*	*EPT Active Task*
1	Loading the substrate	Receiving the substrate Substrate alignment	Substrate load
2	Coating the substrate	Substrate spin (accelerate) Substrate spin (steady) Dispense resist Substrate spin (decelerate)	Substrate coat
3	Unloading the substrate	Substrate alignment Substrate removal	Substrate unload

SEMI INTERNATIONAL STANDARDS

FACILITIES STANDARDS AND SAFETY GUIDELINES

Semiconductor Equipment and Materials International

SEMI F1-96
SPECIFICATION FOR LEAK INTEGRITY OF HIGH-PURITY GAS PIPING SYSTEMS AND COMPONENTS

NOTE: This entire document was revised in 1995.

1 Purpose

This specification defines the leak testing requirements and leakage rates for high-purity gas piping systems and components used in semiconductor manufacturing. It is also intended as an aid in the procurement and installation of equipment, materials, and services.

2 Scope

2.1 This specification applies to high-purity gas piping systems and components used in semiconductor manufacturing facilities and comparable research and development areas.

2.2 It includes testing methods for complete systems, subsystems, and individual components.

2.3 It states requirements for both the user and manufacturer and establishes leak rate limits for acceptance testing and qualification testing.

3 Limitations

3.1 This specification is not a replacement for safety regulations. It is the responsibility of the user to ensure that piping systems and components comply with all applicable safety regulations.

3.2 *Interferences*

3.2.1 Mass spectrometer leak testing with helium can result in misleading indications due to high permeability of polymeric materials by helium. Permeation is often indicated by a delayed leakage indication and a continually rising apparent leakage rate. Helium tracer gas under pressure is absorbed by permeable materials, and subsequent desorption can inhibit later testing at sensitive levels. Therefore, perform the tests in this order: inboard, internal, and outboard.

3.2.2 For low pressure tests, 1 MPa (147 psig) or less, the space to be filled with tracer gas must be purged or evacuated to avoid dilution. This applies both to enclosures and to the interiors of test objects.

3.2.3 Long tubing lines or small diameter tubing at an inlet may require purging to ensure that the tracer gas reaches the test object.

3.2.4 Conductance between the test object and the leak detector must be adequate to ensure test sensitivity. Restrictions such as regulators or check valves between the test object and the leak detector may require testing the test object before installing the downstream components.

3.2.5 Air flow can severely hinder capture of leaking gas by a detector probe. If possible, such air flow should be reduced to a minimum during testing. If testing must be performed in an area with substantial air flow, a protective film, such as is described in ASTM E 499, Method B, should be placed around the probe tip when examining each joint.

3.2.6 Temperature variations may affect leak performance. However, this specification does not address this effect.

All documents cited shall be the latest published revisions.

4.1 *SEMI Document*

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

4.2 *ASTM Standards*[1]

E 493 — Standard Test Methods for Leaks Using the Mass Spectrometer Leak Detector in the Inside-Out Testing Mode

E 498 — Standard Methods of Testing for Leaks Using the Mass Spectrometer Leak Detector or Residual Gas Analyzer in the Tracer Probe Mode

E 499 — Standard Methods of Testing Leaks Using the Mass Spectrometer Leak Detector in the Detector Probe Mode

5 Terminology

5.1 *acceptance test* — A test conducted on each component, subsystem, or system produced. It is the basis for acceptance or rejection by the purchaser. The purpose of acceptance testing is to provide a check to ensure that the component, subsystem, or system has been properly assembled or manufactured.

5.2 *component* — An individual piece or a complete assembly of individual pieces capable of being joined

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

with other pieces or components. The typical components referred to by this specification are valves, fittings, regulators, pressure gauges, pressure and flow sensors, and tubing welded to fittings.

5.3 *design pressure* — Of a system or subsystem, the pressure at the most severe condition of internal and external pressure expected during normal service. The maximum pressure expected in any portion of a system or subsystem is typically determined by the maximum adjustable setting of the last pressure regulator that supplies it, the supply pressure to the regulator, or the actuation pressure of any relief device incorporated.

5.4 *high-purity* — Of a system, subsystem, or component used for the control of chemicals (gases or liquids), designed and constructed in such a manner that it does not introduce significant impurities, particulate or molecular, into the flow stream it controls or regulates.

NOTE: Such systems, subsystems, or components are designed and constructed such that, if an impurity is introduced into the flow path, it can be readily purged to an insignificant level.

5.5 *leak* — A path (or paths) in a sealed system that will pass tracer gas when a pressure differential or diffusion path exists. There are two leak mechanisms: a mechanical passage and a material through which gas can diffuse or permeate. A leak may have both mechanisms operating in parallel.

5.6 *leakage, inboard* — Leakage from outside to inside occurring when the internal pressure is less than the external pressure acting on a component. Inboard leakage is typically determined by introducing a tracer gas around the exterior of the piping system or component under test.

NOTE: Inboard leak tests are easier tests to conduct to high sensitivity levels, but are typically not indicative of pressurized operating conditions. It is difficult to correlate an inboard leak test to the performance of a component, subsystem, or system when under internal pressure. Also, the internal collapsing forces created by external pressure may mask leaks which may exist under pressurized operating conditions.

5.7 *leakage, internal* — Leakage occurring within a component across a flow barrier, such as the seat of a closed valve.

5.8 *leakage, outboard* — Leakage from inside to outside occurring when the internal pressure is greater than the external pressure acting on a component. Outboard leakage is typically determined by introducing a tracer gas into the interior of the piping system or component under test.

5.9 *may* — A term indicating that a provision is neither required nor prohibited by this specification.

5.10 *measured leak rate* — The rate of leakage of a given component, subsystem, or system measured under specific conditions and employing a tracer gas.

NOTE: When testing with high-pressure 100% helium on a mass spectrometer leak detector, measured leak rates must be converted to equivalent standard leak rates.

5.11 *qualification test* — A test conducted on samples of production articles manufactured to a single design to establish the performance rating of a product. The tests are extensive and closely controlled and completely analyze the characteristics of a component for use in a high-purity installation.

5.12 *rated pressure* — The manufacturer's recommended maximum allowable operating pressure at the manufacturer's rated temperature.

5.13 *shall* — A term indicating that a provision is a requirement of this specification.

5.14 *should* — A term indicating that a provision is recommended as good practice but is not a requirement of this specification.

5.15 *shutoff valve* — A valve designed for, and capable of, positive closure to prevent flow within a system. Typical shutoff valves include manually actuated, power-actuated, or spring-actuated, fail-safe shutoff valves. Generally excluded are self-actuated valves such as check valves, pressure regulators, flow controllers, and other devices not intended to provide positive shutoff.

5.16 *standard leak rate* — The flow of helium at 21.1°C (70°F) and 101.3 kPa (1 atm) through a leak when the partial pressure of helium on the high side is 101.3 kPa and the partial pressure on the low side is below 133 Pa (1 torr).

NOTE: Express leak rates in kiloPascal-liters per second (kPa-L/sec). Calculate the standard leak rate of helium from the measured leak rate by multiplying by the ratio of 101.3 kPa to the partial pressure of helium, as follows:

$$\text{Standard} = \frac{101.3\ \text{kPa}(1\ \text{atm}) \times \text{measured leak rate}}{\text{actual He partial pressure}}$$

5.17 *subsystem* — An assembly of two or more components manufactured as a single entity. A subsystem must be combined with one or more additional components or subsystems to form a complete system. The typical subsystems referred to by this specification are gas source manifolds, gas distribution manifolds, and gas control manifolds within the process equipment.

5.18 *system* — An integrated structure of components and subsystems capable of performing, in aggregate, one or more specific functions. For the purpose of this specification, a system includes the gas source manifold, its connection to the gas source, the distribution piping, and the gas control manifold within the process equipment.

6 Ordering Information

Orders for equipment or services requiring leak testing in accordance with this specification shall include:

a. This specification number and date of issue.

b. Acceptance test requirements and applicable test paragraphs of this specification for the specific product being purchased.

c. Qualification test requirements, if any, and applicable test paragraphs of this specification for the specific product being purchased.

d. The design pressure to be used for internal and outboard leakage testing of systems, subsystems, or components.

e. Whether certification of the qualification or acceptance tests and a report of test results is required.

7 Requirements

7.1 *Personnel Qualifications* — Personnel performing tests in accordance with this specification shall have suitable training and experience. Such personnel should, as a minimum:

a. be trained and experienced in the use of mass spectrometer leak detectors,

b. be familiar with the use of the ASTM test methods referenced by this specification, and

c. be familiar with the operation and calibration of the specific equipment used in performing the tests.

7.2 *Tests*

7.2.1 Prior to initial operation, test each component, subsystem, and system in accordance with this specification.

7.2.2 If repairs or additions are made after the leakage tests, retest the affected portions of the component, subsystem, or system.

7.3 *Test Conditions*

7.3.1 All joints, including welds, shall be uninsulated, unpainted, and exposed for examination during the test.

7.3.2 Isolate portions of a system that are not being tested during the test.

7.3.3 Tracer gas pressure shall not exceed the manufacturer's pressure rating.

7.3.4 Conduct leakage tests at a temperature between 18°C (64°F) and 26°C (78°F).

7.4 *Leak Rate Limits*

Table 1

Direction	*Component*	*Component*	*Subsystem*		*System*	
	kPa - L/sec	*atm - cc/sec*	*kPa - L/sec*	*atm - cc/sec*	*kPa - L/sec*	*atm - cc/sec*
Inboard	10^{-10}	10^{-9}	10^{-9}	10^{-8}	10^{-10} (per point)	10^{-9}
Internal	10^{-10}	10^{-9}	10^{-10}	10^{-9}	10^{-10}	10^{-9}
Outboard	10^{-10}	10^{-9}	10^{-9}	10^{-8}		1 ppm
			(or 1 ppm increase in atmospheric concentration if by probe method)		1 ppm increase in atmospheric concentration	

NOTES:

a. The internal leakage specifications apply only if the test object is rated for positive closure.

b. The internal leakage specification applies to each positive closure. If positive shutoff devices are in parallel, the specification applies to the parallel devices as a group.

c. When piping systems or components employ polymeric seals, the internal and outboard leak rates specified above shall be modified by multiplying the stated values by 100.

d. When new construction projects preclude measurement of outboard leakage at the leak rates specified above, the outboard leakage limits shall be modified by multiplying the stated values by 100.

8 Test Methods

8.1 *Dangers*

8.1.1 Testing of systems, subsystems, or components with high pressure gas could cause explosive rupture of these items, with the resulting fragmentation causing death or serious injury. In addition, if a component of the system under test were to fail, an unrestricted supply of tracer gas could cause pressurization and rupture of the test enclosure. Such testing shall not be performed without shielding that will protect the operator and other personnel in the event of equipment failure. The source of tracer gas should be provided with a suitable device that will limit or shut off the flow in the event of component rupture.

8.1.2 Some elements of a piping system may not be designed for pressurization. Pressurization of such system elements could cause explosive rupture, with the resulting fragmentation causing death or serious injury. Such elements shall not be tested in a manner inconsistent with the manufacturer’s specifications. Valves used to isolate these elements of systems must be rated for higher pressure than the proposed test pressure.

8.1.3 Some components may be designed for closure only in one direction or only under pressure or vacuum. Testing of such components in a manner other than that for which they are designed could cause explosive rupture, with the resulting fragmentation causing death or serious injury. Such components shall not be tested in a manner inconsistent with the manufacturer’s specifications.

8.2 *Tracer Gas* — (Unless otherwise specified in Sections 8.4 through 8.6.)

8.2.1 For those tests in which the test object is enclosed in or sprayed with tracer gas, 100% helium.

8.2.2 For those tests in which the test object is pressurized with tracer gas, 101.3 kPa (1 atm) of helium plus nitrogen to pressurize to the design pressure.

8.2.3 The use of helium with a purity level of less than 100 ppb total contaminants and filtered at point of use to less than 0.1 µm is required.

8.2.4 Inboard tests are performed at one atmosphere.

8.2.5 Internal and outboard tests are performed at the design pressure.

8.3 The use of a dry, oil-free helium mass spectrometer leak detector is recommended to prevent hydrocarbon contamination of the piping system or component during inboard and internal leak testing.

8.4 *Components*

8.4.1 *Inboard*

8.4.1.1 *Reference Method* — ASTM E 498, Method A. Component acceptance shall be based upon total component integrity in accordance with ASTM E 498, Article 6.8. Components that are too large to enclose in a single helium envelope may be enclosed in segments to determine total integrity.

8.4.1.2 Test each component for total inboard leakage by introducing helium into a bag or other enclosure around the component. Ensure that the enclosure is sufficiently well-purged of air to minimize dilution of the helium. In instances where the bagging technique is not practical, the inboard leakage method of Section 8.6.1.2 may be substituted.

8.4.1.3 *Test Time* — Monitor the leak rate for 15 seconds.

8.4.2 *Internal–Qualification Test*

8.4.2.1 *Reference Method* — ASTM E 498, Method A. Connect the outlet side of the closed component to the leak detector. Apply tracer gas at the component's design pressure to the inlet side. Inlet and outlet sides shall be as designated by the manufacturer.

8.4.2.2 *Tracer Gas* — 100% helium.

8.4.2.3 *Test Time* — Monitor the leak rate for 15 seconds.

8.4.3 *Internal–Acceptance Test*

8.4.3.1 *Reference Method* — ASTM E 498, Method A. Connect the outlet side of the closed component to leak detector. Apply tracer gas at atmospheric pressure to the inlet side. Inlet and outlet sides shall be as designated by the manufacturer.

8.4.3.2 *Tracer Gas* — 100% helium.

8.4.3.3 *Tracer Gas Pressure* — Atmospheric.

8.4.3.4 *Test Tim* — Monitor the leak rate for 15 seconds.

8.4.4 *Outboard—Method 1*

8.4.4.1 *Reference Method* — ASTM E 498, Method B, modified as follows:

a. Cap the outlet of the component with a high integrity fitting.

b. For valves and regulators, open the flow path through the component. Install the component in a vacuum chamber. A leak tight gas flow passage must extend from the test component to the exterior of the vacuum chamber.

c. Connect the leak detector to the vacuum chamber and evacuate the chamber.

d. Pressurize the test component.

NOTE: Special fixtures may be required to test components with tube stub ends to insure personnel safety and to prevent component damage.

8.4.4.2 *Test Time* — Maintain the test condition for one minute.

8.4.5 *Outboard–Method 2* — Same as for Method 1, except use 100% helium as the tracer gas.

8.4.6 *Unassembled Components*

8.4.6.1 Components that are assembled by the purchaser, rather than the manufacturer, or that are altered or repaired by the purchaser, shall be tested by the purchaser in accordance with this specification.

8.4.6.2 Test of such components by the purchaser shall not be performed under conditions that exceed the manufacturer's ratings.

8.5 *Subsystems*

8.5.1 *Inboard*

8.5.1.1 *Reference Method* — ASTM E 498, Method A. Subsystem acceptance shall be based upon total subsystem integrity in accordance with ASTM E 498, Article 6.8.

8.5.1.2 Test for total inboard leakage by introducing helium into a bag or other enclosure around the subsystem. Ensure that the enclosure is sufficiently well-purged of air to minimize dilution of the helium. In instances where the bagging technique is not practical, the inboard leakage method of Section 8.6.1.2 may be substituted.

8.5.1.3 Test time should be based on actual times to record a standard capillary leak placed at the furthest point in the subsystem from the leak detector.

8.5.1.4 Subsystems that are too large to enclose in a single helium envelope may be tested in segments to determine total integrity.

8.5.2 *Internal—Method 1*

8.5.2.1 *Reference Method* — ASTM E 498, Method A, modified as follows:

a. Close the shutoff valve and pressurize the inlet with tracer gas.

b. Connect the leak detector to the closest point available to the valve outlet. Keep the evacuated portion of the subsystem as small as practicable.

8.5.2.2 Test each subsystem for internal leakage of each shutoff valve.

8.5.2.3 Test time should be based on actual times to record a standard capillary leak placed at the furthest point in the subsystem from the leak detector.

8.5.3 *Internal—Method 2* — As in Method 1, except use 100% helium as the tracer gas.

8.5.4 *Outboard——Method 1*

8.5.4.1 *Reference Method* — ASTM E 493, Method B, modified such that the subsystem shall be prefilled and maintained at constant pressure during the test.

NOTE: The pressure may be different for different portions of the subsystem.

8.5.4.2 *Test Time* — Monitor the leak rate for 15 seconds.

8.5.5 *Outboard——Method 2*

8.5.5.1 *Reference Method* — ASTM E 499, Method A, direct probing. Examine each joint with a detector probe.

8.6 *Systems*

8.6.1 *Inboard*

8.6.1.1 *Reference Method* — ASTM E 498, Method A.

8.6.1.2 Test each system for total inboard leakage by spraying a small stream of tracer gas around each point of possible leakage.

8.6.1.3 Test time should be based on actual times to record a standard capillary leak placed at the furthest point in the system from the leak detector.

8.6.2 *Internal*

8.6.2.1 *Reference Method* — ASTM E 498, Method A, modified as follows:

a. Close the shutoff valve and pressurize the inlet with tracer gas.

b. Connect the leak detector to the closest point available to the valve outlet. Keep the evacuated portion of the subsystem as small as practicable.

8.6.2.2 Test each subsystem for internal leakage of each shutoff valve.

8.6.2.3 Test time should be based on actual time to record a standard capillary leak placed at the furthest point in the subsystem from the leak detector.

8.6.3 *Internal—Method 2* — Same as in Method 1, except use 100% helium as the tracer gas.

8.6.4 *Outboard*

8.6.4.1 *Reference Method* — ASTM E 499, Method A, Direct Probing. Each joint shall be examined with a detector probe.

9 Certification

When specified in the purchase order or contract, the manufacturer's or supplier's certification shall be furnished to the purchaser stating that the articles furnished have been tested in accordance with applicable paragraphs of this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

SEMI F2-94
SPECIFICATION FOR 316L STAINLESS STEEL TUBING FOR GENERAL PURPOSE SEMICONDUCTOR MANUFACTURING APPLICATIONS

1 Purpose

The purpose of this specification is to identify the applicable ASTM tubing specification requirements and to define the special material chemical composition requirements for 316L stainless steel tubing which is to be used for general purpose applications in semiconductor manufacturing facilities.

2 Scope

This specification covers grades of nominal-wall-thickness stainless steel tubing as designated in Table 1 of ASTM A 269, for use in chemical (gas or liquid) distribution systems in semiconductor manufacturing facilities and in comparable research and development areas.

3 Referenced Documents

The referenced documents are to be their current editions as published by their sponsors.

Boiler and Pressure Vessel Code — Section III NCA, The Rules for Construction of Nuclear Power Plant Components

3.4 *ISO Standards*[4]

ISO 9000 — Quality Management and Quality Assurance Standards

4 General Requirements

Material furnished under this specification shall conform to the requirements of ASTM A 269 for nominal sizes 1/2 inch diameter and larger and to the requirements of ASTM A 632 for nominal sizes smaller than 1/2 inch diameter, and to the additional requirements herein.

5 Ordering Information

5.1 Orders for material under this specification shall include the following, as required to describe the material adequately:

- Quantity (meters, feet, or number of lengths)
- Grade (per Table 1 of ASTM A 269)
- Size (nominal outside diameter and nominal wall thickness)
- This specification number
- Surface condition (if applicable)
- Special requirements and any supplementary requirements selected

4 International Organization for Standardization, 1 rue de Varembe, Case postale 56, CH-1211, Geneva 20, Switzerland

6 Process

6.1 The steel shall be processed in accordance with the section on Process of ASTM A 269.

7 Manufacture

Tubing shall be made by the seamless process and must be cold finished.

8 Heat Treatment

8.1 All tubing shall be furnished in the heat treated condition in accordance with the section on Heat Treatment of ASTM A 269. If grain size is restricted by the supplementary requirement specified in Section 17.3 of this specification, the minimum annealing temperature shall not apply, provided that the tubing passes the intergranular corrosion test of Section 13 of this specification.

8.2 All tubing shall be vacuum annealed, or bright annealed in an unmixed hydrogen atmosphere, followed by rapid cooling. The adequacy of the cooling rate shall be confirmed by the intergranular corrosion test of Section 13 of this specification.

9 Surface Condition

9.1 *Inside Surface* — The tubing shall be supplied with a cold finished and annealed inside surface having a maximum surface roughness as specified in the order.

9.2 *Outside Surface* — The outside surface of the tubing shall have a commercial mill finish unless otherwise specified by the purchaser.

9.3 *Surface Roughness* — When specified as per Section 9.1 or 9.2, surface roughness shall be measured in accordance with ANSI B46.1, using a stylus-type instrument and a cutoff of 760 µm (0.030 inches). Results reported shall be Roughness Average (R_a), expressed in micrometers or microinches.

10 Cleanliness

10.1 Tubing shall be supplied in accordance with the supplementary requirement for Cleanliness of ASTM A 632.

10.2 Tubing surface shall be free of any metallic iron that can be detected by either Method 102 or Method 103 of MIL-STD-753.

11 Chemical Composition

11.1 Chemical composition of the steel shall conform to the requirements of the section on Chemical Composition of ASTM A 269 for nominal sizes 1/2 inch diameter and larger and to the section on Chemical Composition of ASTM A 632 for nominal sizes smaller than 1/2 inch diameter.

11.2 Sulfur content shall be 0.003% to 0.010% for all nominal sizes.

12 Mechanical Properties

12.1 Tubing shall conform to the applicable requirements of ASTM A 450/A 450M unless otherwise provided herein.

12.2 Hardness of all sizes shall conform to the section on Hardness Requirements of ASTM A 269.

12.3 Tensile properties of all sizes shall conform to the section on Mechanical Properties of ASTM A 632.

13 Metallurgical Requirements

Tubing shall pass an intergranular corrosion test conducted in accordance with the supplementary requirement for Intergranular Corrosion Test of ASTM A 262. A minimum of two samples per lot shall be tested.

14 Nondestructive Testing Requirement

14.1 Eddy current testing shall be performed in accordance with the procedure and evaluation outlined in the section on Nondestructive Electric Test of ASTM A 450/A 450M except that the calibration reference notches shall not exceed 10% of the specified wall thickness of the tubing or 0.075 mm (0.003 inches), whichever is greater. If the form of product supplied makes this test technically infeasible, alternative non-destructive testing methods shall be agreed upon by the purchaser and supplier.

14.2 At the option of the purchaser, hydrostatic testing shall be conducted and evaluated in accordance with the requirements of the section on Hydrostatic Test of ASTM A 450/A 450M.

15 Permissible Variations in Dimensions

Sampling for dimensional variations shall be performed in accordance with MIL-STD-105 with double normal sampling and a 2 1/2% Acceptable Quality Level (AQL). The permissible variations in dimensions shall be as outlined in Table 3 of ASTM A 269 for nominal sizes 1/2 inch diameter and larger and in Table 3 of ASTM A 632 for nominal sizes smaller than 1/2 inch diameter. Dimensions shall apply after treatment of the inside surface if the supplementary requirements listed in Section 17.1 or 17.2 of this specification are specified.

NOTE: The supplementary requirements listed in Section 17.1 or 17.2 of this specification may remove significant amounts of material. Purchasers should allow for such material removal when specifying dimensions of tubing prior to supplementary surface treatments.

16 Quality Assurance Requirements

The supplier's quality assurance program shall meet the requirements of the ASME Boiler and Pressure Vessel Code, Section III, NCA-3800 or of ISO 9000.

17 Supplementary Requirements

The following supplementary requirements shall apply only when specified by the purchaser on the inquiry, contract, or order.

17.1 *Electropolished Inside Surface* — The tubing shall be supplied with an electropolished inside surface having a maximum surface roughness as specified on the order.

17.2 *Alternative Finish (Inside Surface)* — The purchaser may specify alternate chemical treatment for the inside surface. Such treatment shall not promote grain boundary attack; the intergranular corrosion test requirement of Section 13 shall apply after chemical treatment.

17.3 *Restricted Grain Size* — At the option of the purchaser, ASTM grain size number may be restricted to 7 or finer, per ASTM E 112, provided that a maximum hardness lower than that given in the section on Hardness Requirements of ASTM A 269 is not also imposed.

18 Certification

18.1 The supplier shall provide the following reports and certifications with all shipments of tubing:

18.1.1 Type of tubing (seamless or welded)

18.1.2 Size (nominal outside diameter and wall thickness)

18.1.3 Material composition report shall be provided to verify the above required grade, sulfur content, and grain size

18.1.4 Tubing provided in accordance with this specification shall be mill and heat traceable, and permanently etched for correspondence to the applicable mill test reports.

SEMI F3-94
GUIDE FOR WELDING STAINLESS STEEL TUBING FOR SEMICONDUCTOR MANUFACTURING APPLICATIONS

1 Purpose

1.1 The purpose of this guide is to provide instructions to increase the awareness of the user to the available procedures for welding stainless steel gas distribution systems, and to provide information from which subsequent evaluations and standardization can be derived.

2 Scope

2.1 This guide covers the general requirements for the welding of stainless steel gas distribution systems.

3 Referenced Documents

NOTE: The following documents become part of the guide to the extent that they are included herein.

3.1 The referenced documents are to be their current edition as published by their sponsors.

3.2 SEMI Specification

3.3 *ANSI/ASME Specifications*[1]

B16.25 — Butt Welding Ends

B31.3 — Chemical Plant and Petroleum Refining Piping

Boiler and Pressure Vessel Code — Section IX, Qualification Standard for Welding and Brazing Procedures, Welders, Brazers, and Welding and Brazing Operators

3.4 *AWS Specification*[2]

AWS D10.9 — Specification and Qualification of Welding Procedures and Welders for Piping and Tubing

3.5 *ASTM Specification*[3]

A450 (Section 25) — General Requirements for Carbon, Ferritic Alloy, and Austenitic Steel Tubes

1 American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017

2 American Welding Society, 550 NW LeJeune Road, P.O. Box 351040, Miami, Florida 33135

3 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

4 General Requirements

4.1 All welding performed under this guide should conform to the applicable requirements of the ASME Boiler and Pressure Vessel Code, Section IX, ANSI B16.25, B31.3 Chapter V, and AWS D10.9, to the extent that they are included herein.

5 Materials

5.1 All materials to be welded should be manufactured to ASTM specifications and so certified by the manufacturer. Certification should conform to ASTM A-450, Section 25.

5.2 All seamless austenitic stainless steel tubing should be in conformance with SEMI F2.

6 Testing of Welders

6.1 All welds should be based upon Welding Procedure Specifications and be documented with associated Procedure Qualification Records in accordance with ASME Boiler and Pressure Vessel Code, Section IX, or with AWS D10.9.

6.2 Qualification of the welding procedures to be used, and of the performance of welders and welding operators, should conform to the requirements of the ASME Boiler and Pressure Vessel Code, Section IX, Articles II and III, or AWS D10.9.

7 Welding Procedure

7.1 *Component Preparation*

7.1.1 All weld end preparation should be done in such a manner as to minimize the introduction of contaminants into the system.

7.1.2 All cutting of component or tubing weld ends should be done with a sharp-edged tool. No lubricants of any kind should be allowed.

7.1.3 All component and tubing weld ends that are to be cut should be de-burred without chamfering.

7.1.4 All welding ends requiring preparation for procedures requiring the use of filler material should be prepared in accordance with ANSI/ASME B16.25.

7.1.5 Surfaces for welding should be clean and should be free from oxidation, discoloration, oil, scale, chips, or other material that is detrimental to welding.

7.1.6 All components should be maintained in a clean condition until welded into the system.

7.2 *Welding Requirements*

7.2.1 Welding equipment used to make welds should be operated in accordance with the manufacturer's operating and safety instructions.

7.3 *Welding Procedures*

7.3.1 Prior to the welding of a particular size, wall thickness, alloy, and heat of material, sample welds should be made, dissected, and analyzed.

7.3.2 These welds should be checked for poor penetration, joint contamination, joint soundness, surface oxidation, discoloration, pitting, cracking, defects of fit-up, or defects of workmanship.

7.3.3 Once a sample weld is found to be acceptable, the sample weld should be the on-site work sample against which other welds of the same size, wall thickness, alloy, and heat of material are judged. All essential and supplementary essential variables should be documented in the procedure qualification record.

7.3.4 Any significant deviation(s) from the on-site work sample (7.3.3) will cause the weld(s) to be rejected. Rejected welds should be removed and replaced.

7.3.5 Sample test welds should be made periodically. These tests should be compared to the on-site work sample (7.3.3). Deviation from the on-site work sample should be cause for rejection. The sample test welds should be made at/when:

1. The beginning of each shift.
2. The end of each shift.
3. Any change in welding procedure, materials, tubing size, equipment, or equipment adjustments are made.
4. Any time that a concern or deviation to the weld quality has occurred.

7.3.6 Sample test welds should be kept on file and may be reviewed at any time during the construction.

7.3.7 Where a weld is found defective, the preceding two welds should be tested as indicated in Paragraph 7.3.2. If either of these welds shows signs of poor penetration, joint contamination, lack of joint soundness, surface oxidation, discoloration, pitting, cracking, defects of fit-up, or defects of workmanship, then all welds made since the last welding procedure was established should be removed and replaced.

7.4 *Weld Set-up*

7.4.1 Check parameters and verify that they are in accordance with the qualified welding procedure.

7.5 *Purging*

7.5.1 During welding, all tubes, fittings, valves, sub-assemblies, and all other components should be continuously purged.

7.5.2 Automatic orbital head welding equipment should supply a constant gas-backing shield to the weld head during welding.

7.5.3 During all welding, a sufficient amount of purge/shield gas should be maintained until the weld head is removed from the newly welded parts.

7.5.4 Both purge/shield gas supply lines should contain flow indicators to ensure proper purging.

7.6 *Weld Identification*

7.6.1 A daily log should be maintained on all welds, and as-built drawings recording all data should be maintained in the welding area.

7.6.2 All welds should be identified with a code number and cross-referenced with the drawings for future evaluation.

7.7 *Additional Requirements*

7.7.1 Maintain sufficient distance between weld joints and valve seats to avoid damage to valve seats or valve stem tips.

APPENDIX 1
SAMPLE WELDING SPECIFICATION

NOTE: This related information is not an official part of this SEMI guide and is not intended to modify or supercede the official guide. It has been derived from industry specifications. Publication was authorized by full letter ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

A1-1 General

A1-1.1 The entire piping system will be kept under a continuous purge until all welding is complete.

A1-1.2 All tools and fixtures used for the assembly and welding shall be maintained clean and shall not be removed for use outside of the Class 100 preparation area.

A1-2 Tubing Preparation Requirements

A1-2.1 Use only tools and handling techniques that will not mar, disturb the shape of, or in any way reduce the quality of the materials used in this system.

A1-2.2 Tubing must be under inert gas purge during the cutting and end-facing/truing operation.

A1-2.3 Tube ends shall be covered while the purge is removed using a technique that will minimize the amount of infiltration or contamination. Covers shall be of non-particulating material.

A1-2.4 Cut ends shall be de-burred and faced to be square to an appropriate tolerance, per orbital welding equipment manufacturer's recommendation. The tubing shall not be scratched during de-burring. Abrasive wheels shall not be used. A lathe, milling, or portable end prep tool that clamps to the exterior of the tube is permitted.

A1-2.5 Make all necessary preparations for installing tubing and tube sub-assemblies so that exposure of the interior surface to atmosphere is minimized.

A1-2.6 Tubing and tube sub-assemblies shall be mechanically fitted into place, dimensionally verified, clearances verified, welding parameters set, and all pre-weld procedures completed in readiness to begin the welding process prior to removing protective covers.

A1-3 Welding Process Requirements

A1-3.1 Welding shall be by the gas tungsten arc welding (GTAW) process with backing shielding and inside tubing purge. All stainless steel tubes shall be joined using an automatic orbital butt-welding machine.

A1-3.2 During welding, all gas lines must be continuously purged.

A1-3.2.1 Stainless steel tubing purge lines shall be used. Flow measurement and control shall be with a clean rotameter.

A1-3.2.2 Weld shield purge gas shall be filtered with a 0.01 µm filter connected to the inlet bulkhead fitting of the welder.

A1-3.3 Every weld shall be tagged, logged, and inspected.

A1-3.3.1 A daily log shall be maintained on all welds and an as-built isometric drawing recording all data shall be maintained in the welding area.

A1-3.3.2 All welds shall be identified with a code number and cross-referenced with the isometric drawings for future evaluation.

A1-3.4 As much welding as is feasible will be performed in the preparation area in the form of sub-assemblies.

A1-3.5 Alignment of tubing of nominal size 2" in diameter and larger for orbital welding shall be by an external clamping jig where space permits.

A1-3.6 Valves shall be located so as to allow space to operate the valve after installation at the job site.

A1-4 Welding Procedure Requirements

A1-4.1 All materials, testing of welders, and welding procedures shall comply with the requirements of SEMI F3.

A1-4.2 Set up the fabrication in a suitable preparation area or at the job site.

A1-4.3 Make all necessary preparations for installing tube and tube sub-assemblies such that exposure of the interior surface to atmosphere is minimized. Insure that there is purge flow prior to welding.

A1-4.4 On tubes larger than a nominal size of 1/2", place a reducing cap on the discharge end of the tube with a 12-mm (0.5") or smaller outlet.

A1-4.5 Insert the tube ends into the orbital tube weld holder for butt-welding.

A1-4.6 Perform only one weld joint at a time.

A1-4.7 The completed sections of the piping system should never be without positive purge pressure and flow to all system extremities. System extremities should *not* be capped in such a way as to permit purge flow to stop. This purge must be maintained at all times, including overnight and during weekends and breaks.

A1-4.8 Sub-assemblies, after completion, shall be purged and covered for subsequent installation in the field.

A1-4.9 A backing shield (purge through the weld head) is required during welding.

A1-4.10 Where a weld is found defective, the preceding two welds should be tested as described in Paragraph 7.3.2 of SEMI F3. If either of these welds shows signs of poor penetration, joint contamination, lack of joint soundness, surface oxidation, discoloration, pitting, cracking, defects of fit-up, or defects of workmanship, then all welds made since the last welding procedure was established should be removed and replaced.

A1-4.11 On-site work sample welds shall be made before each series of welding operations. On-site sample welds shall also be made at the start of each workday and any time any welding parameter is changed.

A1-4.12 Sample test welds shall be made periodically. These tests shall be compared to the on-site work sample. Deviation from the on-site work sample shall be cause for rejection. The sample test welds shall be made at/when:

1. The beginning of each shift.
2. The end of each shift.
3. Any change in welding procedure, materials, tubing size, equipment, or equipment adjustments are made.
4. Any time a concern or deviation to the weld quality has occurred.

A1-4.13 If the system becomes contaminated due to a fabrication technique, the contaminated sections shall be re-cleaned.

A1-4.14 Welding at the job site shall be enclosed in a clean work area.

A1-4.15 When the welding is performed in a clean envelope, the envelope shall have openings for the tube to extend in two directions, a clean polyester film window, and openings for the hands. HEPA-filtered air shall be supplied to the envelope under pressure to ensure a clean working environment.

A1-4.16 The envelope shall be installed prior to removal of the tube caps. Full purge through the tube to be welded shall be completed before removing the clean envelope to attach the weld head.

A1-4.17 Final positioning of the weld head and weld process shall be performed within the clean envelope.

APPENDIX 2
HEXAVALENT CHROMIUM ALERT

NOTE: This related information is not an official part of this SEMI guide and is not intended to modify or supercede the official guide. It has been derived from the cited document. Publication was authorized by full letter ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

A2-1 General

A2-1.1 Hexavalent chromium, which is given off when stainless steel is welded, causes lung cancer in humans. For information about hexavalent chromium, refer to HESIS Hazard Alert, June 1992, Hazard Evaluation System & Information Service, California Occupational Health Program, 2151 Berkeley Way, Annex 11, Third Floor, Berkeley, CA 94704.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F4-1000
SPECIFICATION FOR PNEUMATICALLY ACTUATED CYLINDER VALVES

This specification was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilites Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available on SEMI OnLine September 2000; to be published October 2000. Originally published in 1990; previously published February 2000.

1 Purpose

1.1 This specification establishes the minimum design and performance requirements for pneumatically actuated cylinder valves used in semiconductor manufacturing. It is also intended as an aid in the procurement of these valves.

2 Scope

2.1 This specification applies to pneumatically actuated valves for use on cylinders containing gases used in semiconductor manufacturing facilities and in comparable research and development areas.

2.2 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification is not a replacement for safety regulations. It is the responsibility of the user to ensure that pneumatically actuated cylinder valves comply with all applicable safety regulations.

3.2 This specification excludes design or performance requirements for any electrically operated devices used in conjunction with, or as a replacement for, pneumatic actuators.

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Definitions*

5.1.1 *burst pressure* — a pressure at which rupture or uncontrolled leakage of one or more of the pressure retaining components of the device occurs.

---

1 American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017

2 Compressed Gas Association, Inc., 1725 Jefferson Davis Highway, Suite 1004, Arlington, VA 22202

3 International Organization for Standardization, Case Postale 56, Geneve 20, CH-1211, Switzerland

4 Department of Transportation, Superintendent of Documents, U.S. Government Printing Office, Mail Stop: SSOP, Washington, D.C. 20402-9328

5.1.2 *cylinder* — a pressure vessel designed for pressures higher than 276 kPa (40 psia), having a circular cross-section, and a maximum water capacity of less than 454 kg (1,000 lbs.). It does not include a portable tank, multi-unit tank car tank, cargo tank, or tank car.

5.1.3 *cylinder valve* — a mechanical device attached to a compressed gas cylinder that permits flow into or out of the cylinder when the device is in the open position and prevents flow when in the closed position.

5.1.4 *disconnect shutoff* — a device, which will not permit the flow of gas through an open cylinder valve without attachment to an outlet connector.

5.1.5 *flow coefficient* (Cv) — a numeric constant used to characterize the flow capacity of a valve.

5.1.6 *manual locking device* — a device used to prevent the cylinder valve from opening during transportation or service.

5.1.7 *manual override* — a device used for opening the cylinder valve manually.

5.1.8 *normal temperature* — a temperature of 21°C ± 6°C (70°F ± 10°F).

5.1.9 *normally closed* — a design in which the cylinder valve closure member automatically assumes the closed position upon loss of compressed gas to the actuator.

5.1.10 *packless valve* — a valve with a diaphragm or bellows stem seal instead of a packing or O-ring seal at the stem.

5.1.11 *pneumatic actuator* — a device which converts compressed gas pressure into mechanical motion and force to move the cylinder valve closure member.

5.1.12 *proof pressure* — a pressure greater than the cylinder valve's rated pressure that the cylinder valve can withstand without impairing its ability to meet the leak rate limits specified in SEMI F1 upon return to rated pressure.

5.1.13 *rated pressure* — the pressure at which the cylinder valve can meet the performance and qualification requirements of this specification. Rated pressure shall be specified by the manufacturer.

5.1.14 *valve closure member* — that part of the cylinder valve which is positioned in the flow stream to permit or obstruct flow, depending on its closure position.

5.1.15 *wetted surface* — surface within the interior of the cylinder valve, which is in contact with the controlled gas. The surface in contact with the gas used to actuate the cylinder valve is not, for the purpose of this specification, considered a "wetted surface".

6 Design Requirements

6.1 *General* — Components not covered by this specification or CGA Standards shall be constructed such that they do not compromise the safety, substantiality, and durability of the valve or actuator.

6.2 *Configuration* — The cylinder valve shall be a packless valve design with a normally closed actuator.

6.3 *Size* — The cylinder valve and actuator shall be of a design size which permits the use of a protective transportation cover which satisfies the requirements of 49 CFR Section 173.40(d)(2).

6.4 *Materials* — Ferrous materials used for the wetted surfaces shall be per SEMI F20. Other materials may be supplied to satisfy specific material or performance requirements, provided they are compatible with the gas service.

6.5 *Inlet* — The inlet of the cylinder valve shall have tapered external threads as specified by CGA V-1 or other recognized governmental or industry standards for the connection of cylinder valves to gas cylinders.

6.6 *Outlet* — The outlet of the cylinder valve shall conform to a CGA 630/710 series connection in accordance with CGA V-1 or other recognized governmental or industry standards for the outlet connections of gas cylinder valves.

6.7 *Actuator Pressure* — The actuating pressure required to open the cylinder valve fully shall not exceed 550 kPa (gauge) (80 psig).

6.8 *Manual Override* — A manual override shall be supplied.

6.9 *Vents* — Vent hole(s) for mass spectrometer helium leak testing shall be supplied at appropriate locations.

6.10 *Internal Volume* — The wetted surfaces should be configured, and the internal volume minimized, to enhance the efficacy of purging.

6.11 *Particle Control* — The design should minimize accumulation and generation of particles.

6.12 *Threaded Fasteners* — Threaded fasteners used in the covers, housings, casings, and any external mounting brackets shall have threads conforming to, as applicable, the ASME B1.1, ISO 68, or ISO 261 standards.

6.13 *Cleanliness* — The cylinder valve and actuator shall be cleaned, as a minimum, per CGA Standard G-4.1.

7 Optional Design Requirements

7.1 *Flow Limiting Device* — Provision for limiting flow, per SEMI S5, shall be supplied when specified.

7.2 *Pressure Relief Devices* — Pressure relief devices must be required in accordance with CGA S-1.1 or S-7.

7.3 *Disconnect Shutoff* — A disconnect shutoff shall be supplied when specified.

7.4 *Manual Locking Device* — A manual locking device shall be supplied when specified.

7.5 *Electropolish* — Cylinder valves shall be electropolished per SEMI F19 when specified.

7.6 *Cleanliness* — Cleaning above the minimum requirements of CGA G-4.1 may be specified.

7.7 *Position Indicator* — A device for visual confirmation of open or closed position may be specified.

8 Qualification Requirements

8.1 *General* — Any new cylinder valve design or substantially revised cylinder valve design shall be tested prior to production to demonstrate compliance with this specification.

8.1.1 *Leakage* — Cylinder valves shall be leak tested using the methods and leak rate limits specified in SEMI F1 for qualification of components.

8.1.2 *Operating Temperature Range* — The cylinder valves shall perform satisfactorily at any temperature between -40°C (-40°F) and 55°C (131°F).

8.2 *Qualification Cylinder Valve Samples* — Nine cylinder valves shall be selected at random from the pre-production manufacturing phase of the product for qualification to this specification.

a. One cylinder valve shall be used for the Flow Coefficient and Transportation Vibration Tests.

b. Three cylinder valves shall be used for the Pressure Tests.

c. Three cylinder valves shall be used for the Endurance Test.

d. Two cylinder valves shall be used for the Tip-Over Tests.

8.3 *Flow Coefficient Test* — The flow coefficient of a fully open cylinder valve tested without a flow restrictor shall be a minimum of 0.1. The method of test for determining the flow coefficient shall be as prescribed by SEMI F32.

8.4 *Transportation Vibration Test* — After being subjected to vibration for one hour at a frequency of 3400 to 3600 vibrations per minute at an amplitude of 0.8 mm (0.031 in.) to 1.6 mm (0.063 in.), the cylinder valve shall not exceed the inboard, outboard, and internal leak rate limits specified.

8.5 *Pressure Tests*

8.5.1 *Back Pressure* — The cylinder valve shall not exceed the internal leak rate limits specified in SEMI F1 with the cylinder valve closed, the rated pressure applied at the outlet, and the inlet connected to the leak detector.

8.5.2 *Proof Pressure* — The proof pressure at normal temperature shall be a minimum of 1.67 times the rated pressure. Tests shall be conducted following the back pressure test with the cylinder valve open, the outlet capped, and the pressure relief port capped or plugged. After exposure to an aerostatic proof pressure for ten minutes, the cylinder valve shall not exceed the inboard, internal, and outboard leak rate limits specified in SEMI F1.

8.5.3 *Burst Pressure* — The burst pressure at normal temperature shall be a minimum of three times the rated pressure. Tests shall be conducted hydrostatically following the proof pressure test with the cylinder valve open, the outlet capped, and the pressure relief port capped or plugged. Visible outboard leakage is not permitted during the burst test. After testing, the cylinder valve need not be functional.

8.5.3.1 *Pressure Rating Determination* — The rated pressure shall be less than or equal to the pressure determined from the burst pressure test as follows:

$$P \leq 0.33BT_m/T_a$$

Where:

P = Rated pressure

B = The lowest burst pressure recorded for the three specimens tested

T_a = The actual tensile strength of the failed test specimen material obtained from Certified Material Test Reports.

T_m = The specified minimum tensile strength of the failed specimen material.

NOTE 2: The factor of T_m/T_a is included to normalize between the particular steel stock from which the test specimens were made and the minimum tensile strength of the specified steel.

8.6 *Endurance Test* — The cycle life of the cylinder valve shall be at least 5,000 operational cycles. During and after 5,000 operations, the cylinder valve shall not exceed the inboard, internal, and outboard leak rate limits specified in SEMI F1. A cycle shall consist of one opening and one closing of the cylinder valve.

8.6.1 Cylinder valves shall be operated alternately through minimum and maximum temperatures specified in Section 8.1.2 in 1000 cycle increments until completion of the specified number of cycles. The first thermal cycle shall take the cylinder valves to maximum temperature. Cylinder valves shall be at thermal equilibrium while mechanically cycling. Initially, and at the completion of every 1000 cycles, the cylinder valves shall not exceed the inboard, internal, and outboard leakage tests specified in SEMI F1 at normal temperature.

8.6.2 The cylinder valve inlet pressure shall be the cylinder valve rated pressure. Cylinder valves shall be cycled at a rate of one cycle per ten seconds, equally divided between opening and closing. During the off cycle, the cylinder valve's downstream pressure shall be allowed to decay to 50% or less of the inlet pressure.

8.7 *Tip-Over Test* — After being subjected to tip-over tests the cylinder valves shall show no evidence of structural damage, shall not exceed the inboard, internal, and outboard leak rates specified in SEMI F1, and shipping caps or other protective devices shall be able to be removed or adjusted so that the valve can be operated.

8.7.1 Tip-over testing shall be conducted in accordance with CGA V-9, Section 5.2.6.4.

8.7.2 The tip-over tests shall be performed with the cylinder valve installed on a 166 kPa (2400 psig), 250 mm (10 inches) diameter by 1550 mm (61 inches) long (including cap) gas cylinder, or onto a smaller cylinder if the valve is restricted by the manufacture for use on the smaller cylinder.

8.7.3 A shipping cap or other protective device shall be installed onto the cylinder during the tip-over tests. If a special cap or protective device is used it shall conform to the requirements of CGA V-9, Appendix E-49 CFR cylinder drop protocol.

9 Manufacturing Requirements

9.1 *Acceptance Testing*

9.1.1 Each cylinder valve shall be acceptance tested for inboard, internal, and outboard leakage per SEMI F1.

9.1.2 Each actuator shall be tested for leakage of less than 1 sccm at 550 kPa (80 psig).

9.1.3 Each cylinder valve shall be visually inspected for cleanliness, damage, proper markings, and actuator function, as a minimum.

9.2 *Marking* — Each cylinder valve shall be permanently identified with the following minimum information:

9.2.1 Manufacturer's name or logo.

9.2.2 Manufacturer's part number or part number code.

9.2.3 Outlet type (CGA number or other specification identification).

9.2.4 Pressure relief device marked in accordance with CGA pamphlet S-1.1 or other specification identification.

9.2.5 Manufacturer's serial number or code that will provide traceability for materials, test data, and assembly date.

9.2.6 Flow limiting information when the flow limiting device is integral to the cylinder valve and not intended for removal.

9.3 *Traceability* — The manufacturer shall use a program to qualify raw materials, parts, assemblies, and purchased components and to provide traceability of all components (manufactured or purchased) used in production of cylinder valves.

9.4 *Instructions*

9.4.1 Clear, concise instructions and diagrams stated in terms clearly understandable and adequate for proper installation and safe operation shall be provided with each cylinder valve.

9.4.2 Instructions for periodic maintenance or repair, as required, shall be made available by the manufacturer. No repairs or maintenance shall be conducted without these instructions. Parts that require replacement shall be identified.

9.5 *Maintenance* — Ideally, the cylinder valve shall be capable of fulfilling the performance and qualification requirements of this specification after any of the maintenance procedures specified by the cylinder valve manufacturer. Maintenance shall be performed by only those persons the cylinder valve manufacturer deems qualified.

SEMI F5-1101
GUIDE FOR GASEOUS EFFLUENT HANDLING

This guide was technically approved by the Global Environmental Health & Safety Committee and is the direct responsibility of the North American Environmental Health & Safety Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1990.

NOTICE: This document, as balloted, is intended to replace SEMI F5-90 in its entirety.

NOTICE: Paragraphs entitled "NOTE" are not an official part of this guide and are not intended to modify or supersede the official guide. These have been supplied by the Task Force to enhance usage of the guide.

1 Purpose

1.1 The purpose of this guide is to provide the semiconductor industry with the general knowledge and background information for understanding the principles of exhaust systems.

1.2 It includes suggestions for layout and selection as well as application of appropriate methods and equipment for abating emissions.

1.3 This guide is intended for use in abatement selection for both gaseous and particulate contaminant materials potentially emitted from semiconductor manufacturing facilities.

2 Scope

2.1 *Applicability* — This guide presents a review and evaluation of available information including:

- Chemical and physical properties of chemical compounds and elements, that are, or may be, released from semiconductor manufacturing operations,
- Some current industry practices for separating exhaust systems for different groups of materials,
- Potential methods for abating emissions of gaseous and particulate contaminants exhausted from semiconductor manufacturing operations at "End-of-Pipe",
- Potential methods for abating emissions of gaseous and particulate contaminants exhausted from semiconductor manufacturing processes at "Point-of-Use" and reasons why they should be used for some processes,
- Standard industry methods of recovery, replacement, and "usage reduction" for minimizing release of materials.

2.2 *Contents* — This document contains the following sections:

2.3 This guide does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guide makes only a few recommendations regarding the fire protection aspects of exhaust systems. Additional recommendations on the risk assessment of systems, compatibility of materials, and the potential need for use of non-combustible materials or the fitting of fire detectors, sprinklers etc., are within the scope of other documents.

3.2 Methods for treating solid or liquid waste (created by emission abatement processes) and methods for recovery of gases are not discussed in this document.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI S2 — Environmental, Health, and Safety Guideline for Semiconductor Manufacturing Equipment

SEMI S5 — Safety Guideline for Flow Limiting Devices

SEMI S8 — Safety Guidelines for Ergonomics Engineering of Semiconductor Manufacturing Equipment

4.2 *Code of Federal Regulations* — United States Environmental Protection Agency[1]

40 CFR Part 63 (Clean Air Act 112 (b)(1))

4.3 *Uniform Codes*[2]

Uniform Fire Code — Article 80 — Hazardous Material

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CVD* — Chemical Vapor Deposition

5.1.2 *EPI* — epitaxial deposition

5.1.3 *HAP* — Hazardous Air Pollutants [as defined by 40 CFR Part 63 (Clean Air Act 112 (b)(1))

5.1.4 *PFC* — perfluorocompounds

5.1.5 *POU* — Point of use

5.1.6 *VOC* — Volatile Organic Compounds

5.2 *Definitions*

5.2.1 *classification of emissions* — understanding the composition of process exhausts.

5.2.2 *efficiency* — the ratio (or fraction or proportion) of removed chemical species to its input amount

5.2.3 *End-of-Pipe Abatement* — abatement technologies that can be fitted at the discharge point of the exhaust system.

5.2.4 *flow capacity* — the maximum flow any specific equipment can handle.

5.2.5 *occupational exposure limits (OELs)* — for the purpose of this document, OELs are generally established on the basis of an eight-hour workday. Various terms are used to refer to OELs, such as permissible exposure levels, Threshold Limit Values®, maximum acceptable concentrations, maximum exposure limits, and occupational exposure standards. However, the criteria used in determining OELs can differ among the various countries that have established values. Refer to the national bodies responsible for the establishment of OELs. (Threshold Limit Value is a registered trademark of the American Conference of Governmental Industrial Hygienists.)

5.2.6 *Point-of-Use Abatement* — abatement technologies that can be fitted at the point of discharge of the gaseous emission from semiconductor process equipment. These devices are also called exhaust conditioners.

5.2.7 *removal capacity* — amount of a species which can be removed.

5.2.8 *usage reduction* — reducing the total volume of process chemicals requiring abatement.

6 Philosophy

6.1 Gaseous mixtures potentially emitted from numerous processes could also produce hazards within exhaust ducts.

6.2 With increasing legal requirements worldwide on both worker safety and general environmental protection, more effective exhaust management is required.

6.3 This demands a detailed understanding of the chemical and physical properties of the chemical compounds being emitted from processes, and of the conditions under which they are released.

6.4 Careful design of the abatement systems is required to attain both high efficiency and maximum economy.

7 Classification of Emissions

7.1 The following fundamental points regarding exhaust emissions should be considered:

- Exhaust contaminants might be solely the material used in the process (e.g., isopropyl alcohol (IPA) from a rinse chamber)
- In plasma and thermal chambers many reactions occur, both those desired and others; therefore by-products are also key components of exhaust emissions.
- In theory, most possible combinations of the elements in the input gases may be found as compounds in the exhaust. In practice, the main components will be the unused process gas (the percentage consumed in the process varies, and

1 United States Government Code of Federal Regulations, free from the web site at http://www.epa.gov

2 International Conference of Building Officials (ICBO), 5360 Workman Mill Road, Whittier, CA 90601-2298

may be as low as 10%). Additional by-products will have different and sometimes more hazardous properties.

7.2 Considerable research has been conducted into various hazardous by-products of processes, from explosive solids to organochlorine compounds with mutagenic properties. (See Sections 13.1 through 13.3.)

7.3 In considering selection of exhaust systems and abatement technology, it is essential to review all the materials likely to be present in the exhaust.

7.4 Contributions from the materials on the wafer must also be considered, as they often cause blocked exhausts (e.g., aluminum etches produce aluminum chloride (a by-product of removal of aluminum from the wafer with chlorinated gases)).

7.5 Processes that produce specific hazardous by-products should be evaluated for appropriate point-of-use abatement technology before discharge to an exhaust system.

7.6 Gaseous and particulate contaminants emitted from semiconductor manufacturing can be divided conveniently into nine major groups, each of which *might* justify its own exhaust system.

7.6.1 *Group-1 Acid* — Easily hydrolyzable acids, (e.g., hydrogen chloride hydrolyzes into hydrochloric acid.)

7.6.2 *Group-2 Acid aerosols ("difficult–to-scrub")* — This group includes acids that generate aerosols and that are not easily removed by simple water scrubbers (e.g., aqua regia, sulfuric and nitric).

NOTE 2: High concentrations of easily soluble acids will also fall into the "difficult-to-scrub" category.

7.6.3 *Group-3 Ammonia* — Exhaust streams containing ammonia

7.6.4 *Group-4 Volatile Organic Compounds (VOCs)* — Exhausts containing volatile organic compound vapors or flammable gas discharge requiring destruction.

7.6.5 *Group-5 Pyrophoric* — Exhausts containing pyrophoric gases.

7.6.6 *Group-6 Emergency Release Discharges* — Enclosures are provided with additional exhausts to contain sudden unanticipated releases of gas from cylinders, etc.

7.6.7 *Group-7 Special/Direct* — Additional exhausts used to keep specific gases separate for recovery purposes (e.g., hydrogen (H_2) reclamation from EPI or PFC reclamation from CVD tools, Oxides of Nitrogen (NO_x)).

7.6.8 *Group-8 General Exhaust Systems without End-of-Pipe Treatment* — Exhaust of heat or post-treatment exhaust from POU abatement systems.

7.6.9 *Group-9 Highly Toxic Gas Exhaust* — Highly toxic gases especially those with poor warning properties (e.g., arsine, phosphine, diborane, germane). The end user has a primary responsibility to prevent discharge of these gases above a regulated level (e.g., usually one-half (1/2) of Immediately Dangerous to Life and Health (IDLH) levels).

NOTE 3: Facility exhaust systems may be called by a number of different names such as: Acid, Corrosive, Ammonia, Scrubbed, VOC, Solvent, Incinerated, Highly Toxic, Toxic, Dedicated, Special, PFC, General, Heat, Treated, or others. The actual facility exhaust system name, and what groups are routed to each system, will vary by factory and by country.

7.7 The groups listed in Section 7.6 are not a definitive division, but represent a summation of common industry practice for separation. The division is based on three basic principles:

- avoiding mixing of incompatible gases in the exhaust,
- potential need for different end-of-pipe abatement technologies, and,
- keeping materials separate for recovery.

7.8 The number of separate exhaust systems used is entirely a decision for each facility, based on the following:

- processes and chemicals used,
- the number of each type of process,
- whether recovery of gases is required,
- whether point-of-use (POU) abatement is installed, and
- compatibility of emissions with each other or the effluent handling system.

7.9 In theory, if POU abatement systems are fitted to all sources of gaseous effluent all exhaust could then be combined into a single exhaust system.

7.9.1 In practice most facilities operate a compromise between the two extremes with two to four separate exhaust systems and point-of-use abatement systems fitted only to certain sources. The decision (as to which combination to use) will often be based on economic and space constraints.

7.9.2 Safety and environmental factors listed below, should always be considered first when determining specific gaseous sources that require POU abatement systems.

7.10 Many types of process equipment use and exhaust incompatible gases sequentially (e.g., silane and then nitrogen trifluoride (NF_3) as elements of a deposition and cleaning cycle).

7.10.1 With more than one of these processes being discharged asynchronously into a common exhaust duct, undesired reactions may occur.

7.10.2 It is possible to avoid this problem by fitting the equipment outlet with three-way valves to divert the discharge to the correct exhaust system, depending on equipment process step. Three-way valves may not be necessary if pump ballast-gas flow is increased to dilute gases.

7.10.2.1 Switching must accurately account for the gas transmission times from process chamber inlet to the exhaust valve.

7.10.2.2 Introduction of additional mechanical devices could create major hazards, reliability, and service or maintenance issues.

7.10.2.3 Valves must incorporate failsafe designs to ensure pump outlet is not shut off.

7.10.3 An alternative solution is to fit a local POU abatement system that treats at least one component and is not adversely affected by the other components.

7.11 *Point-of-Use (POU) Abatement Devices*

7.11.1 POU abatement devices are designed to operate at the process tool or pump outlet, and to remove hazardous gases BEFORE they enter the exhaust ductwork.

7.11.2 An end-of-pipe scrubber does not protect the facility from reactions in the ductwork. Reactions between process gases, as discussed above, or reactions with other process by-products within the ductwork itself are not prevented by end-of-pipe systems either.

7.11.3 POU abatement devices may be appropriate wherever the exhaust gases can react in the ductwork.

7.11.4 If process systems are not treated with POU abatement devices, the higher concentrations of hazardous gases will present a higher risk during a leak into the facility space.

7.11.5 Improperly functioning POU abatement devices can create backpressure that can increase the risk of a leak.

7.12 Four significant consequences can be foreseen from effluent gas reactions in the ductwork:

7.12.1 *Blocked Ducts* — Reactions between gases, or condensation of vapors, can produce solids and semi-solids (such as crystals, slurries or gels) that will block the ductwork.

7.12.1.1 Collection of solids can create dead leg sections that may contain reactive byproducts or unused raw materials. Catastrophic release of these trapped materials could generate a significant hazard.

7.12.1.2 Extensive downtime (for clean out, or ducts collapsing under the weight of accumulated solids) is a possible undesirable outcome of this condition.

7.12.1.3 Solids deposited (such as from metal etching) can, themselves, be both corrosive and hazardous, leading to health risks for people performing cleaning in ductwork. (See Related Documents 13.1 through 13.3).

7.12.1.4 Blocked ducts may result in toxic process gases or by products escaping into the work area.

7.12.2 *Duct Corrosion* — Etching and some chamber cleaning process emissions are corrosive. Both metallic (including stainless steel) and plastic ducting can be attacked, resulting in the release of hazardous gas or condensed liquids into the workplace.

7.12.3 *Duct Fires or Explosions* — Flammable and pyrophoric gases can ignite in the ductwork. If the ductwork is combustible or has flammable or combustible deposits in it (e.g., hydrocarbon pump oil), facility fires can result.

7.12.4 Additional information on protection of Industrial Exhaust systems from fires may be found in FM Global Loss Prevention Data Sheet 7-78, "Industrial Exhaust Systems".

NOTE 4: Destruction of whole production lines with multi-million dollar cost impact has resulted from such incidents.

7.12.5 *Formation of Ammonium Compounds* — If ammonia is discharged into a duct with acid compounds, a sub-micron ammonium compound fume can be generated, that is not easily removed by end-of-pipe systems.

7.12.5.1 The result is visible discharges.

7.12.5.2 Ammonium compounds produce solids in the duct.

7.13 If any of the above reactions can occur in the process exhaust, POU abatement should be considered.

7.14 Exhausts of oil-lubricated vacuum pumps should be fitted with well-maintained oil mist separators/ filters.

7.15 POU abatement devices may also be needed upstream of the recovery device for the recovery of some gaseous compounds (e.g., hydrogen (H_2), PFC gases).

8 End-of-Pipe Abatement Technologies

8.1 *Group 1 — Acid Abatement*

8.1.1 The appropriate abatement technology for this category is commonly called " wet scrubbing."

8.1.2 Many, if not all, of the semiconductor processes have traditionally been exhausted through centralized wet scrubbers.

8.1.2.1 This procedure has limited technical acceptability and may not meet the requirements of all regulatory agencies.

8.1.2.2 This technology should be targeted at abatement of acid gases, vapors, mists, and fumes emitted from CVD, dry etching, and wet chemical operations.

8.1.2.3 Most wet chemical processes are typically carried out under local exhaust ventilation devices, such as fume hoods, or in specially designed rooms that are totally exhausted. These types of operations include:

- Processes used to clean wafers or clean wafer handling equipment (such as quartz components, tubing),
- Processes used in wafer fabrication for surface treatment such as oxide, silicon nitride and other surface treatments, (e.g., metal etching), and
- Processes used for development of positive photoresist.

8.1.2.4 The chemical species emitted depends on both the chemicals used in the processes and the conditions of use.

8.1.2.5 Volatile acids (e.g., hydrochloric (HCl), hydrofluoric, nitric, and acetic) yield corresponding gases and vapors, especially when heated.

8.1.2.5.1 The reaction of hydrochloric and nitric acids in aqua regia yields nitrosyl chloride (NOCl) vapor and elemental chlorine (Cl_2) gas.

8.1.2.5.2 When sulfuric acid is heated, it yields both sulfuric acid vapor (H_2SO_4) and sulfur trioxide (SO_3).

8.1.2.5.3 Phosphoric acid (H_3PO_4) is not significantly volatile, but spray may be carried over into the exhaust system by mechanical entrainment.

8.1.2.5.4 Under appropriate conditions, spray droplets of any of the chemicals used may be mechanically entrained into the ventilation air exhausted from the various processes.

8.1.3 Design and selection of scrubbing equipment for the acid exhaust systems must take into account both the chemical and physical properties of the materials being emitted.

8.1.4 The principles involved in collection of particulate matter (including liquid aerosols) are entirely different from those determining absorption of gases.

8.1.5 *Current Practice*

8.1.5.1 Exhausts carrying acid compounds comprise the largest volume of air discharged from a typical semiconductor manufacturing plant.

8.1.5.2 The current practice is to connect most or all of the corrosive sources to a central building exhaust system and to discharge the combined gas streams to one or more large wet scrubbers.

8.1.5.2.1 A variety of scrubber types might be used, but the two main types are cross-flow and counter-current scrubbers equipped with packing material of some type.

8.1.5.3 The scrubbers usually are fed with a stream of water (potable, recycled, etc.).

8.1.5.4 A side stream of water is bled from the scrubber to a wastewater line.

8.1.5.5 It is futile to discharge organic solvents to water scrubbers even if the organic solvents are, to some degree, soluble in water.

8.1.5.5.1 Any dissolved organic solvent will eventually be desorbed from the water and will escape to the atmosphere, or be discharged as wastewater. Additionally, these organics could serve to propagate biological growth in the scrubber.

8.1.5.6 Exhausts from process tools are frequently discharged to the appropriate building exhaust systems, either with or without point-of-use abatement.

8.1.5.7 Arsine and phosphine, which have only slight solubility in water, pass through the water scrubbers so that the effect of discharging these gases into the building scrubber system is limited to dilution. Fluorine and chlorine also have limited solubility in water and may pass through water scrubbers without sufficient abatement. POU abatement devices should be considered for these types of gases.

8.1.5.8 Preliminary oxidation of these and numerous other process gases results in formation of fine fumes and other aerosols that will be collected with only low efficiencies by the typical large, low-energy wet scrubbers.

8.1.5.9 If ammonia is discharged into a system that also carries hydrogen chloride, hydrogen fluoride, nitric acid, or sulfuric acid; it will react, in the vapor phase, to form sub-micron solid aerosols of ammonium chloride, ammonium fluoride, ammonium nitrate, or ammonium sulfate, respectively.

8.1.5.10 Any exhausts carrying ammonia should be discharged to a separate scrubber or a point-of-use ammonia abatement used at the process discharge.

8.1.6 *Chemistry of Pollutants*

8.1.6.1 Effective abatement of any compound requires careful consideration of the chemistries and physical states of the specific compounds being abated.

8.1.6.2 The packed-bed scrubbers commonly employed should generally be adequate for absorption of readily soluble gases, if appropriate operating conditions are also maintained.

8.1.6.3 Misuse can negate the potential performance of the scrubbers.

8.1.6.4 As scrubbers are low-energy devices (pressure drops on the order of 2.5 to 10 cm (1-4 inches) of water, they are incapable of effectively collecting fine aerosols such as the ammonium salts mentioned above.

8.1.6.5 The most economic design approach, therefore, is to arrange the exhaust system and use POU abatement devices to avoid formation of such aerosols, where possible.

8.1.6.6 The practice of using only recirculated water in the scrubber, to absorb acid vapors and to neutralize the water bleed stream should be reviewed to ensure that scrubber efficiency is not affected.

8.1.6.7 Acid gases, such as hydrogen chloride and hydrogen fluoride, are readily soluble in water. The partial pressure of acid gases in equilibrium with the solution, which increases with increasing solute concentration, reduces the absorption of additional gas. Reduction in absorption can be minimized by increasing the rate of water blow-down (i.e., using more fresh water make-up).

8.1.6.8 However, increasing the rate proportionately increases the consumption of water and the volume of water that must be treated before discharge as wastewater.

8.1.6.9 The introduction of an alkaline solution (e.g., sodium hydroxide) in the scrubber can assist in removing compounds from the gas stream if the use of water alone does not provide adequate removal efficiencies. The use of additives in the scrubber can, in itself, create safety and environmental concerns.

8.1.6.10 Some of the neutralized absorbent must be bled off from the recirculated stream to prevent the brine concentration from reaching an excessively high level, but water consumption and the volume of waste can still be reduced by alkaline solution.

8.1.6.11 Aqua regia is a reactive mixture of nitric and hydrochloric acids. The reaction produces nitrosyl chloride and elemental chlorine:

$$HNO_3 + 3HCl \rightarrow NOCl + Cl_2 + 2H_2O$$

8.1.6.12 The nitrosyl chloride vapor is readily decomposed by absorption in an alkaline solution:

$$NOCl + 2NaOH \rightarrow NaNO_2 + NaCl + H_2O$$

8.1.6.13 Elemental chlorine has only a limited solubility in water, and an alkaline solution (pH > 10) must be used to attain adequate absorption efficiencies:

$$Cl_2 + 2NaOH \rightarrow NaOCl + NaCl + H_2O$$

8.1.6.14 During the initial reaction of the nitric and hydrochloric acids, hydrogen chloride gas and nitric acid vapors are volatilized along with the nitrosyl chloride and chlorine.

8.1.6.15 Nitrogen dioxide may also be produced by decomposition of nitric acid.

8.1.6.16 All these compounds can be absorbed, to some degree, in an alkaline solution.

8.1.6.17 If a pollutant is in a particulate form (solid or liquid), its collection is only slightly affected by its chemical nature or solubility.

8.1.6.18 The dominant factor determining particulate collectability is particle size.

8.1.6.19 Abatement of particulate compounds requires a high-energy method (usually creating an extremely high pressure-drop across the abatement device) which can be costly in both energy and abatement device size requirements.

8.1.7 *Scrubber Design and Selection*

8.1.7.1 A variety of commercially available scrubbers are applicable to absorption of readily soluble gases.

8.1.7.2 These include packed-bed counter-current, co-current, and horizontal cross-flow scrubbers, horizontal spray chambers, vertical spray towers, and gas-atomizing scrubbers such as the venturi scrubber.

8.1.7.3 To some extent, the choice of scrubber type is a matter of preference, as it is usually possible to obtain equivalent performance on the soluble gases with different types of devices; however, more packing or higher liquid loading may be required on some devices.

8.1.8 The choice is likely to be limited by a consideration of practical or economic factors such as cost, available space, and weight (e.g., it is possible to reduce the size of the scrubber, usually at the cost of increased energy consumption).

NOTE 5: See Appendix 1 for absorber design criteria.

8.2 *Group 2 — Acid Aerosols*

8.2.1 Part of acid emissions may be in the form of mists (fine droplets or aerosols) rather than gases. These may be composed of relatively non-volatile acids such as phosphoric and sulfuric acids.

8.2.1.1 The mechanisms of removal of particulate matter (including liquid aerosols) from gas streams are entirely different from those involved in the absorption of gases (See Sections 13.1 through 13.3).

8.2.1.2 The critical factor in the collection process is the particle size of the mist. If the mist is relatively coarse, as apparently is the case in most instances, the same types of scrubbers that are used for gas absorption should collect the mists with adequate efficiency.

8.2.1.3 If a mist having a particle size in the micrometer or sub-micrometer range is encountered, it will be necessary to use a high-energy scrubber or a scrubber with a high-pressure-drop, sub-micron filter to obtain adequate collection efficiency.

8.2.1.4 Whenever such a fine mist or other aerosol is encountered, the gas stream from the source should be abated at point-of-use or separately from the other exhaust gas streams in the plant so as to minimize energy costs.

8.2.1.5 Abatement systems utilizing a scrubber with a high-pressure-drop, sub-micron filter are being used in the semiconductor industry to reduce emissions from aqua-regia processes, hot nitric baths and spray etchers using nitric acid (entrained in exhaust).

8.2.2 It has been determined experimentally that the collection efficiency of a scrubber on a given mist or dust is a function of the energy consumed in the exposure of the particle to the liquid in the scrubbing process.

8.2.2.1 The relationship between energy consumption and efficiency is little affected by the geometry or size of the scrubber or by the method by which the energy is applied to making contact between the gas and the liquid (See Sections 13.1 through 13.3).

8.2.2.2 The energy consumption required to attain a given efficiency increases with a decrease in the size of the aerosol (e.g., mist or dust). In most of the scrubbers used in the semiconductor industry, the energy consumed is drawn from the gas stream in the form of pressure drop.

8.2.3 The energy/efficiency relationship provides a convenient and practical method for particle and aerosol scrubber design. It is essentially independent of the size of the scrubber, at least down to a very small size (perhaps 150 to 300 L/min (5–10 ft^3/min) capacity, and possibly even smaller). Hence, a small pilot unit can be used to determine performance on an actual plant exhaust stream.

8.2.3.1 Tests can also be made under laboratory conditions, using synthetic aerosols generated for the purpose.

8.2.3.2 The major problem in using synthetic aerosols is in replicating the aerosols actually encountered in practice.

8.2.3.3 The pilot plant scrubber should be tested over a range of pressure drops to give a well-defined pressure drop/efficiency correlation.

8.3 *Group 3 — Ammonia*

8.3.1 Ammonia gas (NH_3) can be either a process gas or evolved from ammonium hydroxide used in wet chemical cleaning of wafers. As previously discussed, ammonia (NH_3) exhausted through the acid system will react with the acids present producing an ammonium salt aerosol that is not easily abated.

8.3.1.1 Packed-bed scrubbers are not very efficient at removing sub-micron ammonium halide aerosols, even though they are water-soluble.

8.3.2 Wet scrubber technologies, as listed above, are suitable for removal of ammonia provided they are operated and maintained at low pH (e.g., 3–5).

8.3.2.1 This is normally achieved by the use of sulfuric acid dosing.

8.3.3 Processes that emit both ammonia and acid gases (such as nitride deposition) should be fitted with a point-of-use ammonia scrubber, prior to being exhausted to the acid exhaust.

8.4 *Group 4 — Volatile Organic Compounds (VOCs)*

8.4.1 VOCs can represent a large proportion of exhausted air streams within typical semiconductor operations. The pollutants are produced from processes such as solvent cleaning, and photoresist application and stripping. Such processes typically contribute flammable, hazardous, and/or environmentally harmful compounds (e.g., VOCs, which participate in ozone formation in the atmosphere) to the exhausted air stream.

8.4.2 There are three primary abatement technologies used at end of pipe for this category: adsorption, recovery and oxidation. Adsorption generally uses hydrophobic zeolite or activated carbon. The oxidation process usually is thermal or may be catalytic.

8.4.3 *Emission Sources and Chemicals Emitted*

8.4.3.1 VOCs usually have high vapor pressures and can be hazardous, flammable, or may tend to form photochemical smog. Processes using them (such as solvent cleaning, photoresist application, vapor degreasing and photoresist stripping) are carried out under local exhaust hoods or in exhausted enclosures.

8.4.3.2 Chemicals emitted may include: acetone, ethyl benzene, ethyl lactate, hexamethyldisilazane (HMDS), isopropyl alcohol, methanol, methyl ethyl ketone (MEK), n-butyl acetate, n-methyl-2-pyrrolidone (NMP), petroleum distillates (VM&P naphtha), propylene glycol monomethyl ether acetate (PGMEA) and xylenes.

8.4.3.3 The chemical species emitted are typically vapors of the specific VOCs being used. These vapors are entrained in large volume air streams and are thus diluted to low levels.

8.4.4 *Current Practices*

8.4.4.1 New regulations and proposed legislation, being implemented worldwide, require significant reductions in total VOC emissions (often measured in terms of mass discharged).

8.4.4.2 Removal of VOCs from exhaust streams can be accomplished by adsorption, (e.g., fluidized bed and concentrator systems), oxidation, or a combination of adsorption and oxidation systems. Adsorption technologies, with subsequent desorption and condensation, can be used to recover VOCs as a liquid.

8.4.4.3 End-of-pipe abatement is most commonly used for VOCs. Point-of-use systems, using the same technologies as end-of-pipe, are employed where exhaust facilities preclude use of an end-of-pipe unit, or as additional abatement to meet regulatory requirements.

NOTE 6: See Appendix 1 for VOC abatement design and selection criteria.

8.5 *Group 5 — Pyrophoric Gases*

8.5.1 Where separate exhausts for pyrophoric gases have been installed, it has been practice to fit a large air dilution chamber at the end of pipe. The reasoning has been that this will ensure safety by dilution and result in oxidation of any residual pyrophoric gases. However, oxidation may not occur since research has shown that silane, once diluted to <1.5 % in nitrogen, does not undergo appreciable oxidation when subsequently mixed with air.

8.5.2 Due to the risks associated with ducting pyrophoric gases through a facility, it is strongly recommended that these gases be abated at point-of-use. This avoids the need for a separate pyrophoric gas exhaust. If POU abatement is provided, the discharge from the POU abatement system can be directed to the acid or general exhaust system.

NOTE 7: See Appendix 2 for POU abatement of pyrophoric gases.

8.6 *Group 6* — See section 10 for Emergency Release Discharge Exhaust provisions.

8.7 *Group-7 — Special/Direct*

8.7.1 Recovery of specific gases such as hydrogen (H_2) may be necessary to reduce the massive risk of duct fire when large quantities of flammable gases are discharged.

8.7.2 PFC reclamation maybe required by environmental permits in some jurisdictions.

8.7.3 Abatement of Oxides of Nitrogen (NO_x) may be necessary to meet environmental regulations in some jurisdictions.

8.8 *Group 8 — General Exhaust*

8.8.1 This exhaust group is used to handle exhaust emissions that include heat and excessive nitrogen flow.

8.8.2 Heat exhaust is used to reduce the heat load on the balance of the building.

8.8.3 Exhaust of large volumes of nitrogen or other asphyxiant gas is used to keep potential asphyxiation hazards away from people.

8.8.4 Discharge from general exhaust should be to a location where the heat or reduced oxygen will not be a hazard to personnel.

8.8.5 General exhaust can sometimes be used for discharge of post-treatment emissions from POU abatement systems.

8.8.5.1 In such a case, the discharge permit for the POU abatement system should be consulted for proper management.

8.9 *Group 9 — Highly Toxic Gases*

8.9.1 Gases such as arsine, phosphine, diborane, germane, etc., can be treated in a variety of ways, depending upon their concentration and their byproducts (e.g., gas reactor columns, adsorption systems).

8.9.2 These gases would not likely be allowed in a burn system (even though many of them might be pyrophoric) because they could release hydrides from the air intake.

8.9.3 These gases may be prohibited, in some jurisdictions, from being discharged with no other treatment than dilution.

8.9.4 Highly toxic gases have also been known to create problems in a thermal oxidation system, because of the residue they leave behind and the periodic need for personnel to clean oxidation systems.

8.9.5 Selectors of systems for discharge of highly toxic gases should be careful to meet all regulatory requirements and should be conscious of the discharge location for the emission residue.

9 Point-of-Use (POU) Abatement Technologies

9.1 The selection of a suitable POU abatement device is dependent on the process exhaust gases to be abated.

9.2 To determine a valid abatement method, identify the exhaust composition from the process as well as the input process gases in order to select a suitable abatement technology.

9.3 The choice may also depend on other factors (e.g., whether removal of PFC gases is required or not).

9.4 The location of a POU abatement system in the process exhaust train must be reviewed for pressure drop, condensation, particles, moisture backstreaming, etc.

9.5 Many types of POU abatement devices are available and they can broadly be divided into six types of technologies listed below.

1. Wet scrubbing systems,
2. Oxidation systems,
3. Cold bed systems (adsorbers/ chemisorbers),
4. Hot chemical bed systems,
5. Reactor systems (e.g., plasma, microwave),
6. Traps/filters/cyclones/precipitators,

NOTE 8: See Appendix 2 for explanations of each technology type.

9.6 Units may employ one or more of these technologies, depending on the application.

9.7 Where a technology using an exhaustible cartridge/canister is employed, consideration must be given to adequate means of detecting bed exhaustion and to proper disposal techniques.

10 Provisions For Emergency Release

10.1 Routine releases, from hazardous gas cylinders and sources are usually minimal (e.g., from gas line purges).

10.2 Emergency or accidental releases, from gas cylinders in use, may be controlled through mechanical systems that lower the frequency, time and rate of releases.

10.3 Enclosing gas cylinders and non-welded mechanical fittings in exhausted gas cabinets that protect the systems from damage can minimize the frequency of accidental releases.

10.3.1 Proper design and installation of gas delivery and purge systems can reduce the likelihood of severe leaks.

10.4 The duration of accidental releases can be lessened by activation of fail-closed valves or gas cylinder closure devices activated by monitoring and/or alarm systems.

10.5 Equipping gas cylinders with restrictive flow orifices can lower the rate of accidental release. SEMI S5 - Safety Guideline for Flow Limiting Devices provides guidance on the use of restrictive flow devices.

10.6 Exhaust of the gas cabinets should be designed to contain sudden unanticipated releases of gas from cylinders and piping.

10.6.1 These exhausts are typically used to manage gas cabinets and other very high volume exhaust flow systems that will only occasionally have emissions present.

10.6.2 Some jurisdictions do not allow for discharge without treatment of emergency release discharges.

10.7 Each system selector should research their own regulations before determining the proper route and method for discharging and treating emergency releases.

10.8 Accidental releases from gas cylinders in use may be controlled through mechanical systems that lower the concentration exhausted into the environment. In some jurisdictions there are requirements (e.g., Uniform Fire Code, Article 80) to lower the concentration of accidental release, in exhaust to the environment, below a threshold (such as one-half (1/2) of Immediately Dangerous to Life and Health (IDLH) levels).

10.8.1 Dilution air, in excess of otherwise required gas cabinet exhaust, can be used to reduce the concentration of gas accidentally released into the exhaust, except where a jurisdiction specifically prohibits this practice.

10.8.2 As another method to reduce the concentration of gas in the atmospheric discharge during accidental releases, abatement devices serving the gas cabinet exhaust can be used instead of, or in addition to, dilution air.

10.8.2.1 Accidental release abatement devices may be any of the types described in this guide.

10.8.2.2 In some applications, gas cabinet exhaust is diverted to an abatement device only upon detection of an accidental release.

10.8.2.3 When designing diversion systems, the ability of the abatement device to operate after extended periods of disuse must be considered.

11 Summary Table

11.1 See Table 1 for suggestions about using POU and end-of-pipe abatement systems for different types of processes, materials, and exhaust systems.

12 Alternative Approaches

12.1 This guide is primarily concerned with handling gas effluents that arise from semiconductor processing. Capture and abatement is not the only approach to avoid release of hazardous materials. If possible, use of the hazardous materials should be avoided. In theory the following approach should be used:

12.1.1 Replace the hazardous material with one that is non-hazardous or less hazardous.

12.1.2 If replacement is not possible, use less of the material.

12.1.3 If possible, totally enclose the system so all material is recovered and reused.

12.1.4 If none of the above can be achieved, fit effective abatement devices.

Table 1 Exhaust System Selection Table

Process	*Gases/Chemicals*	*Reason for POU Abatement*	*POU Abatement Present*	*End-of-pipe Exhaust System Type*
Solvent/strippers	VOC		Yes	General
			No	VOC
Vapor prime	HMDS		No	Acid or ammonia
Acid baths	HCl/HF/Acetic		No	Acid
Acid baths	Aqua regia/hot nitric		No	Acid aerosols
			Yes	Acid
Ammonia baths	NH_3		No	Ammonia
			Yes	Acid
Gas bottle purge	Corrosives		No	Acid
			Yes	Acid
	Ammonia		No	Ammonia
			Yes	Acid
	Hydrides/pyrophorics		Yes	General
			No	General
Chemical dispensing	Ammonia		No	Ammonia
	VOC		No	VOC
	Corrosives		No	Acid
Chemical wafer thinning of raw wafers	HNO_3/NO_x		Yes	Acid
			No	NOx/acid scrubber
EPI	H_2/Hydrides/HCl	Fire and safety Solids blockage	Yes	Acid, H_2 reclaim, or general
Dry etching – metal	Cl and Br chemistries	Blockage/Corrosion	Yes	Acid
Dry etching – oxide/poly/etc.	Fluoride chemistry		No	Acid
LPCVD nitride	SiH_2Cl_2/NH_3	Solids blockage Fire and safety	Yes	Acid
LPCVD poly/oxide	SiH_4/fluoride chemistry	Fire and safety Solids blockage	Yes	Acid
PECVD – poly/oxide	SiH_4/fluoride chemistry	Fire and safety Solids blockage	Yes	Acid
PECVD nitride and tungsten	$SiH_4/WF_6/H_2$	Fire and safety Solids blockage	Yes	Acid
	SiH_4/NH_3	Fire and safety Solids blockage	Yes	Acid
Implant	Hydrides, BF_3	Hazardous deposits	Yes	Acid
RTP	Ammonia		No	Ammonia
			Yes	General

NOTE T1: POU Abatement may be used for the reduction of PFCs and by-products from the process.

A1-1.4 Perry's Chemical Engineers' Handbook[15]

A1-1.5 Absorption and Extraction[16]

A1-1.6 Mass Transfer[17]

A1-1.7 Mass-Transfer in Co-current Gas-Liquid Flow[18]

A1-1.8 Mass-Transfer Operations[19]

A1-2 Principles

A1-2.1 Principles of gas absorption and methods of design of gas absorption equipment are treated extensively in chemical engineering literature (See Sections A1-1.1–A1-1.8). The sources cited present rigorous methods for design.

A1-2.2 Practical design of scrubbers is at least semi-empirical; and in the case of air pollution abatement systems, design is often directly based on experimental data.

A1-2.2.1 Consequently, designs should be based on mass-transfer coefficients that have been determined experimentally under, as nearly as possible, the conditions of expected scrubber operation.

A1-2.2.2 It should be noted that the typical concentrations of the existing empirical data base is several orders of magnitude greater than the typical concentrations of corrosives exiting a semiconductor plant (before end-of-pipe scrubbers), therefore the efficiencies in these data bases may not be representative of low concentrations.

A1-2.2.3 Attempts at developing the empirical database at these low concentrations suggest that actual removal efficiencies are lower than those predicted by most scrubber design texts.

A1-2.2.4 As a result, new scrubbers may need to have additional packing to ensure theoretical removal efficiencies are achieved.

A1-2.3 Rigorous custom design of a scrubber for a particular service requires full knowledge of the conditions that are to be encountered as well as of the performance that is to be attained.

A1-2.3.1 Gas flow rates should normally be known fairly accurately — at least when the plant is originally designed.

A1-2.3.2 Concentrations of acid and caustic gases will need to be estimated.

A1-2.3.3 Conditions to be met may be changed several times over the probable life of the scrubbing equipment, as changes are made in the semiconductor fabrication processes and the exhaust system.

A1-2.3.4 Exhaust flow may also be increased, to accommodate equipment additions, thus raising the possibility the scrubber may become overloaded.

A1-2.4 Studies by SEMATECH indicate that the concentration of corrosives in the exhaust entering the end-of-pipe scrubber(s) range from <1 ppmv to as high as 10 ppmv. Additionally, the typical scrubber with 99+ % theoretical removal efficiency was actually achieving removal efficiencies ranging from 80%–95%.

A1-2.5 Scrubbers being applied to corrosive pollutants are usually standardized units assembled by a number of vendor companies. These units are designed to handle specified ranges of gas flow, but in other respects are not designed but simply built. If they are packed-bed scrubbers, they are usually fitted with standard depths of packing. The liquid flow rates can be varied within limits; but otherwise, the performance potentials are fixed unless there are provisions for changing the depth of packing and perhaps the kind of packing. Once the system is installed, such changes to increase the efficiency will probably increase the

pressure drop of the scrubber, which will require adding to the fan capacity.

A1-2.6 To ensure, in advance, that the scrubber will have adequate removal efficiency, performance tests can be conducted. Measurements should be made of the contaminant concentrations in typical plant exhaust gas streams, and the resulting data should be used to set conservative performance requirements for the scrubber. Performance tests on the scrubber should be conducted prior to exposing the scrubber to the semiconductor plant exhaust, preferably at the vendor's facility. Performance tests should identify the critical operating variables and optimize the settings to achieve optimal removal efficiencies at the lowest cost.

A1-2.6.1 Onsite performance tests may be preferable, when qualifying abatement systems, so that accurate process conditions can be produced. Permit exemptions may be obtained for the time-period of system qualification.

A1-2.7 Design and construction of scrubbers are simplified by two factors: the exhaust gas streams are at essentially ambient temperature, and they carry few insoluble solids. The low temperature allows use of corrosion-resistant plastic construction. The absence of significant solids avoids blockages in the scrubbers, which favors use of efficient gas-liquid contactors such as packed beds.

A1-2.8 Two of the most favored scrubber types are the counter-current packed tower and the horizontal cross-flow scrubber. In some instances, the choice between these devices may be determined by plant layout. As usually constructed, these two scrubber types have low to moderate gas pressure drops and are primarily suited to absorption of gases. They will also collect the coarser mists and sprays but are unsuited to collection of fine mists and fumes having particle sizes under 2 to 3 micrometers.

A1-2.9 In principle, the counter-current tower offers the highest efficiency with the least consumption of absorbent liquid. However, if untreated water is recirculated through the tower, as is commonly done in semiconductor plants, the advantages of the countercurrent operation are lost. On the other hand, if the absorbed gas is reacted with an appropriate reagent in the water, essentially the same performance can be obtained with either the countercurrent or co-current operation (see Section A1-1.7). In co-current operation, it is possible to use higher gas velocities to obtain higher mass transfer rates so that the scrubber can be made smaller. Gas pressure drops will also be increased, but this may be desirable if it is necessary to collect a fine aerosol as well as absorb a gas.

A1-2.10 Horizontal cross-flow packed-bed scrubbers may have advantages where the installation imposes restrictions on height or other similar layout problems. However, in other respects, they do not offer fundamental advantages over the packed tower scrubbers.

A1-2.11 Under special circumstances, other types of scrubbers may be appropriate for collection of aerosols. High-energy scrubbers, of the venturi type, or scrubbers with high-pressure drop, sub-micron filters (e.g., fiber bed) are appropriate where fine aerosols must be collected. Wherever possible, measures should be taken to avoid formation of such aerosols; but when they are unavoidably produced, the source should be ventilated through a separate scrubbing system of appropriate design.

A1-2.12 Packing in scrubbers provides a large interfacial area between the liquid and the gas, and also induces fluid turbulence to promote mass transfer. Packing is commonly placed in scrubbers in a random manner. Raschig and Pall rings as well as Berl saddles were common early packing materials used. In recent years, numerous proprietary packing designs have been introduced, with the objective of providing increased mass-transfer efficiency with reduced gas pressure drop. The validity of claims for superior performance has been established by the SEMATECH experiments in Section 13.1.

A1-2.13 Numerous precautions are required when installing and operating packed-bed scrubbers. It is essential to attain an even distribution of liquid over the packing; channeling of liquid or gas flow results in loss of removal efficiency. Inadequate liquid distribution can result in a reduction of the removal efficiency to as little as one seventh of theoretical (See Referenced Document A1-1.9). The predominant liquid distribution system employed is spray nozzle style. This style is inexpensive, however, it is difficult to maintain and tends to entrain more water than weir-style. Weir-style liquid distribution systems are more expensive. However, they require less preventive maintenance, provide equal liquid distribution over a wide range of flow rates, and are less prone to liquid carry-over. Precautions are treated at length in previously cited literature.

A1-2.14 A critical aspect of any scrubber design is the separation of entrainment. Carry-over of spray from a scrubber can produce maintenance issues and mist emissions. Failure to provide adequate entrainment separation has been one of the most common problems in scrubber installations. The predominant mist separator employed is a mesh style. Mesh style separators are effective on the smaller water droplets associated with spray nozzles; however, maintenance due to solids and/or biological growth is required. The chevron style is typically used in conjunction with a weir, as they are not very effective on the smaller droplet associated with spray nozzles; however they are very immune to plugging from solids and/or biological growth. The entrainment separators are discussed in Sections A1-1.3 and A1-1.5.

A1-2.15 Chlorine, fluorine and possibly other soluble gases can be entrained in scrubber wastewater, and released in facilities drains/vents. Materials such as fluorine are incompatible with many plastics and can damage drains/ vents resulting in leak, odors, and facilities interruptions.

A1-3 VOC Abatement Equipment Design and Selection

A1-3.1 *Design Criteria for Adsorption Systems*

A1-3.1.1 Adequate contact time must be achieved between adsorption media and VOC-laden exhaust stream. The adsorption matrix must be sized so that adequate residence time within the media is maintained. Also, the exhaust stream flow must be distributed uniformly over the adsorption matrix.

A1-3.1.2 Pressure drop across the adsorption matrix should be minimized to reduce energy consumption for air handling equipment.

A1-3.1.3 Materials of construction must be resistant to any corrosive action by the VOC' s or by-products formed during adsorption or adsorbent matrix regeneration.

A1-3.1.4 Hydrophobic zeolites and activated carbon in fixed beds, fluid beds or rotating wheels are being used for adsorption.

A1-3.1.5 Adsorption materials have a finite capacity for VOC adsorption and must be regenerated when their capacity is exhausted.

A1-3.1.6 Monitoring of the exhaust stream as it exits the adsorption bed may be necessary to determine when regeneration or replacement of the adsorption medium is needed.

A1-3.1.7 Pretreatment of the VOC-laden exhaust stream for removal of entrained particles or liquids may be required to prevent plugging of the adsorption unit.

A1-3.1.8 Regeneration is accomplished by flushing the adsorption bed with a carrier, typically steam, hot air or hot nitrogen.

A1-3.1.8.1 Desorbed VOC' s must be recovered or destroyed.

A1-3.1.8.2 Current practices for VOC recovery requires condensation or distillation.

A1-3.1.8.3 Current practices for VOC destruction is usually oxidation.

A1-3.2 *Design Criteria for Oxidation Systems*

A1-3.2.1 Adequate residence time, mixing with air and temperature, must be provided for high efficiency destruction of the VOC' s.

A1-3.2.2 Pretreatment of the VOC-laden exhaust stream for removal of entrained particles or liquids may be required to prevent plugging of the oxidation unit.

A1-3.2.3 Downstream abatement of the oxidation unit exhaust will be required if corrosive combustion products [such as hydrogen chloride (HCl) from chlorinated vapors] or particles [such as silicon dioxide (SiO_2) from hexamethyldisilazane (HMDS)] are present.

A1-3.2.4 Concentrations of the incoming VOC' s should be limited, especially when using a concentrator. Typical incoming VOC concentrations should not exceed 25% of LEL.

A1-3.2.5 Energy costs for heating VOC-laden exhaust streams must be considered. Straight thermal oxidizers are costly to use with high-volume, low VOC concentration exhaust streams. Therefore, a concentration process followed by recuperative or regenerative oxidation offers a more cost-effective solution.

A1-3.2.5.1 Catalytic oxidation may also offer cost savings; however, the composition of incoming compounds must not poison the catalyst.

A1-3.2.5.2 A regenerative thermal oxidizer (without a preceding concentrator) may offer cost savings in certain applications.

A1-3.2.6 Hybrid systems (combinations of adsorption and oxidation systems) may provide a cost-effective approach for abating dilute concentrations of VOCs in exhaust streams by combining adsorption beds with recuperative/regenerative oxidation, to destroy the VOCs.

A1-3.2.6.1 All design considerations for adsorption systems and oxidation systems are relevent for any of the multitude of possible hybrid systems.

A1-3.2.6.2 Levels of oxidation by-products must also be considered such as oxides of nitrogen (NOx), carbon monoxide (CO) and products of incomplete combustion (PICs).

A1-3.2.7 Potential problem areas to be reviewed in any equipment selection procedure:

A1-3.2.7.1 *Halogenated Materials* — Additional care must be exercised with chlorinated compounds, which can be subject to stricter regulatory requirements. Ensure that any oxidation unit does not create new and more hazardous compounds, such as dioxins.

A1-3.2.7.2 *Sulfur and Hexamethyldisilazane (HMDS)* — Both have the potential to poison many catalysts, and hexamethyldisilazane (HMDS) will oxidize to form silicon dioxide, which can result in particle build up in heat exchangers and oxidizers.

A1-3.2.7.3 *Moisture Levels* — Moisture can significantly affect adsorption capability.

APPENDIX 2
POU ABATEMENT TECHNOLOGY TYPES

NOTE: The material in this appendix is an official part of SEMI F5 and was approved by full letter ballot procedures on August 27, 2001.

A2-1 POU Abatement Technology Types:

1. Wet scrubbing systems
2. Oxidation systems
3. Cold bed systems (adsorbers/ chemisorbers)
4. Hot chemical bed systems
5. Reactor systems (e.g., plasma, microwave)
6. Traps/filters/cyclones/precipitators

A2-2 Wet Scrubbing Systems

A2-2.1 *Water Scrubber*

A2-2.1.1 *Principle of Operation* — Exhaust gas is passed through an enclosed space into which water is sprayed. The desired result is that gases will dissolve in or react with the water. A large contact area between gas and water is required to maximize the dissolution or reaction. Numerous designs exist to achieve this. The “packed-bed” scrubber is filled with open structure objects (e.g., hollow balls) that are fully wetted by the water spray. The gas passes over this large wet surface area. If the water spray is in the opposite direction to the gas path the design is “counter current”; if in the same direction, it is “co-current”; and if at 90° it is “cross flow”. Other designs to maximize gas/water contact use meshes, atomized sprays, or multi chamber systems that reverse the gas direction several times.

A2-2.1.2 *Capacity* — Total gas flow is determined by the size of the unit.

A2-2.1.3 *Efficiency* — Efficiency is determined by the solubility of the gas in water and retention time in the unit as well as the given mass transfer from gas to liquid phase. Acid gases are best removed; many other process gases may not be removed. If gas does dissolve in water then effectiveness of unit will be determined by design input gas flow and inlet compound concentrations.

A2-2.1.4 *Limitations* — Water scrubbers are only suitable for water-soluble gases. Many process gases (e.g., silicon compounds) will produce insoluble solids (silica) on contact with water resulting in solids forming that may block the water sprays, scrubber packing or gas inlet port.

NOTE 1: Compatibility of scrubber drains with the compounds being entrained in the liquid effluent should be considered.

A2-2.2 *Water Scrubber with Energy Input (e.g., Venturi)*

A2-1.2.1 *Principle of Operation* — Same as water scrubber but gas and water are forced to mix by the input of energy. Most commonly this is done by a venturi through which the gas and water pass. Other designs have used rapidly rotating blades in the enclosed scrubbing space. The “active” scrubbing area is often combined with a passive spray chamber or packed bed.

A2-2.2.2 *Capacity* — Energy enhanced water scrubbers have the same capacity as water scrubbers.

A2-2.2.3 *Efficiency* — Added energy improves efficiency over water scrubbers due to forced mixing, which improves efficiency of particulate removal.

A2-2.2.4 *Limitations* — The limitations are the same as for water scrubbers.

A2-2.3 *Chemical Dosed Scrubber*

A2-2.3.1 *Principle of Operation* — Chemical Dosed Scrubbers operate the same as a water scrubber but a chemical solution is added to the water. This increases the range of gases that can be removed, from those that dissolve in water to those that will react with the chosen chemical solution. The chemical medium is selected to react with the known input gases producing water-soluble salts. The two reaction systems most commonly employed are acid/base and reduction/oxidation (redox). Addition of solutions of sodium hydroxide (NaOH), potassium hydroxide (KOH) or sulfuric acid are frequently used to enhance effectiveness, and where chemical oxidation is needed hypochlorites, periodates, or peroxides are introduced.

A2-2.3.2 *Capacity* — Same as water scrubber.

A2-2.3.3 *Efficiency* — Same as water scrubber but increased efficiency by using chemical dosing. The number of gases, which can be removed, will also increase.

A2-2.3.4 *Limitations* — Even though a wider range of gases can be removed with this chemical dosing, it is applicable only to those emissions that can be water scrubbed. The potential for fouling by silica solids remains. Potassium hydroxide (KOH) or (sodium hydroxide (NaOH) solutions have to be increased to approximately 5% to ensure dissolution of silicates. Chemical dosing adds another hazardous material and may result in liquid wastes that require treatment.

A2-2.4 *Chemical Dosed Scrubber with Energy Input (e.g., Venturi)*

A2-2.4.1 *Principle of Operation* — Same as Water Scrubber with Energy Input (e.g., Venturi) above, with the benefits of Chemical Dosed Scrubber.

A2-3 Oxidation Systems

A2-3.1 *Burn Systems*

A2-3.1.1 *Principle of Operation* — Burn systems are designed for silane abatement by utilizing the pyrophoric properties of this gas. The process gas containing silane is injected into a steel container through which a stream of air is passing. The silane auto-ignites and oxidizes to form silica powder, which deposits in the system or is carried into the exhaust duct.

A2-3.1.2 *Capacity* — Governed by the build up of powders, small units may need cleaning out every few months, larger units will provide a year's capacity.

A2-3.1.3 *Efficiency* — When burn systems are correctly set up, nearly complete oxidation will occur, providing that the input silane concentration is greater than 1.5%.

A2-3.1.4 *Limitations* — Burn systems are suited only to silane (or other pyrophoric effluent) abatement. Not appropriate for mixed gas process. If silane is diluted to less than 1.5% in nitrogen before input no measurable oxidation will occur and the silane will pass directly to the exhaust.

A2-3.2 *Flame Oxidation*

A2-3.2.1 *Principle of Operation* — Oxidation of hydride gases by combustion. These systems use a chamber containing a fuel gas flame through which the process gas is passed. The resulting oxides from combustion pass into the exhaust and may be abated downstream.

A2-3.2.2 *Flow Capacity* — To calculate flow capacity, combine the total discharge flows that constitute input to the abatement device. Include pump dilution and purge quantities. .

A2-3.2.3 *Efficiency* — For simple burner designs, efficiency can vary widely as gas flow changes; specific units have been designed to ensure good mixing of fuel/air and gas; these can deliver efficiencies greater than 99.9%.

A2-3.2.4 *Limitations* — Suited only to processes where the input gases can be safely combusted. Design must ensure by-products are minimized (e.g., chlorinated compounds like phosgene/dioxins and oxides of nitrogen). Produces combustion byproducts of process gases, therefore, is often combined with a wet scrubber to remove by-products or other water-soluble gases.

A2-3.3 *Hot Chamber Oxidation*

A2-3.3.1 *Principle of Operation* — Exhaust gas is passed into an electrically heated chamber (typically 800° C) where it is mixed with air. The heated mixture oxidizes, more quickly than in a simple burn system, but without a flame from fuel oxidation to assist.

A2-3.3.2 *Flow Capacity* — To calculate flow capacity, combine the total discharge flows that constitute input to the abatement device. Include pump dilution and purge quantities.

A2-3.3.3 *Efficiency* — Hydride gases will be oxidized and removed to below the OEL.

A2-3.3.4 *Limitations* — On its own, hot chamber oxidation technology is suited only to hydrides or other gases that will readily oxidize at the temperature of the hot chamber. This method is often combined with a wet scrubber to remove oxidized by-products or other water-soluble gases.

A2-3.4 *Non-Flame Oxidation*

A2-3.4.1 *Principle of Operation* — Non-flame systems use an incandescent porous wall for combustion without a flame. Fuel and air are mixed and passed through the matrix of the porous wall, which operates at around 900° C. When process exhaust gases are passed into this zone, they are oxidized.

A2-3.4.2 *Flow Capacity* — To calculate flow capacity, combine the total discharge flows that constitute input to the abatement device. Include pump dilution and purge quantities.

A2-3.4.3 *Efficiency* — Hydride gases can be oxidized by a method similar to other combustion techniques. High efficiency oxidation is needed to oxidize more stable fluorinated compounds.

A2-3.4.4 *Limitations* — Non-flame oxidation produces oxidation by-products, and therefore must often be combined with a wet scrubber to remove particulate matter or water-soluble gases.

A2-4 Cold Bed Systems (Adsorbers/ Chemisorbers)

A2-4.1 *Adsorption*

A2-4.1.1 *Principle of Operation* — Exhaust gas is passed through a container (cylinder, canister, or drum) filled with adsorbent granules. These are commonly based on activated charcoal. Some gases are physically adsorbed into the granules while the non-adsorbed gases pass through into the facility exhaust.

A2-4.1.2 *Flow Capacity and Removal Capacity* — Both capacities of these systems are a function of the container size (mass of granules) and surface area.

A2-4.1.3 *Efficiency* — For a single gas, efficiency can approach 100% until the bed capacity is reached. However, since the gas is only held physically it can be displaced by another compound, causing the efficiency to drop significantly.

A2-4.1.4 *Limitations* — Adsorption traps hazardous compounds and does not destroy them. Gases are adsorbed at different rates and the capacity of the bed for different gases will also vary. A more strongly adsorbed gas entering the bed after a less strongly adsorbed compound can displace the first gas re-releasing the first gas to the exhaust. The waste material must be kept sealed in the container and evaluated for hazards. Exposure to air, water, or heat can cause gases adsorbed in the material to be released.

A2-4.2 *Chemisorption*

A2-4.2.1 *Principle of Operation* — Exhaust gas is passed through a container of granules that consist of either:

- adsorbent granule coated with some reactive chemical;
- reactive porous medium e.g., soda lime; or
- a resin matrix coated with some reactive chemical.

A2-4.2.1.1 Gases are adsorbed into the porous matrix and then chemically react either with the granules themselves or with the coating. These reactions are designed to convert the gas into a solid material (typically a salt) that remains attached to the granules.

A2-4.2.1.2 Reactive chemicals are typically either bases (metal hydroxides) or oxidizers (e.g., permanganates, or metal oxides).

A2-4.2.2 *Flow Capacity and Removal Capacity* — Both capacities of these systems are a function of the container size (mass of granules) and surface area.

A2-4.2.3 *Efficiency* — Acid/Base and Redox reactions are most readily accomplished. Therefore, with acidic gases and hydride gases, efficiency can be high; with removal below OEL. With other gases, e.g., PFCs and halogenated carbon compounds, efficiency is often minimal or none.

A2-4.2.4 *Limitations* — There may be adsorption as well as chemisorption, so the spent material must be evaluated for hazards, since gases can desorb from it. This is especially true for chlorine (Cl_2) when the bed uses hydroxides. These will form OCl compounds that on exposure to air or moisture will regenerate chlorine.

A2-4.2.4.1 Materials used for chemisorption can themselves be hazardous (e.g., heavy metals or caustic (KOH/NaOH)) therefore, unused canisters may be classified as hazardous items.

A2-4.3 *Adsorption with Subsequent Air Oxidation*

A2-4.3.1 *Principle of Operation* — These systems are designed and offered mainly for high flows of arsine (AsH_3) and phosphine (PH_3), used in the deposition of III-V materials (such as gallium arsenide (GaAs), indium phosphide (InP)). These gases are adsorbed into a carbon bed, into which air is subsequently fed at a controlled rate to oxidize the adsorbed hydride into oxides that will remain in the granules.

A2-4.3.2 *Flow Capacity and Removal Capacity*— Both capacities of these systems are a function of the container (drum) size (mass of granules) and surface area.

A2-4.3.3 *Efficiency* — Capable of removing hydrides to below OEL.

A2-4.3.4 *Limitations* — Hydride is adsorbed into the carbon bed, the oxidation of this is exothermic. When air is fed in to oxidize the hydride, it is possible to start combustion of the carbon bed, unless the flow rate is well controlled.

A2-5 Hot Chemical Bed Systems

A2-5.1 *Hot Bed Reactors*

A2-5.1.1 *Principle of Operation* — Exhaust gases are passed through a steel container (cartridge/drum) that is filled with reactive material. The material is maintained at an elevated temperature, typically 250 to 550 degrees C. The gases chemically react with the fill material and are converted into inorganic salts that remain fused into the matrix of the fill material. There are versions with a single fill material that are specific to abatement of one gas, and versions with two or more zones of fill material that can abate a wide range of gas compounds.

A2-5.1.2 *Flow Capacity and Removal Capacity* — Both capacities of hot bed systems are a function of the cartridge size (mass of granules) and surface area.

A2-5.1.3 *Efficiency* — Efficiency of these systems is generally high, with gases removed to below OELs. Stable PFC gases are not removed by all systems.

A2-5.1.4 *Limitations* — Fill material can also react with oxygen or moisture so hot bed systems are not always suited to wet processes or where air is used.

A2-5.2 *Hot Catalytic Bed*

A2-5.2.1 *Principle of Operation* — Gas is passed into a steel cartridge, which is held at an elevated temperature, that contains granules of a catalyst. The target-input gas is catalytically converted to other gases [e.g., ammonia (NH_3) to nitrogen (N_2) and hydrogen (H_2), and oxides of nitrogen (NOx) to nitrogen (N_2) and oxygen (O_2)].

A2-5.2.2 *Removal Capacity* — In theory, if not poisoned, a catalyst bed should last for a long time. Units available are claimed to be able to operate for one-year before bed change.

A2-5.2.3 *Efficiency* — Efficiency of hot catalytic bed systems is normally high, with removal of the target gas to below OEL levels.

A2-5.2.4 *Limitations* — Hot catalytic bed units are designed to be gas specific. Catalysts can be sensitive to other compounds; so for complex gas mixtures in process exhausts they may not be suitable on their own.

A2-5.3 *Hot Reactor Beds with Gas Inputs*

A2-5.3.1 *Principle of Operation* — Exhaust gases are passed into a hot bed as in hot bed reactors above, but concurrently with the process gas another gas is introduced (e.g., air or steam). The gases then react together in the bed, either with each other or with the bed material. Hazardous gases are converted either to solid salts that remain fused into the bed matrix, or other gases [e.g., carbon dioxide (CO_2)] that pass on into the exhaust.

A2-5.3.2 *Flow Capacity and Removal Capacity* — Both capacities of these systems are a function of the container (cartridge) size (mass of granules) and surface area.

A2-5.3.3 *Efficiency* — Process gases [e.g., phosphine (PH_3), carbon monoxide (CO)] are normally removed to below the OEL.

A2-5.3.4 *Limitations* — These systems are suited only to processes where the end products will be either stable solids or inert gases.

A2-6 Reactor Systems (Plasma, Microwave, etc.)

A2-6.1 *Principle of Operation* — Gases are abated in the vacuum line (before or after the vacuum pump) by passing them through a reaction chamber, containing plasma, to enhance reaction of gases such as silane into a solid material. For high efficiency PFC conversion, it is necessary to inhibit recombination by the addition of a material (e.g., moisture, or a hydrogen/oxygen mixture). Two types of reactors exist - large plasma volume/small surface area, in which a downstream particle trap is utilized; and small plasma volume/large surface area, where solid films are deposited. Other reactor systems (e.g., microwave systems) are also being developed.

A2-6.2 *Flow Capacity and Removal Capacity* — Reactor systems are designed for the process system effluent and are sized to handle specific process flows.

A2-6.3 *Efficiency* — With inputs of up to 300 sccm of silane, removal efficiencies of greater than 99% have been documented. At higher flows efficiency can be reduced. High removal efficiencies of PFCs have also been demonstrated.

A2-6.4 *Limitations* — Silane will form solids in the plasma. Gaseous by-products will pass into the exhaust. Solids transmission into the vacuum pump will be reduced, but additional abatement devices may be required downstream if by-products need to be removed. Formation of hydrogen (H_2) as a by-product should be considered to ensure that the H_2 outlet concentration is below the lower flammable limit.

A2-7 Traps/Filters/Cyclones/Precipitators

A2-7.1 *Principle of Operation* — Designed to remove the particulate component in exhausts. Some processes produce solid powders (e.g., silica) and other processes generate condensable vapors. These vapors, on compression in the pump and cooling in the exhaust, condense into solid materials. Numerous designs exist to collect these solids out of the gas stream. These include filters (paper/bag etc.), cooled condensation chambers, cyclones, and electrostatic precipitators.

A2-7.2 *Removal Capacity* — Removal capacity is normally measured as the mass of solid the unit can collect before it partially blocks. As they are blocked, these systems generate a backpressure, which can prevent effective removal of material or create a process disturbance.

A2-7.3 *Efficiency*— Efficiency for these various units is difficult to measure. It is usually assessed pragmatically in terms of increased interval between exhaust clean out.

A2-7.4 *Limitations*— These various units must be used with care and only when not associated with hazardous gases. Often solid exhaust materials are mixed with hazardous gases. If these gases are present in the trapped solids a dangerous situation can result. Where gases and solids are mixed it is safer to keep material volatile and abate all by a POU abatement technology from the sections above. If only non-hazardous gases are left these systems can provide cost-effective abatement to keep ducts clear. They can also be used in combination with other technologies.

SEMI F6-92
GUIDE FOR SECONDARY CONTAINMENT OF HAZARDOUS GAS PIPING SYSTEMS

1 Purpose

To provide a guide for the design, fabrication, and operation of secondarily contained distribution piping for hazardous production material (HPM) gases.

2 Scope

This guide covers the general requirements for hazardous production material distribution piping in those industries that are included under the H-6 Classification of the Uniform Building Code, or Articles 51 or 80 of the Uniform Fire Code, or of other applicable local codes. This guide does not include requirements for individual exhausted enclosures (e.g., valve boxes and gas cabinets).

4 Terminology

4.1 *closed secondary containment* — Secondary containment that has a sealed annulus. In closed containment systems, the annular space either holds a certain pressure of gas or a certain level of vacuum. In closed containment, a change in the pressure or vacuum would be indicative of a leak in either the primary or secondary system.

4 National Fire Protection Association, Batterymarch Park, Quincy, MA 02269

5 American Conference of Governmental Industrial Hygienists, 6500 Glenway Avenue, Building D-7, Cincinnati, OH 45211

6 TLV is a registered trademark of ACGIH.

4.2 *controlled work area* — A space within a building where HPM's may be stored, handled, dispensed, or used.

4.3 *equilibrium vapor concentration (EVC)* — The state of a material at which vapor pressure has stabilized and is no longer rising or falling. The EVC value (in parts per million) of a material is determined by multiplying the vapor pressure by 10^6 and dividing by atmospheric pressure (760 mmHg at sea level).

4.4 *hazardous production material (HPM)* — A solid, liquid, or gas that has a degree-of-hazard rating in health, flammability, or reactivity of Class 3 or 4 as ranked by NFPA 704 and that is used directly in research, laboratory, or production processes that have as their end product materials that are not hazardous.

4.5 *highly toxic gas* — A chemical that has a median lethal concentration (LC_{50}) in air of 200 parts per million by volume or less of gas or vapor, or 2 milligrams per liter or less of mist, fume, or dust, when administered by continuous inhalation for one hour (or less if death occurs within one hour) to albino rats weighing between 200 and 300 grams each.

4.6 *immediately dangerous to life and health (IDLH)* — A concentration of airborne contaminants, normally expressed in parts per million or milligrams per cubic meter, which represents the maximum level from which one could escape within thirty minutes without any escape-impairing symptoms or irreversible health effects. This level is established by the National Institute of Occupational Safety and Health (NIOSH).

4.7 *level of concern (LOC)* — Equal to 0.1 of the IDLH value.

4.8 *lower detectable limit of instrument (LDL)* — The lowest concentration of a substance that will give an instrument response with a signal-to-noise ratio of at least 3 db.

4.9 *material hazard index (MHI)* — A numeric value used for ranking chemical production materials in order to determine the level of controls necessary for regulation. MHI is determined by dividing the equilibrium vapor concentration (EVC) of a material at 25°C by the level of concern (LOC) value for the material.

4.10 *open secondary containment* — Secondary containment with an open-ended annular space. This annulus must be directed to a system designed to handle the contained HPM.

4.11 *permissible exposure limit (PEL)* — The maximum permitted eight hour time-weighted average concentration of an airborne contaminant. The maximum permitted time-weighted average exposures to be used are those published in 29 CFR 1910.1000.

4.12 *pressure decay method* — The method of detection of leakage through pressure loss, over a period of time, within a vessel or piping system.

4.13 *primary containment* — The first level of containment (i.e., the inside portion of the container that comes into immediate contact on its inner surface with the material being contained).

4.14 *pyrophoric* — Capable of spontaneous ignition in air at or below a temperature of 54.5°C (130°F).

4.15 *secondary containment* — Level of containment that is external to and separate from primary containment. Secondary containment is a method of safeguarding used to prevent unauthorized releases of toxic or hazardous gases into uncontrolled work areas. Secondary containment means those methods or facilities in addition to the primary containment system.

4.16 *threshold limit value/time-weighted average (TLV/TWA)* — As defined by the American Conference of Governmental Industrial Hygienists (ACGIH).

4.17 *uncontrolled work area* — Any area outside of a secondary containment system where people are likely to be present.

4.18 *vacuum decay method* — Leakage detection determined by the loss of vacuum (increase in pressure), over a period of time within a vessel or piping system.

5 Containment Function

5.1 Secondary containment should, in case of release, segregate the hazardous production material (HPM) from the surrounding area.

5.2 Secondary containment systems should include provisions to contain and detect substances which pose health or property hazards and to direct such substances into areas or facilities that can safely treat, dispose of, or dilute them prior to release into the atmosphere.

6 Containment Application

Secondary containment may be used on any system if deemed appropriate by the authority responsible for the system. Secondary containment should be mandatory for all HPM's that are included in the following categories:

6.1 Those substances with threshold limit values (TLV) below the lower detectable limit (LDL) of the detection systems in use.

6.2 Those substances that provide inadequate warning properties.

6.3 Those substances that fall into the following categories:

6.3.1 Any HPM's which have a material hazard index (MHI) value equal to or greater than 500,000.

6.3.2 Highly toxic gas.

6.3.3 Pyrophorics.

6.3.4 Substances with unknown, but potentially high toxicities (e.g., organometallics).

6.3.5 Materials with an NFPA 704 reactivity rating of 3 or 4.

6.3.6 Any corrosives that are not contained in inert process piping.

6.4 Where piping containing HPM's is installed in a manner to conceal it from view.

6.5 Where piping containing HPM's is installed in uncontrolled or unventilated areas such as drop ceilings or behind walls.

6.6 Where required by UBC H-6 or other existing codes.

6.7 Where there is any reasonable possibility of a leak in the primary containment due to normal wear and tear, possible abuse, or corrosive attack to the piping on the inside or exterior.

7 Containment Methods

The method of containment may take many forms provided that the method is sound in engineering design. This design should be in conformance to nationally recognized codes and standards as well as to the requirements of local safety jurisdictions.

8 Materials of Construction

8.1 *Chemical Compatibility* — If there is a possibility that the HPM, or its reaction products, is corrosive, to any extent, to the secondary containment, one should develop a procedure to verify the integrity of the containment system. This verification procedure need only be performed in the event that the HPM, or its reaction products, contacts the containment (see Section 9).

8.2 *Fire Resistance* — If walls are used as the secondary containment system, they should be constructed of materials resistant of fire. The fire rating of the secondary containment should be as follows:

8.2.1 Two hour rating for pyrophorics;

8.2.2 One hour rating for all others.

9 Design Requirements

9.1 *Design Pressure* — The system should be designed to provide secondary containment with the ability to withstand the pressure of the entire volume of the potential leaking source without leakage.

9.1.1 Closed secondary containment systems should have sufficient design pressure to withstand the pressure of the entire contents of the source of the HPM. The design safety factor must be consistent with ANSI B31.3.

9.1.2 Open secondary containment systems should have sufficient design pressure to withstand the release at full tank pressure or the entire contents of the HPM released within a time of two minutes.

9.1.3 Special consideration should be given to the containment of pyrophorics. Some pyrophorics can develop considerable explosive pressure. The elimination of oxygen from the annulus of a containment system should be considered in lieu of explosive pressure data.

9.2 *Resistance to External Forces* — The method of construction of secondary containment systems should be sufficient to withstand:

9.2.1 Normal physical abuse found in the industrial workplace.

9.2.2 Seismic zone activity as shown in the UBC (Uniform Building Code) or other applicable codes.

9.3 *Leak Integrity* — The system should be designed to provide secondary containment with sufficient leak integrity to prevent exceeding the PEL of the HPM in uncontrolled work areas.

9.3.1 Primary piping should be leak tested in accordance with SEMI F1.

9.3.2 Closed secondary containment systems should have the same leak integrity as the primary containment except the closed secondary containment systems should be leak tested with the annulus pressurized to 2 times the maximum operating pressure with argon containing at least 10% helium. There should be no drop in pressure for a period of 12 hours.

9.3.3 Open secondary containment systems should be leak tested to the same criteria as closed secondary containment systems per 9.3.2 above.

10 Separation of HPM's

A single secondary containment may be used to contain more than one HPM provided that those HPM's are not reactive with any other HPM in the common containment. Documents that should be considered for proper separation of HPM's include:

10.1 SEMI S4, Safety Guideline for the Segregation/Separation of Gas Cylinders Contained in Cabinets

10.2 Materials Safety Data Sheets

10.3 NFPA Fire Protection Guide on Hazardous Materials

11 Cross Connections

There should be no mechanical cross connection of secondary containment systems with other systems not designed specifically for the secondary containment of the particular HPM's.

12 Monitoring

The annulus should be monitored for leakage of the primary system in accordance with the following:

12.1 The sensitivity of the detection system should be sufficient to detect leakage at 1/2 Threshold Limit Values (TLV's) at the discharge to treatment of an open secondary containment system.

12.2 Detection of leakage into the annulus of the secondary containment system should include alarm systems.

12.3 Detection methods may include:

12.3.1 Direct detection of the HPM or its reaction products (open secondary containment system).

12.3.2 Pressure decay method (closed secondary containment system).

12.3.3 Vacuum decay method (closed secondary containment system).

13 Leak Management

The secondary containment system should be designed to control and direct leaking materials. Control of HPM's may consist of dilution, absorption, incineration, scrubbing, venting, or those methods deemed safe and suitable to the governing authorities responsible for the facility. The initiation of the secondary containment alarm system should be automated. This system should automatically institute the management of the leaking HPM in the event of a breach of the primary system.

14 Periodic Testing - After Installation

14.1 Secondarily contained piping systems must be inspectable. The method of inspection must be able to reveal the current strength and leak integrity of the primary and secondary containment systems.

14.2 The secondary containment must be periodically leak tested in accordance with the criteria set forth in Section 9.3 of the above. Structural testing of both the process piping and the secondary containment should be conducted to the maximum pressure specified in Section 9.1 of the above.

14.3 Any secondarily contained piping system failing the periodic inspection should be repaired or replaced immediately.

SEMI

SEMI F7-92 (Reapproved 0299)
TEST METHOD TO DETERMINE THE TENSILE STRENGTH OF TUBE FITTING CONNECTIONS MADE OF FLUOROCARBON MATERIALS

This test method was technically reapproved by the Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available on www.semi.org February 1999; to be published February 1999. Originally published in 1992.

1. Purpose

1.1 This method provides a uniform procedure to determine the tensile strength of tube fitting connections made of fluorocarbon materials.

2. Scope

2.1 This method can be used to characterize tube fitting connections on the basis of test data developed under the conditions described herein, but the results are not intended to imply a performance rating.

2.2 Tube defined in this method has a circular cross section and is made of fluorocarbon materials.

2.3 All parts of the tube fittings tested by this method in contact with the internal fluid are made of fluorocarbon materials.

2.3.1 Parts such as a nuts or grippers are not limited to being made of a fluorocarbon material.

2.4 Only the seal between the tube and tube fitting being evaluated is within the scope of this document. All other, threaded seals are beyond the scope of this document.

2.5 When using this method for making comparisons among various tube fittings and/or manufacturers, the user must be specific in the selection of the tube and tube fittings to be evaluated.

2.6 The International System of Units (SI) is used as the standard unit of measure in this document. The U.S. Customary units are in parentheses for reference purposes only and have been rounded to the nearest whole value.

3. Referenced Documents

3.1 *ASTM Standards*[1]

D3307 PFA — Fluorocarbon Molding and Extrusion Materials

D3296 — Standard Specification for FEP Fluorocarbon Tube

4. Summary of Method

4.1 Subject tube fitting connections made of fluorocarbon materials to extreme tensile forces.

5. Significance and Use

5.1 In the manufacturing of semiconductor products, many types of hazardous chemicals and solvents are required. As a result, tubing and various fitting designs of fluorocarbon materials (which are chemically resistant to these fluids) are used to transport those fluids. It is important to control the testing process when evaluating various fitting designs, so that accurate comparisons of the tensile strength can be made.

5.2 It is the intent of this method to provide a procedure in which the tensile force will be applied to tube fitting connections made of fluorocarbon materials. By using this method, accurate comparisons of various tube fitting designs can be achieved.

5.3 The results obtained when using this method are applicable only to conditions that specifically duplicate the procedures used within this method.

5.4 When using this test method, it is assumed that the test specimens are truly representative of the material and manufacturing process specified for that product. Departure from this assumption could introduce discrepancies that are greater than those introduced by departure from the details of the procedure outlined in this method.

6. Terminology

6.1 *characterize* — To describe the quality of.

6.2 *failure* — Tube separation from a tube fitting connection or tearing of the tube.

6.3 *subject* — To expose to.

6.4 *tensile* — Longitudinal, so as to lengthen the test object.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

7. Description of Test Equipment

7.1 A test apparatus capable of securing the test specimen while accurately providing a uniform rate of pull to the specimen. The test instrument shall have the capability of recording the maximum tensile force applied to the test specimen.

7.2 See Figure 1 for basic tensile test apparatus.

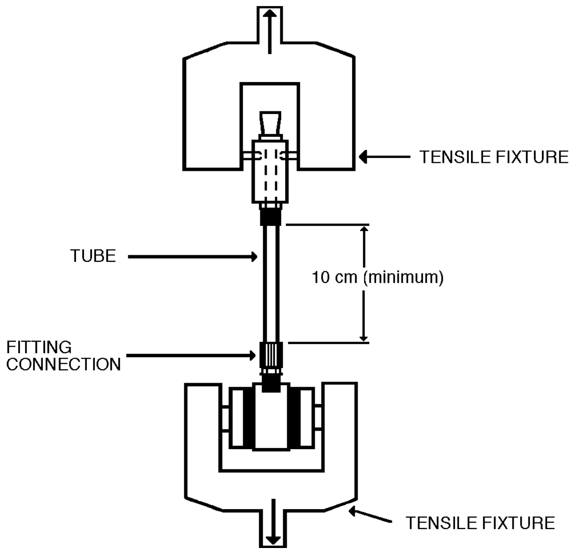

Figure 1
Basic Tensile Test Apparatus

8. Safety Precautions

WARNING: This test method will subject test specimens to conditions that may exceed the normal performance rating of the products under evaluation. Adequate precautions must be taken to prevent injury to the person conducting the test.

9. Test Specimens and Conditioning

9.1 *Sample Size* — A minimum of three specimens shall be tested.

9.2 *Specimen Size* — The specimen length shall be no less than 10 cm (4 in) between the tensile fixture and the tube end of the fitting connection.

9.3 *Specimen Surface* — All surfaces of the specimens shall be free of visible flaws, scratches, or other imperfections, unless typically found on a representative sample of the product.

9.4 *Specimen Conditioning* — All specimens must be conditioned for a minimum of one hour in an air environment of 23° ± 2.8°C (73° ± 5°F) prior to being subjected to tensile forces.

10. Calibration

10.1 Calibrate the tensile test equipment's rate of pull to 2.5 cm (1 in) per minute, ± 5%.

10.2 Calibrate the tensile force instrument to ± 2% full scale.

11. Test Procedure

11.1 Assemble a test fitting connection, per manufacturer's specification, to one end of the tube. (See 9.2.)

11.2 Install the fitting connection to the tensile fixture (see Figure 1) in a manner that prevents distortion of the connection.

11.3 Secure the open end of the tube to the tensile fixture, leaving a minimum of 10 cm (4 in) of exposed tube.

11.4 Begin pulling the test specimen at a rate of 2.5 cm (1 in) per minute.

11.5 Continue applying tensile force until the tube pulls through the fitting connection or until tearing of the tube occurs.

11.5.1 If the tube releases from the tensile fixture, the data from that specimen must be disregarded and an additional specimen tested.

11.6 Record on test data sheet (see Appendix 1 for a sample) the mode of failure and the maximum tensile force applied, in Newtons (lbs).

12. Calculations

12.1 Calculate the average "maximum tensile force" and record.

12.2 Calculate the standard deviation of "maximum tensile force" and record.

13. Data Accuracy

13.1 *Tensile Force* — Newtons: ± 2%.

14. Test Data Sheet

The test data sheet shall include the following information:

14.1 Date tested.

14.2 Operator and test facility.

14.3 Description of items tested, including:

Tubing — manufacturer, O.D., wall thickness, part number, and material type.

Fitting — manufacturer, type, size, part number, and material type.

14.4 Maximum tensile force for each specimen.

14.5 Average and standard deviation of maximum tensile forces.

14.6 Mode of failure for each specimen.

NOTE: A sample test data sheet is provided as Appendix 1.

SEMI F8-0998
TEST METHOD FOR EVALUATING THE SEALING CAPABILITIES OF TUBE FITTING CONNECTIONS MADE OF FLUOROCARBON MATERIALS, WHEN SUBJECTED TO TENSILE FORCES

1 Purpose

1.1 This method provides a uniform procedure to determine the sealing capabilities of tube fitting connections made of fluorocarbon materials when the connections are subjected to tensile forces.

2 Scope

2.1 This method can be used to characterize tube fitting connections on the basis of test data developed under the conditions described herein, but the results are not intended to imply a performance rating.

2.2 Tube defined in this method has a circular cross section and is made of fluorocarbon materials.

2.3 All parts of the tube fittings tested by this method in contact with the internal fluid are made of fluorocarbon materials.

2.3.1 Parts such as a nut or gripper are not limited to being made of a fluorocarbon material.

2.4 Only the seal between the tube and tube fitting being evaluated is within the scope of this document. All other, threaded seals are beyond the scope of this document.

2.5 When using this method for making comparisons between various tube fittings and/or manufacturers, the user must be specific in the selection of the tube and tube fittings to be evaluated.

2.6 The International System of Units (SI) is used as the standard unit of measure in this document. The U.S. Customary units are in parentheses for reference purposes only and have been rounded to the nearest whole value.

3.1 *ASTM Standards*[1]

D 3307 PFA — Fluorocarbon Molding and Extrusion Materials

D 3296 — Standard Specification for FEP Fluorocarbon Tube

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

4 Summary of Method

4.1 Subject tube fitting connections made of fluorocarbon materials to extreme tensile forces, while maintaining a specified pressure to the internal cavity of the fitting and tube.

5 Significance and Use

5.1 In the manufacturing of semiconductor products, many types of hazardous chemicals and solvents are required. As a result, tubing and various fitting designs made of fluorocarbon materials (which are chemically resistant to these fluids) are used to transport those fluids. It is important to control the testing process when evaluating various fitting designs, so that accurate comparisons of the sealing capabilities of tube fitting connections can be made.

5.2 It is the intent of this method to provide a procedure in which the air pressure and tensile force will be applied to tube fitting connections made of fluorocarbon materials. By using this method, accurate comparisons of various tube fitting designs can be achieved.

5.3 The results obtained when using this method are applicable only to conditions that specifically duplicate the procedures used within this method.

5.4 When using this test method, it is assumed that the test specimens are truly representative of the material and manufacturing process specified for that product. Departure from this assumption could introduce discrepancies that are greater than those introduced by departure from the details of the procedure outlined in this method.

6 Terminology

6.1 *Acronyms*

6.1.1 *O.D.* — Outside diameter

6.1.2 *P/N* — Part number

6.2 *Definitions*

6.2.1 *characterize* — To describe the quality of.

6.2.2 *failure* — Tube separation from a tube fitting connection or tearing of the tube.

6.2.3 *standard deviation* — A measure of the variation among the members of a statistical sample.

6.2.4 *submersion tank* — A transparent tank filled with isopropyl alcohol to allow observation of air leakage from the tube fitting connection.

6.2.5 *subject* — To expose to.

6.2.6 *tensile* — Longitudinal, so as to lengthen the test object.

7 Description of Test Equipment

7.1 A supply of compressed air. Pressure to be within ± 2% of specified.

7.2 Isopropyl alcohol.

7.3 An instrument to record the tensile force applied to the test specimen.

7.4 A test apparatus:

7.4.1 Capable of securing the test specimen while allowing the specimen to be internally pressurized.

7.4.2 Capable of accurately providing a uniform rate of pull to the specimen.

7.4.3 With a transparent submersion tank capable of containing a fluid for observing leakage. The minimum fluid level shall be 2.5 cm (1 in) above the test connection.

7.4.4 The apparatus shall allow the test specimen to be internally pressurized to 250 kPa (36 psig).

7.5 See Figure 1 for basic tensile and leak test apparatus.

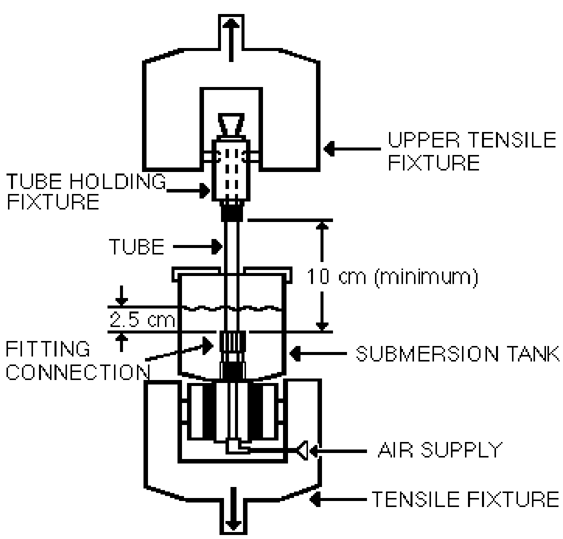

Figure 1
Basic Tensile and Leak Test Apparatus

8 Safety Precautions

WARNING: This test method will subject test specimens to conditions that may exceed the normal performance rating of the products under evaluation. Adequate precautions must be taken to prevent injury to the person conducting the test.

9 Test Specimens and Conditioning

9.1 *Sample Size* — A minimum of three specimens shall be tested.

9.2 *Specimen Size* — The specimen length shall be no less than 10 cm (4 in) between the upper tensile fixture and the tube end of the fitting connection.

9.3 *Specimen Surface* — All surfaces of the specimens shall be free of visible flaws, scratches, or other imperfections, unless typically found on a representative sample of the product.

9.4 *Specimen Conditioning* — All specimens must be conditioned for a minimum of one hour in an air environment of 23° ± 2.8°C (73° ± 5°F) prior to being subjected to pressure and tensile forces.

10 Calibration

10.1 Calibrate the tensile test equipment's rate of pull to 2.5 cm (1 in) per minute, ± 5%.

10.2 Calibrate the tensile force instrument to ± 2% full scale.

11 Test Procedure

11.1 Assemble a test fitting connection, per manufacturer's specification, to one end of the tube.

11.2 Install the fitting connection to the tensile fixture, in the submersion tank (see Figure 1) in a manner that prevents distortion of the connection.

11.3 Secure free end of tube to the upper tensile fixture, leaving a minimum of 10 cm (4 in) of exposed tube.

11.4 Fill the submersion tank with isopropyl alcohol to a height of 2.5 cm (1 in) above the top of the test connection.

11.5 Cover the submersion tank in case of a fluid splash.

11.5.1 The cover must allow for slight clearance around tube.

11.6 Pressurize the test specimen with an internal air pressure of 250 kPa (36 psig), regardless of tube size.

11.7 Begin pulling the test specimen at a rate of 2.5 cm (1 in) per minute.

11.8 Record on test data sheet (see Related Information 1 for a sample), the minimum tensile force in Newtons (lbs) when leakage is first observed from the fitting connection.

11.9 Lower the air pressure to one atmosphere immediately after observing any leakage.

11.10 Continue pulling until the tube pulls through the fitting connection or until tearing of the tube occurs.

11.10.1 If the tube releases from the tensile fixture, the data from that specimen must be disregarded and an additional specimen tested.

11.11 Record on test data sheet the mode of failure and the maximum tensile force applied in Newtons (lbs).

11.11.1 It is possible that the tensile force required to cause leakage and the maximum tensile force may be the same. If this situation occurs, indicate the force reading on both areas of the test data sheet.

12 Calculations

12.1 Calculate the average "force to cause leakage" and record.

12.2 Calculate the average "maximum tensile force" and record.

12.3 Using the three actual forces:

12.3.1 Calculate the standard deviation of "force to cause leakage" and record.

12.3.2 Calculate the standard deviation of "maximum tensile force" and record.

13 Data Accuracy

13.1 *Tensile Force* — Newtons: ± 2%

14 Test Data Sheet

The test data sheet shall include the following information:

14.1 Date tested.

14.2 Operator and test facility.

14.3 Description of items tested, including:

Tubing — manufacturer, O.D., wall thickness, part number, and material type.

Fitting — manufacturer, type, size, part number, and material type.

14.4 Force to cause leakage for each specimen.

14.5 Average and standard deviation of the forces to cause leakage.

14.6 Maximum tensile force for each specimen.

14.7 Average and standard deviation of maximum tensile forces.

14.8 Mode of failure for each specimen.

NOTE: A sample test data sheet is provided as Related Information 1.

TEST METHOD TO DETERMINE THE LEAKAGE CHARACTERISTICS OF TUBE FITTING CONNECTIONS MADE OF FLUOROCARBON MATERIALS, WHEN SUBJECTED TO A SIDE LOAD CONDITION

1 Purpose

1.1 This method provides a uniform procedure to determine the leakage characteristics of tube fitting connections made of fluorocarbon materials, when subjected to side loading.

2 Scope

2.1 This method can be used to characterize tube fitting connections on the basis of test data developed under the conditions described herein, but the results are not intended to imply a performance rating.

2.2 Tube defined in this method has a circular cross section and is made of fluorocarbon materials.

2.3 All parts of the tube fittings tested by this method in contact with the internal fluid are made of fluorocarbon materials.

2.3.1 Parts such as a nut or gripper are not limited to being made of a fluorocarbon material.

2.4 Only the seal between the tube and tube fitting being evaluated is within the scope of this document. All other, threaded seals are beyond the scope of this document.

2.5 When using this method for making comparisons between various tube fittings and/or manufacturers, the user must be specific in the selection of the tube and tube fittings to be evaluated.

2.6 The International System of Units (SI) is used as the standard unit of measure in this document. The U.S. Customary units are in parentheses for reference purposes only and may have been rounded to the nearest whole value.

3 Summary of Method

3.1 Subject tube fitting connections made of fluorocarbon materials to a side load condition that is a result of bending the tube in a uniform arc, while maintaining a specified pressure to the internal cavity of the fitting and tube.

4 Significance and Use

4.1 In the manufacturing of semiconductor products, many types of hazardous chemicals and solvents are required. As a result, tubing and various fitting designs made of fluorocarbon materials (which are chemically resistant to these fluids) are used to transport those fluids. It is important to control the testing process when evaluating various fitting designs, so that accurate comparisons of the side load capabilities can be made.

4.2 It is the intent of this method to provide a procedure in which tube fitting connections made of fluorocarbon materials will be subjected to extreme side loading. By using this method, accurate comparisons of various tube fitting designs can be achieved.

4.3 The results obtained when using this method are applicable only to conditions that specifically duplicate the procedures used within this document.

4.4 When using this test method, it is assumed that the test specimens are truly representative of the material and manufacturing process specified for that product. Departure from this assumption could introduce discrepancies that are greater than those introduced by departure from the details of the procedure outlined in this method.

5.1.2 *P/N* — Part number

5.2 *Definitions*

5.2.1 *bend radius* — The distance from the center of an imaginary circle on which the arc of the bent tube falls to a point on the arc.

5.2.2 *characterize* — To describe the quality of.

5.2.3 *kinking* — A collapse of the tube wall caused by excessive bending.

5.2.4 *"L"* — The tube length required to produce a uniform 180° arc, at a specified tube bend radius.

NOTE: The symbol "L" is unique in that it is used only in this test method.

5.2.5 *"R"* — The theoretical value to determine the tube bend radius, used during testing.

NOTE: The symbol "R" is unique in that it is used only in this test method.

5.2.6 *side load* — A result of bending a tube in a specified arc, consequently subjecting the tube fitting connection to a radial stress.

5.2.7 *subject* — To expose to.

5.2.8 *submersion tank* — A transparent tank, filled with isopropyl alcohol, to allow observation of air leakage from a tube fitting connection.

6 Description of Test Equipment

6.1 A supply of compressed air. Pressure to be within ± 2% of specified value.

6.2 Isopropyl alcohol.

6.3 An instrument for measuring lengths of tubing (e.g., tape measure).

6.4 A special apparatus which has a fixture for attaching the fitting body, while also providing a means to clamp the free end of tube, to maintain a tube bend radius.

6.4.1 The apparatus shall allow the test specimen to be internally pressurized.

6.4.2 The apparatus shall have a transparent submersion tank capable of containing a fluid for observing leakage. The minimum fluid level shall be 2.5 cm (1 in) above the test connection.

6.5 See Figure 1 for a basic side load test apparatus.

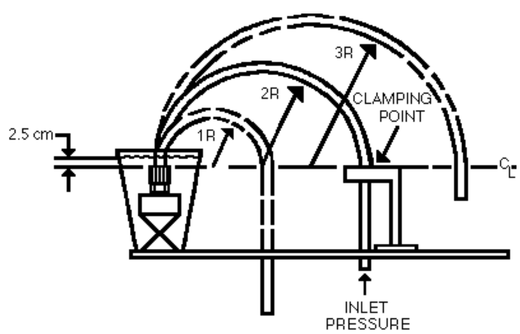

Figure 1
Side Load Test Apparatus

7 Safety Precautions

WARNING: This test method will subject test specimens to conditions that may exceed the normal performance rating of the products under evaluation. Adequate precautions must be taken to prevent injury to the person conducting the test.

8 Test Specimens and Conditioning

8.1 *Sample Size* — A minimum of three specimens shall be tested.

8.2 *Tube* — The tubing used for this evaluation shall be of straight lengths, not previously coiled.

8.3 *Specimen Surface* — All surfaces of the specimens shall be free of visible flaws, scratches, or other imperfections, unless typically found on a representative sample of the product.

8.4 *Specimen Conditioning* — All specimens must be conditioned for a minimum of one hour in an air environment of 23° ± 2.8°C (73° ± 5°F) prior to being subjected to pressurization and bending of the tube.

9 Test Procedure

9.1 Perform the following calculation to determine the "R" value.

9.1.1 For a tubing outside diameter (O.D.) of 1.5 cm (.59 in) or less: R = Tube O.D. × 5.

9.1.2 For a tubing outside diameter (O.D.) greater than 1.5 cm (0.59 in): R = Tube O.D. × 5.

NOTE: The constants (5 and 10) in Sections 9.1.1 and 9.1.2 were derived from the extrapolation of the actual "Minimum Bend Radius" of tubing from various manufacturers.

9.2 Perform the calculation in Section 9.2.1 to determine the tube length required to produce a 180° arc at a tube bend radius of R.

9.2.1 L = R × 3.14

9.3 Cut three tubes of equal length per the following formula: 3L + 15 cm (6 in).

9.4 Install a fitting body to the test fixture, in the submersion tank.

9.5 Install a tube into the fitting body and assemble the connection per manufacturer's specification.

NOTE: To prevent side loading of the fitting connection prior to bending of the tube, provide a method of supporting the tube.

9.6 Measure from the tube end of the fitting connection and place a mark on the tube (within ± 1% of calculated value) in five separate locations as determined below:

- 0.5L
- 1.0L
- 1.5L
- 2.0L
- 3.0L

9.7 Use the following formula to determine the actual tube bend radius used and record on test data sheet (see Related Information 1 for a sample):

- 0.5R
- 1.0R
- 1.5R
- 2.0R
- 3.0R

9.8 Fill the submersion tank with isopropyl alcohol to a minimum height 2.5 cm (1 in) above the top of the test connection.

9.9 Pressurize the test specimen with an internal air pressure of 250 kPa (36 psig), regardless of tube size.

9.10 Observe the connection for a minimum of one minute for bubble leakage (bbl/min) and record on test data sheet under the column entitled “STRAIGHT”.

9.11 Carefully bend the tube in a uniform 180° arc with a radius of 3R and clamp the free end to the test fixture. (See Section 9.7 for specific R value.) Proper tube length at the clamping point is determined in Section 9.6.

9.11.1 R value tolerances =

- Tubes with 1.5 cm (0.59 in) O.D. or less = ± 5%
- Tubes with greater than 1.5 cm (0.59 in) O.D. = ± 1%

9.12 Observe the connection for a minimum of one minute for bubble leakage. Record leakage on the appropriate area of the test data sheet. If no leakage is observed, note as “None”.

9.13 Repeat Sections 9.11 and 9.12 for the remaining tube bend radius of 2R, 1.5R, 1R, and 0.5R, in descending order.

9.13.1 Should any tube kink prior to achieving 0.5R, testing of that sample will be discontinued. The radius at which kinking occurred shall be recorded and noted as “kink”.

9.13.2 To reduce the effects caused by creep of the material the total time from initial bending of the tube until achieving the 0.5R value is to be less than ten minutes.

9.14 After completion of the first sample, replace the fitting and tube with new specimens and repeat Sections 9.4 through 9.13.2 for a total of three samples.

10 Test Data Sheet

The test data sheet shall include the following information:

10.1 Date tested.

10.2 Operator and test facility.

10.3 Description of items tested, including:

Tubing — Manufacturer, O.D., wall thickness, part number, and material type.

Fitting — Manufacturer, type, size, part number, and material type.

10.4 The actual tube bend radius for each nominal bend radius.

10.5 The leakage rate, in bubbles per minute, for each sample at each radius.

NOTE: A sample test data sheet is provided as Related Information 1.

SEMI F10-0698
TEST METHOD TO DETERMINE THE INTERNAL PRESSURE REQUIRED TO PRODUCE A FAILURE OF A TUBE FITTING CONNECTION MADE OF FLUOROCARBON MATERIALS

1 Purpose

1.1 This method provides a uniform procedure to determine the internal pressure required to produce failure of fitting connections made of fluorocarbon materials.

2 Scope

2.1 This method can be used to characterize tube fitting connections on the basis of test data developed under the conditions described herein, but the results are not intended to imply a performance rating.

2.2 Tube defined in this method has a circular cross section and is made of fluorocarbon materials.

2.3 Tube fittings defined in this method are made of fluorocarbon materials for all parts in contact with the internal fluid.

2.3.1 Parts such as a nut or gripper are not limited to being made of a fluorocarbon material.

2.4 Only the seal between the tube and tube fitting being evaluated is within the scope of this document. All other threaded seals are beyond the scope of this document.

2.5 When using this method for making comparisons among various tube fittings and/or manufacturers, the user must be specific in the selection of the tube and tube fittings to be evaluated.

2.6 The International System of Units (SI) is used as the standard unit of measure in this document. The U.S. Customary units are in parentheses for reference purposes only and may have been rounded to the nearest whole value.

3 Referenced Document

3.1 *ASTM Standard*[1]

ASTM D 1599 — Test Method for Short-Time Hydraulic Failure Pressure of Plastic Pipe, Tubing, and Fittings

4 Summary of Method

4.1 This test method consists of pressurizing tube fitting connections made of fluorocarbon materials to failure by continuously increasing the internal hydraulic pressure. New tubing and fitting samples are required at each specific elevated fluid temperature condition, and failures are to occur within 60 to 70 seconds from initial exposure to the high pressure fluid.

5 Significance and Use

5.1 In the manufacturing of semiconductor products, many types of hazardous chemicals and solvents are required. As a result, tubing and various fitting designs made of fluorocarbon materials (which are chemically resistant to these fluids) are used to transport those fluids. It is important to control the testing process when evaluating various fitting designs, so that accurate comparisons of the pressure limits can be made.

5.2 It is the intent of this method to provide a procedure to determine the maximum pressure limits of tube fitting connections made of fluorocarbon materials. By using this method, accurate comparisons of various tube fitting designs can be achieved.

5.3 The results obtained when using this method are applicable only to conditions that specifically duplicate the procedures used within this method.

5.4 When using this test method, it is assumed that the test specimens are truly representative of the material and manufacturing process specified for that product. Departure from this assumption could introduce discrepancies that are greater than those introduced by departure from the details of the procedure outlined in this method.

6 Terminology

6.1 *characterize* — To describe the quality of.

6.2 *failure* — Any external leakage of fluid through the tube wall or the tube fitting connection, whether it be catastrophic or a slow leak.

6.3 *free end closure* — A metal tube fitting connection which is securely fastened to the tube and does not contribute to the restraint of the test specimen.

6.4 *isolation valve* — A valve used to separate the high temperature fluid from the high pressure fluid or to separate the samples from each other.

NOTE: This definition is used in only this test method.

---

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

6.5 *pressure containing envelope* — The internal area of a specimen which contains the fluid media.

6.6 *standard deviation* — A measure of the variation among the members of a statistical sample.

6.7 *subject* — To expose to.

7 Description of Test Equipment

7.1 This test method requires the use of two hydraulic systems.

7.1.1 A high pressure system capable of applying a continuous increase of the internal hydraulic pressure to the test specimen.

7.1.2 A low pressure, high temperature circulation system capable of controlling a fluid temperature within ± 3°C (± 5°F) of a specified test temperature.

7.1.2.1 The pressure is to be 75 kPa (11 psig) or less for all temperatures, within the range of 25° to 200°C (77° to 392°F).

7.2 *Test Fluid* — When testing at or below 82°C (180°F), an SAE 20 weight hydraulic oil may be used. When testing at elevated fluid temperatures, use a synthetic oil that is acceptable for elevated temperatures of up to 200°C (392°F) and compatible with the test stand and test specimens.

7.3 An instrument to record the peak pressure within 1% of full scale.

7.4 An instrument to monitor temperature within ± 1°C (± 2°F).

7.5 *Specimen Support* — Any support is acceptable as long as it does not contribute to the restraint of the specimen in either the circumferential or axial direction.

7.6 An enclosure that will allow observation of the test specimen and that is also capable of controlling the ambient temperature to 31° ± 6°C (88° ± 11°F).

7.7 See Figure 1 for basic pressure and circulation system.

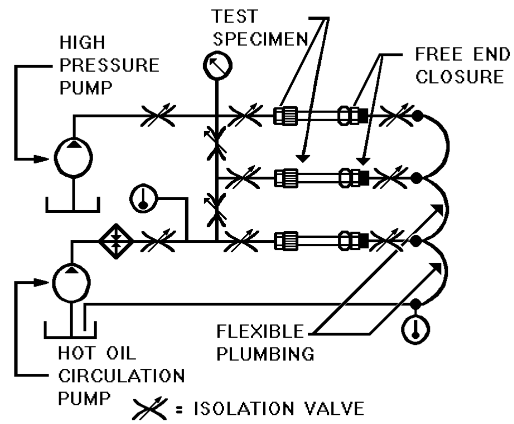

Figure 1
Basic Pressure and Circulation System

8 Safety Precautions

WARNING: This test method will subject test specimens to conditions that exceed the normal performance rating of the product under evaluation. Adequate precautions must be taken to prevent injury to the person conducting the test, as catastrophic failures of the test specimens are expected. The hydraulic plumbing and safety enclosure is to be constructed of materials which are capable of containing a fluid at 200°C (392°F).

9 Test Specimens and Conditioning

9.1 *Sample Size* — A minimum of three specimens shall be tested at each temperature condition.

9.1.1 The three connections will be conditioned simultaneously. See Figure 1 for a basic pressure and circulation system.

9.2 *Specimen Surface* — All surfaces of the specimens shall be free of visible flaws, scratches, or other imperfections, unless typically found on a representative sample of the product.

9.3 *Specimen Conditioning* — All specimens must be conditioned for a minimum of one hour in an air environment of 23° ± 2.8°C (73° ± 5°F) prior to being subjected to pressure.

9.4 A fluid at the specified temperature must be circulated through all the test specimens for a minimum of one-half hour.

10 Test Procedure

10.1 Install three fitting connections, assembled per manufacturer's specifications, to the test system. Allow for a minimum of 30 cm (12 in.) of tube length between the test fitting connection and the free end closure.

10.2 The plumbing *must* permit free movement of each test specimen to allow for distortion.

10.3 Using the low pressure circulation system (see Section 7.1.2), condition the test specimens to 25°C (77°F) per 9.4. The system pressure is not to exceed 75 kPa (11 psig) during conditioning.

10.4 Properly position the isolation valves in such a way that only one specimen will be pressure tested, while the remaining specimens continue to have heated fluid circulating through them.

WARNING: Take all necessary precautions when positioning the isolation valves, due to the potential harm which might be caused by an accidental exposure to the high temperature fluid.

10.4.1 Test each specimen within two minutes after isolating it from the hot oil circulation system.

10.5 Using the high pressure system (see Section 7.1.1), pressurize the specimen until failure occurs.

10.5.1 Increase the pressure at a uniform and constant rate such that failure occurs between 60 to 70 seconds from initial exposure to the high pressure fluid.

10.6 Record on test data sheet (see Appendix 1 for sample test data sheet) the pressure and temperature at which the failure occurred. To identify mode of failure, record pressure reading under column:

"T" — for tube failure.

"F" — for fitting connection failure.

10.7 Repeat 10.1 through 10.5, substituting, for the fluid temperature in Section 10.2, the remaining six temperatures: 75°C (167°F), 100°C (212°F), 125°C (257°F), 150°C (302°F), 175°C (347°F), and 200°C (392°F).

11 Calculations

11.1 Calculate the average pressure for each test temperature and record in kPa (psig).

11.2 Calculate the standard deviation for each test temperature and record.

12 Data Accuracy

12.1 *Pressure* — kPa: ± 2%

12.2 *Fluid Temperature* — ± 1°C (± 2°F)

13 Test Data Sheet

The test data sheet shall include the following information:

13.1 Date tested.

13.2 Operator and test facility.

13.3 Description of items tested, including:

Tubing — manufacturer, O.D., wall thickness, part number, and material type.

Fitting — manufacturer, type, size, part number, and material type.

13.4 The actual temperature for each test.

13.5 The failure pressure for each sample, in the appropriate column.

13.6 The average and standard deviation for each failure mode of each specimen.

NOTE: A sample test data sheet is provided as Related Information 1.

SEMI F11-0998
TEST METHOD TO OBTAIN AN INDICATION OF THE THERMAL CHARACTERISTICS OF TUBE FITTING CONNECTIONS MADE OF FLUOROCARBON MATERIALS

1 Purpose

1.1 This method provides a uniform procedure to determine the thermal characteristics of tube fitting connections made of fluorocarbon materials.

2 Scope

2.1 This method can be used to characterize tube fitting connections on the basis of test data developed under the conditions described herein, but the results are not intended to imply a performance rating.

2.2 Tube defined in this method has a circular cross section and is made of fluorocarbon materials.

2.3 Tube fittings defined in this method are made of fluorocarbon materials for all parts in contact with the internal fluid.

2.3.1 Parts such as a nut or gripper are not limited to being made of a fluorocarbon material.

2.4 Only the seal between the tube and tube fitting being evaluated is within the scope of this document. All other, threaded seals are beyond the scope of this document.

2.5 When using this method for making comparisons among various tube fittings and/or manufacturers, the user must be specific in the selection of the tube and tube fittings to be evaluated.

2.6 The International System of Units (SI) is used as the standard unit of measure in this document. The U.S. Customary units are in parentheses for reference purposes only and have been rounded to the nearest whole value.

3 Summary of Method

Subject tube fitting connections made of fluorocarbon materials to extreme internal pressure and temperature conditions.

3.1 Test specimens are subjected to a constant internal pressure while controlling the increase of fluid temperature in uniform increments, with a cool down period between each elevated temperature condition.

3.2 After completion of the entire temperature range, test a new set of fittings and tubing with an increased pressure.

4 Significance and Use

4.1 In the manufacturing of semiconductor products, many types of hazardous chemicals and solvents are required. As a result, tubing and various fitting designs made of fluorocarbon materials (which are chemically resistant to these fluids) are used to transport those fluids. It is important to control the testing process when evaluating various fitting designs, so that accurate comparisons of the thermal characteristics can be made.

4.2 It is the intent of this method to provide a procedure in which thermal transition testing of tube fitting connections made of fluorocarbon materials will be performed. By using this method, accurate comparisons of various tube fitting designs can be achieved.

4.3 The results obtained when using this method are applicable only to conditions that specifically duplicate the procedures used within this document.

4.4 When using this test method, it is assumed that the test specimens are truly representative of the material and manufacturing process specified for that product. Departure from this assumption could introduce discrepancies that are greater than those introduced by departure from the details of the procedure outlined in this method.

5 Terminology

5.1 *Acronyms*

5.1.1 *O.D.* — Outside Diameter

5.1.2 *P/N* — Part number

5.2 *Definitions*

5.2.1 *characterize* — To describe the quality of.

5.2.2 *free end closure* — A metal tube fitting connection which is securely fastened to the tube and does not contribute to the restraint of the test specimen.

5.2.3 *subject* — To expose to.

5.2.4 *thermal transition* — A change from a specific elevated fluid temperature down to room temperature and then to an elevated temperature higher than previously tested, with the entire process repeated for multiple temperature conditions.

6 Description of Test Equipment

6.1 A hydraulic system capable of applying a constant internal hydraulic pressure to all test specimens while allowing a uniform fluid flow rate through each specimen.

6.1.1 The pressure capability shall range from 100 to 1200, ± 35 kPa (15 to 174, ± 5 psig).

6.1.2 The fluid flow rate shall be adequate to maintain the fluid temperature at each specimen to ± 2.8°C (± 5°F) of the specified fluid temperature.

6.1.3 The fluid temperature capability shall range from 25°C to 200°C (77°F to 392°F), within a one hour time interval from hot to cool and vice versa.

6.2 An enclosure that will allow observation of the test specimens and is capable of controlling the ambient temperature to 31° ± 6°C (88° ± 11°F).

6.3 An instrument to monitor pressure within ± 1% of full scale.

6.4 An instrument to monitor temperature within ± 1°C (2°F).

6.5 An instrument to monitor time.

6.6 *Specimen Support* — Any support is acceptable as long as it does not contribute to the restraint of the specimen in either the circumferential or axial direction.

6.7 See Figure 1 for basic test system.

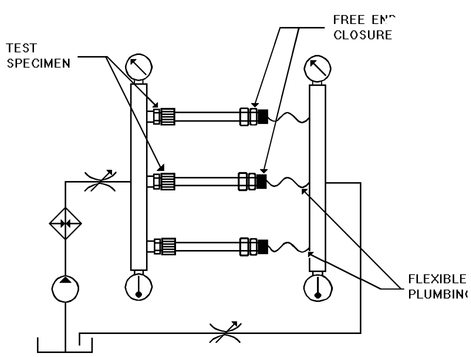

Figure 1
Basic Test System

7 Safety Precautions

WARNING: This test method will subject test specimens to conditions that may exceed the normal performance ratings of the products under evaluation. Adequate precautions must be taken to prevent injury to the person conducting the test. The hydraulic plumbing and safety enclosure are to be constructed of materials which are capable of containing a fluid at 200°C (392°F).

8 Test Specimens and Conditioning

8.1 *Sample Size* — A minimum of three specimens shall be tested at each pressure condition.

8.2 *Specimen Surface* — All surfaces of the specimens shall be free of visible flaws, scratches, or other imperfections, unless typically found on a representative sample of the product.

8.3 *Specimen Conditioning* — All specimens must be conditioned for a minimum of one hour in an air environment of 23° ± 2.8°C (73° ± 5°F) prior to being subjected to pressure.

9 Test Procedure

9.1 Install three fitting connections, assembled per manufacturer's specifications, to the test manifold. Allow for a minimum of 30 cm (12 in) of tube length between the test fitting connection and free end closure. (See Figure 1.)

9.1.1 The apparatus should include a section of flexible line from the free end enclosure to return manifold to allow for expansion.

9.2 Circulate 25°C (77°F) fluid through the test samples with a constant pressure of 100 kPa (15 psig) for one hour.

9.2.1 When three failures occur at any given pressure during the initial room temperature condition (prior to the specimens having been subjected to any elevated temperature conditions), testing is terminated.

9.3 Increase the fluid temperature to 75°C (167°F) for a total time of two hours from the time the temperature was initially increased. The maximum time allowed to achieve the elevated temperature is one hour. (See Figure 2.)

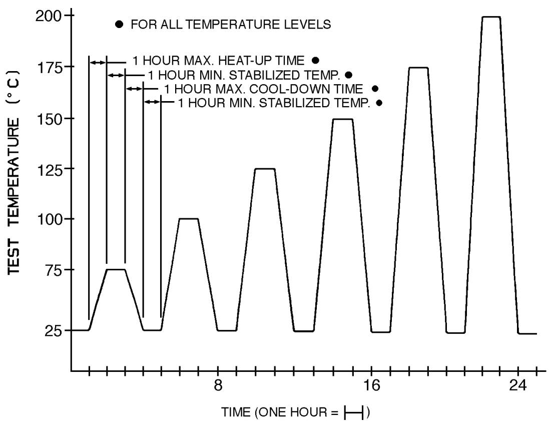

Figure 2
Thermal Transition Chart

9.4 Lower the fluid temperature to 25°C (77°F) for a total of two hours. The maximum time allowed to achieve the 25°C (77°F) temperature condition is one hour.

9.5 Repeat Sections 9.3 and 9.4, substituting, for the fluid temperature in Section 9.3, the remaining five temperatures: 100°C (212°F), 125°C (257°F), 150°C (302°F), 175°C (347°F), and 200°C (392°F).

9.5.1 The test samples should be at 25°C (77°F) prior to stopping the test at the end of a work shift.

9.5.1.1 The two hours at 25°C (77°F) will be equally divided between the present day cool-down time and the next day start-up time.

9.6 Monitor each of the three connections for external leakage throughout all test parameters.

9.7 Any external leakage at a tube connection will be recorded as a failure on the test data sheet (see Related Information 1 for sample test data sheet).

9.7.1 Leakage observed, once an elevated temperature is reached, will be recorded as a failure at that temperature.

9.7.2 Leakage at or during the cool-down cycle is to be recorded as a failure of the previously tested elevated temperature condition.

9.7.3 Leakage observed while increasing the temperature to the next condition is to be recorded as a failure of the previous elevated temperature condition.

9.8 Once a connection shows leakage and its failure pressure and temperature has been recorded, any additional leakage is not taken into consideration.

9.8.1 If leakage is not excessive, the connection can remain in the system until testing at that pressure has been completed.

9.8.2 If leakage of a connection becomes excessive, the connection may be retightened or replaced in order to continue testing of the remaining specimens. Take precautions not to disturb the remaining test specimens.

WARNING: Due to the extreme danger of high temperature fluids, take all necessary precautions when retightening or replacing a connection, to prevent accidental exposure to the heated fluid.

9.9 After three connection failures are recorded, or the 200°C (392°F) temperature has been achieved, a new set of fittings is to be installed for the next pressure condition.

9.10 Repeat Sections 9.2 through 9.9 for the remaining six pressures: 200 kPa (29 psig), 400 kPa (58 psig), 600 kPa (87 psig), 800 kPa (116 psig), 1000 kPa (145 psig), and 1200 kPa (174 psig).

10 Data Accuracy

10.1 Fluid Temperature — ± 1°C (± 2°F)

10.2 Pressure — kPa: ± 2%

11 Test Data Sheet

The test data sheet shall include the following information:

11.1 Date tested.

11.2 Operator and test facility.

11.3 Description of items tested, including:

Tubing — Manufacturer, O.D., wall thickness, part number, and material type.

Fitting — Manufacturer, type, size, part number, and material type.

11.4 The actual temperatures and pressures at which failures occur.

NOTE: A sample test data sheet is provided as Related Information 1.

NOTE: Record the pressures and temperatures at which failures occur.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F12-0998
TEST METHOD TO DETERMINE THE SEALING CAPABILITIES OF FITTINGS, MADE OF FLUOROCARBON MATERIAL, AFTER BEING SUBJECTED TO A HEAT CYCLE

1 Purpose

1.1 This method provides a uniform procedure to determine the sealing capabilities of fluorocarbon resin fittings, after they have been subjected to an elevated ambient temperature and cooled to room temperature (hereafter referred to as a "Heat Cycle").

2 Scope

2.1 This method can be used to characterize the thermal characteristics of tube fitting connections on the basis of test data obtained under the conditions described herein, but the results are not intended to imply a performance rating.

2.2 When using this test method, a fitting body temperature range of 23° – 125°C (73° – 257°F) should be maintained.

2.3 Tube defined in this method is made of fluorocarbon materials.

2.4 Tube fittings defined in this method are made of fluorocarbon materials for all parts in contact with the internal fluid. Parts such as nuts and grippers are not limited to being made of a fluorocarbon material.

2.5 Only the seal between the tube and tube fitting being evaluated is within the scope of this document. All other seals are beyond the scope of this document.

2.6 When using this method for making comparisons between various tube fitting manufacturers, the user must be specific in the selection of the tube and tube fittings to be evaluated.

NOTE: The International System of Units (SI) is used as the standard unit of measure in this document. The U.S. Customary Units are in parentheses for reference purposes only and have been rounded to the nearest whole value.

3 Summary of Method

3.1 Measure the leakage of the tube fitting connection after being exposed to a heat cycle by subjecting the fitting to an internal pressure with nitrogen.

4 Significance and Use

4.1 In the manufacturing of semiconductor products, many types of hazardous chemicals and solvents are required. As a result, tubing and various fittings made of fluorocarbon materials (which are chemically resistant to these fluids) are used to transport those fluids. It is important to control the testing process when evaluating various fitting designs, so that accurate comparisons of the sealing capabilities of tube fitting connections can be made.

4.2 It is the intent of this method to provide a procedure which evaluates the sealing capability of the tube fitting connection when subjected to a change in ambient temperature.

4.3 The results obtained when using this method are applicable only to conditions that specifically duplicate the procedures used within this method.

4.4 When using this test method, it is assumed that the test specimens are truly representative of the material and manufacturing process specified for that product. Departure from this assumption could introduce discrepancies that are greater than those introduced by departure from the details of the procedure outlined in this method.

5 Terminology

5.1 *Acronyms*

5.1.1 *O.D.* — Outside diameter

5.1.2 *P/N* — Part number

5.2 *Definitions*

5.2.1 *constant temperature oven* — Hot-air oven used to condition the specimens to the specified temperature.

5.2.2 *excessive leakage* — Gas leakage (measured in bubbles) from a fitting connection greater than can be humanly counted.

5.2.3 *seal cap* — An end closure or plug to block the open end of a tube or fitting to allow the specimen to be pressurized with nitrogen gas]

5.2.4 *subject* — To expose to.

5.2.5 *submersion tank* — A transparent tank filled with room temperature isopropyl alcohol used for observing leakage of nitrogen from the tube fitting connection. A cover or lid that does not create an air-tight seal is recommended while the specimen is being subjected to pressure.

6 Apparatus

6.1 Constant Temperature Oven

6.1.1 The constant temperature oven must have sufficient capacity to accommodate the specimens and control the temperature within ± 3°C (± 5°F).

6.1.2 See Figure 1 for test set-up.

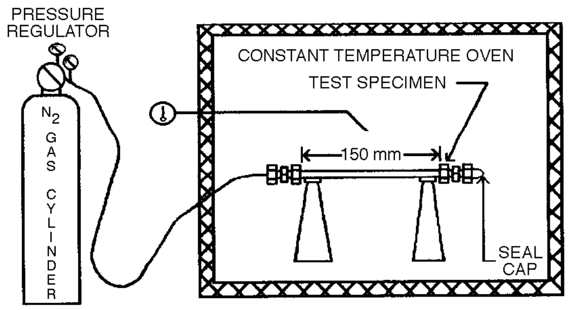

Figure 1
Test Set-Up

6.2 *Nitrogen Supply*

6.2.1 The supply of nitrogen must have a pressure regulator to control the pressure to the specimens accurately.

6.2.2 The nitrogen supply must include an instrument for monitoring pressure to within 2% of the test range (650 kPa, 94 psi).

6.3 *Submersion Tank* — The submersion tank is used for observing leakage of nitrogen from the fitting connection. (See Figure 2.) It consists of a container capable of holding enough isopropyl alcohol to allow the specimen to be submerged 25 ± 5 mm (1 ± .2 in) below the fluid surface at a 45° ± 5° angle.

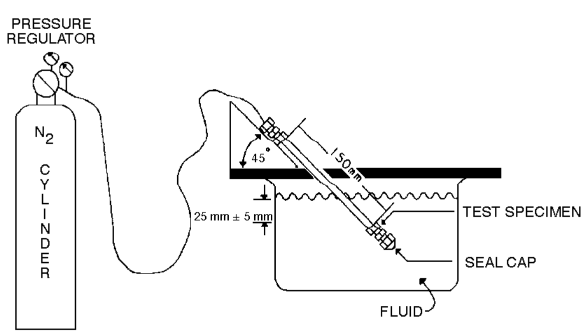

Figure 2
Submersion Tank for Observing

7 Safety Precautions

WARNING: This test method will subject test specimens to conditions that may exceed the normal performance ratings of the products under evaluation. Adequate precautions must be taken to prevent injury to the person conducting the test.

8 Test Specimens and Conditioning

8.1 *Sample Size* — Test at least three specimens at each test condition.

8.2 *Specimen Tubing Length* — At least 150 mm (6 in).

8.3 *Specimen Surface* — All surfaces of the specimens shall be free of visible flaws, scratches, or other imperfections, unless typically found on a representative sample of the product.

8.4 All specimens must be conditioned for a minimum of one hour in an air environment of 23° ± 2.8°C (73° ± 5°F) prior to being subjected to test.

9 Test Procedure

9.1 A representative specimen must be assembled and should accompany the test specimens during the heat cycle but will be used for the sole purpose of monitoring temperature.

NOTE: The representative specimen must be of the same size and type as the test specimens being tested. The representative specimen shall not be pressurized during any portion of the test.

9.1.1 Insert a temperature probe into the center of the representative fitting specimen. Ensure that the temperature probe is sealed from the oven environment to prevent any of the heated air from entering the specimen. (See Figure 3.)

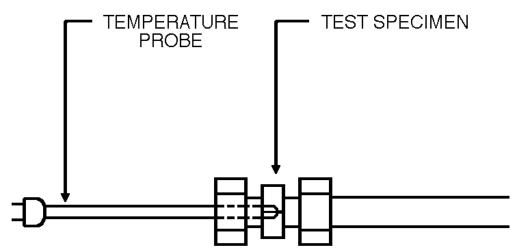

Figure 3
Placement of Probe

9.1.2 Place the representative specimen among the test specimens to monitor temperature during the heat cycle.

9.2 Assemble the test specimens in accordance with manufacturer's specifications. The test specimens shall be as described in Section 8. A seal cap shall also be attached to allow the specimen to be pressurized.

9.3 Submerge each test specimen as shown in Figure 2, and subject it to the specified pressure for the 23°C (73°F) column based on tube size as shown in Table 1. (See Appendix 1.) Observe the fitting connection for leakage for a minimum of one minute. Record the leakage results in the Proof Test area of the Test Data Sheet. (See Related Information 1.) This is a proof test to determine the integrity of the fitting connection before it is subjected to a heat cycle.

9.3.1 If excessive leakage (more than can be humanly counted) occurs, stop the test, and record as excessive leakage on the Test Data Sheet. (See Related Information 1.)

9.4 Condition the specimens to 75°C (167°F) by placing the specimens into the oven (see Figure 1) while subjecting them to the specified pressure for that temperature and tube size as shown in Table 1. (See Appendix 1.)

NOTE: More than one specimen may be conditioned simultaneously. Only fittings with the same test pressure and temperature should be conditioned simultaneously. Specimens must be leak tested individually.

9.4.1 The specimens shall remain in the oven 15 minutes after it has stabilized to the specified temperature.

9.4.2 Release nitrogen pressure from the specimens, remove from the oven, and allow to cool to room temperature 23° ± 2.8°C (73° ± 5°F). Do not disturb the specimens while cooling.

9.4.3 After the temperature of the specimens has reached room temperature, allow the specimens to remain undisturbed for 15 additional minutes before leak testing.

9.5 Submerge each specimen as shown in Figure 2, and pressurize to the specified pressure for the 23°C (73°F) temperature. Observe the fitting connection for leakage for a minimum of one minute.

9.6 Release the pressure in the specimen, and record the results on the Test Data Sheet. (See Related Information 1.)

NOTE: The release of pressure from the specimen when removing from the oven and from the submersion tank is for safety reasons, and compliance is strongly recommended.

9.6.1 Unit of measure for leakage is the number of nitrogen bubbles per minute.

9.6.2 Leakage from the seal cap is beyond the scope of this document and is not required to be measured or recorded.

9.7 After completion of leakage measurement, repeat Sections 9.4 through 9.6 ten times (cycles) at the same pressure and temperature level with the same specimens.

9.7.1 If excessive leakage (more than can be humanly counted) occurs, stop the test, and record as excessive leakage on the Test Data Sheet. (See Related Information 1.)

9.8 After completion of ten cycles, repeat the test with new specimens starting at Section 9.2, but substituting for the temperature in Section 9.4, 100°C (212°F) and 125°C (257°F) as shown in Table 1. (See Appendix 1.)

10 Data Accuracy

10.1 *Pressure* — ± 2%

10.2 *Temperature* — ± 1°C (± 2°F)

11 Test Data Sheet

The test data sheet shall include the following information:

11.1 Date tested.

11.2 Operator and test facility.

11.3 Description of items tested, including:

Tubing — Manufacturer, O.D., wall thickness, part number, and material.

Fitting — Manufacturer, type, size, part number, and material.

11.4 All of the data described in Section 9.

NOTE: A sample test data sheet is included as Related Information 1.

APPENDIX 1

NOTE: This appendix was approved as an official part of SEMI F12 by full letter ballot procedure.

Table 1 Nitrogen Pressure for Each Test Temperature

Tube Size (Diameter × Thickness in mm (in)	*Test Temperature: °C (°F)*

SEMI F13-1101
GUIDE FOR GAS SOURCE CONTROL EQUIPMENT

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1993.

1 Purpose

1.1 The purpose of this document is to provide a guide for the design and operational requirements of gas source control equipment which is used to control pressure and flow from a gas cylinder to the point of use.

2 Scope

2.1 This document describes the components and minimum performance criteria for gas source control equipment used with hazardous production material (HPM) semiconductor gases. This guide also includes recommended component functions and operating requirements.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Related Documents

3.1 These documents should be used in the design, fabrication, installation, and operation of gas source control equipment.

3.2 *SEMI Standards and Safety Guidelines*

5 Terminology

5.1 *automatic shut-off (ASO)* — A remotely actuated valve, preferably the cylinder valve, but possibly a valve located close to the cylinder valve, which can isolate the product as close to the cylinder valve as possible. It may also be a device which attaches to the cylinder valve stem or handle to close the valve.

5.2 *compressed gas association (CGA)* — Organization that sets standards for the handling and safe use of gases. Used in this document to refer to the cylinder valve outlet connection for each product as designated by the CGA.

5.3 *cylinder* — A pressure vessel designed for pressures higher than 276 kPa (40 pounds per square inch absolute) and having a circular cross section. It does not include a portable tank, multi-unit tank car tank, cargo tank, or tank car. It also refers to non-DOT low pressure containers used for liquid product having low vapor pressure.

5.4 *gas source control equipment (GSCE)* — Refers to the equipment assembly beginning at the product exit from the cylinder valve to the beginning of the distribution piping leading to the point of use (POU). These assemblies are usually mounted on panels and are sometimes referred to as process panel systems.

5.5 *hazardous production material (HPM)* — A solid, liquid, or gas that has a degree-of-hazard rating in health, flammability, or reactivity of Class 3 or 4 as ranked by NFPA 704 and which is used directly in research, laboratory, or production processes which have, as their end product, materials which are not hazardous.

5.6 *high pressure isolation (HPI) valve* — A shut-off valve located on the high-pressure side of a gas piping system that, when closed, isolates the purged volume from the pressure regulator and other downstream components.

5.7 *low pressure isolation (LPI) valve* — A shut-off valve located on the low-pressure side of a gas system that, when closed, isolates the purged volume from the distribution piping and all other downstream components.

5.8 *point of use (POU)* — Refers to the manufacturing tool which uses the product. Point of use is distinguished from the GSCE by having its own design criteria, separate function, and physical separation from the GSCE.

5.9 *product* — Refers to the gas phase in the cylinder.

6 Configuration

6.1 *Manual/Auto Operation*

6.1.1 Manual equipment without automation is adequate if it includes an ASO plus excess flow device. (Where required, per UFC articles 51 and 80.) Automated purging is generally more efficient than manual purging and is, therefore, recommended. The ASO function is achieved if the ASO valve automatically defaults to a closed position via a pneumatically actuated valve, or separate actuator that will close a manual cylinder valve. Either method should be fail-safe (default to a closed position on loss of power and/or pneumatics). This could also be initiated by any number of abnormal circumstances.

6.1.2 *Fully Automatic* — This is a broad category of designs using any number of transducers, remotely operated valves, and logic to accomplish safeguarding, monitoring, and automatic purging. Extension of this approach to central data collection, analysis, and reporting via computers and special programs offers the capability of further reducing hazards and enhancing safety.

6.2 *Cylinder Connections*

6.2.1 Compressed gas cylinders are connected to the panel equipment using the connection on the outlet of the cylinder valve. The appropriate regulatory agency has designated one or more connections for each product gas.

6.2.2 Other containers for liquid or low vapor pressure materials may require the connection of two fittings. One of these is used to admit gas, which either pressurizes the product, allowing liquid withdrawal, or absorbs the product, allowing withdrawal of a gas-phase mixture of the product and the gas. The other fitting is used for withdrawal. The types and labeling of the connections vary among suppliers.

6.2.3 *High Pressure Pigtail* — A semi-flexible assembly of piping, subjected to cylinder pressure, which is used to connect the cylinder to the rigidly mounted components on the panel. The intent of this flexible assembly is to accommodate the location of the cylinder outlet.

6.2.4 *No Pigtail* — An alternate acceptable method allows cylinders to be elevated or lowered to match the fixed height of the connection point on fixed panel equipment.

6.3 *Cross Contamination*

6.3.1 *Purge Gas Cylinder Contamination by Process Gas* — Purge gas is supplied from cylinders, with each purge gas cylinder limited to a single process gas panel or several panels using the same process gas class or different mixture ratios of the same process gas class. A check valve should be installed in each line connecting the purge gas to the process panel equipment.

6.3.2 *Process Gas Cylinder Contamination by Purge Gas* — The purpose of purging is to remove air or residual process gas from the panel equipment (or part of it) back to the internal cavity of the closed cylinder valve.

WARNING: Check valves are not acceptable in this part of the process gas system because purging would be defeated. Cross contamination can only be prevented by safeguards which assure complete cylinder valve closure and process gas venting, before purging begins.

6.4 *Materials* — All materials furnished should be manufactured to nationally recognized standards. Metals used for the wetted surfaces should be type 3l6L stainless steel, or other materials that provide equal or improved compatibility with the gas in service. Nonmetallic seals that are used in valve or regulator seats must also be compatible with the product in service.

6.5 *Joints* — All welded joints should be butt welded (no socket welds) and should comply with SEMI F3. Connection fittings should be face seal type.

6.6 *Particle Control* — Particle contamination is controlled through the proper selection of components and system hardware, good design practices, clean fabrication methods, and proper operation of the system.

6.7 *Internal Volume* — The internal cavities should be configured for minimum surface area and internal volume to enhance purging. Dead end legs should be eliminated or kept to a minimum volume and length.

6.8 *Maintainability* — Planned maintenance or forced repair is facilitated or inhibited by specific design concepts and features. From a safety point of view, it is mandatory to be able to purge the entire GSCE (all cavities) and to have a downstream shutoff (low pressure isolation valve) and disconnect fitting.

7 Performance Recommendations

7.1 *Functional Recommendations*

7.1.1 The ASO should be designed to close based on an alarm or fail signal from an auxiliary component. It should be designed to fail closed and should have a working pressure at least 1.1 times the product cylinder pressure. If a pressure sensor is located between the ASO and the cylinder valve, as depicted in Figure 1, it should also have a working pressure at least 1.1 times the product cylinder pressure.

7.1.2 *Pressure Reduction* — Gases are most commonly required at POU at less than 100 psig. Cylinder pressure is reduced to the lower pressure by a gas pressure regulator, when necessary.

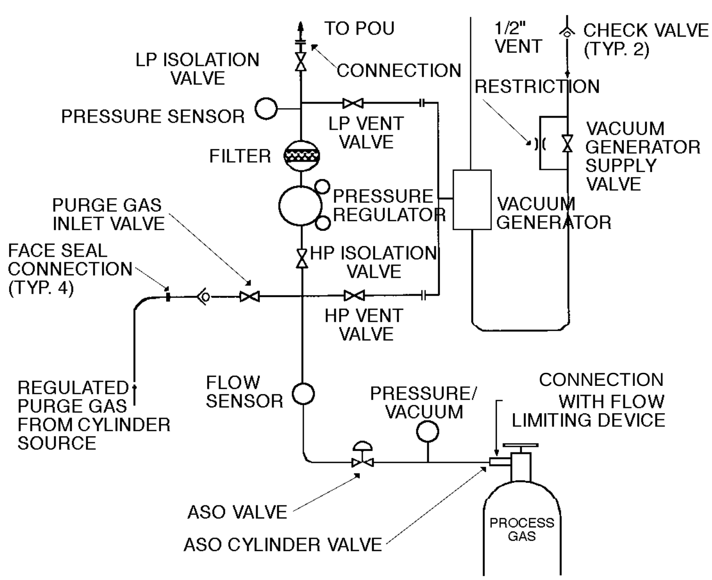

Figure 1
Typical Gas Source Control System

7.1.3 *Excess Pressure Control* — Provisions should be made to protect the distribution piping and process equipment from excessive pressure. This protection may include a pressure transducer, pressure switch, or indicating transmitter connected to close the ASO, a relief valve piped into the exhaust, or a redundant pressure regulator with primary regulator failure indication.

7.1.4 *Cylinder Content*s — The product remaining in the cylinder is determined by gas pressure measured by either a pressure transducer or gauge, or in the case of material in liquid/vapor phase, by the cylinder weight measured by a scale.

7.1.5 *Delivery Pressure* — The pressure delivered by the regulator is displayed by a pressure indicator. This can be either a gauge or transducer readout.

7.1.6 *Filters* — Particles from ambient sources, entering with the product or generated by the system elements, can be captured by including one or more filters at a variety of locations within the system. This practice tends to protect the components and the process.

7.1.7 *Purge Gas Connection* — A purge gas connection is provided via a branched connection to admit clean, dry, inert purge gas through an on-off valve. This is commonly located between the cylinder connection and high pressure isolation valve in the panel system. Gas purging is used for installation of a new system, before disconnecting a spent cylinder, after connecting a fresh cylinder, and for removal of equipment for maintenance purposes.

7.1.8 *Vent Outlets* — The normal purpose of the vent valves is to discharge process gas, air, and purge gas in conjunction with purging operations. Under special circumstances, they are used to reduce pressure in the equipment and/or transfer product. One or more vents may be used at various locations, and downstream venting may be either atmospheric pressure or vacuum from a venturi or pump. Vacuum venting is strongly recommended.

7.1.9 *High Pressure Indication* — A pressure indicator in common with the high pressure line connected to the cylinder valve is required to indicate the presence of residual process gas, or an open or leaking cylinder or panel valve. It also shows application of adequate purge gas pressure, and, in cases where vacuum-assisted purging is employed, an indication of the vacuum level should be included.

7.1.10 *Cylinder Connection Makeup* — After a fresh cylinder has been connected, the integrity of the cylinder valve connection can be tested with the use of the pressure indicator mentioned in Section 7.1.9.

7.2 *Failure Modes* — Any one of a number of conditions will require emergency action. Some are more serious than others. In some cases, the consequence is shutdown of the panel equipment and venting to a properly controlled discharge system. These failures should be addressed in the hardware and operational design phase of the system.

7.2.1 *Excessive Delivery Pressure* — Due to equipment malfunction or operator error.

7.2.2 Leaking fitting or component malfunction may require gas detection monitor.

7.2.3 *Excess Flow* — This can be the result of operator error or catastrophic conditions, such as a sheared delivery line.

7.2.4 Cabinet exhaust failure.

7.2.5 Mechanical failure of panel equipment parts or downstream equipment.

7.2.6 Destruction to plant through fire, explosion, earthquake, crash, etc.

7.2.7 Inadvertent mishandling of distribution equipment.

7.2.8 Process tool problems.

7.2.9 Control system failure.

7.2.10 *System Abuse/Misuse* — Source gas quality may affect service life and operability of the system. Poor gas product quality may cause a reduction in performance of the system that can lead to premature hardware component failures.

8 Acceptance Test

8.1 All gas source control equipment should undergo an acceptance test, agreed to and understood by the customer and supplier, before it is delivered. This test should ensure that all control and operational functions perform as required by the customer's and/or supplier's specifications.

9 Qualification Test

9.1 GSCE should be qualified at its installed location with an inert gas prior to installing the process gas cylinder. This test should include the operation of all control and hardware functions, interface with the process tool and all interconnected safety devices, systems, and alarms. This should also include a system wide leak test of all possible leak points, such as fittings and welds.

10 Labeling

10.1 The GSCE panel should be labeled for the product. Further labeling as defined in SEMI F14 should be affixed to the outside of the door of the enclosure.

11 Instructions

11.1 The purchaser's requirements will dictate the information provided with the equipment. Minimum acceptable instructions will vary with the complexity of the equipment (e.g., manual, automatic, microprocessor or pneumatically controlled, analog or digital, etc.) In all cases, the following information should be included:

11.1.1 "**WARNING:** Read Instructions Before Proceeding. (Instructions No. xxx for System No. xxx)

Do not proceed without understanding the status of the equipment as received, or damage may result."

11.1.2 *Installation*

11.1.2.1 Certified status of equipment as shipped should include:

11.1.2.2 Leak integrity,

11.1.2.3 Particle level,

11.1.2.4 Contaminants,

11.1.2.5 Storage requirements,

11.1.2.6 Status indicators,

11.1.2.7 Removal of shipping safeguards,

11.1.2.8 Physical mounting and connection details, and

11.1.2.9 Purging during preparation and start-up.

11.1.3 *Start-Up Method*

11.1.3.1 Perform purge for initial start,

11.1.3.2 Pre-process (with substitute inert gas),

11.1.3.2.1 Confirm all component functions,

11.1.3.2.2 Confirm all operating levels and setpoints, and

11.1.3.2.3 Confirm leak integrity.

11.1.4 *Process Service* — Operational purge procedures that include the number of purge cycles and purge pressure and vent dwell times, that take into account the configuration of the system and the intended process gas, should be determined before process gas is installed.

11.1.5 *Maintenance* — Maintenance purge procedures and panel repair and replacement procedures should be defined before process gas is installed.

NOTE 3: Special warnings about the potential for dead space in components or fittings, etc. (in normal or failed mode) should be identified to avoid producing a hazardous condition for any subsequent operation or handling at any location.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI F13 and was approved by full letter ballot procedures on August 27, 2001.

A1-1 Scope

A1-1.1 Under special circumstances, it may be necessary to cease using a product and remove it from the cabinet to a safer and/or less populated environment. This can be done in a number of ways.

A1-1.2 If the cylinder valve cannot be opened or closed, the gas supplier must be notified. Prior arrangements between the supplier and user of procedures should be in place, so that the required actions can be readily accomplished.

A1-2 Transfer Out of Cylinder

A1-2.1 Close the low pressure isolation valve, disconnect at the downstream side of either of the vent valves and connect to a suitable receiver with means of pumping if required. This depends upon knowledgeable operators, and the procedure to be followed must reflect the features of the particular GSCE and the product to be transferred. Extreme caution must be observed.

A1-3 Removal of the Cylinder

A1-3.1 A cylinder with a faulty or questionable cylinder valve may have to be removed. When a redundant valve and disconnect is installed in the pigtail, it may be closed, disconnected, and removed with the cylinder with relative ease and security. When a redundant valve is not present and a particular design allows it, the purge inlet valve, vent valve, and the HP isolation valve may be closed and removed with the pigtail still connected to the questionable cylinder. Adequate purging should precede this procedure.

SEMI F14-93 (Reapproved 0699)
GUIDE FOR THE DESIGN OF GAS SOURCE EQUIPMENT ENCLOSURES

This standard was technically reapproved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org February 1999; to be published June 1999. Originally published in 1993.

Editorial changes were made to sections 3.1.1, 6.2.1, and 6.2.2.

1 Purpose

1.1 This document summarizes gas source equipment enclosure design considerations. It is intended for use by manufacturers and purchasers.

2 Scope

2.1 Design considerations pertaining to gas source equipment enclosures are described herein. Modifications required to accommodate specific gases, cylinders, or unusual applications (e.g., process equipment) are not addressed.

3 Referenced Documents

3.1 Various codes and ordinances apply in different municipalities. These documents must be followed for the installation and operation of these systems. These codes may include:

3.1.1 *NFPA Standards*[1]

NFPA 13 — Installation of Sprinkler Systems

NFPA 69 — Explosion Prevention Systems

NFPA 70 — National Electrical Code

NFPA 91 — Exhaust Systems for Air Conveying Materials

3.1.2 *ICBO Model Code*[2]

Uniform Fire Code, 1991 Edition

3.1.3 *SEMI Safety Guideline*

SEMI S4 — Safety Guideline for the Segregation/ Separation of Gas Cylinders Contained in Cabinets

3.1.4 Other Publications

Industrial Ventilation, A Manual of Recommended Practice[3]

BOCA National Building Code[4]

BOCA National Fire Prevention Code[4]

Standard Building Code[5]

3.1.5 *Local Ordinances*

As applicable.

4 Terminology

4.1 *gas cylinder* — Usually means a high pressure compressed gas cylinder governed by Department of Transportation (DOT) regulations. It also refers to non-DOT low pressure containers used for liquid product having low vapor pressure.

4.2 *gas source equipment enclosure (enclosure)* — An enclosure for the storage of gas containers and associated equipment.

5 Functions

5.1 Five important functions are provided by an enclosure and its associated safety devices.

5.1.1 *Leaking Gas Containment* — Personnel, equipment, and the immediate working environment are protected from the hazards of leaking gases.

5.1.2 *Fire Protection* — Personnel and equipment are protected from the consequences of internal and external fires.

5.1.3 *Mechanical Protection* — The cylinder and associated equipment are protected from impact and seismic forces. (For further information, see UFC 51, *Workstations and Fabrication Areas*.)

5.1.4 *Access Control* — Unauthorized persons are inhibited from using gases and operating associated

[1] *National Fire Protection Association, Batterymarch Park, Quincy, MA 02269*

[2] *International Conference of Building Officials, 5360 South Workman Mill Road, Whittier, CA 90601*

[3] *American Conference of Governmental Industrial Hygienists, 6500 Glenway Avenue, Building D-7, Cincinnati, OH 45211*

[5] *Southern Building Code Congress International, 900 Montclair Road, Birmingham, AL 35213*

equipment.

5.1.5 *Gas Separation* — Gases that are chemically incompatible or belong to dissimilar hazard classes should be separated.

6 Design Considerations

6.1 *Regulatory Requirements* — The enclosure should conform to local, state, and federal regulations.

6.2 *Materials*

6.2.1 Enclosure top, sides, and doors should be constructed of 2.7 mm (12 gage) or thicker cold-rolled sheet steel or other suitable material so as to provide adequate mechanical stability.

6.2.2 Floors should be constructed of cold-rolled sheet steel or other suitable material, typically 3.4 mm (10 gage) or thicker, so as to adequately resist deformation by the heaviest intended cylinder.

6.2.3 Windows and skylights should be 6.5 mm (0.25 in) thick wired safety glass or other suitable material.

6.2.4 All materials should be noncombustible.

6.3 *Dimensions* — The enclosure should completely surround the gas cylinders and requisite accessory equipment. The design should incorporate minimum internal dimensions while still allowing safe and easy access to cylinders and equipment.

6.3.1 Heights of shelves for short cylinders should be adjustable so that cylinder valves and associated equipment are readily accessible through the limited-area access port.

6.3.2 Distances above cylinders should be adequate for installation and operation of associated equipment.

6.4 *Enclosure Interior Access*

6.4.1 *Door* — A gasketed door should enable safe and convenient installation and removal of intended cylinders, and installation, removal, and maintenance of associated equipment. The door should be self-closing and self-latching. The threshold should not interfere with cylinder installation and removal.

6.4.2 *Limited-Area Access Port* — The enclosure should have one or more limited-area ports that enable access to controls and associated equipment within the enclosure without compromising the air velocity across the face of the access port(s). The average air velocity across the faces of access ports should not be less than 1 m/s (200 fpm); a minimum air velocity of 0.75 m/s (150 fpm) should exist at any point.

6.4.2.1 Access ports should be self-closing.

6.4.3 *Window* — One or more windows should be provided to enable observation of equipment within the enclosure without compromising enclosure integrity.

6.4.4 *Security* — Lockable doors and access ports should be provided when unauthorized access to the enclosure interior must be precluded.

6.5 *Ventilation* — The enclosure should enable removal of leaking gas by local exhaust ventilation. The advantages of local exhaust ventilation over general ventilation are more fully described in NFPA 69, NFPA 91, and in Industrial Ventilation.

6.5.1 *Exhaust Connection* — The enclosure should enable connection to an exhaust system that will handle the required exhaust at an average duct velocity that does not exceed 8.5 m/s (1,700 fpm). The total exhaust flow includes that across open access ports as well as that through any supplementary air inlets.

6.5.2 *Air Flow Path* — In addition to access ports, the enclosure should include an air inlet located at the extremity of the enclosure opposite from the exhaust connection, so that ventilation of the entire enclosure is provided. The air flow path should adequately scavenge gas from all regions within the enclosure.

6.5.2.1 Structures (e.g., brackets or shelves) within the enclosure should not adversely affect exhaust capability.

6.5.2.2 Gaskets should be provided on all doors, access ports, and other penetrations.

6.6 *Fire Protection*

6.6.1 *Sprinklers* — Provisions for internal sprinklers should be made when necessary.

6.6.1.1 Sprinklers should be capable of providing adequate cooling to maintain cylinders and associated equipment at a temperature that will not actuate relief devices in the event of an internal or external fire.

6.6.1.2 Sprinkler actuation temperature should be greater than the anticipated maximum operating temperature of the enclosure interior under typical operating conditions, but less than the cylinder pressure relief device actuation temperature.

6.6.1.3 When the enclosure may be exposed to corrosive atmospheres, corrosion-resistant sprinklers should be provided. (For further information, see NFPA 13, *Corrosion-Resistant, Wax-Coated, or Similar Sprinklers*.)

6.7 *Mechanical Stabilization*

6.7.1 Provision for anchoring the enclosure to stable architectural elements should be made.

6.7.2 Fasteners should meet anticipated seismic loads in seismically active areas.

6.7.3 A means of securing each cylinder within the enclosure should be provided.

6.8 *Surface Finishes*

6.8.1 All exterior surfaces and equipment should be treated or finished to resist attack by weather elements.

6.8.2 Interior surfaces and equipment should be treated or finished to resist corrosive or solvent effects.

6.8.3 All surfaces should be free of burrs, sharp edges, and other flaws that could injure users.

6.9 *Interior Illumination* — Illumination of the enclosure interior should be adequate for safe operation of contained equipment. When ambient light is inadequate, several approaches may be taken to provide additional lighting:

6.9.1 A skylight may be provided.

6.9.2 With nonflammable gases, internal electric lights may be provided.

6.9.3 With flammable gases, power cables should not penetrate the enclosure interior except as provided for Class I, Division 2 locations (NEC, Article 501). Either internal explosion-proof lights may be provided, or external standard lights may project through an unopenable window.

6.9.4 All interior surfaces should reflect light efficiently.

6.10 *Labels*

6.10.1 *Gas Labels* — A label clearly displaying the chemical formula and common name of the gas should be attached to the enclosure exterior surface; its color should contrast with that of the enclosure.

6.10.2 *Hazard Warning Labels* — A label clearly stating requisite hazard warnings should be mechanically attached to the enclosure exterior surface in accordance with local building code requirements.

6.10.3 *Information Labels* — A label providing important specific information such as, but not limited to, emergency contacts, telephone numbers, manifold schematics, and first aid recommendations should be attached to the enclosure exterior surface.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI

SEMI F15-93 (Reapproved 0699)
TEST METHOD FOR ENCLOSURES USING SULFUR HEXAFLUORIDE TRACER GAS AND GAS CHROMATOGRAPHY

This Test Method was technically reapproved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org February 1999; to be published June 1999. Originally published in 1993.

1 Purpose

1.1 The purpose of this test method is to provide a standardized method to test the ability of enclosures to contain gases and vapors and a standardized format to record and document test results.

2 Scope

2.1 This test method applies to any enclosure that possesses a local exhaust (secondary ventilation) system.

2.2 In this test method, the tracer gas of choice is sulfur hexafluoride (SF_6). It is recognized that other gases have been used as tracers, but for the purposes of this test method, tracer gas means SF_6.

3 Limitations

3.1 This test method is intended to test the containment ability of a local exhaust system within an enclosure under the manufacturer's specified operating conditions. Thus, test data obtained by means of this test method apply only to the local exhaust conditions that existed within the enclosure during the testing. Extrapolation of the test data to other exhaust operating conditions is not usually possible.

3.2 Use of this test method requires a knowledge of the principles of gas analysis as well as flow and pressure measurement, gas chromatographic instrumentation, and gas sampling techniques.

3.3 An acceptable enclosure, as determined in Section 7.1, does not imply a safe condition for routine equipment operation with a leak and/or a tubing/fitting failure. An acceptable enclosure is one that will contain potential worst case leaks in an emergency, non-routine situation. The fact that an enclosure is acceptable does not imply that the enclosure is safe to operate when a hazardous gas leak has been detected.

4.3 *NFPA Standards*[2]

NFPA 13 — Identification of the Hazards of Materials for Emergency Response

NFPA 704 — Standard System for the Identification of Fire Hazards of Materials

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *equivalent release concentration (ERC)* — The theoretical concentration of a process gas that would be measured outside an enclosure in the event of a process line failure. The ERC can be expressed as a percentage of the TLV or PEL of the process gas.

5.2 *hazardous production material (HPM)* — For the purposes of this test method, a gas or vapor that has a degree-of-hazard rating in health, flammability, or reactivity of 3 or 4, as ranked by NFPA 704, that is used directly in a research, laboratory, or production process that has as its end product materials which are not hazardous.

6 Summary of Method

6.1 A test is performed by releasing tracer gas at a constant flow rate within an enclosure to simulate a worst case leak and then measuring on the periphery of the enclosure for the presence or absence of tracer. The lack of measurable tracer indicates that the release of potentially hazardous gases or vapors within the enclosure at the tracer injection point(s) will not result in their migration to the outside of the enclosure. Gas

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

2 National Fire Protection Association, Batterymarch Park, Quincy, MA 02269 samples are taken by means of disposable syringes, sample bags, or sample vials. Gas samples are analyzed by means of electron capture gas chromatography.

7 Procedure

7.1 *Test Design*

7.1.1 Determine the type of enclosure to be tested, such as: non-access, access, vacuum pump, equipment cabinet, or other.

7.1.2 Determine the volume of the enclosure.

7.1.3 Measure the exhaust flow rate from the enclosure.

7.1.4 Calculate the air changes per minute of the enclosure by dividing the exhaust flow rate (7.1.3 above) by the enclosure volume (7.1.2).

7.1.5 Calculate the time at which the tracer concentration in the enclosure will achieve approximate equilibrium. Concentration equilibrium occurs when the tracer concentration in the enclosure stops changing as a function of time for a constant tracer release rate. Divide 3 by the air changes per minute to establish this time. Use this as the time to take the first sample after initiating a test. Appendix 1 provides a derivation of the equilibrium time.

NOTE: This test method is intended to test the containment ability of the local exhaust system within an enclosure when operated according to the manufacturer's specifications. Thus, testing should be performed with the local exhaust operating under its manufacturer's recommended conditions.

7.1.6 If an excess flow control system is used, determine the trip point for each hazardous gas used. If different gases are used in the enclosure, the largest trip point should be used to calculate the tracer release flow rate.

7.1.7 If no excess flow system or flow-restricting orifice is used, the maximum accidental release rate must be calculated from the known maximum system pressure and either valve coefficients or tubing ID. An equation for flow through straight tubing is provided in Appendix 2.

7.1.8 In the absence of guidance in the above two sections, a standard test is the release of tracer gas through 6.35 mm (0.25 inch) OD by 0.89 mm (0.035 inch) wall tubing at a rate of 28 standard liters per minute (slpm) (1 scfm). Appendix 3 derives a general equation, A3-7, that can be used when this is not the case.

7.2 *Reagents and Materials* — Use SF_6 diluted in an inert gas, such as nitrogen or argon, as the tracer source, to minimize measurement difficulties associated with small leaks of pure SF_6 from the supply cylinder and its associated piping.

7.3 *Sampling*

7.3.1 In selecting the location of samples collected outside the enclosure, consider 1) potential leak points, 2) the direction of the release, and 3) laminar flow characteristics in the area surrounding the enclosure. Samples should be collected from all sides of the enclosure, downstream in the prevailing room air flow, and in the operating personnel occupancy areas.

7.3.2 The time required for the enclosure to reach equilibrium should be considered when establishing the time to begin sampling. The first sample after initiating tracer flow should be taken at the enclosure equilibrium time. Collect additional samples at 1 to 2 minute intervals until the tracer source is shut off. One sample should be taken 1 minute after the tracer source is shut off. The test duration can be changed to accommodate a particular test.

7.3.3 Collect background (baseline) samples from the area surrounding the enclosure at predetermined locations. When logistics permit, analyze the background samples before releasing the tracer gas. If background levels above approximately 1 ppb are detected, evaluate the integrity of the SF_6 tracer delivery system, and postpone the test until the concentration is less than 1 ppb. Other sources of SF_6 in the immediate test area may also cause this background.

NOTE: If testing is performed with an SF_6 background, the background concentration must be measured and subtracted from any subsequently measured tracer concentration value.

7.3.4 Release tracer gas within the enclosure being tested by means of an injection manifold, shown schematically in Figure 1. The tracer injection manifold must be capable of measuring flow rates to an accuracy of ± 5%. The tracer gas delivery line must be routed into the enclosure and attached to a potential leak point without violating the integrity of the enclosure.

NOTE: To minimize tracer gas contamination of the area surrounding an enclosure during a test, the end of the tracer injection line should be capped, except when performing an injection test.

7.3.5 Perform several tests with differing directions of release relative to any opening or penetration in the enclosure. The location and direction of the release shall effectively simulate an actual gas release or tubing/fitting failure within the enclosure. A worst case failure can be simulated by locating the tracer injection point at the potential leak location closest to a penetration or opening within the enclosure with the direction of tracer injection pointed directly at the opening or penetration.

7.3.6 After initiation of tracer injection, collect grab air samples from the area surrounding the enclosure at predetermined times and locations. These samples should be analyzed immediately after collection. If this is not possible, they should be sealed. Label the samples as to time and location. Samples may be taken with a) Containers that are non-absorbent, inert, and that have low permeability (such as polyvinyl fluoride film or polyester film sample bags or polyethylene, polypropylene, nylon, or glass bottles) or b) disposable syringes. Disposable syringes can be used to inject samples into the gas chromatograph directly.

7.3.7 Record a) the actual (measured) tracer gas release rate, b) the actual SF_6 concentration in the tracer gas being used, and c) the actual release time during a test.

7.3.8 Collect air samples as described in Section 7.3.6, and analyze them for the presence or absence of tracer gas using a gas chromatograph. The measurement of a non-zero tracer concentration in the area surrounding an enclosure indicates incomplete containment of contaminants within the enclosure.

7.3.9 Analyze samples according to ASTM E 260 and ASTM E 697 in conjunction with the chromatograph manufacturer's operating procedures. Samples may be analyzed immediately after a test, or they may be stored for future analysis. Experience has shown no degradation of concentration in polypropylene syringes when stored for several months as long as the needle or syringe is plugged. Polypropylene syringes should be discarded after one use to eliminate the possibility of cross contamination of samples.

8 Calculations and Interpretation of Results

8.1 The maximum concentration of SF_6 measured in a sample collected outside the enclosure is used to calculate the Equivalent Release Concentration (ERC) by the following formula:

$$\text{ERC} = \frac{\text{Conc. of process gas} \times \text{Measured SF}_6 \text{ Conc.}}{\text{Tracer Injection gas conc.}}$$

The above formula assumes the process gas tubing that fails is the same diameter as the tracer gas injection tubing. Appendix 3 contains a general equation that can be used when this is not the case.

8.2 Compare the Equivalent Release Concentration to the hazardous process gas TLV or PEL, whichever is lower. If the ERC is above the prescribed limits, the enclosure is not considered to be acceptable; if the ERC is less than or equal to the prescribed limit, the enclosure is considered acceptable. SEMI S2 recommends appropriate control limits for an enclosure.

9 Reporting Results

9.1 Present all results in tabular form in a manner which unambiguously notes those enclosure(s) that do not satisfy the criteria of SEMI S2. The exhaust operating conditions during each test must be provided along with each measured ERC value.

9.2 Describe tracer gas injection points within individual enclosures to detail location and proximity to openings, penetrations, exhaust grillwork, access panels, and other potential leakage sites, such that worst case leak conditions have been simulated.

9.3 Describe the unit being tested by manufacturer, model number, and serial number to provide identification of the unit being tested.

9.4 Tabulate and record the name, supply concentration, maximum flow rate, and TLV or PEL for each hazardous gas or vapor used within each enclosure being tested.

APPENDIX 1
EQUILIBRIUM TIME FOR TRACER INJECTION

If a tracer gas is injected at a constant rate into an enclosure that possesses a constant ventilation rate, the concentration as a function of time is given as

$$C(t) = (F/q)\,[1 - \exp\{-(q/V)t\}] \qquad (A1\text{-}1)$$

where $C(t)$ = Concentration within the enclosure
F = Injection rate of tracer gas
q = Ventilation rate of enclosure
V = Volume of enclosure
t = Elapsed time since initiating injection

Note that the term (q/V) contained in the exponential is the air change rate. In order for the concentration C(t) to be constant, the exponential term must be approximately zero. This is generally taken as the time when the exponential term is equal to e^{-3}. The time at which this occurs can be found by setting (q/V)t = 3 and solving for t. Thus,

$$(q/V)t = 3 \qquad (A1\text{-}2)$$

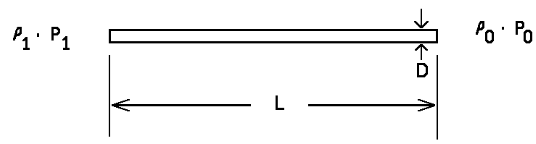
from which it follows that the equilibrium time is given as,

$$t = 3/(q/V) \qquad (A1\text{-}3)$$

$$t = 3(V/q) \qquad (A1\text{-}4)$$

APPENDIX 2
EQUATION FOR FLOW IN A STRAIGHT TUBE

Flow in a straight tube may be calculated if the tube characteristics, as well as the upstream and downstream pressures, are known. In the following, the upstream (drive side) conditions have a subscript of 1, while the downstream (ambient) conditions have a subscript of 0.



$$\gamma M_1^2 = \frac{1-\left(\frac{P_0}{P_1}\right)^2}{4f\left(\frac{L}{D}\right)+\ln\left(\frac{P_1}{P_0}\right)^2} \qquad (A2\text{-}1)$$

$$W = A(\rho_1 P_1 \gamma M_1^2)^{0.5} \qquad (A2\text{-}2)$$

$$\rho_1 = \rho_0\left(\frac{P_1}{P_0}\right) \qquad (A2\text{-}3)$$

where ρ_0 = $0.00129\ g/cm^3$
γ = 1.4
P = Pressure (dynes/cm^2)
$4f$ = 0.02 (*for smooth pipe*)
L = Length (cm)
D = Diameter (cm)
W = Mass Flowrate (g/sec)
A = Area of Flow Line (cm^2)

NOTE: Atmospheric pressure, 10^6 dynes/cm^2, is approximately 14.7 psia.

APPENDIX 3
GENERAL EQUATION RELATING PROCESS GAS FLOW RATE TO TRACER INJECTION RATE

In this appendix, a general equation relating process gas flow rate, tracer injection flow rate, and measured SF_6 concentration outside an enclosure to the ERC is provided. In the following, Q and L are given in volume units per unit time. Concentrations C are given in units of either vol./vol. or %. Whatever units are chosen should be used consistently in Equation A3-7.

Let the tracer injection rate into a volume be Q and the ventilation rate in this volume be L. At equilibrium, the concentration of tracer within this volume is Q/L = C_{source}. If, in the laboratory, one measures a concentration of tracer gas C_{lab}, then the Dilution Ratio, D, can be calculated as equal to

$$C_{lab}/C_{source}\,]_{tracer} = D_{tracer} \qquad \text{(A3-1)}$$

For any conserved chemical specie, D is constant. Thus, for a process gas released within the volume, one can form an analogous ratio

$$C_{lab}/C_{source}\,]_{process} = D_{process} \qquad \text{(A3-2)}$$

For all conserved chemical species, D is constant, hence

$$D_{tracer} = D_{process} \qquad \text{(A3-3)}$$

From this, one can form

$$C_{lab}/C_{source}\,]_{tracer} = C_{lab}/C_{source}\,]_{process} \qquad \text{(A3-4)}$$

so that

$$C_{lab}/C_{source}\,]_{tracer} \times C_{source}\,]_{process} = C_{lab}\,]_{process} \qquad \text{(A3-5)}$$

Here $C_{lab}\,]_{process}$ is the previously identified ERC.

For releases in the same test volume, this equation can be written

$$\{\, C_{lab}\,]_{tracer} \times (Q/L)]_{process}\} \,/\, (Q/L)]_{tracer} = ERC \qquad \text{(A3-6)}$$

Since the ventilation rate is the same

$$C_{lab}\,]_{tracer} \times Q_{process} \,/\, Q_{tracer} = ERC \qquad \text{(A3-7)}$$

This equation allows the calculation of ERC when simulating a leak within an enclosure using a different diameter tubing or different flowrate. In the case where the flowrates (or tubing size and injection pressure) are the same for the tracer and the process gas, Equation A3-7 simplifies to that in Section 5.1.

SEMI F16-94
SPECIFICATION FOR 316L STAINLESS STEEL TUBING WHICH IS TO BE FINISHED AND ELECTROPOLISHED FOR HIGH PURITY SEMICONDUCTOR MANUFACTURING APPLICATIONS

1 Purpose

The purpose of this specification is to identify the applicable ASTM tubing specification requirements and to define the special material composition, wall thickness, ordering, and quality assurance requirements for 316L stainless steel tubing which is to be finished into electropolished tubing, component tube stubs, and fittings made from tubing for use in high purity semiconductor manufacturing facility applications.

2 Scope

This specification defines the special criteria for procuring nominal sizes of unfinished 316L stainless steel tubing which is to be finished into tubing, component tube stubs, and fittings made from tubing for use in high purity chemical (gas or liquid) distribution systems in semiconductor manufacturing facilities.

Boiler and Pressure Vessel Code — Section III NCA, The Rules for Construction of Nuclear Power Plant Components

4 General Requirements

Tubing furnished under this specification shall conform to the requirements of ASTM A 450 and A 269 for nominal sizes 1/2 inch diameter and larger and to the requirements of ASTM A 450 and A 632 for nominal sizes smaller than 1/2 inch diameter, and to the additional requirements herein.

5 Ordering Information

5.1 Orders for material under this specification shall include the following, as required to describe the material adequately:

- Quantity (meters, feet, or number of lengths)
- Grade per Table 1 of ASTM A 269
- Size (nominal outside diameter and nominal wall thickness)
- This specification number
- Surface condition (if applicable)
- Special requirements and any supplementary requirements selected

6 Process

The steel shall be processed in accordance with the section on Process of ASTM A 269.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120

3 American National Standards Institute, 1430 Broadway, New York, NY 10018

7 Manufacture

7.1 Tubing shall be made by the seamless process for all sizes, except that welded tubing may be acceptable for nominal sizes 3 inches and above in diameter if the permissible variations in outside diameter are in accordance with Table 2 of ASTM A 270 and the other criteria specified herein are met.

7.2 Tubing must be cold finished.

8 Heat Treatment

8.1 All tubing shall be furnished in the heat treated condition in accordance with the section on Heat Treatment in ASTM A 269. If grain size is restricted by the supplementary requirement specified in Section 17.2 of this specification, the minimum annealing temperature shall not apply, provided that the tubing passes the intergranular corrosion test of Section 13 of this specification.

8.2 All tubing shall be vacuum annealed, or bright annealed in an undiluted hydrogen atmosphere, followed by rapid cooling. The adequacy of the cooling rate shall be confirmed by the intergranular corrosion test of Section 13 of this specification.

9 Surface Condition

The surface condition of tubing shall be in accordance with the requirements of the section on Finish of ASTM A 270.

10 Cleanliness

10.1 Tubing shall be supplied in accordance with the supplementary requirement for Cleanliness of ASTM A 632.

10.2 Tubing surface shall be sealed with polyethylene caps after being purged with nitrogen or a suitable inert gas. Capped tubing shall be heat sealed in a single 0.15 mm (6 mil) polyethylene bag.

11 Chemical Composition

11.1 Chemical composition of the steel shall conform to the requirements of the section on Chemical Composition in ASTM A 269 for nominal sizes 1/2 inch diameter and larger and to the section on Chemical Composition in ASTM A 632 for nominal sizes smaller than 1/2 inch diameter.

11.2 Sulfur content shall be from 0.003% to 0.010% for all nominal sizes.

12 Mechanical Properties

12.1 Tubing shall conform to the applicable requirements of ASTM A 450/A 450M unless otherwise provided herein.

12.2 Hardness of all sizes shall conform to the section on Hardness Requirements of ASTM A 269.

12.3 Tensile properties of all sizes shall conform to the section on Mechanical Properties of ASTM A 632.

13 Metallurgical Requirements

Tubing shall pass an intergranular corrosion test conducted in accordance with the supplementary requirement for Intergranular Corrosion Test of ASTM A 262. A minimum of two samples per lot shall be tested.

14 Nondestructive Testing Requirement

14.1 Eddy current testing shall be performed in accordance with the procedure and evaluation outlined in the section on Nondestructive Electric Test of ASTM A 450/A 450M except that the calibration reference notches shall not exceed 10% of the specified wall thickness of the tubing or 0.075 mm (0.003 inches), whichever is greater. If the form of product supplied makes this test technically infeasible, alternative non-destructive testing methods shall be agreed upon by the purchaser and supplier.

14.2 At the option of the purchaser, hydrostatic testing shall be conducted and evaluated in accordance with the requirements of the section on Hydrostatic Test of ASTM A 450A/450M.

15 Permissible Variations in Dimensions

15.1 Sampling for dimensional variations shall be performed in accordance with MIL-STD-105 with double normal sampling and a 2 1/2% Acceptable Quality Level (AQL).

15.2 The permissible variations in dimensions shall be as outlined in Table 2 of ASTM A 270 for all sizes.

15.3 Nominal wall thickness for tubing to be finished as shown in Table 1. The finished thicknesses must also comply with ANSI/ASME B31.1 and B31.3 specifications for the intended service temperature and pressure. A tolerance of ±10% shall apply to the wall thicknesses specified.

Table 1 Nominal Wall Thickness for Various Tube Nominal Sizes

Nominal O.D.	*Tube Wall Thickness*
1/4", 3/8"	1.02 mm (0.040")

1/2"	1.32 mm (0.052")
3/4", 1", 1 1/2", 2", 3"	1.75 mm (0.069")
4", 6"	2.11 mm (0.083")

16 Quality Assurance Requirements

The supplier's quality assurance program shall meet the requirements of the ASME Boiler and Pressure Vessel Code, Section III, NCA-3800 or of ISO 9000.

17 Supplementary Requirements

The following supplementary requirements shall apply only when specified by the purchaser on the inquiry, contract, or order.

17.1 *Alternative Finish (Inside Surface)* — The purchaser may specify alternate chemical treatment for the inside surface. Such treatment shall not promote grain boundary attack; the intergranular corrosion test requirement of Section 13 shall apply after chemical treatment.

17.2 *Restricted Grain Size* — At the option of the purchaser, ASTM grain size number may be restricted to 7 or finer, per ASTM E 112, provided that a maximum hardness lower than that given in the section on Hardness Requirements of ASTM A 269 is not also imposed.

18 Certification

18.1 The supplier shall provide the following reports and certifications with all shipments of tubing:

18.1.1 Type of tubing (seamless or welded)

18.1.2 Size (nominal outside diameter and nominal wall thickness)

18.1.3 Material composition report shall be provided to verify the above required grade, sulfur content, and grain size

18.1.4 Tubing provided in accordance with this specification shall be mill and heat traceable and permanently etched for correspondence to the applicable mill test reports.

SEMI F17-95
SPECIFICATION FOR HIGH PURITY QUALITY ELECTROPOLISHED 316L STAINLESS STEEL TUBING, COMPONENT TUBE STUBS, AND FITTINGS MADE FROM TUBING

1 Purpose

The purpose of this specification is to define the ordering, surface condition, and quality assurance requirements for high purity quality electropolished 316L stainless steel tubing, component tube stubs, and fittings made from tubing.

2 Scope

This specification defines the special criteria for nominal sizes of electropolished 316L stainless steel tubing, component tube stubs, and fittings made from tubing for use in high purity chemical (gas or liquid) distribution systems in semiconductor manufacturing facilities.

3 Referenced Documents

The referenced documents are to be to their current editions as published by their sponsors.

3.1 *SEMI Standard*

SEMI F16 — Specification for 316L Stainless Steel Tubing Which Is to Be Finished and Electropolished for High Purity Semiconductor Manufacturing Applications

3.2 *ANSI/ASME Standards*[1]

B31.1 — Power Piping

B31.3 — Chemical Plant and Petroleum Refinery Piping

B46.1 — Surface Texture: Surface Roughness, Waviness, and Lay

3.3 *ASTM Standards*[2]

A 269 — Specification for Seamless and Welded Austenitic Stainless Steel Tubing for General Service

A 632 — Specification for Seamless and Welded Austenitic Stainless Steel Tubing (Small Diameter) for General Service

1 American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017

2 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

4 General Requirements

The finished tubing, component tube stubs, and fittings made from tubing furnished under this specification shall use the tubing governed by SEMI F16 and shall meet the additional finish requirements herein.

5 Ordering Information

Orders for finished tubing, component tube stubs, or fittings made from tubing under this specification shall include the following, as a minimum, to describe the item:

- Quantity (meters, feet, number of items, or number of lengths)
- Type of tubing (seamless or welded)
- Size (nominal outside diameter and wall thickness)
- Length (specific or random)
- Other specific dimensions (such as for fittings).

6 Surface Condition

6.1 The internal surface of all finished tubing, component tube stubs, and fittings made from tubing shall be electropolished.

6.2 The internal surface of the finished tubing, component tube stub, or fitting made from tubing shall be free from all macroscopic pitting, staining or discoloration, and surface flaws. The O.D. of the tube shall be homogeneous in texture and brightness and free of obvious flaws.

6.3 Finished tubing, component tube stubs, and fittings made from tubing shall be measured for internal surface finish. Testing shall verify conformance to a surface roughness standard of one of the following:

Table 1 Roughness Average (R_a)

Multiple Measurements		*Maximum Single Measurement*	
micrometers	*microinches*	*micrometers*	*microinches*
0.25	10	0.30	12
0.18	7	0.25	10
0.13	5	0.18	7

7 Surface Condition Measurements

7.1 *Surface Roughness* — When specified as per Section 6.3, surface roughness shall be measured in accordance with ANSI B46.1, using a stylus-type instrument and a cutoff of 760 micrometers (0.030 inches), or equivalent process (which shall be submitted for approval to the customer prior to order acceptance). The results reported shall be Roughness Average (R_a), expressed in micrometers or microinches.

7.1.1 Measurements shall be made at 0, 90, 180, and 270 degrees around the tube's inner circumference.

7.2 Scanning Electron Microscopy (SEM) photographs of the electropolished internal surfaces of tubing, component tube stubs, and fittings made from tubing shall be provided by the manufacturer in accordance with the sampling frequency criteria specified by the customer. SEM analysis shall verify that no more than 40 defects shall be distinguishable in a 3400 to 3600× field view in a 64 × 89 mm (2 1/2" × 3 1/2") picture.

7.3 Chemical analysis, using electron spectroscopy for chemical analysis (ESCA), shall be performed on the electropolished internal surfaces of tubing, component tube stubs, and fittings made from tubing and shall be provided by the manufacturer in accordance with the sampling frequency criteria specified by the customer. Elemental composition shall be expressed in atomic percent units and shall verify a minimum chromium oxide to iron oxide ratio of 2.2:1.

7.4 Auger Electron Spectroscopy (AES) analysis shall be performed on the electropolished internal surfaces of tubing, component tube stubs, and fittings made from tubing and shall be provided by the manufacturer in accordance with the sampling frequency criteria specified by the customer.

8 Cleanliness

8.1 After electropolishing, finished tubing shall be final cleaned with a process that uses deionized (DI) water with a minimum resistivity of 17.5 megohm-cm at 25°C as the final cleaning agent, and nitrogen or a suitable filtered inert gas, as a drying agent. Both the water and the gas shall be heated to a minimum of 60°C.

8.2 Tubing, component tube stubs, and fittings made from tubing shall be sealed with polyethylene caps pressed over 0.05 mm (1.75 mil) or thicker polyamide squares after having been purged with nitrogen or a suitable inert gas. Capped tubing, stubs, or fittings shall be heat-sealed in a single 0.15 mm (6 mil) or thicker polyethylene bag.

9 Permissible Variations in Dimensions

9.1 The permissible variations in dimensions shall be as outlined in Table 3 of ASTM A 269 for nominal sizes 1/2" diameter and larger and in Table 3 of ASTM A 632 for nominal sizes smaller than 1/2" diameter.

9.2 Finished wall thicknesses for tubing, component tube stubs, and fittings made from tubing are shown in Table 1. The finished thicknesses must also comply with the requirements of ANSI/ASME B31.1 and B31.3 for the intended service temperature and pressure. The appropriate tolerances per Section 9.1 shall apply to these finished wall thicknesses.

Table 2 Finished Wall Thickness for Various Tube Sizes

Nominal O.D.	*Finished Tube Wall Thickness*
1/4", 3/8"	0.89 mm (0.035")
1/2"	1.25 mm (0.049")
3/4", 1", 1 1/2", 2", 3"	1.65 mm (0.065")
4", 6"	2.11 mm (0.083")

10 Certification

The supplier shall provide the following reports and certification with all shipments of electropolished tubing, component tube stubs, or fittings made from tubing:

10.1 Type of tubing (seamless or welded)

10.2 Size (nominal outside diameter and wall thickness)

10.3 Material composition report

10.4 Heat code identification. Tubing, component tube stubs, and fittings made from tubing shall be mill- and heat-traceable and permanently etched for correspondence to the applicable mill test reports

10.5 Surface roughness certification

10.6 Microscopic surface condition certification (SEM)

10.7 Surface chemistry certification (ESCA)

10.8 Surface depth profile certification (Auger).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. SEMI F18-95
GUIDE FOR DETERMINING THE HYDROSTATIC STRENGTH OF, AND DESIGN BASIS FOR, THERMOPLASTIC PIPE AND TUBING

1 Purpose

To identify a test method for measuring the hydrostatic strength of thermoplastic pipe and tubing, a method for estimating long-term hydrostatic strength, and recommendations for developing design bases.

2 Scope

2.1 This guide references the industry-recognized Standard Test Method for determining the time-to-failure of plastic pipe under constant internal pressure.

2.2 This guide references the industry-recognized Standard Test Method for determining the long-term hydrostatic strength of plastic pipe in order to obtain the hydrostatic design basis of the pipe material.

2.3 This guide references the Technical Report of policies and procedures for developing recommended hydrostatic design stresses for thermoplastic pipe materials from 23°C to 93.3°C (73°F to 200°F).

3 Referenced Documents

3.1 *ASTM Standards*[1]

D 1598 — Standard Test Method for Time-to-Failure of Plastic Pipe under Constant Internal Pressure

D 2837 — Standard Test Method for Obtaining Hydrostatic Design Basis for Thermoplastic Pipe Materials

3.2 *PPI Technical Report*[2]

TR-3/92 — Policies and Procedures for Developing Recommended Hydrostatic Design Stresses for Thermoplastic Pipe Materials

4 Terminology

Currently this document contains no terminology.

5 Summary of Referenced Documents

5.1 *ASTM Standards*

5.1.1 *D 1598* — This test method consists of exposing specimens of pipe/tube to a constant internal pressure while in a controlled environment. Such a controlled environment may be accomplished by immersing the specimens in a controlled-temperature water or air bath. The time-to-failure is measured.

5.1.2 *D 2837* — The procedure for estimating long-term hydrostatic strength is essentially an extrapolation, with respect to time, of a stress-time regression line based on data obtained in accordance with ASTM D 1598. Stress-failure time plots are obtained for the selected temperature and environment: the extrapolation is made in such a manner that the long-term hydrostatic strength is estimated for these conditions.

5.2 *PPI Technical Report*

5.2.1 *TR-3/92* — These policies and procedures are for development of recommendations for thermoplastic pipe compounds based on test data from good quality pipes made by specific processing techniques. These recommendations may or may not be valid for pipes made by differing processing techniques.

6 Comments

6.1 The Hydrostatic Stress Committee of the Plastic Pipe Institute (PPI) has recommended a minimum safety factor of 200% based on the hydrostatic design basis. The safety factor is intended to make allowance for manufacturing and testing variables such as normal variations in the material, manufacturing process, dimensions, and in the evaluation procedures (ASTM D 2837 and D 1598).

6.2 Application conditions also need to be taken into consideration and may require an increased safety factor. For example, with liquid hydrocarbons and other chemicals, temperature can have a disproportional effect on the long-term performance of the tubing or pipe. No general safety factor has been established for these types of services, so each case should be designed on its own merit.

NOTE: It is strongly recommended that the user of pipe/tube confirm that the product has been tested per ASTM D 1598, D 2837, and TR-3/92 to ensure a proper pressure rating.

SEMI F19-95
SPECIFICATION FOR THE FINISH OF THE WETTED SURFACES OF ELECTROPOLISHED 316L STAINLESS STEEL COMPONENTS

1 Purpose

The purpose of this specification is to provide a standard for the quality of the internal (wetted) surfaces of electropolished 316L stainless steel components used in the chemical (gas and liquid) distribution systems of semiconductor manufacturing facilities.

2 Scope

2.1 This specification defines the wetted surface characterization requirements and the finish acceptance criteria for electropolished 316L stainless steel components.

2.2 The surface characterization tests to be performed are specified herein, and the existing standards for performing these tests are referenced.

2.3 Terms specific to this technology are either listed herein as they relate to the acceptance criteria of this specification or are defined in the referenced documents as they relate to a specific test process.

3 Referenced Documents

3.1 *SEMI Standards*

A 632 — Specification for Seamless and Welded Austenitic Stainless Steel Tubing (Small Diameter) for General Service

F 1372 — Test Method for SEM Analysis of Metallic Surface Condition for Gas Distribution System Components

4 Terminology

4.1 *Terms Defined in ANSI/ASME B46.1*

4.1.1 *flaws* — Unintentional irregularities which occur at one place or at relatively infrequent or widely varying intervals on the surface. Flaws include such defects as cracks, blowholes, inclusions, checks, ridges, and scratches.

4.1.2 *lay* — The direction of the predominant surface pattern, ordinarily determined by the production method used.

4.1.3 *measured surface* — A representation of the surface obtained by instrument or other means.

1 Draft Documents 2335, 2336, and 2337 will be developed and balloted by the SEMI F&ESH Committee, using materials contributed by SEMATECH. The methods were written and developed by a SEMATECH-sponsored task force, validated by Research Triangle Institute, and subsequently published by SEMATECH as SEMASPEC's. The methods were also proposed, and then withdrawn, by ASTM Committee F1.10.

2 American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017

3 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

4.1.4 *nominal surface* — The intended surface contour, the shape and extent of which is shown and dimensioned on a drawing or descriptive definition.

4.1.5 *roughness* — The finer irregularities of the surface texture, usually including those irregularities which result from the manufacturing process. These are considered to include traverse feed marks and other irregularities within the limits of the roughness sampling length.

4.1.6 *surface texture* — The repetitive or random deviations from the nominal surface which form the three dimensional topography of the surface. Surface texture includes roughness, waviness, lay, and flaws.

4.1.7 *waviness* — The more widely spaced component of surface texture. Unless otherwise noted, waviness is to include all irregularities whose spacing is greater than the roughness sampling length. Waviness may result from such factors as machine or work deflections, vibrations, chatter, heat treatment, or warping strains. Roughness may be considered as superimposed on a "wavy" surface.

4.2 *Additional Terms*

4.2.1 *blistering* — A surface discontinuity whose appearance pattern is like that of orange peel with randomly chipped or flaked off areas.

4.2.2 *dent* — A protrusion on the wetted surface that can be associated with an irregularity on the external surface.

4.2.3 *frostiness* — A continuous surface discontinuity whose appearance pattern is like that of a sparkly, very fine, sandy-textured surface.

4.2.4 *haze* — The appearance of a localized diminishing in brightness or luster of a surface when compared to the adjacent surfaces.

4.2.5 *inclusion* — A piece of foreign material that is embedded in the surface and is visible to the unaided eye.

4.2.6 *orange peel* — A continuous surface discontinuity whose irregular surface appearance pattern is like that of an orange peel.

4.2.7 *pit or stringer (multiple pits)* — A small cavity or series of small cavities visible to the unaided eye.

4.2.8 *scratch* — An elongated mar in the surface, not associated with the predominant surface texture pattern, that is visible to the unaided eye.

5 General Requirements

Electropolished components furnished under this specification shall be in accordance with the surface characterization requirements and the surface finish acceptance criteria defined herein.

6 Material Requirements

Materials used for components to be electropolished, so as to produce the surface characterization requirements contained herein, shall be in accordance with the metallurgical criteria defined in any of the following material specifications:

ASTM A 182, A 240, A 269, A 276, A 479, and A 632

SEMI F2 and SEMI F16

7 Surface Characterization Requirements

7.1 The internal (wetted) surface of all components shall be electropolished in accordance with a qualified process applicable to the material composition and type of component being processed.

7.2 Components used to qualify the electropolishing process shall be maintained by the component supplier.

7.3 Chemical analysis (ESCA) shall have been performed on the electropolished surface of the components used to qualify the process in accordance with a separate document currently under development, so as to certify surface elemental composition and process effectiveness. Elemental composition shall be expressed in atomic percent units, and the analysis shall have verified a minimum chromium-to-iron ratio of 1.5:1 and a chromium oxide enrichment of a minimum chromium oxide-to-iron oxide ratio of 2:1. Certified laboratory analysis reports shall be maintained by the component supplier.

7.4 The chrome oxide layer, as determined by Auger (AES) depth profiling, at 1/2 oxygen peak, shall also have been performed on the electropolished surface of the components used to qualify the process in accordance with SEMI Doc. 2336 so as to certify that the chrome oxide layer is equal to or greater than 2 nanometers (20 Angstroms). Certified laboratory analysis reports shall be maintained by the component supplier.

7.5 Scanning Electron Microscopy (SEM) photographs shall have been taken of the electropolished surface used in accordance with ASTM F 1372 to qualify the process of components made from materials defined in Section 6 above. These photographs shall be maintained by the component supplier.

8 Surface Finish Acceptance/Non-Acceptance Criteria

8.1 Acceptance/non-acceptance for flaws caused by material irregularities, machining processes, or handling shall be in accordance with the following criteria:

8.1.1 Any flaws that have been polished out to the degree that they can be considered waviness as defined above and meet the surface characterization requirements in Section 7 are acceptable.

8.1.2 Process machine marks that fall within the specified surface finish R_a acceptance criteria and meet the surface characterization requirements in Section 7 are acceptable.

8.1.3 Macroscopic pits and inclusions that are within the surface finish R_a acceptance criteria and meet the surface characterization requirements in Section 7 are acceptable.

8.1.4 Scratches caused by machining process or inspection tools that meet the surface finish R_a acceptance criteria and then have been electropolished so as to meet the surface characterization requirements in Section 7 are acceptable. All other scratches of indeterminate source are not acceptable.

8.1.5 Dents are not acceptable.

8.1.6 Any protrusion on the wetted surface that is not associated with an irregularity on the external surface will be judged according to the roughness/waviness acceptance criteria.

8.2 Acceptance/non-acceptance for surface finish effects caused by the electropolishing process shall be in accordance with the following criteria:

8.2.1 Surface contaminants (e.g., water spots, rust, process residue, and chemical staining) are not acceptable.

8.2.2 Electropolished (EP) surfaces shall have no unintentional interruptions in the electropolishing.

8.2.3 Surface finish shall be evaluated using the method specified in SEMI Doc. 2335 for compliance with the R_a surface finishes specified in ANSI B46.1.

8.2.4 The degree to which orange peel is acceptable shall be evaluated using the acceptable/non-acceptable component sample library which was established during the process certification.

8.2.5 Haze is not acceptable.

8.2.6 The degree to which frosting is acceptable shall be evaluated using the acceptable/non-acceptable component sample library which was established during the process certification.

8.2.7 Blistering is not acceptable.

8.3 *Other Acceptance Criteria*

8.3.1 Components electropolished by a process qualified by the customer for the production of components of that model shall be acceptable as long as the process is requalified periodically as agreed by the supplier and customer.

8.3.2 The surface finish of welds, screw slots, bellows and any other irregular-surfaced components will be considered acceptable if they have been electropolished by the process qualified for components of that model.

8.3.3 Frosting, pits, or scratches that occur within 0.020 of the edge of a surface to be welded and which do not exceed 0.010 in depth are acceptable.

9 Quality Assurance Requirements

9.1 The component supplier shall provide the following reports and certifications with all shipments of processed components:

9.1.1 Name/description of component(s)

9.1.2 Quantity of components by size or description,

9.1.3 Certification for each size or category of components that the process was performed in accordance with a qualified process specification which meets the surface chemistry requirements of Section 6 above.

9.1.4 Copies of certified laboratory reports of the surface chemistry analysis performed to qualify the process used (when requested by the customer).

9.1.5 Copies of certified laboratory reports of the surface chemistry analysis performed on specific components or heat lots (when requested by the customer).

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F20-0997
SPECIFICATION FOR 316L STAINLESS STEEL BAR, EXTRUDED SHAPES, PLATE, AND INVESTMENT CASTINGS FOR COMPONENTS USED IN HIGH PURITY SEMICONDUCTOR MANUFACTURING APPLICATIONS

1 Purpose

1.1 The purpose of this specification is to define the restricted melting processes and material composition of 316L stainless steel required for use in the manufacture of components for high-purity chemical (gas or liquid) distribution systems.

2 Scope

2.1 This specification defines the requirements for 316L stainless steel bar, forgings, and extruded shapes as specified in ASTM A 276, plate stock as specified in ASTM A 240, and investment castings as specified in ASTM A 743/A 743M, except as defined herein, for use in the manufacture of components used in high-purity chemical (gas or liquid) distribution systems in semiconductor manufacturing facilities.

3 Referenced Documents

4 Ordering Information

4.1 Orders for bar, forgings, extruded shapes, plate, or investment castings under this specification shall include:

4.1.1 Quantity (kilograms, pounds, meters, inches, or feet)

4.1.2 Cross section description (round, square, hex, etc. or detailed drawing)

4.1.3 Size (nominal diameter or shape dimensions for other than those identified with an extrusion drawing)

4.1.4 Length (specific or random)

4.1.5 This specification number

5 General Requirements

5.1 Bar stock, forgings, extruded shapes, or plate furnished under this specification shall conform to the requirements of ASTM A 182/A 182M, ASTM A 276, ATSM A 479/A 479M, ASTM A 484/A 484M, and the additional requirements herein.

5.2 Plate stock furnished under this specification shall conform to the requirements of ASTM A 240, A 480/A 480M, and the additional requirements herein.

5.3 Investment castings furnished under this specification shall conform to the requirements of ASTM A 743/A 743M except yield/ultimate strengths shall be at least 80% of their respective minimum values.

6 Manufacture

6.1 The steel billet material used for processing shall be manufactured by such primary melting processes as

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

Argon Oxygen Decarburization (AOD), Vacuum Oxygen Decarburization (VOD), or Vacuum Induction Melting (VIM), and such remelt processes as Vacuum Arc Remelt (VAR) or ElectroSlag Remelt (ESR), to conform with the purity requirements specified herein.

6.2 Processed bars shall be furnished annealed and cold-finished, and extruded shapes shall be furnished hot-finished, descaled, and stretch-straightened ("Condition A" in the section on Manufacture in ASTM A 276, except elongation may be a minimum of 20% for "lightly cold worked T316L").

6.3 The annealing temperature used to achieve the grain size requirement of Section 8.1 shall be 982°C (1800°F) minimum.

6.4 The steel billet material used for investment casting shall be manufactured by the Vacuum Induction Melting (VIM) plus Vacuum Arc Remelt (VAR) route per Sections 6.1 and 6.2, and remelted and cast using VIM. Castings shall be furnished in the solution treated and Hot Isostatic Pressed (HIP) condition.

7 Chemical Composition

7.1 *Material Type* — Material shall be type 316L stainless steel, as specified in Table 1 of ASTM A 182/A 182M, ASTM A 240, ASTM A 276, ASTM A 479/A 479M, or ASTM A 743/A 743M except where otherwise specified herein.

7.2 *Composition Tolerance* — No deviations in material composition from the minimum or maximum values specified in the appropriate ASTM document or herein shall be allowed without approval by the purchaser.

7.3 *Sulfur Content* — Sulfur content shall range from 0.001 to 0.004 percent.

7.4 *Product Analysis* — A heat analysis shall be made in accordance with ASTM A 751. The result of the heat analysis shall be reported to the purchaser. In addition to the elements listed in Table 1 of ASTM A 276, the concentrations of the following elements shall be reported and are specified as:

7.4.1 *Aluminum* — 0.02 max

7.4.2 *Calcium* — 0.02 max

7.4.3 *Copper* — 0.25 max

7.4.4 *Niobium* — 0.05 max

7.4.5 *Selenium* — 0.02 max

7.4.6 *Titanium* — 0.02 max

8 Metallurgical Requirements

8.1 *Grain Size* — Grain size per ASTM E 112 shall be predominately 5 or finer for bar stock nominal size of 3 inches in diameter and smaller, and 3 or finer for bar stock greater than 3 inches.

8.2 *Casting Grain Size* — Castings shall have equiaxed grain size appropriate to meeting properties defined in Section 5.3.

8.3 *Nonmetallic Inclusions* — The inclusion content of the material shall be determined from representative samples of the material heat, in accordance with ASTM E 45, Method A, but with ratings based on Plate III. JK ratings at billet stage shall not exceed:

Inclusion Type	*A(Sulfide)*	*B (Alumina)*	*C (Silicate)*	*D (Globular Oxide)*
Thin	1.0	1.0	1.0	1.0
Heavy	1.0	1.0	1.0	1.0

JK ratings shall be provided with the material composition report.

8.4 *Intergranular Corrosion* — Material shall be capable of meeting the intergranular corrosion test specified in Practice E of ASTM A 262. This requirement shall apply in the sensitized condition (1 hour at 677°C [1250°F]).

9 Mechanical Properties

9.1 Mechanical properties of all sizes and shapes shall conform to the section on Mechanical Properties of the appropriate ASTM specification and to Section 6.2 or 5.3.

10 Certification

10.1 A certified copy of the results of all tests required by this specification shall be provided at the time of shipment. The test report shall also include the material melting process, the heat number, and the purchase order, and shall be positively relatable to the lot of material represented.

11 Product Marking

11.1 Bar and extruded shapes shall be permanently marked with the following information:

11.1.1 Manufacturer's name

11.1.2 Purchaser's name and order number

11.1.3 ASTM specification number(s)

11.1.4 This specification number

11.1.5 Heat number

11.1.6 Material type (i.e., 316L)

11.2 Where including all of these is impractical due to size, the heat number and customer purchase order number shall be included as a minimum.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringment of such rights, are entirely their own responsibility.

SEMI

SEMI F21-95
CLASSIFICATION OF AIRBORNE MOLECULAR CONTAMINANT LEVELS IN CLEAN ENVIRONMENTS

1 Purpose

The purpose of this standard is to classify microelectronics clean environments with respect to their molecular (non-particulate) contaminant levels. This standard classification provides a consistent means of communicating acceptable contaminant levels of groups of specific airborne molecular contaminants. See Related Information 1 appended to this standard.

2 Scope

This standard classification is to be used in the specification of semiconductor clean environments (including process tool environments) and of contamination control and measurement equipment performance.

3 Referenced Documents

None.

4 Terminology

4.1 *acid* — A corrosive material whose chemical reaction characteristic is that of an electron acceptor.

4.2 *base* — A corrosive material whose chemical reaction characteristic is that of an electron donor.

4.3 *condensable* — A substance (other than water), typically having a boiling point above room temperature at atmospheric pressure, capable of condensation on a clean surface.

4.4 *dopant* — A chemical element which modifies the electrical properties of a semiconductive material.

5 Basis of Classification

Classification is by the maximum allowable total gas phase concentration of each category of material. This classification system is depicted in Section 6. The combination of a quantitative class for each of the four categories yields a classification describing an environment.

5.1 The maximum cumulative gas phase concentrations of the four categories may be different.

5.2 Each category is designated by the letter "M," followed by the first letter of the category name A, B, C, or D.

5.3 The integer following the category designator shall indicate the maximum total gas phase concentration in parts per trillion molar (pptm 1×10^{-12}). For example, a category M?-10 has a maximum allowable total concentration of 10 parts per trillion molar for the category of interest.

6 Classification

Material Category	*1**	*10**	*100**	*1000**	*10,000**
Acids	MA-1	MA-10	MA-100	MA-1000	MA-10,000
Bases	MB-1	MB-10	MB-100	MB-1000	MB-10,000
Condensables	MC-1	MC-10	MC-100	MC-1000	MC-10,000
Dopants	MD-1	MD-10	MD-100	MD-1000	MD-10,000

*Concentration, in parts per trillion

7 Reference Test Methods

Analytical methods capable of measuring the classified levels at the agreed level of confidence shall be used.

RELATED INFORMATION 1 SPECIFIC CONTAMINANTS TO MEASURE FOR VERIFICATION OF ENVIRONMENTAL COMPLIANCE

NOTE: This related information is not an official part of SEMI F21 and is not intended to modify or supercede the official standard. It has been derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

Although it is difficult to compile an inclusive list, the originating task force recommends that the user test the air for each of the contaminants listed.

R1-1 Acids

- Hydrofluoric
- Sulfuric
- Hydrochloric
- Nitric
- Phosphoric
- Hydrobromic

R1-2 Bases

- Ammonia (ammonium hydroxide)
- Tetramethylammonium hydroxide
- Trimethylamine
- Triethylamine
- Trimethyldisilazane
- NMP
- Cyclohexylamine
- Diethylaminoethanol
- Methylamine
- Dimethylamine
- Ethanolamine
- Morpholine

R1-3 Condensables

- Silicone (boiling point ≥ 150°C)
- Hydrocarbon (boiling point ≥ 150°C)

R1-4 Dopants

- Boron (usually as boric acid)
- Phosphorous (usually as organophosphates)
- Arsenic (usually as arsenates)

RELATED INFORMATION 2
EXAMPLE OF AN ANALYSIS REPORT

Note: This related information is not an official part of SEMI F21 and is not intended to modify or supercede the official standard. It has been derived from the work of the originating task force. Publication was authorized by full ballot procedures. Determination of the suitability of the material is solely the responsibility of the user.

Analysis for compliance with SEMI Standard Classification MA-10:

Site :	FAB 3	
Test date and duration :	18 August 1994, 0800 -1700, 9 hours	
Contaminants measured :	Hydrofluoric acid	1 pptm
	Sulfuric acid	1 pptm
	Hydrochloric acid	2 pptm
	Nitric acid	1 pptm
	Phosphoric acid	2 pptm
	Hydrobromic acid	1 pptm
	Total	8 pptm
Detection Limits :	1 pptm for each analyte	
Confidence Level :	95%	
Assumptions made :	All acids determined as anions after water scrubbing; anions can be from other sources but are assumed to be in the acid form for reporting purposes.	
Conclusion :	This environment meets the MA -10 criterion in SEMI F21.	

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F22-0697
GUIDE FOR GAS DISTRIBUTION SYSTEMS

1 Purpose

This reference document is intended to outline for the user the common systems configurations, components, and subcomponents of high purity gas distribution systems in a semiconductor fabrication facility. Related specifications are also noted.

2 Scope

2.1 Outlined in this document are both bulk and specialty gas distribution systems.

2.2 Components and subcomponents are identified from the point-of-supply to the point-of-connection to the process tool.

3 Limitations

3.1 The gas distribution system configurations noted in this reference document are provided solely as a guide to indicate common industry practice. They are not presented as, or intended to be, a representation of best engineering practice.

3.2 The reference documents noted are provided for general guidance only and are not intended to portray a code compliance protocol. The users should always consult local authorities to determine specific applicable codes and regulations. Agencies, regulatory or otherwise, noted herein are representative only of the U.S.

3.3 Specifications, SEMI Standards or other, are noted to assist the user as a reference only.

4 Referenced Documents

None.

5 Terminology

5.1 *Acronyms*

5.1.1 *AOV* — Air-operated valves

5.1.2 *ASO* — Automatic shutoff valve

5.1.3 *POC* — Point of connection

5.1.4 *POU* — Point of use

5.1.5 *VMB* — Valve manifold box

5.2 *Terminology*

5.2.1 *air-operated valves (AOV)* — Are those which require pneumatic energy to initiate or terminate flow or to change flow path (e.g., normally closed, partially open, double acting).

5.2.2 *automatic shutoff valve (ASO)* — A mechanically, electrically, or pneumatically activated valve which has the sole purpose of terminating flow if a predetermined condition is exceeded. For cryogenic supply systems, ASO's are used in conjunction with a low temperature sensing device.

5.2.3 *check valve* — A mechanical gas system component which prevents reverse flow.

5.2.4 *effluent treatment system* — A device which, through mechanical, chemical, cryogenic, absorbent, or other means, abates hazardous gas effluent to "environmentally safe levels" through dilution, neutralization, entrapment, or distillation.

5.2.5 *excess flow device* — A mechanical or electrical component which senses and signals an AOV or itself to terminate flow in the event predetermined flow is exceeded.

5.2.6 *face seal fitting* — A high purity fitting which incorporates two machined faces and a metallic gasket within a male/female nut configuration to attain a high leak integrity seal.

5.2.7 *filter* — A porous device, generally constructed of polymer, metal, or ceramics and housed in a metal chamber, which traps particles, preventing them from being transported downstream.

5.2.8 *flow restrictor* — A component, generally an orifice, which prohibits gas flow beyond a predetermined flow.

5.2.9 *gas box* — A gas distribution subsystem which generally contains the final shut-off valve(s) prior to the POC. It may also contain filter(s) and a regulator.

5.2.10 *hazardous gas detectors* — Analytical instruments which placed in strategic locations in and around gas distribution systems and components are used to detect potentially unnoticeable releases at extremely low levels.

5.2.11 *low temperature sensing device* — A component which protects the system downstream of the vaporizer from cryogenic temperatures by initiating an alarm or triggering a valve shut-down.

5.2.12 *nitrogen generation plant* — A system which, generally through cryogenic distillation, separates and purifies nitrogen from ambient air. Other air separation techniques may be used but are not considered in this document.

5.2.13 *point of connection (POC)* — Is often used interchangeably with POU, indicating the final connection between the system and the process tool.

5.2.14 *point of use (POU)* — Is often used interchangeably with POC, indicating the final connection between the system and the process tool.

5.2.15 *pressure relief valve* — A device which, at a given design pressure set point, releases gas pressure to prevent system over-pressurization.

5.2.16 *pressure transducer* — A component which mechanically or electrically senses the pressure within a gas system and transmits a signal to a readout or a control device.

5.2.17 *process gas panel* — A subsystem, generally contained within a gas cabinet, that delivers process gas from the cylinder to the specialty gas distribution system.

5.2.18 *purifier* — Generally a catalytic, resinous, or diatomaceous material within a pressure vessel which removes particulate and/or trace gas impurities from a gas stream.

5.2.19 *regulator* — Generally a mechanical device which alters the pressure within a gas system.

5.2.20 *segregation* — A practice in design and operation to prevent non-compatible gases from co-mingling.

5.2.21 *tube trailer* — A bulk gas supply system which manifolds high pressure, DOT-specified, vessels (cylindrical tubes) on a portable trailer.

5.2.22 *vacuum generator* — A component in a process gas panel which, via a suction created by an inert gas venturi, allows for evacuation of the gas system to levels of 16.7 kPa (25" mercury) or less.

5.2.23 *valve manifold box (VMB)* — A gas distribution subsystem designed to allow the distribution of a single process cylinder gas to multiple process tools. Its manifold design uses a series of valves (manual or AOV), regulators, filters, and vacuum generator(s), and may be controlled manually or automatically.

5.2.24 *vaporizer* — A component which, through heat transfer, is designed to convert a cryogenic liquid to a gas.

SEMI F23-0697
PARTICLE SPECIFICATION FOR GRADE 10/0.2 FLAMMABLE SPECIALTY GASES

1 Purpose

The purpose of this document is to set a maximum permissible particle concentration for 10/0.2 grade flammable specialty gases and to describe a reference method for its verification.

2 Scope

This document applies only to flammable gases delivered through specialty gas systems at pressures up to 8×10^5 Pa (8 atmospheres). This method is not suitable for direct sampling from high pressure cylinders at pressures above 8×10^5 Pa (8 atmospheres). This document applies only to the following gas:

Hydrogen (H_2)

3 Referenced Documents

3.1 *SEMI Document*

SEMI C6.3 — Particle Specification for Grade 20/0.2 Hydrogen (H_2) Delivered as Pipeline Gas

3.2 *Other Document*

JIS B 9921 — Japanese Industrial Standard (1989), "Light Scattering Automatic Particle Counter"

4 Terminology

4.1 *Variables*

V_{Mi}=	Volume of the i^th^ sample interval of the system gas
V_{Bi}=	Volume of the i^th^ sample interval of the background
X_{Mi}=	Concentration of particles observed in the i^th^ sample of interval of the system gas
X_{Bi}=	Concentration of particles observed in the i^th^ sample of interval of the background
N_M=	Number of sample intervals of the system gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the system gas sample
$\overline{X}_B$ =	Average observed concentration of background counts
$\overline{X}_C$ =	Calculated concentration of particles in the system gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
S_C=	Standard deviation of $\overline{X}_C$

4.2 *gas sample volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1×10^5 Pa (1 atmosphere) pressure. Standard cubic feet (SCF) is defined at 21.1°C (70°F) and 1×10^5 Pa (1 atmosphere) pressure.

4.3 *average observed concentration of counts* ($\overline{X}_M$, $\overline{X}_B$) — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{\Sigma X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{\Sigma X_{Bi}}{N_B}$$

4.4 *calculated concentration of particles* ($\overline{X}_C$) — The concentration of particles in the system gas obtained by correcting the observed concentration in the system gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

4.5 *standard deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \sqrt{\frac{(X_{Mi} - \overline{X}_M)^2}{(N_M - 1)}}$$

$$S_B = \sqrt{\frac{(X_{Bi} - \overline{X}_B)^2}{(N_B - 1)}}$$

NOTE: The third is obtained from the first two, i.e.:

$$S_C = \sqrt{S_M{}^2 + S_B{}^2}$$

5 Requirements

5.1 *Maximum Permissible Particle Concentration* — 10 particles per 25 standard liters as determined by the instrument specified in Section 6.

5.2 The specification will be considered met if the calculated concentration of particles plus 2 times the standard deviation does not exceed 10 particles per 25 standard liters, i.e.:

$\overline{X}_C + 2 \times S_C \leq 10$ particles/25 standard liters

6 Apparatus

Particle Counter — An instrument suitable for counting particles in compressed flammable gases at a pressure of up to 8×10^5 Pa (8 atmospheres) with a 50% counting efficiency should reach 90% at 0.3 micrometer or smaller. The resolving power of the instrument near 0.2 micrometer should be no worse than 10%. The counting efficiency is determined by a calibration at 1×10^5 Pa (1 atmosphere) pressure using p olystyrene latex spheres in an inert gas and a reference particle counter with a proven counting efficiency of not less than 95% at 0.2 micrometer.

NOTE: Suitable test methods for determining counting efficiency and resolving power are contained in Japanese Industrial Standard JIS B 9921 (1989), "Light Scattering Automatic Particle Counter". More sensitive particle counters result in a higher measured particle concentration.

7 Test Method

NOTE: The details of the sampling configuration, measurement procedure, and instrument calibration procedure and frequency, must be agreed upon by the user and supplier, taking into account good engineering practice. Material safety data sheets should be referred to for safe handling of specialty gases.

7.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing nitrogen, believed to be free of particles 0.2 micrometer or more in diameter, through the instrument and recording the total number of counts. The nitrogen purge assembly for performing this test, using a filter which removes particles in this size range, is shown in Figure 1. Count a minimum of 3 equal intervals, each of at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Calculate $\overline{X}_B$ as defined in Section 4. $\overline{X}_B$ must not exceed 2 counts per 25 standard liters.

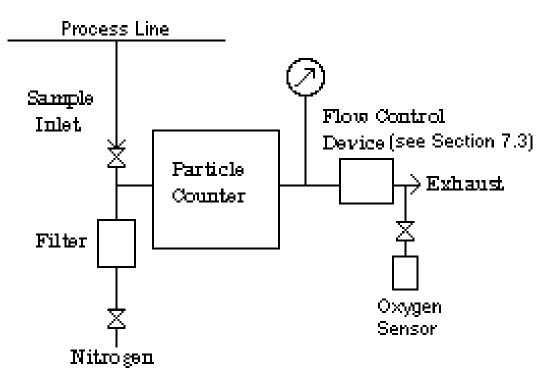

Figure 1
Schematic Diagram of Configuration for Obtaining Particle Samples from Flammable Specialty Gas Systems

7.2 The sampling point should be near the point of use, and sampling lines should be clean and as short as possible.

7.3 The sampling system configuration is shown in Figure 1. The specialty gas system should be connected through a sample valve directly to the particle counter, a pressure gauge, and a flow control device (FCD). When sampling is performed using wall tap sample ports, the aspiration efficiency should be checked using the method described in Related Information 1. The sampling system should contain minimum dead volume and sample tube length. All components in the sampling system should be leak tight and cleaned in accordance with good engineering practice. A leak check of the system should be performed in accordance with normally accepted practice. The FCD may be part of the particle counter. The particle counter should be maintained at the pressure of the gas system. The FCD can be a metering valve and a flow meter or a critical orifice. The exhaust line should be leak tight and piped to an appropriate exhaust system. The exhaust line diameter should be large enough to produce no more than 1×10^4 Pa (1.5 psi) pressure drop during purge and sample flow.

NOTE: The alternative sampling configurations described in SEMI C6.3 can also be used for hydrogen.

7.4 Using the high purity nitrogen system shown in Figure 1, purge the sampling system and particle counter for at least 5 minutes at the instrument manufacturer's specified flow rate. The exact purge time should take into account the reactivity of the gas and should be sufficient to purge the entire exhaust line. An oxygen sensor should be placed at the system exhaust to verify less than 1 ppmv oxygen in the purge nitrogen. The purging must be performed before flammable gas is introduced into the sampling system and after completion of the measurement. The valve leading to the oxygen sensor should be closed when flammable gas is being sampled. The valve leading from the purge nitrogen system should be closed when sampling specialty gases and/or a back flow prevention device should be included in the purge nitrogen system.

NOTE: It is known that flammable gases can react with oxygen present in the sampling system. Nitrogen purging of the sampling system reduces the risk of reaction. The purity of the purge nitrogen should be sufficient to remove reactive substances from the sampling system.

7.5 Count the particles in each of at least 3 equal intervals. Each sample interval must be at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Data obtained during the first 5 minutes after the sample valve is opened may be discarded. Record the number of counts in the sample volume for each interval. Calculate $\overline{X}_C$ and S_C, as defined in Section 4.

NOTE: For small volume specialty gas systems, the user and supplier may agree to a smaller sample gas volume than that stated above. The sample point location and the process line pressure and flow rate during the test should be recorded.

8 Report

The report shall contain the values of all the variables defined in Section 4.

RELATED INFORMATION 1 NOTES ON ASPIRATION EFFICIENCIES OF WALL TAP SAMPLE PORTS

NOTE: This related information is not an official part of SEMI F23 and is not intended to modify or supercede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Introduction

Isokinetic sample probes are usually not provided in speciality gas systems. Particle sampling is usually performed using wall tap sample ports. Wall tap sample ports are oriented 90° to the process line flow as shown in Figure R1-1. Non-isokinetic flow into the sample tube results from the 90° change in flow direction. Additional deviation from isokinesis can result from stream tube contraction or expansion when the velocities U and v are not equal. The effects of non-isokinetic flow on the measurement should be checked. The particle sampling process should be performed with an aspiration efficiency close to 1.

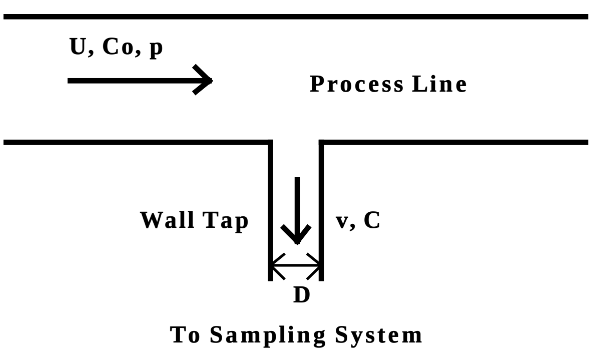

Figure R1-1
Schematic Diagram of Process Line and Wall Tap Sample Port

R1-2 Variables

d_p=	Diameter of particle (cm)
ρ_p=	Intrinsic density of particle (g/cm^3)
η=	Dynamic viscosity of the gas (g/s-cm)
λo=	Mean free path of the gas at atmospheric pressure (cm)
p=	Pressure of the gas (Pa)
P_O=	Atmospheric pressure (= 1×10^5 Pa)
D=	Diameter of wall tap sample tube (cm)
U=	Average velocity of the process line flow (cm/s)
v=	Average velocity of the sample line flow (cm/s)
C*=	Stokes-Cunningham slip correction factor
S_{tk}=	Stokes number
R=	Velocity ratio
Co=	Particle concentration in the process line (cm^{-3})
C=	Particle concentration in the sample line (cm^{-3})

R1-3 Calculations

The Stokes-Cunningham slip correction factor is calculated for particles in the size range of interest:

$$C^* = 1 + 2.492\frac{p_o \lambda o}{p d_p} + 0.84\frac{p_o \lambda o}{p d_p}\ e^{-0.435 p d_p / p_o \lambda 0}$$

Calculate the velocity ratio and Stokes number. The intrinsic particle density may assume a worst case value of 10 g/cm^3:

$$R = U/v$$

$$S_{tk} = \frac{d_p^2\, \rho_p \mathrm{UC}^*}{18\eta \mathrm{D}}$$

A wall tap sample port can be approximated as a sampling probe oriented 90° to the flow. Calculate the aspiration efficiency:

$$\frac{C}{Co} = \frac{1}{1 + 8 S_{tk}\ R^{1/2}}$$

Repeat the calculations for particle sizes in the range of interest. When the aspiration efficiency is significantly different from 1, the calculated efficiency should be used to correct the measured particle concentration, C.

SEMI F24-0697
PARTICLE SPECIFICATION FOR GRADE 10/0.2 INERT SPECIALTY GASES

1 Purpose

The purpose of this document is to set a maximum permissible particle concentration for 10/0.2 grade inert specialty gases and to describe a reference method for its verification.

2 Scope

This document applies only to inert gases delivered through specialty gas systems at pressures up to 8×10^5 Pa (8 atmospheres). This method is not suitable for direct sampling from high pressure cylinders at pressures above 8×10^5 Pa (8 atmospheres). This document applies only to the following gas:

Argon (Ar)
Halocarbon 23 (CHF_3)
Halocarbon 116 (C_2F_6)
Helium (He)
Nitrogen (N_2)
Sulfur Hexafluoride (SF_6)
Tetrafluoromethane (CF_4)

3 Referenced Documents

4 Terminology

4.1 *Variables*

V_{Mi}=	Volume of the i^{th} sample interval of the system gas
V_{Bi}=	Volume of the i^{th} sample interval of the background
X_{Mi}=	Concentration of particles observed in the i^{th} sample of interval of the system gas
X_{Bi}=	Concentration of particles observed in the i^{th} sample of interval of the background
N_M=	Number of sample intervals of the system gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the system gas sample
$\overline{X}_B$ =	Average observed concentration of background counts
$\overline{X}_C$ =	Calculated concentration of particles in the system gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
S_C=	Standard deviation of $\overline{X}_C$

4.2 *gas sample volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1×10^5 Pa (1 atmosphere) pressure. Standard cubic feet (SCF) is defined at 21.1°C (70°F) and 1×10^5 Pa (1 atmosphere) pressure.

4.3 *average observed concentration of counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{\Sigma X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{\Sigma X_{Bi}}{N_B}$$

4.4 *calculated concentration of particles ($\overline{X}_c$)* — The concentration of particles in the system gas obtained by correcting the observed concentration in the system gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

4.5 *standard deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \sqrt{\frac{(X_{Mi} - \overline{X}_M)^2}{(N_M - 1)}}$$

$$S_B = \sqrt{\frac{(X_{Bi} - \overline{X}_B)^2}{(N_B - 1)}}$$

NOTE: The third is obtained from the first two, i.e.:

$$S_C = \sqrt{S_M{}^2 + S_B{}^2}$$

5 Requirements

5.1 *Maximum Permissible Particle Concentration* — 10 particles per 25 standard liters as determined by the instrument specified in Section 6.

5.2 The specification will be considered met if the calculated concentration of particles plus 2 times the standard deviation does not exceed 10 particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2 \times S_C \leq 10 \text{ particles/25 standard liters}$$

6 Apparatus

Particle Counter — An instrument suitable for counting particles in compressed inert gases at a pressure of up to 8×10^5 Pa (8 atmospheres) with a 50% counting efficiency at 0.2 micrometer or smaller. The counting efficiency should reach 90% at 0.3 micrometer or smaller. The resolving power of the instrument near 0.2 micrometer should be no worse than 10%. The counting efficiency is determined by a calibration at 1×10^5 Pa (1 atmosphere) pressure using polystyrene latex spheres in an inert gas and a reference particle counter with a proven counting efficiency of not less than 95% at 0.2 micrometer.

NOTE: Suitable test methods for determining counting efficiency and resolving power are contained in Japanese Industrial Standard JIS B 9921 (1989), "Light Scattering Automatic Particle Counter". More sensitive particle counters result in a higher measured particle concentration.

7 Test Method

NOTE: The details of the sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice. Material safety data sheets should be referred to for safe handling of specialty gases.

7.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing nitrogen, believed to be free of particles 0.2 micrometer or more in diameter, through the instrument and recording the total number of counts. The nitrogen purge assembly for performing this test, using a filter which removes particles in this size range, is shown in Figure 1. Count a minimum of 3 equal intervals, each of at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Calculate $\overline{X}_B$ as defined in Section 4. $\overline{X}_B$ must not exceed 2 counts per 25 standard liters.

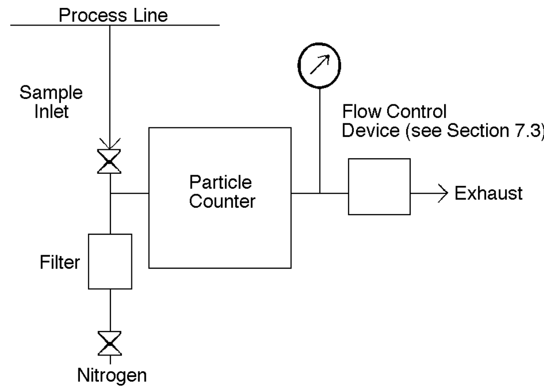

Figure 1
Schematic Diagram of Configuration for Obtaining Particle Samples from Inert Specialty Gas Systems

7.2 The sampling point should be near the point of use, and sampling lines should be clean and as short as possible.

7.3 The sampling system configuration is shown in Figure 1. The specialty gas system should be connected through a sample valve directly to the particle counter, a pressure gauge, and a flow control device (FCD). When sampling is performed using wall tap sample ports, the aspiration efficiency should be checked using the method described in Related Information 1. The sampling system should contain minimum dead volume and sample tube length. All components in the sampling system should be leak tight and cleaned in accordance with good engineering practice. A leak check of the system should be performed in accordance with normally accepted practice. The FCD may be part of the particle counter. The particle counter should be maintained at the pressure of the gas system. The FCD can be a metering valve and a flow meter or a critical orifice. The exhaust line should be leak tight and piped to an appropriate exhaust system. The exhaust line diameter should be large enough to produce no more than 1×10^4 Pa (1.5 psi) pressure drop during purge and sample flow.

NOTE: The alternative sampling configurations described in SEMI C6.5 can also be used for nitrogen or argon.

7.4 Using the high purity nitrogen system shown in Figure 1, purge the sampling system and particle counter for at least 5 minutes at the instrument manufacturer's specified flow rate. The exact purge time should be sufficient to purge the entire exhaust line. The purging must be performed before sample gas is introduced into the sampling system and after completion of the measurement. The valve leading from the purge nitrogen system should be closed when sampling specialty gases and/or a back flow prevention device should be included in the purge nitrogen system.

7.5 Count the particles in each of at least 3 equal intervals. Each sample interval must be at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Data obtained during the first 5 minutes after the sample valve is opened may be discarded. Record the number of counts in the sample volume for each interval. Calculate $\overline{X}_C$ and S_C, as defined in Section 4.

NOTE: For small volume specialty gas systems, the user and supplier may agree to a smaller sample gas volume than that stated above. The sample point location and the process line pressure and flow rate during the test should be recorded.

8 Report

The report shall contain the values of all the variables defined in Section 4.

9 Related Documents

RELATED INFORMATION 1 NOTES ON ASPIRATION EFFICIENCIES OF WALL TAP SAMPLE PORTS

NOTE: This related information is not an official part of SEMI F24 and is not intended to modify or supercede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Introduction

Isokinetic sample probes are usually not provided in speciality gas systems. Particle sampling is usually performed using wall tap sample ports. Wall tap sample ports are oriented 90° to the process line flow as shown in Figure R1-1. Non-isokinetic flow into the sample tube results from the 90° change in flow direction. Additional deviation from isokinesis can result from stream tube contraction or expansion when the velocities U and v are not equal. The effects of non-isokinetic flow on the measurement should be checked. The particle sampling process should be performed with an aspiration efficiency close to 1.

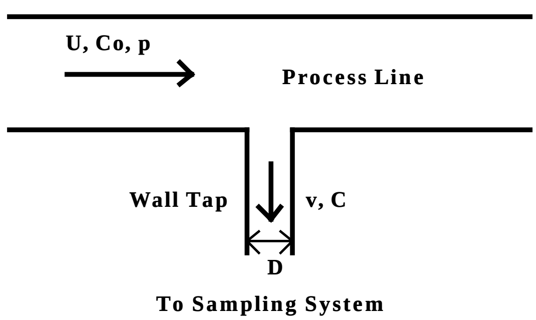

Figure R1-1
Schematic Diagram of Process Line and Wall Tap Sample Port

R1-2 Variables

d_p=	Diameter of particle (cm)
ρ_p=	Intrinsic density of particle (g/cm^3)
η=	Dynamic viscosity of the gas (g/s-cm)
λo=	Mean free path of the gas at atmospheric pressure (cm)
p=	Pressure of the gas (Pa)
P_O=	Atmospheric pressure (= 1×10^5 Pa)
D=	Diameter of wall tap sample tube (cm)
U=	Average velocity of the process line flow (cm/s)
v=	Average velocity of the sample line flow (cm/s)
C*=	Stokes-Cunningham slip correction factor
S_{tk}=	Stokes number
R=	Velocity ratio
Co=	Particle concentration in the process line (cm^{-3})
C=	Particle concentration in the sample line (cm^{-3})

R1-3 Calculations

The Stokes-Cunningham slip correction factor is calculated for particles in the size range of interest:

$$C^* = 1 + 2.492 \frac{p_o \lambda o}{p d_p} + 0.84 \frac{p_o \lambda o}{p d_p} \, e^{-0.435 p d_p / p_o \lambda}$$

Calculate the velocity ratio and Stokes number. The intrinsic particle density may assume a worst case value of 10 g/cm^3:

$$R = U/v$$

$$S_{tk} = \frac{d_p^2 \rho_p U C^*}{18 \eta D}$$

A wall tap sample port can be approximated as a sampling probe oriented 90° to the flow. Calculate the aspiration efficiency:

$$\frac{C}{Co} = \frac{1}{1 + 8 S_{tk} R^{1/2}}$$

Repeat the calculations for particle sizes in the range of interest. When the aspiration efficiency is significantly different from 1, the calculated efficiency should be used to correct the measured particle concentration, C.

4.2 *gas sample volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1×10^5 Pa (1 atmosphere) pressure. Standard cubic feet (SCF) is defined at 21.1°C (70°F) and 1×10^5 Pa (1 atmosphere) pressure.

4.3 *average observed concentration of counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{\Sigma X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{\Sigma X_{Bi}}{N_B}$$

4.4 *calculated concentration of particles ($\overline{X}_C$)* — The concentration of particles in the system gas obtained by correcting the observed concentration in the system gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

4.5 *standard deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \sqrt{\frac{(X_{Mi} - \overline{X}_M)^2}{(N_M - 1)}}$$

$$S_B = \sqrt{\frac{(X_{Bi} - \overline{X}_B)^2}{(N_B - 1)}}$$

NOTE: The third is obtained from the first two, i.e.:

$$S_C = \sqrt{S_M{}^2 + S_B{}^2}$$

5 Requirements

5.1 *Maximum Permissible Particle Concentration* — 10 particles per 25 standard liters as determined by the instrument specified in Section 6.

5.2 The specification will be considered met if the calculated concentration of particles plus 2 times the standard deviation does not exceed 10 particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2 \times S_C \leq 10 \text{ particles/25 standard liters}$$

6 Apparatus

Particle Counter — An instrument suitable for counting particles in compressed oxidant gases at a pressure of up to 8×10^5 Pa (8 atmospheres) with a 50% counting efficiency at 0.2 micrometer or smaller. The counting efficiency should reach 90% at 0.3 micrometer or smaller. The resolving power of the instrument near 0.2 micrometer should be no worse than 10%. The counting efficiency is determined by a calibration at 1×10^5 Pa (1 atmosphere) pressure using polystyrene latex spheres in an inert gas and a reference particle counter with a proven counting efficiency of not less than 95% at 0.2 micrometer.

NOTE: Suitable test methods for determining counting efficiency and resolving power are contained in Japanese Industrial Standard JIS B 9921 (1989), "Light Scattering Automatic Particle Counter". More sensitive particle counters result in a higher measured particle concentration.

7 Test Method

NOTE: The details of the sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice. Material safety data sheets should be referred to for safe handling of specialty gases.

7.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing nitrogen, believed to be free of particles 0.2 micrometer or more in diameter, through the instrument and recording the total number of counts. The nitrogen purge assembly for performing this test, using a filter which removes particles in this size range, is shown in Figure 1. Count a minimum of 3 equal intervals, each of at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Calculate $\overline{X}_B$ as defined in Section 4. $\overline{X}_B$ must not exceed 2 counts per 25 standard liters.

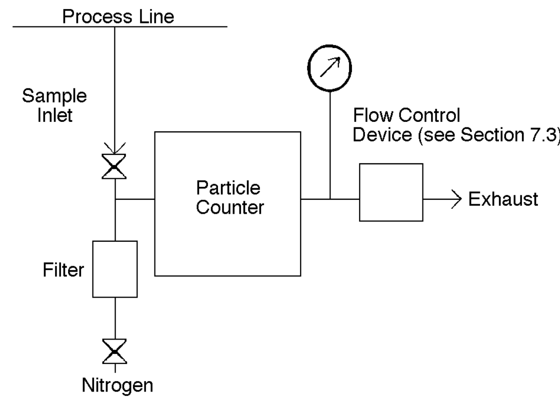

Figure 1
Schematic Diagram of Configuration for Obtaining Particle Samples from Oxidant Specialty Gas Systems

7.2 The sampling point should be near the point of use, and sampling lines should be clean, free of combustible substances, and as short as possible.

7.3 The sampling system configuration is shown in Figure 1. The specialty gas system should be connected through a sample valve directly to the particle counter, a pressure gauge, and a flow control device (FCD). When sampling is performed using wall tap sample ports, the aspiration efficiency should be checked using the method described in Related Information 1. The sampling system should contain minimum dead volume and sample tube length. All components in the sampling system should be leak tight and cleaned in accordance with good engineering practice. A leak check of the system should be performed in accordance with normally accepted practice. The FCD may be part of the particle counter. The particle counter should be maintained at the pressure of the gas system. The FCD can be a metering valve and a flow meter or a critical orifice. The exhaust line should be leak tight and piped to an appropriate exhaust system. The exhaust line diameter should be large enough to produce no more than 1×10^4 Pa (1.5 psi) pressure drop during purge and sample flow.

NOTE: The alternative sampling configurations described in SEMI C6.2 can also be used for oxygen.

7.4 Using the high purity nitrogen system shown in Figure 1, purge the sampling system and particle counter for at least 5 minutes at the instrument manufacturer's specified flow rate. The exact purge time should take into account the reactivity of the gas and should be sufficient to purge the entire exhaust line. The purging must be performed before oxidant gas is introduced into the sampling system and after completion of the measurement. The valve leading from the purge nitrogen system should be closed when sampling specialty gases and/or a back flow prevention device should be included in the purge nitrogen system.

NOTE: It is known that oxidant gases, although non-flammable, may support combustion. Cleaning in accordance with good engineering practice and nitrogen purging of the sampling system reduce the risk of reaction. The purity of the purge nitrogen should be sufficient to remove reactive substances from the sampling system.

7.5 Count the particles in each of at least 3 equal intervals. Each sample interval must be at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Data obtained during the first 5 minutes after the sample valve is opened may be discarded. Record the number of counts in the sample volume for each interval. Calculate $\overline{X}_C$ and S_C, as defined in Section 4.

NOTE: For small volume specialty gas systems, the user and supplier may agree to a smaller sample gas volume than that stated above. The sample point location and the process line pressure and flow rate during the test should be recorded.

8 Report

The report shall contain the values of all the variables defined in Section 4.

RELATED INFORMATION 1
NOTES ON ASPIRATION EFFICIENCIES OF WALL TAP SAMPLE PORTS

NOTE: This related information is not an official part of SEMI F25 and is not intended to modify or supercede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Introduction

Isokinetic sample probes are usually not provided in speciality gas systems. Particle sampling is usually performed using wall tap sample ports. Wall tap sample ports are oriented 90° to the process line flow as shown in Figure R1-1. Non-isokinetic flow into the sample tube results from the 90° change in flow direction. Additional deviation from isokinesis can result from stream tube contraction or expansion when the velocities U and v are not equal. The effects of non-isokinetic flow on the measurement should be checked. The particle sampling process should be performed with an aspiration efficiency close to 1.

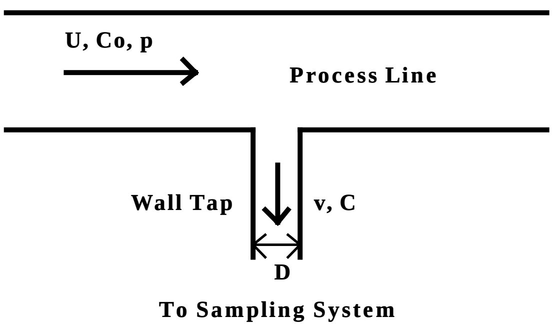

Figure R1-1
Schematic Diagram of Process Line and Wall Tap Sample Port

R1-2 Variables

d_p=	Diameter of particle (cm)
ρ_p=	Intrinsic density of particle (g/cm^3)
η=	Dynamic viscosity of the gas (g/s-cm)
λo=	Mean free path of the gas at atmospheric pressure (cm)
p=	Pressure of the gas (Pa)
P_O=	Atmospheric pressure (= 1×10^5 Pa)
D=	Diameter of wall tap sample tube (cm)
U=	Average velocity of the process line flow (cm/s)
v=	Average velocity of the sample line flow (cm/s)
C*=	Stokes-Cunningham slip correction factor
S_{tk}=	Stokes number
R=	Velocity ratio
Co=	Particle concentration in the process line (cm^{-3})
C=	Particle concentration in the sample line (cm^{-3})

R1-3 Calculations

The Stokes-Cunningham slip correction factor is calculated for particles in the size range of interest:

$$C^* = 1 + 2.492\frac{p_o \lambda o}{pd_p} + 0.84\frac{p_o \lambda o}{pd_p}\ e^{-0.435 pd_p \ / \ p_o \lambda o}$$

Calculate the velocity ratio and Stokes number. The intrinsic particle density may assume a worst case value of 10 g/cm^3:

$$R = U/v$$

$$S_{tk} = \frac{d_p^2\ \rho_p UC^*}{18\eta D}$$

A wall tap sample port can be approximated as a sampling probe oriented 90° to the flow. Calculate the aspiration efficiency:

$$\frac{C}{Co} = \frac{1}{1 + 8 S_{tk}\ R^{1/2}}$$

Repeat the calculations for particle sizes in the range of interest. When the aspiration efficiency is significantly different from 1, the calculated efficiency should be used to correct the measured particle concentration, C.

PARTICLE SPECIFICATION FOR GRADE 10/0.2 TOXIC SPECIALTY GASES

1 Purpose

The purpose of this document is to set a maximum permissible particle concentration for 10/0.2 grade toxic specialty gases and to describe a reference method for its verification.

2 Scope

This document applies only to toxic gases delivered through specialty gas systems at pressures up to 8×10^5 Pa (8 atmospheres). This method is not suitable for direct sampling from high pressure cylinders at pressures above 8×10^5 Pa (8 atmospheres). This document applies only to the following gas:

Ammonia (NH_3)
Arsine (AsH_3)
Phosphine (PH_3)

3 Referenced Documents

3.1 *Japanese Industrial Standard*

JIS B 9921 — Japanese Industrial Standard (1989), "Light Scattering Automatic Particle Counter"

4 Terminology

4.1 *Variables*

V_{Mi}=	Volume of the i^th^ sample interval of the system gas
V_{Bi}=	Volume of the i^th^ sample interval of the background
X_{Mi}=	Concentration of particles observed in the i^th^ sample of interval of the system gas
X_{Bi}=	Concentration of particles observed in the i^th^ sample of interval of the background
N_M=	Number of sample intervals of the system gas
N_B=	Number of sample intervals of the background
$\overline{X}_M$ =	Average observed concentration of counts in the system gas sample
$\overline{X}_B$ =	Average observed concentration of background counts
$\overline{X}_C$ =	Calculated concentration of particles in the system gas
S_M=	Standard deviation of $\overline{X}_M$
S_B=	Standard deviation of $\overline{X}_B$
S_C=	Standard deviation of $\overline{X}_C$

4.2 *gas sample volume (V_{Mi}, V_{Bi})* — The volume of the sample interval, expressed in standard liters at standard conditions, 0°C (32°F) and 1×10^5 Pa (1 atmosphere) pressure. Standard cubic feet (SCF) is defined at 21.1°C (70°F) and 1×10^5 Pa (1 atmosphere) pressure.

4.3 *average observed concentration of counts ($\overline{X}_M$, $\overline{X}_B$)* — The average concentration of counts, i.e.:

$$\overline{X}_M = \frac{\Sigma X_{Mi}}{N_M} \qquad \overline{X}_B = \frac{\Sigma X_{Bi}}{N_B}$$

4.4 *calculated concentration of particles ($\overline{X}_C$)* — The concentration of particles in the system gas obtained by correcting the observed concentration in the system gas for the observed concentration in the background, i.e.:

$$\overline{X}_C = \overline{X}_M - \overline{X}_B$$

4.5 *standard deviation (S_M, S_B, S_C)* — A statistical measure of the spread of the concentration of the counts or particles. The first two are obtained from the interval and average concentrations and the number of intervals, i.e.:

$$S_M = \sqrt{\frac{(X_{Mi} - \overline{X}_M)^2}{(N_M - 1)}}$$

$$S_B = \sqrt{\frac{(X_{Bi} - \overline{X}_B)^2}{(N_B - 1)}}$$

NOTE: The third is obtained from the first two, i.e.:

$$S_C = \sqrt{S_M{}^2 + S_B{}^2}$$

5 Requirements

5.1 *Maximum Permissible Particle Concentration* — 10 particles per 25 standard liters as determined by the instrument specified in Section 6.

5.2 The specification will be considered met if the calculated concentration of particles plus 2 times the standard deviation does not exceed 10 particles per 25 standard liters, i.e.:

$$\overline{X}_C + 2 \times S_C \leq 10 \text{ particles/25 standard liters}$$

6 Apparatus

Particle Counter — An instrument suitable for counting particles in compressed toxic gases at a pressure of up to 8×10^5 Pa (8 atmospheres) with a 50% counting efficiency should reach 90% at 0.3 micrometer or smaller. The resolving power of the instrument near 0.2 micrometer should be no worse than 10%. The counting efficiency is determined by a calibration at 1×10^5 Pa (1 atmosphere) pressure using p olystyrene latex spheres in an inert gas and a reference particle counter with a proven counting efficiency of not less than 95% at 0.2 micrometer.

NOTE: Suitable test methods for determining counting efficiency and resolving power are contained in Japanese Industrial Standard JIS B 9921 (1989), "Light Scattering Automatic Particle Counter". More sensitive particle counters result in a higher measured particle concentration.

7 Test Method

NOTE: The details of the sampling configuration, measurement procedure, and instrument calibration procedure and frequency must be agreed upon by the user and supplier, taking into account good engineering practice. Material safety data sheets should be referred to for safe handling of specialty gases.

7.1 Determine the average observed concentration of counts in the background ($\overline{X}_B$) by passing nitrogen, believed to be free of particles 0.2 micrometer or more in diameter, through the instrument and recording the total number of counts. The nitrogen purge assembly for performing this test, using a filter which removes particles in this size range, is shown in Figure 1. Count a minimum of 3 equal intervals, each of at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Calculate $\overline{X}_B$ as defined in Section 4. $\overline{X}_B$ must not exceed 2 counts per 25 standard liters.

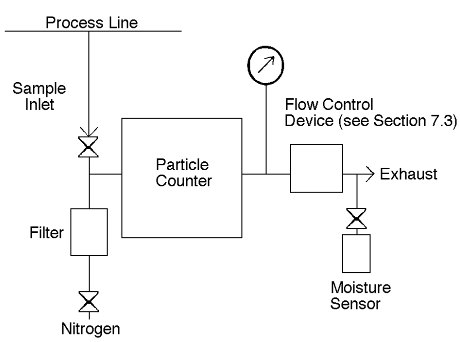

Figure 1
Schematic Diagram of Configuration for Obtaining Particle Samples from Toxic Specialty Gas Systems

7.2 The sampling point should be near the point of use, and sampling lines should be clean and as short as possible.

7.3 The sampling system configuration is shown in Figure 1. The specialty gas system should be connected through a sample valve directly to the particle counter, a pressure gauge, and a flow control device (FCD). When sampling is performed using wall tap sample ports, the aspiration efficiency should be checked using the method described in Related Information 1. The sampling system should contain minimum dead volume and sample tube length. All components in the sampling system should be leak tight and cleaned in accordance with good engineering practice. A leak check of the system should be performed in accordance with normally accepted practice. The FCD may be part of the particle counter. The particle counter should be maintained at the pressure of the gas system. The FCD can be a metering valve and a flow meter or a critical orifice. The exhaust line should be leak tight and piped to an appropriate exhaust system. The exhaust line diameter should be large enough to produce no more than 1×10^4 Pa (1.5 psi) pressure drop during purge and sample flow.

7.4 Using the high purity nitrogen system shown in Figure 1, purge the sampling system and particle counter for at least 5 minutes at the instrument manufacturer's specified flow rate. The exact purge time should take into account the reactivity of the gas and should be sufficient to purge the entire exhaust line. A moisture sensor should be placed at the system exhaust to verify less than 1 ppmv water in the purge nitrogen. The purging must be performed before toxic gas is introduced into the sampling system and after completion of the measurement. The valve leading to the moisture sensor should be closed when toxic gas is being sampled. The valve leading from the purge nitrogen system should be closed when sampling specialty gases and/or a back flow prevention device should be included in the purge nitrogen system.

NOTE: It is known that toxic gases may produce injurious or lethal effects. Nitrogen purging of the sampling system reduces the risk of exposure to toxic gases. The purity of the purge nitrogen should be sufficient to remove reactive substances from the sampling system.

7.5 Count the particles in each of at least 3 equal intervals. Each sample interval must be at least 25 standard liters (0.95 SCF), or 30 minutes, whichever is greater. Data obtained during the first 5 minutes after the sample valve is opened may be discarded. Record the number of counts in the sample volume for each interval. Calculate $\overline{X}_C$ and SC, as defined in Section 4.

NOTE: For small volume specialty gas systems, the user and supplier may agree to a smaller sample gas volume than that stated above. The sample point location and the process line pressure and flow rate during the test should be recorded.

8 Report

The report shall contain the values of all the variables defined in Section 4.

RELATED INFORMATION 1 NOTES ON ASPIRATION EFFICIENCIES OF WALL TAP SAMPLE PORTS

NOTE: This related information is not an official part of SEMI F26 and is not intended to modify or supercede the official standard. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Introduction

Isokinetic sample probes are usually not provided in speciality gas systems. Particle sampling is usually performed using wall tap sample ports. Wall tap sample ports are oriented 90° to the process line flow as shown in Figure R1-1. Non-isokinetic flow into the sample tube results from the 90° change in flow direction. Additional deviation from isokinesis can result from stream tube contraction or expansion when the velocities U and v are not equal. The effects of non-isokinetic flow on the measurement should be checked. The particle sampling process should be performed with an aspiration efficiency close to 1.

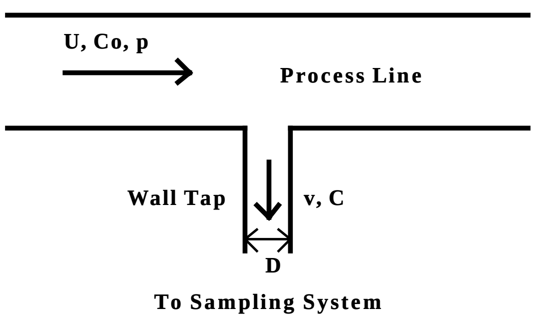

Figure R1-1
Schematic Diagram of Process Line and Wall Tap Sample Port

R1-2 Variables

d_p=	Diameter of particle (cm)
ρ_p=	Intrinsic density of particle (g/cm^3)
η=	Dynamic viscosity of the gas (g/s-cm)
λo=	Mean free path of the gas at atmospheric pressure (cm)
p=	Pressure of the gas (Pa)
P_O=	Atmospheric pressure (= 1×10^5 Pa)
D=	Diameter of wall tap sample tube (cm)
U=	Average velocity of the process line flow (cm/s)
v=	Average velocity of the sample line flow (cm/s)
C*=	Stokes-Cunningham slip correction factor
S_{tk}=	Stokes number
R=	Velocity ratio
Co=	Particle concentration in the process line (cm^{-3})
C=	Particle concentration in the sample line (cm^{-3})

R1-3 Calculations

The Stokes-Cunningham slip correction factor is calculated for particles in the size range of interest:

$$C^* = 1 + 2.492\frac{p_o \lambda o}{p d_p} + 0.84\frac{p_o \lambda o}{p d_p}\ e^{-0.435 p d_p / p_o \lambda o}$$

Calculate the velocity ratio and Stokes number. The intrinsic particle density may assume a worst case value of 10 g/cm^3:

$$R = U/v$$

$$S_{tk} = \frac{d_p^2\ \rho_p U C^*}{18 \eta D}$$

A wall tap sample port can be approximated as a sampling probe oriented 90° to the flow. Calculate the aspiration efficiency:

$$\frac{C}{Co} = \frac{1}{1 + 8 S_{tk}\ R^{1/2}}$$

Repeat the calculations for particle sizes in the range of interest. When the aspiration efficiency is significantly different from 1, the calculated efficiency should be used to correct the measured particle concentration, C.

SEMI F27-0997
TEST METHOD FOR MOISTURE INTERACTION AND CONTENT OF GAS DISTRIBUTION SYSTEMS AND COMPONENTS BY ATMOSPHERIC PRESSURE IONIZATION MASS SPECTROMETRY (APIMS)

1 Purpose

1.1 This test will determine the quantity of removable moisture and the degree of interaction with trace concentrations of gas phase moisture, of gas distribution systems and components. APIMS is currently the technique of choice for such tests because it is essentially the only commercially available method capable of ppt moisture analysis and because of its superior response time. This method may provide guidelines for the application of other techniques with similar detection limits and response time to APIMS which are not commercially available at this time.

1.2 The results of this test can be used for qualitative ranking of systems and components and can also be used, by a sufficiently sophisticated user, as input for numerical simulation of distribution system behavior.

2 Scope

2.1 *System and Component Types* — This procedure applies to in-line components to be used to contain electronics grade materials in semiconductor gas distribution systems. The following components are expected to yield meaningful results when tested according to the present method: tubing, connectors (fittings), particle filters, valves (check, relief, shut-off, and metering), regulators, flow-through transducers/sensors, mass flow controllers and meters. Components with dead volumes, such as pressure gauges, can be tested according to this method, but the results will be difficult to interpret. Additional criteria besides those considered here need to be developed for testing components with dead volumes.

2.1.1 As gas phase moisture levels are dominated by desorption from surfaces, the procedure is expected to be most useful for components of large surface area such as particle filters and tubing. Components with very small wetted surface areas may have moisture interactions which are too small to measure using this test. Check valves and relief valves can be tested only if their operating parameters are consistent with the test conditions.

2.1.2 Tubing samples must be rather long (3 – 4 m) to yield useful results, but they can be bent into a U shape in order to be accommodated into a practical test bench. Radii of curvature should be no less than 6 times the internal diameter of the tube and the minimum number of bends should be used. Most ultra-high purity components are currently supplied with metal gasket connectors, so the test bench employed should be fitted with mating connectors. This type of fitting is usually welded to tubing, which is not recommended as it introduces a potential source of uncontrolled variability to the experiments. Instead, a compression fitting on the tube and a suitable adapter should be used. The compression fitting should not be disconnected after initial connection until the test series is over. In this way, deterioration in integrity of the connection can be avoided. The same type of gasket to compression fitting adapter should be used for all tubing samples.

2.1.3 Purifiers require special test procedures and are not addressed here.

2.1.4 Simple systems consisting of components connected in line can be tested by the present method. Complex systems (i.e., those with more than one potential inlet and/or outlet) will show performance which varies depending on the test configuration (which inlets and outlets are chosen). Testing of such systems is not addressed by the current document.

2.2 *Gases* — The procedure will be carried out in nitrogen. The results will provide a ranking with respect to moisture contribution which may be applied with due caution to components intended for use in other gas streams. Other "inert" gases will have different purging characteristics and may dry a component more quickly or slowly. Reactive gases may react chemically with moisture. Considerations relating to corrosion resistance are outside the scope of the present document, although the test procedure may prove useful in corrosion studies.

2.3 *Operating Situations* — Moisture contribution from a component may be the result of contamination arising in its manufacture, or from subsequent exposure to ambient air or non-dry gas. Thus, it is necessary to consider two main situations:

1. The "initial dry-down" situation, which is determined by the moisture content of the component as received with the effects of manufacturing process and design, surface quality, pretreatment and packaging convoluted together.

2. The “Response to upset” situation, which is determined by the amount of moisture taken up by the component and subsequently released in any exposure after receipt.

3 Limitations

3.1 This test method allows the determination of moisture interactions which can be used, for example, to rank components in order of decreasing moisture interaction. Because different degrees of moisture interaction are desirable in different situations, selecting the “best” components requires consideration of how they will be used in a given distribution system, either qualitatively or through numerical simulation of distribution system behavior.

4 Referenced Documents

4.1 *SEMI Documents*

A test method for moisture contribution as measured using a conventional hygrometer is in preparation by SEMI Japan as of this writing. That test should be considered when certification to ~ 20 ppb moisture is sufficient. The output of the moisture generator, used in this text, shall be verified according to SEMI C15, Test Method for ppm and ppb Humidity Standards.

5 Terminology

5.1 *Acronyms*

5.1.1 *ppm* — Molar parts per million (µmole/mole). The same as ppmv.

5.1.2 *ppb* — Molar parts per billion (nmole/mole). The same as ppbv.

5.1.3 *ppt* — Molar parts per trillion (pimole/mole). The same as pptv.

5.2 *Definitions*

5.2.1 *induction time* — The elapsed time between when humidified gas is input to the test component and when moisture is detected at the moisture analyzer. For a component and test system which are perfectly transparent to moisture the induction time is equal to the residence time of the gas in the system.

5.2.2 *peak height* — The maximum moisture concentration recorded when a moisture input of predefined length and concentration is introduced to a test component.

6 Required Equipment

6.1 *APIMS* — The APIMS used for moisture detection can be of any type. In order to be considered valid, any series of moisture tests shall reference two single point calibrations, one at the beginning and one at the end of the series. These calibrations shall both be made under the same analytical conditions (flow, pressures, plate voltages, etc.) as the tests and the results shall be within 5% of each other. Provided this condition is met, the interval between calibrations may be left to the discretion of the operator; however, it is suggested that calibration should be carried out whenever the equipment is moved and/or every two weeks of operation.

6.2 *Dry Gas and Moisture Generator* — A source of extremely dry nitrogen (less than 100 ppt moisture) and a moisture generator capable of delivering up to 13 slm nitrogen doped with 50 ppb moisture is required. This generator may be the same as used to calibrate the APIMS. The output of the generator shall be verified according to SEMI C15.

Most ultra-high purity components are currently fitted with metal gasket type connectors. The same type of connector should, therefore, be incorporated into the test bench for connection to the test components.

6.3 *Test Blank* — Any series of tests shall include the results of testing a blank. The blank shall be the shortest convenient length (no more than 1 m) of 1/4" electropolished stainless steel (EPSS) tubing with suitable fittings and/or adapters at either end to enable it to be inserted in place of the test specimen.

6.4 *Moisture Pulse Generator* — A valving arrangement capable of switching rapidly between dry and humidified nitrogen is also required. An example of such a design is shown in Figure 1. In this design, flow is maintained in both the humidified and dry gas lines at all times. By simultaneously switching valves V_1 and V_3, or V_2 and V_3, either humidified or dry gas is directed through the test specimen while the other gas stream is directed to vent. Note that there is a bypass loop so that flow can be maintained to the APIMS when the specimen is removed. In this design, all gas lines, but especially those lines between V_1 and V_3 and between V_2 and V_3, should be as short as possible and constructed of EPSS tubing of high quality. Maintaining gas lines at a constant temperature between 50 and 80°C wherever possible is also recommended.

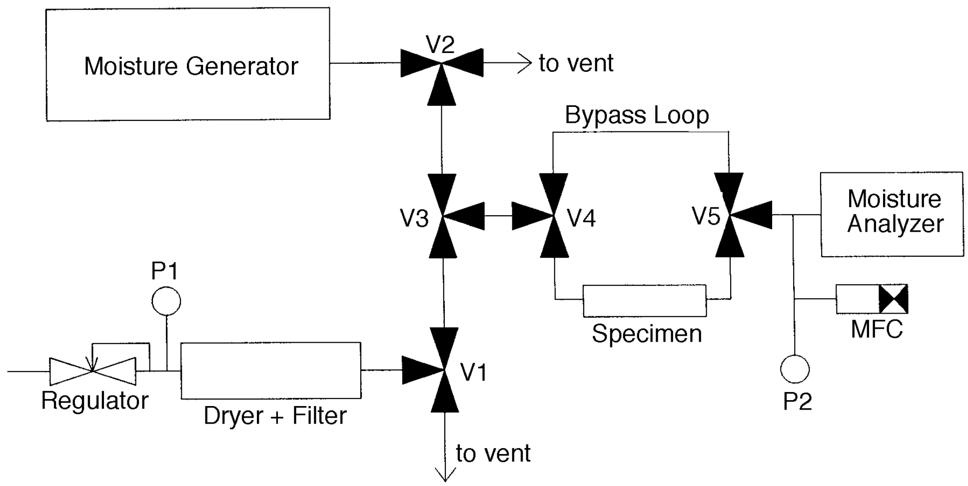

Figure 1
Moisture Test Schematic

6.4.1 The bypass loop will contain a stagnant volume of gas during testing. To avoid exposing the APIMS to a large moisture upset whenever it is fed the gas contained in the bypass loop, the loop should be thoroughly baked out (at ≥ 200°C) and protected from atmospheric contamination thereafter. Valve V_4 should be such that some flow can be maintained through the bypass loop and the test specimen simultaneously as well as through each separately. Use of pneumatic valves to facilitate rapid and simultaneous switching is recommended.

6.4.2 Other arrangements than that shown may also be used. The moisture pulse generator should be designed so as to give the fastest possible response of the blank to a change in input moisture level.

6.4.3 Use of a glove box or other such enclosure about the test specimen and adjacent piping, to minimize exposure of the system to ambient contamination when removing and introducing the test specimen, will improve the precision of moisture content measurements but not of moisture interaction measurements. Use of such an enclosure is, therefore, left to the discretion of the operator.

6.5 *Temperature Control and Measurement* — A stable temperature during the test is of critical importance. The test component shall be kept at 35°C. **TESTS AT DIFFERENT TEMPERATURES CANNOT BE COMPARED**. Ideally, the blank and device under test should be maintained in a temperature-controlled chamber. However, if this is impractical, heating tape can be used. Temperature shall be measured at 1 m intervals on tubing. Measurement at one point is adequate for small components. Temperature control should be to ± 1°C. A continuous record of temperature during the test shall be maintained.

7 Procedure

7.1 *Blank Tests* — A blank test shall be carried out after each calibration. If initial dry-down testing of components is not of interest, the initial dry-down test of the test blank may be omitted and the test blank brought to equilibrium with zero gas in whatever manner is most convenient, except that the test blank should not be heated above 200°C. Permanent changes in moisture interaction have been observed at temperatures above this level.

7.1.1 *Initial Dry Down* — Start the experiment with the blank in place of the test specimen and a flow of dry gas through the APIMS. The APIMS output should be at equilibrium with the lowest moisture level of interest, and in any case no higher than 500 ppt. The flow rate through the test blank should be set according to the Flow Table (see Section 7.3).

7.1.1.1 Switch the gas flow to pass primarily through the bypass loop while maintaining a small flow through the test blank. Remove the test blank completely from the system. If a glove box or other such enclosure is used, do not remove the test blank from the glove box. Immediately reconnect the test blank to V_4, leaving it disconnected from V_5. Allow dry nitrogen to flow through the test blank for five minutes to purge the air from inside before reconnecting to V_5. Switch the gas to flow only through the blank and not through the bypass loop. The APIMS will show an increase in moisture concentration. Record the APIMS output until it reaches 500 ppt or for 24 hours, whichever is less.

7.1.1.2 Repeat the above test twice for a total of three data sets.

7.1.2 *Moisture Input Test* — After the APIMS has returned to equilibrium with its initial moisture level, switch the input gas to 50 ppb moisture (by switching valves V_1, V_2, and V_3 simultaneously, if the arrangement of Figure 1 is used) while recording the APIMS response. Maintain this moisture input for 20 minutes. Switch the input to the test blank back to dry nitrogen and record the decease in moisture level until the initial background is again reached.

7.1.2.1 Repeat the above test twice for a total of three data sets.

7.2 *Tests on Actual Specimen*

7.2.1 *Initial Dry Down* — This portion of the test is designed to determine the quantity of removable moisture on the wetted surfaces of a component in the condition in which it is typically supplied. Thus, the results of this test will reflect, by design, any precautions which the supplier has taken to remove moisture and maintain its dryness during shipping.

7.2.1.1 Start the test as in Section 7.1.1. The test specimen should not be unpacked until after the APIMS has equilibrated with the background moisture level. If a glove box or other such enclosure is used, unpack the component in the glove box. Switch the dry nitrogen flow to pass through the bypass loop while maintaining a small component through the test blank. Undo the final layer of packing and any shipping caps or plugs on the component at this point. Remove the sample blank and connect the test specimen to valve V_4 as quickly as possible. Allow the dry nitrogen flow to purge out any ambient air in the specimen for five minutes, then connect the specimen to V_5. Switch the gas to flow only through the test specimen and not through the bypass loop. The APIMS will show an increase in moisture concentration. Record the APIMS output until it reaches 500 ppt or for 24 hours, whichever is less.

7.2.1.2 After 24 hours, the dry-down part of the test can be terminated. If necessary, the moisture level can be reduced below 500 ppt by baking the component at 200°C or the maximum temperature allowed by the manufacturer for six hours and/or purging at the highest flow of dry gas available. If this is not sufficient to reduce the moisture concentration below 500 ppt, the test may be abandoned.

7.2.2 *Moisture Input Test* — After the APIMS has returned to equilibrium with its initial moisture level, switch the input gas to 50 ppb moisture (by switching valves V_1, V_2, and V_3 simultaneously, if the arrangement of Figure 1 is used) while recording the APIMS response. Maintain this moisture input for 20 minutes. Switch the input to the test blank back to dry nitrogen and record the decease in moisture level until the initial background is again reached.

7.2.2.1 Repeat the above test twice for a total of three data sets.

7.2.2.2 In case the moisture level recorded by the APIMS does not reach 50 ppb within 20 minutes, an additional test should be performed in which the moisture input should be continued until equilibrium is reached. Then switch the input to the test specimen back to dry nitrogen and record the decease in moisture level until the initial background is again reached. This test should be repeated once (two data sets total).

7.2.3 *Bake-Out Test* — Heat component to maximum bake temperature, according to manufacturer's specifications, for three hours. Allow it to return to room temperature. Continue by repeating the moisture input test, after baking, as in Section 7.2.2.

7.3 *Temperature, Flow Rate, and Pressure Specification* — The recommended test pressure is 700 kPa (7 bar). However, lower test pressures are appropriate for some models of APIMS. Also, the maximum pressure rating of the test components should not be exceeded. The component temperature shall be maintained at 35 ± 1°C during the test.

In the case of tubing, the test shall be carried out at a single flow determined by the tubing diameter according to the following table. In the case of valves, regulators, mass flow controllers (MFC's), and passive components (gauges, flow meters, and fittings), the test will be carried out at a single flow determined by the table according to the size of the connecting tube stubs. Regulators should be tested in the fully-open condition (i.e., with the regulator adjusted for minimum pressure drop). The quantity of published data on regulator interaction with moisture is limited, and experiments to investigate the effect of varying the pressure drop across the regulator are encouraged but are not part of this test. MFC's should be tested with a flow control device upstream and the MFC not actively controlling the flow through it (usually referred to as the "purge" setting). It may not be possible to test a given MFC at the specified flow if the flow rating of the MFC is much less than the specified flow. As MFC's are not expected to vary greatly in performance according to their flow rating, MFC's to be tested should generally be chosen to be compatible with the table. If this is not possible, then the MFC should be tested at its rated flow (lower than the flow in the table). This can then be considered a conservative test, as the MFC operated at higher flow would be expected to dry down more quickly.

Particle filters with the same size tubing connectors often have somewhat different sizes and very different flow ratings. In order to be able to make reasonable comparisons between the performance of different filters, it is essential to test filters of similiar size at the same flow. However, the flow dependence of the moisture response of particle filters is more complex than that of tubing, and they must be tested at more than one flow in order to model their behavior. In order to meet this requirement and provide data which can be readily compared with the conditions under which the filters can be expected to be used in practice, filters shall be tested at two flows: The first, according to the size of the connecting tube stubs, the second, to be 25% of the rated flow of the filter or 50 slm, whichever is less.

For systems of components, the system shall be tested at the lowest flow of those determined for each component in the system considered separately. If the system includes a filter, it shall be tested at that flow and additionally, at 25% of the rated flow of the filter or 50 slm, whichever is less.

<table>
<tr><th>Tubing Outer Diameter (nominal)</th><th>Flow (all components)</th><th>Flow for Second Test on Filters</th></tr>
<tr><td>≥ 1/8", < 1/2"
(≥ 3.2 mm, < 12.7 mm)</td><td>6 slm</td><td rowspan="2">25% of rated flow or 50 slm whichever is less</td></tr>
<tr><td>≥ 1/2"
(≥ 12.7 mm)</td><td>13 slm</td></tr>
</table>

8 Reporting Results

Complete moisture response curves for all test specimens and relevant test blanks should be included. A summary sheet may compare components in terms of “induction time,” peak height, and/or decay time. Temperature, pressure, and flow measurements, and as complete a record as possible of all experimental variables should be noted.

SEMI F28-0997
TEST METHOD FOR MEASURING PARTICLE GENERATION FROM PROCESS PANELS

1 Purpose

1.1.1 The purpose of this document is to define a method for testing process panels intended for

1.1.2 nels tested for the purposes of qualification for this installation.

1.2 This document describes a test method designed to draw comparisons of particulate generation performance of process panels. This test method evaluates the cleanliness of process panels in the "as received" condition as well as under normal operating conditions. The "as received" test is intended to enable the user to evaluate the fabrication, cleaning, and packaging techniques of the manufacturer of the process panel. The test under actual operating conditions is intended to allow the user to evaluate the manufacturer's component selection as well as the quality of the panel design. The specific flow rates described in both test methods are representative of relatively high flow conditions for a typical process panel.

2 Scope

2.1 This test method addresses total particle counts greater than the minimum detection limit (MDL) of the particle counter and does not consider classifying data into various size ranges.

2.2 This procedure utilizes a particle counter applied to process panels typically used in semiconductor applications. It applies to process gas supply systems (e.g., gas cabinets) which include a process panel, an inert purge panel, and a system vent. Both automatic and manual process panels are within the scope of this test procedure. Panels, as defined in this test method, are considered to consist of 6.35 mm O. D. × 0.89 mm wall (1/4" O.D. × 0.035" wall) tubing and components.

3 Limitations

3.1 This test method specifies flow and mechanical stress conditions considered typical of conditions which would be expected under moderately aggressive operating conditions. These conditions should not exceed those recommended by the manufacturer. Actual performance under operating conditions at lower flow rates or less aggressive conditions may differ. This test method does not address particle generation under vibrating conditions.

installation in high-purity gas distribution systems. Application of this test method is expected to yield comparable data among process pa

3.2 The test medium is limited to nitrogen, argon, or clean dry air (CDA). Performance with other gases may differ.

3.3 The accuracy of the data generated by this method is limited to the accuracy of the particle measuring instruments utilized.

3.4 This method is written with the assumption that the operator understands the use of the apparatus at a level equivalent to six months of experience.

3.5 This document is not intended as a methodology for monitoring on-going particulate performance once a particular process panel has been tested. Also, this method does not include extended dynamic particle count testing (particle generation after thousands of cycles).

3.6 Auto-crossover systems are not within the scope of this test procedure.

NOTE: It should be mentioned that test results from panels equipped with final outlet filters can differ significantly from test results from panels without filters.

4 Referenced Documents

NOTE: The appropriate particle counter manufacturer's operating and maintenance manuals should be consulted when using this test method.

4.1 *Federal Document*[1]

FED-STD-209 — Federal Standard Clean Room and Work Station Requirements, Controlled Environment

5 Terminology

5.1 *Acronyms*

5.1.1 *CDA* — Clean, dry air

5.1.2 *EP* — Electropolished

5.1.3 *LPC* — Laser particle counter

5.1.4 *psi* — Pounds per square inch

5.1.5 *psia* — Pounds per square inch absolute

1 Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120

5.1.6 *psid* — Pounds per square inch differential

5.1.7 *psig* — Pounds per square inch gauge

5.1.8 *scfm* — Standard cubic feet per minute

5.1.9 *slpm* — Standard liters per minute

5.1.10 *SL* — Standard liters

5.2 *Definitions*

5.2.1 *background counts* — Counts contributed by the test apparatus (including counter electrical noise) with a spool piece in place of the test object.

5.2.2 *Compressed Gas Association (CGA)* — Also frequently used to refer to a fitting, as defined and specified by the Compressed Gas Association, which is used to connect a gas source cylinder to a panel inlet.

5.2.3 *condensation nucleus counter (CNC)* — A discrete particle counting instrument that detects particles, in a gaseous stream, by measuring light scattered from droplets grown to measurable size by condensation of supersaturated vapor upon the particles.

5.2.4 *dynamic test* — A test performed to determine particle contribution as a result of valve actuation or regulator adjustment in a process panel during normal operation.

5.2.5 *process panels* — A gas source control piping system for delivering process gases as defined in SEMI F13.

5.2.6 *sample flow rate* — The volumetric flow rate drawn by the particle counter for particle detection.

5.2.7 *sampling time* — The time increment over which counts are recorded.

5.2.8 *source pressure* — Pressure of the source gas applied to the cylinder connection at the panel inlet.

5.2.9 *spool piece* — A null component consisting of a straight piece of electropolished tubing and appropriate fittings used in place of the test component to establish the baseline.

5.2.10 *standard conditions* — 101.3 kPa, 0.0°C (14.73 psia, 32°F).

5.2.11 *static test* — A test performed on an as-received process panel with all valves in the fully-open position.

5.2.12 *test duration* — Total time required to complete the test procedure.

5.2.13 *test flow rate* — Volumetric flow rate of the test gas at standard conditions as defined in Section 5.2.10.

5.2.14 *test pressure* — Pressure immediately downstream of the test panel.

6 Test Procedure

6.1 *Test Conditions*

6.1.1 *Precautions* — This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations before using this method.

6.1.1.1 Exhaust from the CNC may contain hazardous and/or flammable vapors and should be properly treated before being released to atmosphere.

6.1.2 The test is to be conducted at a normal indoor temperature of between 18°C (64°F) and 26°C (78°F).

6.1.3 Test apparatus must be enclosed in a Class 100 environment (per current revision of Federal Standard 209). Use procedures necessary to maintain Class 100 when handling test apparatus and test components.

6.1.4 Care should be taken to protect the test apparatus from excessive vibration. For example, vacuum pumps and compressors should be isolated from the system.

6.2 *Apparatus and Materials*

6.2.1 *Test Gas* — Clean, dry nitrogen or air is to be used [minimum dryness -60°C dew point at 790 kPa (100 psig) and < 10 ppm total hydrocarbons]

6.2.2 *Filters* — Filters are required to provide “particle-free” test gas. Each filter must be nine-log retentive, per manufacturer’s specifications, to 0.02 µm particles and have a pressure drop of less than 6.9 kPa (1 psid) at the specified test pressure and flow rate. The filter must be capable of achieving less than 1 particle[3] (≥ 0.02 µm) per cubic foot of test gas under test conditions.

6.2.3 *Pressure Regulator* — Pressure regulators are required to maintain system test pressures.

6.2.4 *Pressure Gauge* — Pressure transducers or gauges are required to monitor system test pressures.

6.2.5 *Flow Control Device* — A 0–100 slpm flow control device is required for controlling the test flow rate.

6.2.6 *Tubing* — A 6.35 mm O.D. × 0.89 mm wall (1/4" O.D. × 0.035" wall) tubing is required. The tubing shall have an average surface roughness of 0.25 micrometer (10 microinch) Ra or less. Electropolished tubing (as defined in SEMI F16) is recommended.

6.2.7 *Sampler* — The sampling system consists of a diffuser equipped with a pressure reducing device (e.g., critical orifice) and a sample probe. All parts of the sampling system are to be electropolished with a surface roughness of 0.25 micrometer (10 microinch) Ra or less. If a critical orifice is to be used for pressure reduction, it is not required to be electropolished. The diffuser and sample probe must be sized to obtain isokinetic sampling at the specified test conditions. The critical orifice must be sized to obtain the specified panel pressure at the specified test flow rate.

6.2.8 *Spool Piece* — Spool pieces shall be electropolished 316L stainless steel tubing with a surface finish of 0.25 micrometer (10 microinch) Ra or better. The spool piece is to be installed in the system in place of the test device while obtaining background counts for the system.

6.2.9 *Fittings* — Use face seal connectors or compression fittings depending on test panel end connections.

6.2.10 *Gaskets* — Use non-plated metal gaskets where required.

6.2.11 A CNC capable of detecting particles at least as small as 0.02 µm at a 50% efficiency envelope as defined by Federal Standard 209, with a sampling flow rate of 1.23 SLPM (0.05 scfm) or greater, is to be used for particle counting. A laser particle counter, capable of detecting particles at least as small as 0.1 mm, may be used in addition to, or in place of, the CNC. Test durations in this test method have been established based on a sampling flow rate of 1.23 SLPM (0.05 scfm).

6.2.11.1 Instruments should be calibrated regularly, according to manufacturer's recommendations. For the CNC, this includes routine checks of sample flow rate, working fluid level, and zero.

6.2.11.2 The CNC and data collection equipment should have power surge suppression.

6.2.11.3 *Setup and Schematic* — See Figure 1

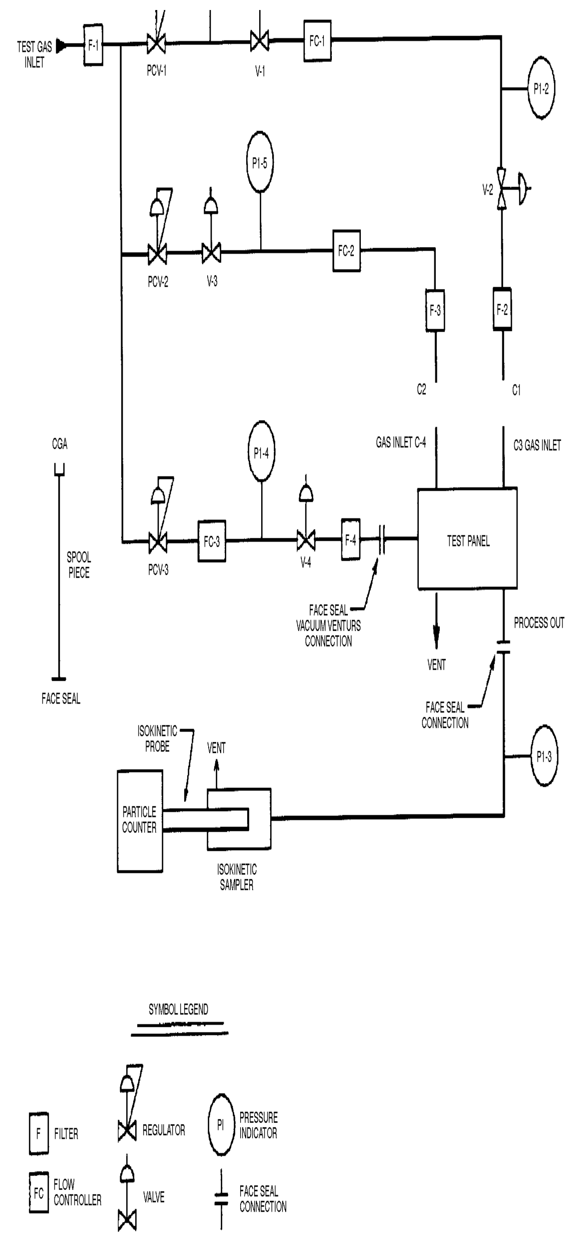

Figure 1
Panel Test Apparatus

6.2.11.4 The spool piece is to be installed when the test stand is not in use. A continuous low flow is to be maintained to purge the system. The particle counter may be turned off. For an extended shutdown, the system (excluding the CNC) should be pressurized and capped.

6.2.11.5 After initial construction, the spool piece should be installed and the system should be cleaned up by running a high-flow rate of test gas (> 60 SLPM) and gently tapping all components (except the CNC) downstream of the final filter. This procedure should be followed by a start-up phase which characterizes system cleanliness by conducting the entire test protocol with the spool piece installed.

6.3 *Test Procedures*

NOTE: Ensure the counter is counting continuously and reporting data each minute. For the duration of the test, the counter should be continuously counting, except where noted in the test protocol.

This test method classifies panels into three pressure ranges: high, medium, and low. The test pressures and flow rates for each pressure classification are given in Table 1 below.

Table 1 Panel Test Conditions

Panel Pressure Class	*High*	*Medium*	*Low*
Inlet Supply Pressure	3450 KPa (500 psig)	550 KPa (80 psig)	210 KPa (30 psig)
Panel Outlet Pressure	210 KPa (30 psig)	210 KPa (30 psig)	0 KPa (0 psig)
Test Flow Rate	60 slpm	60 slpm	5 slpm

The test flow rates stated in the above table are meant to serve as a general guideline. The actual test flow rates may vary depending on the maximum panel flow rate as recommended by the manufacturer. The maximum test flow rate should be the manufacturer's maximum recommended flow rate. If no such maximum flow rate is recommended by the manufacturer, the flow rates in the above table should be used.

6.3.1 *Background Test* — Ensure that all valves depicted in Figure 1 are in the closed position. Connect the spool piece to the purge gas inlet (C-2) and the isokinetic sampler inlet. Ensure that the spool piece and proper adapters are in place on the test apparatus. (C-1 should be capped at this time.)

6.3.1.1 Close valve V-3. Adjust the regulator (PCV-2) until PI-5 indicates the appropriate pressure in Table 1. Open valve V-3 and use FC-2 to establish the specified test flow rate listed in Table 1. Measure the static background count. Background count is established when the counter has sampled a minimum of 74 SL (3 scf), and the arithmetic average during the last 74 SL (3 scf) of gas sampled is < 71 particles/m^3 (< 2 particles/scf). At a sample flow rate of 1.23 SLPM (0.05 scfm), the time required is one hour. Ensure that the background counts are stable or decreasing. If background cannot be achieved after 147 SL (6 scf) have been sampled, there may be a problem with the counter or test apparatus.

6.3.1.2 Disconnect the spool piece from C-2 and connect it to C-1. Cap C-2 at this point.

6.3.1.3 Open valve V-1 and close valve V-2. Adjust the regulator (PCV-1) until PI-2 indicates the appropriate supply pressure listed in Table 1. Open valves V-1 and V-2 to establish flow. Using the flow control device (FC-1) set the appropriate test flow rate listed in Table 1. Measure the static background count. Background count is established when the counter has sampled a minimum of 74 SL (3 scf), and the arithmetic average during the last 74 SL (3 scf) of gas sampled is < 71 particles/m3 (< 2 particles/scf). At a sample flow rate of 1.23 SLPM (0.05 scfm), the time required is one hour. Ensure that the background counts are stable or decreasing. If background cannot be achieved after 147 SL (6 scf) have been sampled, there may be a problem with the counter or test apparatus.

6.3.1.4 Actuate valve V-2 at 1 cycle per minute to measure the background counts under dynamic test conditions. Dynamic background count is established when the counter has sampled a minimum of 74 SL (3 scf), and the arithmetic average during the last 74 SL (3 scf) of gas sampled is < 106 particles/m^3 (< 3 particles/scf). At a sample flow rate of 1.23 SLPM (0.05 scfm), the time required is 1 hour. If dynamic background cannot be achieved after 147 SL (6 scf) have been sampled, there may be a problem with the counter or test apparatus.

6.3.2 *Static Test* — Using the flow control device (FC-1), decrease the flow rate to 2.5–5.0 SLPM (0.1–0.2 scfm), so that some flow remains in the system while the test component is installed.

6.3.2.1 Remove the spool piece by first disconnecting the downstream fitting and then the upstream fitting. Immediately install the test panel with all of the process valves in the fully-open position by first connecting the process gas inlet (C-3) fitting and then the process outlet fitting. Uncap C-2 and connect it to the purge gas inlet (C-4) connection of the panel with V-3 in the closed condition. In order to minimize atmospheric contamination and prevent the counter from cooling off, removal of the spool piece and installation of the test panel should take no longer than 2 minutes. Extreme care should be taken to minimize contamination of the test apparatus during this operation. The test panel is to be removed from its inner bag in the Class 100 test area. If the process outlet connection of the test panel has mechanical fittings, these fittings are to be properly connected. If the process outlet has butt weld tube stubs, the connection is to be made with clean compression fittings. Do not permanently crimp any ferrules onto the tube stubs. Nylon ferrules are acceptable. The purge gas inlet connection (C-4) should also be connected at this time. The outlet vent connection should be capped at this time. If this connection is not capped by the manufacturer, it should be covered with Aclar or Nylon 66 squares and taped so as to insure against contamination by the immediate environment. If applicable, all pneumatic valves should be connected using the maximum recommended actuator pressure as specified by the manufacturer.

6.3.2.2 Adjust the panel's process regulator to obtain the appropriate process outlet pressure as indicated in Table 1. Using the flow control device (FC-1), increase the flow to obtain the appropriate test flow rate as indicated in Section 6.3.

6.3.2.3 Turn on the counter and conduct the steady state test. All of the valves on the process panel are to be tested in a fully-open position until 74 SL (3 scf) of gas have been sampled. Cumulative data should be recorded at one-minute intervals.

NOTE: The flow rates in Section 6.3 represent the maximum test flow rates. If a more thorough test is desired, the static portion of the test should be repeated at intervals of 20%, 40%, 60%, and 80% of the full test flow rate. Testing at the lower flow rates may in some instances be more indicative of panel performance under actual use conditions.

6.3.3 *Dynamic Test* — This test is to immediately follow the static test. To conduct the dynamic test, actuate the panel's final process outlet valve at the rate of 1 cycle/minute for 60 minutes. Each cycle consists of having the valve in the open position for 58 seconds and in the closed position for 2 seconds.

6.3.4 *Cylinder Change Test* — Close V-2, open V-3 and V-4, and adjust PCV-2 until PI-5 reads 3450 Kpag (500 psig). Adjust the flow rate and pressure to the vacuum venturi using FC-3 and PCV-3. The flow rate and pressure should be set to the manufacturer's recommended values. Next perform a simulated cylinder change purge and evacuation sequence following the valve sequencing, dwell times, pressure settings, etc. as specified by the manufacturer.

6.3.5 *Final Steady State Test* — Close V-4, V-3, and open V-2. Repeat the step in Section 6.3.2.3.

6.3.6 *Unregulated Flow Test (optional)* — In some instances, it may be desirable to test the panel with its regulator in the fully-open position. Such a test will give an indication of panel particulate performance without the additional contribution of particles from an operating regulator. In this instance, steps 6.3–6.3.5 should be repeated with the regulator in the wide open condition.

6.4 *Data Analysis and Reporting* — The following test conditions are to be reported in the data presentation:

1. Date and time of test
2. Operator
3. Test flow rate
4. Test pressures
5. Panel type, manufacturer, and serial number
6. Particle counter manufacturer, serial number, sample flow rate, model number, specified particle size sensitivity, and calibration date
7. Test gas type and dew point
8. A schematic of the test apparatus, including manufacturer's and model numbers of all test apparatus components
9. Calibration dates for all instrumentation.

6.4.1 *Data Presentation* — Graph the static and dynamic portions of the test separately as counts/minute (measured by the counter) versus time, including the appropriate background (measured with the spool piece in place) with each. Also graph the entire data set as counts per minute versus time.

6.4.1.1 Present the entire raw data set in tabular form.

6.4.2 *Data Reduction* — The statistical analysis is based on the assumption that the particles generated are randomly distributed and are statistically independent of each other. The background counts are independent of the particle performance of the component. The particle counts observed from the test include the counts from the component and the background count. Let:

$\overline{X}_B$ = *average background particle count*

$\overline{X}_t$ = *average total particle count from test*

$\overline{X}_c$ = *average particle count generated by the test component*

Therefore,

$$\overline{X}_t = \overline{X}_c + \overline{X}_B$$

6.4.2.1 A statistical analysis of the data is performed to determine the mean, standard deviation, and the standard error for each particle size range.

6.4.2.2 The sample mean, X, or average of the data for each state is given by:

$$\overline{X} = \sum_{i=1}^{n} \frac{X_i}{n}$$

where X_i is the observed counts for the state and n is the number of samples.

6.4.2.3 The sample standard deviation is a measure of the variability of the data about the mean. The standard deviation, s, for each state is expressed as:

$$s = \sqrt{\frac{\sum_{i=1}^{n} (Xi - \overline{X})^2}{n-1}}$$

6.4.2.4 The standard error, Se or standard deviation of the sampling distribution of the mean for each state is given below:

$$Se = \frac{s}{\sqrt{n}}$$

6.4.2.5 The average particle count for the total number of particles generated, or the sample mean, is an estimation of the population mean. For a 95% confidence level, the population mean, μ_p, will be within two standard errors of the sample mean, or:

$$\mu_p = \overline{X} \pm 2\ Se$$

6.4.2.6 In order to determine if there is statistical evidence of the component having an effect on the observed particle count, a test must be conducted to see if the actual difference between the average background count, X_B, and the average test count, X_t, exceeds two standard errors in a distribution of differences between means. The average particle count generated by the test component, X_c, is given by:

$$\overline{X}_c = \overline{X}_t - \overline{X}_B$$

6.4.2.7 The standard error in a distribution of differences between means is expressed as:

$$S_{ec} = \sqrt{S_{et}^{\ 2} + S_{eB}^{\ 2}}$$

6.4.2.8 The 95% confidence interval of the test component itself is then determined by:

$$\overline{X}_c \pm 2\ S_{ec}$$

6.4.2.9 If this confidence interval includes 0, then this implies that there is not strong statistical evidence of the component having an effect on the observed particle count. If this interval does not include 0, then this implies there is strong statistical evidence that the component does have an effect on the observed particle count.

6.4.2.10 Present in tabular form the average particle count and the associated upper and lower confidence limits (as calculated in Section 6.4.2) for each test state. In addition, present the background test data separately as a distinct element.

SEMI F29-0997
TEST METHOD FOR PURGE EFFICACY OF GAS SOURCE SYSTEM PANELS

1 Purpose

1.1 This document defines the purge efficacy test method recommended for determining the minimum acceptable level of purge efficacy for gas source systems used in semiconductor manufacturing. It is also intended as an aid to the procurement of gas source equipment.

NOTE: Users of this specification are encouraged to submit suggested revisions or other comments to SEMI.

2 Scope

2.1 This specification applies to gas source equipment used in semiconductor manufacturing facilities and comparable research and development areas. It includes contamination testing requirements for gas source systems.

2.2 The tests covered by this document are as follows:

2.2.1 Purge efficacy with a non-interactive gas using manufacturers' standard purge sequence.

2.2.2 Purge efficacy with a non-interactive gas using the test method specified purge sequence.

2.2.3 Purge efficacy with an interactive gas using manufacturers' standard purge sequence.

2.2.4 Purge efficacy with an interactive gas using the test method specified purge sequence.

3 Limitations

3.1 The document is not intended to determine the safe operation of a gas source system. The test method described here is for determining the removal efficacy of hazardous gas from the pigtail portion of the gas panel during routine cylinder change operations (pre-purge). It does not address the purge condition after the change of the cylinder (post-purge) nor the purge of the entire gas source system which is usually performed following its initial installation or during maintenance (maintenance purge).

3.2 Because the response time of moisture and oxygen analyzers utilizing different technologies can differ significantly, this can lead to the possibility that different instruments will report different peak heights when measuring identical contaminant spikes. Therefore, results of tests should only be compared when similar analyzers are used.

4 Referenced Documents

None.

5 Terminology

5.1.1 *clean dry air (CDA)* — Filtered air filtered to 0.02 mm and dried to a dew point of at least -80°C.

5.1.2 *dry down* — Removal of residual moisture in a gas delivery or distribution system, often accomplished by flowing a stream of high purity dry inert gas continuously through the system for an extended period of time.

5.1.3 *dwell time* — The time for which vacuum or pressure is applied during the evacuation or pressurization steps of a purge operation.

5.1.4 *interactive gas* — A gas that will readily adsorb to the surface of a vessel used to contain or transport it. Examples of interactive gases are hydrogen chloride and moisture.

5.1.5 *non-interactive gas* — A gas that will not adsorb to the surface of a vessel used to contain or transport it. Examples of non-interactive gases are oxygen and nitrogen.

5.1.6 *ppb* — Molar parts per billion, same as ppbv.

5.1.7 *ppm* — Molar parts per million, same as ppmv.

5.1.8 *pigtail* — The pigtail is the part of the gas source equipment that is the flexible connection between the cylinder and the gas panel.

5.1.9 *pigtail bleed* — A pigtail bleed is a reverse flow of purge gas from the pigtail to minimize atmospheric intrusion into the gas panel.

5.1.10 *purge cycle* — Following the initial process vent step, a cycle is defined as a pressurization step followed by an evacuation step.

5.1.11 *purified nitrogen* — Nitrogen purified to meet the following characteristics:

Moisture	< 20 ppb
Oxygen	< 10 ppb
Total hydrocarbons	< 1 ppm
CO_2	< 1 ppm
CO	< 1 ppm

6 Ordering Information

6.1 Orders for equipment or services requiring purge efficacy testing in accordance with this test method shall include the following:

6.1.1 This test method number and date of issue.

6.1.2 Test requirements as defined in the detailed specifications for the specific product being purchased.

6.1.3 Whether certifications of tests and a report of the test results is required.

7 Requirements

7.1 *Personnel Qualification* — Personnel performing tests in accordance with this specification shall have suitable training and experience. Such personnel should, as a minimum,

7.1.1 be trained and experienced in operation of gas source control equipment,

7.1.2 be trained and experienced in the use of oxygen and moisture analyzers, and

7.1.3 be familiar with the operation and calibration of the specific equipment used in performing the tests.

8 Apparatus

8.1 *Oxygen Analyzer* — The oxygen analyzer should meet or exceed the following characteristics:

Limit of Detection	10 ppb
Accuracy	± 10 ppb

8.2 *Moisture Analyzer* — The moisture analyzer should meet or exceed the following characteristics:

Limit of Detection	10 ppb
Accuracy	± 10 ppb

8.3 *Pressure Transducer* — The transducer should be of a high-purity type with minimal dead volume and meet or exceed the following characteristics:

Accuracy	± 3.4 kPa (0.5 psi)
Hysteresis	± 3.4 kPa (0.5 psi)
Non-Repeatability	± 0.7 kPa (0.1 psi)

8.4 *Mass Flow Controller or Flow Meter* — The mass flow controller or flow meter should be accurate to ± 0.2 slpm.

8.5 *Moisture Source* — The moisture source must be capable of providing a 2 slpm continuous flow of 2.0 ± 0.2 ppm moisture in nitrogen mixture at 138 kPa (g) [20 psi (g)] for a minimum of 30 minutes.

9 Procedure

9.1 Purge efficacy determination with non-interactive gas at manufacturer's recommended pressure, vacuum, and dwell times.

9.1.1 Connect gas source equipment as in Figure 1.

NOTE: To avoid biasing the test results by substantially increasing piping volume to be purged, the dead space between the cylinder connection and the valves isolating the analyzer and the contaminant source must be small compared to the total pigtail volume. The use of mono-block valve and flow-through type pressure transducer is highly recommended.

However, the pigtail is connected to the cylinder valve during the purge in an actual cylinder change operation. The small additional volume to be purged in the test setup may be used to account for the volume of the cylinder valve outlet cavity, which must be purged during a cylinder change.

9.1.2 To challenge the gas panel with a known contaminant gas, completely fill and pressurize the gas source system to 207 kPa (g) [30 psi (g)] with CDA as measured at the pigtail with the pressure transducer.

9.1.3 Using purified nitrogen as the purge gas, complete one purge cycle at the manufacturer's recommended pressure, vacuum, and dwell times.

9.1.4 Flow purified nitrogen using a pigtail bleed at 1 slpm or at the oxygen analyzer manufacturer's recommended flow rate, whichever is higher, into the oxygen analyzer for 10 minutes or until below the detection limit of the oxygen analyzer.

9.1.5 Record the pressure and peak oxygen concentration in Table 1. It is highly recommended that, in addition to the peak oxygen concentration, the oxygen concentration readings also be recorded at regular intervals during the measurement, so that a graph of the oxygen concentration level in the pigtail bleed gas versus time can be drawn if necessary.

9.1.6 Repeat steps 9.1.2–9.1.5 for 2, 5, 25, and 50 purge cycles at the manufacturer's recommended pressure, vacuum and dwell times. Additional tests using other purge cycle numbers are encouraged and may provide a more complete characterization of the purge performance of the test piece.

9.1.7 Plot the peak residual oxygen concentration versus cycles as in Figure 2 for manufacturer's recommended pressure, vacuum, and dwell times.

9.2 Purge efficacy determination with non-interactive gas at standard pressure, vacuum and dwell times.

9.2.1 Connect the gas source equipment as in Figure 1.

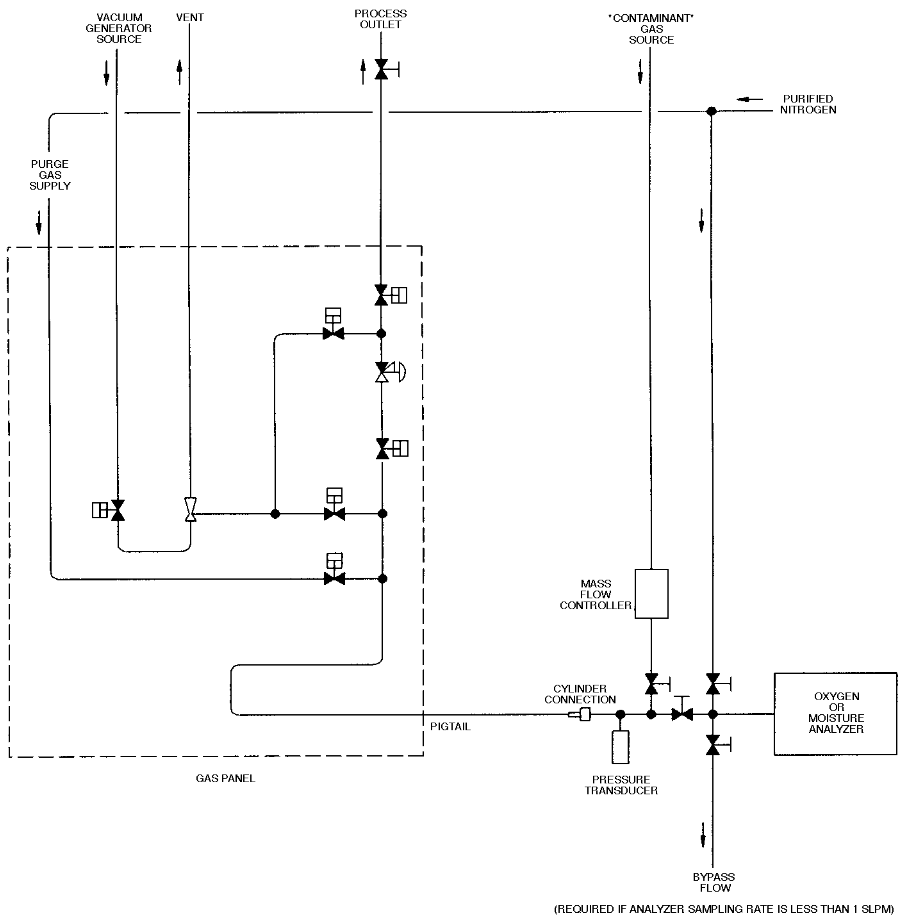

Figure 1
Test Schematic

9.2.2 To challenge the gas panel with a known contaminant gas, completely fill and pressurize the gas source system to 207 kPa (g) [30 psi (g)] with CDA as measured at the pigtail with the pressure transducer.

9.2.3 Using purified nitrogen as the purge gas, complete one purge cycle with the purge gas pressure at 522 kPa (g) [80 psi (g)], vacuum at -75 kPa (g) [-22" Hg (g)], and dwell times for pressurization and vacuum evacuation at 5 and 15 seconds, respectively.

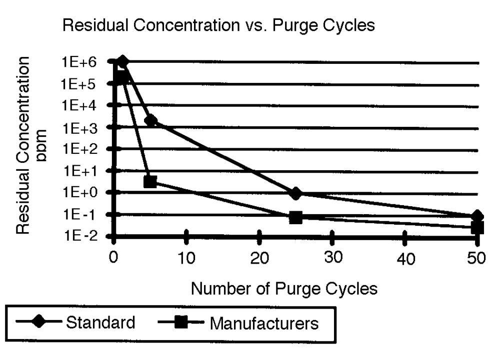

Figure 2
Data Presentation for Purge Efficacy — Non-Interactive Gas

9.2.4 Flow purified nitrogen using a pigtail bleed at 1 slpm or at the oxygen analyzer manufacturer's recommended flow rate, whichever is higher, into the oxygen analyzer for 10 minutes or until below the detection limit of the oxygen analyzer.

9.2.5 Record the pressure and vacuum measured with the transducer and the peak oxygen concentration as in Table 1. It is highly recommended that, in addition to the peak oxygen concentration, the oxygen concentration readings also be recorded at regular intervals during the measurement, so that a graph of the oxygen concentration level in the pigtail bleed gas versus time can be drawn if necessary.

Table 1 Data Collection Form

	Manufacturer's Recommended Purge Parameters	*SEMI Standard Purge Parameters*

50		

9.2.6 Repeat steps 9.2.2–9.2.5 process for 2, 5, 25, and 50 cycles. Additional tests using other purge cycle numbers are encouraged and may provide a more complete characterization of the purge performance of the test piece.

9.2.7 Plot the peak residual oxygen concentration versus number of cycles as in Figure 2 for standard pressures, vacuum, and dwell time.

9.3 Purge efficacy determination with interactive gas at manufacturer's pressure, vacuum, and dwell times.

9.3.1 Connect gas source equipment as in Figure 1.

9.3.2 To challenge the gas panel with a known contaminant gas, flow wet (2 ppm) N_2 at 2 slpm and 138 kPa (g) [20 psi (g)] for 30 minutes or until the process outlet concentration reaches the inlet concentration, whichever is less.

9.3.3 Using purified nitrogen as the purge gas, complete one purge cycle at manufacturer's recommended pressure, vacuum, and dwell times.

9.3.4 Flow purified nitrogen using a pigtail bleed at 1 slpm or at the moisture analyzer manufacturer's recommended flow rate, whichever is higher, into the moisture analyzer for 30 minutes or until below the detection limit of the moisture analyzer.

9.3.5 Record the pressure and vacuum measured with the pressure transducer and peak residual moisture concentration in Table 2. It is highly recommended that, in addition to the peak moisture concentration, the moisture concentration readings also be recorded at regular intervals during the measurement, so that a graph of the moisture concentration level in the pigtail bleed gas versus time can be drawn if necessary.

9.3.6 Repeat steps 9.3.2–9.3.5 process for 2, 3, 4, 5, 10, 25, and 50 cycles. Additional tests using other purge cycle numbers are encouraged and may provide a more complete characterization of the purge performance of the test piece.

9.3.7 Plot the peak residual moisture concentration versus number of cycles as in Figure 3 for manufacturer's pressure, vacuum, and dwell time.

SEMI F30-0298
START-UP AND VERIFICATION OF PURIFIER PERFORMANCE TESTING FOR TRACE GAS IMPURITIES AND PARTICLES AT AN INSTALLATION SITE

1 Purpose

1.1 The purpose of this procedure is to verify the performance of purifiers by employing analytical instrumentation to measure gas impurities and particles to customer specifications. If specific inlet challenge(s) and/or inlet measurements are required, it should be discussed beforehand with the customer. Inlet impurities must be measured by part-per-million (PPM) or part-per-billion (PPB) analytical equipment. This procedure applies only to large scale bulk purifiers rated at greater than 50 liters-per-minute (LPM) flowrate.

2 Scope

2.1 Verify performance of large scale purifiers in nitrogen, argon, helium, oxygen, and hydrogen service. Verification tests are done at PPB or sub-PPB levels of gaseous impurities and sub-micron sizes of particles measured downstream of any installed filter modules. Tests are done at maximum achievable flow of purifier, and/or customer's specified percentages of maximum flow.

3 Limitations

3.1 PPB and sub-PPB gaseous impurity levels are achievable using atmospheric presssure ionization mass spectrometry (APIMS), which is the preferred method of choice, and the reduction gas detector (RGD)-gas chromatograph. APIMS is currently not available for oxygen service. A partial list of non-APIMS measuring equipment for use in oxygen service is in Appendix 1 for commonly measured impurities.

4 Referenced Documents

4.1 Approved procedures for operation of analytical equipment.

4.2 Approved gas sampling and purifier procedures.

5 Terminology

None.

6 Summary of Method

6.1 The purifier is started, and the operation is checked. Each purifier bed is regenerated, and analytical tests are done. The analytical results determine if the purified gas meets the customer specifications.

7 Interferences

7.1 The following sources might contribute to misleading or high analytical results. Some identified sources are unpurged, dead-ended piping or isolation valves, leaks in gas distribution system, insufficient purge flow, and insufficient system clean-up time.

8 Apparatus

8.1 Face seal fitting(s) with metal gaskets and stainless steel tubing for sampling.

8.2 Dynamic dilution system for diluting calibration standards to PPB and sub-PPB levels for calibration of analytical equipment.

8.3 *APIMS* — The sample gas, nitrogen, is introduced into an APIMS where a small amount of it is ionized. By collision with ionized nitrogen, impurity molecules are ionized with high efficiency. The mass analyzer, which can be a quadrupole, time-of-flight (TOF), or even a magnetic sector, separates and focusses the ions by their mass-to-charge ratio. An electron multiplier detects and counts each ion fragment and amount.

8.4 *Reduction Gas Detector-Gas Chromatograph (RGD-GC)* — The reduction gas detector is a heated mercuric oxide bed that reacts with reducing gases, such as hydrogen and carbon monoxide. The mercury evolved is detected and displayed as a peak. The GC employs a heated molecular sieve column to separate the H_2 and CO.

8.5 *Ultratrace Analytical Instrumentation Required other than APIMS* — Ultratrace instrumentation is defined as having sufficient sensitivity to measure all impurities of interest at the specified level of the customer at the PPB or sub-PPB.

8.6 Particle counter.

8.7 Data collection and reduction system.

9 Reagents and Materials

9.1 Certified calibration standards.

10 Safety Precautions

10.1 The testing area should have adequate room ventilation and atmospheric monitors.

10.2 Instruments should be exhausted to vent, and if required in Class 1 environments, should be case-purged or in an approved enclosure.

10.3 Testing personnel should be aware of customer alarm and evacuation procedures.

10.4 Designated customer contact required during testing.

11 Sampling

11.1 Test each purifier bed independently to verify performance to customer specifications. Refer to gas supplier's certificate of conformance for inlet impurity levels. Refer to Figure 1 for overall test sequence.

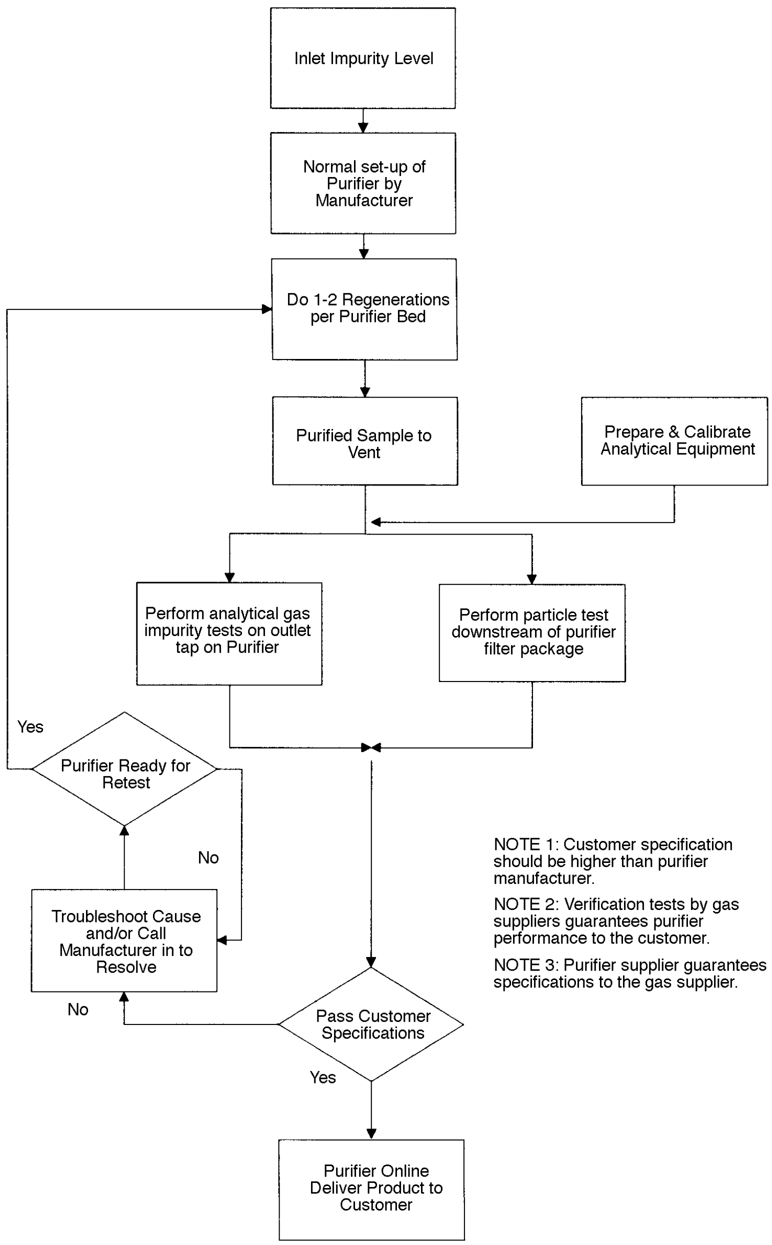

Figure 1
Overall Test Sequence

12 Preparation of Apparatus

12.1 *Sampling System* — Use appropriate clean tubing and fittings, or clean before use. Purge system prior to sampling.

12.2 *Dynamic Dilution System* — Use certified standards and dilute using equation (1) to calculate final concentration (C_F). For moisture, certified moisture permeation devices can be used.

(1) $C_c \times D.F. = C_F$

C_c = PPM - or PPB - certified cylinder standard concentration.

C_F = final concentration.

D.F. = dilution factor which is calculated by taking the flow (in liters) of the certified standard and dividing by total flow (in liters). Dilution factors can be multiplied in series, if diluting more than once.

Example 1: What is the final concentration for dynamically diluting 10 ml of a 100 PPB impurity into 1 liter?

$$100 \text{ PPB} \times [0.010 \text{ liter}/1.010 \text{ liter}] = 0.99 \text{ PPB}$$

12.2.1 Calibration should be done in the region specified by the purifier manufacturer. For example, if the purifier has an outlet impurity guarantee of 1 PPB of each impurity, then the test equipment should be calibrated with levels at approximately 1 PPB, not at 30 PPB and extrapolated down. Also, multipoint calibration data is preferred.

12.3 APIMS, RGD-GC, ultratrace analytical instrumentation. Particle counter.

12.3.1 Start-up and purge the instrumentation. Perform calibration. Determine if calibration is satisfactory. Proceed to sampling section.

12.4 *Data Collection System* — Check for proper signal inputs, range inputs, and sampling intervals.

12.5 *Data Reduction System* — Prepare data as print-outs and/or graphs. Include statistical analysis as required. Generate final report.

13 Calibration and Standardization

13.1 See Section 12, Preparation of Apparatus.

14 Procedure

14.1 *Trace Gas Impurity Measurement*

14.1.1 Connect sample source to analytical equipment.

14.1.2 Start data collection.

14.1.3 Stop sampling. Review preliminary data. If it is within customer specification, disconnect sample source. If it does not meet specifications, investigate cause or refer to manufacturer literature to resolve. Once condition is corrected, repeat tests.

14.1.4 Repeat procedure for next bed or sampling point. If instrumentation is relocated, calibration check is required.

14.2 *Particle Counting*

14.2.1 Select sample location. Ideal location is a permanently installed pitot probe.

14.2.2 Select where the particle tests will be done on the pipe.

14.2.3 Use Reynold's equation to determine the required gas rate for turbulent flow to the particle counter. Use this value or higher for sampling purposes. Reynold's number greater than 2100 are suggested for turbulent flow.

14.2.4 Reduce incoming sample pressure to the particle counter by following manufacturer's recommendation or by best practice.

14.2.5 Test particles with turbulent flow through pipeline, if possible. However, do not exceed the manufacturer's maximum rated flow for the purifier.

14.2.6 Start data collection.

14.2.7 Stop sampling. Review preliminary data. If it is within customer specification, disconnect sample source. If it does not meet specifications, investigate cause or refer to manufacturer's literature to resolve. Once condition is corrected, repeat tests.

14.2.8 Repeat procedure for next bed or sampling point.

15 Calculations or Interpretation of Results

15.1 Results are interpreted by trending analysis, averaging, or steady-state analysis.

16 Reporting Results

16.1 Sample location.

16.2 Operator identification.

16.3 Test parameters and conditions (pressures, flowrates, temperatures, etc.).

16.4 Test date and duration.

16.5 Description of instrumentation.

16.6 Calibration information for analyzer(s).

16.7 Report test results by data table and/or graphs.

16.8 Comments on testing.

16.9 Conclusion.

APPENDIX 1

NOTE: This appendix was approved as an official part of SEMI F30 by full letter ballot procedure.

SEMI F31-0698
GUIDE FOR BULK CHEMICAL DISTRIBUTION SYSTEMS

1 Purpose

1.1 This guide defines components of Bulk Chemical Distribution Systems and sets forth Basic Design Elements and optional design features common to BCD Systems.

2 Scope

2.1 This guide applies to BCD Systems used in semiconductor manufacturing facilities for supplying liquid chemicals to wafer cleaning and other manufacturing processes.

3 Limitations

3.1 This guide is not intended to be applicable to every possible use and type of chemical dispensing system but only to those systems that originate with sources of single lots of liquid materials of 55 gallons or more, and which operate in a way that splits a single liquid stream into multiple streams. This guide excludes slurry systems, small liquid chemical dispensing systems, chemical waste systems, and many other types of systems that dispense fluids.

3.2 This guide excludes construction protocols for BCD Systems, such as clean manufacturing practices, integrity of fabrication, and prequalification of materials.

3.3 This guide does not intend to cover all the important safety considerations which relate to Bulk Chemical Distribution Systems.

3.4 References to "containers" in this document are not limited to "Bulk Containers" as defined in the Code of Federal Regulations (CFR) Section 49 or Department of Transportation (DOT) Regulations.

4 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

5 Terminology

5.1 *Acronyms*

5.1.1 *CDM* — Chemical Dispensing Module

5.1.2 *CDU* — Chemical Dispensing Unit

5.1.3 *DIW* — Deionized Water

5.1.4 *MDU* — Modular Dispensing Unit

5.2 *Definitions*

5.2.1 *blending* — Combination of two or more chemicals to create a mixture which contains a desired ratio of constituents.

5.2.2 *chemical dispense system* — The module used for filtering and for dispensing chemical into the distribution piping network which may be referred to by a number of manufacturer's specific designations: CDM, CDU, and MDU.

5.2.3 *chemical reprocessing unit* — A subsystem which purifies or recycles a chemical.

5.2.4 *chemical transfer* — The technique used to move chemical between different points in the distribution system.

5.2.4.1 *pressurization* — The use of high purity nitrogen or other appropriate gas to displace liquid through the distribution system.

5.2.4.2 *pumping* — A mechanical or pneumatically operated technique used to create hydraulic force in the system.

5.2.4.3 *hybrid system* — A combination of pressurization and pumping techniques used to transfer chemical.

5.2.5 *day tank* — A vessel that stores that amount of chemical which may be consumed within one or more days. This holding vessel usually stores prefiltered

1 Department of Transportation, 400 Seventh Street, SW, Washington, D.C. 20590

2 United States Government Printing Office, Washington, D.C. 20402

chemical until it is transferred to the manufacturing process.

5.2.6 *decontamination* — Cleaning up of a BCD System, or any subsystems thereof, by introducing chemical solutions into the piping systems. This procedure occurs during qualification and prior to commissioning the system.

5.2.7 *dilution* — Combination of a concentrated chemical and DIW to create a lower concentration of the aqueous chemical.

5.2.8 *on-site gas-to-chemical generation* — The contacting of a liquid and gas phase to create a stable liquid solution. The chemical is generated on-site in a form suitable for distribution through a dispense system.

5.2.9 *pickling* — Conditioning of the system by filling it with the actual chemical or another chemical for which the system is designed. This chemical will stay in the system for a specified period of time. The purpose of this conditioning is to leach out impurities prior to actually using any chemical in the manufacturing process.

5.2.10 *polishing* — The process of flowing chemical through a filter one or more times to reduce the particulate levels of the chemical.

5.2.11 *primary containment* — Tubing, piping, or components whose wetted surface is directly in contact with the chemical. These components are generally made from fluoropolymer materials such as Perfluoroalkoxy (PFA).

5.2.12 *secondary containment* — Tubing or piping which contains the primary piping or tubing. The purpose of this configuration is to control leaks and to protect against spills. Secondary containment of solvent systems generally uses stainless steel material, and acid or base systems generally use Schedule 40 Polyvinylchloride (PVC) material boxes such as VMB. This may also be used as secondary containment.

5.2.13 *stabilized filtration* — A design feature that provides for the continuous flow of chemical through filters to minimize shocking and pulsating of the filters.

5.2.14 *surge suppression* — Use of a device or in-line chamber that minimizes flow pulsations caused by a pump. This may also be referred to as pulsation dampener.

5.2.15 *valve manifold box (VMB)* — A chemical-resistant enclosure which houses manual and/or pnuematically actuated valves, tees, and fittings.

5.2.16 *vessel* — A vessel fabricated from or containing an inner lining of chemically inert and resistant materials which is specifically designed to maintain the purity level of the chemical for a long period of time. All containers are fabricated from or at least contain an inner lining of chemically inert and resistant materials and are specifically designed to maintain the purity level of the chemical for long periods of time. The larger containers are generally designed in conformance to Department of Transportation Regulations (DOT) and may be transported by ground. These containers have fittings which are compatible to this purpose so that they may be hooked up to the BCD Systems directly. Such containers include:

5.2.16.1 *drum* — A container for storing chemicals, generally with a cylindrical shape and not more than 55 gallons or 200 liters in size.

5.2.16.2 *tote* — A container for storing chemicals, generally 110, 220, or 330 gallons in size and requiring an outer shell to provide structural support to the vessel.

5.2.16.3 *ISO container* — A container for storing chemicals, usually large in size, able to be transported directly, and designed in compliance with criteria from the International Standards Organization.

5.2.17 *wetted surface* — Any surface which comes into contact with the chemical.

6 General Requirements

6.1 *Materials* — Components of the BCD Systems must be appropriate to the application and conform to electrical, mechanical, and chemical requirements as defined by the physical installation environment, local and national code interpretations, process requirements, and delivery specifications.

6.2 *System Installation* — The Bulk Chemical Distribution System is installed according to a protocol which ensures mechanical integrity, leakproof operation, and minimal contamination to any liquids being distributed throughout the system.

6.2.1 System Installation procedures include a rinsedown protocol which may include any of the following: (1) a flushing procedure with DIW; (2) a sanitization step using hydrogen peroxide; (3) a drying step using nitrogen gas; and (4) a “pickling” process using the actual chemical, or a less concentrated form of the chemical. For solvent systems, the rinse-down chemicals introduced are generally the same as the solvent that is designated to be used in the system, whereas for acid systems, the rinse down solutions may include DIW, ozonated water, or a dilute form of hydrogen peroxide.

6.2.2 The protocol for System Installation and start-up follows a predefined sequence of events which incorporates all of the physical activities and testing parameters and establishes check points for approvals at each stage.

6.3 *Acceptance Tests* — Acceptance tests are conducted on each subsystem or system produced. They are the basis for acceptance or rejection by the purchaser.

6.3.1 Acceptance testing may include performance demonstrations, demonstration of reliability criteria, and achievement of purity standards. Safety considerations are addressed elsewhere.

6.4 *Qualification Testing* — Qualification testing is performed on the liquid chemicals being transported through each chemical piping subsystem.

6.4.1 Qualification testing may include tests for trace metals, anions, particles, and total organic carbon. Assay analysis is recommended for blending or dilution operations.

6.5 *Chemical Specifications* — Particulate BCD Systems are specified as to the level of impurities at the point of use as compared to the quality of the incoming chemical. Impurities in the chemical are generally specified in terms of particles per ml; metallic impurities are specified for each element and for total adders; and organic impurities are specified for total added.

7 Basic Design Elements

7.1 *General* — Each Bulk Chemical Distribution System contains certain basic components and a variety of design options to meet particular customer and facility needs. A simple example system is shown in Figure 1.

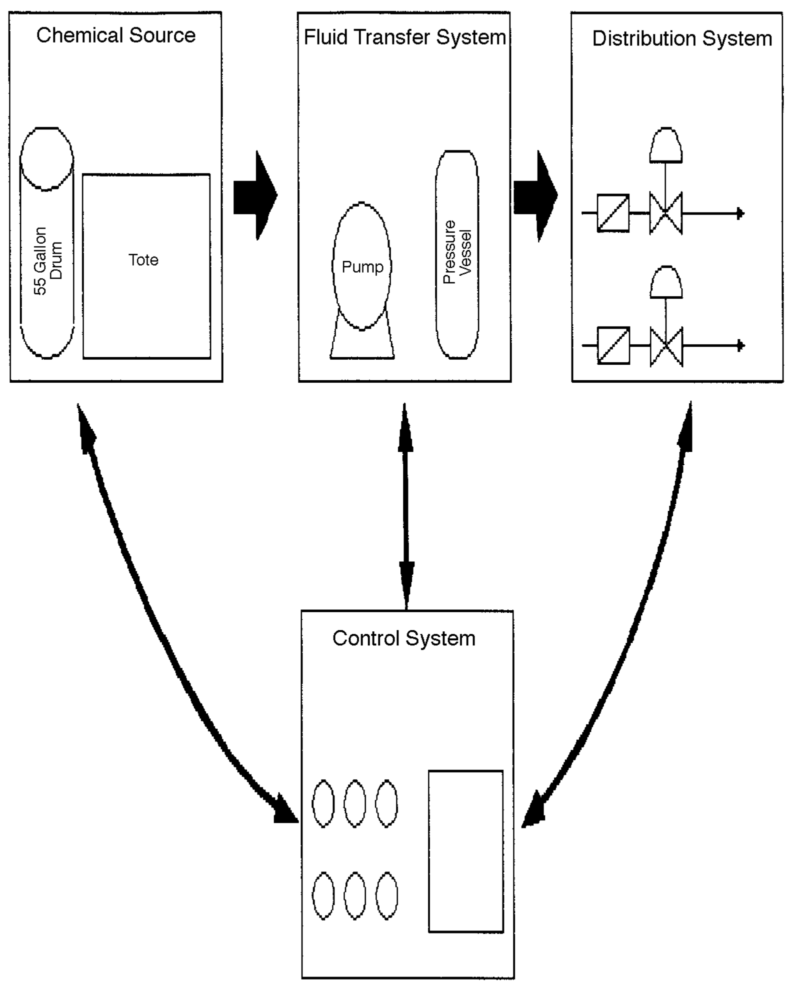

Figure 1
Schematic of Basic Bulk Chemical Distribution System

7.2 *Source* — The source of all fluids for incoming Bulk Chemical Distribution Systems is a container suitable for holding reactive chemicals in a size 55 gallons or greater, which may include drums, totes, vessels, or ISO containers.

7.3 *Fluid Transfer* — Fluids in the Bulk Chemical Distribution Systems are transported through pipes using either a pumping system, a pressure differential system, or some combination of the two types of basic systems. All fluids are transported in secondary containment piping systems for safety reasons.

7.4 *Distribution* — The transfer is made from the source by means of certain types of mechanisms, usually through one or more valve manifold boxes, that direct the fluid to a point of use, to subordinate levels of distribution, and/or to a day tank.

7.5 *Control Systems* — Manual and/or automated mechanical, pneumatic, hydraulic, optical, and electronic systems control the movement of the liquids. This includes the volume, flow rate, pressure, start-up, and shut-off.

8 Optional Design Features

8.1 *Polishing* — BCD Systems may be designed with the possibility of chemical recirculation (1) from the incoming source and back, to polish the incoming chemical; (2) from the day tank and back for further polishing or timed recirculation if activity is limited; and (3) fabwide in continuous recirculation.

8.2 *Filtration* — Chemicals in the system may be recirculated through filters placed on-line in the system. The relevant design issues include types of filters, efficiency, useful lifetime, qualification, filter bleed, removal, and replacement.

8.3 *Day Tank* — The vessel that generally stores a limited amount of chemical volume generally equivalent to that used in about one day of operation. This holding vessel usually stores prefiltered chemical before it is transferred to the manufacturing process.

8.4 *Blending* — Certain chemicals in distribution are blended together for use in the semiconductor manufacturing process. For example, Buffered Oxide Etchant is a blend of Hydrofluoric Acid and Ammonium Fluoride and may be sourced as two separate chemicals and blended together in the correct concentrations within the BCD Systems.

8.5 *Dilution* — Certain chemicals used in the semiconductor manufacturing process require various concentrations, depending on the process used at a particular point in the system. For example, 49% Hydrofluoric Acid is brought in as the source chemical and then mixed with DIW in a blend unit to achieve various concentrations of 10:1, 100:1, etc., depending on the requirements of the manufacturing process.

8.6 *Automated Control Systems* — Electronic systems may be programmed to control system parameters such as volume, pressure, fill rate, flow, drain times, maintenance diagnostics, purge cycles, recirculation, and bypass.

8.7 *Sampling Ports* — Sampling ports may be incorporated into the system to facilitate chemical sampling for qualification and monitoring programs.

8.8 *On-Site Chemical Generation* — Liquid chemicals, such as Ammonium Hydroxide, may be generated on-site at the required concentration from a clean Ammonia gas source and DIW to the required concentration. Generally, this activity is done in a location apart from the dispense room. The resulting chemical is used as a source for the distribution system.

8.9 *Reprocessing* — Integrated with the general chemical distribution system may be a chemical reprocessing unit which purifies or recycles a chemical such as sulfuric acid, isopropanol, or hydrofluoric acid. Such a system enables the chemical to reenter the system as a clean source of material for manufacturing processing.

8.10 *Stabilized Filtration* — Some systems include a design feature that provides for the continuous flow of chemical over filters to minimize shocking and pulsating of the filters.

8.11 *Surge Suppression* — Some systems include a device or in-line chamber that minimizes hydraulic forces caused by a pump. This option may also be referred to as pulsation dampener.

9 Monitoring and Maintenance of Systems

9.1 *General Considerations* — Bulk Chemical Distribution Systems may require a significant level of maintenance and monitoring to determine that specifications and performance are initially and continually met.

9.2 *Functional Management System* — The entire dispense system can be monitored by means of PC/PLC/ or any hybrid system, recording events as they occur and alerting operators as necessary to take corrective action. Monitoring systems may include a variety of operational parameters:

9.2.1 on-line real-time monitoring of all chemical dispense units

9.2.2 status of components and subsystems

9.2.3 events logging

9.2.4 data management

9.2.5 reliability parameters, including lead detection

9.2.6 chemical usage

9.2.7 display of dispense systems

9.2.8 communication gateway to the factory alarm system

9.2.9 on-line documentation

9.2.10 predictive maintenance planning

9.2.11 chemical interruptions to the fab by location, indicating location of fault.

9.3 *Maintenance* — Maintenance of the BCD Systems includes routine and preventative maintenance of pumps, filters, valves, and other components.

9.4 *Monitoring Programs* — Each BCD System should be monitored to determine if liquid chemicals delivered to the tools for use in the manufacturing process continually meet specifications and are within initial and ongoing established process control limits.

9.4.1 Monitoring programs may include periodic testing of the liquid chemicals to determine levels of particles, trace metals assay, and other parameters of interest. Certain tests may be done continuously on-line (e.g., particles), and other analytical tests are performed periodically from samples taken at various points in the system.

SEMI F32-0998
TEST METHOD FOR DETERMINATION OF FLOW COEFFICIENT FOR HIGH PURITY SHUTOFF VALVES

1 Purpose

1.1 This test method describes how to determine two criteria used in selecting valves of appropriate size for gases and liquids.

1.2 Methods and equations are specified and/or referenced to assist in accurate calculation of pressure drops across valves tested by this method.

2 Scope

2.1 This method establishes the testing criteria for determination of two coefficients specified in ANSI/ISA-S75.02:

- Valve flow coefficient (C_v)
- Critical pressure drop ratio factor (x_T)

2.2 This method is to be used with ANSI/ISA-S75.02. This method applies to manual and actuated valves for use in both gas and liquid distribution systems used in semiconductor manufacturing facilities. It is a test method, where existing test methods are referenced and limitations are imposed on test conditions. Specific equations for calculating flow coefficients, choked flow parameters, and pressure drops are referenced to the appropriate ISA section.

3 Limitations

3.1 This method will limit the use and interpretation of ANSI/ISA-S75.02 for use by manufacturers and users of valves designed for the semiconductor industry.

3.2 This method is not intended to be used to determine flow coefficients for valves used in vacuum service.

ANSI/ISA-S-75.01 — Flow Equations for Sizing Control Valves

ANSI/ISA-S75.02 — Control Valve Capacity Test Procedure

5 Terminology

5.1 *Acronyms*

5.1.1 ΔP — Pressure drop across valve, kPa (psi).

5.1.2 F_k — Ratio of specific heats factor, where:

$$F_k = \frac{k}{1.40}$$

5.1.3 F_L — Liquid pressure recovery factor

$$F_L = \frac{Q_{\max\, m^3/h}}{0.0865 * C_v * \sqrt{\dfrac{P_{1\,kPa} - 0.96 * P_{v\,kPa}}{S_f}}}$$

$$F_L = \frac{Q_{\max\, gpm}}{1.00 * C_v * \sqrt{\dfrac{P_{1\,psia} - 0.96 * P_{v\,psia}}{S_f}}}$$

5.1.4 *gpm* — Gallons per minute

5.1.5 *k* — Specific heat ratio

5.1.6 P_1 — Absolute pressure at upstream pressure tap, kPa (psi).

5.1.7 P_2 — Absolute pressure at downstream pressure tap, kPa (psi).

5.1.8 P_v — Absolute vapor pressure of liquid at inlet temperature, kPa (psi).

5.1.9 *psia* — Pounds per square inch absolute

5.1.10 *psid* — Pounds per square inch differential

5.1.11 *Q* — Volumetric flow rate

5.1.12 Q_{max} — Maximum flow rate (choked flow conditions) at a given upstream condition.

5.1.13 *scfh* — Standard cubic feet per hour

5.1.14 S_f — Specific gravity of a liquid relative to water.

5.1.15 S_g — Specific gravity of a gas relative to air.

5.1.16 *T* — Absolute temperature of test gas or liquid, °K (°R).

1 American National Standards Institute, 11 West 42nd St., New York, NY 10036, Telephone: 212.642.4900, Fax: 212.398.0023

5.1.17 x — Ratio of pressure drop to absolute inlet pressure, dimensionless, where:

$$x = \frac{\Delta P_{kPa}}{P_{1_{kPa}}} \mid x = \frac{\Delta P_{psid}}{P_{1_{psia}}} \mid$$

5.1.18 x_T — Ratio of pressure drop to absolute inlet pressure ($\Delta p/p_1$) at choked flow condition, dimensionless.

5.1.19 Y — Expansion factor for compressible fluids, where:

$$Y = 1 - \frac{x}{3 \times F_k \times x_T}$$

5.2 *Definitions*

5.2.1 *flow coefficient* C_v — A numeric constant used to characterize the flow capacity of a valve.

5.2.2 *vapor pressure condensation point* — Pressure at which fluid phase changes from liquid to gas, for a given upstream condition.

5.2.3 *vena contracta* — Point in a duct where the diameter of the fluid stream is smaller than the diameter of the duct.

6 Test Fluids

6.1 *Incompressible (Liquid) Fluid* — Water is the standard liquid test fluid.

6.2 *Compressible (Gaseous) Fluid* — Nitrogen is the standard gaseous test fluid. When using Nitrogen, care should be taken to assure that the fluid does not approach the vapor pressure condensation point at the vena contracta.

7 Test Setup

7.1 *Test Valve*

7.1.1 The test valve can be any high purity valve, or a combination of valve with tube connections, fittings connection, or expanders which are normally attached as part of the valve assembly as purchased. It is important to note that the definition of the "test valve" is inclusive of all connections and fittings, as supplied by the manufacturer. This specifically differs from the ISA procedure, whereby a method is provided to differentiate the pressure drop contribution of the attached fittings. It is recognized that flow coefficients may vary slightly depending upon the end connection used. Examples of typical test valves are shown in Figure 1.

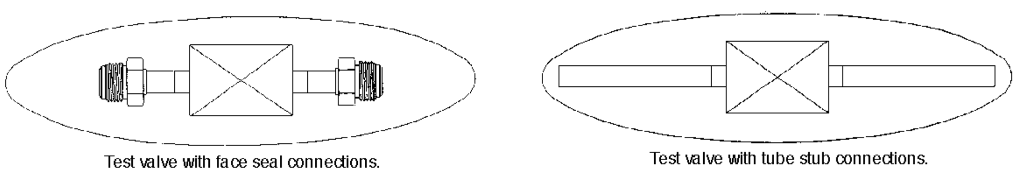

Figure 1
Test Valve with Various Connections

7.2 *Test Section Requirements*

7.2.1 Fixturing of the test valve shall be made in accordance with ANSI/ISA-S75.02, Table 1, where the test valve is the complete valve assembly including connections, as described above. For reference, ANSI/ISA-S75.02 test setup is shown in Figure 2.

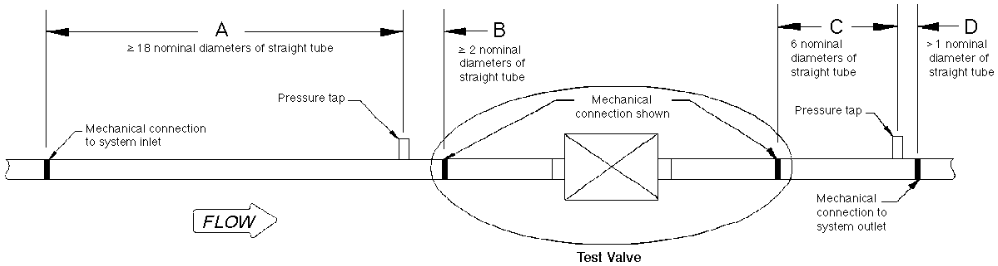

Figure 2
Fixturing Requirements, Standard Test Section

7.2.2 *Tube Connections* — Connections to the test valve are to be the same as would normally be performed by the end user as installed. Tube connections are to be full penetration welded by automatic orbital head, with purge gas.

7.2.3 *Face Seal Connections* — Face seal connectors supplied with the test valve may be either male or female. An appropriate mating connector shall be welded into the inlet and outlet tubing using full penetration orbital head welds, and connected to the valve with standard seals.

7.2.4 *Compression Fitting Connections* — Valves supplied with tube stubs may be connected with compression fittings.

8 Test Procedure

8.1 *Setup* — The test setup shall be as shown in ANSI/ISA-S75.02, Section 3.1. For reference, see Figure 3. The flowmeter may be upstream or downstream of the test valve, and can also be placed downstream of the throttle valve when necessary to vent to atmosphere.

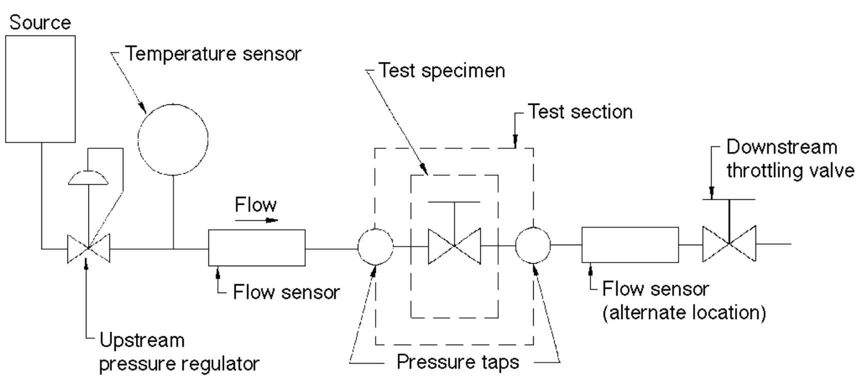

Figure 3
Test Setup

8.1.1 *Pressure Taps* — Pressure taps should be welded into the system per ANSI/ISA-S75.02.

8.1.2 *Pressure Measurement* — Pressure measurement devices can be analog gauge, electronic transducer, or both. They should be calibrated to maintain the minimum accuracy necessary for the governing flow equations.

8.1.3 *Throttle Valve(s)* — A throttle valve shall be positioned downstream. There is no valve style restriction, however they should be sized sufficiently for the required flowrate.

8.1.4 *Flow Measurement* — Depending upon the test media, several types of flow measurement devices may be used. These devices may include: turbine meter, orifice plate, bell prover, mass flow meter, and timed volumetric capture. Flow measurement devices should be calibrated to maintain the minimum accuracy necessary for the governing flow equations. All flow measurements should be normalized to standard conditions per ANSI 2530. Install and calibrate per manufacturer's recommended procedure.

8.1.5 *Temperature Measurement* — Temperature measurement devices should be calibrated to maintain the minimum accuracy necessary for the governing flow equations.

8.2 *Incompressible Fluid*

8.2.1 *Procedure*

8.2.1.1 The test procedure is specified in ANSI/ISA-S75.02, Section 5.1.

8.2.2 *Test Limitations*

8.2.2.1 It is critical that the absolute upstream pressure meets the criteria specified in ANSI/ISA-S75.02, paragraph 5.1.3, as referenced below:

$$P_{1_{kPa}} = \frac{2 \times \Delta P_{kPa}}{F_L^{\,2}} \mid P_{1psia} = \frac{2 \times \Delta P_{psid}}{F_L^{\,2}} \mid$$

Equation 1
Absolute Upstream Pressure

8.2.2.2 The liquid pressure recovery factor, F_L is calculated from the maximum attainable flowrate, Q_{max}. If Q_{max} cannot be experimentally determined, the value of F_L can be estimated. See the referenced section for details.

8.3 *Compressible Fluid*

8.3.1 *Procedure*

8.3.1.1 The test procedure is specified in ANSI/ISA-S75.02, paragraph 7.1.

8.3.2 *Test Limitations*

8.3.2.1 If possible, at least 3 data points should be taken at flowrates where the fluid approaches incompressible behavior. To attain these conditions, the pressure drop ratio, x, should be less than or equal to 0.02. Additional data points should be taken at increasing flowrates up to the maximum possible for the system.

9 Coefficients Calculation

9.1 *Flow Coefficient, C_v*

9.1.1 The flow coefficient, C_v, can be calculated using both incompressible and compressible fluids. For incompressible fluids, ISA provides a relatively simple method for determining C_v. For compressible fluids, the ISA test method for calculating C_v requires the determination of the choked flow pressure drop ratio, x_T,, and ultimately the expansion factor, Y, which characterizes the valve geometry and fluid properties at sonic velocities in the vena contracta. It has been determined through considerable testing that the expansion factor is critical in calculating actual pressure drops across a valve when flow rates cause the fluid density to change due to pressure and velocity changes.

9.2 *Pressure Drop Ratio Factor, x_T*

9.2.1 The ISA test method requires the experimental determination of the flow coefficient C_v and a second coefficient x_T, the pressure drop ratio factor.

9.2.2 x_T is equal to the critical pressure ratio of the ISA flow equation, and is close but not necessarily identical to the experimentally observed pressure ratio at choked flow. x_T is chosen to correlate the experimentally observed choked flow. The ISA equation will then predict choking at a pressure drop ratio close to, but not identical with, the experimentally observed value.

9.2.3 There are two methods to determine the pressure drop ratio factor. The procedure of ANSI/ISA-S75.02, Section 7.2 requires that C_v be determined at values of x less than 0.02, and that choking actually be achieved to determine x_T. The alternate procedure of paragraph 7.3 does not actually require choked flow and uses all the data points to determine C_v, not just a few points at a small value of x.

9.2.4 In practice, valves used in the semiconductor manufacturing facility, when connected as described above, may not be able to achieve choked flow across the pressure taps provided by this procedure. This will happen when choked flow occurs first in some other part of the test setup or connections. However, the alternative test procedure of ANSI/ISA-S75.02, Section 7.3 will give the correct values of C_v and x_T in this case.

9.2.5 The ISA alternative method determines the pressure drop ratio factor by measuring flowrate vs.

pressure ratio, and analyzes the data to compute the choked flow pressure drop ratio, x_T. This method has been found, through exhaustive testing, to be a very accurate and reliable method to determine the expansion factor, without having to achieve choked flow in the test valve itself.

10 Pressure Drop Calculation

10.1 The determination of both flow coefficient and expansion factor are critical in calculating the pressure drop across a valve flowing compressible fluid. Use of the flow coefficient C_v only, will yield a pressure drop which is lower than the actual value.

10.1.1 *Incompressible Flow*

10.1.1.1 To calculate pressure drop across a valve flowing an incompressible media, only the C_v coefficient must be provided by the valve manufacturer. The following equation has been derived from ANSI/ISA-S75.01, Section 4.1, and should be used for pressure drop computations:

$$\Delta P_{kPa} = 0.0865 * \left(\frac{Q_{m^3/hr}}{C_v} \right)^2 \times S_f$$

$$\left(\Delta P_{psid} = \left(\frac{Q_{gpm}}{C_v} \right)^2 \times S_f \right)$$

Equation 2
Pressure Drop for Incompressible Flow

10.1.2 *Compressible Flow*

10.1.2.1 To calculate pressure drop across a valve flowing a compressible media, both C_v and x_T coefficients may be used to determine more accurately the pressure drop. Contact the valve manufacturer for values of C_V and x_T coefficients. Equation 3 has been derived from ANSI/ISA-S75.01, Section 6.1, and should be used for pressure drop computations. Equation 4 is a close approximation of Equation 3 that computes pressure drop directly.

$$\Delta P_{kPa} = \left(\frac{Q_{m^3/hr}}{4.17 \times C_v \times Y \times P_{1kPa}} \right)^2 \times S_g \times T_{\circ K} \times P_{1_{KPa}}$$

$$\left(\Delta P_{psid} = \left(\frac{Q_{scfh}}{1360 \times C_v \times Y \times P_{1_{psia}}} \right)^2 \times S_g \times T_{\circ R} \times P_{1_{psia}} \right)$$

Equation 3
Pressure Drop for Compressible Flow – ISA Iterative Solution

$$\Delta P = \frac{P_{1_{kPa}} \times x_T}{1.125} \left[1 - \sqrt{1 - \frac{1.125}{x_T} \left(\frac{S_g \times Q_{m^3/hr}}{3905.6 \times C_v \times P_{1_{kPa}}} \sqrt{\frac{T_{\circ K}}{S_g}} \right)^2} \right]$$

$$\left(\Delta P = \frac{P_{1_{psia}} \times x_T}{1.125} \left[1 - \sqrt{1 - \frac{1.125}{x_T} \left(\frac{S_g \times Q_{scfm}}{16.04 \times C_v \times P_{1_{psia}}} \sqrt{\frac{T_{\circ R}}{S_g}} \right)^2} \right] \right)$$

Equation 4
Pressure Drop for Compressible Flow – Non-Iterative Solution

NOTE: The numerical value of x used in these equations must not exceed the choking limit (x_T) regardless of the actual value of x.

SEMI F33-0998
METHOD FOR CALIBRATION OF ATMOSPHERIC PRESSURE IONIZATION MASS SPECTROMETER (APIMS)

1 Purpose

1.1 This test method may provide guidelines for the calibration of the APIMS for measurement of impurities in nitrogen, argon, helium and hydrogen. APIMS is currently the technique of choice for measurements of low level impurities in gas distribution systems and components because it is essentially the only commercially available method capable of ppt impurity analysis and it has a superior response time. This method may provide guidelines for application of other techniques with similar detection limits and response time to APIMS which are not commercially available at this time.

2 Scope

2.1 This method applies to the analyte calibration of the APIMS for a target impurity range of 100 ppt to as high as 100 ppb impurity range. The actual calibration range should bracket the impurity measurement range of interest, dependent upon the measurement to be conducted. Anything else is outside the range of the calibration.

3 Limitations

3.1 The actual range of calibration will depend upon the type of APIMS used. Counting detection electronics will saturate in the 200,000 CPS to 1,000,000 CPS range, depending upon the make and model. Counting detection will have to use different ions in different concentration regions, depending upon the impurity. The actual calibration procedure will be different for APIMS using analog detection versus counting detection. Interference between impurities can cause limitation in measurements in the presence of multiple impurity species.

5.1.7 *ppt* — Molar parts per trillion (pimole/mole). The same as pptv.

5.1.8 R^2 — The statistic described by the ratio of the sum of squares of the regression divided by the total sum of the squares.

5.2 *Definitions*

5.2.1 *zero gas* — Nitrogen, argon, helium or hydrogen with an estimated level an order of magnitude, or more, lower than the lowest calibration point for each impurity of interest.

6 Summary of Method

6.1 The calibration of the APIMS is conducted by adding known concentrations of impurities to a zero gas and measuring the corresponding ion intensities. A calibration response factor can be determined by regression analysis.

7 Interferences

7.1 It is essential to confirm that the mass chosen is indeed representative of the species of interest and that other commonly present impurities do not contribute at the same mass. For example: the intensity of the peak at m/z = 29 correlates with the concentration of H_2 in N_2, because of the N_2H^+ formation. However, spurious signal at this peak can arise in two different ways:

(i) Contributions of other ions of the same mass, such as $N^{14}N^{15+}$ or $C_2H_5^+$.

(ii) Contributions of the same ion from different parent species, i.e., N_2H^+ due to recombination of matrix gas nitrogen with fragments of H_2O, CH_4, etc. Before using m/z = 29 as a measure of H_2 in N_2, interference such as these must be understood. This also may apply to other ions.

7.2 High impurity levels can cause clustering with, or quenching of, the other impurity ions and affect the sensitivity of the APIMS for those impurities. This is especially true for impurity levels of 10 ppb and above.

8 Apparatus

8.1 *APIMS* — The APIMS used for impurity detection can be of any type.

8.2 *Impurity Standard* — Any device (either standard cylinder or permeation tube based or of any other type) that can reliably deliver impurity concentrations usually in the range of 100 ppb to 10 ppm with an accuracy of ± 5%. The standards should be traceable to an applicable national standard, such as NIST.

8.3 *Dynamic Dilution System* — A dilution system that can dilute the output gas of the impurity standard with a zero gas to produce a gas with impurity concentrations in the range of interest.

9 Reagents and Materials

9.1 Zero gas

9.2 Impurity standard

10 Safety Precautions

10.1 This method applies to calibration and measurement of impurities in nitrogen, argon, helium and hydrogen. This method does not address the additional safety precautions for APIMS calibration and impurity measurement in hydrogen gas.

11 Test Specimen

11.1 Not applicable.

12 Preparation of Apparatus

12.1 The impurity standard and zero gas should be connected to the dynamic dilution system, which is in turn connected to the inlet of the APIMS. The entire dilution system should be purged until all impurities have stabilized at a constant dilution system flow, for all components in the dilution system. The relative standard deviation for each analyte should be less than 10% for the past 12 hours before the calibration. Constant pressure and flow should be maintained to the APIMS ionization region at all time.

13 Calibration and Standardization

13.1 *Definition of an Impurity Standard* — An impurity “standard” is defined to be any device capable of delivering a flow of known impurity level gas at a controlled pressure. (See Section 8.2.)

13.2 *Examples of Standards* — Some examples of impurity standards and the principles upon which they are based are as follows:

13.2.1 *Cylinder Standards* — The “standard” will include a regulator specified for use with the cylinder. The impurity concentration can be calculated based on that added to the cylinder in preparation. A minimum use pressure must be specified.

13.2.2 Permeation and effusion tube standards. These must include purification means and some means of regulating the outlet pressure. The impurity delivery rate can be calculated based on the weight loss of the tube as a function of time.

13.2.3 Moisture standard methods based on saturation of gas with water vapor at a fixed temperature and pressure. The moisture concentration in the gas may then be calculated from a knowledge of the saturation vapor pressure of water over a plane of the pure phase of ice at the saturation temperature and of the interaction virial coefficients of the gas-vapor mixture. The two-pressure and two temperature methods are refinements of this approach requiring additional chambers whose temperature and pressure must be known.

13.3 *Dilution of Standards* — For all impurity generation methods, lower concentrations can be generated by dynamic dilution, i.e., by combining a known flow of the standard gas with a known flow of zero gas. A diluted standard is acceptable provided:

13.3.1 The zero gas should have an impurity level at least an order of magnitude below the stated level of the analysis (to be verified using the same flow path as during the subsequent analysis, and at the lowest flow rate actually used in the calibration).

13.3.2 The absolute accuracy of the dilution system components are verified by comparison with a reliable flow standard. The frequency of verification must take into account the transport of the instrument and other changes that will affect the dilution system.

13.3.3 The linearity of the dilution system can be demonstrated over the entire range of operation. This last criterion is particularly important whenever some portion of the combined flow is discarded, as mixing problems can easily arise at large dilution factors.

13.4 *Mass Calibration* — The mass scale of the mass spectrometer should be calibrated according to the manufacturer’s instructions over the mass range of interest.

13.4.1 The validity of the mass selected for each impurity must be confirmed (i) by demonstrating that the intensity at the mass increases monotomically with added concentration of the impurity species of interest and (ii) that other usually present impurity species do not make significant contributions to the intensity at that mass. Tables 1–4 list the typical masses for various species in argon, nitrogen, hydrogen and helium.

14 Procedure

14.1 Zero gas should be passed through the dilution system and the APIMS. Based on prior calibrations, the system should be below 100 ppt, or at least an order of magnitude lower than the lowest calibration point, for the impurities to be calibrated.

14.2 Prior to beginning the calibration, record all relevant parameters, such as discharge voltage, lens voltages, ionization chamber pressure and/or flow, gas type, etc.

14.3 The user should use the zero gas only, plus a minimum of 5 challenge concentrations, with a minimum of 5 data points, with the blended data points spanning the range of interest of impurity measurement, excluding the zero point, while maintaining constant flow to the APIMS. Allow each challenge concentration to stabilize for at least 15 minutes, and the signal variation should be less than 3% before taking data points at that concentration. Record the relevant ion intensities as a function of time, for each stabilized concentration.

14.4 Once the linearity of the calibration has been established, a single point calibration check is permitted, as long as the accuracy of the dilution system is confirmed.

15 Calculations or Interpretation of Results

15.1 Perform a regression analysis for the individual ion intensities against the impurity concentration. Be sure to use only ion intensities below the saturation region of your APIMS ion counting electronics, if using counting detection. (Ask the manufacturer for the saturation region of the units counting electronics.) The R^2 from the fit of all the regression coefficients should be 0.98 or above. If this is not the case, the calibration will have to be repeated as described in the previous section.

16 Reporting Results

16.1 As a minimum, the calibration will include the following information for each impurity:

$$y = c_0 + c_1 * x \quad (1)$$

where,

y is the ion intensity, c_0 is ion intensity background, c_1 is the linear response factor, and x is the impurity level.

16.2 As an option, a quadratic regression may be reported for the calibration, and will include the following information for each impurity:

$$y = c_0 + c_1 * x + c_2 * x^2 \quad (2)$$

where,

y is the ion intensity, c_0 is ion intensity background, c_1 is the first order response factor, c_2 is the second order response factor and x is the impurity level.

The c_0/c_1 ratio or negative x - intercept is useful to define the background concentration of each particular ion. All regression coefficients should be reported.

17 Precision and Accuracy

17.1 This method does not explicitly consider the estimation of the accuracy of the impurity standard in detail, because such a calculation can be made by applying procedures described elsewhere. The precision and accuracy required in validation will vary with the proposed application and may be left to the discretion of the user of the method. If an accuracy statement is given, then a propagation of error calculation must be provided to estimate the accuracy of the validation.

SEMI F34-0998
GUIDE FOR LIQUID CHEMICAL PIPE LABELING

1 Purpose

1.1 This document establishes a recommended scheme for labeling liquid process chemical piping systems used in semiconductor manufacturing facilities and equipment.

1.2 consistent labeling system facilitates rapid identification of piping contents and avoids confusion within the industry by eliminating the need for each company or locality to develop their own guides.

2 Scope

2.1 This guide applies to components typically found in a liquid process chemical piping system for semiconductor manufacturing processes. The following list of included components is not exhaustive:

- Piping
- Valves
- Filters
- Regulators
- Tubing

3 Limitations

3.1 This guide does not replace or supersede any labeling or identification requirements established by local, state, or national authorities. Local laws and regulations should be reviewed to ensure compliance.

3.2 This guide does not apply to containers regulated by the United States Department of Transportation (DOT), International Air Transport Association (IATA) or other regulatory bodies.

3.3 This guide was prepared to address piping systems conveying liquid process chemicals located within semiconductor facilities. See Sections 6.6 and 6.11 for application inside equipment.

4 Referenced Documents

NOTE: All documents cited should be the latest published versions.

4.1 *ANSI Document*[1]

ANSI/ASME A13.1 — Scheme for the Identification of Piping Systems

5 Terminology

5.1 *liquid chemical distribution system* — The collection of components and subsystems used to control and deliver liquid process chemicals from a source location to a point of use in a semiconductor manufacturing facility.

6 Recommendations

6.1 Piping system labels and identification, should be designed, and implemented in accordance with the following recommendations.

6.2 The following color schemes should be used to identify all liquid process chemical piping systems. When a chemical has characteristics of more than one category, the color scheme should be determined by the most significant health or safety hazard of the chemical.

6.3 Background colors may be applied to the piping by using pigments, paints, or other means acceptable to the owner; or may be applied as the background color for labels or tags used to identify the contents of the piping system.

6.4 Primary label information consists of the name of the material contained in the piping system; spelled out in the predominant language of the country or region where the piping system is used. Additional languages may be used to supplement the primary language.

1 American National Standards Institute, 11 West 42nd Street, 13th floor, New York, NY 10036, USA, Telephone:+ 1.212.642.4900, Telefax:+ 1.212.398.0023, E-mail: info@ansi.org, WWW: http://www.ansi.org/

Table 1 Piping and Label Color Codes

Chemical Category	*Background Color*	*Text Color*
Highly Toxic, Poisonous	Black	White
Flammable, Combustible, and Pyrophoric	Red	White
Acidic	Orange	Black
Basic (Caustic)	Magenta	White
Oxidizer	Yellow	Black
Non-Toxic, Non-Flammable,Low to Moderate Physical Hazard	Green	White

6.5 Additional information such as the chemical category, chemical formula, acronyms, hazard ratings, or other information may be added, provided that it does not interfere with the primary information required. A separate label may be used for the additional information.

6.6 The color field label length and lettering sizes shown in Table 2 should be used for all diameters of pipe and tubing. For pipe diameters smaller than 12.7 mm (0.5 inch), the label should be large enough to wrap at least half way around the pipe, and not obstruct the text. If labeling inside equipment, the size of the labels may be adjusted, provided they remain easily seen and readable. Consideration should be given to using tags instead of labels.

NOTE: Labeling sizes for piping 19 mm (0.75 inch) or larger in outside diameter were taken directly from ANSI A13.1. Smaller sizes were developed for this guide.

6.7 The height of the label should be at least two times (2×) the height of the text, with the text centered in the label. The label should allow a length of background color on each end of the text at least one half pipe diameter in length but not less than 12.7 mm (0.5 inch).

6.8 The orientation of text on the label should conform to local customs, conventions, or practices.

6.9 Directional flow arrows should be applied to all piping systems indicating the direction of material flow within the system. The arrow(s) should be included as part of the primary label but may be applied separately within close proximity to the primary label (e.g., less than 5 cm (2 inches) for pipe diameters up to 5 cm (2 inches); less than 15 cm for larger pipe diameters).

6.10 Labels should be applied to the piping system at the following minimum locations:

- On both sides of a barrier penetration (i.e., walls, floors, ceilings, equipment enclosures, etc.). The labels should be applied within 1 meter (3.3 feet) or as close as practical to the barrier.
- As close as practical to all changes in direction where the length of run in the new direction is 1 meter (3.3 feet) or greater. Where several directional changes are made within a short length of run, labels need not be applied at every change in direction, but should be applied at sufficient intervals to readily identify the piping.
- On long runs, the labels should be applied at intervals not exceeding 6 meters (20 feet). Shorter intervals should be used for small diameter pipe and where several pipes are run in close proximity.
- Where several pipes are run parallel to each other, the labeling for all pipes should be in line with each other (i.e., should not be staggered).
- A sufficient number of labels should be applied at each location to ensure that they can be readily seen and read from all viewing or approach direction(s).
- Each side of a “T” connection should be labeled within 1 meter (3.3 feet) of the “T”.

Table 2 Recommended Label and Text Sizes for Various Piping Diameters

Outside Diameter of Pipe or Covering		*Minimum Length of Label*		*Minimum Height of Letters*	
Millimeters	*Inches*	*Millimeters*	*Inches*	*Millimeters*	*Inches*
Less than 13	Less than 0.5	51	2	3	0.125
13–19	0.5–0.75	102	4	6	0.25
19–38	0.75–1.5	203	8	13	0.5
38–64	1.5–2.5	203	8	19	0.75
64–203	2.5–8	305	12	32	1.25
203–254	8–10	610	24	64	2.5
Over 254	Over 10	813	32	89	3.5

6.11 Where it is impractical to attach markings or labels directly to the pipe, a tag may be used. The tag should be durable for the environment in which it is used and should be securely attached to the piping system such that it cannot be easily removed or relocated from its installed position. The tag or tags should contain the same information as defined for labels in Sections 6.4 and 6.5. Standard color-coding for tags should be the same as defined for labels in Table 1. Tags should be installed at the same locations as required for other identification methods defined in Section 6.10.

SEMI F35-0998
TEST METHOD FOR ULTRA-HIGH PURITY GAS DISTRIBUTION SYSTEM INTEGRATION VERIFICATION USING NON-INVASIVE OXYGEN MEASUREMENT

NOTE: This document that was previously designated as SEMI E71 (Test Method for Ultra-High Purity Gas Distribution System Integration Verification Using Non-Invasive Oxygen Measurement) has been re-designated as SEMI F35.

1 Purpose

1.1 This test method defines a procedure to monitor the integrity of ultra-high purity (UHP) gas distribution systems by detecting the ingress of atmospheric oxygen. This test method would be used to evaluate an "active" UHP gas distribution system on a continuous basis by using *non-invasive* O_2 measurement, without requiring an interruption of the process tools using the UHP gases of interest.

1.2 This test method should be used to protect semiconductor fabrication processes using the UHP gases, which may be sensitive to contamination by any of the common atmospheric impurities, such as N_2, O_2, H_2O, CO_2, before product yield problems develop.

1.3 This is the first such test method that describes a noninvasive leak detection and locating procedure. It differs from SEMI F1, which is an invasive technique for identifying leak sources using a mass spectrometer and a helium tracer gas.

2 Scope

2.1 This test method applies to UHP gas distribution systems used in semiconductor manufacturing facilities and comparable research and development areas.

2.2 This test method applies to bulk gas distribution systems carrying UHP gases such as N_2, Ar, He, H_2, N_2O, SF_6, and many halocarbons. In most cases, O_2 is present only in ultra-low trace levels (typically less than 1.0 ppb).

2.3 This test method will provide real-time monitoring of UHP gas distribution systems, resulting in meaningful system integrity verification, atmospheric contaminant trending analysis, and leak locating.

2.4 This test method will provide the user with sufficient information to identify and troubleshoot sources of atmospheric leakage into the UHP gas distribution system.

2.5 This test method includes the specification of the required O_2 analytical equipment, standard methods for proper use of the O_2 analytical equipment, and manipulation of the O_2 data in identifying atmospheric leak sources.

3 Limitations

3.1 This test method will only be successful in identifying the presence and location of leaks from atmospheric air using O_2 as the tracer gas representative of all atmospheric air contaminants (i.e., N_2, O_2, H_2O, CO_2). There is no capability to identify cross-contaminant species between different UHP gases which only contain ultra-low trace levels of O_2 or outward leaks to atmosphere.

3.2 This test method will not focus specifically on the process of detecting the exact location of every possible atmospheric air leakage source. Rather, it will describe techniques and examples demonstrating how atmospheric air leaks can be reliably identified and located, in general.

3.3 Results from this test method may not ensure that other common atmospheric impurities (e.g., H_2O) are below their required specification limits after a leak has been identified, corrected, and O_2 levels have returned to normal. For example, since O_2 diffuses more quickly and has a weaker surface adsorption than H_2O, O_2 will be the first atmospheric impurity detected. However, H_2O will likely be the last atmospheric impurity to be purged out once a leak has been identified and repaired.

3.4 This test method is not a direct substitution for SEMI F1.

3.5 This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations before using this method.

4 Referenced Documents

4.1 *SEMI Standard*

SEMI F1 — Specification for Leak Integrity of HighPurity Gas Piping Systems and Components

5 Terminology

5.1 *atmospheric impurities* — The common impurities to UHP gases that are found in atmospheric air.

NOTE: Impurities such as N_2, O_2, H_2O, CO_2.

5.2 *contaminant signature* — Typical baseline performance of a specific sample point within a large distribution system with respect to its O_2 impurity concentration. This is considered to be a normal and acceptable impurity level.

5.3 *critical sample point* — Gas sample point which is monitored continuously because it is deemed in a critical location in the distribution system, or that which is most sensitive to causing product/process quality problems from the ingress of atmospheric air impurities.

5.4 *investigative sample point* — Gas sample point which is selected for spot checking analysis as part of an investigation to locate an atmospheric air leak source.

5.5 *low detectable limit* — Defined as the smallest level of O_2 measurement which can be quantified after performing a blank test on zero gas. For our purposes, this is determined to be 2 times the total peak-to-peak noise over 8 hours while the O_2 analyzer is sampling on zero gas.

5.6 *ppbv* — Parts per billion by volume.

5.7 *point of use* — The connection point where the gas distribution system connects to the process tool which uses the UHP gas.

5.8 *sensitivity* — Defined as the smallest detectable step change in O_2 that the analyzer is capable of sensing.

5.9 *ultra-high purity (UHP) gas distribution system* — Semiconductor fab gas delivery system which typically contains impurities from atmospheric air of < 0.2 ppb at the input source, and atmospheric impurities at the point-of-use of typically < 1 ppb.

5.10 *weekly zero drift* — Total analyzer drift while measuring zero gas over a 1-week time period. Includes all components of analyzer drift.

5.11 *zero gas* — Test gas which is known to contain less than 0.1 ppb of O_2 as an impurity.

6 Summary of Method

6.1 The user must identify critical sampling locations in the UHP gas distribution system. These points are either specific process tool points-of-use or key lateral branch lines, which must avoid atmospheric contamination, or representative of a critical purity zone containing process tools that are particularly sensitive to atmospheric contaminants.

6.2 Connect O_2 analysis equipment to these critical sample points for continuous monitoring.

6.3 Qualify the performance of the O_2 analysis equipment before collecting data.

6.4 Begin continuous monitoring of critical sample points. Identify typical or baseline “contaminant signature” performance of the UHP gas distribution system.

6.5 Use continuous trend data to identify problematic events (contaminant spikes) and/or significant changes from the “contaminant signature” performance level.

6.6 Use additional investigative sample point measurements (spot checks) along with observable correlations to gas distribution system usage to locate and correct atmospheric leak sources.

7 Interferences

7.1 While sampling from any point in the gas distribution system, it is critical that the sample be delivered to the O_2 analytical equipment without introducing additional atmospheric O_2. This could create significant errors in the analysis. Observing a higher O_2 reading after reducing the sample flow to the analyzer may be an indication that there is a leak between the sample point and the O_2 analysis equipment.

7.2 An O_2 analyzer may become inaccurate due to improper calibration or simply due to long-term analyzer drift. This will cause inaccurate O_2 readings which do not represent the true performance of the UHP gas distribution system. The O_2 analyzer must be operated per the manufacturer’s recommendation for calibration technique, calibration frequency, and other routine maintenance.

7.3 Some O_2 analytical methods have cross-sensitivity to other gaseous components which may be found in UHP gases (i.e., H_2, CO, CH_4, and other hydrocarbons).

8 Requirements

8.1 *Personnel Qualification* — Personnel performing these tests in accordance with this test method shall have suitable training and experience. Such personnel shall, as a minimum, be knowledgeable of:

8.1.1 The operation and calibration of the specific equipment used in performing this test.

8.1.2 The proper procedures in handling UHP gases as agreed upon by supplier and user.

8.1.3 The proper safety procedure in handling combustible or toxic gases as agreed upon by supplier and user.

8.1.4 The behavior of atmospheric leak sources relative to position, pressure/flow, and gas usage.

9 Apparatus

9.1 An analyzer must be selected which is capable of continuous ultra-low trace O_2 measurements, with the ability to report measurements with at least once per minute frequency.

9.2 The ultra-low trace O_2 analyzer shall meet or exceed the following specifications. These specifications are appropriately defined in Section 5:

Sensitivity	< 0.1 ppb
Low Detectable Limit	< 0.3 ppb
Weekly Zero Drift	< 0.5 ppb
Response Time	< 10 minutes for 90% of a 0–1 ppb O_2 step change

NOTE: The O_2 analysis must be conducted using an analytical method which meets or exceeds the specifications required by this test method. If not, the user will not be able to confidently distinguish true gas distribution system impurity trends from false analyzer trends.

10 Safety Precautions

10.1 This test method is not a replacement for safety regulations. It is the responsibility of the user to ensure that the UHP gas distribution systems under analysis comply with applicable safety regulations, as agreed to between gas supplier and user.

10.2 It is also the responsibility of the user to comply with applicable safety regulations governing the operation of the required O_2 analytical equipment, as specified by the analyzer manufacturer.

11 Identify Sample Point Locations

11.1 Identify the critical sample point locations in the UHP gas distribution system which allow for a continuous gauging of overall system integrity. These shall include, at a minimum:

11.1.1 An exit purity O_2 measurement of the UHP gas at the furthest point of the gas distribution system within the fab.

11.1.2 Sample point locations representing sub-sections of the UHP gas distribution system, which are deemed critical for the avoidance of atmospheric impurities.

11.1.3 Point-of-use process tool locations which are deemed critical for the avoidance of atmospheric impurities.

11.2 A source purity O_2 measurement of the UHP gas entering the gas distribution system is suggested to be used as a reference comparison against other points within the fab.

11.3 Additional investigative (spot check) O_2 measurements may be required at sample point locations which aid in deducing the location of suspected atmospheric leak sources. This will vary from situation to situation. (See Section 16.)

11.4 The exact sample tap location must be representative of the measurement point of interest. Avoid measurement of dead-leg locations.

12 Preparation of Sample Point Locations

12.1 Thoroughly pre-purge the sample point prior to connecting the O_2 analyzer.

12.2 Thoroughly cycle-purge any regulators or other components in the sample system. Cycle the pressure at least 20 times with a high/low pressure ratio of at least 5 times.

12.3 Connect the O_2 analyzer to the sample point using appropriate UHP gas lines and fittings. Avoid using long lengths of bellows-type tubing because of long purge-down requirements. Avoid using Teflon or plastic tubing of any kind. Teflon and most other plastics are extremely permeable to O_2 and will cause atmospheric O_2 leakage. Only a few feet of plastic tubing can introduce ppm levels of O_2.

12.4 Establish flow from the sample point to the O_2 analyzer per the manufacturer's recommendations.

13 Calibration and Qualification

13.1 Follow the manufacturer's recommendations for initial start-up and calibration of the O_2 analyzer.

13.2 After initial start-up and calibration, adhere to the manufacturer's recommendations for routine calibration and maintenance needed to achieve the required performance specification as described in Section 9.2.

13.3 There will be two modes of O_2 measurement:

13.3.1 *Critical Sample Point O_2 Measurement*

13.3.1.1 Applicable to O_2 measurements performed continuously on the critical sample point locations identified earlier.

13.3.1.2 Prior to continuous data collection use of the analyzer, validate it by demonstrating the capability required in the specification for Weekly Zero Drift. Chart the zero baseline drift and peak-to-peak noise while on zero gas for 1 week.

13.3.1.3 Re-validate the O_2 analyzer performance by running a 24-hour blank test on zero gas monthly.

13.3.2 *Investigative Sample Point O_2 Measurement*

13.3.2.1 Applicable to spot check O_2 measurements performed in the investigation of locating atmospheric leak sources.

13.3.2.2 The O_2 analyzer must be operated for a time period sufficient to establish the "contaminant signature" at the point of interest.

13.3.2.3 Validate the O_2 analyzer with a blank test prior to each use. Chart zero baseline drift over a period of time which is twice as long as the expected time required to make the O_2 measurement. If a measurement can typically be made successfully in less than one hour, then verify the zero drift and peak-topeak noise with a two-hour blank test.

14 Data Collection Procedure

14.1 Collect all O_2 measurement data at a minimum of 1 point/minute using a chart recorder or data acquisition device.

14.2 Graph data points with sufficient resolution to observe trends over a one-week period. The graph must also be able to resolve O_2 spikes which may last only 10–15 minutes.

15 Interpretation of Results

15.1 Generate graphs of the baseline "contaminant signature" for each critical sample point location. Compare the baseline "contaminant signature" with the O_2 analyzer's blank run on zero gas to validate that the analyzer is producing useful data. The base-line "contaminant signature" should exhibit equal or greater O_2 variation than the blank run on zero gas.

15.2 *Problem Identification*

15.2.1 Observe data from critical sample point locations and look for deviations (abnormal trends or events) from the baseline "contaminant signature".

15.2.2 Determine if deviations (observed trends or events) are sufficient to impede mandatory atmospheric impurity specifications or influence critical product/process quality.

15.2.2.1 If yes, proceed into Section 16.

15.2.2.2 If no, continue observing O_2 data from critical sample point locations.

16 Atmospheric Leak Locating Procedure

16.1 Familiarize yourself with Figure 1 before proceeding with the remainder of Section 16.

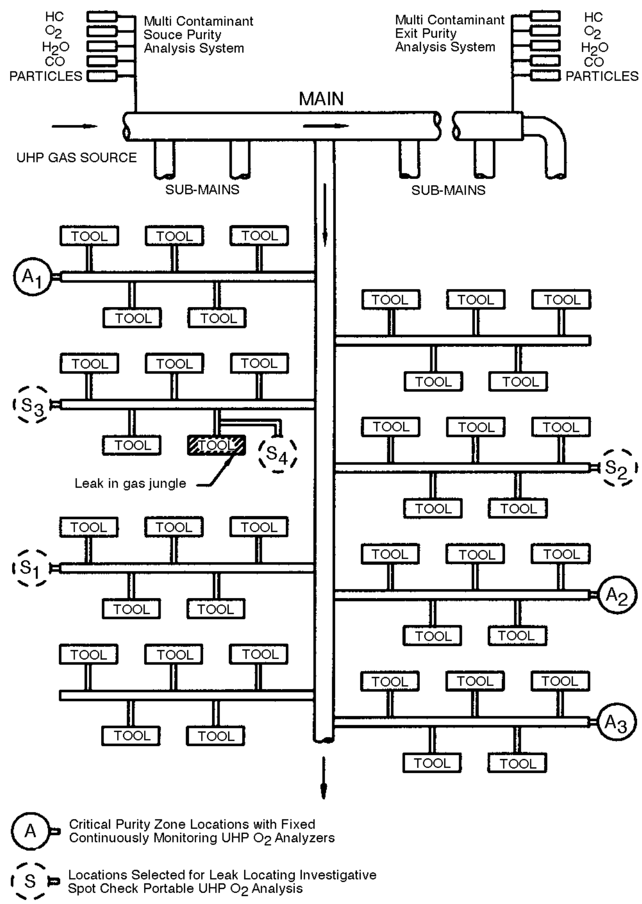

Figure 1
Typical Fab UHP Gas Distribution System

16.2 Isolate a zone where the contamination is likely to originate from by comparing the O_2 levels at the critical continuous monitoring sample point locations. Assume the leak source is somewhere between the last uncontaminated sample point and the first contaminated sample point going downstream. Some knowledge of the gas distribution flow path will be required here.

16.3 Compare the data from the O_2 analyzer detecting the contamination with pressure and flow data, or gas usage demand over time in the specific lateral of the gas distribution system where the O_2 analysis is being made.

16.4 Correlate the changes in O_2 readings which show abnormally high O_2 levels with specific tool cycles that cause the UHP gas pressure and flow in the lateral line to change. The timing of the analyzer's response to these usage demands will give some clues as to the approximate position of the atmospheric leak source.

NOTE: Back-contamination is likely originating in a leg which is dead at the time the O_2 analyzer responds. Actual response time will depend on the time needed for the contaminant to travel to the O_2 analyzer plus the response time of the O_2 analyzer.

16.5 If no demand cycles in the lateral cause O_2 readings to change, then the source of contamination is likely to occur further upstream in the distribution system, prior to the intersection of the lateral in question. This assumes that there is always a net flow of gas in the line leading to the intersection of the lateral being checked.

16.6 Perform an investigative O_2 measurement (spot check) with a portable O_2 analyzer at each lateral location that is suspected in causing contamination in the main or sub-main line which supplies the lateral where the contamination was originally detected. Work upstream away from the lateral which showed a sign of contamination.

16.7 Once the lateral with the contamination source has been identified, use the steps outlined in Sections 16.3 and 16.4 to locate the exact point of the atmospheric leak source.

16.8 Refine the selection of investigative sample point locations along with a careful study of system flow dynamics until the leak is pinpointed and repaired.

16.9 Confirm that the leak source has been corrected by providing an investigative O_2 measurement downstream of the leak source.

17 Example in Locating Leak Source

17.1 See Figure 1 which is a schematic representation of a typical fab branching type gas distribution system. Since a loop type gas distribution system has one less piping level between the main line and the tools, it is more straightforward to monitor and diagnose. This example, although more complex, has been demonstrated in practice. It shows how an atmospheric leak originating at a single tool location can back-contaminate a sub-main distribution line, yet not contaminate all the way back to the main line. In this example, the contamination would not be detected by the UHP analysis instrumentation typically installed on the main line.

17.2 The "contaminant signature" oxygen analyzers are installed at critical purity locations, shown in Figure 1 as A_1, A_2, and A_3. These analyzers show baseline "contaminant signature" O levels of 0.2–0.5 ppb. By definition, as established by the user for each critical purity location, these are normal contaminant levels at these locations.

A_2 and A_3 begin showing excursions up to 1–2 ppb that last for several minutes, then settle back into the normal 0.2–0.5 ppb range. The excursions take place infrequently at first, but then develop some regularity. Although the absolute O_2 level detected does not yet indicate that the potential atmospheric leak (H_2O and N_2 included) would pose a direct risk to the critical purity of process tools located nearby, it does differ significantly from the baseline "contaminant signature". This prompts an investigation before a full-scale process production problem results.

Each of the lateral lines being monitored by A_2 and A_3 shows the same level of O_2 contamination, so it is deduced that the contamination is coming from the sub-main line which feeds both laterals. Since analyzer A_1 does not show the contamination, it is further deduced that the leak source is located between A_1 and A_2.

17.3 Working back upstream along the sub-main, investigative O_2 measurements are made at each lateral location ahead of the A_2 lateral. These investigative O_2 measurements are made using a portable O_2 analyzer per Sections 12 and 13.

17.4 At S_1 and S_2, similar O_2 contamination events are observed as compared with points A_2 and A_3. Further, no lateral line flow changes (due to tool gas demand cycles in those laterals) cause any change in the O_2 level.

17.5 At the third lateral, sampled as S_3 in Figure 1, the O_2 level is significantly higher (ranging between 5–10 ppb), with periodic spikes of 50–100 ppb. At this point, it is observed that when the usage in lateral S_3 drops to zero (a dead leg condition), analyzers A_2 and A_3 show O_2 readings above the "contaminant signature". It is therefore deduced that the S_3 lateral is the source of the atmospheric leak.

17.6 By correlating the O_2 data at S_3 with the gas usage from the tools on this lateral, the leak source can be further traced within this lateral. (Refer to Figure 2.)

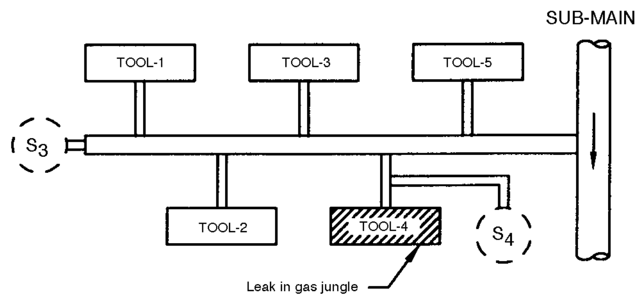

Figure 2
Branch UHP Gas Line with Ambient Air Leak Contaminating Sub-Main Line

17.6.1 When Tool-1, Tool-2, or Tool-3 demands gas, the O_2 reading drops in proportion to the total flow of gas in the lateral line. The higher flow rates act to dilute the effects of the leak source and thus lower the O_2 reading at S_3.

17.6.2 It is observed that when Tool-5 demands gas, there is no change in the O_2 reading at S_3. Therefore, it is deduced that the leak source is located further out along the lateral line.

17.6.3 When Tool-4 demands gas, it causes a more significant drop in the O_2 reading at S_3. Further, it is observed that the time required for the analyzer to respond after Tool-4 begins demanding gas correlates to the time needed for the analyzer's sample flow alone to purge down the lateral line volume up to the analyzer, when Tool-1, -2, and -3 are not demanding gas.

17.6.4 This deductive inference technique pinpoints the leak source to the Tool-4 lateral line.

17.6.5 After Tool-4 has stopped demanding gas (yet before any other Tools on this lateral demand gas), the O_2 reading at S_3 continues to drop gradually over several minutes. It then gradually begins to elevate once again. This indicates that the actual leak is not very close to the connection of Tool-4 at the lateral line. It suggests more that the leak source is closer to the tool itself.

17.7 A final investigative sample point is selected along the line leading to Tool-4. This is shown as S_4 in Figure 2. It is observed that the O_2 readings drop to 0.2–0.5 ppb when Tool-4 demands gas. S_4 begins to show an O_2 elevation after the Tool-4 stops demanding gas. This concludes that the leak source is originating from Tool-4 itself.

SEMI F36-0299
GUIDE FOR DIMENSIONS AND CONNECTIONS OF GAS DISTRIBUTION COMPONENTS

1. Purpose

1.1 The purpose of this guide is standardization of dimensional and mechanical/electrical connection attributes for components used within gas distribution systems. Standardization of these component interfaces will allow for interchangeability of gas distribution system components. Filters/purifiers, shut-off valves, pressure regulators, MFC/MFMs, and pressure transducers are the types of gas distribution components that would benefit from being interchangeable.

2. Scope

2.1 This guide is for use with 1/4-inch distribution systems at operating pressures no greater than 345 kPa (50 psi).

2.2 The guide includes the following items:

a) Physical characteristics specific to each component. These include a generalized drawing of the component, specific end-to-end lengths for each type of end connection, maximum envelope dimensions, base-to-centerline dimensions, tolerances, and bottom mounting information.

b) Electrical connections specific to each component, where applicable. These include pin-outs and types of connectors.

3. Limitations

3.1 This guide is not intended to dictate how to build a gas distribution system, but to allow for interchangeability of components.

3.2 This standard does not include recommendations for sensor-bus compliant interfaces.

3.3 This standard does not apply to surface mount components used in modular type gas systems.

4. Referenced Documents

4.1 None.

5. Terminology

5.1 *component* — An individual piece or a complete assembly of individual pieces capable of being joined with other pieces or components.

5.2 *filter* — A porous device, generally constructed of polymer, metal, or ceramics and housed in a metal chamber, which traps particles, preventing them from being transported downstream.

5.3 *mass flow controller* (MFC) — A self-contained device (consisting of a transducer, control valve, and control and signal-processing electronics) commonly used in the semiconductor industry to measure and regulate the mass flow of gas.

5.4 *mass flow meter* (MFM) — A self-contained device, consisting of a mass flow transducer and signal-processing electronics, commonly used in the semiconductor industry to measure the mass flow of gas.

5.5 *pressure regulator* — A valve designed to reduce a high incoming pressure (for example, from a cylinder) to a lower outlet pressure by automatically opening to allow flow until a desired, preset pressure on the outlet side is reached, then automatically throttling closed to stop further pressure increase.

5.6 *pressure transducer* — A component which mechanically or electrically senses gas pressure. It typically consists of a sensor and signal-processing electronics which enables remote indication of gas pressure.

5.7 *purifier* — An in-line device used for the removal of homogeneous impurities from gases, typically consisting of a packed-bed of active solids contained in a stainless steel housing. The active purification media may remove impurities such as moisture, oxygen, CO, CO_2, hydrocarbons, hydrogen, or nitrogen from specific gases using a variety of chemical reaction, physisorption, or chemisorption mechanisms. Point-of-use purifiers often contain a particle filter within the same housing.

5.8 *valve* — A device that controls the flow or pressure of a gas. Valve functions can include shutoff, metering, backflow prevention, and pressure relief.

6. Ordering Information

6.1 Device manufacturers may use this guide when procuring processing equipment to communicate to the equipment supplier the interface specifications required for interchangeability of components. This document may also be used by semiconductor processing equipment suppliers to specify standardized interfaces to component and module suppliers.

6.2 Orders for components in accordance with this standard shall include:

a) This standard number and date of issue.

b) Reference to the table number.

c) Reference to the option number, if applicable.

7. Filters and Purifiers

7.1 Filters less than 30 SLM and purifiers less than 1 SLM should conform to the interface design recommendations appearing in Figure 1 and Table 1.

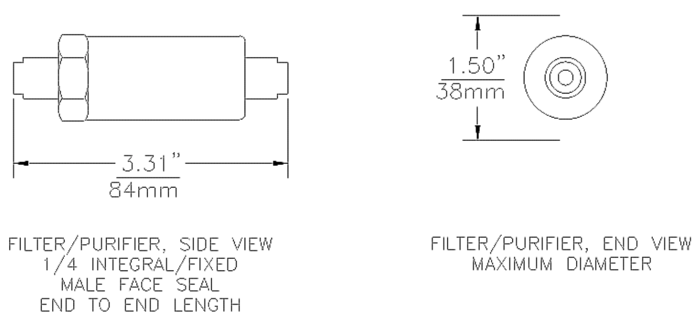

Figure 1
Filter and Purifier Interface Design

Table 1 Filter and Purifier Interface Recommendations

	Filter and Purifier
End-to-End Lengths:	
1/4-inch Integral/fixed male face seal	84 mm (3.31 in.)
1/4-inch Swivel face seal (male or female)	-
1/4-inch Tube weld	-
NOTE: The tolerance on length for machined components is ± 0.15 mm (0.006 in.) from the component centerline to each end. The tolerance on length for welded components is ± 0.5 mm (0.020 in.) from the component centerline to each end.	
Overall Component Envelope:	
Maximum Diameter	38 mm (1.5 in.)
Base to Centerline of Flow Path:	-
Mounting provisions:	
Threaded holes	None required
Pattern	-
Fittings:	
Process	1/4-inch
Control:	None required

8. Shut-off Valves

8.1 Shut-off valves should conform to the interface design recommendations appearing in Figure 2 and Table 2.

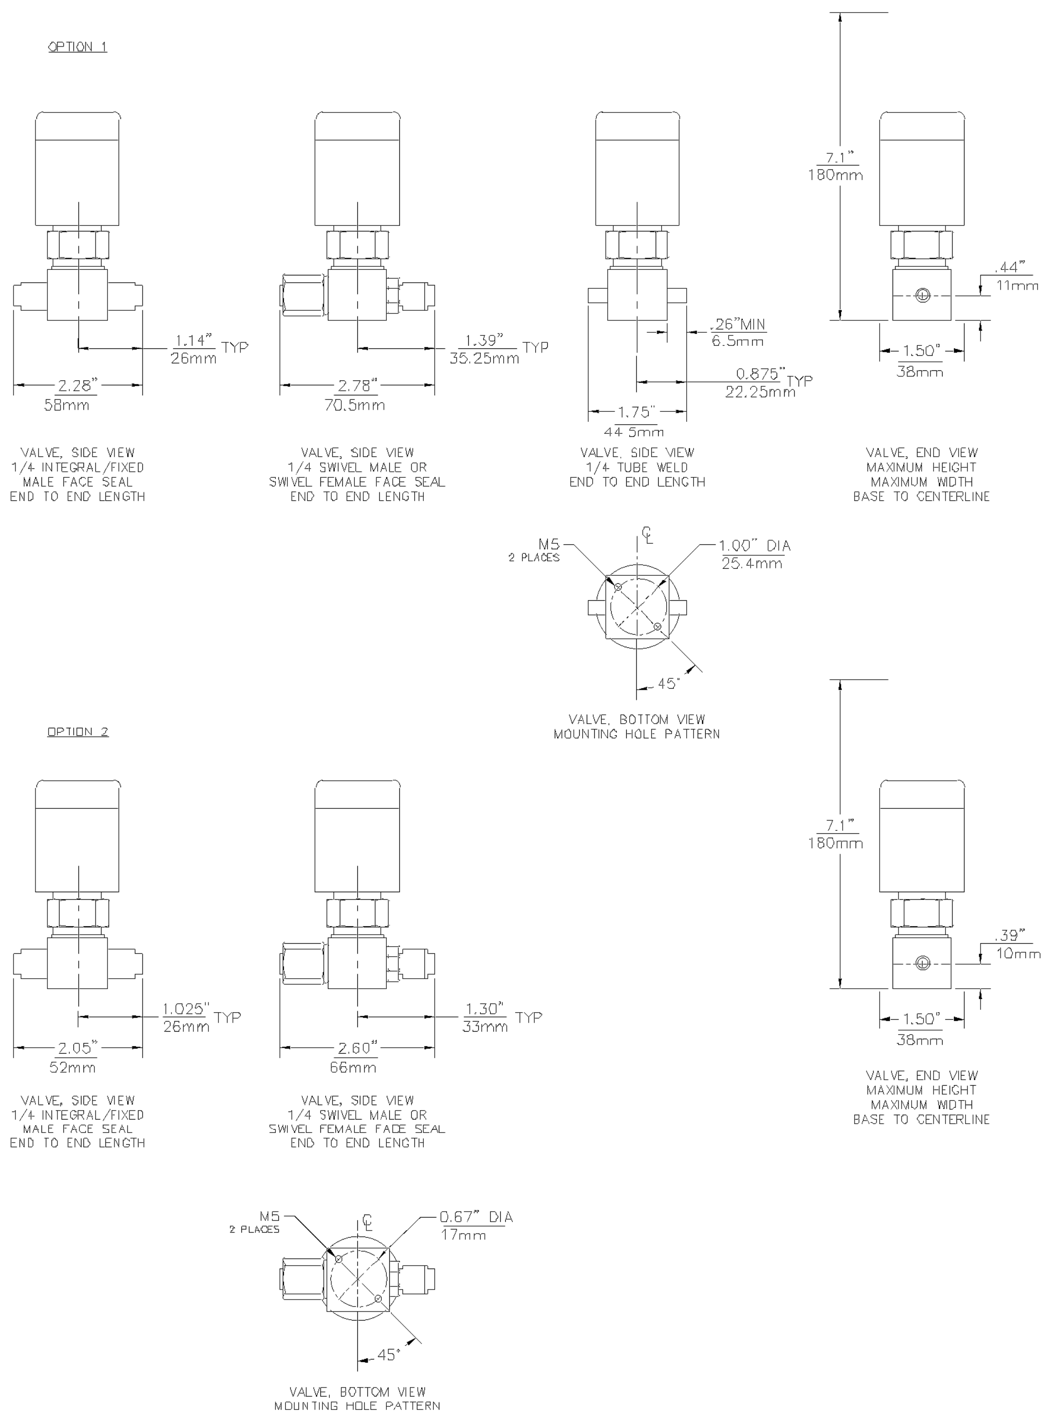

Figure 2
Shut-off Valve Interface Design

Table 2 Shut-off Valve Interface Recommendations

	Option 1 Shut-off Valves	Option 2 Shut-off Valves
End-to-End Lengths:		
1/4 inch Integral/fixed male face seal	58 mm (2.28 in.)	52 mm (2.05 in.)
1/4 inch Swivel face seal (male or female)	70.5 mm (2.78 in.)	66 mm (2.60 in.)
1/4 inch Tube weld	44.5 mm (1.75 in.)	-
NOTES: 1) The minimum length for each tube weld stub should be 6.5 mm (0.26 in.). 2) The tolerance on length for machined components is ± 0.15 mm (0.006 in.) from the component centerline to each end. The tolerance on length for welded components is ± 0.50 mm (0.020 in.) from the component centerline to each end.		
Overall Component Envelope:		
Maximum height	180 mm (7.1 in.)	
Maximum width (Excluding lever and toggle handles)	38 mm (1.5 in.)	
Base to Centerline of Flow Path:	11 mm (0.44 in.) ± 0.3 mm (0.012 in.)	10 mm (0.39 in.) ± 0.3 mm (0.012 in.)
Mounting Provisions:		
Threaded holes	M5 × 0.8 – 6H; 6 mm (0.24 in.) perfect thread depth	M5 × 0.8 – 6H; 5mm (0.20 in.) perfect thread depth
Pattern	25.4 mm (1.00 in.) bolt circle centered on bottom of base with two threaded holes 180° apart and 45° off of the vertical or horizontal axis. One hole in each of the upper left and lower right quadrants when looking at the bottom of the component.	17 mm (0.67 in.) bolt circle centered on bottom of base with two threaded holes 180° apart and 45° off of the vertical or horizontal axis. One hole in each of the upper left and lower right quadrants when looking at the bottom of the component.
NOTE: The M5 × 0.8 threaded mounting holes will accept 10–32 screws, but 10–32 threaded holes will not accept M5 × 0.8 screws.		
Fittings:		
Process	1/4-inch	
Control:	Manual and Pneumatic	

9. Pressure Regulators

9.1 Pressure regulators should conform to the interface design recommendations appearing in Figure 3 and Table 3.

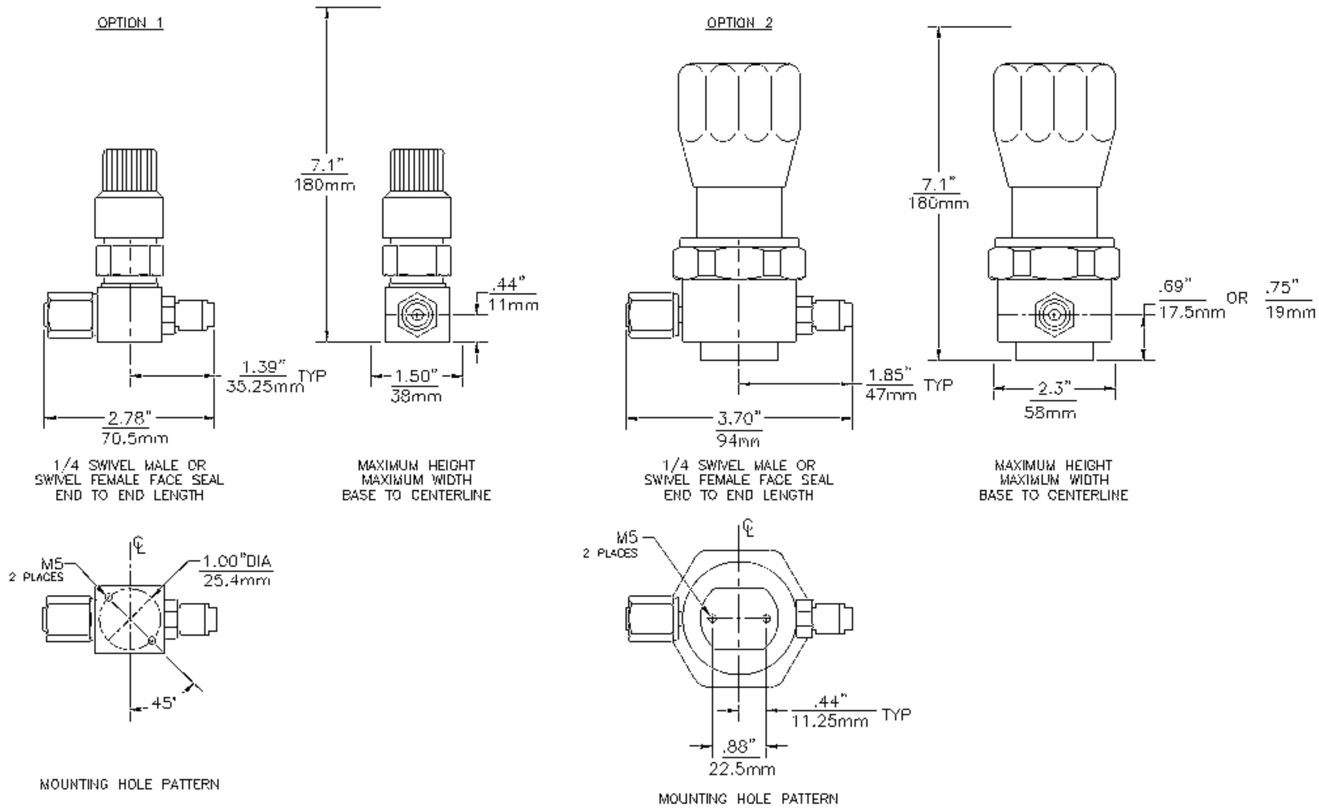

Figure 3
Pressure Regulator Interface Design

Table 3 Pressure Regulator Interface Recommendations

	Option 1 Pressure Regulators	Option 2 Pressure Regulators
End-to-End Lengths:		
1/4-inch Integral/fixed male face seal	-	-
1/4-inch Swivel face seal (male or female)	70.5 mm (2.78 in.)	94 mm (3.70 in.)
1/4-inch Tube weld	-	-
NOTE: The tolerance on length for machined components is ± 0.15 mm (0.006 in.) from the component centerline to each end. The tolerance on length for welded components is ± 0.50 mm (0.020 in.) from the component centerline to each end.		
Overall Component Envelope:		
Maximum height	180 mm (7.1 in.)	180 mm (7.1 in.)
Maximum width	38 mm (1.5 in.)	58 mm (2.3 in.)
Base to Centerline of Flow Path:	11 mm (0.44 in.) ± 0.3 mm (0.012 in.)	17.5 mm (0.69 in.) ± 0.3 mm (0.012 in.) or 19 mm (0.75 in.) ± 0.3 mm (0.012 in.)
Mounting Provisions:		
Threaded holes	M5 × 0.8 – 6H; 6 mm (0.24 in.) perfect thread depth	M5 × 0.8 – 6H; 6 mm (0.24 in.) perfect thread depth
Pattern	25.4 mm (1.00 in.) bolt circle centered on bottom of base with two threaded holes 180° apart and 45° off of the vertical or horizontal axis. One hole in each of the upper left and lower right quadrants when looking at the bottom of the component.	Two threaded holes, centered on bottom of base, in line with flow path, spaced 22.5 mm (0.88 in.) between centers
NOTE: The M5 × 0.8 threaded mounting holes will accept 10–32 screws, but 10–32 threaded holes will not accept M5 × 0.8 screws.		
Fittings:		
Process	1/4-inch	
Control:	Manual	

10. MFCs and MFMs

10.1 MFCs and MFMs should conform to the interface design recommendations appearing in Figure 4 and Table 4.

10.2 A nine pin connector was specified along with a signal for each pin to allow for MFC/MFM interchangeability. If additional signals are required, an additional connector should be specified. If signals are different, an alternate connector should be specified.

10.3 Current technology limits the MFC and MFM base-to-centerline dimension to 12.7 mm (0.50 in.). If future technologies permit, 11 mm (0.44 in.) should be considered as an option for the base-to-centerline dimension. This recommendation would improve modularity by permitting selection of each component type with a common base-to-centerline dimension.

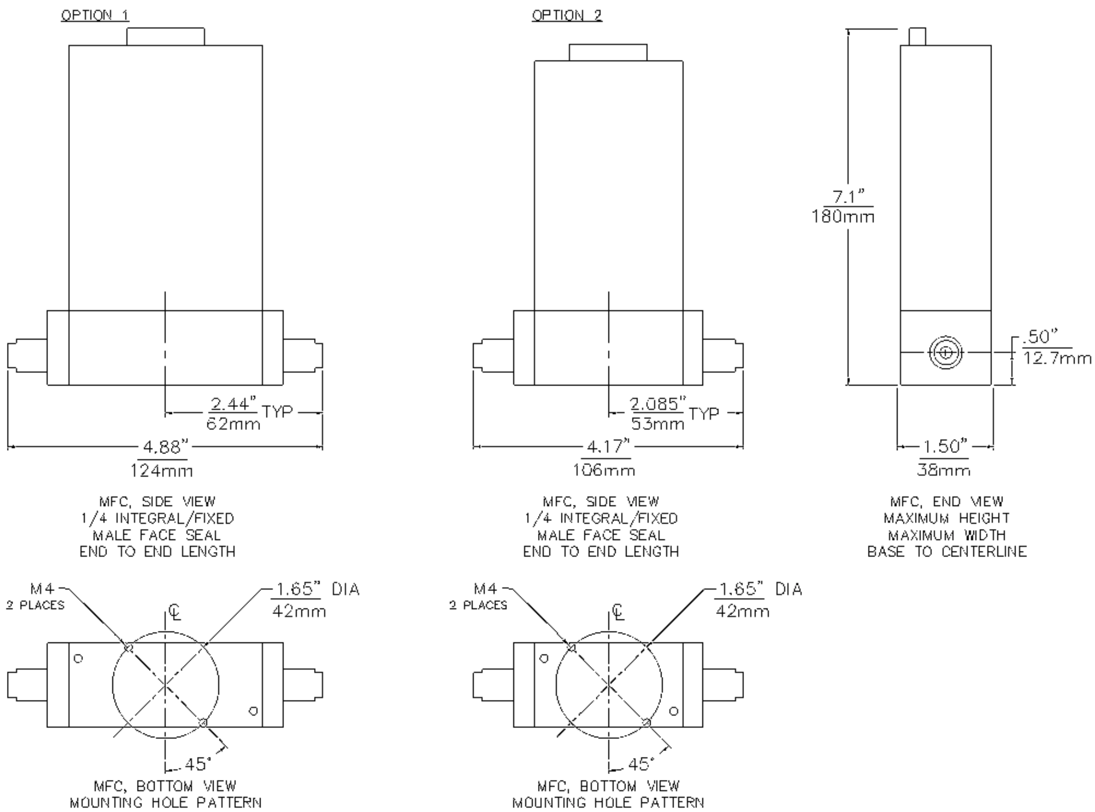

Figure 4
MFC and MFM Interface Design

Table 4 MFC and MFM Interface Recommendations

	Option 1 **MFC and MFM**	**Option 2** **MFC and MFM**
End-to-End Lengths:		
1/4-inch Integral/fixed male face seal	124 mm (4.88 in.)	106 mm (4.17 in.)
1/4-inch Swivel face seal (male or female)	-	-
1/4-inch Tube weld	-	-
NOTE: The tolerance on length is ± 0.50 mm (0.020 in.) from the component centerline to each end.		
Overall Component Envelope:		
Maximum height	180 mm (7.1 in.)	
Maximum width	38 mm (1.5 in.)	
Base to Centerline of Flow Path:	12.7 mm (0.50 in.) ± 0.3 mm (0.012 in.)	
Mounting provisions:		
Threaded holes	M4 × 0.7 – 6H; 3 mm (0.12 in.) minimum perfect thread depth	
Pattern	42 mm (1.65 in.) bolt circle centered on bottom of base with two threaded holes 180° apart and 45° off of the vertical or horizontal axis. One hole in each of the upper left and lower right quadrants when looking at the bottom of the component.	
Fittings:		
Process	1/4-inch	
Control:	Electrical 9-pin sub-D connector Analog signal pin out as follows:	
	Pin 1.	Valve Closed (Ground Pin to Close Valve)
	Pin 2.	0–5 V_{DC} Flow Signal Output
	Pin 3.	+15 V_{DC} Power Supply
	Pin 4.	Power Common
	Pin 5.	-15 V_{DC} Power Supply
	Pin 6.	0–5 V_{DC} Setpoint Input
	Pin 7.	Output Common
	Pin 8.	Setpoint Common
	Pin 9.	Valve Test Point

11. Pressure Transducers

11.1 Pressure transducers should conform to the interface design recommendations appearing in Figure 5 and Table 5.

11.2 To improve modularity of gas distribution systems the following recommendation should be considered for future pressure transducer design. This recommendation would match the pressure transducer interface design to the dimensions of both the shut-off valve Option 1 found in Table 2 and pressure regulator Option 1 found in Table 3.

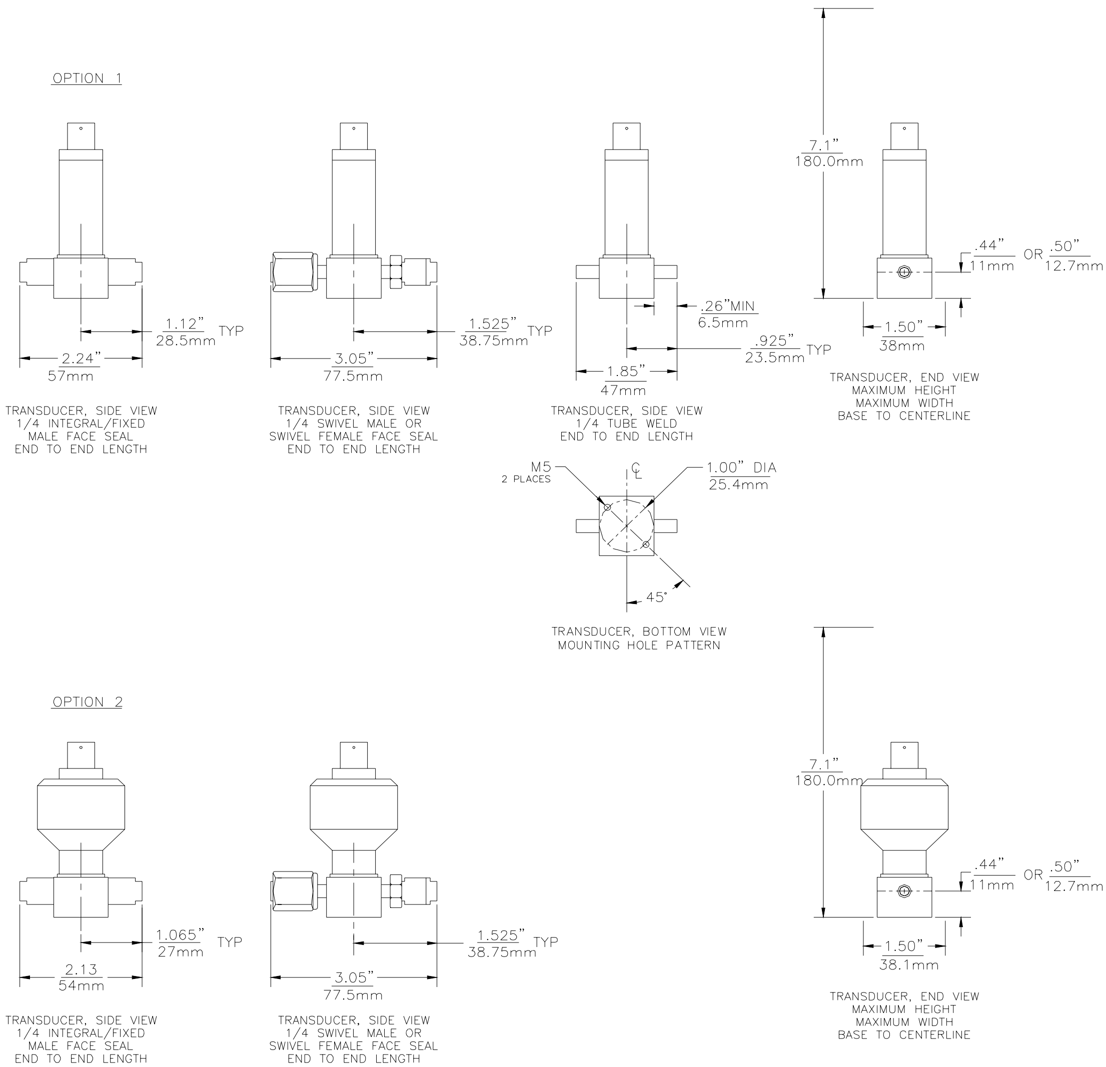

Figure 5
Pressure Transducer Interface Design

Table 5 Pressure Transducer Interface Recommendations

	Option 1 Pressure Transducers with Four-pin Connector	Option 2 Pressure Transducers with Six-pin Connector
End-to-End Lengths:

SEMI F37-0299
METHOD FOR DETERMINATION OF SURFACE ROUGHNESS PARAMETERS FOR GAS DISTRIBUTION SYSTEM COMPONENTS

1. Purpose

1.1 The purpose of this test method is to define a method for determining numerical values for surface roughness parameters measured on gas distribution system components. Application of this method is intended to yield comparable data among users of this method.

2. Scope

2.1 This document will specify methods, measuring equipment, and test conditions for mechanical profile surface roughness measurement of gas distribution system components. This test method will not require nor recommend numerical values for specific surface roughness parameters. This test method is intended for use in quality control and process development for specification of and manufacturing of gas distribution system components.

3. Limitations

3.1 Numerical values for specific surface roughness parameters obtained using this test method may not provide sufficient information for determining the performance of the component, such as dry down times, corrosion resistance or amount of particle generation. Surface roughness measurement is one of many evaluation techniques for assessing the performance or quality of a surface. This document is not concerned with characteristics such as component design, material, dimensions, appearance, etc. While surface defects traversed by the stylus may be included in the roughness measurement, this method does not govern the evaluation of surface defects. Surface defects may be measured by methods such as SEM and EDX. This test method is intended to measure surface features on the order of 10 μm in size. It is not intended to detect submicron surface features.

4. Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *ASME Document*[1]

B46.1 — Surface Texture (Surface Roughness, Waviness, and Lay)

4.2 *ASQ Document*[2]

Z1.9 — Sampling Procedures and Tables for Inspection by Variables for Percent Nonconforming

5. Terminology

5.1 *Acronyms*

5.1.1 *EDX* — Energy Dispersive X-Ray Spectroscopy

5.1.2 *SEM* — Scanning Electron Microscopy

5.1.3 *SEM* — Scanning Electron Microscope

5.2 *Definitions*

5.2.1 *cutoff* — A length selected to limit the spacing of surface irregularities. It separates a surface's roughness from its waviness.

5.2.2 *distinct regions* — Visually unique areas of a surface defined by patterns of lay or differences in the appearance of surface roughness. In-line bores of different sizes or orientations and each leg of a shaped component should be considered distinct regions.

5.2.3 *evaluation length* — The actual length over which surface roughness is assessed.

5.2.4 *lay* — The general direction of orientation of surface features.

5.2.5 *skid* — A stylus probe support which acts as both a filter and a datum for probe movements.

5.2.6 *skidless* — A type of instrument that does not use an external skid attached to the probe to act as a datum. Instead, it references a datum plane internal to the measurement equipment.

5.2.7 *stylus* — The object which mechanically probes the surface.

5.2.8 *surface roughness* — The finer irregularities of the surface texture, usually including those

1 The American Society of Mechanical Engineers, 345 E. 47th Street, New York, NY 10017

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202 irregularities that result from the inherent action of the production process, for example traverse feed marks from cutting tools [ASME B46.1-1995].

5.2.9 *surface texture* — Repetitive or random deviations from the nominal surface that forms the three-dimensional topography of the surface. Surface texture includes roughness, waviness, lay, and flaws [ASME B46.1-1995].

5.2.10 *waviness* — The more widely spaced component of surface texture. Waviness may result from such factors as machine or workpiece deflections, vibrations, chatter, heat treatment, or warping strains. Roughness may be considered as superimposed on a "wavy" surface.

6. Sampling

6.1 Acceptability criteria should be specified by the user and be developed in accordance with published sampling plans such as *ASQ Z1.9, Sampling Procedures and Tables for Inspection by Variables for Percent Nonconforming*.

7. Apparatus

7.1 The instrument should be a stylus type as defined by ASME B46.1, Section 2. Due to the limitations of skidded instruments (Type IV and V), a skidless instrument (Type I) is preferable.

7.2 The instrument should be calibrated using standard laboratory practices and manufacturer's recommendations with a roughness metrology standard calibrated by a certified testing laboratory and traceable to NIST[3].

7.3 In order to resolve the features of the surface, a stylus with a conical tipped radius of 5 µm (200 µin) should be used.

8. Units of Measure

8.1 Surface roughness should be described by means of the Roughness Average, R_a, as defined per ASME B46.1.

8.2 Measurements should be specified in micrometers (µm) or microinches (µin).

9. Preparation of Apparatus

9.1 The surface should be clean and free from loose debris before taking a measurement.

9.2 The instrument should be sufficiently isolated from vibrations, which will artificially increase roughness measurements.

9.3 Surfaces inaccessible to the stylus probe may be exposed by sectioning a sample(s). Samples should be sectioned to avoid damage to the surface to be measured and should be cleaned appropriately to remove sectioning debris.

10. Procedure

10.1 Select a single random location for measurement within each distinct region of interest on each component.

10.2 Measurements shall be taken perpendicular to the lay. If this is not practical, measurements may be taken in the direction of process gas flow through the component.

10.3 Instrument cutoff length should be set to 0.800 mm (0.030 in.).

10.4 The evaluation length, or measurement length, should be at least 3.81 mm (0.150 in.) where sufficient length is available.

11. Reporting

11.1 Average R_a is defined as the average of all R_a measurements taken over a population.

11.2 Maximum R_a is defined as the maximum of all R_a measurements taken over a population.

11.3 Both Average R_a and Maximum R_a should be reported for a given population. A population can be defined as:

- a set of single measurements on multiple components
- a set of multiple measurements on a single component
- a set of multiple measurements on multiple components

12. Precision and Accuracy

12.1 Some variance in Roughness Average is to be expected on a single surface from measurement to measurement. No two measurements (as taken by different operators, on different instruments, or at different locations on the surface of a component) will contain the same data points. Because different instruments will acquire data points at different rates, and evaluation lengths may differ, a typical Roughness Average measurement can include hundreds to tens of thousands of data points.

[3] *National Institute of Standards and Technology, Gaithersburg, MD 20899*

Reported measurements on the same surface can be expected to deviate up to 20%.

SEMI F38-0699
TEST METHOD FOR EFFICIENCY QUALIFICATION OF POINT-OF-USE GAS FILTERS

This Test Method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org January 1999; to be published June 1999.

1 Purpose

1.1 The purpose of this document is to define a comprehensive standard test sequence to qualify the particle filtration efficiency achievable using Point-of-Use (POU) gas filters.

2 Scope

2.1 This test method defines an evaluation method for Point-of-Use filters of various media (e.g., metallic, ceramic, and polymeric) typically used for filtering inert and process gases in semiconductor applications. Point-of-Use filters are designed to handle relatively low flow rates (0.5 – 50 slm.) and moderately high pressure drops. The filter housing and filtration element are combined into one sealed and inseparable unit.

2.2 This test method is intended to demonstrate the ability of a Point-of-Use gas filter to equal or exceed a specific particle filtration efficiency class when challenged with a monodispersed aerosol in the size range described in Section 6.6.

2.2.1 The efficiency class of the test method is defined as the log reduction value (LRV), where LRV is the Log [Input Concentration/System Background Level].

3 Limitations

3.1 These test methods do not apply to gas filter cartridges.

3.2 These test methods do not apply to bulk gas filters.

3.3 The various media (e.g., metallic, ceramic, and polymeric) may have slightly different critical particle sizes (most penetrating particle sizes). Therefore, many challenge tests have to be performed over a range of particle sizes to assure that the "worst case" challenge has been performed.

3.4 The efficiency test is for steady state flow and room temperature only. Comparison to efficiency in pulsed flow, elevated temperature etc., will have to be developed separately.

3.5 Statistical evaluation on the variability in efficiency of a media type should be done with a valid sample size. This evaluation is not within the scope of this test method.

3.6 The upper concentration limit of the CNC as specified by the manufacturer should not be exceeded. Exceeding the CNC concentration will understate the challenge concentration due to coincidence counting, thus affecting filter efficiency calculations.

3.7 This is not intended as a method for precise determination of filter efficiency. It is intended as a means for determining if a filter has an efficiency equal to or better than an approximate nominal value.

3.8 Commercially available radioactive neutralizers have pressure limitations. Users should be aware of these limits.

4 Referenced Documents

4.1 None.

5 Summary of Method

5.1 The test sequence consists of three steps:

5.1.1 Static background with filter.

5.1.2 Filter challenge with first monodispersed particle size (see Section 6.6 for particle size test sequence).

5.1.3 Filter challenge with subsequent monodispersed particle sizes.

6 Apparatus and Facility

6.1 *Gas Source* — Clean, dry gas (nitrogen or air) with less than 0.5 ppm moisture and less than 0.5 ppm total hydrocarbons.

6.2 *Particle Detector* — A condensation nucleus counter (CNC) with a counting efficiency of 50% at 0.01 micron, as reported by the manufacturer, is recommended to measure total particle concentration of particles greater than 0.01 micron. The CNC must meet a background level as specified in Section 7.1.2.

6.3 *Test Environment* — Particle challenge testing does not require a clean area. Testing in a Class 100 area is recommended but not required. Refer to Section 6.7 for installation precautions.

6.4 *Configuration for Efficiency Test* — One example of the configuration is shown in Figure 1. The setup shown in Figure 1 is intended only as a guideline. This system consists of:

- an aerosol generation system
- aerosol concentration detectors
- an air flow measuring system
- a filter pressure drop sensor
- the test filters.

6.5 *Test Flow Rate* — Maximum manufacturer's rated flow rate.

6.6 *Challenge Particle Sizes* — Experimentation of various media (e.g., metallic, ceramic, and polymeric) have resulted in most penetrating particle sizes ranging from .05 - .11 micron.[1 2 3 4]

6.6.1 Several monodispersed particle challenge tests shall be done over a range of particle sizes so that testing at the most penetrating particle size is performed. An electrostatic classifier must be used to produce a monodispersed challenge.

6.6.2 Due to the effects of particle loading in relation to filtration efficiency, a clean filter should be used for each particle size challenge. The differential pressure across the test filter should be continuously monitored to eliminate the possibility of particle loading. The following particle increments are a guideline. Smaller increments are achievable and are desirable.

6.6.2.1 Challenge Particle Size In Microns:

- 0.05
- 0.07
- 0.10

6.7 *Sample Installation* — Reasonable precautions shall be taken when installing the test filter to avoid particle contamination of the system from ambient. These precautions may include, but are not limited to: installation in a Class 100 laminar flow area, installation in a purged glove bag or other controlled ambient enclosure, use of a purge flow downstream of the sample point so that all parts of the system are under purge, isolation, or termination of the CNC sample flow, and isolation of the isokinetic sampler exhaust from ambient.

6.8 Customary practices shall be employed for the design of the sampling system. This includes any specialized equipment or procedures recommended by the CNC manufacturer. Every effort should be taken to minimize differences in the particle concentrations of the sampling volume relative to the actual test volume. Care should be taken to provide an adequate exhaust length so that back diffusion of particles does not affect background at 2 times the sampling flow rate. This length will depend upon the particle concentration in the ambient environment and on other factors.

6.9 *Test Particle* — Solid non-volatile particles. Sodium chloride is recommended, but other particles could be used such as polystyrene latex beads (PSL) if sufficiently high concentrations can be generated.

7 Procedure

7.1 *Static Background Test*

7.1.1 Purge the system at a high velocity flush of 100 slm or the maximum flow rate that the system components will allow.

7.1.2 Purge the system at test flow rate (Section 6.5). Measure the particle concentration with clean gas to determine the background concentration. The background count is established when the counter has sampled a minimum of 3 scf (85 sl), and the arithmetic average during the last 3 scf (85 sl) of gas sampled is <2 particles/scf (<0.07 particles/sl). The sample interval shall be 1 minute in duration. Ensure that the background counts are stable or decreasing. If background cannot be achieved after 6 scf (170 sl) have been sampled, there may be a problem with the counter or test apparatus. Past experience has shown this to be an adequate volume of gas to give a satisfactory low level background particle counts.

7.2 *Penetration Test*

7.2.1 An example of the apparatus is shown in Figure 1. The input particle concentration is measured by CNC-B, while the output particle concentration is measured by CNC-A. The pressure and flow rates in both legs should be carefully balanced (by maintaining

[1] *Rubow, K.L., C.B. Davis (1991) "Particle Penetration Characteristics of Porous Metal Filter Media for High Purity Gas Filtration", Proceedings of Institute of Environmental Sciences Annual Technical Meeting*

[2] *Rubow, K.L., and Liu, B.Y.H., Evaluation of Ultra-High Efficiency Membrane Filters, Proceedings of the 30th Annual Technical Meeting, Institute of Environmental Sciences, 1984.*

[3] *Rubow, K.L., Liu, B.Y.H., and Grant, D.C., Characteristics of Ultra-High Efficiency Membrane Filters in Gas Applications; Journal of Environmental Sciences, May/June, 1988.*

[4] *B. Gotlinsky, P. Conner, D. Capitanio, L. Johnson, and S. Tousi, Testing of All-Metal Filters for High Purity Semiconductor Process Gases, Proceedings of the 37th Annual Technical Meeting, Institute of Environmentak Sciences, 1991.*

an identical differential pressure in both legs) to insure that the challenge level is the same.

7.2.2 Set the first and subsequent challenge particle sizes per Section 6.6.

7.2.3 Particle challenge concentrations should be set to the maximum output of the electrostatic classifier for each of the particle size tests (Section 6.6). This will determine the test volume and the duration of the test. Generally this requires generating a polydispersed aerosol having a mean size close to the desired monodispersed aerosol size. Any difference between the flow rate exiting the electrostatic classifier and the test flow rate specified in Section 6.5 will be made up by dilution gas as shown in Figure 1.

7.2.4 The total particle challenge must be limited to 1×10^9 particles per liter of filter rated flow in slm. This is done to limit the effects of a particle cake build-up which would enhance the efficiency of the test filter. The test should be concluded upon exposure to 1×10^9 particles per liter of rated flow or after 10 downstream counts are observed, whichever occurs first.

7.2.4.1 As an example, a 10 liter per minute filter would be challenged in one minute with (10 slm) × (1 minute) × (1×10^9 particles/liter) or 1×10^{10} particles. If the challenge concentration is 1×10^8 particles per liter and the flow rate is 10 slm, then the test would need to last 10 minutes or when 10 downstream particles were observed.

7.2.4.2 The sample interval shall be 1 minute in duration. The sample interval in the penetration test is equivalent to the sample interval in the system background test (Section 7.1.2).

7.2.5 Measure the input and output particle concentration.

7.2.6 Calculate the ratio of output to input particle concentration.

8 Reporting of Test Results

8.1 Raw data shall be reported for each test in the format of a table, including the number of sample intervals, the sampling volume of each interval, the sampling time of each interval, and the total number of particles registered in each interval. In addition, the relevant parameters for each test described in Sections 8.2 and 8.3 should be identified.

8.2 *Static Background Test* — Identify the period of time required to obtain 45 consecutive sampling intervals without a particle being detected for the spool piece and test filter.

8.3 *Penetration Test* — Identify the input concentration, the output concentration, the ratio of output to input concentration (fractional penetration), and the challenge particle size. The most penetrating particle size is the challenge particle at the largest fractional penetration. Care must be taken to distinguish between true penetration and system background counts (see Section 8.5) as measured in Section 7.1.2.

8.4 *Efficiency Class*

8.4.1 If no penetration is observed then report the POU Gas Filter passed a X LRV efficiency test, where X = the maximum detectable efficiency for the test (as defined in Section 2.2). No penetration is defined as when the filter output is not statistically different from the system background (as defined in Section 8.5).

8.4.2 If penetration is observed , then report that the POU Gas Filter failed a X LRV efficiency test, where X is the maximum detectable efficiency for the test (as defined in Section 2.2). Penetration is defined as when the filter output is statistically different from the system background (as defined in Section 8.5).

The LRV defines the number of nines in the efficiency.

Example: A filter with a fractional penetration of 0.00001 has a LRV of 5 and an efficiency of 99.999%

8.5 *Data Reduction*

8.5.1 The statistical analysis is based on the assumption that the particles generated are randomly distributed and are statistically independent of each other. The background counts are independent of the particle performance of the component. The particle counts observed from the test include the counts from the component and the background count.

Let:

$\overline{X}_B$ = average background particle count

$\overline{X}_t$ = average total particle count from test

$\overline{X}_c$ = average particle count generated by the test component

Therefore,

$$\overline{X}_t = \overline{X}_c + \overline{X}_B$$

8.5.2 A statistical analysis of the data is performed to determine the mean, standard deviation, and the standard error for each particle size range.

8.5.3 The sample mean, X, or average of the data for each state is given by:

$$\bar{X} = \sum_{i=1}^{n} \frac{X_i}{n}$$

where X_i

is the observed counts for the state and n is the number of samples.

8.5.4 The sample standard deviation is a measure of the variability of the data about the mean. The standard deviation, s, for each state is expressed as:

$$s = \sqrt{\frac{\sum_{i=1}^{n} (Xi - \bar{X})^2}{n-1}}$$

8.5.5 The standard error, Se or standard deviation of the sampling distribution of the mean for each state is given below:

$$Se = \frac{s}{\sqrt{n}}$$

8.5.6 The average particle count for the total number of particles generated, or the sample mean, is an estimation of the population mean. For a 95% confidence level, the population mean, μ_p, will be within two standard errors of the sample mean, or:

$$\mu_p = \bar{X} \pm 2 \ Se$$

8.5.7 In order to determine if there is statistical evidence of the component having an effect on the observed particle count, a test must be conducted to see if the actual difference between the average background count, X_B, and the average test count, X_t, exceeds two standard errors in a distribution of differences between means. The average particle count generated by the test component, X_C, is given by:

$$\bar{X}_c = \bar{X}_t - \bar{X}_B$$

8.5.8 The standard error in a distribution of differences between means is expressed as:

$$S_{ec} = \sqrt{S_{et}^2 + S_{eB}^2}$$

8.5.9 The 95% confidence interval of the test component itself is then determined by:

$$\bar{X}_c \pm 2 \ S_{ec}$$

8.5.10 If this confidence interval includes 0, then this implies that there is not strong statistical evidence of the component having an effect on the observed particle count. If this interval does not include 0, then this implies there is strong statistical evidence that the component does have an effect on the observed particle count.

8.5.11 Present in tabular form the average particle count and the associated 95% confidence limits (as calculated in Section 8.5.9) for each test state. In addition, present the background test data separately as a distinct element.

8.5.12 Calculation of the Efficiency Class

8.5.12.1 The efficiency class shall be calculated in such a fashion that that:

LRV = Log [Input Concentration / $\bar{X}_B + 2S_{eB}$].

SEMI F39-0699
GUIDELINE FOR CHEMICAL BLENDING SYSTEMS

This guideline was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org January 1999; to be published June 1999.

1 Purpose

1.1 This guideline establishes terminology, classification, performance characterization, and qualification methods for chemical blending equipment.

2 Scope

2.1 This guideline applies to chemical blending equipment interfaced with Bulk Chemical Distribution Systems (BCDS).

3 Limitations

3.1 This guideline does not cover subject matter concerning chemical distribution capability of some chemical blending equipment, chemical blending methodology, or materials of construction used in this equipment.

4 Referenced Documents

4.1 *SEMI F31* — Guide for Bulk Chemical Distribution Systems

5 Terminology

5.1 *accuracy* — A quantity describing the deviation of the mean blend ratio produced by the chemical blending equipment from the desired constituent ratio.

5.2 *assay* — A term used to determine the amount of a chemical constituent in a blend.

5.3 *baseline contamination level* — The level of impurity measured in the source fluids, including UPW and chemical.

5.4 *batch* — The end quantity of chemical resulting from the blending of the chemical constituents.

5.5 *blending* — Combination of two or more chemicals to create a mixture which contains a desired ratio of constituents. A dilution process by this definition is also a blending process. However, blending is a more general case where UPW is not always one of the constituents. Therefore, the term blending will be used in the remainder of the document.

5.6 *Central Limit Theorem (CLT)* — The CLT is a probability theorem which allows the approximation of normality for any distribution. The CLT applied to chemical blending states that if a sufficient number of random samples are taken from the distribution of all chemical produced by chemical blending equipment, then the average measurement of these samples can be approximated to follow a normal distribution. A rule of thumb for the "sufficient number of batches" is thirty or greater.

5.7 *dilution* — Combination of a concentrated chemical and UPW to create a lower concentration of the aqueous chemical.

5.8 *duty cycle* — The normal percentage of time that the chemical blending equipment is operating.

5.9 *mixing* — Mechanical energy imparted to a combination of two or more chemical constituents used to create a homogenous solution.

5.10 *on-site blending* — Chemical blending equipment used for blending chemical on location of the semiconductor manufacturing facility

5.11 *precision or repeatability* — A quantity describing the degree of achieving the same ratio of chemical constituents in the blend over time.

5.12 *production rate* — The volume of chemical able to be blended and provided to the BCDS per day.

6 Classification

6.1 Batch Blending — The process of chemical blending where the chemical constituents are combined and mixed in a tank before being made available for use.

6.2 Feed-forward Controlled Blending — Blending process which uses information (i.e. incoming chemical assay) of the chemical constituents as the basis for combining these constituents. Examples of feed-forward blending processes include, but are not limited to, those processes that use weight or volume for control.

6.3 Feedback Controlled Blending — Blending process which combines constituents based on measurements of the blended chemical. Examples of feedback controlled blending process include, but are not limited to, those processes controlled by measurements of density, conductivity, and chemical assay (by titration).

6.4 In-line Blending — The process of chemical blending where the chemical constituents are combined in line and are immediately available for use.

7 Performance Characterization

7.1 *Blending Repeatability* :

7.1.1 *Batch Blending*

7.1.1.1 Sample Collection: A sample of at least thirty batches of blended chemical is taken. Assay of this chemical is measured.

7.1.1.2 Calculations: The mean and standard deviation of the batches are computed.

7.1.1.3 Reporting: When reporting repeatability, either of two methods is acceptable. Both methods quote precision in terms of the chemical assay.

7.1.1.3.1 Repeatability at one concentration = mean ± 3σ (where σ is in units of concentration)

7.1.1.3.2 Repeatability in range of concentrations: Individually calculate percent relative standard deviation at 3σ = (3σ / mean) × 100% for representative concentrations within the desired range (30 samples for each concentration, calculate a standard deviation and mean for each concentration). Repeat largest percent relative standard deviations at 3σ and concentration range examined or report percent relative standard deviation at 3σ for each individual concentration.

7.1.1.3.3 Multiple Components: If more than one non-aqueous chemical constituent exists in the blend, the precision for each must be quoted individually.

7.1.2 *In-Line Blending*

7.1.2.1 Sample Collection: At least thirty samples of blended chemical are taken. The time interval between samples must be at least one hour. Assay of this chemical is measured.

7.1.2.2 Calculations: The mean and standard deviation of the samples are computed.

7.1.2.3 Reporting: When reporting repeatability one of two methods is acceptable. Both methods quote precision in terms of the chemical assay.

7.1.2.3.1 Repeatability at one concentration = mean ± 3σ (where σ is in units of concentration)

7.1.2.3.2 Repeatability in range of concentrations: Individually calculate percent relative standard deviation at 3σ = (3σ / mean) × 100% for representative concentrations within the desired range (30 samples for each concentration, calculate a standard deviation and mean for each concentration). Repeat largest percent relative standard deviations at 3σ and concentration range examined or report percent relative standard deviation at 3σ for each individual concentration.

7.1.2.3.3 Multiple Components: If more than one non-aqueous chemical constituent exists in the blend, the precision for each must be quoted individually.

7.2 *Blending Accuracy*

7.2.1 Since calculation of accuracy takes into account both equipment operational parameters (calibration frequency and drift) and also changes in chemical input (feed forward blending), calculation of blend accuracy will not be standardized. However, by definition, a reported accuracy can not be less than blend precision.

7.2.2 *Reporting of Accuracy*

7.2.2.1 Accuracy at one concentration = desired concentration ± 3σ

7.2.2.2 Accuracy in range of concentrations: Report range of concentrations where this accuracy applies and the accuracy in terms of a percentage of the chemical concentration. Report accuracy with statistical significance of 3σ.

7.3 *Production Rate*

7.3.1 All production rates described should reference the duty cycle, i.e. the percentage of time that the equipment is operating to achieve the quoted production rate.

7.3.2 Batch Production Rate = batch volume / time to produce one batch (hours) × 24 hours × duty cycle

7.3.3 In-line Production Rate = flow rate (volume /day) of blended chemical × duty cycle

7.4 *Purity*

7.4.1 Particles — Particle performance should be expressed in the same manner as BCDS (i.e. ≤ x particles / ml @ ≥ 0.y μm)

7.4.2 Trace Metals — Metallic purity performance should be expressed in a similar manner as BCDS. However, blending systems, by definition, have several source materials, which could include water. Each source material contributes to the "baseline contamination level" (equivalent to drum contamination level in BCDS). A volumetric combination (based on the volumetric combination of source materials) of the contamination levels should be used to construct the baseline contamination level.

7.4.3 Ionic Contamination / TOC — Should be expressed in a similar manner as BCDS.

7.5 *Uptime*

7.5.1 MTBA — Mean Time Between Assists should be expressed in the same manner as BCDS

7.5.2 MTBF — Mean Time Between Failures should be expressed in the same manner as BCDS

8 Qualification Methods

8.1 Purity — The purity of the equipment will be qualified in a similar manner to that of BCDS.

8.2 Assay — The assay of each of the chemical constituents ($c_{mean,blend}$) should be compared to that of the customers upper ($UCL_{specification}$) and lower ($LCL_{specification}$) control limits for the chemical assay. The customer specification must be expressed as their desired 3σ limits. The standard deviation for the blend (σ_{blend}) should be determined by the same method described for determining blending repeatability. The number of batches or samples to determine this standard deviation should be agreed upon by the equipment supplier and the customer. The blending unit shall be deemed qualified when both of the following are satisfied for all constituents.

8.2.1 $UCL_{specification} > C_{mean, blend} + 3\sigma_{blend}$

8.2.2 $LCL_{specification} < C_{mean,blend} - 3\sigma_{blend}$

SEMI F40-0699
PRACTICE FOR PREPARING LIQUID CHEMICAL DISTRIBUTION COMPONENTS FOR CHEMICAL TESTING

This practice was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org January 1999; to be published June 1999.

1 Purpose

1.1 This document defines component preparation and pretreatment procedures for chemical test methods used to evaluate liquid chemical distribution system components.

2 Scope

2.1 This document includes preparation procedures that can be applied to components such as tubing, piping, valves, regulators, fittings, gaskets, O-rings, and filter housings.

2.2 This document defines and specifies all of the component pretreatment and analyze preparation procedures for liquid chemical distribution system components common to the test methods listed (see Table 3). Each type of component should be pretreated and prepared according to the procedures of this document before it can be tested using the identified chemical test methods.

2.3 This document defines preparation and pretreatment procedures used for the evaluation of liquid chemical distribution system components in test fluids. This practice is intended for use with 49% HF, 30% H_2O_2, 29% NH_4OH, IPA and ultrapure water. The document defines the purity of chemicals that can be used for leaching and rinsing liquid chemical distribution system components.

3 Limitations

3.1 Although ozonated water is commonly used in ultrapure water systems, no provisions are made in this document for evaluations using ozonated water. Therefore, some of the procedures may not be directly applicable to ozonated water.

3.2 The preparation procedures described in this practice primarily involve static testing including agitation. Dynamic testing, i.e., continuous flow, may alter the chemical test results. Static component preparation procedures are not directly applicable to dynamic testing.

3.3 This preparation procedure applies to ambient temperature only with the exception of ultrapure water which may be tested at ambient temperature and up to 85°C.

3.4 Filter cartridges are not covered in this document due to the requirement for dynamic testing.

4 Referenced Documents

4.1 None.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *DSC* — differential scanning calorimetry

5.1.2 *FEP* — fluorinated ethylene-propylene

5.1.3 *FTIR* — Fourier transform infrared spectroscopy

5.1.4 H_2O_2 — hydrogen peroxide

5.1.5 *HF* — hydrofluoric acid

5.1.6 *IPA* — Isopropyl alcohol

5.1.7 NH_4OH — ammmonium hydroxide

5.1.8 *NVR* — nonvolatile residue

5.1.9 *PE* — polyethylene

5.1.10 *PFA* — perfluoroalkoxy

5.1.11 *PP* — polypropylene

5.1.12 *PVDF* — polyvinylidene fluoride

5.1.13 *TGA* — thermal gravimetric analysis

5.1.14 *TOC* — total organic carbon

5.1.15 *UPW* — ultrapure water

5.2 *Definitions*

5.2.1 *blank extraction* — A container of test fluid which does not see the component under test. It follows the entire procedure and is handled in the same manner in order to show the background of the lab or test area.

6 Summary of Practice

6.1 This document describes two different component preparation procedures (see Figure 1):

a) procedure for preparing components and collecting a sample for extraction analyses

b) procedure for pretreating or preparing components for bulk polymer analysis.

6.2 Table 1 specifies the flush time, soak time, and container material for extracting leachable contaminants. Sample size requirements for bulk analyses are listed in Table 2.

6.3 This practice should be performed before analysis by industry standard extraction and bulk test methods used to evaluate liquid chemical distribution component. Available industry standard test methods are listed in Table 3 and the Related Documents section.

7 Apparatus and Materials

7.1 *Containers*, as defined in Table 1.

7.1.1 All containers and caps used in component and blank extraction should be thoroughly cleaned. A typical recommended cleaning procedure is outlined in Section 11.3. However, any cleaning procedure is acceptable as long as the subsequent blank extraction yields impurity concentrations that do not exceed 10% of the specification for the material being tested. For example, if a given impurity is specified for a maximum of 1.0 $\mu g/cm^2$, the blank extraction concentration should not exceed 0.1 $\mu g/cm^2$.

NOTE: In situations where the detection limit is greater than 10% of the specification for the polymer material, the detection limit of the instrument converted into $\mu g/cm^2$ will suffice, provided it does not exceed the specification for the material being tested.

7.2 *Test Fluids*

7.2.1 For purposes of this practice, references to water shall be understood to mean ultrapure water as defined by maximum individual metal and anion impurity levels of 0.1 parts per billion by weight 1×10^{-9} (ppbw) or less, total organic carbon (TOC) levels of 10 ppbw or less, nonvolatile residue levels of 0.1 parts per million by weight 1×10^{-6} (ppmw) or less, resistivity of 18 megohm-cm or greater, and reactive silica impurity of less than 1.0 ppb.

7.2.2 References to HF, NH_4OH and H_2O_2 shall be understood to refer to chemicals with a minimum of a semiconductor grade purity and meet the criteria in section 7.1.1. The impurity concentrations of the chemical must not exceed 10% of the lowest anticipated concentration for the analyte(s) of interest.

7.2.3 *Ultrapure Nitric Acid*, less than 1 ppb for each trace metal.

7.2.4 *Ultrapure Hydrochloric Acid*, less than 1 ppb for each trace metal.

7.2.5 *Ultrapure Isopropyl Alcohol*, less than 1 ppb for each trace metal.

8 Precautions

8.1 *Safety Precautions*

8.1.1 This practice may involve hazardous materials, operations, and equipment. This practice does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and to determine the applicability of regulatory limitations before using this practice.

8.2 *Technical Precautions*

8.2.1 The component preparations must be conducted in clean environments that prevent contamination of the components and containers at the parts per trillion level for the analyte(s) of interest. A clean environment may require the use of a cleanroom (for those procedures which can be performed in a cleanroom).

8.2.2 For all testing other than differential scanning calorimetry (DSC), thermal gravimetric analysis (TGA), and Fourier transform infrared spectroscopy (FTIR), the component preparation should take place in a controlled environment to minimize contamination.

9 Sampling and Test Specimens

9.1 The components selected for testing should reflect the current manufacturing capabilities of the supplier.

10 Procedure for Preparing Components and Collecting an Extraction Sample for Analysis

10.1 Component preparation for contaminants that can be leached from liquid chemical distribution components is different from component preparation for bulk polymer analysis. Components are flushed and then soaked to extract surface contamination. Refer to Table 1 for procedures for handling specific components.

10.2 The liquid chemical distribution system components described in this section are divided into two groups:

a) Components that require capping (see Section 9.5).

b) Components that require a container (see Section 9.6).

10.3 Each group is discussed individually. Use Table 1 to determine the appropriate group for each component.

10.4 *General Procedure*

10.4.1 The blank extraction is a container of test fluid without a component which follows the entire procedure and is handled in the same manner. Please consult the specific test method for the number of test fluid samples to be prepared and the statistical treatment. This would include a number of containers for both component and blank extractant. Use cleaned containers that meet the criteria specified in Section 7.1.1. An example of a cleaning procedure is outlined in Section 11.3.

10.4.2 Use UPW to fill and then drain the component or container 10 times. After each fill, leave the water in the component or container for two minutes before draining.

10.4.3 Fill an 11th time with the appropriate test fluid (see Section 2.3); use this fill for the test. Refer to Table 1 to determine the soak time for each component or container.

10.4.4 Agitate once a day for one minute. Orbital shakers or manual agitation can be used, but no foreign materials may contact the test fluid; therefore, stir bars cannot be used. Components and/or containers are to remain sealed during agitation to prevent splashing or spilling. Components in containers (such as gaskets) should remain completely submerged throughout the extraction.

10.5 *Components that Require Capping (Tubing, Piping, Valves, Regulators, and Filter Housings)*

10.5.1 This practice is appropriate for static samples with one end permanently sealed and one end loosely capped. Since the sealing process may contaminate the sample, one end should be sealed prior to precleaning. Use cleaned caps meeting the criteria specified in Section 7.6.1. The cap must be manufactured from the same material as the component or from a compatible material that will not contaminate the sample.

10.5.2 As surfactants and solvents may leave a residue that could alter the test results, do not use them for precleaning.

10.5.3 During sample collection for metal analysis, the components must be acid stabilized to a pH of 2 (approximately 3 drops of concentrated nitric acid per 250 mL of UPW) to stabilize for certain trace metals (i.e., iron and chromium).

10.5.4 *Tubing and piping:* Fill the component with test fluid to within one inch of the top of the component to allow free space for agitation. In the case of tubing or pipes, to maximize the exposed surface area of the pipe to the volume of fluid and to minimize the surface area of the end cap, it is recommended that the ratio of the surface area of the pipe to the surface area of the end cap be 10 or greater. The equation to determine the ratio is 4L/D, where L is the length of the pipe or tubing and D is the diameter.

10.5.5 *Valves, regulators, and fittings:* To allow for maximum fluid volume, fill valves, regulators, and fittings with the appropriate test fluid to within five mL of the top to allow for agitation. Multiple components may be required to obtain the necessary volume for the test. Valves, regulators, and fittings must be capped at both ends. In the case of valves, this practice assumes that normally opened valves will be used.

10.5.6 *Filter housings:* Fill the component with the appropriate test fluid to within one inch of the top of the housing to allow free space for agitation. The inlet and outlet of the housing must be capped.

10.5.7 Example of procedure for components that require capping

10.5.7.1 Clean and prepare 8 covered containers per Sections 10.4.1 and 7.1.1.

10.5.7.2 Flush component and blank extraction containers (3 components and 5 blank extraction containers) according to Section 10.4.2 (rinse 10 times for 2 minutes per Table 1).

10.5.7.3 Fill all components and blank extraction containers with the test media of choice (see Section 2.3 for definition of test media).

10.5.7.4 Soak according to Section 10.4.3 (soak one week per table 1), agitate all components and blank extraction containers once a day for one minute per Section 10.4.4.

10.5.7.5 Decant the contents of the component into 3 remaining empty containers.

10.5.7.6 At completion of this practice analytical tests should be performed on test fluid from each container see test methods noted in Table 3 and related documents section.

10.6 *Components that Require a Container (Gaskets, and O-Rings)*

10.6.1 Containers must have sufficient internal volume to perform the required test. Often, 100 mL of extracted test fluid will be required per test.

10.6.2 Surfactants and solvents may leave a residue that could alter the test results; do not use them for pre-cleaning.

10.6.3 During sample collection for metal analysis, the components must be acid stabilized to a pH of 2 (approximately 3 drops of concentrated nitric acid per 250 mL of UPW) to stabilize for certain trace metals (i.e., iron and chromium).

10.6.4 *Gaskets and O-rings:* A minimum of two grams of component per 100 mL of test fluid is required to perform any of the tests. To concentrate a sample and lower the detection limit of the test method, increase the amount of component per 100 mL of fluid.

10.6.5 Example of procedure for components that require a container

10.6.5.1 Clean and prepare 8 covered containers per Section 10.4.1 and 7.1.1.

10.6.5.2 Place the component into 3 containers per Section 10.6.

10.6.5.3 Flush all containers (3 with components and 5 as blanks) according to Section 10.4.2 (rinse 10 times for 2 minutes per Table 1).

10.6.5.4 Fill all containers with the test media of choice (see Section 2.3 for definition of test media).

10.6.5.5 Soak according to Section 10.4.3 (soak one week per table 1), agitate all containers once a day for one minute per Section 10.4.4.

10.6.5.6 At completion of this practice analytical tests should be performed on test fluid from each container see test methods noted in Table 3 and related documents section.

11 Procedure for Preparing Components for Bulk Polymer Analysis

11.1 Table 2 lists the amount of material required to achieve the indicated level of detection. Obtaining the amount may require using 1) an entire component, 2) a segment of a large component (such as piece of piping or valve), or 3) an appropriate quantity of smaller components (such as O-rings).

11.2 No further pretreatment is required except for inorganic analysis. See Section 11.3.

11.3 *Additional Pretreatment for Inorganic Bulk Analysis*

11.3.1 If the intent of the inorganic analysis is to examine the as-received material from a supplier, no further pretreatment is required.

11.3.2 After the proper amount of the material is obtained, place it in a clean container and clean it using the procedure outlined below.

NOTE: This procedure may also be used to pre-clean containers and caps to meet the criteria specified in Section 7.1.1. If pre-cleaning performance criteria is not achieved with this procedure another procedure should be used or the concentrations, times, and temperatures noted in this procedure could be varied to achieve required result.

11.3.3 Agitate the material in ultrapure IPA for 2 minutes. Drain the IPA from the material and replenish with ultrapure IPA. Allow the material to soak for 30 minutes.

11.3.4 Drain the IPA from the material and replace with UPW. Agitate the material for 2 minutes.

11.3.5 Soak the material in 1:1 ultrapure nitric acid : UPW for 2–4 hours.

11.3.6 Drain the nitric acid from the material and replace with UPW. Agitate the material for 2 minutes.

11.3.7 Soak the material in 1:1 ultrapure HCl : UPW for 2–4 hours.

11.3.8 Drain the HCl from the material and replace with the test fluid. Agitate the material for 2 minutes. Drain the material and replenish with test fluid and agitate for an additional two minutes.

12 Data Presentation

12.1 See Table 3 for a list of the units to report for individual component types. Record the following:

a) Report the test fluid used and test temperature.

b) Report if the components were prepared for testing as received or after the rinse pretreatment.

c) Report the volume of test fluid used.

d) Report the soak time

e) Report the wetted surface area of the component. If the precise wetted surface area is not known please record the assumed or estimated wetted surface area and note it is estimated.

f) If multiple components (such as gaskets, or O-rings) were used, report the total wetted surface area of the components.

g) Report the manufacturer, model number, and lot number (if known) for each component tested.

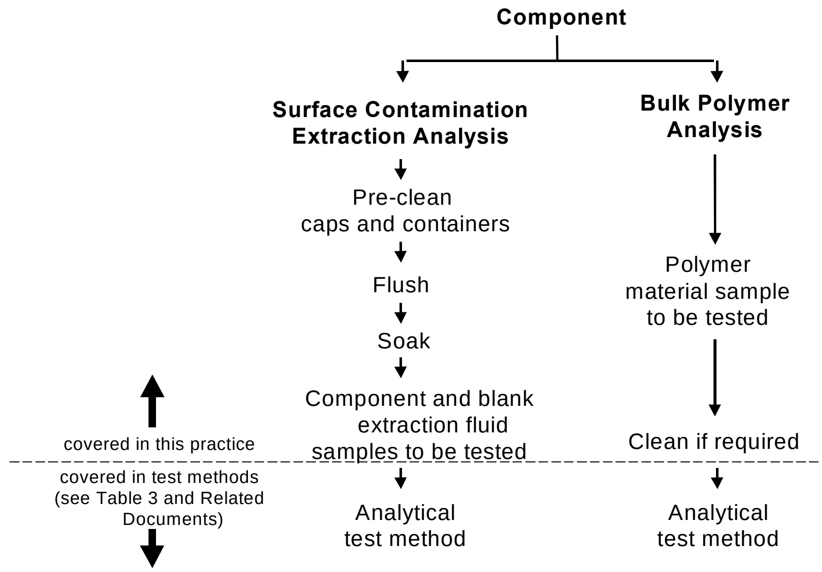

Figure 1
Summary of Practice

Table 1 Component Handling for Extraction Test Preparation

Component	No. of Flushes x Flush Time (min.)	Soak Time	Capped Component or Container	Container Material	Section
Tubing, Piping	10 x 2 min.	1 week	capped component	N/A	9.5.4
Valves, Regulators, Fittings	10 x 2 min.	1 week	capped component	N/A	9.5.5
Filter Housings	10 x 2 min.	1 week	capped component	N/A	9.5.6
O-rings, Gaskets	10 x 2 min.	1 week	container	PFA FEP PP glass (see NOTE*)	9.6.4

***** NOTE: The container and transfer vessel materials used depend on the test to be performed. Use the following materials for the noted test methods.

Test Method	**Material**
TOC, NVR	glass
anions	PP, glass
inorganics, resistivity, silica	PFA, FEP

Table 2 Material Requirements for Bulk Analysis

	Inorganics	FTIR	Thermal Analysis	Water Absorption
Weight (gms)	1–2	< 5	0.007–0.01	10
Detection Limit	0.1 ppm	N/A	N/A	0.1%

Table 3 Reporting Units for Aqueous Liquid Components

Test Method	Aqueous Liquid Component	Reporting Units
Leachable Trace Inorganics, Anions, TOC	tubing, piping, valves, regulators, fittings, gaskets, O-rings, filter housings	$\mu g/cm^2$
Bulk Trace Inorganics	tubing, piping, valves, regulators, fittings, gaskets, O-rings, filter housings	$\mu g/cm^2$
Nonvolatile Residue	tubing, piping, valves, regulators, fittings, gaskets, O-rings, filter housings	$\mu g/cm^2$

SEMI F41-0699
GUIDE FOR QUALIFICATION OF A BULK CHEMICAL DISTRIBUTION SYSTEM USED IN SEMICONDUCTOR PROCESSING

This Guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org January 1999; to be published June 1999.

1 Purpose

1.1 This Guide sets forth a logical and systematic approach to the qualification of a Bulk Chemical Distribution System that may be used by users and suppliers as a basis for developing site-specific BCDS specifications and performance criteria.

2 Scope

2.1 The qualification process includes evaluation of chemical from the chemical source, the fluid transfer system, the distribution piping, the day tank, as well as other intermediary points of transfer and storage that may be included in the qualification plan.

2.2 This guide assumes that the BCDS has been installed per the BCDS manufacturer's recommendations and the customer's specifications, and has been appropriately leak tested and shown to meet all requirements of mechanical and physical integrity up to the POU.

2.3 BCDS are typically tested for particle levels and trace metal impurities according to specified levels agreed upon in advance. For certain applications or specific chemicals, other testing may become incorporated in the qualification process. These other tests may include assay analysis, anion analysis, TOC analysis, moisture analysis, etc.

3 Limitations

3.1 This guide does not define the test methods that should be used for evaluation of samples taken during the qualification process, or distinguish test methods that will generate accurate and reliable results from those that will not generate accurate or reliable results.

3.2 This guide does not define or describe the sampling methodologies that are required in order to physically take a representative and a non-contaminated batch sample. However, appropriate sampling procedures and equipment must be used consistent with the actual specifications.

3.3 This guide does not define the type of containers that should be used for sampling. Pretreatment of containers is necessary to assure that the data generated by testing actually measures the chemical being delivered to the process tool and not the impurities in the container itself, from the environment, or from human handling.

3.4 This guide does not address the type, level, or frequency of testing necessary and appropriate for ongoing monitoring of a BCDS.

3.5 This guide does not address the special case of a system designed and used for the generation and distribution of high purity water used in semiconductor processing.

3.6 This guide does not address the testing and prequalification of materials, subassemblies, or components used in a BCDS.

3.7 This guide does not address the protocols and requirements defined by the manufacturer concerning the installation of the BCDS.

3.8 This guide does not define the actual specifications generally negotiated between the user and the manufacturer of the BCDS, against which chemical samples are tested and qualification is passed.

3.9 This guide does not address the qualification process for chemicals through the process tool. While the sampling considerations and timing make the initial tool qualification a natural adjunct to the BCDS qualification, the responsibility for this task generally falls within a different jurisdiction and is generally handled separately.

4.2 *Other Document*

4.2.1 *SIA National Technology Roadmap For Process Chemicals*[1]

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *BCDS* — Bulk Chemical Distribution System

5.2 *Definitions*

5.2.1 *pickling* — To condition the BCDS by exposing to an aggressive chemical that extracts impurities from the internal surfaces of the system.

5.2.2 *sample* — Sample taken from a system into a sampling container and measured off-line.

6 Pre-Chemical Qualification

6.1 Advantage of Pre-Chemical Qualification — The pre-chemical qualification is designed to ensure that the piping systems and storage tanks are able to accept chemicals. This step is often initiated after the UPW system is functional and an acceptable resistivity is achieved but before chemicals are authorized to be brought on-site. Although UPW does not extract high levels of metallic and ionic impurities from the BCDS materials of construction, this step can ensure that the BCDS and distribution piping is free of any gross contamination that may have been introduced into the system during installation. In addition, the UPW flush can be effective for the elimination of some types of particles.

6.2 Particle Qualification — The BCDS is flushed with UPW and the levels of particles are measured using an on-line optical particle counter. The steps followed include:

6.2.1 Install an acceptable UPW water filter element(s) per the filter and BCDS manufacturer's specifications.

6.2.2 Fill the BCDS with UPW and recirculate internally to ensure that all piping is filled with UPW.

6.2.3 Begin sampling to a liquid particle counter downstream of the filters either at the outlet of the BCDS, the POU, or both. Follow an approved particle counting sampling procedure.

6.2.4 Continue recirculating and flushing until the particle concentrations in the desired channel or channels are observed at levels below the agreed-upon specification. An example of typical specification is the average of five consecutive ten minute readings of <X particles/ml @ ≥ Y micron.

[1] *Semiconductor Industry Association, 181 Metro Drive, Ste 150, San Jose, CA 95110, USA*

6.3 Metallic Qualification — After reaching the particle specification for the UPW, a sample of UPW may be taken for trace metal analysis. This sample can be taken at the outlet of the BCDS, at an end point sample station and/or at the POU. An appropriate sample bottle precleaned for this test should be used to collect a sample. The sample bottle should be preconditioned before use and contamination-free techniques used for the actual sampling.

6.3.1 The steps to follow are:

6.3.1.1 Fill the sample bottle with the required volume for the analytical method to be used. The volume varies depending on analytical procedures and lab instrumentation.

6.3.1.2 Send samples to a designated laboratory capable of performing trace metal analysis. Use only a laboratory that has experience with these types of samples and that can test reliably in the sub-ppb range. The number of elements and concentrations that are to be analyzed will vary depending on customers' requirements.

6.3.1.3 Evaluate data and compare to the agreed-upon specification. A typical specification is <X ppb total and <X ppb per element.

6.3.1.4 If the trace metal specification is not met, drain or flush the entire BCDS and distribution piping and repeat the process.

6.3.1.5 If a maximum level of impurities is desired, a sample of the UPW used to charge the system should be tested to establish a baseline and to ensure that the incoming UPW is not the source of high impurities.

6.3.1.6 Once the BCDS has been qualified for particles and trace metals in UPW, the qualification of the BCDS in Chemical may be initiated.

7 Chemical Conditioning of The System

7.1 Advantages of Conditioning the System — Another precleaning step that may be used independently or in conjunction with a UPW flush is to condition the BCDS by actively flushing it with an aggressive chemical that extracts impurities from the internal surfaces of the system. This step is sometimes referred to as "pickling" the system. This extra step can help minimize the amount of time consumed in the qualification process by utilizing a chemical with more aggressive extraction properties than the actual chemical to be used in the line, thereby increasing the rate at which impurities are removed. This can shorten the amount of time needed until the actual chemical can be put into the line and shown to meet the qualification specifications. Since a goal of a well-designed qualification protocol is to minimize the amount of high purity chemical flushed to drain during the qualification process, this approach may also prove to be more cost effective depending on the cost of the chemical used for pickling, compared to the cost of the process chemical designated for use in the line.

7.2 Conditioning With Same Chemical — A variation on the above approach is to "pickle" the system with the process chemical that is intended to be used in the BCDS line a 24-72 hour soak period and flushing the chemical to drain. While the process chemical may not be as aggressive in cleaning up the line, this approach has the advantage that the extracted metals have the same fingerprint as those that might otherwise be observed during the final qualification testing, and the final qualification may be done immediately following this step, without further preparation.

7.3 Testing the Preconditioning Chemical — Rather than relying on an arbitrary or predetermined lengths of time for preconditioning the BCDS, test samples are often taken and analyzed to ensure that the required level of impurities has actually been obtained. This testing is often commissioned by the equipment manufacturer and not reported to the customer as part of the BCDS qualification. Indicator elements are often analyzed that are either of particular concern in the process chemical, or elements such as Ca, Cr, Cu, Fe, Mg, Na, Ni, and Zn, that are known as common impurities in chemicals and that are also highly detrimental in semiconductor processing.

7.4 Conditioning Procedure — The three most common chemicals (HCL, HF, and HNO3) used for precleaning the BCDS are aggressive in extracting metallic impurities and particles. The steps followed include:

7.4.1 Install an acceptable chemical filter element(s) per the filter and BCDS manufacturer's specifications.

7.4.2 Fill the BCDS and distribution piping with the chemical of choice and recirculate internally to ensure that all piping is filled. This may include all distribution piping. Let the chemical soak the materials of construction in a static manner for a period of 24 to 72 hours, or continue recirculating the chemical as a closed loop for the same amount of time.

7.4.3 Flush the chemical from the system.

7.4.4 Depending on the chemical used, a UPW rinse step or an inert gas purge step for drying may be required prior to filling the system with the actual chemical for the qualification testing.

Note: The precleaning chemicals used may add undesirable contaminants (i.e. F^- from Hydrofluoric acid, Cl^- from hydrochloric acid, etc.). Therefore, if any of these chemicals are used, additional testing may be required to determine that these materials have not added contaminants in excess of any specification. These contaminants may be tested in the UPW rinse step or in the final chemical qualification step.

7.5 Solvent Systems — The type of chemical used for flushing solvent BCDS systems is different than that used for oxidizers and corrosive chemicals since solvent systems can be made from stainless steel and metal materials for reasons of safety and chemical compatibility. Generally, IPA, or the chemical to be used in the system, is used for the aqueous pre-clean step in flushing a system where solvents are to be used.

8 Final Chemical Qualification

8.1 Initial Considerations — Notwithstanding any of the steps taken to prepare the BCDS for qualification testing, certain issues should be considered prior to starting any sampling required in the qualification process:

8.1.1 Determination about the adequacy of the sampling points. — The sampling points are generally coincident with the location of pre-existing sample ports on the Valve Manifold Box, day tank and other distribution points. The adequacy of the sampling points depends on their accessibility, environmental controls, ability to flush prior to sampling, and safety considerations.

8.1.2 Adequacy of data. — Due to sampling error, possibility of environmental contamination, handling problems, and impurities in sampling containers, samples should be taken in duplicate or triplicate, with two samples sent to the lab for testing and one sample retained in case of a dispute.

8.1.3 Use of proper precleaned sampling containers. — Sampling containers must be chemically compatible and precleaned in a manner consistent with the desired specification level for impurities. Sample bottle preparation differs depending on the type of testing to be performed.

8.1.4 Use of a contamination-free sampling device for samples pulled from an open vessel or a drum.

8.1.5 Proper training for personnel assigned to sampling. — The proper training is required to ensure that personnel charged with sampling follow appropriate safety and contamination-free protocols.

8.2 Particle Qualification — For most accurate results, particle levels should be measured on-line with a optical particle counter capable of measuring the size of particle that is included in the guaranteed specification. Batch samples may be taken and measured for particles in a lab, but special care is needed to prequalify containers used for this sampling, and data integrity may be compromised for the smallest sized particles due to various contamination sources. An example of a protocol generally followed to measure particle on-line includes:

8.2.1 Remove all UPW in the BCDS and distribution piping.

8.2.2 Remove UPW filters or replace incompatible chemical filters if present.

8.2.3 Install specified filter element per the BCDS and filter manufacture's specifications.

8.2.4 Commission the BCDS and distribution piping with the process chemical.

8.2.5 Recirculate chemical through the BCDS and through all POU to drain.

8.2.6 Drain all chemicals from the BCDS and distribution piping.

8.2.7 Refill entire system with chemical and begin circulation through filters and out to POU to drain.

8.2.8 Begin sampling to a liquid particle counter downstream of the filters either at the outlet of the BCDS, the POU, or both. Follow a prescribed particle counting sampling procedure.

8.2.9 The number of particle samples and sample duration time should be calculated based on the total volume of chemical desired to be examined by the particle counter. A "sufficient" volume of chemical should be examined by the particle counter during the qualification period. As an example, the particle concentration could be measured over at least a five-hour period with thirty consecutive ten-minute samples taken. In this example, the average of the last consecutive 30 samples would be calculated and compared to the specification.

8.2.10 The particle concentration is considered acceptable if the average is less than the specification.

8.3 Metallic Qualification — Metallic impurities are generally specified both in terms of level of impurity by element and total amount of impurities. The customer's specification generally lists each element to be included in the analysis or may refer to the list of elements published by SEMI for each chemical at different purity grades. The maximum impurity levels may be described as an absolute value (e.g. 1ppb maximum impurity), or in terms of the quantity of impurities that may be added by the BCDS including the distribution piping. This amount of "total adders" is determined by measuring the impurity levels of the incoming chemical from the storage or supply vessel compared to the purity level of the chemical at the end point sample station or POU. The number of samples and location of samples vary depending on the type of specification. When qualifying to a “metallic impurities added” specification, a sample must be taken from the incoming chemical supply drums for an incoming baseline. The testing protocols includes:

8.3.1 Precondition all sampling bottles before use and follow appropriate sampling protocol.

8.3.2 Send samples to a lab for trace metal analysis specifying the level of testing required and the number of elements to be tested. The level of testing required depends on the agreed upon specification. As a rule of thumb, the detection limits of the analysis should be at least 10X's lower than the impurity level to be achieved for each element. In addition, the lab should follow high standards of quality control for trace metal analysis including analysis in duplicate, duplicate blanks, use of internal standards, instrument calibration using primary standards, and QC checks.

8.3.3 Review the data that is reported and compare it to the customer requirement.

8.3.4 If the system does not meet the specification then repeat the procedure until the system is qualified.

8.3.5 Where maximum levels of impurities are specified, a sample of the incoming chemical should either be measured as part of the qualification process, or retained, to ensure that the incoming chemical is not a significant source of contamination.

8.3.6 For purposes of metallic qualification, soak periods similar to those referenced in Section 7.2 are recommended.

9 Other Considerations

9.1 Accelerated Qualification Techniques — Although process chemicals such as hydrofluoric and hydrochloric acid may reach acceptable levels of purity after a few weeks in the BCDS, other chemicals such as sulfuric acid and ammonium hydroxide extract impurities much more slowly and significant levels of impurities are observed even after several months. The BCDS conditioning process described above is one approach to preleaching impurities from the BCDS. Other variations include combinations of static and dynamic rinses and emphasis on the use of dilute HF as the aqueous preclean chemical that is particularly effective for iron removal, however, it contributes high levels of fluoride which may be a concern for some qualification processes.

9.2 Specialty Chemicals — Certain CVD chemicals have high levels of organics which raise concerns about chemical decomposition, residues and particulate formation. These concerns may require customized approaches to the design of a BCDS qualification. For example, reservoir replacement for these types of chemicals with vapor pressure from 1-5 Torr and above may require the use of vacuum less than the vapor pressure of the chemical whereas low vapor pressure chemicals with vapor pressures from 1-5 Torr, and viscous materials, may require a solvent purge. In addition, purging and pickling of he BCDS and chemical delivery lines should be performed per Sections 7.1 and 7.2. CAUTION: UPW introduced into the lines frequently interacts with the CVD chemicals causing decomposition.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. SEMI F42-0600
TEST METHOD FOR SEMICONDUCTOR PROCESSING EQUIPMENT VOLTAGE SAG IMMUNITY

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on March 2 and April 10, 2000. Initially available on www.semi.org May 2000; to be published June 2000. Originally published June 1999.

1 Purpose

1.1 The purpose of this document is to define the test method used to characterize the susceptibility of semiconductor processing, metrology, and automated test equipment to voltage sags.

2 Scope

2.1 This document defines the testing procedures and test equipment required to characterize the susceptibility of equipment to voltage sags by showing voltage sag duration and magnitude performance data for the equipment.

NOTE 1: Characterizing equipment voltage sag immunity allows for the identification of tolerances, if any, that may exist between the actual equipment immunity and any one or more voltage sag performance specifications.

2.2 This test method is intended for, but not limited to, the following equipment types:

- Etch equipment (Dry & Wet)
- Film deposition equipment (CVD & PVD)
- Thermal equipment
- Surface prep and clean
- Photolithography equipment (Stepper & Tracks)
- Chemical Mechanical Polishing equipment
- Ion Implant equipment
- Metrology equipment
- Automated test equipment

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard does not address testing for over-voltage conditions.

3.2 International, national and local codes, regulations and laws should be consulted to ensure that the equipment and procedures meets regulatory requirements in each location.

4 Referenced Standards

4.1 *SEMI Standard*

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

4.2 *IEEE Standard* [1]

IEEE 1250 — Guide for Service to Equipment Sensitive to Momentary Voltage Disturbances

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Definitions*

5.1.1 *device under test (DUT)* — the semiconductor process, metrology, or automated test equipment intended to be tested, including the equipment mainframe and all subsystems whose electrical power is directly affected by the operation of the equipment's EMO system.

5.1.2 *emergency off circuit (EMO)* — a control circuit which when de-activated, places the equipment into a safe shut down condition and will restrict all hazardous potentials to the main power enclosure. This is a state in which all hazardous voltage has been removed from the equipment, all hazardous production materials flow has been stopped, any radiation sources de-energized or totally contained, any capacitors grounded, all moving parts stopped, internal and external heat sources shut off, and the equipment presents minimum hazard to personnel or the facility. [SEMI S2]

5.1.3 *point of connection (POC)* — the point where the facility utility connects to the exterior of the equipment.

5.1.4 *ride-through capability* — the ability of equipment to withstand momentary interruptions or sags [IEEE 1250]. Also known as voltage sag immunity.

1 The Institute of Electrical and Electronic Engineers, Inc., 345 East 47th Street, New York, NY 10017-2394, USA

5.1.5 *sag generator* — test apparatus capable of reducing voltage supplied to the device under test for specific time durations.

5.1.6 *voltage sag* — an rms reduction in the ac voltage, at power frequency, for durations from half-cycle to a few seconds [IEEE 1250]. Also known as voltage dip.

6 Test Apparatus

6.1 *Data Acquisition System (DAS):* The DAS will allow monitoring of the device under test and selected subsystems during the test. The DAS must measure the voltage and current at least two cycles (40/33 ms) before, during, and at least two cycles (40/33 ms) after the voltage sag event. The DAS must have the performance characteristics defined in Table 1.

NOTE 3: (40/33 ms) refers to 40 ms at 50 Hz or 33 ms at 60 Hz.

Table 1 Data Acquisition System Performance Requirements

Parameter	*Requirement*
Measurement Accuracy	± 3 percent of reading
Minimum Sample Rate	900 Hz
Minimum Number of Analog Inputs	As required by the Test Plan (see Section 10.1.4)

6.2 *Digital Volt Meter (DVM)* — A digital meter with current and voltage measurement probes. Minimum performance requirements of 1% accuracy, true rms, and resolution of 3 1/2 digits.

6.3 *Sag Generator* — The sag generator must be capable of providing voltage sags of controlled magnitude and duration relative to the nominal supply voltage of the DUT. The sag generator must be able to create voltage sags over the range of durations and magnitudes as required. The sag generator must be capable of producing independent output voltages on each phase of the load. The sag generator must have the performance characteristics in Table 2 (see Related Information 1).

Table 2 Sag Generator Performance Requirements

Parameter	*Requirement*
Insertion loss (the difference between sag generator input and output voltages when set to 100% of nominal)	Less than 1.5%
Change in output voltage as load is varied from 0–100% (steady state load regulation)	± 5%
Output current capability	As required by the DUT.
Capability to supply inrush current	Not to be limited by the sag generator.
Under all conditions, the maximum deviation from required voltage (dynamic load regulation)	Less than ± 10% for not more than 1 cycle (20/17 ms).

7 Safety Precautions

NOTE 4: The following are safety guidelines for voltage sag testing and as such should be considered only recommendations since regional safety regulations vary. International, national and local codes, regulations and laws should be consulted to ensure that the equipment and procedures meet regulatory requirements in each testing location.

7.1 Work should be conducted in accordance with industry standard safety procedures. Since panels may need to be open in order to connect voltage probes and route power leads to and from the sag generator, this work is classified as Type 2 Energized Electrical Work per SEMI S2. Test equipment manufacturer's safety recommendations should be followed.

7.2 *Worker Safety*

7.2.1 During testing lock and tag (lockout/tagout) procedures should be followed to control hazardous energy (reference appropriate regional regulations and requirements). No circuit should be connected or wired when electricity is present. This includes power connections as well as the connection of various monitoring probes.

7.2.2 The area immediately surrounding the device under test (DUT) should be cordoned off and appropriate signs like "Test In Progress" should be posted.

7.2.3 Appropriate personal protective equipment should be worn at all times.

7.2.4 Only authorized personnel should be allowed within the cordoned off test area.

7.2.5 Work should be done as described in the test procedure (see Section 10).

7.2.6 Proper connections should be traced and verified before energizing.

7.3 *Equipment Safety*

7.3.1 The sag generator should have a fail-safe design.

NOTE 5: Subjecting equipment to repeated voltage sags of less than 80% nominal for longer than 3 seconds may damage equipment.

7.3.2 The sag generator should be protected by an appropriately sized branch circuit breaker at the utility power source. This will protect the sag generator and DUT from short circuits and overcurrent conditions.

7.3.3 Every effort should be made to protect the DUT. As with other equipment tests damage to the DUT is possible. Although only a remote possibility, the equipment owner should be made aware of the potential for damage.

8 Sampling and Test Specimens

8.1 Characterization tests are conducted on samples of production articles, not on each item produced. Characterization tests apply to equipment that is manufactured to a single design either in multiple quantities or one-of-a-kind. The equipment selected for testing should reflect current production models of the supplier.

8.2 The intent of this document is to make reasonable efforts to test the semiconductor process, metrology, and automated test equipment as a complete operating system under the actual intended conditions of end use. To simulate the worst-case condition, the tests described in this document should be performed during the most sensitive process mode of the equipment as determined by the equipment supplier.

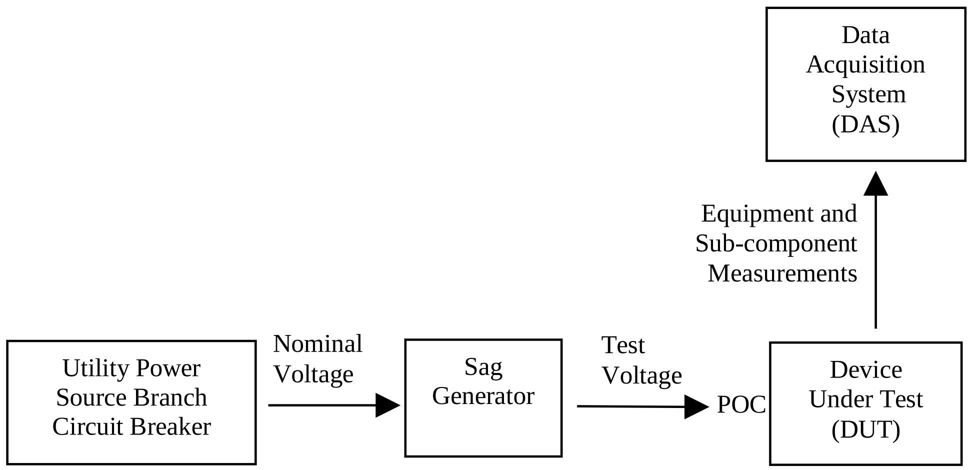
9 Test Setup

9.1 The test setup should consist of a sag generator and a data acquisition system as shown in Figure 1.

9.2 When the current required by the DUT is within the sag generator's rating, the sag generator shall be connected between the incoming utility power source and the point of connection (POC) on the DUT. If the current required by the DUT is greater than the rating of the sag generator, then individual subsystems of the DUT can be tested separately.

9.2.1 If DUT subsystem testing is required due to the limitation of the sag generator, each subsystem must be tested independently with the other parts of the DUT operating. Tested in this manner, any interlocks or alarms that might activate during the test will be apparent. Testing the DUT main power module may require providing power to only the main power module, leaving the subsystems turned off. After the characteristics of the DUT main power module EMO circuit are known, testing of DUT subsystems can begin as described.

9.2.2 Power down the DUT.



NOTE: Single-phase test fixture is shown for clarity.

Figure 1
Test Setup

9.2.3 De-energize and lockout/tagout the DUT POC.

9.2.4 De-energize and lockout/tagout the voltage supply at the DUT utility power source branch circuit breaker.

9.2.5 Identify the utility power source branch circuit breaker to be used to power the sag generator, then, turn off and lockout/tagout this device.

9.2.6 Following the sag generator manufacturer's instructions, connect the input of the sag generator for each phase, ground, and neutral (if required) to the utility power source branch circuit breaker identified in Section 9.2.5.

9.2.7 Following the sag generator manufacturer's instructions, connect the output of the sag generator to the DUT POC.

9.2.8 Following the DAS manufacturer's instructions, connect the DAS channels to the appropriate measurement points on the DUT. The data acquisition measurement points should be defined in the test plan (see Section 10.1.4). Typical data acquisition measurement points for semiconductor equipment are listed in Table 3.

Table 3 Typical Data Acquisition Measurement Points

No	*Data Acquisition Measurement Points*
1	Ia, phase A current
2	Ib, phase B current
3	Ic, phase C current
4	Va-n, phase a-n voltage
5	Vb-n, phase b-n voltage
6	Vc-n, phase c-n voltage
7	Instrument Power Supplies output voltage
8	Emergency Off Relay contact
9	Equipment power contactor contact
10	Equipment controller power supplies output voltage

9.2.9 During all voltage sag tests, the output of the sag generator must be monitored by the DAS system. The magnitude of the DAS monitored sag waveform must be used to determine the magnitude of the actual event since the magnitude may vary from the pre-sag setting on the test equipment.

9.2.10 Visually inspect all connections.

9.2.11 Remove the lockout/tagout at the sag generator utility power supply branch circuit breaker.

9.2.12 Energize the sag generator's utility power source branch circuit.

9.2.13 Initialize the sag generator system and set the output for 100% of the DUT nameplate nominal voltage.

9.2.14 Using a digital voltmeter, measure and record the phase voltage(s) at the output of the sag generator.

9.2.15 Remove lockout/tagout at the DUT POC.

9.2.16 Energize the DUT.

9.2.17 Bring the DUT on-line in an idle state.

9.2.18 Using a digital voltmeter, measure and record the phase voltage(s) at the output of the sag generator. If needed, adjust the output of the sag generator for 100% of the DUT nameplate nominal voltage.

9.2.19 Set the sag generator for a 95% of DUT nominal, 10 cycle (200/167 ms) sag voltage on one phase.

9.2.20 From the sag generator controller, trigger the sag event.

9.2.21 From the DAS, verify that the test sag event is within the specified tolerance.

9.2.22 From the DAS, verify that all monitoring points are recording the expected status information.

10 Test Procedure

10.1 In order to arrive at meaningful and comparable results from voltage sag immunity testing on semiconductor equipment the following steps should be followed.

10.1.1 The test engineer should first study and understand the DUT power flow and safety interlocking systems of the DUT.

10.1.2 The test engineer should then determine the purpose of the test (e.g. To characterize the susceptibility of the DUT to voltage sags within a defined duration range and to a defined minimum voltage magnitude).

10.1.2.1 The test engineer should define the duration range minimum and maximum over which the test voltage sag should be applied to the DUT (e.g. 0.05 seconds to 1.0 seconds, as described in voltage sag ride-through specification, etc.).

10.1.2.2 The test engineer should define the voltage magnitude minimum(s) that should be applied to the DUT over the test duration range (e.g. 0 volts nominal for maximum duration, as described in voltage sag ride-through specification, etc.).

10.1.3 The test engineer should define that testing is complete for each phase mode when either an equipment interrupt occurs at the minimum test duration regardless of the voltage magnitude, or, the test is conducted at the defined minimum voltage magnitude without equipment interrupt.

10.1.4 Based on the knowledge gained in the study of the DUT and the purpose of the test, the test engineer should prepare a specific Test Plan that references this test method with date of issue and includes, at a minimum:

- identify the most sensitive process mode and the process mode(s) to be used during tests
- minimum sag voltage to be applied (e.g. 0%, 50%, etc.)
- sag voltage incremental change not greater than 5% (e.g. 5%)
- maximum sag duration at each sag voltage (e.g. determined by voltage sag ride-through specification, potential for DUT damage, etc.)
- sag test durations (e.g. 0.05, 0.2, 0.5, 1.0 seconds)
- phase modes required (e.g. phase-to-neutral, phase-to-phase)
- point-on-wave of the sags (location on the sine wave where voltage sag begins): if controllable, set at 0°. If not controllable, noted as such.
- data acquisition measurement points (e.g. Table 3).

10.2 The following test procedure should be conducted in both the DUT idle state and the DUT's most sensitive process mode (see Section 8.2).

10.3 The following test procedure should be conducted with the sags applied in each phase mode identified in the Test Plan (see Section 10.1.4).

10.3.1 For single-phase loads, the sags should be applied from phase-to-neutral, for a total of one mode.

10.3.2 For three-phase loads without a neutral conductor, the sags should be applied from phase-to-phase between each pair of phases, for a total of three modes.

10.3.3 For three-phase loads with a neutral conductor, the sags should be applied from phase-to-neutral for each phase, and from phase-to-phase between each pair of phases, for a total of six modes.

10.4 Using a DVM, measure and record the actual test site voltages at the line side of the sag generator, phase-to-neutral (if available) and phase-to-phase (if available).

10.5 Verify that the test setup is complete (see Section 9).

10.6 Set the sag generator to 100% of the DUT nameplate nominal voltage. Cycle through the following test procedure.

10.6.1 Set the sag generator to the next lower sag voltage based on the sag voltage increment determined in the Test Plan, not greater than 5% (see Section 10.1.4).

10.6.2 Set the sag generator to the minimum sag duration for this sag voltage in the Test Plan (see Section 10.1.4).

10.6.3 Trigger the sag event. Record the results, including the magnitude (sag depth) and duration.

NOTE 6: It is advantageous to record additional detail, such as DAS waveforms, if a DUT interruption occurs.

10.6.4 Set the sag generator to the next longer sag duration for this sag voltage in the Test Plan (see Section 10.1.4)

10.6.5 Trigger the sag event. Record the results, including the magnitude (sag depth) and duration.

10.6.6 Repeat Sections 10.6.4 thru 10.6.5 until all durations are complete for this sag voltage magnitude per the Test Plan, then, continue to Section 10.6.7.

10.6.7 Repeat Sections 10.6.1 thru 10.6.6 until all sag voltage magnitudes are complete for this phase mode per the Test Plan, then, continue to Section 10.6.8.

10.6.8 If required, reconfigure the test setup for the next phase mode and repeat Sections 10.6.1 thru 10.6.7 until the test is complete for all phase modes, then, continue to Section 10.6.9.

10.6.9 If required, return the test setup to the original phase mode and repeat Sections 10.6.1 thru 10.6.8 until the test is complete for all process modes (e.g. idle state, most sensitive process mode).

11 Interpretation of Test Results

11.1 The injection of voltage sags into semiconductor equipment can lead to numerous shutdown mechanisms. Typical semiconductor equipment voltage sag shutdown mechanisms include EMO circuitry, instrument and controller power supplies, motion control drives, and voltage monitoring relays.

11.2 The shutdown or dropout of equipment components is best identified when monitored by a DAS that is tightly coupled to the control of the sag generator. Figures 2 and 3 display the shutdown of a power supply during a 55% of nominal 10-cycle (200/167 ms) voltage sag.

11.3 Figure 2 displays the actual voltage sag output from the sag generator and Figure 3 displays the output of the power supply. With the DAS it can be seen that the power supply output begins to decay 3 cycles (60/50 ms) into the 55% of nominal sag event, causing the DUT to interrupt.

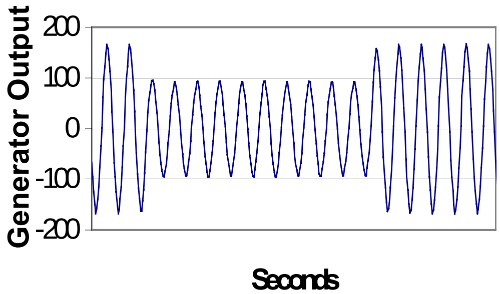


Figure 2
Sag Generator Output

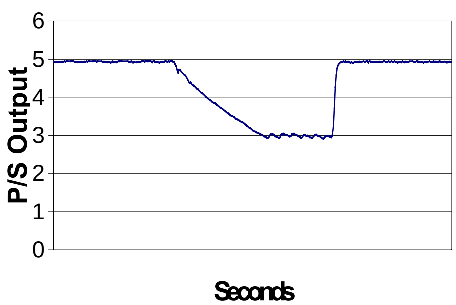

Figure 3
Power Supply Voltage Sag Shut Down Example

12 Reporting Test Results

12.1 Report the specific test plan used and, if used, the voltage sag ride-through specification.

12.2 Report the manufacturer, model number, revision (if known) and process application for the DUT.

12.3 Report the type of sag generator and the accuracy of the test apparatus.

12.4 Report the outcome of the voltage sag testing in both a tabular form (see Tables 4 and 5) and plotted on a graph(s), voltage magnitude (Y axis) and duration (X axis). Separate graphs should be plotted in order to represent the results of the single-phase testing and the phase-to-phase testing. If used, overlay a plot of the voltage sag ride-through specification onto the voltage sag testing outcome graph(s) (see Figures 4 and 5).

12.5 Report the outcome of the sag event including the cause of the DUT interrupt (e.g., EMO relay dropped out, power supply shutdown, etc.).

12.6 Report conclusions of voltage sag immunity testing of the DUT (e.g., Key immunity data points, compliance/non-compliance with voltage sag ride-through specification, corrective actions taken, etc.).

RELATED INFORMATION 1
SAG GENERATORS

NOTE: This related information is not an official part of SEMI F42 and has been derived from the work of the originating task force. This related information was approved for publication by full letter ballot procedures on December 18, 1998. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Types of Sag Generators

R1-1.1 As defined in the test instrumentation section of IEC-61000-4-11, there are two common types of voltage sag generator devices – variable transformer-switch type and the power amplifier type.

R1-1.2 Both units shown in this section can inject phase-shifting into the output waveform. All units except the contactor based transformer-switch type are capable of some point-on-wave controllability.

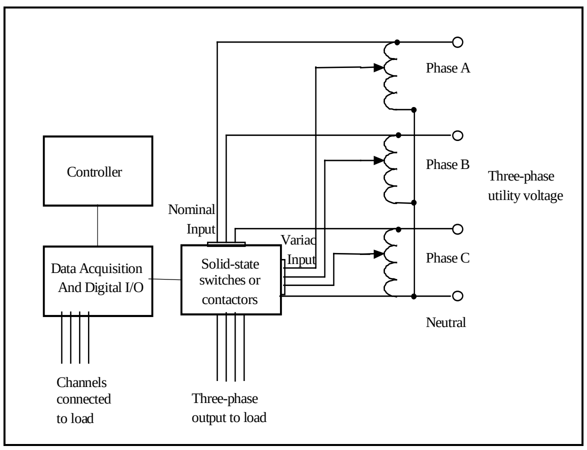

Figure R1-1
Transformer-Switch Type Sag Generator

R1-2 Transformer-Switch Type

R1-2.1 This type of sag generator has been built with either insulated gate bipolar transistor (IGBT), silicon control rectifier (SCR), or contactors used as the switching devices. The IGBT based switch is the most controllable with the ability to precisely control the point on the waveform in which the voltage sag starts and finishes (0-360 degrees). With an SCR switch, the point on wave of the voltage sag starts can be controlled, but the cutoff point of the voltage sag will be fixed at zero degrees. In real power systems, the point-on-wave in which the voltage sag occurs is somewhat random and unpredictable. A contactor based unit simulates the randomness of a real power system in that the point-on-wave in which the voltage sag begins is not controllable, but is dependent on the lag time between energizing the coil of the contactor and contactor closure. Figure R1-1 below displays a three-phase sag generator test fixture with data acquisition.

R1-2.2 As shown in Figure R1-1, voltage sags are injected into the load referenced to the neutral. Since the three variable transformers shown only need to carry current during the voltage sag, they do not need to be rated for continuous current.

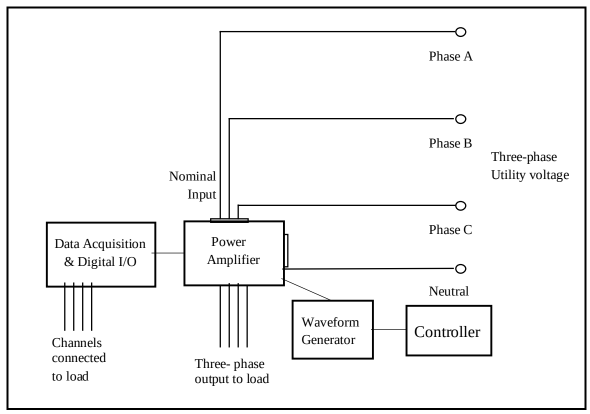

Figure R1-2
Power Amplifier Type Sag Generator

R1-3 Power Amplifier Type

R1-3.1 This type of system utilizes a controller, wave-form generator, data acquisition systems, and power amplifier section. Since this type of amplifier can be highly configurable, it can simulate most any point-on-wave or phase-shift desired. The power amplifier-based sag generator will be typically heavier and less portable than its transformer-switch counterpart. A conceptual three-phase version of this type of sag generator test fixture is shown in Figure R1-2.

SEMI F43-0699
TEST METHOD FOR DETERMINATION OF PARTICLE CONTRIBUTION BY POINT-OF-USE PURIFIERS

This Test Method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available on www.semi.org February 1999; to be published June 1999.

1 Purpose

1.1 The purpose of this document is to define a method for testing POU purifiers intended for installation into a high-purity gas distribution system and semiconductor manufacturing process equipment. Application of this test method is expected to yield comparable data among POU purifiers tested for the purposes of qualification for its installation.

2 Scope

2.1 This document describes a test method designed to draw comparisons of particulate generation performance of POU purifiers tested under standard conditions. The procedure utilizes a condensation nucleus counter (CNC) applied to in-line gas purifiers typically used in semiconductor applications. It applies to purifiers of various media and up to 5 cm (~ 2 in.) i.d. in size and for room temperature operation. The purifier's rated flow should be in the range of 0-50 standard liter per minute (slpm). For applications of this method to larger purifiers, the testing flow rate should be higher than specified in this method.

2.2 The experimental set up described in this method can be used for testing either POU purifiers or stand-alone POU filters.

3 Limitations

3.1 This procedure addresses total particle count greater than the minimum detection limit (MDL) of the condensation nucleus particle counter and does not consider classifying data into various size ranges.

3.2 This methodology specifies flow and mechanical stress conditions in excess of those considered typical. These conditions shall not exceed those recommended by the manufacturer. Actual performance under normal operating conditions may differ.

3.3 The test medium is limited to nitrogen and argon. Performance with other gases may vary.

3.4 This method does not include extended particle count testing or testing under challenging conditions.

3.5 The accuracy of the data generated by this method is limited to the accuracy of the particle measuring instruments utilized.

3.6 This method is written with the assumption that the operator understands the use of the apparatus at a level equivalent to six months of experience.

5 Terminology

5.1 *Acronyms*

CNC – condensation nucleus counter

DUT – device under test

EP – electropolished

kPa – kiloPascal

LPC – laser particle counter

POU – point of use

psi – pounds per square inch

psia – pounds per square inch absolute

psid – pounds per square inch differential

psig – pounds per square inch guage

Ra – roughness average

Rmax – roughness maximum

scfm – standard cubic feet per minute

slpm – standard liters per minute

5.2 *Definitions*

5.2.1 *background counts* — counts contributed by the test apparatus (including counter electrical noise) with the spool piece in place of the test object.

5.2.2 *CNC* — condensation nucleus counter. A light scattering instrument that detects particles in a gaseous stream by condensing supersaturated vapor on the particles.

5.2.3 *control product* — a sample component that gives consistent, stabilized counts at or below the expected counts from the test components. The product is run periodically in accordance with the test protocol to assure that the system is not contributing particles significantly different from expected levels. In the absence of a control product, a spool piece can be used as a control product of low particle emission rate.

NOTE 1: The control product may have to be changed periodically if its performance degrades with testing. Between tests, the control product must be bagged in accordance with the original manufacturer's packaging and stored in a clean manner. The control product is used to allow the system to consider the disruption caused by changes in flow due to the actuation of any valve, such as significant fluctuations in flow, pressure, turbulence, and vibration.

5.2.4 *dynamic test* — a test performed to determine particle contribution as a result of pulsing flow through the DUT.

5.2.5 *impact test* — a test performed to determine particle contribution as a result of mechanical shock applied to the DUT.

5.2.6 *Nine–log retention* — number of particles upstream of the purifier or filter are 1,000,000,000; number of particles down-stream of the purifier or filter is 1.

5.2.7 *sample flow rate* — the volumetric flow rate drawn by the counter for particle detection. The counter may draw higher flow for other purposes (e.g., sheath gas).

5.2.8 *sampling time* — the time increment over which counts are recorded.

5.2.9 *spool piece* — a null component consisting of a straight piece of electropolished tubing and appropriate fittings used in place of the DUT to establish the baseline.

5.2.10 *static test* — a test performed to determine particle contribution under steady flow condition through the DUT.

5.2.11 *test duration* — total time required to complete the test procedure. (See Section 7.3)

5.2.12 *test flow rate* — mass flow through device under test.

5.2.13 *test pressure* — pressure immediately downstream of the test component. (See Figure 1.)

5.2.14 *test temperature* - ambient temperature at which the experiment is being conducted.

6 Safety Precautions

6.1 This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations before using this method.

6.2 Exhaust from the CNC may contain hazardous and/or flammable vapors and should be properly vented.

6.2.1 Only inert gases like nitrogen and argon should be used for purifier testing. **No air is allowed in the purifier testing procedure described in this document**.

6.3 Care should be taken to minimize the purifier's exposure to room air during and after testing.

7 Test Protocol

7.1 *Test Conditions*

7.1.1 The test is to be conducted at a normal indoor temperature of between 18°C (64°F) and 26°C (78°F). Environmental temperature within this range is not expected to have any measurable effect on particle detection. Follow manufacturer's recommended handling procedures.

7.1.2 Test apparatus must be enclosed in a Class 100 environment (per current revision of Federal Standard 209). If a clean hood is used, the hood should be located within a clean environment. Use procedures necessary to maintain Class 100 when handling test apparatus and test component.

7.1.3 Care should be taken to protect the test apparatus from excessive vibration. For example, vacuum pumps and compressors should be isolated from the system.

7.2 *Apparatus*

7.2.1 *Materials*

7.2.1.1 *Test gas* — Nitrogen of minimum dryness of <10 PPM moisture at 790.57 kPa (100psig) with <10 ppm of total hydrocarbons.

7.2.1.2 *Filters* — Electronics grade filters are required to provide "particle-free" test gas. Each filter must be nine-log retentive per manufacturer's specifications to 0.02 µm. The filter must be capable of achieving less than 2 particles ≥ 0.02 µm per cubic foot of test gas under test conditions.

7.2.1.3 *Pressure regulator* — Made of electropolished 316L with an internal surface finish of 0.18 µm (7 µin.) Ra and 0.25 µm (10 µin.) Rmax to maintain system pressure.

7.2.1.4 *Pressure gauge* — made of electropolished 316L stainless steel, with an internal surface finish of 0.18 µm (7 µin.) Ra and 0.25 µm (10 µin.) Rmax, to monitor system test pressure.

7.2.1.5 *Standard testing flow control device* — Use flow meters with ranges appropriate for testing from 0-50 slpm.

7.2.1.6 *Tubing* — Made of electropolished 316L stainless steel, with and internal surface finish of 0.18 µm (7 µin.) Ra and 0.25 µm (10 µin.) Rmax.

7.2.1.7 *Sampler* — The sampler is to be constructed according to the drawing and sampler design criteria given in Appendix 1 Sampler Design Criteria. The sampler collects gas from the stream exiting the test device, where the sample is near-isokinetic in design.

7.2.1.8 *Upstream adapter* — The upstream adapter piece connects 12.7 mm (1/2–in.) tubing to the test device. For 12.7 mm (1/2–in.) test devices, the adapter is a simple face-seal connector. For 6.35 mm (1/4–in.) test devices, the adapter is a tapered cone between 6.35 mm and 12.7 mm (1/4– and 1/2–in.) face-seal connections.

7.2.1.9 *Downstream adapter* — The downstream adapter piece connects 12.7 mm (1/2–in.) tubing of the sampler to the test device. For 12.7 mm (1/2–in.) test devices, the adapter is a simple face seal connector. For 6.35 mm (1/4–in.) test devices, the adapter is a tapered cone between 6.35 mm (1/4–in.) and 12.7 mm (1/2–in.) face-seal connections.

7.2.1.10 *Spool Pieces* — Spool pieces shall be the same diameter as the fittings on the test piece and be 15 cm (6 in.) in length. The spool piece is to be installed in the system in place of the DUT while obtaining background counts for the system.

7.2.1.11 *Fittings* — Face seal connectors or compression fittings dependent on test component end connections. The end connection fittings of each DUT being compared must be of the same type.

7.2.1.12 *Gaskets* — Use metal gaskets for attaching the test device and adapter pieces. New gaskets should be used for each new connection. The use of metal gaskets is recommended in order to minimize the particles that may be generated by installation of the test piece. The use of silver plated metal gaskets should be avoided because they shed particles after installation.

7.2.1.13 *Mechanical shock device* — To provide mechanical shock by impact to the test device (see Figure 2).

7.2.1.14 *Actuator* — A gas (compressed air or nitrogen) operated device connected to the valve stem to open and close the valve.

7.2.1.15 *Actuator pressure* — Minimum actuator gas line pressure required to fully open and close the valve during the dynamic test.

7.2.2 *Instrumentation*

7.2.2.1 A CNC whose counting efficiency characteristics fall within the envelope defined in FED STD 209 for counting ultrafine particles is to be used for particle counting. Test durations in this test method have been established based on a sampling flow rate of 0.05 scfm.

7.2.2.2 Instruments should be calibrated regularly, according to manufacturer's recommendations. For the CNC, this includes routine checks of instrument operation as specified by the manufacturer.

7.2.2.3 The CNC and data collection equipment must have power surge suppression.

7.2.3 *Setup and Schematic*

7.2.3.1 Assemble the test apparatus according to the schematic drawing of the test apparatus used shown in Figure 1. Install the test apparatus inside a class 100 clean room. Adjust the inlet gas pressure to the required pressure of 30 psig using the pressure regulator R1 as indicated by an electronics grade pressure gauge P1. The filtered gas flow is then diverted to flow through either of the two flowmeters located downstream of the valve V1.

7.2.3.1.1 The test gas delivered from the flow meters is filtered again by an electronics grade filter F2. The test gas pressure at this point is measured by another electronics grade pressure gauge P2 installed upstream of filter F2. A pneumatic valve PV1 is installed downstream of the filter F2 for obtaining the particle counts for the dynamic test portion (including the background) of the test method. The test gas is filtered once again by another electronics grade filter F3 before it is delivered to the spool piece and the test component.

7.2.3.1.2 Particles released from the spool piece and the test component are measured by a CNC located downstream of these components. A representative sample of the gas flow is sampled by the CNC through an isokinetic sampler located downstream of the test devices. The CNC measures particle concentration every minute, sampling at a flow rate of 0.05 scfm, to provide a continuous measurement of particle counts for the static, dynamic, and impact tests on the test pieces. The particle data can also be collected and stored in a computer using a data acquisition program.

7.2.3.1.3 A schematic drawing of a recommended test apparatus is given in Figure 1. A list of parts used in the construction of the recommended test stand is presented in Table 1. The dimensions of the tubing and components used for the construction of the recommended test apparatus are given because they have been found to be critical to the proper operation of the test apparatus as required by the specification. Deviations from these dimensions have resulted in some lab facilities not meeting the requirements of the specification.

7.2.3.2 The spool piece is to be installed when the test stand is not in use. A continuous low flow (0.1 scfm) is to be maintained to purge the system. The particle counter may be turned off. For an extended shutdown, the system (excluding the CNC) should be pressurized and capped.

7.2.3.3 After initial construction, the spool piece should be installed and the test apparatus (except the CNC) should be pressurized and tested for leaks in the system. It is recommended that a helium leak detector or a pressure decay method be used to detect leaks in the system. The system should then be cleaned by running a high flow rate of test gas with simultaneous gentle tapping of all components (except the CNC) downstream of the final filter F3. This procedure should be followed by a start-up phase which characterizes system cleanliness by conducting the entire test protocol with the control product installed. This start-up phase should continue and be repeated as necessary until the counts from the control product have stabilized at or below the expected number of counts from the test components.

7.3 *Test Procedures*

NOTE: Ensure the counter is counting continuously and reporting data every minute. For the duration of the test, the counter should be continuously counting, except where noted in the test protocol.

7.3.1 *Background Test*

7.3.1.1 Ensure that the spool piece and proper adapters are in place on the test apparatus.

7.3.1.2 *Static Test* — Close the pneumatic valve (PV1). Set regulator R1 to 30 psig. Open the pneumatic valve (PV1) to establish flow. Using the flow control device, set the test flow to manufacturer's recommended maximum flow. Measure the static background count. Background count is established when the counter has sampled a minimum of 3 scf, and the arithmetic average during the last 3 scf of gas sampled is <2 particles/scf. At a sample flow rate of 0.05 scfm, the time required is one hour. Ensure that the background counts are stable or decreasing. If background cannot be achieved after 6 scf have been sampled, there may be a problem with the counter or test apparatus.

7.3.1.3 *Dynamic Test* — Set the actuator pressure of PV1 to its minimum pressure recommended by the manufacturer to fully open the valve. Actuate the pneumatic valve PV1 at 30 cycles per minute to measure the background counts under dynamic test conditions. Dynamic background count is established when the counter has sampled a minimum of 3 scf, and the arithmetic average during the last 3 scf of gas sampled is < 3 particles/scf. (Estimated dynamic background count will be verified and altered if necessary during the validation phase of this test method.) At a sample flow rate of 0.05 scfm, the time required is 1 hour. If dynamic background cannot be achieved after 6 scf have been sampled, there may be a problem with the counter or test apparatus.

7.3.1.4 Stop the pneumatic valve cycling. Flush the system for 10 minutes under static test conditions.

7.3.1.5 *Purifier Impact Test* — Impact the spool piece once per minute for ten minutes with the mechanical shock device (See Figure 2). The impact background count should be <4 particles/scf over the ten minutes of the test. (Estimated impact background count will be verified and altered if necessary during the validation phase of this test method.) If impact background cannot be achieved, repeat the shock a second time. If the impact background count specification still cannot be met, there may be a problem with the counter or test apparatus.

7.3.1.6 Flush the system for 30 minutes at the test flow rate. Record the resulting count.

7.3.1.7 Turn the CNC pump off while leaving the CNC power on.

7.3.2 *Purifier Static Test*

7.3.2.1 Using the flow control device, decrease the flow rate to 0.1–0.2 scfm, so that some flow remains in the system while the test purifier is installed.

7.3.2.2 Remove the spool piece by first disconnecting the downstream fitting and then the upstream fitting. Immediately install the test component in a fully open position by first connecting the upstream fitting and then the downstream fitting. Removal of the spool piece and installation of the test component to minimize reactions of the purifier with room air and extraneous contamination and prevent the counter from cooling off should take no longer than 3 minutes. Extreme care should be taken to minimize contamination of the test apparatus during this operation. The test component is to be removed from its inner bag in the Class 100 test area. If the test component has mechanical fittings, these fittings are to be properly connected. If the test component has tube ends, the component is to be installed with clean compression fittings. Do not permanently crimp any ferrules onto the tube stubs. Nylon ferrules are acceptable.

7.3.2.3 Using the flow control device, set the test flow to manufacturer's recommended maximum flow.

7.3.2.4 Turn on the counter pump and conduct the static test. The purifier is to be tested with the valve PV1 in the fully open position until 85 standard liters (3 scf) of gas have been sampled. Cumulative data should be recorded at one-minute intervals.

7.3.3 *Purifier Dynamic Test*

7.3.3.1 This test is to immediately follow the static test. To conduct the dynamic test, set the actuator pressure of the actuator attached to valve PV1 to its minimum actuator pressure as recommended by the manufacturer to fully open the valve. Actuate valve PV1 at the rate of 30 cycles/minute for 60 minutes. A cycle consists of off *and* on actuation of the valve. The off and on cycles should be of equal duration.

7.3.4 *Purifier Impact Test*

7.3.4.1 This test is to immediately follow the dynamic test. Maintain the test flow rate for 10 minutes, with the valve PV1 in the fully open position. Impact the purifier once a minute for 10 minutes, using the mechanical shock device. Purge the test component by maintaining the test flow rate for 30 minutes.

7.3.5 Turn the counter pump off and then decrease the test gas flow rate to ~ 5 slpm.

7.3.6 Remove the test purifier by first disconnecting the downstream fitting and then the upstream fitting, and immediately install the spool piece by connecting the upstream fitting followed by the downstream fitting. The removed purifier should be immediately valved off or capped to prevent its exposure to room air.

7.4 *Data Presentation*

7.4.1 The following test conditions are to be reported in the data presentation:

- Date and time of test
- Operator
- Test flow rate (scfm)
- Test pressure (psig)
- Test temperature (°C)
- Purifier type, manufacturer, serial number, lot number, and model number
- CNC manufacturer, serial number, sample flow rate (scfm), model number, and calibration date
- Test gas type and dew point (°C)
- A schematic of the test apparatus, including manufacturer's and model numbers of all test apparatus components
- Calibration dates for the flow meters and the test date

7.4.2 Graph the static, dynamic and impact portions of the test separately as counts/minute (measured by the counter) versus time, including the appropriate background (measured with the spool piece in place) with each. Also graph the entire data set as counts per minute versus time. If different filters are to be compared, graph their entire data sets together.

7.4.3 Present the entire raw data set in tabular form.

Item number	Description
1	1/4 in. diameter electropolished (EP) SS tube
2	1/4 in. to 1/2 in. tube reducing union
3	1/2 in. diameter EP SS tube
4	PTFE membrane filter with 3/8 in. face seal
5	Pressure regulator, 0-300 inlet pressure, 0-100 outlet pressure
6	1/2 in. butt weld tee
7	1/2 in. tube to 3/8 in. NPT female connector
8	0-60 psig electronics grade pressure gauge
9	1/2 in. to 1/2 in. union
10	1/2 in. 3-way SS ball valve
11	1/4 in. tube to 1/2 in. port reducer
12	0.2-2 std ft^3 flowmeter
13	1-15 std ft^3 flowmeter
14	1/2 in. SS union
15	1/2 in. dia, 3-ft flexible SS tube
16	1/2 in. union elbow
17	1/2 in. pneumatic valve
18	1/2 in. to 1/4 in. SS reducer gland
19	Test component
20	3-way normally closed solenoid air valve
21	Solenoid valve cycle controller
22	1/2 in. welded tee
23	1 1/2 in. dia., 4-ft long exhaust tube
24	1/2 in. tube to 1/4 in. NPT adapter
25	1/8 in. dia., 17 in. long SS sample tube
26	1/4 in. to 1/8 in. reducer union
27	1/4 in. dia., 30 in. long SS sample loop
28	1/4 in. to 3/8 in. reducer union
29	Condensation Nucleus Counter

APPENDIX 1
SAMPLER DESIGN CRITERIA

A-1.1 The average velocity of gas flowing through the sampler should approximate the average velocity in the tubing in which the sampler is inserted. The sample flow rate used to calculate the sampler diameter is the total flow drawn by the counter.

A-1.2 Gradual expansion to atmospheric pressure is recommended for sampling. Critical orifice expansion may alter the particle level of the sample.

A-1.3 The tip of the sampling probe should have a 30 degree taper on the outside diameter.

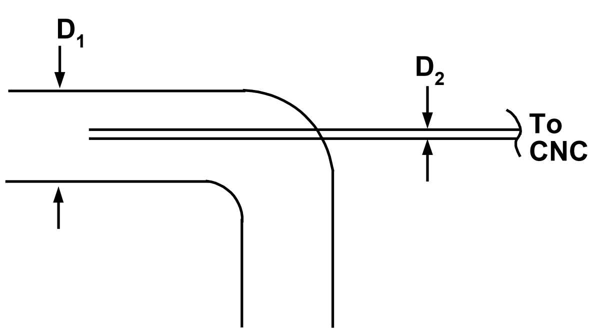
A-1.4 The pick-off point should be approximately centered within the flow stream.

A-1.5 The pick-off point should be approximately 15 diameters of the primary flow tube upstream or downstream of any connection.

A-1.6 There should be enough volume in the exhaust portion of the sampler to supply the CNC for one minute. This volume represents 60 times the volume that will be drawn by the CNC while the valve is closed during the dynamic testing. Minimum sample flow through the CNC is 5 slpm.

A-1.7 State the minimum volume after the probe or generate a sample blank using the stated volume until background counts are reached.

Under static flow conditions, the sampler size is within 50% of the size required to achieve isokinetic sampling. For particles of interest <0.5 um, Hinds[1] and Fissan[2] indicate that any unlikely isokinetic sampling biases are significant. During dynamic testing, isokinetic sampling is compromised regardless of the sample tube size.



Isokinetic Sampler Calculation

To establish isokinetic sampling condition:

$V_1 = V_2$
$Q = AV$ or $V = Q/A$
so $Q_1/A_1 = Q_2/A_2$
therefore, $A_2 = A_1\,(Q_2/Q_1)$ or $D_2 = D_1\,(Q_2/Q_1)^{1/2}$

where:

Q = flow rate (volumetric)
A = area (internal cross section)
V = velocity (average)
D = diameter (internal)

subscripts:

1 = main flow line
2 = sample flow line

If pressure correction at point of flow control device is needed, then:

$$Q_s = [(P + 14.7)/14.7]^{1/2} \times Q_A$$

where:

Q_A = actual flow rate
Q_S = standard flow rate
P = pressure, psig

Temperature variances are assumed to be negligible.

SEMI F44-0699
GUIDELINE FOR STANDARDIZATION OF MACHINED STAINLESS STEEL WELD FITTINGS

This guideline was technically approved by the Global Facilities Committee and is the direct responsibility of the Japanese Facilities Committee. Current edition approved by the Japanese Regional Standards Committee on March 17, 1999. Initially available on www.semi.org May 1999; to be published June 1999.

1 Purpose

1.1 The purpose of this guideline is to prevent confusion among the manufacturers of stainless steel weld fittings, piping fabricators and end users and to standardize the dimensions of weld fittings.

2 Scope

2.1 This guideline applies to 6.35 mm (1/4in.), 9.53 mm (3/8in.) and 12.7 mm (1/2in.); the machined stainless steel weld fittings elbows and tees made for use in the semiconductor industry.

3 Referenced Documents

3.1 None.

4 Terminology

4.1 *elbow weld fittings* — machined fittings shaped like the letter "L", for welding tubes in a right angle. (see Figure 1)

4.2 *tee weld fittings* — machined fittings shaped like the letter "T", for welding tubes in a T-shape. (see Figure 2)

4.3 *weld fittings* — machined fittings to be welded or welded fittings.

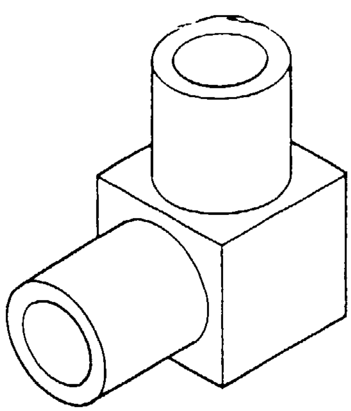

Figure 1
Elbow Weld Fittings

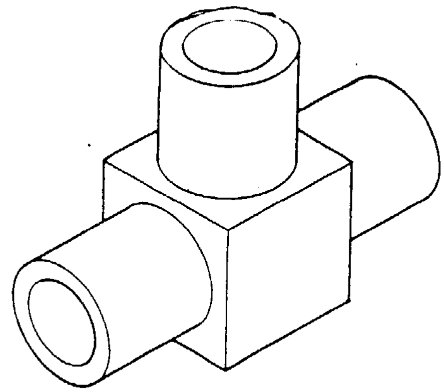

Figure 2
Tee Weld Fittings

5 Dimensions of Weld Fittings

5.1 *Elbow Weld Fittings* (see Figures 3A and 3B)

5.2 *Tee Weld Fittings* (see Figures 4A and 4B)

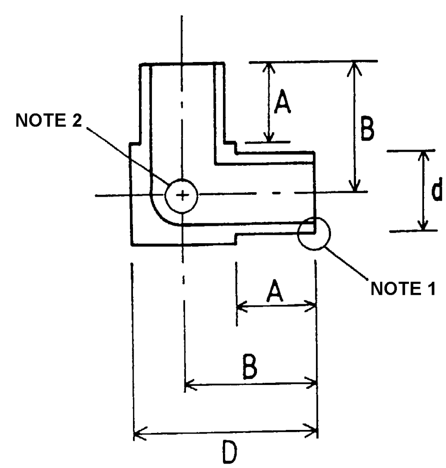

Figure 3A
Dimensions of Elbow Weld Fittings

NOTE 1: Machined tube weld ends shall be square tolerance ± 0.5°.

NOTE 2: Intersection shall be square tolerance ± 0.5°.

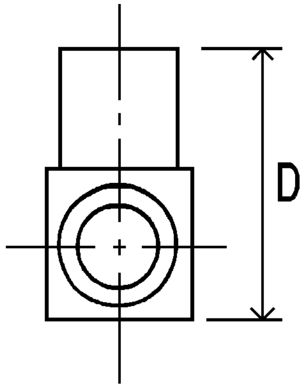

Figure 3B

6 Marking The Weld Fittings

6.1 Marks include 1), 2), 3), 4), 5), 6) and 7). Marks 1) through 4) shall be made on the weld fittings body. Marks 5) - 7) shall be made on weld fittings body or its package (both individual bagging and box).

1) Manufacturer's name
2) Material designator
3) Surface finish designator
4) Heat Number (optional)
5) Lot Number
6) Model (Part Number)
7) Wall thickness of tube end

6.2 To be agreed upon between supplier and user for marking items and marking locations. The example below explains marking applications. (see Figures 5A and 5B)

6.3 Manufacturer's name, Material designator, Surface finish designator and Heat Number should be marked on the body. The Heat Number shall be marked either on the body of the cube along with the other information, but if space is limited, then the Heat Number marked on the tube Outside Diameter close to the body block is permissible.

Marking Application Example

7 Outside Diameter Tolerance

7.1 The Outside Diameter tolerance of 6.35 mm (1/4 in.), 9.53 mm (3/8 in.) and 12.7 mm (1/2 in.) is + 0.1 mm, - 0.0 mm (+ 0.004 in., - 0.000 in.).

8 Wall Thickness of Tube End

8.1 Wall thickness of tube end should be either 1 mm (0.039 in.) or 0.89 mm (0.035 in.), 1.24 mm (0.049 in.) and the thickness should be marked on the weld fitting body or its package. Wall thickness tolerance is ± 8%.

SEMI F46-0999
GUIDE FOR ON-SITE CHEMICAL GENERATION (OSCG) SYSTEMS

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on April 15, 1999. Initially available on www.semi.org August 1999; to be published September 1999.

1 Purpose

1.1 This guide establishes the minimum System and Overall Implementation requirements for requirement of On-Site Chemical Generation (OSCG) used in semiconductor manufacturing. It is also intended to establish a common basis for developing detailed guides in subsequent documents concerning design, performance, and certification of OSCG systems.

2 Scope

2.1 This guide applies to the OSCG system design used for the generation of chemicals, particularly ultra high purity, used in the silicon wafer, integrated circuit, and/or substrate manufacturing processes. These will include, but are not limited to, various concentrations of NH_4OH, HCl, HF, and NH_4F aqueous solutions.

2.2 This standard does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicablity of regulatory limitations prior to use.

3 Limitations

3.1 This guide is not intended to cover all chemicals used in these processes but only to those that can be generated, on-site, by means of reacting ultra-pure process gas with the appropriate liquid solution.

3.2 This guide is not intended to be applicable to "Point-of Use" generated process solutions.

3.3 This guide excludes construction protocols for OSCG such as clean manufacturing, integrity of fabrication, and prequalification of materials.

3.4 This guide does not intend to cover all the important safety considerations which relate to the OSCG systems, feed gas, equipment, or installations.

4 Referenced Standards

4.1 *SEMI Standard*

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

blending (or dilution) — the combination of two or more chemicals (one of which may be DI water) to create the desired solution mixture.

clean sampling — a specifically designed scheme to allow for the taking of chemical samples, avoiding any contamination from the operator or background environment of the area.

day tank — a chemical storage vessel, of appropriate material(s), used to store a volume of product chemical that could be consumed in one or more days.

DI water — high purity 18 megohm water

OSCG system — the stand-alone unit that produces (or uses) a high purity gas and reacts it with water (or the appropriate aqueous solution) to produce the desired ultra pure chemical solution. This unit is intended for use on the manufacturing site and in a centralized scheme to support all or a portion of the site's chemical requirement(s).

overall implementation — this term is used to refer to the entire scope for an OSCG installation, including the Gas Storage/Supply system, the OSCG system, chemical storage tanks, chemical plumbing, and interface with the chemical distribution system. Gas supplies are covered in related guides.

process plumbing — tubing or piping whose surface is directly in contact with the chemical. Typically constructed from high purity perfluorinated materials or other high purity polymers.

product chemical — the name given to the actual chemical produced on site by the OSCG system.

pump — a mechanical or pneumatically operated device used to create hydraulic force for chemical transfer.

QC tank — storage tank for the staging of chemical to be quality verified prior to release to the Product storage tank. This optional quality verification scheme allows for 100% chemical verification.

secondary containment — pipe or tubing that contains the process plumbing intended to provide a second level of containment in the event of failure of the primary process plumbing. Clear PVC pipe is typically, but not exclusively, used for the secondary containment.

SPC scheme — an alternate quality verification scheme that would involve random sampling and analysis of product chemical. This scheme relies on Statistical Process Control to monitor and ensure product chemical quality.

6 General Requirements

6.1 *Materials* — Only specific materials are permitted to be in direct contact with the gas(es) and/or chemical(s) used or produced in the OSCG system. This is driven by both chemical compatibility to ensure long term system survivability and product chemical purity.

6.1.1 *Cabinet Construction* — Polypropylene or other suitable materials house chemical handling components (pumps, valves, filters, etc). All cabinets must be designed to be leak tight and provide a minimum of 110% liquid containment within the cabinet.

6.1.2 *Process Plumbing and Components* — Polymeric materials are recommended for all plumbing and components that will be in direct, routine contact with the chemical solutions.

6.1.3 *Feed Gas Plumbing and Components* — Feed Gas, prior to purification (when gas purification is part of the OSCG system), will be plumbed using compatible materials such as stainless steel.

6.1.4 *Storage Tanks* — Liner materials used in chemical storage tanks that will be in direct contact with the chemical solution will be chosen to maintain chemical purity.

6.2 *Overall System Installation*

6.2.1 All OSCG systems, support equipment, process plumbing, and tanks will be installed and facilitated according to vendor guide which ensures mechanical integrity, leak integrity, minimal contamination, and overall proper operation.

6.2.2 All OSCG implementations will require the following basic components: Feed Gas Storage and Delivery Subsystem, the OSCG system(s), some type of Quality Control Scheme with "Clean Sampling" provisions, Product Chemical Storage with a suitable volume of Product storage, and, optionally, a Back-up Chemical scheme.

6.2.3 Prior to any introduction of chemical to any system or subsystem, a complete water test is performed to verify leak integrity. This process will also be used to provide the initial clean-up of all systems, tanks, and process plumbing.

6.2.4 The protocol for the installation and start-up of all systems and subsystems follows a predefined procedure and timeline which incorporates all of the physical activities, testing parameters, and check points for approval at each stage.

6.2.5 Cleanroom environment is not necessary.

6.3 *Initial System Qualification* — The following general procedure will be required for the initial mechanical and chemical qualification of the OSCG installation.

6.3.1 Electro-mechanical check-out

6.3.2 Initial chemical charge

6.3.3 Initial processing to fill and purge all systems, plumbing, and tanks with chemical.

6.3.4 Initial sampling to verify purity and assay.

6.3.5 Continuous processing to prove purity and capacity through a specific number of samples.

6.3.6 Continuous processing to establish overall system reliability.

7 Basic Design Specifications

7.1 *General* — Each OSCG installation contains certain basic components and a variety of design options to meet a specific customer's needs. This section describes the basic installation requirements.

7.2 *Feed Gas Storage* — All OSCG implementation will require an appropriately sized Feed Gas storage vessel.

7.2.1 The Feed Gas Storage vessel should be of sufficient volume per customer, vendor, and logistical considerations.

7.2.2 The gas delivery system must be designed to deliver sufficient gas flowrates at the correct pressure to the OSCG system.

7.2.3 The appropriate containment and controls are required to ensure safe and reliable operation.

7.3 *Gas Supply Plumbing* — Gas supply plumbing will be required to bring Feed gas from the storage vessel to the OSCG system.

7.3.1 Materials used for the gas supply plumbing will be chosen based on compatibility with the specific feed gas.

7.3.2 Supply plumbing size will be chosen based on the flow requirements and delivery distance to ensure adequate supply volume and pressure at the OSCG system.

7.3.3 Secondary containment may be required based on the Feed gas, delivery plumbing routing, and local and/or company codes.

7.3.4 An appropriate component design must be used for the gas/liquid interface(s).

7.4 *The OSCG System* — The appropriate OSCG system will be defined based on overall capacity requirements.

7.4.1 The OSCG system can provide feed gas purification and chemical generation within a stand alone packaged unit or use externally purified feed gases. Optional Feed gas purification may also be provided in this package.

7.4.2 The OSCG system will have a dedicated control system to control all process parameters and monitor all system safety interlocks including external safety systems.

7.4.3 The OSCG will provide pressurized chemical to the Product Quality verification subsystem.

7.5 *Product Quality Verification* — All OSCG installation will include some type of Product sampling and quality verification scheme.

7.5.1 The standard quality verification scheme will provide for an in-line, "Clean Sample" station to allow for random samples to be taken for analysis.

7.5.2 A SPC quality assurance scheme can be utilized to track and record product chemical purity and assay guides. Readings are plotted using X-bar/R format and reacted to based on standard SPC rules.

7.5.3 In this scheme product chemical is transferred to the Product storage tank directly from the OSCG system, through the sampling subsystem or directly to chemical delivery systems.

7.6 *Product Storage* — All OSCG implementation will include a Product chemical storage scheme to ensure chemical availability to the customer.

7.6.1 Product storage is achieved, typically, by including an appropriately sized storage tank. This tank becomes the source to the chemical distribution system.

7.6.2 Product storage volume is defined to provide suitable inventory of product chemical storage. This will provide chemical available to the distribution system during periods of both scheduled and unscheduled maintenance.

7.6.3 Additionally, a back-up supply of prequalified chemical may be available to transfer into the Product tank, if required.

7.7 *Central Monitoring System* — A central CPU based monitoring system is required for multiple purposes in the overall implementation.

7.7.1 The central CPU will communicate with all subsystems and tanks to share information, as required, to ensure total system operations.

7.7.2 The central CPU also provides data logging and database features to track and log product quality and system failure data as required.

7.7.3 The central CPU can also provide a remote monitoring feature and interface with the customer's facility tracking system (if desired).

8 Optional Configurations and Support Systems

8.1 *Feed Gas Supply* — Some customers may already have an existing source of an appropriate Feed gas for the OSCG system. Implementation schemes can be configured to utilize this existing gas storage and supply system. The existing system will need to meet the vendors guides for gas purity and line pressures.

8.2 *Product Storage and Staging Tanks* — Some customers may already have tanks that can be used for Product Storage and/or staging applications. Implementation schemes can be configured to utilize these existing storage tanks. The existing tanks must meet vendors guides for materials, inlets/outlets, and volume. Level sensor data will be provided to the central CPU system.

8.3 *Multiple OSCG Systems* — Depending on capacity requirements, OSCG installations can be configured to have multiple Generator systems in parallel. All product outputs should have the capability to be sampled individually before combining into a common product stream for storage.

8.4 *Support Systems* — Various support systems and options can be provided to support the overall implementation scheme.

8.4.1 Stand-alone, water-cooled Chiller(s) may be required, if the house chilled water is not available.

8.4.2 Redundant pump options should be available in any pumping system to allow for either manual switch over or automatic back-up.

8.4.3 Transfer pumping systems or transfer options should be available for the transfer of chemical from or to remote storage tanks.

8.5 *Chemical Distribution* — Chemical distribution systems may or may not be in existence at specific customer sites. The distribution of chemical from the product storage to use points will be important to maintain chemical purity. These distribution systems should be available as a directly supplied option or offered through a sub-contracted supplier.

8.6 *Filtration Options* — Recirculation filtration of either QC tanks or the Product storage tank is important to control particle levels in the final chemical. Recirculation filtration options should be provided, depending on the specific chemical storage configuration.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F47-0200
SPECIFICATION FOR SEMICONDUCTOR PROCESSING EQUIPMENT VOLTAGE SAG IMMUNITY

This specification was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available on www.semi.org January 2000; to be published February 2000. Originally published September 1999.

1 Purpose

1.1 Semiconductor factories require high levels of power quality due to the sensitivity of equipment and process controls. Semiconductor processing equipment is especially vulnerable to voltage sags. This document defines the voltage sag ride-through capability required for semiconductor processing, metrology, and automated test equipment.

1.2 The requirements in this international standard were developed to satisfy semiconductor industry needs. While more stringent than existing generic standards, this industry-specific specification is not in conflict with known generic equipment regulations from other regions or generic equipment standards from other organizations (see Related Information section).

1.3 It is the intent of this standard to provide specifications for semiconductor processing equipment that will lead to improved selection criteria for sub-components and improvements in equipment systems design. While it is recognized that in certain extreme cases or for specific functions battery storage devices may be appropriate, it is not the intent of this standard to increase the size or use of battery storage devices provided with equipment. Focus on improvements in equipment component and system design should lead to a reduction or elimination in the use of battery storage devices to achieve equipment reliability during voltage sag events.

2 Scope

2.1 This document specifies the minimum voltage sag ride-through capability design requirements for equipment used in the semiconductor industry. The expected equipment performance capability is shown graphically on a chart representing voltage sag duration and percent deviation of equipment nominal voltage. Standard evaluation test method references are also included.

2.2 The primary focus for this specification is semiconductor processing equipment including but not limited to the following tool types:

- Etch equipment (Dry & Wet),
- Film deposition equipment (CVD & PVD),
- Thermal equipment,
- Surface prep and clean,
- Photolithography equipment (Stepper & Tracks),
- Chemical Mechanical Polishing equipment,
- Ion Implant equipment,
- Metrology equipment, and
- Automated test equipment.

2.3 This specification applies to semiconductor processing equipment to include the equipment mainframe and all subsystems whose electrical power is directly affected by the operation of the equipment's EMO system.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Not included in this standard are over voltage conditions, voltage sag duration of less than 0.05 seconds (50 milliseconds), and voltage sag duration of greater than 1.0 seconds. If necessary, the Information Technology Industry Council (ITIC) "CBEMA-curve" contained in IEEE 446, IEEE 1100, and SEMI E51 can be used to specify additional requirements outside the range of this document (see Related Information, Section R1-1).

3.2 This specification does not address wafer quality with regard to processing variation caused by voltage sags. It is recommended that each equipment supplier consider the effects of voltage sags on their equipment processes. If voltage sags above the defined line can result in known wafer quality problems, then an appropriate notification-only scheme should be considered in the equipment design. To be in conformance with this standard that notification scheme should not be classified as an equipment interrupt per SEMI E10.

3.3 This standard addresses specifications for semiconductor processing equipment voltage sag immunity. Factory systems voltage sag immunity and electric utility voltage sag performance are covered in other related standards.

3.4 This standard is intended to be a performance specification, it is not intended to address design issues related to safety which are covered elsewhere in the SEMI Standards (see SEMI S2).

NOTE 1: Safety related systems may require ride-through capability for conditions up to and including full power failure. Further, if hazards could result from voltage sags greater than those allowable in Table 1, provisions should be made to negate or eliminate such hazards.

3.5 International, national and local codes, regulations and laws should be consulted to ensure that the equipment meets regulatory requirements in each location.

4.2 *IEEE Standards* [1]

IEEE 446 — IEEE Recommended Practice for Emergency and Standby Power Systems for Industrial and Commercial Applications (IEEE Orange Book)

IEEE 1100 — IEEE Recommended Practice for Powering and Grounding Sensitive Electronic Equipment (IEEE Emerald Book)

IEEE 1250 — IEEE Guide for Service to Equipment Sensitive to Momentary Voltage Disturbances

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *assist* — an unplanned interruption that occurs during an equipment cycle where all three of the following conditions apply:

- The interrupted equipment cycle is resumed through external intervention (e.g., by an operator or user, either human or host computer).
- There is no replacement of a part, other than specified consumables.
- There is no further variation from specification of equipment operation [SEMI E10].

5.2 *failure* — any unplanned interruption or variance from the specifications of equipment operation other than assists [SEMI E10].

5.3 *interrupt* — any assist or failure [SEMI E10].

5.4 *ride-through capability* — the ability of equipment to withstand momentary interruptions or sags [IEEE 1250]. Also known as voltage sag immunity.

5.5 *voltage sag* — an rms reduction in the ac voltage at power frequency for durations from half-cycle to a few seconds [IEEE 1250]. Also known as voltage dip.

6 Ordering Information

6.1 Semiconductor manufacturers may use this standard when procuring processing equipment to specify equipment ride-through requirements capability to the equipment supplier. This document may also be used by semiconductor processing equipment suppliers to specify ride-through requirements to component and module suppliers.

6.2 Orders for equipment in accordance with this standard shall include:

a) This specification number and date of issue.

b) Requirements for qualification testing per SEMI F42.

c) Any certification showing passage of qualification tests required to be provided (optional).

d) Any test results required to be included in reports to be provided (optional).

7 Requirements

7.1 Semiconductor processing, metrology, and automated test equipment must be designed and built to conform to the voltage sag ride-through capability shown in Figure 1. Equipment must continue to operate without interrupt (see Terminology) during conditions identified in the area above the defined line.

7.2 The requirements defined in this specification apply to two phase (phase-to-phase) and single phase (phase-to-neutral) voltage incidents.

7.3 The performance curve is defined by values shown in Table 1—voltage sag duration and percent deviation from equipment nominal voltage.

NOTE 3: For recommendations on equipment ride-through capability below 0.05 seconds (50 milliseconds) and above 1.0 seconds, see Related Information at the end of this document.

1 The Institute of Electrical and Electronic Engineers, Inc., 345 East 47th Street, New York, NY 10017-2394, USA

8 Test Methods

8.1 Qualification tests are conducted on samples of production articles, not each item produced. Qualification testing of equipment to requirements in this specification should be performed per SEMI F42.

Required Semiconductor Equipment Voltage Sag Ride-Through Capability Curve

RELATED INFORMATION 1
RELATIONSHIP TO OTHER ELECTRICAL STANDARDS

NOTE: This related information is not an official part of SEMI F47 and is not intended to modify or supersede the official standard. It has been derived from the work of the originating task force. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Basis for this Industry-Specific Semiconductor Standard

R1-1.1 The Information Technology Industry Council (ITIC) "CBEMA-curve," contained in IEEE 446, IEEE 1100, and SEMI E51, was used as a starting point in establishing recommended ride-through limits. The following curve (see Figure R1-1) was developed to define voltage sag ride-through for use with semiconductor processing equipment. Primarily due to testing limitations, only the portion between 0.05 seconds (50 milliseconds) and 1.0 seconds was selected for inclusion in the specification. As future test equipment, methods, and data are developed the specified duration limits may be expanded. Recommended voltage sag ride-through capability limits from zero to 100 seconds are included here for reference (see Figure R1-1). While not currently included in this SEMI specification the wider range should be considered when designing equipment and selecting components.

R1-1.2 Over voltage conditions also covered in the ITIC CBEMA-curve contained in IEEE 446, IEEE 1100, and SEMI E51, are not considered in the scope of this industry-specific specification primarily due to the extremely low number of semiconductor equipment interruptions caused by over voltage events. While not in the scope of this specification, over voltage conditions should not be ignored and use of existing equipment protection techniques should be continued (see SEMI E51 or IEEE 446 for generic equipment over voltage ride-through specifications).

R1-2 Relationship to Generic Electrical Standards

R1-2.1 This SEMI standard is intended to be coordinated with related SEMI, IEC and IEEE standards. The relationship of this SEMI specification to many other standards that address equipment immunity, test methods, and safety was considered in development of this specification. For example, the emerging IEC Generic Immunity standard for industrial environments currently published by CENELEC as EN 50082-2 recommends a generic equipment immunity limit for Europe. When published by IEC, this standard will provide a generic equipment voltage sag immunity limit. Another example is the US National Fire Protection Association on Industrial Machinery (NFPA 79), which sets a generic equipment voltage sag immunity limit for the United States.

R1-2.2 These emerging generic limits were considered in the establishment of ride-through limits for semiconductor equipment. However, most generic equipment limits are less stringent than the existing CBEMA-curve currently referenced in SEMI E51. For most installations meeting the CBEMA limits (a specification which was developed for computer business equipment) still results in an unacceptable number of semiconductor equipment interrupts. Therefore, the requirements in this international standard were developed to better suit the semiconductor industry. While more stringent, this industry-specific specification is not in conflict with known generic equipment regulations from other regions or generic equipment standards from other organizations.

R1-2.3 Another published IEC standard defines a generic immunity test method for voltage sags (dips), IEC 61000-4-11. This standard does not provide limits but does provide a voltage sag test method for single-phase equipment rated less than 16 amps. It has been considered in defining voltage sag ride-through parameters and it may provide an interim voltage sag immunity test method. As noted in this document, a test method for three-phase equipment greater than 16 amps is being developed for use with semiconductor equipment.

R1-2.4 The generic type standards developed for industrial or consumer equipment by organizations like IEC, ITIC, and IEEE provide a foundation for industry-specific standards like those published by SEMI Standards. In acknowledgement of this tiered approach to standardization there are provisions for recognizing industry-specific or product-type standards by organizations like IEC. Typically, product-type standards when developed by industry-specific organizations take precedent over the broader based generic industrial standards.

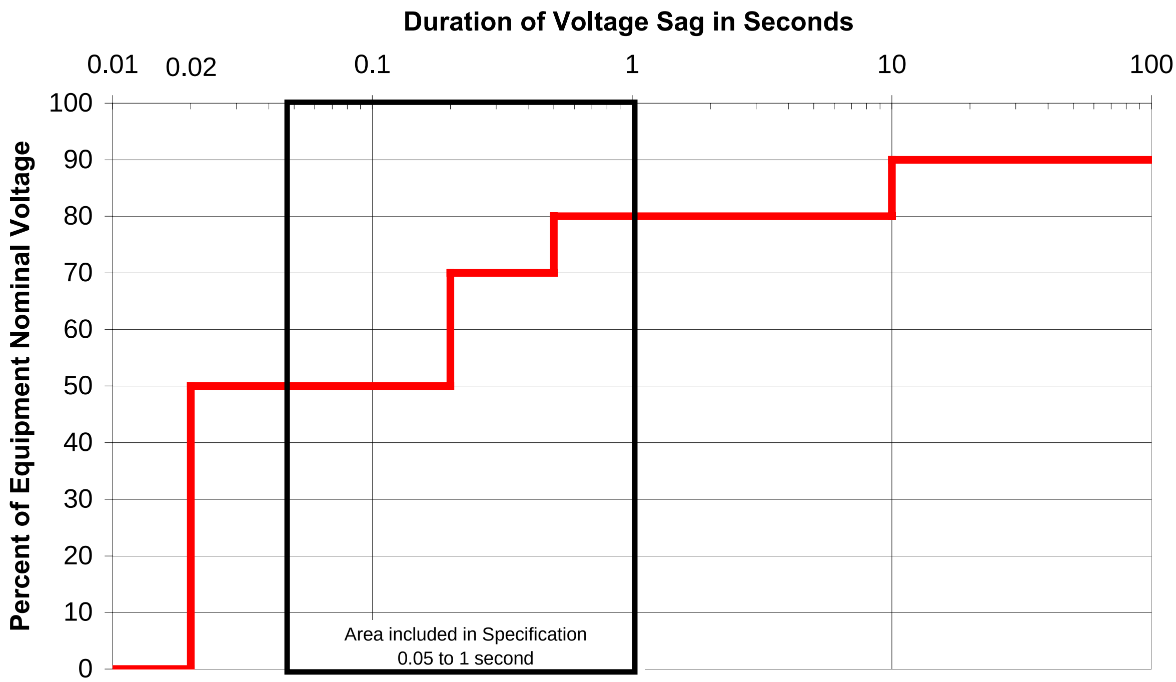

Figure R1-1
Recommended Semiconductor Equipment Voltage Sag Ride-Through Capability Curve from 0 to 100 Seconds

SEMI

SEMI F48-0600
TEST METHOD FOR DETERMINING TRACE METALS IN POLYMER MATERIALS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available on www.semi.org April 2000; to be published June 2000.

1 Purpose

1.1 This method provides a procedure for determining the nonvolatile trace inorganic impurities in bulk polymeric materials.

2 Scope

2.1 Following digestion by dry ashing (DDA) or digestion in closed vessel (DCV) preparation techniques, samples previously obtained and cleaned according to SEMI F40 are analyzed for trace inorganics using inductively coupled plasma-mass spectrometry (ICP–MS), graphite furnace atomic absorption spectroscopy (GFAAS), and/or inductively coupled plasma-atomic emission spectroscopy (ICP–AES).

2.2 Materials for analysis include, but are not limited to:

- Raw polymer materials (resins), such as pellets of perfluoroalkoxy (PFA), polyvinylidene fluoride (PVDF), ethylenechlorotrifluoroethylene (ECTFE), polyetheretherketone (PEEK), polypropylene (PP), polyethylene (PE), acetal resin, polyvinyl chloride (PVC), Perfluoromethylether-based Perfluoroalkoxy (MFA) and powders of polytetrafluoroethylene (PTFE).
- Polymer components of tubing, piping, fittings, valves, regulators, filter housings, filter cartridges, O–rings and gaskets used in ultrapure water (UPW) and liquid chemical distribution systems (LCDS). See Section 3.8 for further information.
- Ion-exchange resins
- Polymer products used in the manufacturing of semiconductor devices, such as wafer carriers and wands, as well as accessories internal to wet equipment (e.g., drums in spin rinse dryers, tanks in quick dump rinsers). See Section 3.8 for further information.

2.3 The DDA sections of this document refer to an ashing technique, whereby the sample is placed into a platinum or quartz crucible and thermally decomposed. Thermal decomposition in muffle furnace or microwave muffle furnace may also be used. Additionally, oxygen plasma may be used separately or in conjunction with these techniques.

2.4 The DCV sections of this document refer to closed vessel microwave acid decomposition at elevated temperature and pressure. Alternatively closed vessel thermal conduction heating may also be applied.

2.5 ICP–MS, GFAAS, and ICP–AES are all appropriate methods for inorganic analysis. ICP–MS is the preferred method because it is more sensitive and efficient. Alternate procedures may be used if they meet the same analytical performance criteria. Each laboratory is responsible for verifying the validity of each method within its own operation.

2.6 This method is applicable for the elements found in Table 1:

Table 1 List of Applicable Elements (See NOTE 1.)

Aluminum	Magnesium
Barium	Manganese
Calcium	Nickel
Chromium	Potassium
Cobalt	Sodium
Copper	Strontium
Iron	Tin
Lead	Titanium
Lithium	Zinc
Molybdenum	Zirconium

NOTE 1: See Limitations, Section 3.3.

2.7 This method may be used for other materials, or other nonvolatile elements, if the end-user wishes and performance is demonstrated for the analyte of interest, in the matrices of interest, at the concentration levels of interest.

2.8 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The accuracy of the method is limited by the detection limits of the instruments and by the sample preparation procedure.

3.2 This procedure anticipates analysis levels in the ppm (mass/mass) range. Impurities less than 0.1 ppm may not be detected by this method.

3.3 When extending the method to other elements recovery should be evaluated during validation. Poor recovery rates are often found for volatile elements such as boron (B), arsenic (As), antimony (Sb), mercury (Hg), gold (Au), and tungsten (W) because of the relatively high temperature sample preparation method and poor stability of some elements in aqueous solution. Elements forming volatile halogenides can be affected due to the in-situ production of hydrogen halogenides when halogenated polymers are ashed.

3.4 This is a bulk analysis technique. For leachable testing or surface analysis refer to the Related Documents (Section 16) of this method.

3.5 Due to the rapid advances in digestion technology, consult the manufacturer's recommended instructions for guidance when conducting analyses using the DCV sections of this document.

3.6 DCV techniques can generate gaseous digestion reaction products, very reactive, or volatile materials at high pressures. Spontaneous venting which can occur during sample heating may cause venting of the vessels with potential loss of sample and analytes. Sample sizes greater than 0.25 g may accentuate this event.

3.7 In the use of the DCV technique, TiO2, alumina, and other oxides may not be totally dissolved. Sequestering of target analyte elements may occur.

3.8 Although this method allows the sampling of small pieces of polymer that are mechnically removed from a larger item, obtaining such samples in a clean manner may be difficult. Multiple sampling, separation and preparation techniques might be necessary to establish confidence in the results.

3.9 This document is not intended to supersede international, national or local codes, regulations, and laws. Each should be consulted to ensure that the method meets regulatory requirements in each location.

5.1.10 *UPW* — ultrapure water (see Section 9.4)

6 Summary of Test Method

6.1 Samples previously prepared using SEMI F40 are ashed or digested under pressure within a digestion device, and trace inorganics in the residue are dissolved into acid and UPW. The sample is then analyzed by ICP–MS, GFAAS, and/or ICP–AES to determine the inorganic content of the material. This method applies only to nonvolatile metals (i.e., alkali metals, alkaline earths, and transition metals).

6.2 Data from different tests can be compared to determine the inorganic content in different materials and in the same material from different manufacturers.

7 Significance and Use

7.1 Determining the metallic contamination concentration in bulk polymer materials used in either distribution systems for process fluids or products in direct contact with the wafer is important criterion for deciding the suitability of a material. For example, ultrapure water contaminated by distribution system components may adversely affect microelectronic and other processes.

7.2 This method measures the total amount of impurities in the bulk of the material. These impurities will not necessarily leach into a process fluid stream.

8 Apparatus

8.1 *Muffle Furnace* — With temperature control ranging up to a minimum of 700°C and equipped with a means to regulate air circulation.

8.2 Microwave Muffle Furnace

8.3 *Crucibles* — Made of either platinum or quartz and with a 30 mL capacity.

8.4 ICP–MS

8.5 GFAAS

8.6 *ICP–AES* — Either simultaneous or sequential reading type.

8.7 Chemical Fume Hood

8.8 Propane Torch or Appropriate Heating Source with a minimum temperature of 650°C.

8.9 Device for digestions under a pressure of at least 30 bar (435 psi), with temperature control. This can be a laboratory microwave-based system or a system based on other heating sources.

8.9.1 In the case of microwave digestion devices: Laboratory microwave digestion systems should be used that possess appropriate temperature control of chemical reactions. Closed microwave systems must have controlled pressure relief.

8.9.2 Digestion vessels of appropriate internal volume should be used and construction should be of appropriate chemically inert materials. If the vessel is pressurized, it should be capable of withstanding a minimum pressure of 30 atm (30 bar or 435 psi), with controlled pressure relief of reagents and digestion products.

NOTE 2: Only microwave manufacturer's approved vessels for that device should be used.

8.9.3 In case of a laboratory microwave digestion device: Oscillating turntable to insure homogeneous distribution of microwave radiation to all vessels.

8.9.4 Filter paper, qualitative or equivalent.

8.9.5 Filter funnel, polypropylene, polyethylene or equivalent.

8.10 Volumetric flasks, 20 mL or 50 mL capacity or equivalent.

8.11 Analytical balance, of appropriate capacity, with a ± 0.0001 g or appropriate precision for the weighing of the sample. Optionally, the vessel with sample and reagents may be weighed, with an appropriate precision balance, before and after microwave processing to evaluate the seal integrity in some vessel types.

9 Materials

9.1 Argon Gas 99.99% pure or better.

9.2 *Standards and Reference Materials*

9.2.1 For preparation of multi-element standard solutions, use NIST[2], NIST-traceable, or other appropriate international standards as stock solutions.

9.2.2 From these stock solutions, multi-element working standard solutions must be prepared daily by pipeting the appropriate volumes of the trace metal standards and diluting to the desired concentrations.

NOTE 3: Prepare these working standards using the same amount of acid as used for the sample.

9.2.3 For validation purposes, use appropriate international reference materials that match the sample matrix as close as possible.

9.3 All reagents should be of appropriate purity or high purity (acids for example, should be sub-boiling distilled where possible) to minimize the blank levels due to elemental contamination. If the purity of a reagent is questionable, analyze the reagent to determine the level of impurities. The reagent blank must be less than the minimum detection limit in order to be used.

9.3.1 Ultrapure Hydrochloric Acid less than 1 ppb for each trace metal.

9.3.2 Ultrapure Nitric Acid less than 1 ppb for each trace metal.

9.4 *Ultrapure Water*

9.4.1 For purposes of this test, references to water shall be understood to mean ultrapure water as defined by maximum individual metal and anion impurity levels of 0.1 ppb or less, nonvolatile residue levels of 0.1 ppm or less, resistivity of 18 megohm-cm or greater, and reactive silica impurity of less than 1.0 ppb.

10 Precautions

10.1 *Safety Precautions*

10.1.1 This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and to determine the applicability of regulatory limitations before using this method.

2 National Institute of Standards and Technology, 100 Bureau Dr., Gaithersburg, MD, 20899-001 USA, (301) 975-6478, <www.nist.gov>

10.1.2 Care must be taken in the handling and use of the acids to avoid acid burns or contamination of the acid. Acid should be neutralized before disposal.

10.1.3 Care must be taken when using the propane torch to avoid burns. The torch should not be used near flammable materials or solvents.

10.1.4 Care must be taken when using the muffle furnace to avoid burns.

10.1.5 When ashing fluoropolymeric materials, the ashing must be performed in a fume hood. When heated, fluoropolymer materials outgas hydrofluoric acid fumes and may also emit fluoropolymeric particles which, if inhaled, can cause a condition known as "polymer fume fever." If hot fluoropolymer fumes are inhaled, remove the individual to a well-ventilated area and seek medical attention.

10.1.6 The outer layers of vessels used in the DCV technique are frequently not as acid or reagent resistant as the liner material. To retain the performance and safety required these outer layers must be neither chemically degraded nor physically damaged. Routine examination of the vessel materials may be required to ensure their safe use.

10.1.7 Only DCV containers with pressure relief or control mechanisms or containers with suitably inert polymeric or quartz liners and pressure relief mechanisms are considered acceptable for use with this process.

NOTE 4: Only microwave manufacturer's approved vessels for that device should be used.

10.1.8 Use of laboratory microwave systems is required for this method. Users are advised not to use domestic (kitchen) type microwave ovens or cookware. Nor should inappropriately sealed containers without pressure relief for microwave acid digestions be used. See Section 16.3.1 for additional information on safety issues concerning the use of laboratory microwave systems.

10.1.9 Toxic nitrogen oxide(s), hydrogen fluoride, and toxic chlorine (from the addition of hydrochloric acid) fumes are usually produced during digestion. Therefore, all steps involving open or the opening of digestion vessels must be performed in a properly operating fume ventilation system.

10.1.10 The analyst should wear appropriate protective clothing, such as gloves and face protection, and must not at any time permit a solution containing hydrofluoric acid to come in contact with skin or lungs.

10.2 *Technical Precautions – Digestion by Dry Ashing (DDA)*

10.2.1 Flaming and ashing temperatures must be controlled so that they do not exceed 650°C to minimize metal loss due to volatilization. If the crucible becomes excessively hot for longer than about one minute during flaming, it may have overheated. When testing the method for recovery rates, it will become apparent that the sample has been overheated from the low recovery of metals.

10.2.2 One method of cleaning the crucibles and covers is to flame them with a propane torch or other appropriate heating source until they are sufficiently hot, allow them to cool, rinse in dilute ultrapure nitric acid, and then rinse in ultrapure water.

10.2.3 When ashing a sample, take care that all of the ash residue remains in the crucible.

10.2.4 Several factors concerning selection of crucible materials should be considered when performing the DDA technique. For example, the crucible itself can contribute elevated levels of its own composition into samples at trace levels. Temperature restrictions are another factor to consider in the selection of the crucible material. Corrosion of the crucible during the decomposition of the sample should also be considered. For example, in the ashing of fluorinated materials, platinum is preferred over quartz glass that could be etched by the liberated hydrogen fluoride.

10.3 *Technical Precautions – Digestion in Closed Vessel (DCV)*

10.3.1 Trace analysis requires a thorough cleaning. One method of cleaning the vessels is to leach with hot (1:1) hydrochloric acid (greater than 80 C, but less than boiling) for a minimum of two hours followed with hot (1:1) nitric acid (greater than 80 C, but less than boiling) for a minimum of two hours and rinsed with reagent water and dried in a clean environment.

10.4 *Other Technical Precautions*

10.4.1 When switching between high concentration samples and low concentration samples, all crucibles or digestion vessels should be cleaned according to the corresponding and recommended cleaning procedure. This cleaning procedure should also be used whenever the prior use of the digestion vessels is unknown or cross contamination from vessels is suspected.

10.4.2 Trace metallic levels of reagent blanks must be significantly lower than those in the sample in order to obtain accurate results for the analyte of interest.

10.4.3 Perform sample preparation in a clean environment and under a fume hood to minimize contamination.

11 Sampling

11.1 *Sampling of Test Specimens*

11.1.1 Test specimens shall be representative of the polymer material being tested and shall be free of embedded particles and extraneous surface contamination when visually inspected.

11.1.2 Two samples of each material shall be prepared per SEMI F40. This test is performed in duplicate. More samples may be analyzed if desired.

NOTE 5: The samples are cleaned and weighed according to SEMI F40. The sample preparation described in this document begins with either the ashing (DDA) or digestion under pressure (DCV) of the polymer material.

11.2 *Sample Preparation – Digestion by Dry Ashing (DDA)*

NOTE 6: Digestion by ashing using an oxygen plasma asher differs considerably from the described procedures that refer to ashing in open crucibles. Specific instructions are available from the instrument manufacturers.

11.2.1 Clean the digestion container and cover using appropriate methods for the vessel materials and procedures being employed.

11.2.2 Place the sample into a cleaned crucible. For at least two additional samples, add the recovery spike as discussed in Section 12.

11.2.3 Use a propane torch or other appropriate heating source to carefully flame the outside of the crucible until the polymer inside the crucible is completely charred. Do not flame exceedingly, i.e., do not allow a platinum crucible, for example, to become red hot, as excessive heat will allow some metals to volatilize.

NOTE 7: This step must be carried out in a well-ventilated fume hood.

11.2.4 Prepare at least three procedural blanks by flaming three or more empty crucibles using the method discussed in Section 11.2.3. The results from these blanks will be used to determine the metallic contribution from the crucibles themselves, from the reagents and from the test procedure. These procedural blanks should be treated like any other sample. Crucibles should be rotated in and out of service so that the same crucibles are not always used for blanks.

11.2.5 Place the charred sample crucibles and blank crucibles in a muffle furnace, cover the crucibles with the cleaned covers, and continue to char at 500 to 650°C until all the carbon is removed (usually over a period of 6–18 hrs). The removal of all carbon is indicated by the absence of black material in the sample.

NOTE 8: Some oxides (such as SnO_2) are black and may confound this determination. If a sample is still black after 18 hours, assume that it is an oxide and continue with the procedure.

11.2.6 Allow the crucibles to cool.

11.2.7 Add the appropriate amount (1–2 mL) of concentrated ultrapure hydrochloric acid to each crucible.

11.2.8 Evaporate the hydrochloric acid to dryness in a chemical hood at less than 100°C if necessary to permit instrumental compatibility.

NOTE 9: The presence of chloride in the sample can result in interferences for the determination of arsenic and vanadium by ICP-MS.

11.2.9 Continue preparing the sample as described in Section 11.4.

11.3 *Sample Preparation – Digestion in Closed Vessel (DCV)*

11.3.1 Clean the digestion container and cover using appropriate methods for the vessel materials and procedures being employed.

11.3.2 Place the sample into a cleaned digestion container. For at least two additional samples, add the recovery spike as discussed in Section 12.

11.3.3 Add the reagents needed for the digestion.

11.3.4 Prepare at least three procedural blanks by adding the same amount of all reagents, but no sample, to three or more additional containers. The results from these blanks will be used to determine the metallic contribution from the containers themselves, from the reagents and from the test procedure. These procedural blanks should be treated like any other sample. Containers should be rotated in and out of service so that the same containers are not always used for blanks.

11.3.5 The analyst should be aware of the potential for a vigorous reaction. If a vigorous reaction occurs upon the initial addition of reagent or the sample is suspected of containing easily oxidizable materials, allow the sample to predigest in the uncapped digestion vessel. Heat may be added in this step for safety considerations (for example the rapid release of carbon dioxide from easily oxidized polymeric material). Once the initial reaction has ceased, the sample may continue through the digestion procedure.

11.3.6 Seal the vessel according to the manufacturer's directions.

11.3.7 Properly place the vessel in the digestion system according to the manufacturer's recommended specifications and connect appropriate temperature and pressure sensors to vessels according to manufacturer's specifications.

11.3.8 Set the parameters of the digestion device to manufacturer's recommendations.

NOTE 10: If the pressure exceeds the pressure limits of the vessel, the pressure will be reduced by the relief mechanism of the vessel.

NOTE 11: Pressure control for a specific matrix is applicable if instrument conditions are established using temperature control. Because each matrix will have a different reaction profile, performance using temperature control must be developed for every specific matrix type prior to use of the pressure control system.

11.3.9 At the end of the digestion program, allow the vessels to cool for an appropriate period of time before removing them from the system. When the vessels have cooled to near room temperature, determine if the microwave vessels have maintained a seal throughout the digestion. Due to the wide variability of vessel designs, a single procedure is not appropriate. The use of a spiked control sample is appropriate to ensure that analyte loss has not occurred due to vessel venting. For vessels with burst disks, a careful visual inspection of the disk may identify compromised sample digestions.

11.3.10 Complete the preparation of the sample by carefully uncapping and venting each vessel in a fume hood. Vent the vessels using the procedure recommended by the vessel manufacturer. Transfer the sample to an appropriate acid cleaned container.

11.3.11 If the digested sample contains particulates, which may clog nebulizers or interfere with injection of the sample into the instrument, the sample may be centrifuged, allowed to settle, or filtered.

11.3.11.1 If necessary, centrifugation at 2,000–3,000 rpm for 10 minutes is usually sufficient to clear the supernatant.

11.3.11.2 *Settling* — If undissolved material remains such as TiO, or other refractory oxides, allow the sample to stand until the supernatant is clear. Allowing a sample to stand overnight will usually accomplish this.

11.3.11.3 *Filtering* — If necessary, the filtering apparatus must be thoroughly cleaned and pre-rinsed with dilute (approximately 10% V/V) nitric acid. Filter the sample through qualitative filter paper into a second acid-cleaned container.

11.3.12 Continue preparing the sample as described in Section 11.4.

11.4 *Preparation of the Sample for Analysis*

11.4.1 If the sample was obtained from the DDA method, add 0.5 mL concentrated nitric acid to each crucible.

11.4.2 For samples obtained from the DCV method, transfer or decant the sample into volumetric ware.

11.4.3 Dilute either obtained sample to a required volume with ultrapure water (usually 20 mL). Alternatively, a gravimetric dilution of the samples is also appropriate. The samples are now ready for analysis. See Related Documents, Section 16 for applicable trace inorganics test methods.

12 Recovery Preparation and Percentage Recovery Rate Determination

12.1 Metal recovery percentage must be determined for all instruments by the individual laboratory. This is accomplished via spiking a crucible or digestion vessel containing a polymer sample with a known concentration of metals. Then, determining the percentage of each metal recovered after the decomposition process or acid digestion. The following provides the recommended method for spiking:

12.1.1 Add a known volume of a standard to a crucible or digestion container containing a polymer sample.

12.1.2 *For DDA* — Gently evaporate the standard solution to dryness.

12.1.3 Digest the dried standard and dried polymer using the same procedure as for the samples. Typical recovery rates are 70–110% for the alkali, alkaline earths, and most transition metals.

13 Data Analysis

13.1 *Calculations*

13.1.1 The concentration of trace metals in the solution must be calculated to determine the concentration in µg/g (ppm) of the polymeric material using the following equation:

polymer concentration (µg/g) =
= solution concentration
(µg/L) × solution volume (L) / mass of the polymer(g)

13.1.2 Since the procedural blank does not contain a weighed sample, the results must be transformed to solid concentrations (in µg/g) by using the average weight of the samples (see Section 11.1.2 and corresponding NOTE).

14 Data Presentation

NOTE 12: Use the Report Form provided in Section 17 of this document.

14.1 *Sample Information*

14.1.1 Provide the date(s) of the test, the person and/or company requesting the analysis, the method in which the sample was obtained (e.g., if it was separated from a larger component and delivered to the laboratory), operator and laboratory performing the test, type of material (e.g., PFA pellets, injection molded PVDF valve, perfluoroelastomer O-ring), material supplier, material model and lot number(s), date sample was obtained and if the sample is a prototype or production material.

14.2 *Methods*

14.2.1 Provide the method of cleaning the sample as well as indicating if the sample arrived pre-cleaned from the requester or if it was cleaned in the laboratory performing the test.

14.2.2 Check the applicable box for the type of digestion. Complete as well the information regarding the conditions.

14.3 *Results*

14.3.1 Use Table 1, Trace Metals in Bulk Polymer Worksheet in Section 17.3 to report the results of the analysis along with detection limits and recovery rates for all elements required in the samples.

NOTE 13: For this document, the detection limit is defined as the concentration equivalent to three standard deviations of the results of the procedural blanks (see Section 13.1.2).

NOTE 14: The procedural blanks should be averaged and then subtracted from each sample (see Columns 3 and 4 of Table 1).

NOTE 15: If multiple samples of the same polymer material are evaluated, an average and standard deviation must be reported.

15 Precision and Bias

15.1 Expected variations in the blank are due to environmental and instrument variation.

15.2 Expected variation in the samples is 20–30% and is due to environmental, instrumental, and ashing or digestion variations.

15.3 This test does not give an indication of the variations found in the polymer sample material.

15.3.1 Analyze multiple samples of the same polymer material to determine the variation.

15.3.2 Refer to ASTM D4375 for information regarding sample populations to determine differences between materials.

SEMI F49-0200
GUIDE FOR SEMICONDUCTOR FACTORY SYSTEMS VOLTAGE SAG IMMUNITY

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available on www.semi.org February 2000; to be published February 2000.

1 Purpose

1.1 A guide defining a systems approach to power conditioning is needed for semiconductor and flat panel display (FPD) facilities. Semiconductor and FPD factories require high levels of power quality due to the sensitivity of equipment and process controls. Semiconductor and FPD processing equipment is especially vulnerable to voltage sags. The facility electrical system distributes power to process equipment, support equipment, and facility infrastructure equipment. Facility electrical distribution systems should be designed to integrate the voltage sag susceptibility of all the equipment with the power quality supplied by the utility. Installing effective and efficient facilities power conditioning requires identification of appropriate conditioning technologies and properly applying the conditioning equipment.

1.2 Utilizing recommendations in this guide should result in effective power conditioning of the facility electrical distribution system such that the process equipment, associated support equipment and facilities infrastructure equipment function within acceptable ranges.

2 Scope

2.1 This guide is intended for facilities engineers, equipment engineers, and facilities managers who specify compatibility requirements for equipment and utility services, and in particular for electrical power requirements such as those found in SEMI E51.

2.2 This document provides recommendations for implementing a systems approach to identification and resolution of voltage sag events that disturb the performance of semiconductor process equipment. A program recommending facilities electrical distribution system monitoring and control strategies for both the direct and indirect effect of voltage sags on wafer processing is outlined as follows:

- Reasons for monitoring and conditioning (see Section 7.1).
- Facilities electrical distribution system power monitoring and conditioning (see Section 7.2).
- Quantifying process equipment performance (see Section 7.3).
- Quantifying support equipment and facilities infrastructure equipment performance (see Section 7.4).
- Utility power monitoring strategies (see Section 7.5).
- Measurement and modeling strategies (see Section 7.6).
- Power enhancing and conditioning strategies for use in the facilities electrical distribution system (see Section 7.7).

2.3 This guide does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guide addresses power quality monitoring and conditioning solutions primarily within the facilities electrical distribution system. Process equipment and utility performance are covered in other related standards.

3.2 This guide does not address the impact of voltage sags on equipment beyond the effect to the electrical components. Effects on interdependent equipment interlocks are not examined in detail in this document.

3.3 This guide is not intended to address design or materials issues related to safety which are addressed elsewhere in the SEMI guidelines (see SEMI S2).

3.4 This document is not intended to supersede international, national or local codes, regulations and laws. Each should be consulted to ensure that the equipment meets regulatory requirements in each location.

4.2 *IEEE Standards*[1]

IEEE 1100 — IEEE Recommended Practice for Powering and Grounding Sensitive Electronic Equipment

IEEE 1159 — IEEE Recommended Practice on Monitoring Electrical Power Quality

IEEE 1346 — IEEE Recommended Practice for Evaluating Electric Power System Compatibility with Electronic Process Equipment

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *facilities infrastructure equipment* — component, modules, and systems used to transport materials like chemicals, power, water, effluent, and exhaust in semiconductor factories.

5.2 *process equipment* — fabrication equipment, inspection equipment, and cassette stage equipment used in semiconductor manufacturing.

5.3 *support equipment* — ancillary equipment not part of the process equipment main chassis.

5.4 *voltage sag* — an rms reduction in the ac voltage, at power frequency, for durations from half-cycle to a few seconds.

6 Impact

6.1 The primary goal of this guide is mitigation of the effects of utility voltage sags on semiconductor processing equipment, support equipment, and facilities infrastructure equipment. A voltage sag event adversely affecting only one of these pieces of equipment can cause processing equipment to malfunction. Both the direct and indirect effect of voltage sags on process equipment should be managed. Voltage sags can effect process equipment directly through the electrical power points of connection. Voltage sags can also indirectly effect process equipment through fluctuations in air, gas, liquid, and other utility streams caused when voltage sags effect support equipment and facility infrastructure equipment.

6.2 Examples of processing equipment, support equipment, and facilities infrastructure equipment are listed below. The interaction of these three types of equipment is shown in Figure 1.

6.2.1 *Process Equipment*

- Etch (dry & wet)
- Film deposition (CVD & PVD)
- Thermal
- Surface prep and clean
- Photolithography (exposure & coater/developer)
- Chemical Mechanical Polishing
- Ion Implant
- Metrology
- Automated test

6.2.2 *Support Equipment*

- Vacuum system (roughing, turbo, and cryogenic pumps)
- RF generator
- Residual gas analyzer (RGA)
- Water heater
- Chiller
- Photolithography stepper laser light source power supplies
- Photolithography coat/developer temperature/ humidity controllers
- Emission control (burn boxes)

6.2.3 *Facilities Infrastructure Equipment*

- Exhaust systems (scrubbers and VOC exhaust fans and controls)
- Process cooling water system (pumps and controls)
- Air compressors (and controls)
- Vacuum system (pumps and controls)
- Bulk and specialty gas distribution systems (pumps and controls)
- Liquid chemical distribution systems (pumps and controls)
- Power distribution systems

7 Power Monitoring and Conditioning Recommendations

7.1 *Reasons for Monitoring and Conditioning*

7.1.1 Semiconductor manufacturing facility electrical distribution systems should be designed to transport power to process equipment, support equipment, and other facilities infrastructure equipment without degradation to the electrical power quality. The system should recognize electrical power that does not meet specification and provide proper power conditioning so as not to impact wafer processing.

7.1.2 Power monitoring is used to measure electrical system power quality performance for the following reasons.

a) Monitoring data can be compared to equipment voltage sag specifications to identify problems.

b) Selection and control of power conditioning devices are dependent upon monitoring measurements.

7.1.3 Power conditioning is implemented to correct for gaps in equipment voltage sag susceptibility and point of connection electrical power performance. Power conditioning is occasionally implemented where the risk of unacceptable equipment performance is high, where equipment performance tolerance is outside specifications, and where equipment interruption is costly.

7.2 *Monitoring and Conditioning Program*

7.2.1 Quantify the process equipment, support equipment, and facilities infrastructure equipment voltage sag susceptibility using industry standard specifications and test methods. (See Sections 7.3 and 7.4.)

7.2.2 Set-up monitors for utility power quality (see Section 7.5).

7.2.3 Measure and/or model the impact of the facility electrical distribution system on the utility power delivered to the process equipment (see Section 7.6).

7.2.4 Model and evaluate cost/benefit of power conditioning solutions where there are gaps or high risks. Select and implement identified power conditioning solutions into the facilities electrical distribution system. (See Section 7.7.)

7.2.5 Maintain the installed power conditioning equipment and monitor the power either continuously or periodically to assure performance and evaluate results.

7.3 *Process Equipment Performance*

7.3.1 Facility design specifications should include requirements for processing equipment voltage sag immunity (see industry specification for semiconductor processing equipment voltage sag immunity). (See Related Documents section.)

7.3.2 Variability in process equipment manufacturing and supplied utility power quality preclude interruption free manufacturing. This variation comes from multiple sources:

a) Verification of representative samples of equipment does not guarantee 100% of the equipment will meet the same requirements.

b) Factors such as location, load changes, capacity, weather, and transmission/ distribution equipment, limit how well utility power quality can be controlled.

c) The tests, themselves, are not variation free; the test equipment, calibration processes, and the test personnel can introduce further variability.

7.3.3 The risk of manufacturing interruptions can be considerably reduced through two approaches.

a) Create a margin between allowable voltage sag for the supplied utility power and process equipment voltage sag immunity.

b) Provide added protection from interruptions due to voltage sag events by enhancing the power quality in the facilities distribution system. (This approach is covered in this document, see Scope and the middle segment of Figure 1.)

7.4 *Support and Facilities Infrastructure Equipment Performance*

7.4.1 The effects that support equipment and facilities infrastructure equipment have on process equipment should be considered.

7.4.2 Process and support equipment typically contain flow, temperature, or pressure sensors. If facility infrastructure equipment malfunctions due to a voltage sag event, the diminished flow of a required fluid or gas will cause the support or process equipment to alarm, malfunction, or stop.

7.4.3 A typical interconnection of facility infrastructure equipment with process and support equipment is illustrated in Figure 2. The various support and facilities infrastructure systems that can have an indirect effect on process equipment performance when subjected to voltage sag events are listed below:

- Process cooling water,
- Scrubbed exhaust,
- Volatile organic compound (VOC) exhaust,
- Gas cabinets and gas monitoring system controllers,
- Compressed dry air,
- Process vacuum,
- Automated wafer transport systems,
- Computer integrated manufacturing (CIM) systems,
- Gas leak detection systems,
- Exhaust abatement systems, and
- Bulk chemical delivery system.

7.4.4 Since the supplied utility power quality effects all the equipment within the factory, performance requirements for support equipment and facilities infrastructure equipment should be specified using the same standards used for processing equipment. Applying the same voltage sag susceptibility specifications for semiconductor processing equipment (see industry specification for semiconductor processing equipment voltage sag immunity) to the support equipment and the facilities infrastructure equipment has the following benefits: (See Related Documents section.)

a) Use of the same specification for all equipment allows for consistency when monitoring and conditioning for the effects of voltage sag events.

b) The same performance verification test methods as those used for processing equipment can be applied to the support equipment and facilities infrastructure equipment.

7.4.5 Where it is inefficient to have support and/or facilities infrastructure equipment supplied to meet the same specifications as process equipment, the facility electrical distribution system may be required to compensate for any specification gap.

7.5 *Monitoring Strategies*

7.5.1 Use power disturbance monitors and/or digital fault recorders to monitor voltage to detect compliance (see IEEE 1159). Monitor current to identify disturbance sources and assist in solutions.

7.5.2 Locate continuous monitoring at the electrical utility service, all major facility electrical distribution centers, and all critical equipment electrical points of connection. Perform periodic monitoring for at least one location of each equipment type in order to characterize the electrical environment under normal conditions (i.e., to create a baseline). Additional monitoring should be performed when experiencing unexplained operational problems. A comparison of baseline data to monitored data for equipment experiencing problems is recommended for evaluating the power supplied to the equipment.

7.5.3 Provide time synchronization for multiple monitors to allow for the correlation of a single voltage sag event between all monitors.

7.5.4 In order to understand the impact, correlate monitored voltage sag events with known wafer processing effects within the process equipment.

7.6 *Measuring and Modeling Strategies*

7.6.1 A single voltage sag event originating outside the factory will vary in magnitude and duration when measured at differing locations throughout the facility. This is largely due to differing lengths and type of distribution conductors feeding equipment located throughout the facility. In addition, the electrical interactions of the reactive and non-linear elements of equipment effect the voltage sag measurements.

7.6.2 Voltage sag events that originate within the facility electrical distribution system will vary in magnitude and duration when measured at differing locations throughout the facility. These voltage sag events are usually a result of a current flow increase and the associated voltage drop across the conductors between the source and load. The location along the current flow path greatly effects the voltage sag measured.

7.6.3 Computer design tools should be used to model the electrical distribution system in order to calculate anticipated voltage sags for utility or site originated faults. If limitations exist such that voltage sag monitors are not located at every piece of equipment, then event measurements can be adjusted from modeling information to determine voltage sag values at other locations.

7.6.4 As a means for measuring effectiveness in a business environment, it would be useful to statistically model the effect of voltage sag events on the manufacturing processes. The variations mentioned in Section 7.3.2, above, preclude a deterministic approach to how well a wafer fabrication process will perform for a given voltage sag event. A statistical correlation model would aid in estimating the correlation between voltage sags and manufacturing cost, and can be used to validate the effectiveness of power enhancement and conditioning programs.

7.6.5 *Example of Voltage Sag Event Modeling*

7.6.5.1 A voltage sag event originating on the electrical utility system often exhibits different characteristics when measured at different locations on facility electrical distribution systems. The variance in voltage sag characteristics can create different effects on similar equipment. Variances can usually be explained by examining 1) the characteristics of voltage sag at the utility interfaces, 2) the type and connection configuration of voltage transformations, and 3) the voltage levels and corresponding phase relationships at the terminals of infrastructure, support, and process equipment within the facility.

7.6.5.2 The types of faults that can occur on a utility system are:

- Line to line to line,
- Line to line to line to ground,
- Line to line,
- Line to line to ground, and
- Line to ground.

7.6.5.3 The utility network can be modeled to predict the voltage sag characteristics due to various types of faults at the electrical interfaces between a semiconductor manufacturing facility and utility. The most common utility system fault type is a single line to ground fault. An example of the translation of a voltage sag resulting from a line to ground voltage sag event is provided in the following sections.

7.6.5.4 Typical voltage transformations from the utility interface to utilization voltage levels are illustrated in Figure 3. Under normal conditions, the three phase voltages are all approximately equal and displaced 120º from each other. During a voltage sag event due to an unbalanced fault, this relationship changes. Delta-wye transformers between the origin of the fault and the equipment being studied will further affect the phase and magnitude relationships. The degree to which voltage phase shift and magnitude changes occur at each transformation throughout the facility distribution system should be considered when examining impacts on individual equipment.

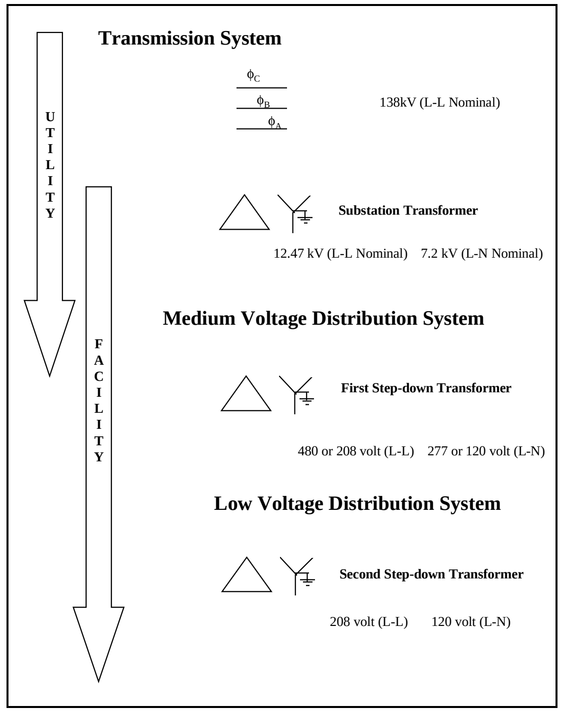

Figure 3
Typical Semiconductor Factory Voltage Transformations

7.6.5.5 Figure 4 illustrates the variations in magnitude of a voltage sag event within a facility during a single line to ground fault on a utility transmission line. This example illustrates a worst case situation, where a single-phase fault occurs at a substation transformer primary-side terminal. (See Related Documents section.)

7.6.5.6 Many devices in process, support, and facilities infrastructure equipment are not connected to all three phases. Because the voltage sag response of these devices may dictate the sag response for the entire equipment assembly, understanding device connection configuration and sag response characteristics is of critical importance. Sag depth and duration, the point on the wave at which the sag begins, and the corresponding phase relationships are all known to be factors in determining the sag response of many common devices.

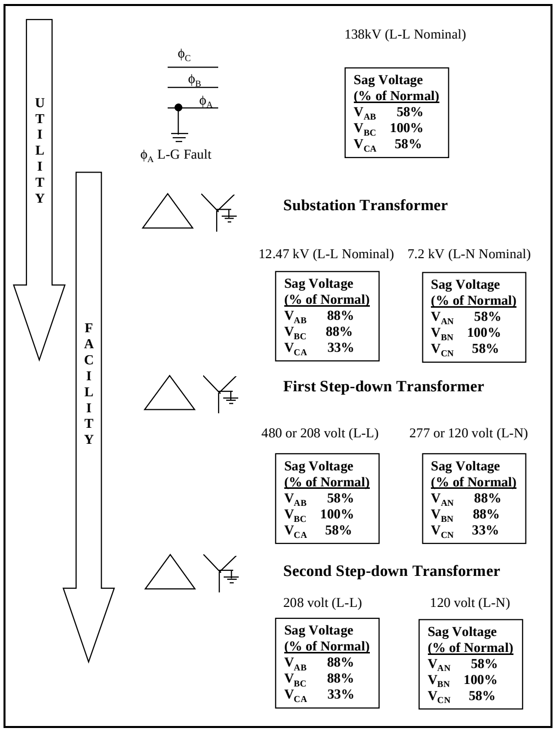

Figure 4
Example of Voltage Sag Levels during a Single Line to Ground Fault

7.6.5.7 Figure 4 illustrates the importance of phase relationships in the sag response of a 120-volt control circuit emergency off (EMO) relay which is connected to phase A (or phase B) in a 208-volt facility distribution system derived with only one low voltage transformation. In this example the voltage sags to only 88% of nominal on these phases, but drops to 33% of nominal on phase C. The industry specification for semiconductor processing equipment voltage sag immunity does not specify that equipment ride-through a sag to 33% of nominal voltage.

7.6.5.8 If two low voltage transformations were used to derive the 208-volt facility system (see Figure 4), phase B voltage would be unaffected during the utility voltage sag, but phases A and C would sag to 58% of nominal. Industry standards typically require equipment to ride-through a sag of this depth. However, a tolerance designed into the facility system may be necessary to provide adequate system protection.

7.7 *Power Enhancing and Conditioning Strategies*

7.7.1 While it is desirable to reduce and eliminate battery storage devices provided by equipment suppliers with individual pieces of process equipment, battery storage devices may be appropriate as a centralized or distributed part of a facilities distribution system (when evaluated in a systems approach to power enhancement and conditioning).

7.7.2 Facility power systems enhancements should be examined on a case-by-case approach to determine the appropriate measure of power conditioning to be applied. In general, the following types of equipment are frequently used to mitigate the effects of utility voltage sag events in semiconductor factories.

- Constant voltage transformers (typically applied on control systems)
- Diesel engine based uninterruptible power supplies (UPS)
- Magnetic synthesizers
- Motor-generators
- Rotary UPS
- Static UPS
- Static transfer switches with alternate power systems

7.7.3 Other power enhancement techniques and equipment available for use in facilities electrical distribution systems include but are not limited to the following:

- Capacitors for voltage regulation,
- Filters for power conditioning,
- High resistance grounding,
- Isolation of electrical circuit from other loads,
- Power line conditioners,
- Primary and secondary selective rather than radial distribution systems,
- Super-conducting magnetic energy storage systems,
- Transformer load tap changers, and
- Voltage regulators.

7.7.4 Power enhancement and conditioning equipment can be applied at selected equipment components, selected distribution circuits, or selected distribution buses. For power conditioning equipment application guidelines see IEEE 1100 and 1346.

SEMI F50-0200
GUIDE FOR ELECTRIC UTILITY VOLTAGE SAG PERFORMANCE FOR SEMICONDUCTOR FACTORIES

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available on www.semi.org February 2000; to be published February 2000.

1 Purpose

1.1 This guide provides a framework for semiconductor and flat panel display (FPD) manufacturers and their electric utility service providers to minimize the effect of voltage sag events on semiconductor processing. In particular, this guide focuses on electric utility power quality performance goals that are complementary to voltage sag immunity levels for semiconductor processing equipment and facilities infrastructure equipment (see Figure 1). Recommendations for measuring and evaluating voltage sag performance, evaluating utility system enhancements, and implementation of a continuous improvement process are included since no electric utility industry standards exist.

1.2 Utility systems are designed, constructed, and operated to meet utility industry regulations and requirements. One important requirement for semiconductor factories is power system reliability. Utilities measure reliability in minutes of voltage outages per customer per year. Semiconductor factories require a high level of power system reliability, any service outage is usually unacceptable. A second important requirement is power quality. Power quality relates to disturbed voltage waveforms, not outages. When utilities implement measures to increase power system reliability, power quality can be adversely affected. The structured approach defined in this guide can achieve high levels of power quality without sacrificing power reliability.

1.3 The intent of this guide is to help semiconductor manufacturers achieve both high levels of power reliability and power quality from energy utility providers. By becoming familiar with the cause and effect relationships of voltage sag events on the utility's side of the electric meter, semiconductor manufacturers and electric utilities can work together to pursue efficient solutions for improved voltage sag ride-through in semiconductor factories.

2 Scope

2.1 The scope of this guide extends beyond a discussion of typical electric utility reliability and quality improvement techniques to developing a continuous improvement process for electric utility voltage sag performance (depicted graphically in Figure 2). Factors in this process include the following:

- Define desired performance criteria by setting goals for voltage sag event duration and magnitude (see Section 6.1).
- Measure performance for both proposed and existing semiconductor factory sites (see Section 6.2).
- Summarize voltage sag event data and identify the impact on semiconductor processing and facilities infrastructure equipment (see Section 6.3).
- Recommend improvements that include consideration of cost, benefit, and risk. Improvements can include corrective action to eliminate system faults, changes to service configurations, and power enhancements (see Section 6.4).
- Select and implement improvements. Establish a continuous improvement process (see Section 6.5).

2.2 For the purposes of this document, the term Electric Utility refers to energy service providers (that sell energy to semiconductor manufacturers) and/or electric transmission and distribution providers (that deliver energy through their power lines).

2.3 This guide does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

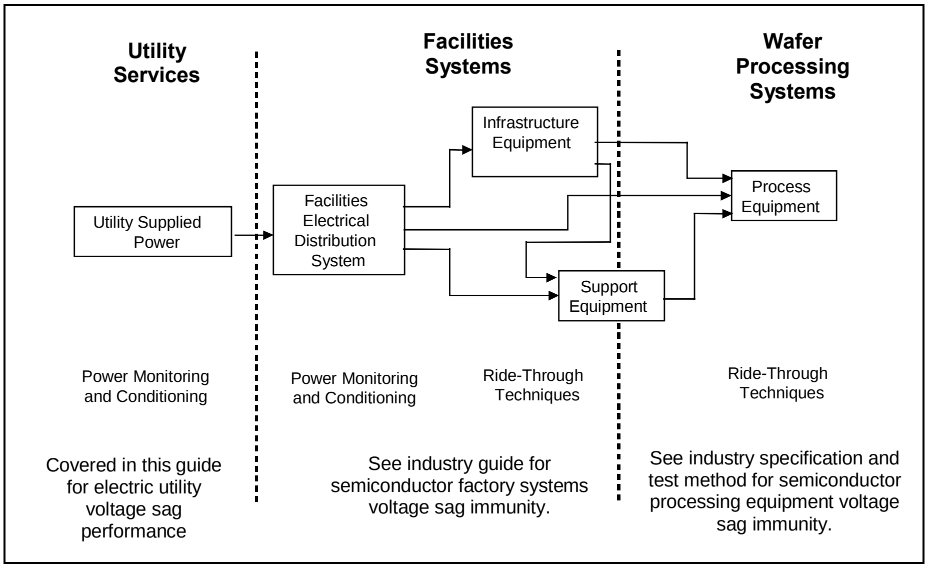

Figure 1
Power Quality Interfaces
(See Related Documents section.)

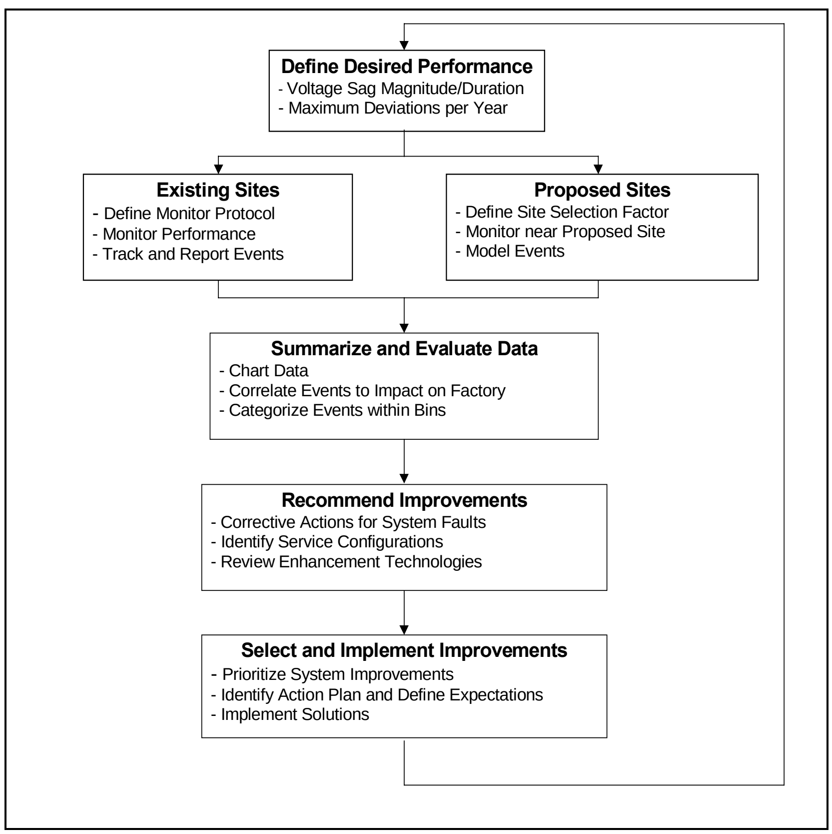

Figure 2
Continuous Improvement Process

3 Limitations

3.1 This guide addresses electric utility power quality monitoring and enhancement techniques primarily related to semiconductor factory energy utility providers. Process equipment and factory systems are covered in other related standards.

3.2 This standard is not intended to address design or materials issues related to safety which are addressed elsewhere in the SEMI guidelines (see SEMI S2).

3.3 This document is not intended to supersede international, national or local codes, regulations and laws. Each should be consulted to ensure that the equipment meets regulatory requirements in each location.

5 Terminology

5.1 *electric utility* — the company identified as the contractual provider of electrical power and energy to the customer point of delivery. Also known as the electric service provider.

5.2 *voltage sag* — an rms reduction in the ac voltage at power frequency for durations from half-cycle to a few seconds (see IEEE 1250). Also known as voltage dip.

6 Electric Utility Voltage Sag Performance Recommendations

6.1 *Define Voltage Sag Performance*

6.1.1 Defining a goal for acceptable voltage sag duration and magnitude is useful in establishing a benchmark or reference point for monitoring improvement. Events can be identified and categorized within the realm of the electric utility or the semiconductor manufacturer. Industry specifications for semiconductor processing equipment voltage sag immunity (which define the level of voltage sag immunity required for semiconductor processing equipment) are recommended as a performance goal. Using this goal for the performance of electric utility services will provide consistency with semiconductor processing equipment capabilities. (See Related Documents section.)

6.1.2 The goal for the maximum number of deviations from specified performance per year is zero. However, it is useful to recognize that utility generation, transmission, and distribution systems are subject to environmental and regulatory conditions that may negatively influence the ability to provide zero deviations on a continuous basis.

6.1.2.1 Document regulatory and environmental requirements that will limit the electric utility's choices when implementing improvements, such as rate structures or rights-of-way.

6.2 *Measure Performance*

6.2.1 *Measuring Performance at Proposed Semiconductor Factory Sites*

6.2.1.1 Factory site selection teams should consider the importance of power and power quality when evaluating potential sites. To insure that power quality considerations are properly factored into the site selection process, a selection factor should be assigned to power quality and reliability criteria.

6.2.1.2 Utility electrical service configurations should be considered when measuring and comparing reliability and power quality performance at different locations. The load profile for the proposed factory is used to determine the standard utility electrical service configuration. Usually, larger factories (> 10 MW) exceed allowable loading for lower voltage distribution systems (< 69 kV), therefore a high voltage service is the typical configuration for larger semiconductor factories. Selection of the highest available service voltage is preferred for reliability due to two factors. First, the area of exposure is greater for lower voltages since they include both higher and lower voltage system distribution lines and equipment. Second, higher voltage systems can provide energy to lower voltage system faults with little or no impact to high voltage system voltages, whereas, lower voltage systems are greatly impacted by faults not buffered by transformers.

6.2.1.3 The preferred method for comparing power quality and reliability from different locations involves creating a summary of the number of voltage sag events

1 The Institute of Electrical and Electronic Engineers, Inc., 345 East 47th Street, New York, NY 10017-2394, USA

that fall into different magnitude-duration categories. Data from different categories should be adjusted by weighting factors to enable valid comparison. See IEEE 1346 for suggested voltage sag event category and weighting factors.

6.2.1.4 Model events.

6.2.1.4.1 If actual disturbance data is not available, modeling results based on simulation of actual electrical faults should be calculated and reviewed. These studies called area of vulnerability analysis determine transmission lines and equipment where faults can adversely impact a semiconductor factory.

NOTE 2: As monitoring data is later collected, the modeling results should be validated.

6.2.1.5 Monitor events near proposed site(s).

6.2.1.5.1 Define monitoring protocol per the method outlined in Section 6.2.2.2.

6.2.1.5.2 Upon establishing an appropriate electrical service configuration, reliability and power quality information relative to that service configuration should be requested from the electric utility. Depending upon utility rate structures, semiconductor manufacturers may be required to pay separately for this analysis. Where available, the information provided should include actual disturbance data from other selected sites collected in accordance with IEEE 1159. Strive for data on sites that have similar electrical service configurations and are located electrically close to the proposed site (e.g., ideally, from the same transmission or distribution line).

6.2.2 *Measuring Performance at Existing Semi-conductor Factory Sites*

6.2.2.1 Preparation for monitoring.

6.2.2.1.1 Review existing industry typical voltage sag performance data for utility point-of-service.

6.2.2.1.2 Review existing site voltage sag performance data, usually taken at a variety of locations within the factory.

6.2.2.1.3 Review existing utility voltage sag performance data for the area around the factory site, usually a 20–30 mile radius of the service area is sufficient.

6.2.2.1.4 Review existing utility area of vulnerability modeling studies for power flow and system power quality.

6.2.2.1.5 Document the existing utility and manufacturing site electrical design and operating procedures.

6.2.2.2 Define the monitoring protocol.

6.2.2.2.1 Define where measurement devices will be located, how many to be installed, who will operate and maintain them, and what are the standards for calibration.

6.2.2.2.2 Define sensitivity settings. Usually magnitude triggers are set as tightly as possible (95% of nominal voltage). This will generate a large amount of data that will verify trends and maximize comparison opportunities between cause and effect. After several evaluation cycles magnitude triggers can be moved closer to the criteria (90% of nominal voltage), in order to focus improvement efforts on the more significant sags.

6.2.2.3 Monitor the voltage sag performance.

6.2.2.3.1 Location of monitor(s) should be such that the utility point-of-service to the factory is represented by the recorded data. Data recorded remote from the utility point-of-service will be effected by other utility or factory system components. Remote data should be adjusted to represent a utility point-of-service equivalent.

6.2.2.4 Track and report events.

6.2.2.4.1 Define the reporting format for all events and who will receive the reports. (Example: Reports to contain magnitude, duration, time/date stamp and impact on process, if known. All events are summarized and reported monthly. All out-of-specification events only are reported same day as event. All reports distributed to both factory and utility representatives.)

6.3 *Summarize Data and Evaluate Impact*

6.3.1 Summarizing monitoring data.

6.3.1.1 Figure 3 shows how monitoring data can be graphically reported using charts representing magnitude and duration.

6.3.1.2 Monitored and measuring power quality performance provides the semiconductor manufacturer and their electric utility with empirical data on which to base voltage sag performance and improvement decisions.

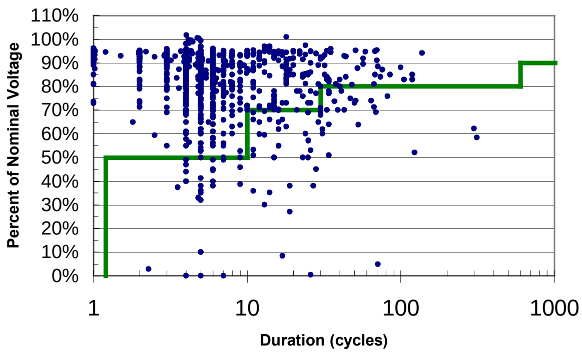

Figure 3
Example of Chart Summarizing Monitoring Data

6.3.2 Correlate data to impact on factory.

6.3.2.1 For new sites, categorize voltage sag events within magnitude/duration bins.

6.3.2.2 When evaluating new sites that are located in different electrical utility service areas it is beneficial to normalize the voltage sag data prior to comparison. The use of magnitude/duration bins to place historical or predicted event data creates discrete blocks of like kind events. The impact on factories, causes of events, and potential improvements may be evaluated on each individual bin or groups of bins. Increasing the number of magnitude/duration bins used in the data comparison refines the accuracy, but also increases the effort needed to translate events into discrete data bins. (See IEEE 1346 and Related Information 2.)

6.3.2.3 For existing sites, define categories of event impact on manufacturing process. For example:

- In Spec Event/No known impact
- In Spec Event/Minor impact
- In Spec Event/Major impact
- Out of Spec Event/No known impact
- Out of Spec Event/Minor impact
- Out of Spec Event/Major impact

6.3.2.3.1 The boundary between major and minor impact is often cost or number of wafer moves lost converted to an equivalent cost.

6.4 *Recommend Improvements*

6.4.1 Analyze costs, benefits, and risks.

6.4.1.1 The improvement recommendation process should include the equivalent of identifying the costs related to the disturbances, the costs related to improvements, and the effectiveness of improvements. The risks should be identified for taking no action, the possibility that events will occur during the implementation of improvements, and that events will occur as a result of unknown factors resulting from the installation of improvements. Improvements can include corrective action to eliminate system faults, changes to service configurations, and power enhancements.

6.4.2 Corrective action to eliminate system faults.

6.4.2.1 The key to influencing an electric utility's voltage sag performance is mutual understanding of measurement and improvement processes. Voltage sags on utility electric systems are created because of faults (short circuits) caused by a variety of events, including lightning, trees contacting power lines, equipment failure, and vehicles striking power poles. In order to reduce the number of voltage sag events, it is important to understand the specific cause of each fault. Semiconductor manufacturers should request that electric utilities share disturbance investigation reports and statistics. If data is not available, or tracking fault causes is not a focus (many utilities track only outage causes) then a fault tracking system should be established.

6.4.2.2 Many times, the initially identified fault cause (for example lightning) has a more specific cause (for example a contaminated insulator), with an even more specific root cause (for example salt contamination on coastal power lines in dry weather seasons). Identifying this root cause helps to establish the appropriate corrective action (for example, improved insulator cleaning practices to include weather considerations on coastal lines). Semiconductor manufacturers and their electric utilities should work together to ensure voltage sag event root cause identification processes exists.

6.4.2.3 Analysis steps for electric utilities to identify the root cause of system faults include the following:

Step 1 Locate the fault and identify what initiated the fault.

Step 2 Investigate the underlying causes of the fault to discover the root cause.

Step 3 Track faults and root causes in a database.

Step 4 Identify corrective actions.

6.4.2.4 Some of the more obvious corrective actions include additional animal guards on exposed electrical devices to reduce the effects from inadvertent touch. Additional patrols and early removal of birds nests, sources of nesting material, reduction in potential roosting and nesting sites, sealing any possible entry to electrical equipment against wildlife intrusion, and designs using larger phase spacing and higher Basic

Impulse Insulation Levels (BIL) are just some of the ways that events can be eliminated.

6.4.3 *Service Configurations*

6.4.3.1 Determine the factors that are fixed for the purposes of improvement development and evaluation. Some examples include, but are not limited to, physical location of site, utility system configuration beyond the immediate vicinity of the site, and electric rate structures.

6.4.3.2 Once the electrical reliability and power quality needs of a semiconductor factory are identified and the reliability and power quality of the electrical network in the area has been characterized, electric utility service configuration can be considered. The electric utility and the semiconductor manufacturer should jointly develop a plan that balances reliability and power quality. This plan should consider the following service configuration options.

6.4.3.3 High voltage service configurations.

6.4.3.3.1 Utility electrical service configurations have a significant effect on the levels of power quality and reliability. Semiconductor manufacturing facilities can typically derive the highest service quality and reliability from electrical service provided at the highest voltage level. By bringing service to the semiconductor factory from the highest available voltage system, semiconductor facilities can eliminate their exposure to electrical disturbances on lower voltage systems. Seldom are disturbances that result from events originating in lower voltage systems transferred into the higher voltage systems to any significant degree. Utility industry studies have indicated approximately 60–75% fewer voltage sag events (below 70% of nominal) on the high voltage systems.

6.4.3.3.2 For plants with loads greater than 10 MW, the highest voltage available is usually service at a voltage between 69 kV and 345 kV. Voltages above this range, while widely used by utilities, are not usually economical to adapt to loads less than 60 MW and may require lengthy regulatory approvals. If new overhead power lines are required, environmental and public issues associated with locating the lines may reduce access to higher voltage lines.

6.4.3.4 Redundancy.

6.4.3.4.1 All on-site facilities and internal factory distribution should have at least N+1 component redundancy. Where N is the number of components required to operate for maximum loading conditions and +1 indicates a single additional component that will operate to maintain the system capability in the event that one of the original components is out-of-service. If the plant is to be operated with no annual shutdowns for maintenance, then the system should be designed with enough redundancy to maintain every component in the plant without dropping service to any load. This requires at least a dual feed system that originates with two or more utility sources and continues throughout the semiconductor factory with appropriate transfer schemes to keep the loads energized at all times and to transfer loads without interruptions.

6.4.3.4.2 The most reliable service is one where there are multiple sources connected in a network to the semiconductor factory. This allows for adequate power supply, even if one of the sources fails. If a network is not available, a dual feed system can be configured to provide an immediate transfer to the backup system in the case of primary source failure, reducing outage time to near zero. Additionally, if the two sources are independent, a static transfer switch may increase quality to a level higher than that of a network. If only one source is available to a semiconductor factory with a load of less than five megawatts, an alternative is on site generation combined with a voltage sag ride-through system.

6.4.3.5 Minimize exposure.

6.4.3.5.1 When choosing source configurations, it is important to consider exposure at the semiconductor factory site. The more line length the factory is connected to, the more exposure there is.

a) It might not be desirable to have three lines serving the plant if one is a long line that is prone to failures. As a rule of thumb, more than three lines connected in a network may reduce quality without adding significantly to reliability.

b) If service is taken from a distribution class circuit, then consider purchasing a so-called express or dedicated feeder from the utility to isolate the plant from neighboring facilities.

c) Review the line routes with the utility and consider changes to reduce exposures, such as: where the poles are vulnerable to being struck by vehicles, or where trees are growing close to the transmission lines.

6.4.4 *Power Enhancements Technologies*

6.4.4.1 All disturbances will not be eliminated from the utility grid. In order to achieve the next step in plant protection, it may be necessary to implement some type of custom power option. Custom power is so called because it is thought to be a custom solution tailored to the needs of the process and the unique situation of the site. Custom power options usually involve some type of power enhancement and conditioning system. These power electronics systems are most often connected between the semiconductor factory and the electric utility at the point of common coupling (also known as the electrical service point). Many custom power options include some energy storage to ride through the disturbance, but they are usually designed to carry the factory through only momentary interruptions. In fact, for large factories (>10 MW) some available ride-through systems only operate to boost the voltage during sags and will not carry the factory site through even short outages. The trade-off is cost versus protection. The systems should be economically evaluated as well as matched technically to the needs of the site.

6.4.4.2 Electric utility provided custom power options should be balanced against factory system voltage sag immunity covered in industry guide for factory systems voltage sag immunity.

6.5 *Select and Implement Improvements*

6.5.1 Both the electric utility and the semiconductor manufacturer should agree criteria methodology for prioritizing improvements. The following are examples of prioritization criteria.

- Expected frequency of disturbances.
- Impact of fault on electric utility and semiconductor processing.
- Relative cost of system improvement.
- Ability of action to reduce effects.

6.5.2 Select improvement to be implemented, identify the schedules for installation, and define the new system performance expectations.

6.5.3 Implement selected improvements.

6.5.4 With identified fault tracking and root cause analysis processes electric utilities will be in a position to communicate the cause of events, their corrective actions, and the impact of improvements. Results will be both immediate and long-term, but to ensure that the continuous improvement process remains successful, the impacts of improvements should be tracked. The results of this tracking should provide feedback to the continuous improvement process as a whole.

RELATED INFORMATION 1
VOLTAGE SAG PERFORMANCE AT SEMICONDUCTOR FACTORY SITES

NOTE: This related information is not an official part of SEMI F50 and was derived from the work of the originating task force. This related information was approved for publication by full letter ballot procedures on December 15, 1999. Determination of the suitability of the material is solely the responsibility of the user.

R1-1 Typical Electric Utility System Performance

R1-1.1 Although most large semiconductor sites are served from dedicated substations, data collected from utility (medium-voltage) distribution circuits can be useful in establishing a baseline for electric utility system performance. As part of the EPRI*[2] Distribution Power Quality (DPQ) study, data was collected for a two-year period from approximately 300 different BMI PQNode monitors. These monitors were located on 100 different feeders at 24 geographically dispersed utilities. The power quality database created in conjunction with this study is probably the most extensive in existence. The data derived from this study provides a statistically based assessment of the level of power quality on electric utility distribution circuits (voltage range from 4.16kV to 34.5kV).

R1-1.2 Almost every category of power quality data was collected in the DPQ study, however, only voltage sag and interruption data is assumed to be pertinent to this activity. In the DPQ study, a voltage sag event was initiated when the rms voltage dropped below 95% of nominal for one cycle (data analysis was performed only for events with magnitudes less than or equal to 90%). An interruption event was initiated when the voltage dropped below 10% of nominal for 120 seconds. Although waveforms were captured for most sag and interruption events, almost all of the data analysis was performed on the basis of minimum voltage magnitude (as a percentage on nominal) and maximum duration during the event.

R1-1.3 *DPQ Key Results*

- The average interruption rate per site, per month was approximately 0.5.
- The average sag rate per site, per month was approximately 4 (10% < V < = 90%).
- The ratio of voltage sags to interruptions was approximately 10:1.
- Almost all voltage sag events have only a single component.
- Most voltage sags had duration of less than 10 cycles.

R1-1.4 The Figure R1-1 represents a summary of the voltage sag and interruption data in a contour format. The contour lines on the graph represent the expected number of disturbance events that are more severe (longer or deeper) than the duration and magnitude grid.

R1-2 Semiconductor Factory Site Disturbance Data

R1-2.1 The DPQ study provides a baseline of the power quality that exists on typical utility distribution systems. However, only one of the semiconductor manufacturing sites from which data was collected is served from a typical utility distribution system. Fourteen of the fifteen semiconductor sites surveyed were served from dedicated substations owned by either the customer or the utility. A comparison between DPQ and semiconductor site data (for large facilities) indicates that application of DPQ data would yield a more restrictive tool tolerance standard. It is recommended, therefore, that data from semiconductor sites be utilized to develop an initial curve and that the curve be validated against DPQ data.

R1-2.2 Voltage sag and interruption data was accumulated for 14 different semiconductor manufacturing sites geographically dispersed throughout the United States. One additional site was located outside of the United States. Data represented in this report was provided by semiconductor manufacturing companies.

R1-2.3 All of the data collected was in the form of magnitude and duration point values. Although the validity of characterizing the electrical system performance is this manner has been questioned, it remains the most common data format for disturbance data.

R1-2.4 The coverage of the disturbance data is typically represented as the product of number of years (or months) monitored and the number of monitors present. In this report, the unit for data coverage is Monitor-Years. One Monitor-Year of data is the quantity of data derived by one monitor for a one-year period. The data for semiconductor sites covers 30.5

2 Electric Power Research Institute, Inc., 3412 Hillview Ave., Palo Alto, CA 94304-1395, USA

Monitor-Years. The minimum coverage for a site was 0.8 Monitor-Years (one monitor for 10 months). The site with the maximum coverage had eight Monitor-Years of data. The average for all sites was approximately 1.9 Monitor-Years.

R1-2.5 Shown below is a scatter graph of all of the 1076 disturbances that were reported. The graph represents the magnitudes and duration for all voltage sags and interruptions at all sites. The magnitude value is the minimum voltage level during the sag represented as a percent of the nominal voltage. Also shown on the graph is the pertinent portion of the Information Technology Industry Council (ITIC) “CBEMA-curve,” contained in IEEE Standards 446 and 1100.

R1-2.6 The total number of events on or below the CBEMA curve was 166. Thirteen of the fifteen semiconductor sites averaged at least one event below the CBEMA each year. The average number of events below CBEMA, per site, each year was approximately 5.4. If the semiconductor manufacturers employed the new CBEMA curve for a tolerance standard, most would have experienced a significant number of equipment interruptions.

RELATED INFORMATION 2
EXAMPLE OF MEASURED PERFORMANCE DATA REPORTED IN MAGNITUDE AND DURATION BINS

NOTE: This related information is not an official part of SEMI F50 and was derived from the work of the originating task force. This related information was approved for publication by full letter ballot procedures on December 15, 1999. Determination of the suitability of the material is solely the responsibility of the user.

NOTE: This related information section is reprinted from IEEE 1346. The IEEE disclaims any responsibility or liability resulting from the placement and use in the described manner. Information is reprinted with the permission of the IEEE.

R2-1 Excerpt from IEEE 1346 – Annex D Constructing Coordination Charts [3]

R2-1.1 The use of bins to count the number of voltage sag events on a utility service is developed in IEEE 1346[4] as a step within a procedure for developing number of sags per year contour graphs. The bin tables are themselves useful as a tool for comparison of voltage sag performance of electrical systems. The paragraphs and tables below have been included to explain the use of bins in the standardization of historical or predicted events.

R2-1.2 Table R2-1 shows a grid of nine sag magnitude ranges in rows and five sag duration ranges in columns. The combination of nine rows and five columns produce a total of 45 magnitude/duration bins. Each measured or predicted sag will have a magnitude and duration that fits in only one of the 45 bins. The magnitude bin is a range of sag voltages expressed as a percentage of nominal. The time bin is a range of sag durations expressed as seconds. Each sag will have associated with it one magnitude and one time bin. The number in each table entry will correspond to the number of sags that have magnitudes and times in the same bins. Interruptions would go into the lower row of bins according to the duration. The number bins may vary depending on coordination needs for a particular case. However, this selection of 45 bins is reasonably convenient.

R2-1.3 For this example, assume each of the 45 bins contains one sag event. This means there are 45 sags per year and the characteristics of each sag fits in a unique bin. The 15 bins in the lower-right corner have bold italic highlighting to promote understanding as this example continues.

R2-1.4 Table R1-2 shows the cumulative number of sag events that are worse than or equal to each bin from Table R1-1. “Worse than” means the magnitude is lower and the duration is longer. The row and column headings show only single values instead of ranges. For example, there are 15 sags in the 50% magnitude, 0.4s entry of Table R1-2. The bold number 15 in Table R1-2 is the sum of all 15 individual bold entries in Table R1-1. This means 15 sags will have magnitude less than or equal to 50% and duration longer than 0.4s.

SEMI F51-0200
GUIDE FOR ELASTOMETRIC SEALING TECHNOLOGY

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available on www.semi.org February 2000; to be published February 2000.

1 Purpose

1.1 The purpose of this document is to introduce a basic guide for the use of seals in semiconductor fabrication equipment. Also, to introduce the diverse chemical and physical requirements for the many process applications, and to reduce cost of ownership and improve up-time through the use of appropriate sealing materials. It is important that equipment users, suppliers, OEMs, and seal manufacturers use the same terminology and that communication can take place at the same level so that actual performance of the equipment can be discussed.

2 Scope

2.1 This guide is applicable to the use of seals in specific operating environments used in the fabrication of semiconductor devices. The guide will aid in defining the seal parameters for the various process environments. It includes those elastomeric seals that come in contact with process liquids and or gases.

2.2 This guide does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The application of this guide is limited to elastomeric sealing technology performance as used in semiconductor manufacturing and related process equipment.

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *ATM* — Atmospheric

5.1.2 *BCD* — Bulk Chemical Dispensing System

5.1.3 *CVD* — Chemical Vapor Deposition

5.1.4 *DI* — De-ionized

5.1.5 *HDP* — High Density Plasma

5.1.6 *HF* — Hydrofluoric Acid

5.1.7 *LPCVD* — Low Pressure Chemical Vapor Deposition

5.1.8 *MOCVD* — Metal Organic Chemical Vapor Deposition

5.1.9 *OEM* — Original Equipment Manufacturer

5.1.10 *PPB* — Parts per Billion

5.1.11 *PVD* — Physical Vapor Deposition

5.1.12 *RF* — Radio Frequency

5.1.13 *RTP* — Rapid Thermal Process

5.1.14 *T.O.C. (total organic carbons*) — hydrocarbons which can appear in a process from a variety of sources including breakdown of O-ring materials.

5.1.15 *UPDI* — Ultra Pure De-ionized

5.1.16 *UV* — Ultraviolet

5.2 *Definitions*

5.2.1 *acid* — a corrosive material whose chemical reaction characteristic is that of an electron acceptor (SEMI F21, SEMI S4).

5.2.2 *anion* — a negatively charged ion that is attracted to an anode in electrolysis.

5.2.3 *cation* — a positively charged ion; an ion that is attracted to the cathode in electrolysis. These are typically ions of metallic elements.

5.2.4 *chemical/mechanical wear* — injury to the surface of an object or partial obliteration of or altering caused by rubbing, stress or chemical/mechanical use.

5.2.5 *chemical breakdown* — the degradation of a seal as the result of a chemical reaction.

5.2.6 *chemical property* — chemical durability is a measure of corrosion or attack of a glass surface when subjected to a specific reagent, such as acid, base, or water at a specific concentration for a specific time and temperature (SEMI D9).

5.2.7 *chemical reaction* — a process that involves change in the structure of ions or molecules.

5.2.8 *compatibility* — the ability of the molecules of a seal to coexist with process chemistries without the degradation of either.

5.2.9 *corrosives* — a chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the site of contact. A chemical is considered to be corrosive if, when tested on the intact skin of albino rabbits by the method described in the U.S. Department of Transportation in Appendix A to 49 CFR 173, it destroys or changes irreversibly the structure of the tissue at the site of contact following an exposure period of four hours. This term shall not refer to action on inanimate surfaces (SEMI S4).

5.2.10 *de-ionized water* — (specified with specific resistivity $\geq$ 18 MΩcm, cations: Na, Fe, Ca $\leq$ 0.2 µg/l) (SEMI E45).

5.2.11 *degradation* — a chemical reaction leading to the reduction to a simpler molecular structure. See also chemical breakdown.

5.2.12 *ion* — an atom or group of atoms that has lost or gained one or more electrons.

5.2.13 *leachables* — atoms or molecules which escape from the body of a material under vacuum, heat or chemical attack.

5.2.14 *leak rate* — rate at which an environment loses a vacuum (Millitorr litres/second).

5.2.15 *outgassing* — process whereby molecules of air or other gases adhere to the surface of the vacuum vessel or component therein and become liberated under vacuum conditions. Sometimes known as degassing.

5.2.16 *oxidizer gas* — a gas which will support combustion or increase the burning rate of a combustible material with which it may come in contact (SEMI S4).

5.2.17 *particle* — materials which can be distinguished from the film whether on the film surface or embedded in the film (SEMI P5).

5.2.18 *particle generation* — molecules of material generated due to degradation of a material.

5.2.19 *permeation* — the tendency for a gas or liquid to pass through a seal structure by osmosis or diffusion.

5.2.20 *silica* — silicon dioxide, occurring as quartz, etc.

5.2.21 *swell resistance* — the ability of a material to resist increasing its volume when it has been immersed in a liquid or exposed to vapor.

5.2.22 *temperature* — a measure of heat usually expressed in degrees Celsius or Fahrenheit. Temperature values shall be expressed in degrees Celsius (SEMI C3).

5.2.23 *weight loss* — reduction in mass of a sealing compound through the result of a chemical or physical reaction.

5.2.24 *vacuum integrity* — a subjective measure of the efficiency of a vacuum vessel.

7 Considerations for Use in Ultra Pure De-ionized Water (UPDI)

NOTE 2: See Figure 1.

7.1 De-ionized water is used in many wafer processing steps and shall not contribute any contaminants to the processes. The most common sealing requirements in DI water systems are filters, valves, flow and pressure regulators, and fittings.

7.2 Contaminants in DI water fall primarily into three categories. They are ion contamination, T.O.C.'s and bacterial growth. Contaminant levels are usually measured in parts per billion (PPB).

7.3 Ion contamination problems are caused by anionic and cationic elements in DI water such as fluorides, chlorides, sulfates, etc. These can be leached from seals as well as the DI plumbing.

7.4 Cations (mostly metallic ions) are leached from seals as well as the plumbing that delivers the DI water. In order to kill bacteria which have a propensity to grow in DI water, the water is either heated (80°C+), ozonated, or bombarded with UV light, or possibly a combination of these three elements. This poses unique problems for seals used in the DI system and can cause the following problems: Contamination of the DI water caused by T.O.C.'s being leached from the seals and plumbing.

7.5 Seal breakdown caused by ozone attack, or seal deterioration due to UV exposure. T.O.C.'s are of great concern since they can adhere to wafers and result in degraded oxide quality and hazy films. Ozone and UV deterioration of the seals usually leads to particulate contamination. These can be as small as single atoms or molecules to gross particle size contamination.

7.6 Considerations:

- What method of sterilization (i.e., chemical, thermal or radiation)?
- Concerns for cations, anions, or T.O.C.'s?
- Seal life expectation?

8 Considerations for Use in Corrosives (Acids, Bases), Oxidizers, and Solvents

NOTE 3: See Figure 2.

8.1 Inorganic wet chemicals at high concentration levels and in some cases at elevated temperatures are readily used in front-end semiconductor processing in the fabrication of semiconductor devices. Most common sealing requirements are in acid recirculation and chemical distribution systems (mostly BCD's). Component systems include pumps, filters, megasonic seals, gaskets for pipeline interfaces and valves.

8.2 Of primary concern when specifying a specific seal for an application are issues relating to resistance to chemical reaction. Design considerations should include resistance to chemical breakdown, static vs. dynamic environments, pressure, temperature, leachables, particle generation.

8.3 Chemical and Thermal Degradation involves the incompatibility of the seals to the process chemistries. An example is Hydroflouric Acid (HF) dissolves silicone elastomers. The same is true of temperature degradation (i.e., Piranha or Phosphoric Acids) where the process temperature causes thermally and chemically induced effects on the seal. That also contributes to the mechanical failure of the seal.

8.4 Leaching is most commonly associated with metal filler systems of the seal, which usually introduce metallic ions. This is a continuous occurrence as long as the seal is in the system.

8.4.1 *Particles* — Particles can be the result of mechanical damage of the seal or as a result of leaching or chemical degradation or foreign material present on the seal surface. Particles can end up on the wafer and cause defects.

8.4.2 *Summary* — All cases of the above contamination can create electrical shorts, voids, and unwanted doping.

8.4.3 *Solvents* — Incompatibility of elastomers or seals with solvent chemistries may cause contamination.

8.4.3.1 For example, there are degrees of incompatibility:

8.4.3.1.1 If the seal is dissolved by the solvent, then a catastrophic failure occurs where the solvent leaks out of the liquid process loop. This is associated with mis-processed wafers.

8.4.3.1.2 Another type of solvent seal interaction is the swelling of the elastomer or the leaching of small amounts of elastomer. Excessive swelling of the elastomer can result in premature seal failures and a higher cost of ownership caused by increased frequency of seal change outs.

9 Considerations for Use In Thermal Processes

NOTE 4: See Figure 3.

9.1 Diffusion processes are used primarily for growth of oxide layers and to anneal crystal damage caused by implant. Diffusion furnaces are usually batch process equipment where the process atmosphere is constrained within quartz tubes. The seals of these tubes are exposed to temperatures of 250–300°C. This requires that the seals not only be capable of withstanding these high temperatures but also that they not out-gas or permeate adversely affecting the purity of the process. Also of concern is the possible particle generation caused by the seals as they expand and contract due to temperature cycling (see Section 8.4.1).

9.1.1 Factors include:

- Temperature capability of material and process temperature.
- Static or dynamic state of seal.
- Proper sizing and fit of seal to gland.

10 Considerations for Use in Plasma Systems (Etch, CVD, and PVD)

NOTE 5: See Figure 4.

10.1 Considerations for sealing components for use in plasma applications shall include proximity to plasma, plasma reactor temperature, chemical composition of plasma, plasma energy, and chemical leaching by the plasma.

10.2 Contamination from the inherent seal components and particle generation is directly related to other considerations mentioned above.

10.2.1 Factors include:

- Seal composition and resistance to chemical attack.
- Proximity to source and intensity of RF.
- Temperature capability of material and process temperature.
- Static or dynamic state of seal.
- Proper sizing and fit of seal to gland.

SEMI F52-1101
DIMENSIONAL SPECIFICATION FOR METRIC PFA TUBES FOR LIQUID CHEMICAL DISTRIBUTION IN SEMICONDUCTOR AND FLAT PANEL DISPLAY MANUFACTURING

This specification was technically approved by the Global Liquid Chemical Distribution Systems Committee and is the direct responsibility of the Japanese Liquid Chemical Distribution Systems Committee. Current edition approved by the Japanese Regional Standards Committee on June 19, 2001. Initially available on www.semi.org August 2001; to be published November 2001. Originally published June 2000.

1 Purpose

1.1 This document defines sizes and their measurement methods of metric PFA tubes for liquid chemical distribution in semiconductor and flat panel display manufacturing equipment and facilities.

2 Scope

2.1 This document applies to metric tubes made from PFA.

2.2 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Society of Automotive Engineers, 400 Commonwealth Drive, Warrendale, PA 15096-0001.

4.2.5 *wall thickness* — thickness of the wall of the PFA tube.

4.2.6 *wall thickness deviation* — deviation of wall thickness.

4.2.7 *wall thickness tolerance* — allowable deviation of actual measurement of wall thickness from its specification.

5 Nominal Size and Dimensional Specification

5.1 A nominal tube size is indicated by “outside diameters/inside diameter”. This document provides specifications for eight nominal tube sizes as shown in Table 1.

5.2 The indication of the nominal size for metric PFA tubes is preferably printed on each package for shipping.

Table 1 Tube Size (mm)

OD/ID	25/22	19/16	12/10	10/8	8/6	6/4	4/3	3/2
OD Tolerance	± 0.2	± 0.15	± 0.15	± 0.12	± 0.12	± 0.1	± 0.1	± 0.1
Wall Thickness	1.5	1.5	1.0	1.0	1.0	1.0	0.5	0.5
Wall Thickness Tolerance	± 0.15	± 0.15	± 0.1	± 0.1	± 0.1	± 0.1	± 0.05	± 0.05
Wall Thickness Deviation	0.15	0.15	0.1	0.1	0.1	0.1	0.05	0.05

NOTE 1: The specified sizes should be measured at 23 ± 3°C. The specimen should be kept in the environment for more than 1 hour prior to the measurement.
NOTE 2: Refer to JASO F 409-91 and JASO M 317-73 for outside and inside diameter of 10/8, 8/6 and 6/4 tubes.
NOTE 3: Refer to JIS B 8183 for outside and inside diameter of 8/6 and 6/4 tubes.
NOTE 4: Refer to JIS B 6890 for outside and inside diameter of 12/10, 10/8, 8/6, 6/4, 4/3 and 3/2 tubes.
NOTE 5: Refer to SAE J 844 for outside diameter of 19/16 tube.
NOTE 6: Refer to SAE J 1394 for outside and inside diameter of 8/6 and 6/4 tubes.
NOTE 7: Refer to ISO 4397 for outside diameter of 25/22, 12/10, 10/8, 8/6 and 4/3 tubes.

6 Measurement Procedures

6.1 *Outside Diameter* — Measure the diameters at both ends of tube with a dial thickness gauge at 4 points in 45 degree intervals (see Figure 1). It is calculated with the following formula:

*Outside Diameter = 1/2 * (maximum reading + minimum reading)*

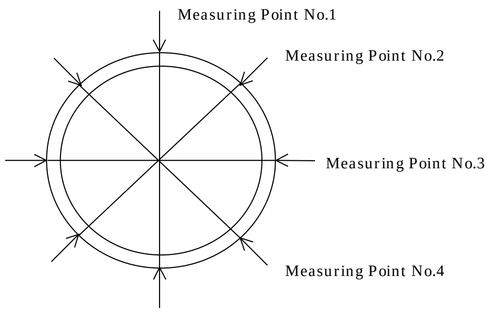

Figure 1
Outside Diameter Measurement

6.2 *Wall Thickness* — Measure the wall thickness at both ends of tube with a dial thickness gauge at 8 points in 45 degree intervals (see Figure 2). If it is not practical to use a dial thickness gauge, prepare a 1 mm long test piece and measure it with a projector. It is calculated with the following formula:

*Wall Thickness = 1/2 * (maximum reading + minimum reading)*

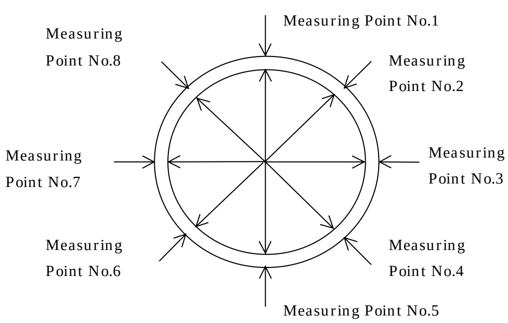

Figure 2
Wall Thickness Measurement

6.3 *Wall Thickness Deviation* — Use maximum and minimum readings of Section 6.2 and calculate the deviation with the following formula:

Wall Thickness Deviation = maximum reading – minimum reading

6.4 Other specifications including surface roughness, deviation from circular form, and physical property values may be determined upon agreement between the supplier and user.

6.5 Refer to JIS B 7502, External Micrometer for a dial thickness gauge.

SEMI F53-0600
TEST METHOD FOR EVALUATING THE ELECTROMAGNETIC SUSCEPTIBILITY OF THERMAL MASS FLOW CONTROLLERS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on March 2, 2000. Initially available on www.semi.org April 2000; to be published June 2000.

1 Purpose

1.1 The purpose of this document is to define a structured method for testing and evaluating the electromagnetic susceptibility of thermal mass flow controllers.

2 Scope

2.1 This document contains the requirements and test method that can be used to evaluate whether a thermal mass flow controller will maintain its functional characteristics when subjected to EMI levels typical of the industry. The test method covers both the radiated susceptibility (RS) and conducted susceptibility (CS) of the controller when exposed to EMI. The electromagnetic susceptibility requirements are extracted from MIL-STD-461C and SAMA PMC-33.1, and the test method is a composite of the RS03, CS01, CS02, and CS06 test methods defined in MIL-STD 462.

2.2 This test method does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this test method to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This test method is not designed for AC-powered MFCs. The test method addresses electromagnetic susceptibility of MFCs through DC power leads and control signals.

MIL-STD-461C — Electromagnetic Emission and Susceptibility Requirements for the Control of Electromagnetic Interference

MIL-STD-462 — Measurement of Electromagnetic Interference Characteristics

MIL-STD-463A — Electromagnetic Interference and Electromagnetic Compatibility Technology Definitions and Systems of Units

4.2 *Scientific Apparatus Makers Associations* [2]

SAMA PMC — 33.1 Electromagnetic Susceptibility of Process Control Instrumentation, Scientific Apparatus Makers Associations

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CS* — conducted susceptibility

5.1.2 *dB* — decibels

5.1.3 *DC* — direct current

5.1.4 *EMC* — electromagnetic compatibility

5.1.5 *EMI* — electromagnetic interference

5.1.6 *GHz* — gigahertz

5.1.7 *kHz* — kilohertz

5.1.8 *MFC* — mass flow controller

5.1.9 *MHz* — megahertz

5.1.10 *MIL-STD* — Military Standard

5.1.11 *psia* — pounds per square inch absolute

5.1.12 *psig* — pounds per square inch gauge

5.1.13 *RF* — radio frequency

5.1.14 *RG-58* — a specification for a particular type of coaxial cable

5.1.15 *rms* — root mean square

5.1.16 *RS* — radiated susceptibility

5.1.17 *T* — teslas

2 Portions of this method are excerpted from SAMA Standard PMC 31.1-1980 with permission of the publisher, Process Measurements & Control Section, SAMA, 1101 16th St., N. W. Washington, DC 20036

5.1.18 *V* — volt

5.1.19 *V/m* — volts/meter

5.2 *Definitions*

5.2.1 *conducted susceptibility* — equipment vulnerability to conducted emissions.

5.2.2 *electromagnetic* — all energy of electrical or magnetic nature; i.e., electric current flow or magnetic field.

5.2.3 *electromagnetic compatibility* — the capability of electronic equipment or systems to be operated in the intended operational electromagnetic environment at designed levels of efficiency.

5.2.4 *electromagnetic interference* — impairment of a wanted electromagnetic signal by an electromagnetic disturbance.

5.2.5 *ground* — a conducting connection, whether intentional or accidental, by which an electric circuit or piece of equipment is connected to the earth, or to some conducting body of relatively large extent.

5.2.6 *limit* — the level of susceptibility that a stated standard allows.

5.2.7 *noise (electrical)* — unwanted electrical signals that produce undesirable effects in the circuits of control systems in which they occur.

5.2.8 *radiated susceptibility* — equipment vulnerable to radiated emissions.

5.2.9 *stable* — the state a signal level obtains when its magnitude varies by less than or equal to ± 2.0% of full scale over a one minute period.

6 Summary of Method

6.1 This test method describes the test equipment and procedures for determining if the thermal mass flow controller is susceptible to both radiated and conducted interference. Initially, the controller is exposed to radiated electric fields over a frequency range from 14 kHz to 1 GHz at field strength levels less than 10 volts/meter (V/m). Furthermore, the controller's power leads will be tested for susceptibility to voltage transients with 10 µs rise times. See flow chart of the test method, Figure 1.

7 Interferences

7.1 MFCs are located in areas where electromagnetic (EM) fields are present. If an MFC is susceptible to the fields, then the delivered flow by the MFC could be adversely effected. The magnitude of the EM field's effect on the MFC performance shall be quantified by this test method.

8 Apparatus

8.1 Radiated Electric Field Susceptibility (RS-03)

8.2 Signal Generator, 14 kHz to 1 GHz

8.3 Audio Power Amplifier, 14 kHz to 1 MHz

8.4 RF Power Amplifier #1, 1 MHz to 400 MHz

8.5 RF Power Amplifier #2, 500 MHz to 1 GHz

8.6 Field Strength Meter

8.7 Oscilloscope

8.8 Parallel Element Antenna, 14 kHz to 20 MHz

8.9 Biconical Antenna, 30 MHz to 200 MHz

8.10 Conical Log Spiral Antenna, 300 MHz to one GHz

8.11 Tripod

8.12 Coaxial Cable, 50-ft, RG-58, with BNC male plugs at each end.

8.13 X10 Attenuator Scope Probe

8.14 Assorted Coax Cables for Interconnects

8.15 *Flow Standard* — Installed downstream and in series with the flow through the MFC. The flow standard shall be capable of measuring flow to within ± 0.3% of full scale.

8.16 *Flow Output Monitor* — Connected to the MFC output and signal common/ground points. The monitor/recorder shall be capable of measuring over a range of 0–10 VDC to within ± 5 mV.

8.17 Transient Susceptibility of Power and Control Leads (CS-06) (Conducted Susceptibility)

8.18 Spike Generator, with series and parallel outputs

8.19 Oscilloscope, dual channel

8.20 X10 Attenuator Probe

8.21 X100 Scope Attenuator Probe, two each

8.22 Test Leads, 12-in long with banana plugs at each end, four each

9 Reagents and Materials

9.1 *Test Gas* — Nitrogen with a dew point of less than or equal to -40°C and at a source delivery pressure of 35 psig.

10 Safety Precautions

10.1 *Safety Precautions* — This test method may involve hazardous materials, operations, and equipment.

10.2 The user must have a working knowledge of the respective instrumentation, must practice proper handling of test components, and must understand good laboratory practices. The user should not operate the components in such a manner as to exceed the ratings (i.e., pressure, temperature, flow, and voltage).

10.3 *Technical Precautions* — These tests are to be performed in a shielded or screened room to prevent possible problems with nearby instrumentation or electrical systems caused by the EM fields. At a minimum, the instrumentation associated with this test series (see Figure 2) must be shielded from the EM fields to ensure their proper operation.

11 Preparation of Apparatus

11.1 The test gas source and delivery system must be capable of satisfying the test volume flow rate at a constant pressure, ± 0.1 psia.

11.2 The test gas source and delivery system must be capable of delivering a gas at ambient temperature ± 1°C for the duration of each analysis. The ambient temperature shall be held to 22°C ± 1°C.

12 Calibration and Standardization

12.1 For each test, verify that calibration of test equipment is up-to-date.

13 Procedure

13.1 Install the MFC into the test setup per manufacturer's recommendations.

13.2 Apply power to all devices shown in Figure 3 per manufacturer's specifications. Allow the devices to warm up for the duration specified by the equipment manufacturer.

13.3 Purge the system with nitrogen for a length of time equal to ten times the amount of time it takes to replace the system volume once, when the test MFC is at its full-scale rated flow rate.

13.4 Close inlet shut-off valve. Then close the outlet shut-off valve located adjacent to the MFC (see Figure 2). Adjust the MFC setpoint to zero flow. Wait for the signals to become stable. Record the following on the data sheet:

- MFC indicated flow,
- Flow standard flow,
- Ambient temperature,
- Gas temperature, and
- Gas pressure.

13.5 Ensure that the inlet and outlet shut-off valves adjacent to the MFC (see Figure 2) are open. Adjust the MFC setpoint to 50%. Ensure that all manufacturer's recommended conditions are met for the MFC. Once the output signals become stable, record the MFC output signal, the flow standard output signal, the ambient and gas temperature, and the gas pressure on the data sheet in Table 1.

13.6 Ensure that the MFC power leads and control signal cables are shielded in the area that will be irradiated by the EM fields. The cable shielding shall be intact up to the connector. The type of shielding and connector shall be recorded on the data sheet in Table 1.

13.7 *Radiated Electric Field Susceptibility (RS-03)*

13.7.1 Testing from 14 kHz to 20 MHz:

13.7.1.1 Mount the parallel element antenna on a tripod at a distance of one meter from the controller and connect the antenna to the audio power amplifier using the 50-ft length of RG-58 coaxial cable (see Figure 3). Set the switch to low frequency range.

13.7.1.2 Connect the amplifier input to the signal generator output.

13.7.1.3 Turn on amplifier and signal generator.

13.7.1.4 Using the X10 probe, connect the scope across the antenna terminals.

NOTE 2: It is important to use the X10 probe rather than a coax that terminates in 50 ohms. The audio amplifier will not drive the required voltage into 50 ohms.

13.7.1.5 Set frequency output of the signal generator to 14 kHz.

13.7.1.6 Turn off signal generator modulation and set voltage across the antenna input connector at 35-V rms.

NOTE 3: With this voltage applied to the antenna at frequencies below one MHz, the required field strength of 10 V/m at a distance of one meter from the antenna should be established.

13.7.1.7 If, at any frequency, the required voltage cannot be developed across the antenna terminals, set to the maximum possible without exceeding equipment ratings.

13.7.1.8 When voltage is set, turn on modulation and adjust for 50% amplitude modulation with the internal one kHz source.

13.7.1.9 Check operation of the controller in the presence of this radiated field. Record the MFC indicated flow, flow standard output, and the frequency on the data sheet in Table 1.

13.7.1.10 Before changing frequency as described in Sections 13.7.1.10–13.7.1.15, reduce the voltage amplitude to zero.

13.7.1.11 Set frequency to 20 kHz and repeat Sections 13.7.1.6–13.7.1.9.

13.7.1.12 Set frequency to 50 kHz and repeat Sections 13.7.1.6–13.7.1.9.

13.7.1.13 Set frequency to 100 kHz and repeat Sections 13.7.1.6–13.7.1.9.

13.7.1.14 Set frequency to 200 kHz and repeat Sections 13.7.1.6–13.7.1.9.

13.7.1.15 Set frequency to 500 kHz and repeat Sections 13.7.1.6–13.7.1.9.

13.7.1.16 Set frequency to one MHz and repeat Sections 13.7.1.6–13.7.1.9.

13.7.1.17 Shut down the test equipment. Then remove the audio amplifier and install RF power amplifier #1 in its place.

13.7.1.18 Having exceeded one MHz, turn antenna switch to the high frequency range.

13.7.1.19 Turn on test equipment and resume testing.

13.7.1.20 Set output of the signal generator to two MHz and set field strength to 10 V/m, using field strength meter at the controller location.

NOTE 4: If, at any frequency, the required field cannot be developed, set to the maximum possible without exceeding equipment ratings.

13.7.1.21 When voltage is set, turn on modulation and adjust for 50% amplitude modulation with the internal one kHz source.

13.7.1.22 Check operation of the controller in the presence of this radiated field. Record the MFC indicated flow, the flow standard output, and the frequency on the data sheet.

13.7.1.23 Before changing frequency as described in Sections 13.7.1.23–13.7.1.25 reduce the field amplitude to zero.

13.7.1.24 Set frequency to 5 MHz and repeat Sections 13.7.1.19–13.7.1.22.

13.7.1.25 Set frequency to 10 MHz and repeat Sections 13.7.1.19–13.7.1.22.

13.7.1.26 Set frequency to 20 MHz and repeat Sections 13.7.1.19–13.7.1.22.

13.7.1.27 After testing at fixed frequencies, sweep the signal source from 50 kHz to 20 MHz at an amplitude of about 35 V rms or 10 V/m. If a malfunction occurs during the sweep, stop and go back to that frequency range and try to find the malfunction by testing at single frequencies. Record the MFC indicated flow, the flow standard outputs, and the frequency. If the malfunction cannot be found by testing at single frequencies and only shows up when sweeping, the problem is probably that the signal source has to switch ranges at certain frequencies and during the switching can create strong transient noise. Only the results at single frequencies can be trusted; the sweep is only to locate the problems, not to completely define them.

13.7.1.28 Reduce signal source output to zero and de-energize test equipment.

13.7.1.29 Disconnect and remove parallel element antenna.

13.7.1.30 Testing from 30 MHz to 200 MHz:

13.7.1.31 Mount biconical antenna on the tripod. Test in a sequence similar to that in Sections 13.7.1.1–13.7.1.9.

13.7.1.32 Verify that RF power amplifier #1 is still in place.

13.7.1.33 At a minimum, test at the following frequencies: 30 MHz, 40 MHz, 50 MHz, 60 MHz, 70 MHz, 80 MHz, 90 MHz, 100 MHz, 120 MHz, 140 MHz, 160 MHz, 180 MHz, and 200 MHz.

13.7.1.34 At each frequency, set the field strength to 10 V/m using the field strength meter at the controller location with the antenna in both the vertical and the horizontal positions.

13.7.1.35 Check operation of the controller in the presence of the radiated fields generated. Record the MFC indicated flow, the flow standard outputs, and the frequency on the data sheet.

13.7.1.36 After testing at fixed frequencies, sweep the signal source from 30 MHz to 200 MHz. If a malfunction occurs during the sweep, stop and go back to the faulty frequency range and try to find the malfunction by testing at single frequencies. Record the MFC indicated flow, the flow standard outputs, and the frequency on the data sheet. If the malfunction cannot be found by testing at single frequencies and only shows up when sweeping, the problem is probably that the signal source has to switch ranges at certain frequencies and can create strong transient noise during the switching. Only the results at single frequencies can be trusted; the sweep is only to locate problems, not to completely define them.

13.7.1.37 Reduce signal source output to zero and de-energize test equipment.

13.7.2 Testing from 300 MHz to one GHz:

13.7.2.1 Mount the conical log spiral antenna on the tripod. Test in a sequence similar to that in Sections 13.7.1.1–13.7.1.9.

13.7.2.2 Verify that RF power amplifier #1 is still in place.

13.7.2.3 Test at the following frequencies, using RF power amplifier #1: 300 MHz and 400 MHz. Record the MFC indicated flow, flow standard outputs, and the frequency for each test point on the data sheet.

13.7.2.4 After completion of the test at 400 MHz, reduce amplitude of signal source to zero and shut down test equipment.

13.7.2.5 Disconnect RF power amplifier #1, install RF power amplifier #2, turn on equipment, and resume testing.

13.7.2.6 Test at the following frequencies using RF power amplifier #2: 500 MHz, 600 MHz, 700 MHz, 800 MHz, 900 MHz, and 990 MHz.

13.7.2.7 Check operation of the controller in the presence of the fields generated. Record the MFC indicated flow, the flow standard outputs, and the frequency for each test point on the data sheet.

13.7.2.8 After testing at fixed frequencies, sweep the signal source from 300 MHz to 990 MHz. If a malfunction occurs during the sweep, stop and go back to that frequency range and try to find the malfunction by testing at single frequencies. Record the MFC indicated flow, the flow standard outputs, and the frequency on the data sheet. If the malfunction cannot be found by testing at single frequencies and only shows up when sweeping, the problem is probably that the signal source has to switch ranges at certain frequencies and during the switching can create strong transient noise. Only the results at single frequencies can be trusted; the sweep is only to locate problems, not to completely define them.

13.7.2.9 Reduce signal source output to zero, de-energize test equipment, and disassemble test setup.

13.8 *Transient Susceptibility of Power and Control Leads (CS-06) (Conducted Susceptibility)*

NOTE 5: If any calibration is required during the performance of this procedure, such calibration shall be done in accordance with manufacturers' specifications.

13.8.1 *Spikes on DC Power Lines*

13.8.1.1 Verify that the test equipment and DC power are off before making connections for performing tests on DC-powered equipment.

13.8.1.2 Connect the parallel output of the spike generator between the binding posts as shown in Figure 4.

NOTE 6: The output from the spike generator must be from the *parallel output*. Otherwise, the DC power supply would be shorted by a low DC resistance.

13.8.1.3 The spike is injected across the DC power line to ground, not in series.

13.8.2 Spike on positive DC Lead:

13.8.2.1 Connect spike generator output between positive DC lead and ground and adjust spike generator output control for minimum amplitude.

13.8.2.2 Using the X100 probe, connect one channel on the scope to monitor the amplitude of the spike applied on the positive lead. Put the scope probe ground clip on the green wire safety ground, not on any of the spike generator output terminals.

13.8.2.3 Energize test equipment and observe polarity of low amplitude spikes to determine the polarity of the transient. Connection to the generator output should be such that positive spikes are applied on the positive lead. If the pulses are negative, reverse leads at the generator output.

13.8.2.4 Apply DC power.

13.8.2.5 With the scope synchronized to line voltage and the spike repetition rate set so that the spike will move slowly across the screen, increase spike amplitude to 100% of the voltage rating of the input power or MFC malfunction. Record the MFC indicated flow, the flow standard outputs, and the spike amplitude on the data sheet.

13.8.2.6 If the controller is not initially susceptible below the voltage rating and if the equipment is digital, hold the upper limit condition for five minutes. This condition need only be held momentarily if the controller is analog. Record the MFC indicated flow and flow standard outputs on the data sheet.

13.8.2.7 Reduce spike amplitude control, de-energize test equipment, and turn off DC power before switching spike polarity.

13.8.2.8 Reverse leads at the spike generator output to apply negative spikes to the controller.

13.8.2.9 Energize test equipment.

13.8.2.10 Repeat Sections 13.8.2.4 through 13.8.2.6 with the negative voltage spikes applied to the positive lead. Then go on to Section 13.8.2.11.

13.8.2.11 Reduce spike amplitude to zero, de-energize test equipment, and turn off DC power.

13.8.3 Spike on negative DC Lead:

13.8.3.1 Connect spike generator output between negative DC lead and ground and adjust spike generator output control for minimum amplitude.

13.8.3.2 Using the X100 probe, connect one channel of the scope to the negative lead in order to monitor the amplitude of the spike applied on the negative lead. Put the scope probe ground clip on the green wire safety ground, not on any of the spike generator output terminals.

13.8.3.3 Energize test equipment and observe polarity of low amplitude spikes to determine the polarity of the transient. Connection to the generator output should be such that positive spikes are applied on the negative lead. If pulses are negative, reverse leads at generator output.

13.8.3.4 Repeat Sections 13.8.2.4 through 13.8.2.6 with the positive voltage spikes applied to the negative lead. Then go on to Section 13.8.3.5.

13.8.3.5 Reduce spike amplitude control, de-energize test equipment, and turn off DC power before switching spike polarity.

13.8.3.6 Reverse leads at the spike generator output to apply negative spikes to the controller.

13.8.3.7 Energize test equipment.

13.8.3.8 Repeat Sections 13.8.2.4 through 13.8.2.6 with the negative voltage spikes applied to the negative lead. Then go on to Section 13.8.3.9.

13.8.3.9 Reduce spike amplitude to zero, de-energize test equipment, turn off the DC power, and disconnect equipment from test setup patch panel.

13.8.4 Spike on control (setpoint) signal lead:

13.8.4.1 Connect spike generator output between control signal lead and ground and adjust spike generator output control for minimum amplitude.

13.8.4.2 Using the X100 probe, connect one channel on the scope to monitor the amplitude of the spike applied on the setpoint lead. Put the scope probe ground clip on the green wire safety ground, not on any of the spike generator output terminals.

13.8.4.3 Energize test equipment and observe polarity of low amplitude spikes to determine the polarity of the transient. Connection to the generator output should be such that positive spikes are applied on the setpoint lead. If pulses are negative, reverse leads at generator output.

13.8.4.4 Apply the maximum DC control signal level.

13.8.4.5 Repeat Sections 13.8.2.5 and 13.8.2.6 with the positive voltage spikes applied to the setpoint lead. Then go on to Section 13.8.4.6.

13.8.4.6 Reduce spike amplitude control, de-energize test equipment, and turn off DC power before switching spike polarity.

13.8.4.7 Reverse leads at the spike generator output to apply negative spikes to the controller.

13.8.4.8 Energize test equipment.

13.8.4.9 Apply the maximum DC control signal level.

13.8.4.10 Repeat Sections 13.8.2.5 and 13.8.2.6 with negative voltage spike applied to the setpoint lead.

13.8.4.11 Reduce spike amplitude to zero, de-energize test equipment, turn off the DC power, and disconnect equipment from test setup patch panel.

14 Calculations or Interpretation of Results

14.1 *Calculations*

NOTE 7: Use the data sheet (see Table 1) to record the test data. Then record the calculated values at each data point in Table 2.

14.1.1 Convert MFC indicated flow output data (v) and the flow standard output data to percent of full-scale flow as follows:

MFC Indicated Flow:

Percent of Full-Scale Flow =

$$\frac{\text{Output Data (v)} \times 100}{\text{Full Scale output (v)}}$$

14.1.2 Record on data sheet for each measurement point.

14.1.3 Flow Standard (actual flow)

14.1.3.1 Follow the manufacturer's recommendations for the flow standard output conversion to percent of full scale.

14.1.4 Record on data sheet for each measurement point.

14.1.5 Calculate the zero-corrected percent of full-scale values for both the MFC indicated flow and the flow standard output as follows:

MFC Indicated Flow or Standard Flow = MFC or Flow Standard Value (%FS) at a Data Point – MFC or Flow Standard Value (%FS) at the Zero Flow

14.1.6 Record these values at each data point in Table 2.

14.1.7 Calculate the change in flow for the MFC and flow standard as follows:

Change in Flow (%FS) = MFC Standard Value (%FS) Corrected for Zero – MFC or Flow Standard Value (%FS) Corrected for Zero at Reference Conditions

14.1.7.1 Where reference conditions are defined by 50% FS flow with the EMI source at zero field strength.

14.1.8 Record these values in Table 2.

14.2 *Interpretation of Results*

14.2.1 The changes in flow columns in Table 2 give an indication of the effect of EM susceptibility, both radiated and conducted. If the effect is larger than can be tolerated for the process in the fab, two steps may be necessary. EM field strength and frequency measurements should be made at the fab under normal operating conditions. If EM measurements in the fab match areas that cause unacceptable effects on the MFC, shielding may be necessary to reduce the effect. Shielding design is beyond the scope of this test method.

SEMI F54-1000
TEST METHOD FOR MEASURING THE COUNTING EFFICIENCY OF CONDENSATION NUCLEUS COUNTERS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on July 13, 2000. Initially available on SEMI OnLine August 2000; to be published October 2000. Previously published June 2000.

1 Purpose

1.1 Particle specifications for gases require the use of condensation nucleus counters (CNCs) having specified counting efficiencies. This document provides the test method for determining the counting efficiencies of CNCs.

2 Scope

2.1 This document provides the method for 1) generating an aerosol standard consisting of sodium chloride (NaCl) particles having sizes 0.01 micrometer and larger suspended in air at atmospheric pressure (1×10^5 Pa), 2) controlling the size and concentration of particles in the aerosol, and 3) using the aerosol to determine the counting efficiency of a CNC as a function of particle size. This method is suitable for CNCs having a lower size sensitivity of 0.01 micrometer or larger.

NOTE 1: Suitable test methods for calibrating optical particle counters are contained in ASTM F328 and JIS B 9921.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document does not provide the method for adjusting the CNC's counting efficiency.

3.2 This document does not provide the method for determining the CNC's background noise level, maximum concentration limit, or maximum detectable particle size.

4 Referenced Standards

4.1 *ASTM standards*[1]

ASTM D1193 — Standard Specification for Reagent Water

ASTM F328 — Standard Practice for Calibration of an Airborne Particle Counter Using Monodisperse Spherical Particles

4.2 *JIS standard*[2]

JIS B 9921 — Japanese Industrial Standard, Light Scattering Automatic Particle Counter

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *aerosol electrometer* — an instrument that converts the charge flow in an aerosol stream to an electrical current signal.

5.2 *aerosol standard* — an aerosol containing particles of a known size and concentration.

5.3 *coincidence error* — the inaccuracy in a measured particle concentration caused by multiple particles in the optical sensing volume of an instrument.

5.4 *concentration limit* — the maximum concentration of particles in an aerosol to avoid a coincidence error of 10% or greater in an instrument.

5.5 *counting efficiency* — the ratio of the concentration of particles reported by the CNC to that reported simultaneously from the same aerosol by a reference instrument.

5.6 *lower size sensitivity* — the particle size corresponding to 50% counting efficiency for the CNC.

5.7 *monodisperse aerosol* — *a*n aerosol having a narrow distribution of particle sizes. The maximum band width of a monodisperse aerosol is defined in Section 8.7.

5.8 *particle concentration* — the number of particles per unit volume in a gas.

5.9 *polydisperse aerosol* — an aerosol having a wide distribution of particle sizes.

NOTE 3: Additional terminology is contained in ASTM F328 and JIS B 9921.

1 American Society of Testing and Materials, 1916 Race Street, Philadelphia, PA 19103, USA

2 Japanese Standards Association, 1-24, Akasaka 4-chome, Minato-ku, Tokyo 107, Japan

6 Summary of Method

6.1 The measurement is performed using aerosol standards consisting of NaCl particles suspended in air. Aerosols are produced by nebulizing a solution of NaCl in water. After drying and charge neutralization, particles of the required size are extracted from the aerosol using an electrostatic classifier (EC). The concentration of particles in the resulting monodisperse aerosol is then recorded by the CNC and compared to that measured simultaneously by a reference instrument. Examples of suitable reference instruments are described in Section 8.8.

NOTE 4: This method has been shown to provide repeatable results in tests performed in separate laboratories on similar CNCs. Examples of these tests are found in Agarwal and Sem[3] and Bartz, et al[4].

7 Requirements

7.1 The reference instrument must have a proven counting efficiency of not less than 95% over the entire range of particle sizes tested. Low counting efficiency in the reference instrument results in an error in the measured particle concentration. The counting efficiency for the reference instrument must be checked by the manufacturer against a calibrated standard, such as a calibrated aerosol electrometer.

7.2 Coincidence error in either the CNC or the reference instrument causes inaccuracy in the measured particle concentration. The concentration limit for each instrument must be obtained from the manufacturer's specifications. The particle concentration in the aerosol standard must be kept below both concentration limits.

7.3 When an aerosol electrometer is used as the reference instrument, the minimum detectable particle concentration must be obtained from the manufacturer's specifications. A particle concentration below the minimum detectable value will cause inaccurate results. The particle concentration in the aerosol standard must be kept above the minimum detectable particle concentration.

7.4 The transport loss of particles from the EC to the CNC, and from the EC to the reference instrument must be checked. Any disparity in particle transport loss to the two instruments will cause erroneous results. The method for calculating the transport loss of particles in sample lines is found in Pui, et al[5]. The transport loss must be calculated for each particle size tested. Record all transport loss calculations.

7.5 When an aerosol electrometer is used as the reference instrument, a correction must be made for multiple charging of particles in the aerosol standard. Multiple charging can cause substantial error when measuring particles larger than 0.06 micrometer. The correction factor for multiple charging must be obtained from the manufacturer of the EC. An example of the method for calculating the correction factor is found in Liu and Pui[6].

8 Apparatus

8.1 *Atomizer* — A sub-micrometer aerosol generator capable of nebulizing a liquid solution. The atomizer must be capable of producing a stable aerosol containing particles as small as 0.01 micrometer after drying.

8.2 *Liquid Trap* — A device which allows free passage of an aerosol stream containing sub-micrometer particles, but which removes the entrained liquid phase by gravitational settling into a reservoir.

8.3 *Diffusion Drier* — A device which allows free passage of an aerosol stream containing sub-micrometer particles, but which dries the aerosol by diffusion of water vapor into a surrounding desiccant medium. The design flow rate of the diffusion drier must at least match the output flow rate of the atomizer.

8.4 *Aerosol Neutralizer* — A bipolar charging device which neutralizes aerosols by producing both positive and negative air ions. The neutralizer must reduce the charge on the particles to the Boltzmann equilibrium level. The design flow rate of the neutralizer must at least match the output flow rate of the atomizer.

8.5 *Bypass Filter* — A high efficiency point of use gas filter. The design flow rate of the bypass filter must at least match the output flow rate of the atomizer.

8.6 *Mixing Vessel* — A device which disperses particles in a flowing aerosol by inducing turbulence.

8.7 *Electrostatic Classifier* (EC) — A device which extracts particles from a polydisperse aerosol according to their electrical mobility. The electrical mobility of a particle depends upon its size and charge. The EC must extract a monodisperse aerosol standard having a

narrow band width. The mobility band width of the extracted aerosol must be no greater than 20% of the mean particle mobility. The method for calculating electrical mobility and mobility band width are found in Liu and Pui[6].

8.8 *Reference Instrument* — An instrument which can measure the concentration of particles in an aerosol. The calibration of the reference instrument must have been checked against a calibrated standard within the past 12 months. Calibration and maintenance records for the reference instrument must be maintained. Suitable reference instruments include aerosol electrometers and CNCs having lower size sensitivities below 0.01 micrometer.

8.9 *Condensation Nucleus Counter (CNC) or Condensation Particle Counter (CPC)* — The particle counter to be used in process gas particle measurements, and for which the calibration check is required. The CNC detects sub-micrometer particles using nucleation and droplet growth of a super-saturated working fluid.

8.10 *Tubing* — In order to minimize particle losses, all tubing used to transport charged aerosol particles must be constructed from electrically conductive materials (e.g., stainless steel) and grounded.

9 Reagents and Materials

9.1 De-ionized or distilled water in accordance with ASTM D1193, Type 1 is required to dissolve NaCl for aerosol generation.

9.2 NaCl is required for aerosol generation.

9.3 A supply of dry, oil-free compressed air is required to generate and transport aerosols in the apparatus.

10 Preparation of Apparatus

10.1 The test apparatus is shown in Figure 1. The particle concentration in the aerosol is controlled using a bypass filter. If the flow rate of the monodisperse aerosol from the EC is insufficient to supply the CNC and reference instrument simultaneously, filtered air must be added to the stream. The air must be added to the aerosol upstream of a mixing vessel. If the flow rate of the monodisperse aerosol from the EC is greater than that required to supply the CNC and reference instrument simultaneously, the excess aerosol must be vented.

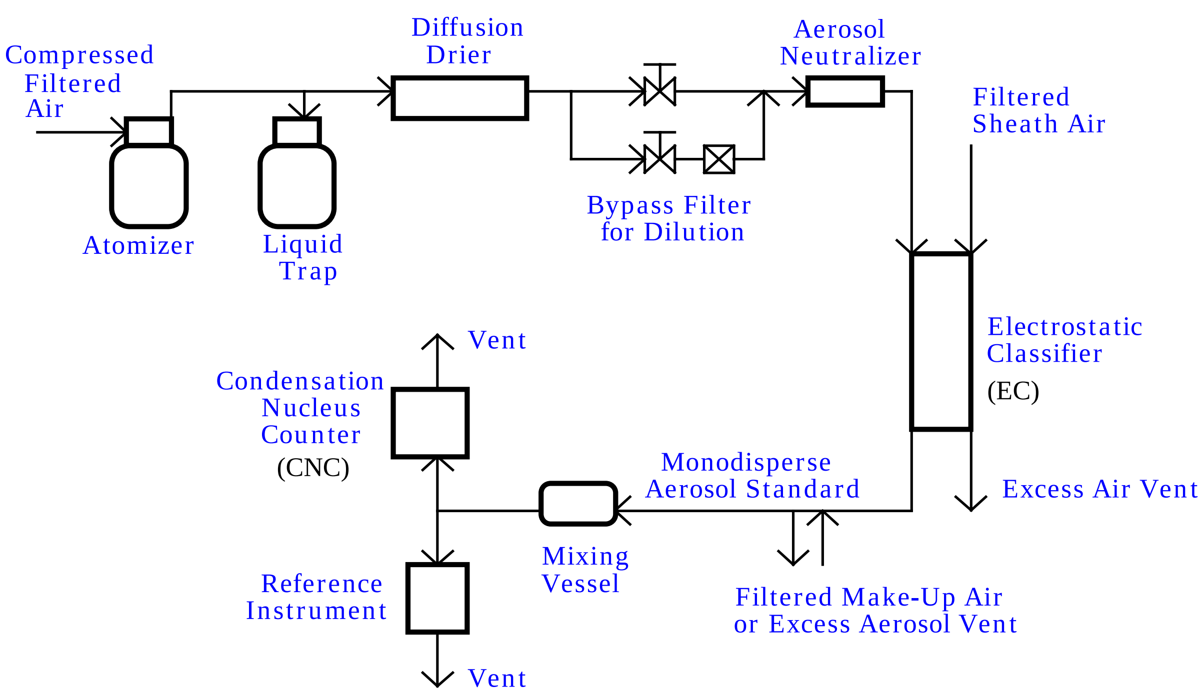

Figure 1
Schematic Diagram of Test Apparatus

11 Calibration and Standardization

11.1 All flow meters and voltage indicators used in the apparatus, including instruments incorporated into the EC and particle counters, must have been checked for proper calibration against calibrated standards within the past 12 months. Record all calibration data.

12 Procedure

12.1 Fill the atomizer reservoir with a solution of NaCl in water. The required NaCl concentration depends upon the range of particle sizes to be tested, and must be determined from the atomizer manufacturer's specifications. Record the concentration of NaCl in the solution.

12.2 Determine the required aerosol, sheath air and excess air flow rates for the EC. The flow rates depend upon the range of particle sizes to be tested and the required mobility bandwidth, and must be determined from the EC manufacturer's specifications.

12.3 Close the bypass filter valve. Adjust the flow rates of the atomizer, CNC, and reference instrument to their manufacturer's specified values. Adjust the flow rates of the EC to their required values as described in Section 12.2. Adjust the flow rate of the make-up air or aerosol vent to the required value as described in Section 10.

12.4 Set the EC voltage to obtain the selected particle size for testing. Record the voltage setting and the selected particle size.

12.5 Observe the particle concentration indicated by the reference instrument. If the particle concentration exceeds the concentration limit of the reference instrument or the CNC, adjust the flow rate through the bypass filter to lower the aerosol particle concentration. After adjusting the bypass flow rate, check all flow rates to ensure that they remain at the required values. Record all flow rates.

12.6 Wait for the particle concentrations indicated by the CNC and reference instrument to become steady; the concentrations indicated by each instrument must not change by more than 5% over a five minute interval. In order to minimize the error in the recorded particle concentrations, a minimum of 500 particles must be counted in a sample. Record the steady particle concentrations indicated by the CNC and reference instrument.

12.7 If another particle size is to be tested, return to Section 12.4.

NOTE 5: At least eight different particle sizes must be tested. The particle sizes must be selected such that the measured CNC counting efficiency at least spans the range 50% to 95% (0.50 to 0.95). In order to eliminate systematic error, the particles sizes must be tested in random order.

13 Calculation and Interpretation of Results

13.1 When an aerosol electrometer is used as the reference instrument, correct the measured particle concentrations for multiple charging, as described in Section 7.5.

13.2 For each particle size tested, calculate the ratio of the concentration of particles reported by the CNC to that reported by the reference instrument. This ratio represents the counting efficiency of the CNC.

13.3 Plot the calculated counting efficiency against the particle size as shown in Figure 2. This plot shows the measured counting efficiency curve of the CNC.

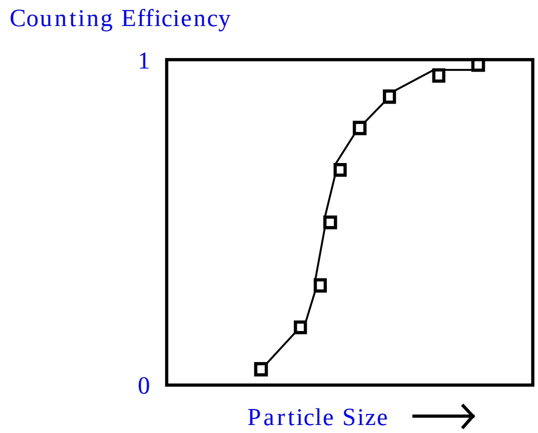

Figure 2
Schematic Plot of Measured Counting Efficiency

13.4 Determine the lower size sensitivity of the CNC, as defined in Section 5. (The counting efficiency at any particle size can be estimated using linear interpolation between the data points.)

14 Reporting Results

14.1 The test record must include the following items:

a. test date;

b. test operator;

c. serial numbers of the reference instrument, CNC and EC;

d. all particle transport loss calculations as described in Section 7.4;

e. all flow meter and voltage indicator calibration data as described in Section 11;

f. all raw data and calculations utilized in the test method as listed in Sections 12 and 13;

g. counting efficiency of the CNC as a function of particle size; and

h. the lower size sensitivity of the CNC.

Appendix 1 contains an example report form.

15 Precision and Accuracy

15.1 This method requires a minimum of 500 particles counted in a sample. For Poisson distributed data, the relative standard deviation of the measured particle concentration is less than 5% when at least 500 particles are counted in a sample.

The determination of the suitability of the test method is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These test methods are subject to change without notice.

The user's attention is called to the possibility that compliance with this test method may require use of copyrighted material or of an invention covered by patent rights. By publication of this test method, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this test method. Users of this test method are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F55-0600
TEST METHOD FOR DETERMINING THE CORROSION RESISTANCE OF MASS FLOW CONTROLLERS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on April 10, 2000. Initially available on www.semi.org May 2000; to be published June 2000.

1 Purpose

1.1 A mass flow controller (MFC) is often used to control corrosive gases under unfavorable conditions. This test method is intended to help differentiate between MFC designs on the basis of relative resistance to corrosion-induced failure.

2 Scope

2.1 This test is intended to show the effect of corrosion caused when a corrosive gas such as HCl is contaminated by an oxidizer such as atmospheric moisture. For the purpose of this test HCl is the preferred test gas, however this test can also be performed with other gasses. This test method describes a corrosive gas exposure test for mass flow controllers. The test is intended to accelerate the corrosion while simulating conditions that may be found within process equipment and gas systems in the semiconductor industry. As the relationship between corrosion and performance may differ with MFC design, corrosion is not measured directly. The effects of corrosion are detected by observing changes in MFC calibration and other operating parameters.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This test method should not be expected to yield comparable quantitative results from one test facility to another.

3.2 Results may be compromised by the methods used to construct the apparatus.

3.3 This test is designed to be a destructive test. The MFC tested will be destroyed. This test is intended only for MFCs manufactured for use in HCl or a similar highly corrosive gaseous environment. MFCs manufactured for non-corrosive service may develop leaks or other catastrophic failures if tested by this method. For practical reasons in constructing and operating the test bed, test samples may be limited to 100 sccm N_2 equivalent full scale (FS) flow.

3.4 This method does not measure corrosion directly by analyzing or inspecting the gas-wetted surfaces following exposure to a corrosive. No attempt is made to detect particles in the exit gas stream resulting from the corrosion process.

SEMI F1 — Specification for Leak Integrity of High-Purity Gas Piping Systems and Components

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *DUT* — device under test

5.1.2 *FS* — full scale

5.1.3 *kPa* — kiloPascal

5.1.4 *MFC* — mass flow controller

5.1.5 *MFM* — mass flow meter

5.1.6 *ppbv* — parts per billion by volume

5.1.7 *ppmv* — parts per million by volume

5.1.8 *sccm* — standard cubic centimeters per minute using a standard temperature of 0° C and a standard pressure of 101.32 kPa.

5.2 *Definitions*

5.2.1 *actual flow* — for the purpose of this standard, the output value of the reference flowmeter.

5.2.2 *ambient temperature* — the temperature of the medium surrounding the device. Under ordinary laboratory benchtop conditions, ambient temperature is the temperature of the room.

5.2.3 *indicated flow* — the electrical output of the device under test (DUT).

5.2.4 *valve drive* — electrical output from the DUT which is analogous to the level of power supplied to the control valve. This output is sometimes called valve voltage.

6 Summary of Method

6.1 Corrosive gas and moisture-containing N_2 are alternately flowed through the DUT with intervening dry N_2 purges. The test MFC is monitored over time for changes in performance resulting from corrosion.

6.2 This test is intended to be an accelerated simulation of the effects of alternating corrosive and moisture-exposure conditions. The test records how long it takes for corrosion to affect calibration. MFCs that are more resistant to corrosion failures should last longer under the test conditions. A dry N_2 purge separates each MFC's exposure to the corrosive gas and to the moisture-containing gas. This purging favors MFC designs that perform well in corrosive service because those MFCs can be dried out quickly with limited purging.

6.3 This method is expected to yield data that can be used to compare the relative performance of components tested for the purpose of qualification.

7 Interference's

7.1 Portions of the gas system exposed to HCl may require replacement or cleaning and refurbishment between test sequences to avoid invalidating subsequent tests by prematurely contaminating DUTs. Take care in the design and maintenance of the system so that particles shed from upstream piping components as a byproduct of corrosion are minimized so that they do not affect the DUT.

8 Apparatus

8.1 *Containment System* — to contain corrosive gas leaks that may develop in the DUT or gas system. The portion of the system that contains the corrosive gas should be operated in a suitable secondary containment environment.

8.2 *Power Supply*, *Controls*, and *Data Collection Devices* — capable of recording data 20 times per second. Signals should be measured with a resolution of one mV or better. Data may be recorded in convenient units such as volts, sccm, or percent of FS. For the purpose of analysis and reporting, data should be converted to percent of FS except for valve drive, which may be reported in either percent of maximum drive or volts.

8.3 *DUT*

8.4 *Data Acquisition System* — Recommended as a data collection system to facilitate test sequencing and data collection.

8.5 *Plumbing* — with tubing and gas-switching valves constructed from 316L electropolished stainless steel or other material that exhibits superior corrosion resistance compared to 316L. The use of materials such as plastics, which retain or are permeable to water vapor, are not appropriate. All-metal sealed valves (no elastomers) are readily available and must be used.

8.6 The test plumbing is intended to represent the technology level found in the semiconductor process gas piping in which a typical DUT will operate.

8.7 A filter has not been specified immediately upstream of the DUT because it would harbor contaminates and make it difficult to alternate gas types.

8.8 *Dry N_2 Source* — pressure regulated source with a moisture level no greater than 50 ppbv.

8.9 *Dry HCl Source* — pressure regulated source with a moisture level no greater than 500 ppbv.

8.10 *Reference Flowmeter* — traceable with calibration certificate, calibrated for N_2, FS flow 100% to 125% of the FS N_2 equivalent flow range of the DUT Accuracy better than 5%, linear to 0.5% FS repeatable to 0.15% over a three-hour period, and reproducible to 0.3% of the test flow for the duration of the test .

NOTE 2: As this test is concerned with changes in DUT calibration and not the value of DUT calibration itself, the accuracy of the reference flowmeter is not paramount.

8.11 *Moisture Generator* — to introduce water vapor in a concentration of 100 ppmv (μl/l) ± 20% in N_2.

8.12 *Moisture Analyzer* — to periodically verify the output of moisture generator.

9 Reagents and Materials

9.1 *HCl*

9.2 *N_2*

10 Safety Precautions

10.1 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.

NOTE 3: The DUT will be contaminated with corrosive material at the conclusion of this test. Caution should be exercised in handling. A contaminated DUT should be properly decontaminated.

10.2 Become familiar with the safe handling practices associated with the corrosive gas before undertaking this test.

11 Preparation of Apparatus

11.1 The test apparatus is the source of three gases—dry N_2, dry HCl, and N_2 containing a known level of water vapor. Each gas can be valved through the DUT individually with minimal cross contamination. The DUT actively controls the gas flow in each case. The gas then flows into either a scrubbed exhaust system for safe disposal or a reclamation system. A reference flowmeter in the dry N_2 supply line is used to detect changes in calibration of the DUT when dry N_2 is flowing in series through both devices.

11.2 *Setup and Schematic* — See Figure 1 for a schematic of the test apparatus. This schematic may not show in detail all the components required in an actual system.

11.3 Supply the manufacturer's recommended power to the DUT. Provide MFC setpoint and purge command (if available). Monitor the following:

11.3.1 DUT setpoint input.

11.3.2 DUT indicated flow output.

11.3.3 DUT valve drive output (if available)

11.3.4 actual flow (output of reference flowmeter)

11.4 Verify that the proper moisture levels exist in each of the test gases.

11.5 Provide a purge flow loop that maintains a constant flow of dry N_2 in the line from the DUT to the exhaust system. Flow in this loop must be sufficient to prevent back diffusion into the DUT of moisture generated in the exhaust system, particularly when flow into the DUT is shut off for measuring zero.

11.6 If the moisture generator is supplied from the same N_2 source that supplies the dry N_2, take precautions to avoid the diffusion of moisture from the moisture generator into the dry N_2 line. Such precautions may include the use of separate pressure regulators and other valving.

11.7 Moisture generators typically take time to stabilize. A continuous flow should be maintained through the moisture generator during the test to maintain a stable moisture flow. This may require diverting the output flow to a vent when not flowing through the DUT.

11.8 Periodically verify the moisture concentration of wet N_2 with a suitable moisture analyzer.

11.9 Follow manufacturer set-up procedures for all equipment.

11.10 Conduct the test at an ambient temperature of 22 ± 2°C.

11.11 The DUT moisture generator, flowmeters, and other instrumentation should have been stabilized at room temperature for 24 hours before beginning the tests. It is not necessary to flow gas during this stabilization time.

11.12 All portions of the plumbing system that could contain HCl must be helium leak tested per SEMI F1 before introducing HCl into the system. When changing the DUT or other components, at least those portions of the system that were changed must be re-tested.

NOTE 4: Small leaks in a corrosive gas system can become much larger without warning.

12 Calibration and Standardization

12.1 Calibrate all instrumentation using current standards that are traceable to an appropriate standards laboratory. In the absence of appropriate standards, use manufacturer recommendations for calibration.

13 Procedure

NOTE 5: Refer to Figure 2 for a flowchart of the following test.

13.1 Set the pressure of each of the HCl and Dry N_2 gas sources at 140 kPa ± 5%. Set the pressure of the N2 to the moisture generator to the appropriate value recommended by the manufacturer. If the test must be run at some other pressure, because of a limitation of the DUT, report this fact in the test results.

13.2 Start the wet N_2 flow to vent or through the moisture analyzer. Establish a stable moisture concentration at 100 ppmv ± 20% before beginning the test sequence. Set the wet N_2 to flow within ± 5% of the DUT flow that will be run during the test.

13.3 Place the DUT control valve in the purge or fully open position by supplying a purge command or a 200% setpoint. Purge with dry N_2 at a rate of one to two times FS flow for one hour to establish initial conditions. The purge rate is controlled by adjusting the supply pressure and is monitored by a purge-rate flowmeter located in the gas-supply path. Follow the manufacturer's procedure for fully opening the DUT control valve.

13.4 Provide a setpoint to the DUT for 80 ± 5% of FS flow.

13.5 Determining the Test Baseline and Measurement Repeatability.

NOTE 6: Data throughout this test may be recorded in a format similar to that found in Table A1.1.

13.6 Open valve V1 and flow dry N_2 at a setpoint of 80% ± 5% of the DUT FS and wait 10 minutes.

13.7 Record:

13.7.1 DUT setpoint

13.7.2 DUT indicated flow

13.7.3 DUT valve drive output (if available)

13.7.4 Actual flow

13.8 Stop flow by closing V1. Drive the MFC control valve to a closed position by providing a zero setpoint or as otherwise provided by the manufacturer. Allow the MFC indicated flow output to stabilize for a minimum of three minutes.

13.9 Record the DUT indicated flow and the actual flow during the zero flow condition.

13.10 Repeat Sections 13.6 through 13.9 twelve times. This will yield 12 data points for each of the six measured parameters.

13.11 For each of the six parameters recorded, perform the following calculation on the 12 baseline data points to determine the repeatability of the measurement:

$$\frac{(\text{highest value - lowest value})}{\text{average of the 12 values}} \times 100$$

13.12 If each of the six parameters is not repeatable within 0.2% during these two hours, subsequent test data may not be valid and the problem should be resolved before proceeding with the test.

13.13 Baseline

NOTE 7: Use the averaged value of the measurements made in Section 13.13 for each parameter as the baseline for that parameter in the following tests.

13.14 *Test Sequence* — Without changing the DUT setpoint, repeat the test sequence in Sections 13.19-13.22 every 30 minutes, continuously, 24 hours per day, seven days per week until one of the following test termination conditions is met.

13.15 The test should not be interrupted because the DUT may continue to corrode during the interruption, making test results non-repeatable. The output of the moisture generator should be measured periodically during the test sequence to ensure that it remains within the test specifications.

13.16 Terminate the test sequence if:

13.16.1 The DUT fails to function

13.16.2 The actual-flow shift from baseline exceeds 25%

13.16.3 The valve drive exceeds the manufacturer's limits

13.16.4 The DUT indicated flow differs from commanded setpoint by > 5%

13.16.5 The test exceeds 5000 cycles

13.17 Flow dry N_2 for five minutes. After five minutes, record data on the six test parameters as done in Section 13.7, interrupting flow to record the DUT indicated flow and reference flowmeter output at zero flow. After taking measurements, flow dry N_2 again so that the total length of this step is 10 minutes. Record data as shown in Figure 3.

13.18 Flow dry HCl for seven minutes.

13.19 Repeat Section 13.19 and then proceed to Section 13.22.

13.20 Flow wet N_2 for three minutes. If no test termination condition is met as described in Section 13.18, repeat Sections 13.19 - 13.22. If a test termination condition is met, proceed to Section 13.23.

13.21 After the test has been completed, place the DUT control valve in the purge or fully open position. Purge with dry N_2 for one hour or at least 50 volume changes. Cycle the purge gas for 15 seconds on and 15 seconds off by opening and closing V1 for the duration of the purge. Follow the manufacturer's procedure for fully opening the DUT control valve.

NOTE 8: Verify purge flow with the reference flowmeter or by using other means. Corrosion may have rendered the control valve inoperable. An alternate approach for purging any corrosive material from the system may have to be followed.

13.22 Alternate Approach to Purging.

13.23 If gas cannot be purged through the DUT, cycle-purge each end of the DUT separately using Sections 13.26 through 13.28.

13.24 With valves V2 and V3 closed for the duration of the procedure, close valve V6 and pressurize both sides of the system by opening V1 and V7 for 15 seconds.

13.25 Vent pressure through the exhaust system by closing V1 and opening V6 for 15 seconds.

13.26 Repeat pressure and vent cycles for a minimum of one hour.

13.27 Remove the DUT. Preserve the test system, if desired, by taking steps to exclude atmospheric moisture. Such steps could include capping the system and shutting all valves. Alternately, the DUT may be replaced with a spool piece. The system can then be continuously purged with dry N_2.

NOTE 9: The DUT will be contaminated with corrosive material. See *Precautions* in Section 10. Preserve the DUT for failure analysis, if desired.

14 Calculations or Interpretation of Results

14.1 Report data in a tabular format and graph per Appendix 1. Any parameter which changes more than 1% from its baseline should also be graphed. Note the reason the test was terminated. Test results may be summarized in a single parameter by reporting the number of test cycles to reach a 2% shift in actual flow or to reach DUT failure, whichever occurs first. In this test, more data is reported than is required to calculate the gross test result. The extra data is used when analyzing test results to determine the cause of failure. Further explanation of the significance of the data is beyond the scope of this test method.

15 Data Analysis.

15.1 Calculate any parameter-shift in percent as follows:

$$\frac{\text{(baseline value - current value)}}{\text{baseline value}} \times 100$$

16 Reporting Results

16.1 Report the number of test cycles to reach a 2% shift in actual flow or to reach DUT failure, whichever occurs first.

17 Precision and Accuracy

17.1 This method is limited in its precision by the calibration of the measurement devices, the temperature of the apparatus, and the concentration of water vapor in N_2. Sources of bias are unknown at this time, but they probably include peculiarities in the construction of the apparatus.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI F56-0600
TEST METHOD FOR DETERMINING STEADY-STATE SUPPLY VOLTAGE EFFECTS FOR MASS FLOW CONTROLLERS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on April 10, 2000. Initially available on www.semi.org May 2000; to be published June 2000.

1 Purpose

1.1 The purpose of this document is to define a method for characterizing mass flow controllers (MFCs) being considered for installation into a high-purity gas distribution system. This method will quantify the steady-state supply voltage effects on the MFC's ability to accurately deliver set point flow values.

2 Scope

2.1 This procedure applies to thermal mass flow controllers. It is intended to measure the delivered mass flow rate variation as a function of deviation from the reference steady-state supply voltage. The test method is designed for DC-powered MFCs. The supply voltage effects include voltage depression and over-voltage variations in the DC supply.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This test method is not designed for AC-powered MFCs. This test method addresses steady-state effects and does not address any effects caused by transient power supply behavior.

4 Referenced Standards

4.1 None.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *DUT* — device under test

5.1.2 *MFC* — mass flow controller

5.1.3 *NIST* — National Institute of Standards and Technology

5.1.4 *psia* — pounds per square inch absolute

5.1.5 *psig* — pounds per square inch gauge

5.2 *Definitions*

5.2.1 *actual flow* — flow value measured by the flow standard.

5.2.2 *indicated flow* — flow value derived from the MFC.

5.2.3 *Reference voltage(s)* — manufacturer's recommended power supply voltage(s).

5.2.4 *stable* — the state a signal level obtains when its magnitude varies by less than or equal to ±2.0% of full scale over a one-minute period.

6 Summary of Method

6.1 This test method consists of varying the steady-state supply voltage to an MFC in ±1% (of rated supply) increments from the reference voltage span. Both the positive and negative supply voltages will be varied independently and together in 1% increments. The MFC flow output is monitored at 0% and 100% of its operating range (see Table 1). At each incremental change as well as at the reference supply voltage, the MFC flow and flow standard outputs are recorded at 0% and 100% of its operating range. The test shall end when a ±3% of full-scale output flow change is noted between the flow at the reference voltage and at an incremental change point. A flow chart outlines the procedure (see Figure 1).

7 Interference's

7.1 Because of fluctuations in ambient temperature or a changing load on the power supply, the reference steady-state supply voltages may change. These changes in supply voltages may adversely effect the MFC's ability to deliver setpoint flow. The magnitude of this effect can be measured by this test method.

7.2 The user of an MFC can use the data generated by this method to evaluate the impact of steady-state supply voltage variations on the MFC's ability to deliver setpoint flow values. Knowing the magnitude of this effect and the power level variations, allows the user to decide on what measures to take to reduce this effect, if necessary.

8 Apparatus

8.1 The equipment and instrumentation required to complete this test method are shown in Figure 2.

8.2 *DC Power Supply*, to provide the required voltage to the MFC under test, with the capability to vary its output over the range of ±30 VDC at 500 mA, and with ripple less than 0.1% rms.

8.3 DC Power Supply Monitor/Recorder, placed in parallel with the DC power supply, and capable of measuring the DC voltage to within ±5 mV over the entire operating range of the supply.

8.4 Flow Output Monitor, connected to the MFC output and signal common/ground points. The monitor/recorder shall be capable of measuring over a range of 0–10 VDC to within ±5 mV.

8.5 *Flow Standard*, installed downstream and in series with the flow through the MFC. The flow standard shall be capable of measuring flow changes within ±0.3% of full scale.

8.6 *Current Meter*, connected in series in the power common line of the DC power supply, capable of measuring over a range of 0–200 mA to within ±1 mA.

9 Reagents and Materials

9.1 *Test Gas*, nitrogen

10 Safety Precautions

10.1 The user must know the respective instrumentation, practice proper handling of test components, and understand good laboratory practices.

10.2 The user should not exceed the ratings (such as pressure, temperature, flow, and voltage) of the components.

11 Preparation of Apparatus

11.1 *Setup and Schematic* — See Figures 2 and 3.

11.2 The test gas source and delivery system must be capable of satisfying the test volume flow rate at a constant pressure, ±0.1 psia.

11.3 The test gas source and delivery system must be capable of delivering a gas at ambient temperature ±2°C for the duration of each analysis. The ambient temperature shall be held to 22 ±1°C.

12 Calibration and Standardization

12.1 All instrumentation shall be calibrated with NIST traceable standards and shall be under current calibration.

13 Procedure

13.1 Install the MFC into the test setup per manufacturer's recommendations.

13.2 Apply power to all devices shown in Figure 2 per manufacturer's specifications. Allow the devices to warm up for the duration specified by the equipment manufacturer.

13.3 Set the DC power supply to the manufacturers recommended reference voltage. Verify the voltage magnitude using the power supply monitor.

13.4 Purge the system with nitrogen for a length of time equal to ten times the amount of time it takes to replace the system volume with the test MFC at its full-scale rated flow rate.

13.5 Close the inlet shut-off valve and then the outlet shut-off valve located adjacent to the MFC (see Figure 3). Adjust the MFC setpoint to zero flow. Follow the manufacturer's recommendations for adjusting the MFC zero. If the MFC has an auto-zero function, leave it active and note this fact on the data sheet in Table 1. Wait for the signals to become stable. Record on the data sheet (see Table 1) three separate readings of the MFC flow output, the power supply voltages, and the current of the power supply common.

13.6 Vary the positive DC power supply voltage in +1% steps from the reference value while holding the negative supply at its reference value.

NOTE 1: If reference voltage is +15 V, the first step is a change in voltage of +0.15 V.

13.7 After the monitored signals become stable, record the MFC zero value, the current value, and the power supply voltage magnitudes. Record the measurements at each step-change of power level on the data sheet. Continue to increase the positive supply voltage span until the MFC zero point changes by ±3% of full scale flow, the MFC zero output point remains unstable for five minutes, or the voltage level changes to +115% of original value.

13.8 Return the power supply level to the original reference value and repeat Section 13.5.

13.9 Repeat the procedure described in Section 13.6, with the following exception: Decrease the power supply span in 1% decrements until either the MFC zero changes by ±3% of full scale, the zero output point remains unstable for five minutes, or 85% of the original value is reached.

13.10 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 13.10.

13.11 Repeat Sections 13.6 through 13.9, with the following exception: Vary the negative DC power supply while holding the positive power supply at its reference value.

13.12 Vary both DC power supply voltages together in +1% steps from the reference value.

NOTE 2: If the reference voltages are ±15 V (30 V span), the first step is a change in voltage of ±0.15 V increasing the span to ±15.15 V (30.3 V span).

13.13 After the monitored signals become stable, record the MFC zero value, the current value, and the power supply voltage magnitudes. Record the measurements at each step change of power level on the data sheet. Continue to increase the supply voltage span until the MFC zero point changes by ±3% of full scale flow, the MFC zero output point remains unstable for five minutes, or the voltage level changes to +115% of original value.

13.14 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 13.13.

13.15 Repeat Section 13.11, with the following exception: Decrement the power supply voltages by 1% and go to Section 13.14.

13.16 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 13.15.

13.17 Open the inlet and outlet shut-off valves that are adjacent to the MFC (see Figure 3) and adjust the MFC set point to 100%. Insure that all reference conditions are within the specified tolerances. Once the output signals become stable, record the MFC output signal, the power supply voltage, the flow standard output, and the current value.

13.18 Vary the positive DC power supply voltage in +1% increments from the reference while holding the negative power supply at its reference value as described in Section 12.6. Record, on the data sheet, the measurements of MFC flow output, power supply voltage, flow standard output, and current meter signal after the values become stable. Continue to increase the voltage in 1% increments until the MFC or flow standard signal changes by ± 3% of full scale, or the MFC output signal remains unstable for five minutes, or the voltage level changes to +115% of original value.

13.19 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 13.18.

13.20 Open the inlet and outlet shut-off valves that are adjacent to the MFC and adjust the MFC setpoint to 100%. Repeat the procedure described in Section 12.16, but decrease the positive supply voltage in 1% decrements until either the flow signal changes by ±3% of full scale, the MFC output signal remains unstable for five minutes, or 85% of the original value is reached.

13.21 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 13.20.

13.22 Repeat Sections 13.15 through 13.19, with the following exception: Vary the negative DC supply voltage level while holding the positive power supply at its reference value and go to Section 13.21.

13.23 Repeat Section 13.15 and then go to Section 13.22.

13.24 Vary both DC power supply voltages together in +1% steps from the reference value.

NOTE 3: If the reference voltages are ± 15 V (30 V span), then the first step is a change in voltage of ±0.15 V increasing the span to ±15.15 V.

13.25 After the monitored signals become stable, record the MFC flow and flow standard values, the current value, and the power supply voltage magnitudes. Record three measurements at each step-change of power level on the data sheet. Continue to increase the supply voltage span until either the flow changes by ± 3% of full scale flow, the MFC zero output point remains unstable for five minutes, or the power level has been changed to +110% of span (±16.5 V).

13.26 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 13.24.

13.27 Open the inlet and outlet shut-off valves that are adjacent to the MFC and adjust the MFC setpoint to 100%. Repeat the procedure described in Section 13.22, with the following exception: Decrease the supply voltages together in 1% decrements until either the flow signal changes by ± 3% of full scale, the MFC output signal remains unstable for five minutes, or until the supply voltage span has changed ± 15% (± 12.75 V). Then go to Section 13.25.

13.28 Return the power supply level to the original reference value, repeat Section 13.5, and go to Section 14.

14 Calculations or Interpretation of Results

14.1 Convert the MFC indicated flow output data and the flow standard output data to percent of full scale flow as follows:

14.2 MFC Indicated Flow:

$$\%FullScaleFlow \cdots = \cdots \left(OutputData(v) \div FullScaleOutput \right) \times 100$$

where the output data is in Column B in data sheet. Record this result in Column G on the data sheet.

14.3 Flow Standard (actual flow):

14.3.1 Follow the manufacturer's recommendation for the flow standard output (Column C in data sheet) conversion to percent of full-scale flow. Record this result in Column H of the data sheet.

14.4 Calculate the average value of the three data-flow points at each power level setting for the MFC indicated flow (Column G) and the flow standard (Column H) in the data sheet. Record the averages in Columns I and J of the data sheet, respectively.

14.5 Determine the span by subtracting the zero value (Column G or H) at a particular power supply variation setting from the 100% flow value (Column G or H) at the same power variation setting. These span values for the MFC and the flow standard are to be recorded in Table 2.

$$Span = 100\% avg.(ColumnG \vdots or \vdots H) - 0\% avg.(ColumnG \vdots or \vdots H)$$
$$@the \vdots same \vdots power \vdots variation \vdots setting$$

14.6 Calculate the change in flow at a power supply level by subtracting the MFC indicated value (Column I) from the flow standard value (Column J). Record these results in Column K of the data sheet. Calculate the voltage variation from the reference voltage value as a percent change as follows:

$$\text{voltage change (VC)} = \frac{\text{voltage value - reference voltage}}{\text{reference voltage}} \times 100$$

Record this result in Column L and M of the data sheet for the positive and negative power supplies, respectively.

15 Reporting Results

15.1 Present the data as shown in Table 2 for both zero and span.

15.2 Present the data plots for the values in Table 2 as illustrated in Figure 4.

16 Precision and Accuracy

16.1 The precision and bias of this test method will be determined during validation.

SEMI F57-0301
PROVISIONAL SPECIFICATION FOR POLYMER COMPONENTS USED IN ULTRAPURE WATER AND LIQUID CHEMICAL DISTRIBUTION SYSTEMS

This specification was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on October 18, 2000. Initially available on www.semi.org November 2000; to be published March 2001. Originally published October 2000.

NOTE: This specification is considered provisional since it lacks a complete set of requirements for particles in Table 2 as well as particle test methods for components as noted in Table 1. At the time of publication, only a small database of values existed for PFA valves. Test methodologies will be generated for components and this document will be re-balloted at a later date.

1 Purpose

1.1 This document specifies minimum performance requirements for ultrahigh purity (UHP) polymer components used throughout semiconductor ultrapure water and liquid chemical distribution systems including bulk supply, facility distribution, and process equipment applications.

2 Scope

2.1 Polymer component purity and mechanical specifications are included in this standard along with references for qualification test methods. Certification, traceability, and packaging requirements are also included.

Purity Requirements:

- Particle Contribution
- Ionic Contamination
- Metallic Contamination
- Total Organic Carbon Contamination
- Surface Roughness

Mechanical Requirements:

- Temperature/Pressure Rating
- Chemical Resistance Rating
- Reliability

2.2 Polymer piping system components consisting of but not limited to the items shown in Table 1 are designed to contain and supply the following types of liquid chemicals:

- Acids, bases and oxidizers
- Aqueous salt solutions
- Ultrapure Water (UPW)

Table 1 Required Performance Specifications and Testing by Component Type

Test	*Particles*	*Ionic Contamination*	*Metallic Contamination*	*Total Organic Carbon*	*Surface Roughness*
Section	*7.2*	*7.3*	*7.4*	*7.5*	*7.6*
Table	*2*	*3*	*4*	*5*	*6*
Pipe/Tubing		x	x	x	x
Fittings		x	x	x	x
Valves	(See NOTE 1.)	x	x	x	x
Filter Housings		x	x	x	x
Pressure Transducers		x	x		x
Flow Meters		x	x		x
Gauge Guards		x	x		x
Regulators		x	x		x

NOTE 1: A method for this requirement is being developed. At the time of publication, only a small database of values existed for PFA valves. As the database encompasses more polymer materials, limits will be set for this parameter. Then, this document will be re-balloted.

2.3 Unless purchased separately, polymer components constructed of sub-pieces, such as o-rings, gaskets, and diaphragms, must meet the requirements of this document at the functional component level, not as individual sub-pieces. For example an o-ring in a union must not degrade the overall quality of the union such that it fails to meet the requirements of this document. Components and spare parts purchased separately, such as gaskets and O-rings, must meet this standard, if applicable.

2.4 This document and associated tests specify wetted stream performance requirements for polymer components in an as supplied, native state and reflect the current capabilities of the manufacturers of polymer components.

2.5 Leach out tests and associated requirements referenced within this document provide values from static, not dynamic, conditions. To determine the corresponding concentration that may result in a flowing dynamic stream, please see the Related Information Section on Theoretical Dynamic Concentration (TDC) located at the end of this document.

2.6 *Polymer Materials*

2.6.1 It is the intent of this specification to focus component qualification on performance. However, a discussion of recommended materials may benefit the reader and is therefore included.

2.6.2 Care must be taken to ensure that the materials are compatible with the liquid streams (as shown in Section 2.2) for long term applications. Additionally, it is important that the materials used be compatible with the application temperature and/or methods for bacterial reduction such as ozone, UV light and/or hydrogen peroxide.

2.6.3 The requirements of this specification often mandate the use of existing materials of choice, such as high purity grades of perfluoroalkoxy (PFA), polytetrafluoroethylene (PTFE), and polyvinylidene fluoride (PVDF). However, unique design specifications or new materials may result in instances where significant efficiencies may be achieved while maintaining substantially equivalent performance with regard to this specification. These scenarios could result in the use of new or existing materials such as ethylenechlorotrifluoroethylene (ECTFE), polyetheretherketone (PEEK), polypropylene (PP), acetal resin (such as Delrin®™[1], Celcon®™[1] and others), polyvinyl chloride (PVC), perfluoromethylether-based perfluoroalkoxy (MFA), etc.

1 Delrin is a trademark of DuPont; Celcon is a trademark of Hoechst Celanese.

2.6.4 Due to purity and traceability issues, reprocessed or regrind material must not be used.

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document applies solely to polymer components. Performance specifications for subassemblies or bulk distribution systems may be found in other SEMI standards (see Related Documents Section 12.6).

3.2 This document does not include specifications for pumps, storage tanks, ion exchange resin tanks, drums, day tanks, pressure vessels, lined stainless steel products, filters, UV sterilization systems, reverse osmosis systems and ancillary equipment, sensors, monitors, or ultra-filtration equipment.

3.3 Organic liquids, such as isopropyl alcohol and methyl alcohol, are typically in contact with stainless steel or other non-polymeric components. The polymer components described within this document are NOT intended for use with such organic liquids.

3.4 Polymer components described within this document are intended for use in UHP service only. Their specified performance requirements may exceed the needs of components used in drainage and other lesser quality liquids.

3.5 This standard is not intended to address design or materials issues related to safety which are addressed elsewhere in the SEMI guidelines (see SEMI S2).

3.6 The tests referenced in this document are designed to assess contamination from the polymer components in an as received state. Assembly steps, such as welding and cleaning, may actually add some contaminants. The effects of the assembly are beyond the scope of this document, but should be considered by the supplier and/or user (see SEMI E49.7).

3.7 Leach out values listed in Tables 3, 4 and 5 reflect testing in UPW for polymer component comparison purposes. The relative leach out performance of polymer components in actual use with other chemicals (e.g. acids and bases) cannot be directly derived by using the UPW data. It is incumbent upon the user to determine if a component is suitable for use based on these requirements (see Section 2.6.2).

3.8 This document is not intended to supersede international, national or local codes, regulations, and laws. Each should be consulted to ensure that the manufactured polymer components meet regulatory requirements in each location.

6 Ordering Information

6.1 Device manufacturers may use this standard when procuring facilities or processing equipment to specify required component performance to the supplier. Facilities services and process equipment suppliers may also use this document to specify performance requirements to component and subassembly suppliers.

6.2 Orders for polymer components or subassemblies in accordance with this standard shall include the specification number and date of issue.

7 Purity Requirements

7.1 The values found in Tables 3 through 6 were constructed from existing databases of high purity grades of PVDF and PFA. They represent characteristics of piping system polymer components, which are currently providing end-users with satisfactory results. Other materials with other particle leach out or surface roughness characteristics may or may not be acceptable. The end-user may need to test such materials to determine if they will meet both the static values of this document as well as any final delivered fluid requirements.

7.2 *Particle Contribution*

7.2.1 Importance of Test: Particles released from within polymer components can come into direct contact with wafers and cause unwanted surface contamination or disrupt photolithography process steps, thereby decreasing yields.

7.2.2 Particle contribution specification and testing are restricted to polymer components as indicated in Table 1.

7.2.3 Polymer components shall conform to the particle contribution specifications appearing in Table 2.

7.2.4 A Rinse Time Test (see Table 2) provides a measure of the particle shedding from a component when it is initially removed from its packaging in a cleanroom environment and immediately tested.

7.2.5 The various cycle evaluations (see Table 2) provide a measure of the particle shedding that results from actuating the valve and the subsequent cleanup over time. In addition, these tests provide a measure of degradation (increased particle shedding) of the valve as it is cycled.

7.2.6 The performance requirement values in Table 2 for the Initial Cycle Test, the 2000 Cycle Test and the 200,000 Cycle Test represent averages after subtracting a pre-cycle test background average.

7.3 *Ionic Contamination*

7.3.1 Importance of Test: Ionic contamination can have a corrosion and/or etching effect on semiconductor devices during fabrication, causing immediate or future device failure. Evaporation of solutions containing ionics may leave surface residue.

7.3.2 Ionic contamination specification and testing are required for all polymer components as indicated in Table 1. The ionic contaminants specified within this document have been derived, in part, from industry guidelines for UPW used in semiconductor processing.

7.3.3 Polymer components shall conform to the ionic contamination specifications appearing in Table 3. Use SEMI F40 to prepare the component for analysis and ASTM D4327 to analyze polymer components.

7.3.4 The Static Value is derived from a prolonged static leach out test, using UPW as the test media and lasting for a period of 7 days. Static values do not directly relate to the trace contaminant values, which could be present in a flowing stream of liquid. Testing temperature of polymer components shall be 85 ± 5°C. A specific testing temperature is specified to achieve comparable data for polymer components and is not indicative of service temperatures. For most contaminants, testing at a lower temperature will give lower static values.

7.3.5 A mathematical relationship between the static leach out value (provided in this specification) and the corresponding concentration which may result in a flowing stream can be theoretically calculated. This value is offered for demonstration purposes only and is known as the Theoretical Dynamic Concentration (TDC). It is expressed in parts per billion (μg/liter) in the example calculation provided in the Related Information 1 Section of this document.

7.4 *Metallic Contamination*

7.4.1 Importance of Test: Metallic contamination can have an effect on altering the electrical properties of semiconductor devices.

7.4.2 Metallic contamination specification and testing are required for all polymer components as indicated in Table 1. The metallic contaminants specified within this document have been derived, in part, from industry guidelines for UPW used in semiconductor processing

7.4.3 Polymer components shall conform to the metallic contamination specifications appearing in Table 4. Use SEMI F40 to prepare the component for analysis and an industry standard test method to analyze polymer components (see Related Documents Section 12.5 for an applicable leachable trace inorganics test method).

7.4.4 See Section 7.3.4 for Static Value definition.

7.4.5 See Related Information 1 for Theoretical Dynamic Concentration calculation.

7.5 *Total Organic Carbon (TOC)*

7.5.1 Importance of Test: TOC can have an effect on silicon oxidation, uniformity of etching and gate oxide breakdown voltage of semiconductor devices.

7.5.2 TOC specification and testing are restricted to polymer components as indicated in Table 1.

7.5.3 Polymer components shall conform to the TOC contamination specifications appearing in Table 5. Use SEMI F40 to prepare the component for analysis and ASTM D4779 or D5904 to analyze polymer components.

7.5.4 See Section 7.3.4 for Static Value definition.

7.5.5 See Related Information 1 for Theoretical Dynamic Concentration calculation.

7.6 *Surface Roughness*

7.6.1 Importance of Test: Surface roughness can influence microbial proliferation, provide an entrapment area for microcontamination build up and/or promote shedding of the polymer itself within a distribution system.

7.6.2 Surface Roughness specification and testing is required for all polymer components as indicated in Table 1.

7.6.3 Polymer components shall conform to surface roughness specifications appearing in Table 6. For ease of use and comparison purposes, the preferred method of testing is by use of a stylus in direct contact with the component surface, known as contact profilometry (see Related Documents Section 12.5 for an applicable surface roughness test method).

7.6.4 As softer plastics may exhibit microscopic damage due to the stylus and give smoother than expected results, additional testing may be required. When initially setting up the equipment, evaluate softer plastics immediately with a 10x magnification visual examination to make sure damage has not occurred. Lines, scratches or artifacts originating from stylus contact would indicate damage. In the event that damage is present, a lighter stylus head should be used.

Table 2 Particle Contribution Requirements

Description	*Qualification Test Method*	*Units*	*Value*	*Notes*
Rinse Time Test	TBD	Hours	TBD	Section 7.2
Initial Cycle Test	TBD	*Particles/liter ≥ 0.1 µm	TBD	Section 7.2
2000 Cycle Test	TBD	*Particles/liter ≥ 0.1 µm	TBD	Section 7.2
200,000 Cycle Test	TBD	*Particles/liter ≥ 0.1 µm	TBD	Section 7.2

* Cycle Test values are a result of subtracting the pre-cycle test background average. See Section 7.2.6.

TBD = To be determined (see NOTE 1 under Table 1).

Table 3 Surface Extractable Ionic Contamination Requirements

Description	*Component Preparation Practice*	*Qualification Test Method*	*Static Value at 85 ± 5°C for 7 days (µg/m²)*	*Notes*
Bromide	SEMI F40	ASTM D4327	≤ 100	Section 7.3
Chloride	SEMI F40	ASTM D4327	≤ 3000	Section 7.3

Machined	(See NOTE 1.)	µm (µin)	≤ 0.62 (≤ 25)	Section 7.6

NOTE 1: See Related Documents Section 12.5 for an applicable surface roughness test method.

8 Mechanical Requirements

8.1 Upon request, suppliers shall provide data and/or information for the following polymer components mechanical requirements. This information is typically found in product catalogs and component data sheets.

- dimensional tolerances
- flow characteristics
- leak integrity
- mechanical strength characteristics

8.2 All polymer components will conform to supplier's provided data and/or information regarding dimensional tolerances, flow characteristics, leak integrity, and mechanical strength characteristics.

8.3 *Temperature/Pressure Rating*

8.3.1 Polymer components are required to be manufactured in such a manner so as to meet the temperature and internal pressure requirements of ISO 1167, ISO 12162, or other superseding local regulations as applicable.

8.4 *Chemical Resistance Rating*

8.4.1 Polymer components are required to be manufactured to meet the chemical resistance requirements specified by the component suppler, and/or other superseding local regulations as applicable.

8.5 *Reliability*

8.5.1 Upon request, the manufacturer should provide component reliability data accompanied by the associated test and failure analysis methods. This typically involves life cycle testing of components to include results expressed in cycles (e.g. >1,000,000 cycles for valves). The test media used for life cycle testing of polymer components can effect life cycle testing results and should be considered when comparing and selecting polymer components.

9 Certification

9.1 The component supplier is responsible for defining, establishing, and executing a testing program for polymer components based on the requirements outlined within this document.

9.2 Such a program will specify the frequency of testing, the test component(s) and any necessary corrective action plan in the event that a test component fails to meet these requirements during testing.

9.3 To avoid the inefficiencies involved in testing every size of every product type, test polymer components shall be selected by the component supplier which will be representative product of similar processing, or production techniques.

9.4 Upon request, the component supplier is responsible for maintaining and supplying documentation that proves their polymer components consistently meet the requirements of this document.

9.5 The supplier is not required to perform all tests on each individual lot or product type of polymer components shipped. Instead, the product will be certified as meeting the requirements in this document based on the outcome of the representative component tests and periodic testing program. However, if the purchaser performs the test(s) and the product fails to meet the requirement(s), the product may be subject to rejection.

9.6 Qualification tests and certification documents shall reflect current production capabilities.

10 Traceability Requirements

10.1 It will be the responsibility of the component supplier to establish and maintain an incoming raw material certification, inspection, and traceability process, which will ensure that manufactured polymer components meet the requirements of this document.

10.2 Every deliverable item shall have some scheme of identification on the exterior bag or box so that traceability is provided from the raw material supplier to the final finished, packaged product.

10.3 In addition, piping, tubing, valves, gauge guards, pressure transducers, and pressure regulators shall have permanent, non-contaminating identification (e.g. laser marking, heat stamping, or chemical resistant label) on the product itself to provide traceability.

10.4 In the event that component installation by the purchaser obliterates such identification, it becomes the responsibility of the purchaser to maintain traceability records.

11 Packaging Requirements

11.1 Double bagging using a clear material that will allow inspection is required for polymer components specified in this document. Both the inner and outer bags will be heat-sealed and shall prevent damage from normal handling. Vacuum sealing, air evacuation, and/or dry inert gas purging are optional on the inner bag.

11.2 The ends of valves, gauge guards, pressure regulators, and tubing will be protected using some non-contaminating method before bagging.

11.3 The outer bag will have a label affixed which clearly identifies the component, part number, lot number and any other necessary traceability characteristics (see Section 10).

11.4 Shipping containers and cartons must provide adequate protection of polymer components so those articles will meet the requirements contained within this document upon delivery to the purchaser.

11.5 It should be noted that some packaging materials could release substantial amounts of TOC when they are heat-sealed. This might lead to an organic deposition on the polymer component.

RELATED INFORMATION 1
THEORETICAL DYNAMIC CONCENTRATION (TDC)

NOTE: This related information is not an official part of SEMI F57 and was derived from the work of the originating task force. This related information was approved for publication by full letter ballot procedures on August 28, 2000.

R1-1 TDC Definition and Calculation

R1-1.1 For purposes of demonstrating a theoretical mathematical relationship between the maximum allowed static leach out values (provided in this specification) and a corresponding concentration which may result in a flowing stream, this related information on Theoretical Dynamic Concentration (TDC) is being provided.

R1-1.2 The Static Value as defined in this document (see Section 7.3.4) is a measure of the weekly accumulated mass transfer of contaminant (contaminant flux per week) from the material being tested into static ultrapure water (UPW). The value is calculated based upon measurement of total leached mass of a contaminant per unit area of the surface that was wetted in the test apparatus. Since the duration of the static test is fixed at 7 days, the information is simply reported as mass/area (Tables 3, 4, and 5 use units of $\mu g/m^2$).

R1-1.3 The Theoretical Dynamic Concentration (TDC) is a mathematical conversion of the static value into a theoretical prediction of concentration of a contaminant incorporated into the flowing liquid by contact with the contaminant generating (or transmitting) polymer component wall. The conversion depends upon a model which assumes a uniform rate of contaminant generation that is equal to the average rate over the 7 day Static Value test (7d * 24 hr/d * 3600 sec/hr = 6.05 x 10^5 sec). The model also assumes a non-depleting source of the contaminant in steady state transport conditions through the component/liquid interface. In general, this assumption is only true early in the life of the piping system installation. Values have been found to decrease in time. Calculation of TDC for specification limit purposes can be derived by dividing the static value limit for the component (adjusted for wetted surface area of the component) by the volume of liquid affected by contact with the component.

R1-2 TDC Example

R1-2.1 Referring to the concentrations shown in Tables 3, 4 and 5, a 1 meter long, 60 mm inner diameter pipe with an UPW constant fluid velocity of 1.5 meters/second is selected as an example. Since several factors will affect the actual concentration in a flowing stream the TDC should be considered as approximate, not absolute.

I.D. $d = 60$ mm

Length $l = 1.0$ m

Fluid velocity = 1.5 m/sec

R1- 2.2 Example of TDC Calculation:

a) Surface area of tube I.D.

$= \pi dl$
$= (\pi)(0.060 \text{ m})(1.0 \text{ m})$
$= 0.188 \text{ m}^2$
$= 1.88 \times 10^{-1} \text{ m}^2$

b) Volume of tube I.D.

$= \pi (d/2)^2 l$
$= (\pi)(0.060/2 \text{ m})^2 \ (1.0 \text{ m})$
$= 2.83 \times 10^{-3} \text{ m}^3$
$= (2.83 \times 10^{-3} \text{ m}^3)(1 \times 10^3 \text{ liter/m}^3)$
$= 2.83$ liter

c) Volume of liquid transported through tube per second

= (1.5 m/sec) (2.83 liter/m)
= 4.25 liter/sec

d) Volume of liquid transported through tube per week

$= (4.25 \text{ liter/sec})(6.05 \text{ x } 10^5 \text{ sec/wk})$
$= 2.57 \times 10^6$ liter/wk

e) Assume a Static Value limit of $10 \mu g/m^2$

$= (10 \ \mu g/m^2)(1.88 \times 10^{-1} \text{ m}^2)$
$= 1.88 \ \mu g$

f) Using the values from d and e, above,

TDC = $1.88 \ \mu g / 2.57 \times 10^6$ liter

TDC = 7.3×10^{-7} µg/liter

(or, 7.3×10^{-4} parts per trillion in liquids with an approximate density of 1 gram/cm^3)

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. SEMI F58-1000
TEST METHOD FOR DETERMINATION OF MOISTURE DRY-DOWN CHARACTERISTICS OF SURFACE-MOUNTED AND CONVENTIONAL GAS DISTRIBUTION SYSTEMS BY ATMOSPHERIC PRESSURE IONIZATION MASS SPECTROMETRY (APIMS)

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available on SEMI OnLine August 2000; to be published October 2000.

1 Purpose

1.1 This document describes the procedure for determination of the moisture dry-down characteristics (quantity of removable moisture) of surface mounted and conventional gas distribution systems (integrated gas distribution systems). APIMS is currently the method of choice for such dynamic tests because it is the commercially available technique capable of ppt moisture analysis with the fastest response time. This test method may provide guidelines for the application of other techniques with similar detection limits and response time to APIMS which are not commercially available at this time.

1.2 The results of this test can be used for qualitative ranking of gas delivery based on the design. It can also be used by a sufficiently sophisticated user as input for numerical simulation of distribution system behavior.

2 Scope

2.1 This test method applies to all types of surface mounted and conventional gas distribution systems used in semiconductor processing.

2.2 *Test Medium* — The test procedure will be carried out in nitrogen. Other "inert" gases will have different purging characteristics and may dry a system more quickly or slowly. Reactive gases may react chemically with moisture. Considerations relating to corrosion resistance are outside the scope of the present document, although the test procedure may prove useful in corrosion studies. The results will provide a ranking with respect to moisture contribution arising as a result of differences in design, which may be applied with due caution to systems intended for use in other gas applications.

2.3 *Operating Situations* — Moisture contribution from a gas delivery system may be the result of contamination arising in its manufacture, or from subsequent exposure to ambient air or non-dry gas. Thus, it is necessary to consider two main situations:

2.3.1 The "initial dry-down" situation, which is determined by the moisture content of the components in the system (as received) with the effects of manufacturing process and design, surface quality, pre-treatment and packaging convoluted together.

2.3.2 The "response to upset" situation, which is determined by the amount of moisture taken up by the system and subsequently released in any exposure after receipt.

2.4 *Safety Issues* — This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This test method allows the determination of moisture interactions which can be used, for example, to rank systems in order of decreasing moisture interaction. Because different degrees of moisture interaction are permissible in different situations, selecting the "best" system requires consideration of how they will be used, either qualitatively or through a numerical simulation of distribution system behavior. The results of this test can only be used for qualification for gas delivery systems based on different designs. It cannot be used for production purposes and/or certification/testing.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI C15 — Test Method for ppm and ppb Humidity Standards

SEMI F27 — Test Method for Moisture Interaction and Content of Gas Distribution Systems and Components by Atmospheric Pressure Ionization Mass Spectrometry (APIMS)

SEMI F33 — Method for Calibration of Atmospheric Pressure Ionization Mass Spectrometer (APIMS)

4.2 *ASTM Standards*[1]

ASTM-F1397-93 — Standard Test Method for Determination of Moisture Contribution by Gas Distribution System Components

5 Summary of Test Method

5.1 This test method consists of initial drydown and moisture input tests for both surface-mounted and conventional gas delivery systems.

6 Terminology

6.1 *Abbreviations and Acronyms*

6.1.1 *APIMS* — Atmospheric Pressure Ionization Mass Spectrometry.

6.1.2 *EPSS* — electropolished stainless steel.

6.1.3 *ppm* — molar parts per million (µmole/mole). The same as ppmv.

6.1.4 *ppb* — molar parts per billion (nmole/mole). The same as ppbv.

6.1.5 *ppt* — molar parts per trillion (pmole/mole). The same as pptv.

6.1.6 *slpm* — standard liters per minute, the gas volumetric flow rate measured in liters per minute at 0°C and 1 atm.

6.2 *Definitions*

6.2.1 *baseline* — an instrument response under steady state conditions.

6.2.2 *glove box* — an enclosure that contains a controlled atmosphere, usually inert.

6.2.3 *induction time* — the elapsed time between when humidified gas is introduced to the test system and when moisture is detected at the moisture analyzer. For a test system which is perfectly transparent to moisture, the induction time is equal to the residence time of the gas in the system.

6.2.4 *peak height* — the maximum moisture concentration recorded when a moisture input of pre-defined length and concentration is introduced to a test system.

6.2.5 *response time* — the time required for the test system to reach steady state after a change in concentration.

1 Available from American Society for Testing and Materials, 100 Barr Harbor Dr, West Conshohocken, PA 19428. Fax: 1-610-832-9555. World Wide Web: http://www.astm.org.

6.2.6 *test system* — the gas delivery system under test

7 Required Equipment

7.1 *APIMS* — The APIMS used for moisture detection can be of any type. Calibration of the APIMS shall be performed as per SEMI F33, one at the beginning and one at the end of the series. These calibrations shall both be made under the same analytical conditions (flow, pressures, plate voltages, etc.) as the tests and the results shall be within 5% of each other. Provided this condition is met, the interval between calibrations may be left to the discretion of the operator; however, it is suggested that calibration should be carried out whenever the equipment is moved and/or every two weeks of operation.

7.2 *Dry Gas and Moisture Generator* — A source of extremely dry nitrogen (less than 200 ppt moisture) and a moisture generator capable of delivering up to 13 slpm nitrogen doped with 200 ppb moisture is required. This generator may be the same as used to calibrate the APIMS. The output of the generator shall be verified according to SEMI C15.

7.2.1 Most ultra-high purity gas panels are currently fitted with metal gasket type connectors. The same type of connector should, therefore, be incorporated into the test bench for connection to the test system.

7.3 *Test Blank* — Any series of tests shall include the results of testing a blank. The blank shall be the shortest convenient length (no more than 1 m) of 1/4" EPSS tubing with suitable fittings and/or adapters at either end to enable it to be inserted in place of the test system.

7.4 *Moisture Pulse Generator* — A valve arrangement capable of switching instantaneously between dry and humidified nitrogen is also required. An example of such a design is shown in Figure 1. In this design, flow is maintained in both the humidified and dry gas lines at all times. By simultaneously switching valves V_1 and V_3, or V_2 and V_3, either humidified or dry gas is directed through the test system while the other gas stream is directed to vent. Note that there is a bypass loop so that flow can be maintained to the APIMS when the test system is removed. In this design, all gas lines, but especially those lines between V_1 and V_3 and between V_2 and V_3, should be as short as possible and constructed of EPSS tubing of high quality. Maintaining gas lines at a constant temperature between 50 and 80ºC wherever possible is also recommended.

7.4.1 The bypass loop will contain a stagnant volume of gas during testing. To avoid exposing the APIMS to a large moisture upset whenever it is fed with the gas contained in the bypass loop, the loop should be thoroughly baked out (at ≥ 200°C) and protected from atmospheric contamination thereafter. Valve V_4 should be such that some flow can be maintained through the bypass loop and the test system simultaneously as well as through each separately. Use of pneumatic valves to facilitate rapid and simultaneous switching is recommended.

7.4.2 Other arrangements than that shown may also be used. The moisture pulse generator should be designed so as to give the fastest possible response of the blank to a change in input moisture level.

7.5 *Temperature Control and Measurement* — A stable temperature during the test is of critical importance. The test system shall be kept at 30ºC. TESTS AT DIFFERENT TEMPERATURES CANNOT BE COMPARED. Ideally, the blank and test system should be maintained in a temperature-controlled chamber. However, if this is impractical, a heating tape can be used. Temperature control should be to ± 1ºC. A continuous record of temperature during the test shall be maintained.

8 Procedure

8.1 *Blank Tests* — A blank test shall be carried out after each calibration. If initial dry-down testing of system is not of interest, the initial dry-down test of the test blank may be omitted and the test blank brought to equilibrium with zero gas in whatever manner is most convenient, except that the test blank should not be heated above 200ºC. Permanent changes in moisture interaction have been observed at temperatures above this level.

8.1.1 *Initial Dry-down* — Start the experiment with the blank in place of the test system and a flow of dry gas through the APIMS. The APIMS output should be at equilibrium with the lowest moisture level of interest, and in any case no higher than 200 ppt.

8.1.1.1 Switch the gas flow to pass primarily through the bypass loop while maintaining a small flow through the test blank. Remove the test blank completely from the system. If a glove box or other such enclosure is used, do not remove the test blank from the glove box. Immediately reconnect the test blank to V_4, leaving it disconnected from V_5. Allow dry nitrogen to flow through the test blank for five minutes to purge the air from inside before reconnecting to V_5. Switch the gas to flow only through the blank and not through the bypass loop. The APIMS will show an increase in moisture concentration. Record the APIMS output until it reaches 800 ppt or 48 hours, whichever is less.

8.1.1.2 Repeat the above test twice for a total of three data sets.

8.2 *Tests on Actual Test System*

8.2.1 *Initial Dry-down* — This portion of the test is designed to determine the quantity of removable moisture on the wetted surfaces of the system in the condition in which it is typically supplied. Thus, the results of this test will reflect, by design, any precautions which the supplier has taken to remove moisture and maintain its dryness during shipping.

8.2.1.1 Start the test as in Section 8.1.1. The test system should not be unpacked until after the APIMS has equilibrated with the background moisture level. If a glove box or other such enclosure is used, unpack the system in the glove box. Switch the dry nitrogen flow to pass through the bypass loop while maintaining a small flow through the test blank. Bake the sample line to APIMS at 170°C for 10 min and the APIMS ion chamber at 150°C for 10 min. Undo the final layer of packing and any shipping caps or plugs on the system at this point. Remove the sample blank and connect the test system to valve V_4 as quickly as possible. Ensure that the gas lines going to APIMS will be under N_2 purge during the removal of test blank and installation of test system. Allow the dry nitrogen flow to purge out any ambient air in the system for five minutes, then connect the system to V_5. Switch the gas to flow (1.2 slpm) only through the test system and not through the bypass loop. The APIMS will show an increase in moisture concentration. Record the APIMS output until it reaches 200 ppt or for 24–48 hours, whichever is less.

8.2.1.2 After 24–48 hours, the initial dry-down part of the test can be terminated. Remove the filters from the test system and install special spool pieces. This is done since filters have a large surface area and would dominate the dry-down performance.

8.2.2 *Moisture Input Test* — Flow 1.2 slpm of dry nitrogen gas (200 ppt moisture) through appropriate process channels of the test system. Connect the outlet of the gas panel to the sample line connecting to the APIMS. Bake the appropriate process channels using heater tapes at 60°C for 12 h to remove atmospheric contamination.

8.2.2.1 At the conclusion of baking, equilibrate the test system to 30°C. Bake the sample line at 170°C for 10 min and ion source of APIMS at 150°C for 10 min. Perform a leak check at the inlet and outlet connections of the test system using 1% methane gas in nitrogen, after warming up the APIMS for 30 min. Switch the input gas to nitrogen with 200 ppb moisture (by switching valves V_1, V_2, and V_3 simultaneously, if the arrangement shown in Figure 1 is used) while recording the APIMS response. Maintain this input for 20 min and then switch the input gas to dry nitrogen (200 ppt moisture) and monitor the dry-down.

9 Reporting Results

9.1 Complete moisture response curves for all test systems and relevant test blanks should be included. A summary sheet may compare systems in terms of "induction time," peak height, and/or decay time (detected moisture concentrations may be plotted as a function of time for the test systems). Temperature, pressure, and flow measurements, and as complete a record as possible of all experimental variables should be noted.

SEMI F59-0302
TEST METHOD FOR DETERMINATION OF FILTER OR GAS SYSTEM FLOW PRESSURE DROP CURVES

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition aproved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published October 2000.

NOTE: This document was entirely rewritten for publication in 2002.

1 Purpose

1.1 The purpose of this document is to define a method for testing filters or gas systems being considered for installation into a high-purity gas distribution system or on semiconductor manufacturing equipment, respectively. Application of this test method is expected to yield comparable data among filters or gas systems.

1.2 This document establishes a test method for preparing a pressure drop versus flow rate curves for filters and gas systems.

2 Scope

2.1 This procedure applies to clean filters including those cartridges of metal, ceramic and membrane construction. The pressure drops for integral housing/cartridge combination units are determined as a single set of values. For housings with removable filter cartridges, the flow curves of the housing and housing/cartridge combination are determined separately.

2.2 This procedure applies to high-purity gas systems. This procedure applies to face-seal, surface mount—modular, and monolithic integrated gas systems.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate and safety health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 For separable filtration units, a single cartridge pressure drop value cannot be combined to give the pressure drop value for an extended length cartridge, because of the limitations imposed by a common outlet port for the assembly.

3.2 This method is written with the assumption that the operator understands the use of the apparatus at a level equivalent to six months of experience.

3.3 This method is written to test a filter under normal operating conditions. It does not prescribe a procedure for reverse flow testing since operation of the filter in this manner is not recommended by the manufacturers.

3.4 Components that induce line pressure changes on a system such as pressure regulators, and MFCs are not considered in this test method.

3.5 Proper flow of low vapor pressure gases can be effected by small pressure drops and may need to be evaluated independently.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *ASME Performance Test Code PTC 19.5, 1972* — "Applications." Part II of "Fluid Meters, Interim Supplement on Instruments and Apparatus."[1]

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CDA* — clean, dry air

5.1.2 *°C* — degrees Celsius

5.1.3 *DUT* — device under test

5.1.4 *kg* — kilogram

5.1.5 *kPa* — kilopascals, (kNm^{-2})

5.1.6 *m* — meter

5.1.7 *MFC* — mass flow controller

5.1.8 *N* — Newton ($kg\ m/s^2$)

5.1.9 *P* — pressure in kiloPascal (kPa)

5.1.10 *POC* — point of connection

5.1.11 *psi* — pounds per square inch

5.1.12 *psia* — pounds per square inch absolute

5.1.13 *psid* — pounds per square inch differential

5.1.14 *psig* — pounds per square inch gauge

1 American Society of Mechanical Engineers (ASME) International, 3 Park Avenue, New York, NY 10016-5990

5.1.15 *s* — second

5.1.16 *scfm* — standard cubic feet per minute

5.1.17 *slpm* — standard liters per minute

5.1.18 *T* — (K) temperature in Kelvin

5.1.19 *ΔP* — differential pressure in kPa

5.1.20 *ΔP(Housing)* — (kPa, differential) differential pressure of housing in kiloPascal, differential

5.1.21 *ΔP(Unit)* — (kPa, differential) differential pressure of filtration unit in kiloPascal, differential

5.1.22 *ΔP(cartridge)* — (kPa, differential) differential pressure of cartridge element in kiloPascal, differential

5.2 *Definitions*

5.2.1 *filter cartridge* — the filtration element.

5.2.2 *filter housing* — the shell that contains the filter cartridge.

5.2.3 *filtration unit* — the assembly consisting of a filter cartridge and housing.

5.2.4 *gas box* — a gas distribution subsystem which generally contains the final shut-off valve(s) prior to the POC.

5.2.5 *gas pallet* — individual gas distribution subsystems within a gas box that control flow of gas to individual process chambers.

5.2.6 *gas stick* — a series of components for an individual gas within a gas box. It may contain valves, a regulator, a pressure transducer, a purge line, an MFC, and a filter.

5.2.7 *integral unit* — the filter cartridge and housing are not separable.

5.2.8 *normal conditions* — 101.3 kPa (14.7 psia) and ambient temperature conditions 293.15 K (20 °C).

5.2.9 *separable unit* — the filter cartridge and housing can be disassembled.

5.2.10 *spool flow through component* — a null component consisting of an electropolished flow passage and appropriate fittings used in place of the test component.

5.2.11 *standard conditions* — 101.3 kPa, 273.15 K (14.7 psia, 0°C).

6 Summary of Method

6.1 This test method describes the test equipment and procedures for determining the flow pressure drop of filters or gas systems. The differential pressure is measured across a DUT at various inlet pressures and flows. If the filtration unit is separable the individual contributions from the housing and cartridge are determined.

7 Interferences

7.1 Test stand must be of adequate dimensions so that it does not limit the flow through the test DUT. The pressure drop for the test stand must be insignificant compared to the pressure drop for a DUT at the test flow rate.

8 Apparatus

8.1 pressure regulator

8.2 downstream flow regulating valve

8.3 flow meter capable of measuring flow rates to better than 5% full scale and of appropriate range.

8.4 several pressure transducers or gauges

8.5 differential pressure transducer (0.67 kPa, (0.1 psi) sensitivity)

8.6 Test stand

8.7 Temperature measuring device (°C)

9 Reagents and Materials

9.1 Test Gas nitrogen or CDA filtered to < 0.02 micrometer with a dew point of less than or equal to –40°C.

10 Safety Precautions

10.1 *Safety Precautions* — This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address all of the safety problems associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to its use.

10.2 The user must have a working knowledge of the respective instrumentation, must practice proper handling of test components, and must understand good laboratory practices. The user should not operate the components in such a manner as to exceed the ratings (i.e., pressure, temperature, flow and voltage).

11 Test Specimen

11.1 A gas box may consist of several gas pallets that uniquely control flow of gases to a specific process chamber. More than one gas stick layout is possible on the pallet. The user shall test only one stick at a time for pressure drop measurement. The gas stick may be removed from the pallet to attach to the test fixture.

11.2 Pressure regulators and MFCs shall be maintained in their fully open position during testing.

11.3 When comparing different gas system designs, it is useful to use components of similar design.

11.4 If the stick design contains a filter that dominates the pressure drop on the system, such filters shall be replaced by spool flow through components

12 Preparation of Apparatus

12.1 Construct a test stand for the measurement of gas flow rates and pressure drop across a DUT. Examples of such a test stand are shown in Figures 1a or 1b as schematic drawings.

12.2 The gas supply is filtered by an electronics grade high purity point-of-use gas filter before it is delivered to the DUT through a pressure regulator.

12.3 A flow meter can be installed either upstream or downstream of the DUT. See Figures 1a or 1b. The test filter is upstream of a throttle valve to allow for control of the flow through the DUT.

12.4 Inlet pressure is measured immediately upstream of the DUT by a pressure gauge or pressure transducer.

12.5 Pressure drop across the test specimen is measured by an electronic differential pressure transducer capable of reading 0.67 kPa (0.1 psid) across the test device.

12.6 Flow measurements are carried out through a flow meter installed upstream or downstream of the test filter. See Figures 1a or 1b.

NOTE 2: The flow measurement can be influenced by both upstream and downstream pressure fluctuations. It is necessary to verify the accuracy of any flow measurement under the test conditions used to complete this testing.

12.7 A temperature measurement device can be installed in the test stand to measure the gas stream temperature.

12.8 Figure 2 gives the piping requirements for the test stand configuration.

12.9 Figure 3 gives the recommended pressure connection to be followed in constructing the test apparatus.

13 Calibration and Standardization

13.1 For each test, verify that calibration of test equipment is up-to-date.

13.2 A series of flow meters should be used to cover the full range of flows that will be tested.

14 Procedure

14.1 *Integral Filtration Unit*

14.1.1 Assemble the filtration unit into the test apparatus. (See Figure 1.)

14.1.2 Set the inlet pressure using the pressure regulator to 10% of the filter's maximum rated inlet pressure or to 205 kPa (29.7 psia) whichever is less. Pressure is read on the inlet pressure gauge.

14.1.3 Adjust the flow rate using the regulating valve to give 10 % of the maximum rated flow. Adjustments to the inlet pressure regulator may be required to maintain a constant inlet pressure of 205 kPa (29.7 psia). The flow and pressure adjustments can be an iterative process requiring several iterations to achieve the desired flow rate and inlet pressure. The flow rate is read on the flow meter and recorded.

14.1.4 Read and record the ambient temperature, inlet pressure, pressure drop across the test filter, ambient pressure, and flow rate corrected for upstream pressure based on manufacturer's recommendation.

14.1.5 Repeat steps in Sections 14.1.3 and 14.1.4 at 25%, 50%, 75% and 100% of the maximum rated flow.

14.1.6 Repeat steps in Sections 14.1.2 through 14.1.5 at several inlet pressures: 309 kPa (44.7 psia), 516 kPa (74.7 psia), and 723 kPa (104.7 psia).

14.1.7 Additional testing of the filter at higher pressures can be completed up to the maximum rated pressure.

14.1.8 When the filter has a lower maximum pressure rating than 90 psig, it is recommended that the filter be tested at pressures of 33%, 67% and 100% of the filter's maximum pressure rating, with tests being limited by the sensitivity of the differential pressure device.

14.2 *Separable Filtration Unit* **-** *Filter Housing*

14.2.1 Assemble the empty filter housing into the test apparatus.

14.2.2 Set the inlet pressure using the pressure regulator to 10% of the housing's maximum rated inlet pressure or to 205 kPa (29.7 psia) whichever is less. The inlet pressure is read on the inlet pressure gauge and recorded.

14.2.3 Adjust the flow rate using the regulating valve to give 10% of the maximum rated flow. Adjustments to the inlet pressure regulator may be required to maintain a constant inlet pressure of 205 kPa (29.7 psia). The flow and pressure adjustments can be an iterative process requiring several iterations to achieve the desired flow rate and inlet pressure. The flow rate is read on the flow meter and recorded.

14.2.4 Read and record the ambient temperature, ambient pressure, inlet pressure, pressure drop across the test filter, and flow rate corrected for upstream pressure based on manufacturer's recommendation.

14.2.5 Repeat steps in Sections 14.2.3 and 14.2.4 at 25%, 50%, 75%, 100% of the filter cartridge's maximum rated flow.

14.2.6 Repeat steps in Sections 14.2.2 through 14.2.5 at several inlet pressures. For example, test at 309 kPa (44.7 psia), 516 kPa (74.7 psia), and 723 kPa (104.7 psia).

14.2.7 Additional testing of the filter at higher pressures can be completed up to the maximum rated pressure.

14.2.8 When the filter has a lower maximum pressure rating than 90 psig, it is recommended that the filter be tested at pressures of 33%, 67% and 100% of the filter's maximum pressure rating, with tests being limited by the sensitivity of the differential pressure device.

14.3 *Separable Filtration Unit – Assembled Cartridge and Housing*

14.3.1 Assemble the filter cartridge into the filter housing.

14.3.2 Assemble the filtration unit into the test apparatus.

14.3.3 Set the inlet pressure using the pressure regulator to 10% of the filter's maximum rated inlet pressure, or to 205 kPa (29.7 psia), whichever is less. The inlet pressure is read on the inlet pressure gauge/transducer and recorded. This pressure should be the same as used for the filter housing test in Section 14.2.2.

14.3.4 Adjust the flow rate using the regulating valve to give 10% of the maximum rated flow. Adjustments to the inlet pressure regulator may be required to maintain a constant inlet pressure of 205 kPa (29.7 psia). The flow and pressure adjustments can be an iterative process requiring several iterations to achieve the desired flow rate and inlet pressure. The flow rate is read on the flow meter and recorded. This should be the same as used for the filter housing test in Section 14.2.3.

14.3.5 Read and record the ambient temperature, ambient pressure, inlet pressure, pressure drop, and flow rate.

14.3.6 Repeat steps in Sections 14.3.3 and 14.3.5 at 25%, 50%, 75% and 100% of the maximum rated flow. These should be the same flow settings as used in Section 14.2.5.

14.3.7 Repeat steps in Sections 14.3.2 through 14.3.6 at several inlet pressures. For example, test at 309 kPa (44.7 psia), 516 kPa (74.7 psia), and 723 kPa (104.7 psia).

14.3.8 Additional testing of the filter at higher pressures can be completed up to the maximum rated pressure. These inlet pressure settings should be the same as used in Section 14.2.7.

14.3.9 When the filter has a lower maximum pressure rating, it is recommended that the filter be tested at pressures of 33%, 67% and 100% of the filter's maximum pressure rating, with tests being limited by the sensitivity of the differential pressure device.

14.3.10 The flow curve for the filter cartridge is determined by subtracting the pressure drop of the housing from the pressure drop of the assembled filtration unit at respective flow rates and inlet test pressures.

14.4 *Gas System*

14.4.1 Assemble the DUT into the test apparatus. (See Figure 1.)

14.4.2 Set the inlet pressure using the pressure regulator to 205 kPa (29.7 psia). Pressure is read on the inlet pressure gauge.

14.4.3 Adjust the flow rate using the regulating valve to give 1 slpm. Adjustments to the inlet pressure regulator may be required to maintain a constant inlet pressure of 205 kPa (29.7 psia). The flow and pressure adjustments can be an iterative process requiring several iterations to achieve the desired flow rate and inlet pressure. The flow rate is read on the flow meter and recorded.

14.4.4 Read and record the ambient temperature, inlet pressure, pressure drop across the DUT, ambient pressure, and flow rate.

14.4.5 Repeat steps in Sections 14.4.2 through 14.4.4 at flow rates of 5, 10, 25, 50, 75, and 100 slpm.

14.4.6 Repeat steps in Sections 14.4.2 through 14.4.5 at several inlet pressures: 308 kPa (44.7 psia), 515 kPa (74.7 psia), and 791 kPa (114.7 psia).

14.4.7 Additional testing of the DUT may be performed at higher pressures up to the maximum rated pressure. Where components are not specified to operate at the required flow rates and pressures listed in Sections 14.4.5 and 14.4.6 then tests shall be performed to the highest pressures and flows attainable while remaining within the component's maximum operating specification.

15 Calculations or Interpretation of Results

15.1 Complete Tables 1–3 as needed for the DUT.

15.2 Graph the pressure drop versus the flow rate. An example of such a graph is shown in Figure 4 with separate lines for different inlet pressure settings.

16 Precision and Accuracy

16.1 All measurements shall be recorded to the greatest precision allowed by the instruments unless accuracy in the overall measurement is not affected by lower precision.

16.2 Accuracy of all instruments shall be recorded.

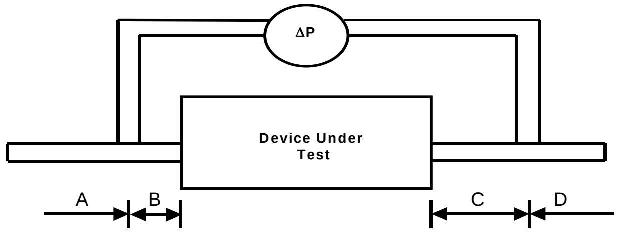
Sample Gas System for Testing



A — At least 16 nominal pipe diameters of straight pipe.

B — 2 Nominal pipe diameters of straight pipe.

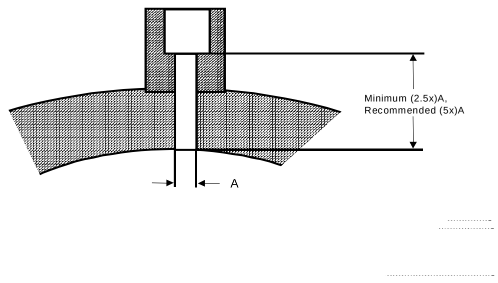
C — 6 Nominal pipe diameters of straight pipe.

D — At least 1 nominal pipe diameters of straight pipe.

NOTE 1: Dimension “A” may be reduced to 8 nominal diameters if straightening vanes are used. Design of straightening vnes can be found in ASME Performance Test Code PTC 19.5-1972, “Applications – Part 2 of “Fluid Meters, Interim Supplement on Instruments and Apparatus.”

NOTE 2: If an upstream flow disturbance consists of two elbows in series and they are in different planes, dimension “A” must exceed 16 nominal pipe diameters unless straightening vanes are used.

Figure 2
Piping Requirements – Standard Test Section



Size of Pipe	*“A” Not Exceeding*	*“A” Not Less than*
Less than 50 mm (2 in.)	6 mm (1/4 in.)	3 mm (1/8 in.)
50 mm to 75 mm (2–3 in.)	9 mm (3/8 in.)	3 mm (1/8 in.)
100 mm to 200 mm (4–8 in.)	13 mm (1/2 in.)	3 mm (1/8 in.)
250 mm and greater (10 in. and greater)	19 mm (3/4 in.)	3 mm (1/8 in.)

NOTE 1: Edge of hole must be clean and sharp or slightly rounded, free from burrs, wire edges or other irregularities. In no case shall fitting protrude inside pipe.

NOTE 2: Any suitable method of making the physical connection is acceptable if above recommendations are adhered to.

See ASME Performance Test Code PTC 19.5-1972, “Applications. Part II of Fluid Meters, Interim Supplement on Instruments and Apparatus.

SEMI F60-0301
TEST METHOD FOR ESCA EVALUATION OF SURFACE COMPOSITION OF WETTED SURFACES OF PASSIVATED 316L STAINLESS STEEL COMPONENTS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org December 2000; to be published March 2001.

1 Purpose

1.1 The purpose of this document is to define a method for testing passivated 316L stainless steel components being considered for installation into a high-purity gas distribution system. Application of this test method is expected to yield comparable results among components tested for the purposes of qualification for this installation.

1.2 This document defines a method of testing the interior surfaces of stainless steel tubing, fittings, valves, and other components to determine the surface composition and chemistry, as a measure of the effectiveness of passivation processes.

1.3 The objective of this method is to describe a general set of instrument parameters and conditions that will achieve precise and reproducible measurements of important surface chemistry within the chromium-enriched oxide layer.

2 Scope

2.1 This document describes a test method to characterize "as received" surface composition and chemistry encompassing all chromium-enriched stainless steel surfaces in tubing, fittings, valves, and other components. This procedure involves measurement of total Cr/Fe ratios, Cr^{ox}/Fe^{ox} oxide species ratios, and the surface elemental compositions by Electron Spectroscopy for Chemical Analysis (ESCA), also called X-ray Photoelectron Spectroscopy (XPS).

2.2 This document also describes the test method for a compositional ESCA depth profile measurement for Cr, Fe, Ni, O and C from the as-received surface, through the oxide layers, and extending into the base metal. The depth profile measurement evaluates the oxide thickness and the relative composition throughout the modified surface layer as a result of the passivation process.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This test method is intended to be used by ESCA analysts familiar with the instrumentation and technique. The ESCA instrument must be calibrated and maintained to pertinent manufacturer's specifications. The method is not intended to preclude the use of any particular brand or model of surface analysis equipment. While most of the test methodology has been developed using specific instrumentation, this method can be adapted to most surface analytical instrumentation.

3.2 The effects of the depth of analysis of the technique and surface contamination affect the results of this test method. These are discussed in the attached appendix. Surface roughness, non-planarity of the surface, and differential sputtering rates for the different chemical species also cause measurement uncertainties in this test method

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

Moulder, et al. — Handbook of X-ray Photoelectron Spectroscopy.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *ESCA* — Electron Spectroscopy for Chemical Analysis.

5.1.2 *XPS* — X-ray Photoelectron Spectroscopy, an equivalent name for ESCA.

5.2 *Definitions*

5.2.1 *sampling volume* — the volume from which photoelectrons are detected. The x-ray spot size and/or the lens and aperture system of the electron analyzer determine lateral dimensions. A length of three times the photoelectron mean free path is considered the maximum depth sensitivity. Sampling volume is dependent on the sample material and TOA. The acceptance angle of the analyzer will also influence the distribution of the depth information.

5.2.2 *take-off angle (TOA)* — the angle that the collection lens forms with the sample plane.

6 Summary of Method

6.1 *Data Acquisition*

6.1.1 Acquire elemental survey and calculate elemental composition of "as received" wetted surface.

6.1.2 Acquire chromium and iron regions at high resolution. Calculate total Cr/Fe ratio and Cr oxide/Fe oxide ratios from these regions.

6.1.3 Acquire a compositional depth profile to determine the relative abundance of C, O, Cr, Fe and Ni. Additional elements may be included as desired (i.e., molybdenum, silicon and nitrogen). If minor elements are included in the profile the instrument parameters should be chosen to allow for a detection limit of 1 atomic percent (at%) or better.

6.2 *Reporting* — Data is provided consisting of:

6.2.1 A survey spectrum extending from at least 0-1100eV.

6.2.2 The high-resolution Cr ($2p_{3/2}$) and Fe ($2p_{3/2}$) spectra from the as-received surface.

6.2.3 A compositional depth profile plot including C, O, Cr, Fe and Ni as a function of sputtering time.

7 Possible Interferences

7.1 *Mo (3d) and S (2s)* — use S (2p) for quantification of sulfur. Molybdenum will appear as a doublet; quantity may be overestimated.

7.2 *Fe ($2p_{3/2}$) and Ni Auger* — ignore.

7.3 *Mo (3p) and N (1s)* — the ability to accurately quantify the nitrogen will depend upon the chemical state of both the nitrogen and molybdenum. In some cases the nitrogen will be overestimated from a survey scan quantification.

8 Apparatus

8.1 *Instrumentation* — Any ESCA instrument with definable area of analysis approximately 1 mm or less and sufficient count rate to provide detection of low level contaminants at one atomic percent or greater. A count rate of at least 100,000 counts per minute for clean Au ($4f_{7/2}$) should indicate sufficient sensitivity.

8.2 The instrument should have peak resolution of 1 eV FWHM Au ($4f_{7/2}$) or better (i.e., < 1 eV) to ensure species separation of metallic and oxide forms of chromium and iron.

8.3 If the instrument is of a variable take-off angle (TOA) design, the geometry should be set to a TOA of approximately 35^{o}. Instruments with geometries significantly different from this, or with magnetic electron collection lens may provide analysis from a different sampling volume. The angle of the incident X-ray irradiation with respect to the sample plane and TOA must be recorded.

8.4 Data reduction software must have the ability to select an iterated Shirley-curve background.

9 Reagents and Materials

9.1 *Instrument Calibration Materials* — Refer to instrument manufacturer recommendations or ASTM E902. A measurement of the binding energy difference between the Au ($4f_{7/2}$) at 84.0 eV and Cu ($2p_{3/2}$) at 932.6 eV is an acceptable method of calibrating analyzer linearity. A value of $\pm 3\sigma$ based upon a minimum of 10 historical measurements of less than ± 0.25 eV is acceptable.

2 National Institute of Standards and Technology, Gaithersburg, MD 20899

3 Physical Electronics, Eden Prairie, MN 55344

9.2 *Statistical Process Control Material* — A nominal 316L material with a composition range within the guidelines of ASTM A276. The composition of the bulk material should be determined by methods consistent with ASTM A751.

10 Safety Precautions

10.1 This test method does not purport to address the safety considerations associated with use of high voltage, vacuum, and X-ray producing equipment. The method assumes an ESCA analyst with knowledge of instrumentation and associated safety precautions.

11 Test Specimen

11.1 Specimens are to be sectioned to appropriate size for the particular ESCA instrument using a clean, dry hacksaw or dry low speed bandsaw. Any sample preparation shall avoid introducing contamination onto the surface to be measured. In addition, preparation must avoid excessive heating of the sample, i.e., the surface temperature shall not exceed 50°C, to avoid oxide growth or change in surface composition.

11.2 Sample preparation should preferably be done by the component manufacturer. Following sectioning the sample(s) are to be cleaned and packaged per the manufacturer's standard final cleaning and packaging procedures.

11.3 If sample preparation is done by other than the manufacturer, the sample(s) may be cleaned in DI water. If the sample(s) are not to be analyzed immediately they should be packaged by wrapping in clean metal foil or sealing in cleanroom quality nylon bags.

11.4 If sample preparation is done by other than the manufacturer this shall be stated in the report narrative and the analytical results are not to be interpreted as indicative of the manufacturer's quality of cleaning and packaging procedures. A note to this effect shall be included in all tables of reported results of the composition of the surface.

11.5 After preparation, samples should be analyzed promptly, with allowance for shipping times and queuing time at the analyst.

12 Preparation of Apparatus

12.1 Instruments shall be routinely tested in accordance with manufacturer recommendations to assure proper performance. The instrument vacuum shall be 1.0E-7 Torr or better during the analysis.

13 Calibration and Standardization

13.1 Proper instrument calibration is necessary to provide the most accurate and reproducible results, particularly if results are compared among different laboratories. Instrument calibration for sensitivity factors and binding energies shall be performed in accordance with the instrument manufacturer recommendations or other accepted method, such as that provided in ASTM E902.

13.2 The general ESCA calibration procedures described above are suitable for most analyses and provide reasonably accurate relative quantitative information regarding the surface chemistry. However, in order to establish the most accurate measurement practical and to maintain the desired level of reproducibility over time, an application-specific statistical process control (SPC) shall be established for this test method to determine the appropriate sensitivity factors for Cr, Fe, Ni and Mo in 316L stainless steel. The bulk composition of the SPC material should have an assay consistent with the acceptable composition range of 316L for Cr, Fe, Ni and Mo, as set forth in ASTM A276. The bulk composition of the SPC material should be determined by methods consistent with ASTM A751. The relative sensitivity factors established for the quantification of data should reflect the nominal composition of the bulk 316L SPC standard after a sputter cleaning sufficient to remove any surface contamination and the oxide passive layer. A $\pm 3\sigma$ relative precision should be established from a minimum of 10 SPC measurements with the following tolerances:

Cr	± 10%
Fe	± 10%
Ni	± 25%
Mo	± 30%

As referenced from ASTM A276-97, a typical 316L material has a composition range in terms of wt% of:

Cr	16–18
Ni	10–14
Mo	2–3
C	< 0.03
Mn	< 2.0
P	< 0.045
S	< 0.03
Si	< 1.0
N	< 0.1
Fe	Balance.

Note that ESCA data is reported in atomic percent.

13.3 The sputter conditions established for the SPC surface cleaning shall be the same as those established for the ESCA depth profile measurement part of this standard. A minimum sputtering etch cleaning of the SPC sample of ≥ 10 nanometers is recommended in order to remove surface contamination, the oxide passive layer and establish equilibrium. Note that the degree of preferential sputtering and other ion etching artifacts are a function of the matrix material and the ion gun conditions.

13.4 Calibration frequency of the application specific SPC should be designed to establish a record of the reproducibility and accuracy of the measurement, as reflected by the nominal composition of the 316L standard. A minimum frequency of one per week is recommended, or immediately prior to performing a measurement in accordance with this test method.

13.5 A sputter rate calibration shall be performed prior to an ESCA profile measurement conducted in accordance to this test method. The ion sputter rate determination shall be made using standard thin films of 100 nanometers or less of SiO_2 on Si. The method of determining the thickness of the oxide film shall be based upon the oxygen concentration profile. The oxide – substrate interface shall be specified as the point at which the oxygen concentration decreases to ½ its maximum value in the SiO_2 film, ignoring the first sputter cycle.

13.6 Multiple samples may be analyzed following a single sputter rate determination if the ion gun parameters have not been adjusted and the ion gun performance is documented as stable over the period in question.

14 Procedure

14.1 *As-Received Surface Analysis*— The sample is to be mounted in accordance with manufacturer's recommendations and in a manner consistent with ultra-high vacuum surface analytical procedures. Some of these practices are detailed in ASTM-E1078. The area to be analyzed should be mounted parallel to the sample holder surface so that TOA is well known.

14.1.1 Place the sample in the ESCA introduction chamber for pump down. Transfer to the analytical chamber at the manufacturer's recommended base pressure. Align the sample with respect to the X-ray beam and analyzer so that optimum count rate from the desired analytical location is obtained. The use of a collimated high voltage electron beam to align the sample should be avoided, as this may pyrolyze surface carbon and potentially alter surface oxide chemistry. The surface area to be analyzed should be free of visible particles and large defect features, if possible.

14.1.2 A beam size as close to 1 mm as possible should be used to ensure measurement of a representative surface. If surface curvature is great (e.g., < 1/4" tubing), a smaller beam may be employed. Elemental survey data (0–1100 eV) are to be measured from the sample surface to determine the elements present and their approximate surface abundance. A high throughput analyzer setting may be used to obtain a signal to noise ratio (S/N) sufficient to detect common surface contaminants such as sulfur and phosphorus at one atomic percent or better.

14.1.3 Using instrument settings sufficient to provide a FWHM peak width of 1.0 eV or less on Au ($4f_{7/2}$), measure chromium, iron, and carbon regions. A typical region width is 20 eV. Suggested ranges are as follows: Cr ($2p_{3/2}$) from 570 to 590 eV, Fe ($2p_{3/2}$) from 700 to 720 eV, and C (1s) from 275 to 295 eV. Signal to noise ratios of greater than 20 are suggested.

14.1.4 A consistent method of data reduction of high-resolution surface spectra is necessary in order to provide meaningful comparison of the relative Cr:Fe ratios.

14.1.5 The spectra shall be charge compensated with respect to the maximum of the Cr ($2p_{3/2}$) set to 577 eV. An iterated Shirley method of background subtraction shall be applied to the Fe ($2p_{3/2}$) and Cr ($2p_{3/2}$) spectral regions, using a minimum of three iterations.

14.1.6 The curve fit regions shall typically extend from:

Cr ($2p_{3/2}$)	570–582 eV
Fe ($2p_{3/2}$)	704–717 eV

14.1.7 The curve fit peak parameters should be initialized as follows:

Cr ($2p_{3/2}$)	Peak Position	FWHM	% gaussian
1	574	1.5	80
2	576.5	2.0	80
3	577.5	2.0	80

Fe ($2p_{3/2}$)	Peak Position	FWHM	% gaussian
1	707	1.0	80
2	708	1.0	80
3	710	1.4	80
4	711.5	1.4	80
5	713	1.4	80

14.1.8 The curve fit routine should apply the following tolerances for the band limit parameters of all peaks defined above:

FWHM delta	≤ 0.2 eV
% gaussian delta	≤ 10%
Curve fit position delta	≤ 0.25 eV

14.1.9 An automated form of data reduction is recommended to enhance reproducibility and minimize analyst subjectivity associated with the curve fit procedure. If it is necessary to deviate from the curve fit parameters outlined above in order to obtain a satisfactory curve fit it should be noted in the formal report. Possible sources for the anomalous behavior include an excessive concentration of iron oxide or a sufficiently aged sample surface, such that the oxide surface chemistry and structure has modified.

14.2 *Depth Profile Analysis*— The ESCA depth profile may be performed following acquisition of the initial as-received surface survey scan and high-resolution spectra using the same sample x-y position and take-off angle of 35°.

14.2.1 The depth profile may be acquired in either continuous mode (simultaneous sputter etching and data acquisition) or alternating sputter etch/data acquisition mode. The following acquisition windows are recommended:

Spectral line	Lower limit	Range
C	280 eV	15 eV
O	525 eV	15 eV
Cr	570 eV	15 eV
Ni	848 eV	15 eV
Fe	700 eV	25 eV

14.2.2 If only an elemental compositional profile is acquired, any pass energy may be selected as long as the remaining acquisition parameters defined by the number of sweeps, step size and dwell time result in ≤ 1.0at% detection of the matrix elements followed in the depth profile.

14.2.3 The composition profile should extend far enough into the depth of the sample to reach the base metal composition of the 316L material, but a minimum of 100Å from the surface as referenced to the calibrated sputter rate in SiO_2.

15 Calculations and Interpretation of Results

15.1 Most manufacturers supply software for determination of elemental composition. The elemental composition should be calculated using sensitivity factors appropriate to the instrument, each element, and resolution settings for each measurement.

15.2 The total Cr/Fe ratio is calculated by adding peak areas from all species of each element, adjusting for different numbers of scans and sensitivity factors, and dividing the Cr result by the Fe result. The Cr oxide/ Fe oxide ratio is calculated in a similar manner, except that only peaks 2 and 3 for Cr and only peaks 3 through 5 for Fe (oxide species) are used. The formulas are as follows:

$$\text{Total Cr/Fe} = \frac{(\Sigma \text{ Cr peak areas})/\text{\# Cr scans/Cr sensitivity factor}}{(\Sigma \text{ Fe peak areas})/\text{\# Fe scans/Fe sensitivity factor}}$$

$$\frac{\text{Cr Oxide/}}{\text{Fe Oxide}} = \frac{(\Sigma \text{ Cr oxide peak areas})/\text{\# Cr scans/Cr sens. factor}}{(\Sigma \text{ Fe oxide peak areas})/\text{\# Fe scans/Fe sens. factor}}$$

16 Reporting Results

16.1 *As-Received Surface Results* — A tabular summary of the elemental composition of all elements detected in the surface survey spectrum is to be supplied with the associated elemental survey spectrum. If sample preparation has been done by other than the component manufacturer all tables of as-received surface analysis results shall include a note stating: "Sample preparation was not performed by the component manufacturer. Results are not to be interpreted as indicative of the component manufacturer's quality of cleaning and packaging procedures."

16.1.1 Tabular summaries of total Cr/Fe ratio and Cr oxide/ Fe oxide are also to be supplied, with associated $Cr(2p_{3/2})$, $Fe(2p_{3/2})$, and C(1s) narrow region spectra.

16.1.2 Acquisition parameters, including manufacturer, model and TOA; X-ray source (Al or Mg); beam size; and other pertinent settings are to be supplied. Analyst identity and analysis date are also required information. Each table and graph must be clearly labeled with sample identification.

16.2 *Depth Profile Results* — Compositional depth profile data plots shall display the atomic concentration of Fe, Cr, Ni, C, and O at minimum versus the sputter time or the equivalent depth from the calibrated sputter rate in SiO_2.

16.2.1 The method applied to determine the oxide thickness shall be specified in the report. A commonly accepted method of quantifying the oxide thickness is determined as the sputter time/depth at which the oxygen concentration decreases to ½ the maximum value. The carbon thickness may be determined similarly.

APPENDIX 1
DISCUSSION OF EFFECTS OF DEPTH OF ANALYSIS ON DEPTH PROFILE ANALYSIS BY ELECTRON SPECTROSCOPY FOR CHEMICAL ANALYSIS OF PASSIVATED STAINLESS STEEL

NOTE: This appendix is being balloted as an official part of SEMI F## by full letter ballot procedure, but the recommendation in this appendix are optional and are not required to conform to this standard. This appendix is derived from presentations made to the SEMI Surface Analysis Task Force.

A1-1.1 The purpose of this appendix is to describe the ESCA (sometimes referred to as X-Ray Photoelectron Spectroscopy (XPS)) technique and explain the interpretation of the depth profile analysis with respect to the structure and composition of the passive oxide layer on stainless steel. The effect of the depth of analysis on the measured chromium to iron ratio, the oxide thickness, and the depth of enrichment is discussed. The discussion applies to depth profile analyses performed by Auger electron spectroscopy, also.

A1-1.2 *ESCA* — The ESCA technique makes use of an X-ray beam for a probe. The surface of interest is illuminated with X-rays, typically Al kα radiation, which has a well-defined energy of 1486.6 eV. When an x-ray photon and an electron interact, the electron adsorbs all of the energy of the photon, 1486.5 eV; it cannot react with it partially. The electron then has sufficient energy to leave the atom and move into the matrix. The electron's energy in the matrix is 1486.6 eV minus its binding energy to the atom from which it escaped. Its binding energy is indicative of the element or compound from which it came and the orbital from which it was removed. Such an electron is termed a "photoelectron".

A1-1.3 In a typical ESCA instrument, a monochromatic beam of x-rays is focused at a point of interest on a surface. A cloud of electrons is generated at the surface by the x-rays. This electron cloud is made up of secondary electrons, Auger electrons and photoelectrons. (NOTE: The generation of Auger electrons is a byproduct of the process. If the photoelectron was an inner shell electron, when it leaves the atom it creates an ion in an excited state. Once the ion is created it can de-excite via the Auger process. The presence of Auger electrons in an ESCA survey can be used to determine what elements were present.) The mechanisms of ESCA photoelectron and Auger electron generation are illustrated in Figure A1-1.

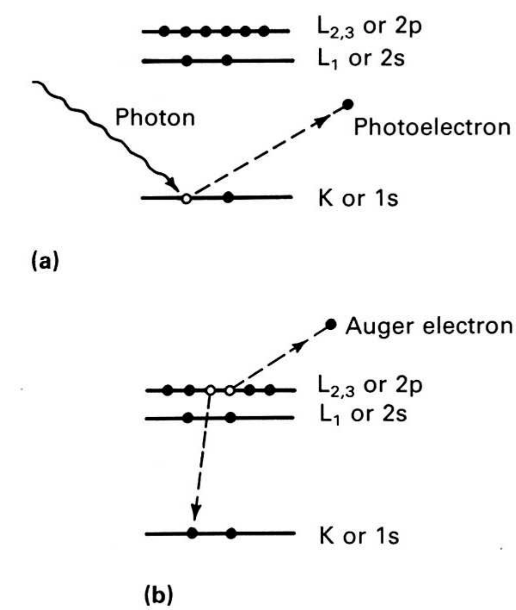

Figure A1-1
Schematic representation of the ESCA photoelectron and Auger electron generation processes.

A1-1.4 An electron lens is focused at the same point as the x-ray beam and a portion of the electron cloud enters the lens. From the lens, the electrons enter an electron analyzer that measures the number of electrons as a function of their kinetic energy. The kinetic energy is subtracted from the incident x-ray photon energy, and the resulting binding energy is then plotted as the x-axis with the number of electrons at each energy on the y-axis. An example is shown in Figure A1-2. The binding energy can be indicative not only of the element from which the electron came but also the chemical bonding state of the element.

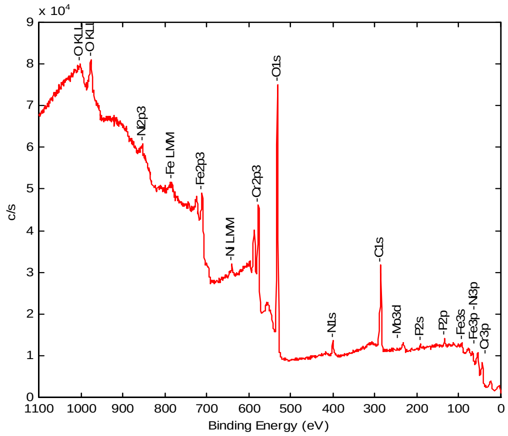

Figure A1-2
Example of ESCA spectrum of the oxide passive surface of stainless steel

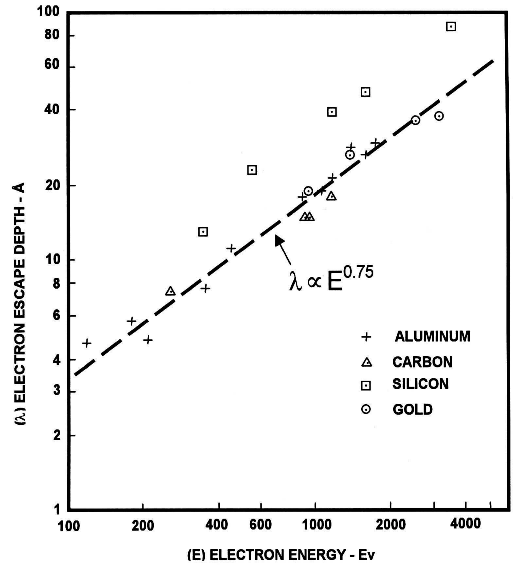

Figure A1-3
The electron escape depth of low energy electrons in some metals.

A1-1.5 *Illuminated Volume and Surface Sensitivity* — The incident x-ray beam penetrates well below the surface. Photoelectrons and Auger electrons are generated all through this illuminated volume. The inelastic mean free path (IMFP) of an electron in a solid is the mean distance through the solid that an electron can travel before losing some of its energy (suffering an inelastic interaction). The IMFP is a function of the electron's energy and the matrix through which it is traveling. Electrons with an energy of approximately 1 keV have an IMFP of about 10 Å. That means that a 1 keV electron will travel, on average, 10 Å before interacting with the matrix and giving up some of its energy. In other words it will be scattered to lower energy and will not be part of the photoelectron or Auger electron line for its element. The IMFP is a statistical parameter and an electron may travel several IMFPs before having a collision. The "several IMFPs" is called the escape depth of the electron, or the depth of analysis, as shown in Figure A1-3. Although ESCA and Auger are considered surface analytical tools, their depth of analysis is on the order of 50 Å, or about one to two times the depth of the oxide film found on a typical passivated stainless steel surface.

A1-1.6 *Depth of Analysis Function* — There has been some discussion with respect to the "Depth of Analysis Function". There is one school that believes that it is 5 IMFPs and another that uses 3 IMFPs. These two functions will be referred to as 5λ and 3λ respectively. It will be seen that it makes little difference which function is used even though the depth of the oxide films is of the order of the functions. These functions are seen in Figure A1-4, which shows the proportion of the total signal generated from each depth below the surface. The y-axis is in decimal and the x-axis is in angstroms from the surface. The first point of the 5λ curve is 0.16 at the 1st angstrom level. That means that 16% of the signal comes from the 1st angstrom, 14% from the 2nd angstrom level and so on down to 1% from the 25th angstrom level. Thus elements that do not appear on the surface or in the first 24 angstroms in from the surface, but do exist at the 25 Å level will be detected.

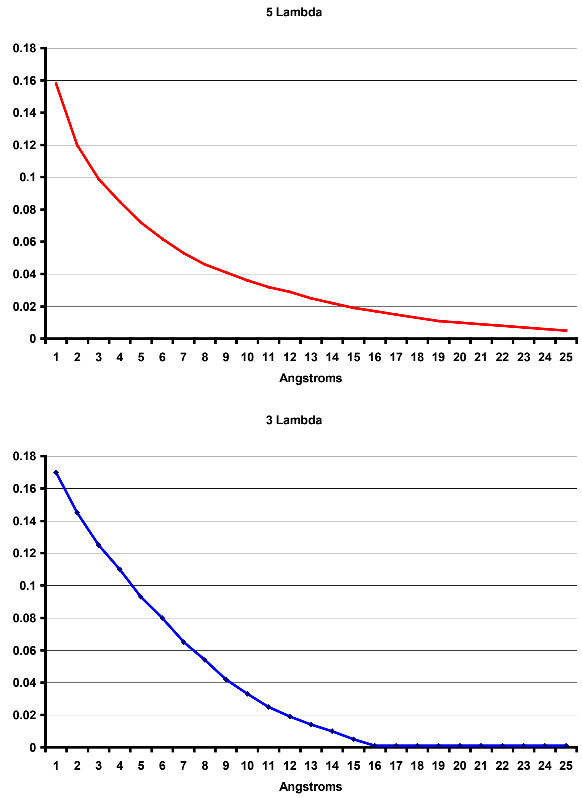

Figure A1-4
These two graphs represent the "Depth of Analysis" that will be seen when analyzing 1 keV electrons. The top curve is the 5λ curve and bottom the 3λ.

A1-1.7 *Modeling* — Figure A1-5 is the composition profile of a "perfect" oxide. It represents 25 Å of pure Cr_2O_3 on an atomically flat 316L stainless steel surface, with no surface or interfacial contamination present. Figures A1-6a and A1-6b are the theoretical depth profiles derived by assuming a depth of analysis of 5λ and 3λ respectively. The first factor to note is that Fe, Ni and Mo appear most or all of the way through the depth profile of the oxide due to the contribution of the metal substrate to the detected signal, the "depth of analysis" effect as introduced above. 1 keV electrons can escape from as deep as 25 Å. This must be appreciated when interpreting these depth profiles.

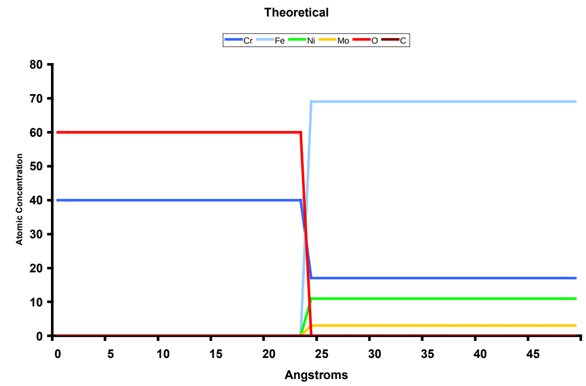

Figure A1-5
Composition versus depth of a pure Cr_2O_3 layer on stainless steel.

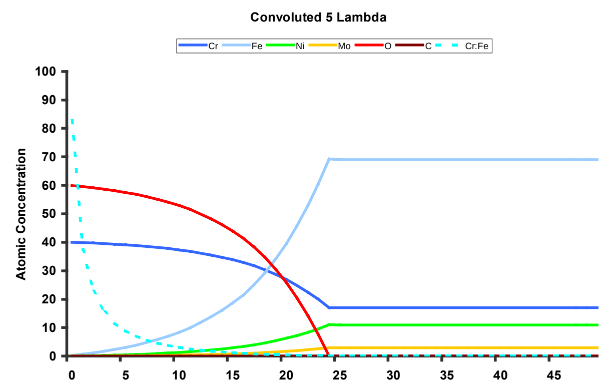

Figure A1-6a
Theoretical depth profile of Figure A1-5 assuming 5λ depth of analysis.

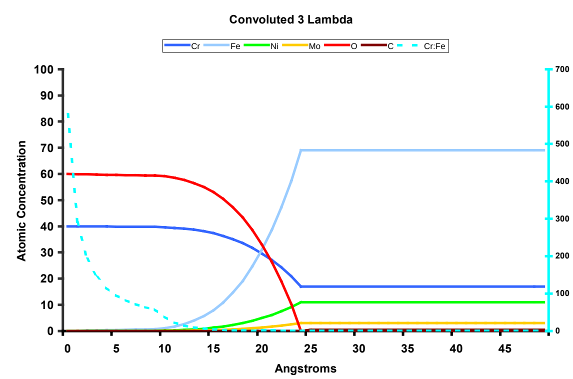

Figure A1-6b
Theoretical depth profile of Figure A1-5 assuming 3λ depth of analysis.

A1-1.8 The second factor to notice is the thickness of the oxide. Historically, the FWHM of the oxygen profile has been used as the measure of oxide thickness.

It is apparent in Figures A1-5 and A1-6 that this underestimates the oxide thickness by 15 to 20%.

A1-1.8.1 It should also be noted that the Cr:Fe ratio measured from Figures A1-5 and A1-6 has its maximum value at the initial surface, decreasing as the depth profile progresses, whereas the actual Cr:Fe ratio in Figure A1-5 is infinite down to 25 Å. Most actual depth profiles exhibit a maximum of the Cr:Fe ratio at some depth below the initial surface, referred to as the depth of maximum enrichment. This is a consequence of variation in the actual composition of the oxide, possibly having a higher concentration of Fe near the surface, a phenomenon commonly termed a "detached iron oxide layer", or of contamination on the surface, generally hydrocarbons. These are discussed in the next section.

A1-1.9 *Effects of Detached Iron Oxide Layer and Surface Contamination* — The model composition profile of Figure A1-7 shows 3 Å of pure Fe_2O_3 over 22 Å of pure Cr_2O_3 on 316L stainless steel. This is a model of a detached iron oxide layer. Figure A1-8 is the theoretical depth profile of this model derived assuming a depth of analysis of 5 lambda. Note that the initial Cr value in the profile is higher than the Fe value, even though the surface is pure Fe_2O_3. This is a consequence of the depth of analysis detecting the Cr from levels beneath the surface. The Cr:Fe ratio for this model has its maximum value at 3 Å below the initial surface. The theoretical depth profile using a depth of analysis of 3λ is very similar.

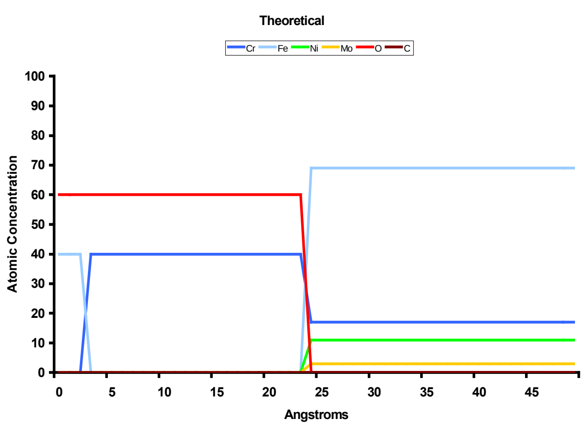

Figure A1-7
Composition versus depth of a Fe_2O_3 layer over a Cr_2O_3 layer on stainless steel.

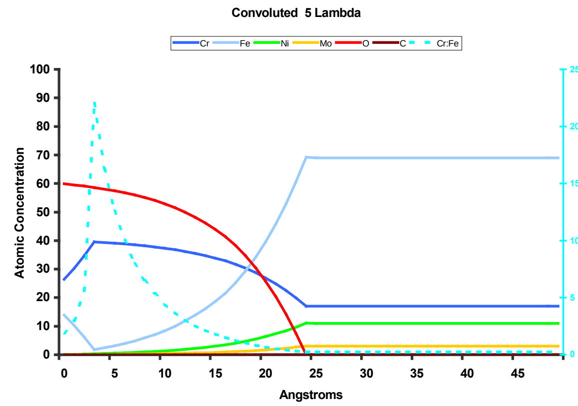

Figure A1-8
Theoretical depth profile of Figure A1-7 assuming 5λ depth of analysis.

A1-1.10 The model composition profile of Figure A1-9 shows 3 Å of pure carbon over 22 Å of pure Cr_2O_3 on 316L stainless steel, representing an idealized model of the adsorbed hydrocarbon contamination generally found on stainless steel surfaces exposed to the atmosphere. Figure A1-10 is the theoretical depth profile of this model assuming a depth of analysis of 5λ. In this case the O, Cr and Fe atomic concentration values are reduced by the presence of the carbon until the depth profiling proceeds past the carbon, but they have the same relative values (ie: same Cr:Fe ratio) versus depth as derived in the uncontaminated model. The maximum of the Cr:Fe ratio is seen to be at the initial surface. Although the actual oxide thickness is less in this model, the FWHM measure of the oxide thickness from the depth profile is the same due to the presence of the carbon layer. Note that the Oxygen concentration profile initially increases to a maximum, then decreases. This is typical of Oxygen concentration profiles seen on actual samples, which will generally have some adsorbed hydrocarbon contamination on the surface.

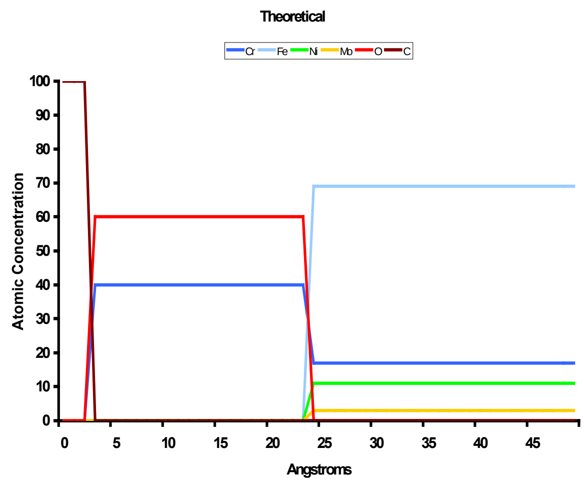

Figure A1-9
Composition versus depth of a carbon layer over a Cr_2O_3 layer on stainless steel.

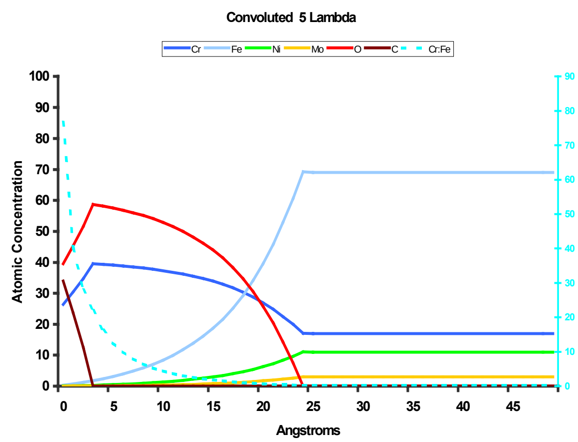

Figure A1-10
Theoretical depth profile of Figure A1-9 assuming 5λ depth of analysis.

A1-1.11 The model composition profile of Figure A1-11 shows a 3 angstrom carbon layer over 3 Å of pure Fe_2O_3 over 19 Å of pure Cr_2O_3 on 316L stainless steel. Figure A1-12 is the theoretical depth profile of this model assuming a depth of analysis of 5λ. This profile is seen to be similar to the depth profiles generally observed for passivated stainless steel. The Cr:Fe ratio maximum occurs below the initial surface, and the initial surface atomic concentrations of the elements of interest are diluted by the presence of the carbon layer on the surface. The oxide thickness, as measured by the FWHM technique, is affected by both the presence of the carbon layer and the depth of analysis.

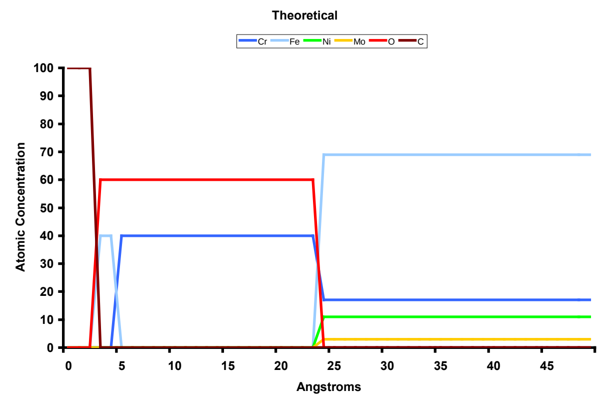

Figure A1-11
Composition versus depth of a carbon layer over a Fe_2O_3 layer over a Cr_2O_3 layer on stainless steel.

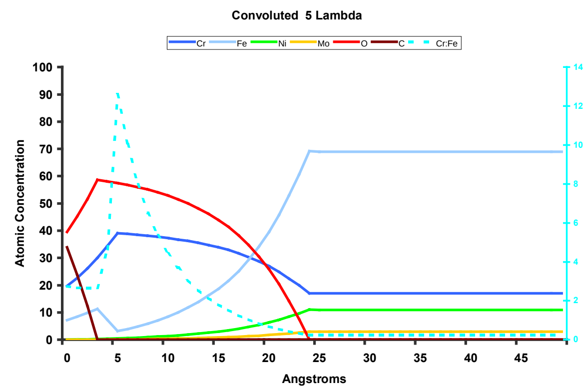

Figure A1-12
Theoretical depth profile of Figure A1-11 assuming 5λ depth of analysis.

A1-1.12 It must be emphasized that these derived depth profiles are for models with perfect interfaces and perfect compositions instead of the compositional gradients observed in real systems. Additional measurement uncertainties result from roughness and non-planarity of the surface, and from differential sputtering rates for different chemical species during depth profiling.

A1-1.13 The depth profiles of real systems must be interpreted with an understanding of the effects described in this Appendix and a realization that they are not ideal. The same considerations pertain to Auger depth profile analysis.

SEMI F61-0301
GUIDE FOR ULTRAPURE WATER SYSTEM USED IN SEMICONDUCTOR PROCESSING

This guide was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org December 2000; to be published March 2001.

1 Purpose

1.1 This guide establishes the typical definitional requirements for an ultrapure water (UPW) system used in semiconductor manufacturing. It is intended to establish a common basis for developing detailed specifications in subsequent documents concerning design, performance and certification and monitoring of UPW systems.

1.2 This document may be used by users and suppliers as a basis for developing site-specific UPW specifications and performance criteria.

2 Scope

2.1 This guide applies to ultrapure water systems used in semiconductor manufacturing facilities for supplying high purity water for chemical dilutions, wafer processing and other manufacturing processes.

2.2 This guide can be used to understand the design elements and functionality of all UPW systems, which includes a Reverse Osmosis (RO) and a Deionization (DI) process. However, it is most applicable to newer designed UPW systems that support submicron linewidth device manufacturing.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guide does not define the actual specifications generally negotiated between the user and the manufacturer of the UPW system, against which water samples are tested and qualification is passed.

3.2 This guide does not address the testing and prequalification of materials, subassemblies, or components used in a UPW system.

3.3 This guide does not address the protocols and requirements defined by the manufacturer concerning the installation of the UPW system.

3.4 This guide does not address the type, level, or frequency of testing necessary and appropriate for ongoing monitoring of a UPW system.

3.5 This guide does not address the frequency or scope of ongoing maintenance for UPW systems including change out of resin beds and replacement of filters.

3.6 This guide does not intend to cover any of the important safety considerations that relate to the proper installation, operation, or maintenance of a UPW system.

4 Terminology

4.1 *Acronyms and Abbreviations*

4.1.1 *TOC* — Total organic carbon, also Total Oxidizable Carbon. Refers to organic compounds.

4.1.2 *UPW* — Ultrapure Water System consisting of multiple components including a Reverse Osmosis (RO) and a Deionization (DI) process.

4.2 *Definitions*

4.2.1 *activated Carbon* — a media filter used to remove oxidizing agents, like chlorine and chloramines, and remove (adsorb) certain TOC compounds.

4.2.2 *anion* — a negatively charged ion.

4.2.3 *cation* — a positively charged ion.

4.2.4 *clarifier* — a piece of water treatment equipment, typically used at municipal drinking water plants, to remove suspended solids from surface water and/or to soften surface water.

4.2.5 *degasification* — the removal of a certain amount of volatile compounds dissolved in water.

4.2.6 *deionization* (DI) — the removal of undesirable ions from water.

4.2.7 *DI storage* — generally refers to a storage tank that contains DI water, located between the primary and polishing ion exchange subsystems.

4.2.8 *DI (deionized) water* — generally refers to water that has passed through a full-train ion exchange system or RO water that has been polished by ion exchange.

4.2.9 *dissolved solids* — contaminants in water that are so small that they are uniformly distributed, including ions and the smallest TOC and silica compounds.

4.2.10 *dual-beds* — an ion exchange scheme where a cation exchange unit is followed by an anion exchange unit.

4.2.11 *electrodeionization (EDI)* — a water treatment technology that utilizes mixed-bed ion exchange plus an electrical potential to remove undesirable dissolved solids. Also referred to in the industry as CDI (Continuous Deionization).

4.2.12 *filtration* — the removal of suspended solids by passing water through some form of solid or semi-solid medium.

4.2.13 *final filter* — generally the final treatment step in a UPW system; used to remove suspended solids.

4.2.14 *full-train DI* — an ion exchange scheme where a cation exchange unit is followed by an anion exchange unit and a mixed-bed ion exchange unit.

4.2.15 *ground water* — water located below the surface of the earth, also called *well water*.

4.2.16 *heat exchanger* — a piece of equipment used to control the temperature of a water stream.

4.2.17 *ion exchange* — a water treatment technology used in a high-purity water treatment application to exchange undesirable cations for hydrogen ions and undesirable anions for hydroxide ions.

4.2.18 *loop* — the distribution system that includes the continuous circulation of UPW from the Final Filter back to the DI storage tank. End users draw off of the loop.

4.2.19 *low-pressure UV units* — units that use UV lamps that have a slight vacuum within. Typically, low-pressure lamps are called *254 nm* for ozone destruction and bacterial inactivation or *185 nm* for TOC reduction.

4.2.20 *medium-pressure UV units* — units that use UV lamps that have a positive pressure within. Used with bacterial inactivation/ozone destruction lamps or TOC reduction lamps.

4.2.21 *microfiltration* — generally refers to filters designed to remove suspended solids less then one micron in size but greater than 0.1 micron in size.

4.2.22 *mixed-beds* — ion exchange vessels used to polish already purified water, in which both cation and anion exchange occurs.

4.2.23 *multimedia filter* — generally refers to a suspended-solids removal piece of equipment that contains two or more filtering media such as anthracite and sand, or anthracite, sand and garnet.

4.2.24 *Ozone* — Ozone (O_3) may be injected into the *Supply* and/or *Return* line to control microbiological contaminants and also to enhance the action of TOC breakdown in downstream TOC reducing UV units.

4.2.25 *polishing ion exchange* — a cation/anion exchange step located downstream of primary ion exchange.

4.2.26 *pretreated water* — generally refers to treated water that is fed to reverse osmosis (RO) units.

4.2.27 *primary ion exchange* — the first cation/anion exchange step in a high purity water treatment scheme.

4.2.28 *raw water* — any untreated natural water like river water, lake water, ground water, or seawater. May also refer to the treated feed water that enters a plant from a municipal drinking water source or other source.

4.2.29 *return* — the UPW sent to but not used by end users that returns to the DI storage tank.

4.2.30 *reverse osmosis (RO)* — a filtration technology that utilizes a semi-permeable membrane to remove essentially all suspended solids and the vast majority of all dissolved solids. Generally refers to water (permeate) that has passed through a reverse osmosis (RO) membrane.

4.2.31 *RO storage* — generally refers to a storage tank that contains RO water.

4.2.32 *scale inhibitor* — a chemical used to minimize or eliminate the precipitation of slightly-soluble salts, like calcium carbonate (limestone) or calcium sulfate (gypsum), within water treatment equipment.

4.2.33 *supply* — the UPW sent to end users.

4.2.34 *surface water* — water located on the surface of the earth, such as river water, lake water, and seawater.

4.2.35 *TOC* — total organic carbon, also Total Oxidizable Carbon. Refers to organic compounds.

4.2.36 *treated water* — water that has passed through water treatment equipment and/or received chemical injections in order to modify the dissolved and/or suspended solids content of the water.

4.2.37 *ultrafiltration* — generally refers to filters designed to remove all submicron suspended solids.

4.2.38 *ultraviolet (UV)* — electromagnetic energy with around a 100–400 nm (nanometer) wavelength.

4.2.39 *UPW (ultra pure water)* — the highest purity water produced by a semiconductor water treatment system, which is sent to the end users for use in manufacturing.

5 General Requirements

5.1 *Materials* — Components of the UPW system must be appropriate to the application and conform to electrical, mechanical, and purity requirements, as well as the corrosive properties of the UPW chemistry. These requirements are defined by the physical installation environment, local and national code interpretations, process requirements, and delivery specifications.

5.2 *System Installation* — The UPW system is installed according to a protocol that ensures mechanical integrity, leakproof operation, and no or minimal contamination being added from distribution throughout the system.

5.3 *Acceptance Tests* — Acceptance tests are conducted on each subsystem or system produced. Such tests may include performance demonstrations, demonstrations of reliability criteria, and achievement of purity standards. Such tests are the basis for acceptance or rejection by the purchaser against a pre-negotiated set of criteria for the performance of the system.

5.4 *Qualification Testing* — Qualification testing may include tests for resistivity, temperature, pressure, TOC, dissolved oxygen, particle levels, bacteria, total silica, dissolved silica, non-volatile residue, ions, and metals.

5.5 *Monitoring* — UPW systems are monitored for continuing performance against desired and achievable levels of quality. Action limits are generally set to determine when system performance suggests that corrective action is required.

5.6 *UPW specifications* — UPW systems are generally guaranteed to deliver a certain quality of water on an ongoing basis. The guaranteed performance is established in advance between the UPW equipment manufacturer and the system owner. Both qualification testing and monitoring testing use the guaranteed specifications to determine the parameters and levels of purity to be tested.

5.7 *Recycle/Reclaim Opportunities* — There can be several opportunities for using water within a UPW system, and should be recognized during the design phase when possible. Examples are; use of 1st pass reject for cooling tower make-up water, returning UF reject to Primary or Feed water Tank, re-use of last stage rinse waters as UPW for lower grade use areas, i.e., CMP, isolation of CMP waste stream, for possible reclaim/reuse.

6 Source Water

6.1 *Raw Water* — is the raw material from which UPW is made. Untreated raw water is natural water that is obtained from a surface source such as a lake or river, or from a ground water source. The raw water to a UPW system is most frequently treated *Municipal Drinking Water*.

6.2 *Municipal Drinking Water* — Most natural raw waters must be treated in order to produce drinking water that meets federal and state requirements. There are upper limits for inorganic contaminants (e.g., asbestos, arsenic, copper, and lead), pesticides, volatile organic chemicals (e.g., benzene, trichloroethylene, toluene, and xylene), turbidity, microbiological contaminants, and radiological contaminants (e.g., radon 226, radon 228, tritium, and strontium 90). *Municipal Water Treatment* may utilize only chlorination, or filtration and chlorination for certain ground water sources. For many surface water sources, coagulation (injection of aluminum or iron salts), flocculation (injection of a long-chain polymer), sedimentation, lime or lime/soda ash softening, filtration, chlorination or chloramination (chlorine plus ammonia) and other steps may be required.

7 Major Treatment Processes

7.1 *Pretreatment* includes all of the water treatment steps ahead of the *Reverse Osmosis Membrane Treatment* step. These steps are primarily required to protect the membrane units from scaling with sparingly soluble salts, fouling with living or non-living suspended particles, or chemical attack by pH, oxidizing agents or other dissolved contaminants. Pretreatment equipment may include media filtration, micro filtration, or ultrafiltration (bulk suspended solids removal), 1–5 micron cartridge filtration (polishing step for suspended solids removal), sodium-cycle cation exchange (softening, to remove scale-forming cations), acid injection (to minimize cellulose acetate membrane damage and/or to control carbonate scales), scale inhibitor injection (to control scaling), activated carbon filtration (to remove oxidizing agents and certain organic molecules), and sulfite ion injection (to remove oxidizing agents).

7.2 Reverse osmosis *Membrane Treatment* provides extremely high rejection of dissolved ions (charged atoms and molecules), organic (carbon containing) compounds, silica (silicon containing) compounds, and virtually complete rejection of suspended contaminants, but will not reject dissolved gases and volatile organic compounds as well. Reverse osmosis (RO) units may be configured in a *double-pass* arrangement consisting of two RO membrane units in series. *Permeate* (filtered water) from the first RO unit is sent to the second RO unit to be filtered again. It is not uncommon for the permeate from a double-pass RO unit to have a resistivity reading up to 0.5–4 Megohm-cm, with less than one milligram per liter of organic and silica contaminants. The more contaminants removed in the membrane treatment step, the lower the loading on the *Polishing* steps.

7.3 *Volatiles Removal* — The removal of dissolved oxygen, carbon dioxide, other gases, and volatile organic compounds is a necessary treatment step. The removal of these volatile contaminants is accomplished to acceptable levels in vacuum degasifiers and in membrane degasification units. The removal of volatiles that can form ions and the removal of volatile organic compounds reduce the loading on downstream *Polishing* equipment.

7.4 *Polishing* — The relatively low level of contaminants that were not removed in the *Membrane Treatment* and *Volatiles Removal* steps are polished down to acceptable levels in the *Polishing* steps. Ionic, organic, and silica contaminants are removed in typically two stages of *Ion Exchange* in series (primary beds and polishing beds). Organic compounds, measured as TOC (Total Organic Carbon, or Total Oxidizable Carbon), that are found downstream of the RO membrane units may be subjected to *TOC Reduction* ultraviolet (UV) irradiation (185 nanometer low pressure units or medium pressure units) to convert most of them into ionic compounds that can be effectively removed by *Primary Ion Exchange Units* (usually consisting of Separate Beds, Mixed Beds or EDI/CDI/E-Cell). TOC compounds that exit the primary ion exchange units are typically subjected to TOC reducing UV irradiation to break them into ionized compounds to be removed by the *Polishing Ion Exchange Units*. The vast majority of all living suspended particles (mainly bacteria) that enter any 254 nm UV unit are inactivated. Downstream filters with a pore size of less than or equal to 0.45 micron remove the inactivated bacterial bodies. The final filter prior to *Distribution* typically has a pore size of less than 0.2 micron.

8 Distribution

8.1 *Distribution* is frequently composed of one or more *Loops*. Each loop consists of UPW that continuously recirculates through appropriate piping from the final filters, to the manufacturing areas requiring UPW (end users), and back to a tank located within the *Polishing* section to be polished again. The UPW to the end-user area is commonly called the *Supply*. The UPW that travels from the end-user area back to the water treatment area is commonly called the *Return*. Ozone may be injected into the *Supply* and/or *Return* line to control microbiological contaminants and also to enhance the action of TOC breakdown in downstream TOC reducing UV units. Sometimes ozone is injected into the *Supply* line for similar reasons (requires de-ozonation at the end-use points). Sometimes the UPW in the distribution loop is heated (hot loop) for particular processes.

8.2 *Basic System Components*

8.3 *General* — Each UPW system contains certain basic components and a variety of design options to meet particular customer and facility needs. An example of a UPW system is shown in Figure 1 attached.

SEMI F62-0701
TEST METHOD FOR DETERMINING MASS FLOW CONTROLLER PERFORMANCE CHARACTERISITICS FROM AMBIENT AND GAS TEMPERATURE EFFECTS

This specification was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Facilities Committee on March 22, 2001. Initially available at www.semi.org May 2001; to be published July 2001.

1 Purpose

1.1 The purpose of this document is to define a method for testing MFCs being considered for installation into a gas distribution system and to quantify ambient and gas temperature effects on the MFC's indicated and actual flow.

2 Scope

2.1 This test method applies to metal and polymer sealed MFCs with flow rates up to 30 slpm. The tests include those listed below and are to be performed in the following order:

1. Ambient Temperature Effects (Steady State and Transient)
2. Gas Temperature Effects (Steady State and Transient)

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This method evaluates mass flow controllers in typically encountered, realistic operating conditions.

3.2 This test method does not address operational influences outside of the manufacturer's published limitations.

4 Referenced Standards

4.1 None.

5 Terminology

5.1 *Acronyms and Abbreviations*

5.1.1 *DUT* — device under test

5.1.2 *g* — gravity

5.1.3 *kPa* — kiloPascal

5.1.4 *MFC* — mass flow controller

5.1.5 *NIST* — National Institute of Standard Technologies

5.1.6 *sccm* — standard cubic centimeters per minute

5.1.7 *slpm* — standard liters per minute

5.2 *Definitions*

5.2.1 *stability, long term* — reading ± 2% for over one hour.

5.2.2 *stability, short term* — reading ± 2% within five minutes.

5.2.3 *zero setpoint* — manufacturer's setpoint for no flow from the MFC.

5.3 *Descriptions of Terms*

5.3.1 MFC_1 — inlet mass flow controller.

5.3.2 T_a — the temperature in the environmental control chamber.

5.3.3 T_g — gas temperature at the inlet to the DUT.

5.3.4 T_{max} — maximum manufacturer-rated temperature for an MFC.

5.3.5 T_{min} — 20°C or manufacturer rated minimum temperature, whichever is greater.

5.3.6 TC_g — temperature coefficient due to changing gas temperature of DUT.

5.3.7 TC_e — temperature coefficient due to changing environmental temperature of DUT.

5.3.8 Q_a — for the purpose of this method, the output value of the flow standard in units of mass flow.

5.3.9 Q_{ind} — for the purpose of this method, the output value of the device under test in units of mass flow.

5.3.10 Q_{sp} — for the purpose of this method, the intended output in mass flow units for a particular setpoint.

5.3.11 V_a — valve A

5.3.12 V_b — valve B

5.3.13 $V_{I\,i}$ — inlet isolation valve

5.3.14 V_{io} — outlet isolation valve

6 Significance and Use

6.1 This test method defines a procedure for testing components being considered for installation in a gas distribution system. Application of this method is expected to yield data allowing an end user to choose among components tested for the purpose of qualification for this installation.

7 Apparatus

7.1 See Figures 1a and 1b for schematics of the set-ups.

7.2 *Flow Measurement Device*, National Institute of Standard Technologies (NIST) traceable and capable of measuring steady-state and transient flow characteristics, preferably with differential pressure sensors across a flow restriction. This device should have a relative accuracy of at least 2 to 1 with respect to the DUT.

7.3 *Temperature Measurement Device*, to measure test gas temperature, NIST traceable and capable of real-time measurement, with a low mass (< 0.05 g) sensor and with low thermal losses through the leads (< 0.3 mW/°C).

7.4 *Pressure Measurement Device*, to measure test gas pressure, NIST traceable, and capable of real-time measurement to measure test gas pressure.

7.5 *Gas Pressure Control Regulators*, to maintain test gas pressure at 275 kPa ± 5 kPa.

7.6 *Gas Temperature Control*, heat exchangers and heaters to maintain the gas temperature equal to the test temperature within ± 1 °C at the test flow rates.

7.7 *Environmental Chamber*, capable of stable temperature control (± 1°C) from at least T_{min} to a point exceeding the maximum rated MFC temperature by 10°C.

8 Reagents and Materials

8.1 *Test Gas*, clean, dry nitrogen.

8.2 *Tubing*, cleaned and maintained to have no adverse effects on the test.

8.3 *Valves*, capable of unimpaired operation at 100°C.

9 Safety Precautions

9.1 All manufacturers' recommendations should be followed and noted when testing the unit. Any safety precautions should always be followed.

9.2 This standard does not purport to address all of the safety problems, if any associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and to determine the applicability of regulatory limitations before using this method.

10 Technical Precautions

10.1 The flow standard may read a non-zero value due to heating of the gas in the test to determine transient effects on the zero. These readings should be noted.

11 Preparation of Apparatus

11.1 *Setup and Schematic*, (see Figure 1a) *Ambient Temperature Effects*

11.1.1 Install an ambient temperature sensing device within 5–10 centimeters horizontally adjacent to the MFC body. The probe should not be in contact with the MFC body or the environmental chamber walls.

11.1.2 Position the gas temperature sensor in the center of the gas stream no more than 10 cm upstream from the inlet surface of the MFC body.

11.1.3 After installation of the MFC, flow nitrogen at a 100% setpoint to purge the system for a sufficient time to remove atmospheric contamination.

11.1.4 If the MFC has a selectable Auto Zero function, note this on all data presentation documents before proceeding with the test.

11.1.5 Minimize the length of tubing between the heater and the device under test to reduce gas temperature changes.

11.2 *Setup and Schematic*, (see Figure 1b) *Gas Temperature Effects*

11.2.1 Install a base temperature sensing device, T_e adjacent to the MFC body. The probe should be in contact with the MFC body.

11.2.2 Install an ambient temperature sensing device within 5–10 centimeters horizontally adjacent to the MFC body. The probe should not be in contact with the MFC body or the environmental chamber walls.

11.2.3 Position the gas temperature sensor in the center of the gas stream no more than 10 cm upstream from the inlet surface of the MFC body.

11.2.4 After installation of the MFC, flow nitrogen at a 100% setpoint to purge the system for a sufficient time to remove atmospheric contamination.

11.2.5 If the MFC has a selectable Auto Zero function, note this on all data presentation documents before proceeding with the test.

12 Calibration and Standardization

12.1 The flow standard, temperature standards, and pressure standards used are to be NIST traceable.

12.2 All ancillary equipment must be calibrated and maintained to the manufacturer's recommendations. Current calibration records must be maintained.

13 Conditioning

13.1 Reference conditions as listed in Appendix 1 are to be maintained unless otherwise noted.

14 Procedure

14.1 *Environmental Temperature Effect*

14.1.1 Install the test specimen in the test set-up according to the manufacturer's recommendations, see Figure 1a.

14.1.2 Set the environmental chamber temperature (T_e) to T_{min} and allow it to stabilize for one hour. Ensure that gas temperature (T_g) and ambient temperature (T_e) are within 2°C of each other before beginning data collection.

14.1.3 Close V_{ii} and V_{io}, and record the MFC Q_{ind} at a zero setpoint.

14.1.4 Open V_{ii} and V_{io}. Change the MFC flow setpoints to 25%, 50%, 75%, and 100% of full rated scale.

NOTE 1: T_g and T_e must be within 2°C of each other.

14.1.5 At each setpoint, record T_g, Q_{ind} once, and a minimum of 10 values at a maximum of five second intervals of T_e and Q_a for at least 60 seconds. Record the average of the 10 values as shown in Table 3.

14.1.6 Repeat Section 14.1.3.

14.1.7 Maintain the setpoint at zero and change the environmental chamber temperature T_{em} to the next level indicated in Figure 2.

14.1.8 Record the Q_{ind} at the zero setpoint in real time (max 30-second intervals) as the temperature T_e is changing. See example of data collection shown in Table 4.

14.1.9 Allow temperature T_e to stabilize for a minimum of one hour.

NOTE 2: The time for the T_e to stabilize at each level should be increased to two hours if the indicated flow at T_e level 1 and 9, or 2 and 8, or 3 and 7, or 4 and 6 are not within 5% of each other. See Figure 2.

14.1.10 Open the isolation valves V_{ii} and V_{io}.

14.1.11 Repeat Sections 14.1.3–14.1.9 for each T_e level, as shown in Figure 2.

14.2 *Gas Temperature Effect*

14.2.1 Install the test specimen in the test set-up according to the manufacturer's recommendations, see Figure 1b.

14.2.2 Allow the system to stabilize for one hour. See Figure 1. Refer to Figure 4 for flow chart.

14.2.3 Set the heater temperature to raise the gas temperature, T_g, such that T_g is elevated 10°C above ambient.

14.2.4 Simultaneously open V_{ii} and close V_{io}. Continue to monitor T_g, T_e, indicated flow, and actual flow for one hour. If after one hour, the actual flow or T_g has not achieved long-term stability, or if T_g is not equal to T_e + 10 (±2°C), continue until these conditions are met or until an additional one hour period has elapsed. If long-term stability is not achieved, note this occurrence and record the average value of 10 samples minimum taken at maximum five-second intervals for each of T_g, T_e, indicated flow, and actual flow as shown in Table 5, for at least 60 seconds.

NOTE 3: If T_g is not 10°C above ambient return to 14.2.3 and adjust the temperature.

14.2.5 Repeat 14.2.3–14.2.4 until all required setpoints have been run.

15 Calculations or Interpretation of Results

15.1 *Calculations*

15.1.1 The measured values for Q_{ind}, Q_a, and T_g are determined by an arithmetic average of samples taken at time intervals after stability has been achieved at each temperature and flow condition.

15.1.2 The ambient temperature coefficient of flow shall be calculated as follows:

$$TC_e(\%/°C) = \frac{Q_a2 - Q_a1}{Q_{sp}\ x\ (T_e2 - T_e1)}\ x\ 100$$

where Q_{a1} and Q_{a2} are the actual flow rates measured at ambient temperatures T_{e1} and T_{e2} respectively. For zero setpoint use the following.

$$TC_{zero} = \frac{Q_a2 - Q_a1}{Q_{fullscale}\ x\ (T_g2 - T_g1)}\ x\ 100$$

This yields a result expressed as a percent of reading per °C. See example of data collection and analysis shown in Table 3. Final TC_e is to be presented in Table 2 format.

15.1.3 The gas temperature coefficient of flow is to be calculated as follows:

$$TC_g(\%/°C) = \frac{Q_a2 - Q_a1}{Q_{sp}\, x\, (T_g2 - T_g1)}\, x\, 100$$

where Q_{a1} and Q_{a2} are the actual flow rates measured at gas temperatures T_{g1} and T_{g2} respectively. For zero setpoint use the following.

$$TC_{zero} = \frac{Q_a2 - Q_a1}{Q_{fullscale}\, x\, (T_g2 - T_g1)}\, x\, 100$$

This yields a result expressed as a percent of reading per °C. Refer to Table 5 for an example of data collection and analysis. Final TCg is to be presented in Table 1 format.

16 Reporting Results

NOTE 4: All special features (remote electronics, auto zero, etc.) should be noted on the testing results for comparative analysis.

16.1 The gas temperature coefficient at each flow rate is to be displayed as shown in Table 1.

16.2 The gas temperature coefficient data from Table 1 is to be displayed as shown in Figure 5. The gas temperature, actual flow, and indicated flow are to be displayed versus time as shown in Figure 6.

16.3 The ambient temperature coefficient is to be presented in tabular form as shown in Table 2.

16.4 The data for the steady-state effect from Table 2 should be presented as shown in Figure 7. The data for the transient effect from Table 4 should be presented as shown in Figure 8.

NOTE 1: Plot as in Figure 8.

Table 5 Gas Temperature Data Collection

Set point (sccm)	T_s (℃)	T_g (℃)	T_b (℃)	T_e (℃)	Q_a (sccm)	Q_{ind}
0		22.0		21.8	0.00	
25		22.1		21.9	24.94	
25		33.2		22.2	24.52	
50		22.1		21.8	50.08	
50		32.1		21.7	49.21	
75		22.0		21.6	75.13	
75		31.8		21.5	74.02	
100		21.9		21.4	100.18	
100		31.7		21.4	98.83	

$$TC_g = \frac{Q_{af}-Q_{ai}}{[(T_g-T_e)_f-(T_g-T_e)_i]\ Q_{sp}} \times 100\%$$

Example: For the 50 sccm setpoint data collection sample,

$$TC_g = \frac{49.21\text{ sccm}-50.08\text{ sccm}}{[(32.1°C-21.7°C)-(22.1°C-21.8°C)](50\text{ sccm})} \times 100\%$$

$= -0.17\%$ of reading at 50 sccm

APPENDIX 1

NOTE: This appendix is being balloted as an official part of SEMI F062-0701 by full letter ballot procedure. Determination of the suitability of the material herein is solely the responsibility of the user.

(Mandatory Information)

A1-1 Reference Values

Ambient Temperature	23 ±2°C
Gas Temperature	Same as Ambient
Ambient Pressure	101.3 kPa +4.7 kPa (1013 mbar +4.7 kPa - 15.3 kPa)
Gas Pressure, Inlet	274 ± 34 kPa
Gas Pressure, Outlet	101.3 kPa
Gas Pressure, Inlet	172 ± 34 kPa
Gas Pressure, Outlet	< 0.13 kPa
Relative Humidity	40% ± 10%, Noncondensing
Magnetic Field	< 50 µT
Electromagnetic Field	< 100 µV/m
Vibration	< 0.5 m/s
Shock	≤ 3g

SEMI F63-0701
GUIDELINES FOR ULTRAPURE WATER USED IN SEMICONDUCTOR PROCESSING

This specification was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Facilities Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001.

1 Purpose

1.1 This guide is provided for multiple purposes. It may be used as a basis for establishing performance criteria for purchases of new UPW equipment. It may also be used internally by facility engineers to set process control parameters for the operation of their UPW systems. This guide may be used by process engineers to establish reasonable expectations about the quality of the UPW being supplied to them by facilities.

NOTICE: These suggested guidelines are published as technical information and are intended for informational purposes only.

2 Scope

2.1 Water is used extensively in the production of semiconductor devices for all wet processing steps such as the rinsing of wafers. Ultrapure Water (UPW) is typically produced for this purpose using Reverse Osmosis/Deionized resin bed technologies. The quality of the water impacts device yield and as linewidths decrease, requirements for higher purity water may increase.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *SEMI Standards*

SEMI F61 — Guide For Ultrapure Water System Used in Semiconductor Processing

3.2 *ASTM Standards*[1]

ASTM D-5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry.

ASTM F-1094 — Test Method For Microbiological Monitoring of Water Used For Processing Electron and Microelectronic Devices by Direct- Pressure Tap Sampling Valve and by the Pre-sterilized Plastic Bag Method.

4 Limitations

4.1 This guide is not intended to set an absolute number for performance of a particular UPW system. Performance guidelines should be determined based on the design of the UPW system, the components used in the water system, the sensitivity of the manufacturing process to the purity of the water, the sensitivity of the instrumentation, and the budget available to maintain and monitor the water system.

4.2 This set of guidelines has been established from a variety of sources and inputs including 1.) an industry survey that SEMI provided to members of its standards activities in facilities; 2.) typical UPW levels from a large selection of semiconductor UPW systems as measured by several independent laboratories that test high purity water for the semiconductor industry; 3.) specifications from water system equipment manufacturers; 4.) and input from producers and users of UPW during SEMI standards committee meetings and through the balloting process. However, it is up to each individual owner of a UPW system to set specifications for the purity of its water based on its own needs and available resources.

4.3 This guide is reflective of a particular design approach for a UPW system. The guidelines can be produced from a properly maintained UPW system as described and diagrammed in SEMI F61 and is typical output from existing high-end semiconductor manufacturing plants with state-of-the-art water systems. The purity of water generated in other types of water systems may differ greatly.

4.4 The guidelines are targeted to UPW produced for semiconductor manufacturing. There exists an ASTM standard D5127 which should be considered in setting specifications for the purity of reagent grade water needed in a laboratory for analytical testing of semiconductor materials and process chemicals.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959, website: www.astm.org

5 Use of the Guidelines

5.1 Sampling methods and contamination control are of paramount importance when attempting to measure the listed parameters at the levels specified.

5.2 The quality of the data measured will depend on which testing method and calibration techniques are used. Consequently, trends observed in the values may be more meaningful than absolute values.

6 Units

6.1 Parts per billion (ppb) is equivalent to ng/mL or µg/L.

6.2 Parts per million (ppm) is equivalent to mg/L.

6.3 Micron is a unit of length equal to one millionth of a meter, or one thousandth of a millimeter.

6.4 Colony Forming Units (CFU) is a measurement of bacteria organisms.

7 Description of Parameter Tests

NOTE 2: Since SEMI Guidelines do not require analytical data or methods to support them, the recommendation of specific analytical methods are only for informational purposes. Alternative methods may also be applicable.

7.1 *Resistivity (megohm-centimeters or Mohm–cm)*

7.1.1 Resistivity (conductivity) is only measured accurately with on-line instrumentation.18.25 MOhm is the theoretical upper limit for pure water at 25°C.

7.2 *Total Oxidizable Carbon (TOC) (ppb)*

7.2.1 Involves oxidation of organic materials and detection of carbon dioxide produced by the reaction, as measured in conductivity or infrared photometry.

7.3 Dissolved oxygen (ppb) is only measured accurately with on-line instrumentation.

7.4 *Particulate Matter (Particles/L)*

7.4.1 On-line methods using laser technology are recommended for accurate trend analysis.

7.5 *Bacteria (CFU/L)*

7.5.1 Triplicate samples are cultured based on the ASTM method F 1094 using a minimum sample size of 1L.

7.6 *Silica*

7.6.1 Total Silica (ppb) may be measured by Graphite Furnace Atomic Absorption Spectrophotometry (GFAAS), Inductively-Coupled Plasma Atomic Emission Spectroscopy (ICP-AES) or Inductively Coupled Plasma Mass Spectroscopy (ICP-MS).

7.6.2 Dissolved Silica (ppb as SiO_2) may be measured by heteropoly blue photometry or by Ion Chromatography.

7.7 *Ions and Metals (ppb)*

7.7.1 Many anions and cations may be determined using Ion Chromatography.

7.7.2 Up to 68 metals may be determined by GFAAS, ICP-AES, or ICP-MS. Most typically measured metals are shown in Table 1.

8 Parameters and Typical Concentrations

8.1 Table 1 lists each parameter with its range of performance.

Table 1 Parameters and Range of Performance

Typical Linewidth	*0.13 to 0.5 MICRONS*
PARAMETER	**RANGE OF PERFORMANCE**
Resistivity on-line @ 25°C (Mohm–cm)	17.9 to 18.2
TOC on-line (ppb)	1 to 5
Dissolved Oxygen on-line (ppb)	0.5 to 20
On-line Particles/L (micron range)	
0.05–0.1	100 to 1000
0.1–0.2	50 to 500
0.2–0.3	20 to 100
0.3–0.5	10 to 50
> 0.5	0 to 4
Bacteria (CFU/L)	
1 L Sample	0 to 5
Silica	
Silica - total (ppb)	0.5 to 3
Silica - dissolved (ppb as SiO_2)	0.2 to 1
Ions & Metals (ppb)	
Ammonium	0.02 to 0.1
Bromide	0.02 to 0.1
Chloride	0.02 to 0.1
Fluoride	0.02 to 0.1
Nitrate	0.02 to 0.1
Nitrite	0.02 to 0.1
Phosphate	0.02 to 0.1
Sulphate	0.02 to 0.1
Aluminum	0.02 to 0.1
Barium	0.02 to 0.1
Boron	0.02 to 20
Calcium	0.02 to 0.1
Chromium	0.02 to 0.1

Typical Linewidth	*0.13 to 0.5 MICRONS*
Copper	0.02 to 0.1
Iron	0.02 to 0.1
Lead	0.02 to 0.1
Lithium	0.02 to 0.1
Magnesium	0.02 to 0.1
Manganese	0.02 to 0.1
Nickel	0.02 to 0.1
Potassium	0.02 to 0.1
Sodium	0.02 to 0.1
Strontium	0.02 to 0.1
Zinc	0.02 to 0.1

SEMI F64-0701
TEST METHOD FOR DETERMINING PRESSURE EFFECTS ON INDICATED AND ACTUAL FLOW FOR MASS FLOW CONTROLLERS

This specification was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Facilities Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001.

1 Purpose

1.1 The purpose of this document is to define a method for characterizing a MFC being considered for installation into a gas distribution system. This method will quantify the effect of transient and steady state inlet and outlet pressure conditions on the performance of the MFC.

1.2 This document provides a common basis for communication between manufacturers and users regarding testing and describing MFC pressure effects.

2 Scope

2.1 This test method measures the upstream (inlet) and downstream (outlet) transient pressure influences on indicated and actual flow.

2.2 This test method yields the results of actual output flow versus MFC set-point and indicated flow as influenced by steady state inlet pressure.

2.3 This test method applies to MFCs with maximum flow ranges of up to 1000 sccm.

NOTE 1: Due to the higher sensitivity of lower flow rate MFC's when pressure transients occur, the flow range for this document is limited to 1000 sccm.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This test method is limited to analyzing the effect of pressure on performance characteristics of MFCs and is not a verification of the state of calibration, linearity, or accuracy.

3.2 This test method does not address pressures in excess of the DUT's maximum working pressure as specified by the manufacturer.

3.3 This test method is limited to reasonable pressure transients; i.e., fluctuations that are otherwise tolerated by common semiconductor process equipment.

3.4 This test method does not address operational influences outside of the manufacturer's published limitations.

3.5 This test method does not address the effects of interruptions of the gas supply.

4 Referenced Standards

4.1 None.

5 Terminology

5.1 *Definitions*

5.1.1 *actual flow* — flow as indicated by flow standard (see Figures 1 and 2).

5.1.2 *indicated flow* — flow as indicated by the device under test (DUT).

5.1.3 *ramp* — constant rate of change in pressure (dp/dt = k).

5.1.4 *stability* — the ability of a condition to exhibit only natural, random variation in absence of unnatural, assignable cause variation.

5.1.5 *step change* — an exponential step in pressure with a time constant of one second or less.

5.2 *Abbreviations and Acronyms*

5.2.1 δM — deviation of mass of material relative to steady-state mass delivery.

5.2.2 ΔP — change in pressure with respect to time

5.2.3 ΔQ — steady state deviation of actual flow during inlet pressure ramp from that while inlet pressure is constant.

5.2.4 δQ_- — maximum negative deviation of actual flow from nominal.

5.2.5 δQ_+ — maximum positive deviation of actual flow from nominal.

5.2.6 τ — pneumatic time constant

5.2.7 *DUT* — device under test

5.2.8 *MFC* — mass flow controller

5.2.9 *MV* — metering valve

5.2.10 P_1 — inlet pressure

5.2.11 P_2 — outlet pressure

5.2.12 PC_A — pressure coefficient of actual flow per pressure change at a set point.

5.2.13 PC_O — pressure coefficient of indicated flow per pressure change at zero flow.

5.2.14 PC_S — pressure coefficient of span flow per pressure change.

5.2.15 *Psia* — pounds per square inch absolute

5.2.16 *Psig* — pounds per square inch gauge

5.2.17 Q_A — actual flow

5.2.18 Q_{FS} — rated full scale flow

5.2.19 Q_I — indicated flow

5.2.20 Q_N — nominal actual flow during steady state conditions.

5.2.21 Q_R — steady state actual flow while inlet pressure is being ramped.

5.2.22 Q_{SP} — set-point flow

5.2.23 T — time

5.2.24 t_f — time when Q_A is within 0.5% of reading of Q_N.

5.2.25 t_o — time when pressure transient is initiated.

5.2.26 t_s — settling time to Q_N

5.2.27 v — voltage

5.2.28 V_{eq} — equivalent internal control volume of the DUT.

5.2.29 V_{ip} — valve, pump isolation

6 Summary of Test Method

6.1 *Inlet Pressure Step and Ramp Change* — The effects of fast-step and slow-ramp changes to the pressure on actual flow out of the MFC is observed. See Figures 6 and 7.

6.2 *Inlet Pressure Effect Steady State* — The effects of a pressure increase/decrease on actual flow is observed once the increase/decrease has reached steady state. See Figure 8.

6.3 *Outlet Pressure Step Change* — The effects of an outlet pressure change on actual flow is observed. See Figure 9.

6.4 *Crosstalk Pressure Effect* – The effects of pressure changes due to switching multiple flow devices on the same gas line. See Figure 11.

7 Interferences

7.1 The accuracy rating of the measuring equipment shall be superior to that of the DUT. Preferably the measuring equipment will have an accuracy that is four times better than the DUT. Calibration equipment must have a valid calibration certificate.

7.2 Take care when using test instruments with a specified accuracy expressed in percent of full scale as the accuracy is limited at lower percentages.

7.3 Installation effects on the flow should be minimized.

7.4 Verify electrical signals directly at the DUT connector to ensure that the signals at the DUT and standard agree with the signals at the data recording equipment.

7.5 All electrical measurements should be read on devices with at least 4.5 digits of resolution. These devices must have valid calibration certifications.

7.6 The results of this test method depend on the accuracy and repeatability of the pressure measurement devices used in the test system. Take care to stay within the specified pressure ranges of these devices and verify their accuracy prior to and following MFC evaluation activities.

7.7 The cleanliness level of the test gas should be compatible with the DUT. The minimum requirement placed on the test gas is that it be free of contamination that could influence the operational characteristics of the test article and instruments.

7.8 The test gas source and delivery system must be capable of satisfying the test volume flow rate at a constant pressure ± 0.7 kPa (± 0.1 psi).

7.9 The ambient temperature should be held to 22°C ±2°C for the duration of each analysis.

8 Significance and Use

8.1 The significance of the stability calculations in this method is to allow the MFC user to assess the transient pressure effects on the DUT. In application, this method will provide a consideration affecting gas system designs and MFC selection.

9 Apparatus

9.1 *Equipment Required for Methods A–1 and A–2*

9.1.1 Inlet test gas filter

9.1.2 Shutoff valve (qty 2).

9.1.3 Pressure transducers, available range 0–446 kPa (0–50 psig), with measurement accuracy of ± 0.2% and time constant less than 20 msec (qty 2).

9.1.4 Dome-loaded pressure control, or other device capable of producing specified pressure transients.

9.1.5 Flow standard, with time constant less than 20 msec and with full scale that is 200% of the DUT's full scale, accurate to 1% of full scale, linear to 0.5% of full scale, and capable of resolving to 0.2% of full scale.

9.1.6 Data acquisition system measures the electrical signals from the device under test. The data acquisition system may also read the signals from the flow standard, record test data and control the test sequence.

9.2 *Equipment Required for Method B*

9.2.1 Inlet test gas filter.

9.2.2 Shutoff valve (qty 2).

9.2.3 Pressure transducer, available range 0–791 kPa (0–100 psig), with measurement accuracy of ± 0.1% and time constant less than 20 msec.

9.2.4 Two-stage pressure regulator, capable of 0–690 kPa (100 psia) control.

9.2.5 Flow standard, with full scale that is at least 120% of the DUT's full scale, accurate to 1% of full scale, linear to 0.5% of full scale, and capable of resolving to 0.2% of full scale.

9.2.6 Data acquisition system measures the electrical signals from the device under test. The data acquisition system may also read the signals from the flow standard, record test data and control the test sequence.

9.3 *Equipment Required for Method C*

9.3.1 Inlet test gas filter.

9.3.2 Manual metering valve.

9.3.3 Pressure transducer, available range 0–446 kPa (0–50 psig), with measurement accuracy of ± 0.2% and time constant less than 20 msec.

9.3.4 Pressure transducer, 0–101.325 kPa ± 1% and with time constant less than 20 msec (qty 1).

9.3.5 Shutoff valves (qty 2).

9.3.6 Isolation valve (qty 1).

9.3.7 Vacuum pump, with pumping speed of at least 30 lpm, with throttling and isolation valve.

9.3.8 Flow standard, with time constant less than 20 msec and with full scale that is 200% of DUT full scale accurate to 1% of full scale, linear to 0.5% of full scale, and capable of resolving to 0.2% of full scale.

9.3.9 Data acquisition system measures the electrical signals from the device under test. The data acquisition system may also read the signals from the flow standard, record test data and control the test sequence.

9.4 *Equipment Required for method D*

9.4.1 Pressure transducer, available range 0–446 kPa (0–50 psig), with measurement accuracy of ± 0.2% and time constant less than 20 msec. (2)

9.4.2 Flow standard, with time constant less than 20 msec and with full scale that is 200% of DUT full scale accurate to 1% of full scale, linear to 0.5% of full scale, and capable of resolving to 0.2% of full scale.

9.4.3 Isolation valve (qty 1).

9.4.4 Data acquisition system measures the electrical signals from the device under test. The data acquisition system may also read the signals from the flow standard, record test data and control the test sequence.

9.4.5 MFC with time constant less than 20 msec and a full scale flow rate that is 10 times the full scale flow rate of the DUT.

10 Materials

10.1 Clean, dry nitrogen, with a dew point less than or equal to -40°C, at a delivery pressure of 791 kPa (100 psig).

11 Safety Precautions

11.1 This test method may involve hazardous materials, operations, and equipment. This test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and to determine the applicability of regulatory limitations before using this method.

12 Test Specimen

12.1 Allow all components in the test apparatus to warm up following the manufacturer's specification.

12.2 Take necessary steps when switching gases to ensure that only the desired gas is in the DUT and flow standard at the time the test is performed.

13 Preparation of Apparatus

13.1 *Setup and Schematic* — See Figures 1, 2, and 10.

13.2 *Plumbing Design Requirements for Methods A and C*

13.3 The test system must be highly conductive and must have no changes in direction closer than 20 tubing diameters upstream of the DUT.

13.4 The pneumatic time constant for the system shall be calculated as shown below:

τ = (Volume × Pressure Drop)/(Pressure × Volumetric Flow)

where:

- Volume is measured between the flow standard and the DUT
- Pressure drop is across the flow standard
- Pressure is the pressure in the defined volume
- Volumetric flow is as measured by the standard

13.5 The pneumatic time constant added to the flow standard time constant should ideally be less than 100 msec and should be recorded if larger. For method C, the volume between MV and V_{ip} should be kept to a minimum.

13.6 The system must be relatively leak free, i.e., the maximum inboard leak rate should be 2×10^{-7} atm cc/s He.

13.7 The system must be supported and isolated in a manner that keeps it from vibration, shock, and other conditions that could influence the results of this test.

14 Procedure

14.1 *Inlet Transient Pressure Effects (Method A-1)*

14.1.1 Assemble the test MFC into the test apparatus. (See Figure 1.)

14.1.2 Satisfy the manufacturer's warm-up requirements for the MFC.

14.1.3 Set the inlet pressure (P_1) to 274 kPa (25 psig).

14.1.4 Give the DUT a 50% set-point (Q_{SP} = ½Q_{FS}) and wait for Q_I to reach stability.

14.1.5 Adjust the pressure control device to initiate a step in P_1 to 287 kPa (27 psig) with a time constant of one second (see Figure 3c).

14.1.6 Wait until Q_I and Q_A have reached stability.

14.1.7 Using the pressure control device, initiate a step in P_1 to 274 kPa (25 psig) with a time constant of one second.

14.1.8 Give the DUT a 100% set-point (Q_{SP} = Q_{FS}) and wait for stability.

14.1.9 Repeat Sections 14.1.5 through 14.1.7.

14.2 *Process Side Effects (Method A-2)*

14.2.1 Assemble the test MFC into the test apparatus (see Figure 1).

14.2.2 Satisfy the manufacturer's warm-up requirements for the MFC.

14.2.3 Set the inlet pressure (P_1) to 274 kPa (25 psig).

14.2.4 Give the DUT a 50% set point (Q_{SP} = ½Q_{FS}) and wait for Q_I to reach stability.

14.2.5 Using the pressure control device, initiate a ramp in P_1 to 356 kPa (37 psig) (see graph in Figure 4c). Use a ramp rate between 0.7 kPa (0.1 psi) per second and 21.0 kPa (3psi) per second. Record the ramp rate used on the data sheet.

14.2.6 Wait until Q_I and Q_A have reached stability.

14.2.7 Using the pressure control device, initiate a ramp as in 14.2.5, initiate a ramp in P_1 to 274 kPa (25 psig) (see graph in Figure 4c).

14.2.8 Repeat Sections 14.2.5 through 14.2.7.

14.3 *Inlet Pressure Effects, Steady State (Method B)*

14.3.1 Assemble the DUT in the test apparatus (see Figure 1).

14.3.2 Satisfy the manufacturer's warm-up requirements for the DUT.

14.3.3 Set the inlet pressure (P_1) to 205 kPa (15 psig).

14.3.4 Close V_{io}, open DUT control valve.

14.3.5 Wait until Q_R and Q_A have reached stability. Record P_1, Q_I and Q_A (see Table A3.1).

14.3.6 Open V_{io} and give the DUT a 50% set-point. (Q_{SP} = ½Q_{FS}).

14.3.7 Wait until Q_I and Q_A have reached stability. Record P_1, Q_I and Q_A (see Table A3.1).

14.3.8 Give the DUT a 100% set-point (Q_{SP} = Q_{FS}).

14.3.9 Wait until Q_I and Q_A have reached stability. Record P_1, Q_I and Q_A (see Table A3.1).

14.3.10 Set inlet pressure (P_1) to 446 kPa (50 psig) and repeat Sections 14.3.4 through 14.3.9.

14.4 *Outlet Pressure, Step Change (Method C)*

14.4.1 Assemble the test MFC into the test apparatus. (See Figure 1.)

14.4.2 Satisfy the manufacturer's warm-up requirements for the MFC.

14.4.3 Set the inlet pressure (P_1) to 274 kPa (25 psig) (see Figure 9).

14.4.4 Give the DUT a 50% set point (Q_{SP} = ½Q_{FS}).

14.4.5 Throttle the pump rate until P2 = 26.664 kPa.

14.4.6 Open V_{io} and adjust the metering valve, MV, until P_2 = 101.325 kPa.

14.4.7 Allow Q_I to reach stability. Record P_1, Q_I, and Q_A (see Table A3).

14.4.8 Close V_{io}. P_2 should = 26.664 kPa.

14.4.9 Allow Q_I to reach stability. Record P_1, Q_I, and Q_A (see Table A3).

14.4.10 Give the DUT a 100% set point and repeat Sections 14.4.5 through 14.4.9.

14.5 *Crosstalk Pressure Effect (Method D)*

14.5.1 Assemble the DUT in the test apparatus (see Figure 10).

14.5.2 Satisfy the manufacturer's warm-up requirements for the DUT.

14.5.3 Set the inlet pressure (P_1) to 274 kPa (25 psig)

14.5.4 Give the DUT a 100% set point ($Q_{SP} = Q_{FS}$).

14.5.5 Give the 10× MFC a 100% set point ($Q_{SP} = Q_{FS}$).

14.5.6 Wait until the DUT and MFC achieve stability.

14.5.7 Record P_1, P_2, the indicated flow from the DUT, the indicated flow from the MFC and the indicated flow from the flow standard continuously with the data acquisition system.

14.5.8 While monitoring command the 10 × MFC to a zero set-point. Wait until the DUT becomes stable then command the 10× MFC to a 100% set Point.

14.5.9 Sample Plot is shown in Figure 11.

15 Calculations or Interpretation of Results

15.1 See Appendix 1 for detailed information on data collection and interpretation for Methods A-1, A-2, B, and C.

15.2 *Calculations* — The indicated MFC flow output data and the flow standard output data should be converted to percent of full scale flow as follows:

$$\%\text{ of full scale flow} = \frac{\text{output data (v)}}{\text{full scale output (v)}} \times 100 \qquad (1)$$

15.3 *Interpretation* — Collect the following data and report as an effect of transient pressure conditions:

15.4 Plot of indicated flow, actual flow, and flow set point versus time.

15.5 Duration of instability. Maximum and minimum deviations from the steady state actual and indicated flows. Calculate the positive and negative integrals, along with the total integral of variations in the actual and indicated flows.

15.6 Inlet (P_1) and outlet (P_2) values.

15.7 The number of repetitions required to achieve a confidence factor of 95% for each test step.

15.8 Data plots for the measured values must be generated and presented in a manner similar to that shown in Figures 3, 4, and 5 and in Table 1.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI F64 and was approved by full letter ballot procedures on April 30, 2001 by the Facilities Regional Standards Committee.

A1–1 Data Analysis: Method A-1

Table A1–1 Sample Data Sheet: Methods A-1 and A-2

Date: ________________ Time: __________
D.U.T. # ________________ Ambient Temp __________°C
Standard Flow Device:________________
Full Scale:________________ sccm
Ramp Rate (Method A-2) ______________kPa/sec

Time (sec)	*P1 (psig)*	*Q_A (sccm)*	*Q_I (sccm)*
0	25.01	50.00	50.01
0.05	25.01	50.01	50.01
0.10	25.02	50.00	50.02
0.15	25.01	49.99	50.01
. . .	. . .	. . .	. . .
2.20	25.40	52.68	51.38
2.25	25.85	55.23	52.56
. . .	. . .	. . .	. . .
6.30	26.89	46.28	49.23

A1–1.1 *Data Interpretation, Method A-1*

A1–1.1.1 δQ_+ = maximum positive deviation of actual flow from nominal

$\delta Q_+ = Q_{max} - Q_N$

where:

Q_{max} = maximum value of Q_A

Q_N = average value of Q_A during time when P_1 = initial steady state

δQ_- = maximum negative deviation of actual flow from nominal

$\delta Q_- = Q_{min} - Q_N$

where:

Q_{min} = minimum value of Q_A

For example (see Table A1–1), if Q_N = 50.01 sccm, Q_{max} = 55.23 sccm, and Q_{min} = 46.28 sccm, then

δQ_+ = 55.23 sccm - 50.01 sccm = 5.22 sccm

δQ_- = 46.28 sccm - 50.01 sccm = -3.73 sccm

A1–1.1.2 t_s is settling time to Q_N; i.e.,

t_s = elapsed time from initiation of pressure transient (t_o) to when Q_A is within 0.5% of reading of Q_N (t_f) = t_f - t_o

δM is deviation of mass of material delivered during the disturbance relative to steady state mass delivery; i.e.,

$$\delta M = \sum_{t_i=t_o}^{t_f} \frac{(Q_A - Q_N)(t_{ih} - t_i)}{60\ \text{sec / min}} \qquad (2)$$

This quantity may be thought of as the net area between the Q_A versus time curve and the Q_N versus time line. See Figure A1–1 below.

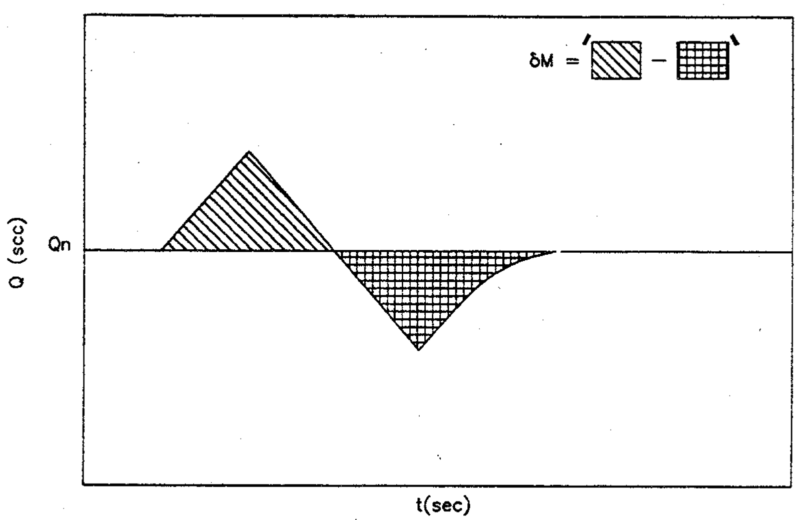

Figure A1–1
Q_N versus t (sec)

NOTE 1: δM is expressed in units of sccm.

A1–2 Data Analysis: Method A-2

Refer again to Table A1–1

A1–2.1 *Data Interpretation, Method A-2*

Q_R is the steady state actual flow while the inlet pressure is being ramped. It is calculated by averaging Q_A values from time t_o + 50 sec to t_o + 110 sec.

ΔQ is the steady state deviation of actual flow during the inlet pressure ramp from that while inlet pressure is constant; i.e.,

$$\Delta Q = Q_R - Q_N \qquad (3)$$

V_{eq} is the equivalent internal control volume of the DUT. Note that it may not represent the actual internal volume of the DUT; i.e.,

$$V_{eq} = \frac{\Delta Q}{P_1} x (\frac{14.7 \text{ psi/std. atm}}{60 \sec / \min}) \tag{4}$$

For example, if ΔQ = 5.02 sccm and P1 = 0.7 kPa (0.1 psi)/sec, then

Veq = [(5.02 sccm)/(0.7 kPa (0.1 psi)/sec)] × [(101.325 kPa (14.7 psi)/std. atm)/(60 sec/min)] = 12.3 ccm

A1–3 Data Analysis: Method B

Table A1–2 Sample Data Sheet: Method B

Date:________________ Time: __________
DUT #________________ Ambient Temp __________°C
Standard Flow Device ________________
Full Scale________________ sccm

P1 (psig)	*Setpoint Flow (sccm)*	*Q_A (sccm)*	*Q_I (sccm)*
15.02	0	0.00	-0.01
15.00	50	50.01	50.01
15.01	100	100.12	100.01
50.06	0	0.00	-0.05
50.04	50	50.12	50.01
50.03	100	100.56	100.02

A1–3.1 *Data Interpretation, Method B*

PC_o is the pressure coefficient of indicated flow per pressure change at zero flow; i.e.,

$$PC_A(\%) = \frac{\Delta Q_A}{\Delta P_1 Q_{sp}} x100 \tag{5}$$

$$PC_o(\%) = \frac{Q_{If} - Q_{Ii}}{(P_{If} - P_{Ii})Q_{FS}} x100 \tag{6}$$

PC_A is the pressure coefficient of actual flow per pressure change at a setpoint; i.e.,

For example, from Table A2.1,

PC_o (%) = {[-0.05 sccm-(-0.01 sccm)]/[(50.06 psig-15.02 psig)(100 sccm)]} × 100
= -0.0011% of FS/psi

PC_A (@ 50%) = [50.12 sccm-50.01 sccm]/[(50.04 psig-15.00 psig)(50 sccm)] × 100
= 0.0063% of reading/psi at 50 sccm

PC_A (@ FS = [100.56 sccm-100.12 sccm]/[(50.03 psig-15.01 psig)(100 sccm)] × 100
= 0.013% of reading/psi at 100 sccm

SEMI F65-1101
DIMENSIONAL SPECIFICATION FOR MOUNTING BASES OF DIAPHRAGM VALVES USED WITH METRIC PFA TUBES

This specification was technically approved by the Global Liquid Chemical Distribution Systems Committee and is the direct responsibility of the Japanese Liquid Chemical Distribution Systems Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This document specifies dimensions of mounting base and their clearance hole sizes for bolts and the hole locations of diaphragm valves used with metric PFA tubes in liquid chemical distribution facilities and process equipment for semiconductor and flat panel display manufacturing.

1.2 To avoid any disturbance of future development and to facilitate interchangeability of diaphragm valves, this document has a limited scope as specified in Section 2.

2 Scope

2.1 This document applies to mounting bases for two way valves with a diaphragm designed to shut off and/or regulate a liquid chemical flow in tubes whose sizes are listed in Table 1.

2.2 The valves are made from materials such as PTFE or PFA, which have high corrosion resistance and low contamination contribution to the fluid.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *ISO Standards*[1]

ISO 273 — Fasteners – Clearance Holes for Bolts and Screws

ISO 2768-1 — General Tolerance – Part 1: Tolerances for linear and angular dimensions without individual tolerance indications

3.2 *JIS Standards*[2]

JIS B 1001 — Diameter of Clearance Holes and Counterbores for Bolts and Screws

JIS B 0405 — General Tolerance – Part 1: Tolerances for linear and angular dimensions without individual tolerance indications

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 *Abbreviations and Acronyms*

4.1.1 *PFA* — tetrafluoroethylene perfluoroalkylvinyl-ether copolymer

4.1.2 *PTFE* — polytetrafluoroethylene

4.2 *Definitions*

4.2.1 *back pressure* — a maximum allowable pressure applied to outlet of a diaphragm valve.

4.2.2 *liquid chemicals* — acid, alkali, organic solvent, and pure water used for wet stations; resists and developers used for track system; and other chemicals used for process or maintenance (such as slurry of chemical-mechanical polishing) of equipment or facilities.

4.2.3 *mounting bases* — plates which are attached to diaphragm valves to mount the valves to equipment or a facility.

5 Dimensional Specification

5.1 *Mounting Base Dimensions* — the length (l) and width (w) of the mount base plate indicated in the Figure 1 and the values for different tube sizes are specified in Table 1.

5.2 *Clearance Hole Locations* — the location of the clearance holes for bolts are indicated with “w” and “l” in the Figure 1 and the values for different tube sizes are specified in Table 1.

5.3 *Clearance Hole Sizes* — the size of clearance holes (ϕD) for different tube sizes are specified in the Table 1 according to ISO 273 (JIS B 1001).

1 International Organization for Standardization (ISO), 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland.

2 Japan Standards Association, 4-1-24, Akasaka, Minato-ku, Tokyo, Japan 107-8440.

5.4 Where the dimension depends on the valve design considering the back pressure, the upper row in Table 1 applies to the valves that withstand up to 0.2 megapascals (MPa) (29 pounds per square inch (psi)) back pressure, and the lower row applies to the valves that withstand more than 0.2 MPa (29 psi) back pressure.

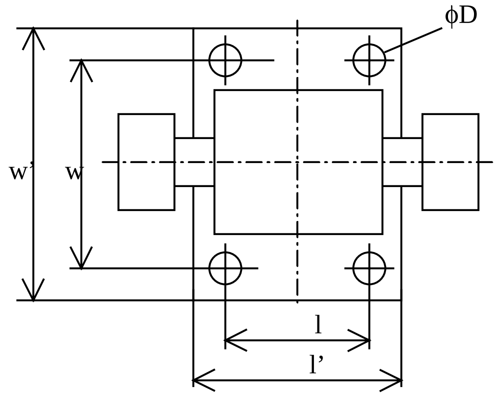

Figure 1
Top View of A Typical Diaphragm Valve with A Mounting Base

Table 1 Dimensional Specifications

*Tube Size (mm) (OD / ID)**	*Back Pressure (Mpa)*	*l' (mm)*	*l (mm)*	*w' (mm)*	*w (mm)*	*ϕD (mm)*	*Bolt Type (example)*
25 / 22	≤ 0.2	60	48	96	84	7	M6
	> 0.2	68	56				
19 / 16	≤ 0.2	44	32	76	64	7	M6
	> 0.2	52	40	84	72		
12 / 10	≤ 0.2	34	22	62	50	7	M6
	> 0.2	46	34	70	58		
10 / 8	≤ 0.2	34	22	62	50	7	M6
	> 0.2	46	34	68	56		
6 / 4	≤ 0.2	32	20	56	44	7	M6
	> 0.2	40	28	60	48		

Note 1: OD and ID are outside diameter and inside diameter of the tube respectively.
Note 2: Refer to ISO 2768-1 or JIS B 0405 for tolerances.

6 Measurements

6.1 The mounting base must be conditioned for a minimum of one hour in an air environment of 23 ± 3ºC (73.4 ± 5.4ºF) prior to measuring the dimensions.

SEMI F66-1101
SPECIFICATION FOR PORT MARKING AND SYMBOL OF STAINLESS STEEL VESSELS FOR LIQUID CHEMICALS

This specification was technically approved by the Global Liquid Chemical Distribution Systems Committee and is the direct responsibility of the Japanese Liquid Chemical Distribution Systems Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This document specifies port marking and symbol of stainless steel vessels for liquid chemicals used in semiconductor and flat panel display manufacturing equipment and liquid chemical distribution facilities.

2 Scope

2.1 This document covers stainless steel vessels with tubes that penetrate into the vessels as inlets or outlets of liquid chemical to/from the vessels.

2.2 A vessel which uses coupling (quick coupling) at its tube end (port) is excepted from the scope.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 None.

4 Terminology

4.1 *dip tube* — a piece of tube which penetrates into a vessel as an inlet or outlet of liquid chemical to/from the vessel.

4.2 *liquid chemical* — organic or inorganic liquid chemical used for semiconductor or flat panel display manufacturing.

4.3 *port* — an end of a tube attached to a vessel.

5 Requirements for Port Marking

5.1 The dip tube port shall be marked as "DIP". If more than one dip tube port exists on a vessel, each port shall be marked as "DIP".

5.2 *Additional Marking* — A description to identify multiple ports may be added to the dip port marking such as DIP-1 or DIP (1).

5.3 *Location of Marking* — "DIP" marking shall be located where it will clearly identify the dip tube port. If more than one dip tube ports exist on a vessel, each marking shall be located so that the corresponding port is clearly identified.

5.4 *Method of Marking* — The marking shall be engraved, etched, or labeled properly so that the "DIP" marking shall not be removed. Color of the marking is optional.

5.5 *Size of Marking* — The marking shall be sized so that it is clearly readable.

6 Requirements for Symbol

6.1 A symbol illustrated in Figure 1 shall be used to draw a stainless steel vessel with a dip tube. A dip tube shall be identified in the symbol as a line penetrating into a rectangle.

6.2 If more than one dip tube exists on a vessel, the symbol shall have the same number of lines which correspond to the dip tubes.

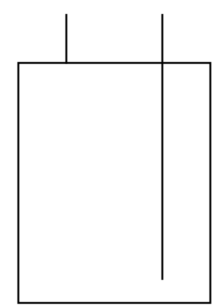

Figure 1
Symbol for Stainless Steel Vessel with a Dip Tube

By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights or copyrights asserted in connection with any items mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights are entirely their own responsibility.

SEMI F67-1101
TEST METHOD FOR DETERMINING INERT GAS PURIFIER CAPACITY

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 The purpose of this document is to define a test method to quantify impurity removal capacity of inert gas purifiers.

2 Scope

2.1 To determine the impurity capacity of a gas purifier at the point of breakthrough. Capacity tests are done by adding ppm levels of a given gaseous impurity to a pure zero gas and monitoring the effluent of the test purifier for active impurity species.

NOTE 1: Mixtures of two or more impurities for multi impurity removal purifiers is a more representative method for determining capacity.

2.2 This document is intended for point of use (POU) inert gas purifiers where inlet purity is 99.9995% or higher.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate and safety health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The inherent limitation to this method is the limit of detection (LOD) of the analytical instrument employed by the user.

3.2 This test method can only be used to compare purifier capacity results if the user application for flow rate, pressure, and temperature are the same as the test conditions. Different users and/or different operating conditions may result in different purifier performance results.

3.3 In testing mixtures of impurities, some impurities may influence the capacity results. Discussion with the manufacturer is highly recommended prior to testing.

3.4 The test method does not apply to particulates.

3.5 This test method can only be used to compare the capacity of different purifiers, when the purifiers are sized for the appropriate flow rate. Comparing purifiers of different maximum flow ratings will result in misleading information.

3.6 This test method will provide capacity information only for impurities that are used in the challenge gas.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E29 — Standard Terminology for the Calibration of Mass Flow Controllers and Mass Flow Meters

SEMI F6 — Guide for Secondary Containment of Hazardous Gas Piping Systems

4.2 *ANSI Standards*[1]

ANSI B46.1 — Surface Texture (Surface Roughness, Waviness, and Lay)

NOTE 2: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *APIMS* — atmospheric pressure ionization mass spectrometer

5.1.2 *°C* — degrees Celsius

5.1.3 *DUT* — device under test

5.1.4 *°F* — degrees Fahrenheit

5.1.5 *in* — inch

5.1.6 *kPa* — kiloPascal

5.1.7 *LOD* — limit of detection

5.1.8 *m* — meter

5.1.9 *MFC* — mass flow controller

5.1.10 *NMHC* — non methane hydrocarbons

5.1.11 *POU* — point of use

5.1.12 *ppb* — parts per billion, volume basis

1 American National Standards Institute, New York Office: 11 West 42nd Street, New York, NY 10036, USA. Telephone: 212.642.4900; Fax: 212.398.0023 Website: www.ansi.org

5.1.13 *ppm* — parts per million, volume basis

5.1.14 *psi* — pounds per square inch

5.1.15 *psia* — pounds per square inch absolute

5.1.16 *psig* — pounds per square inch gauge

5.1.17 R_a — surface roughness average (as defined in ANSI B46.1)

5.1.18 $R_{a,max}$ — surface roughness maximum (as defined in ANSI B46.1)

5.1.19 *s* — second

5.1.20 *sccm* — standard cubic centimeters per minute

5.1.21 *slpm* — standard liter per minute

5.2 *Definitions*

5.2.1 *activation* — the process of initially preparing the purifier media to be chemically reactive with gas impurities.

5.2.2 *activation temperature* — temperature at which DUT was initially prepared.

5.2.3 *atmospheric pressure ionization mass spectrometer (APIMS)* — an instrument consisting of an atmospheric pressure ion source where gas phase impurities are ionized via charge exchange reactions with the bulk gas. These ions are directed into a vacuum chamber where they are then separated by a mass analyzer and detected by an electron multiplier.

5.2.3.1 *ion source* — the section of a mass spectrometer used to generate sample ions by electron impact, chemical ionization, or charge exchange.

5.2.3.2 *mass analyzer* — a device that utilizes electric and/or magnetic fields to separate charged particles or ions according to their mass-to-charge (m/e) ratios. Examples of mass analyzers include quadrupole, magnetic and/or electric sector, time of flight, and ion traps.

5.2.3.3 *electron multiplier* — a device that detects and amplifies electro-magnetic phenomena such as positive/negative ions.

5.2.4 *back pressure regulator* — a self-contained device, consisting of a mechanical or electrical sensor and control device, commonly used in the semiconductor industry to maintain a constant pressure upstream of the regulator.

5.2.5 *breakthrough* — the point in time when an individual impurity level in the purifier effluent exceeds the level specified by the manufacturer. Typically in the range of 1–100 ppb.

5.2.6 *challenge gas* — a gas mixture containing high levels of gas impurities. Typically, a challenge gas has impurities of between 500 ppm to 1% which is used to shorten the test duration; however, challenges in the range of 1–10 ppm for the impurities is more representative.

5.2.7 *gaseous impurities* — gas phase elements and compounds in the gas stream other than the process or base gas.

5.2.8 *impurity analyzer* — an appropriate analyzer to measure the concentration of desired impurities in a gas stream from the ppm to the percent (%) concentration range.

5.2.9 *inert gas* — a gas, which at ambient conditions, does not react chemically with other materials or chemicals.

5.2.10 *limit of detection (LOD)* — lowest concentration that can be detected by an instrument. LOD is typically defined as three times the standard deviation of the mean noise level (see SEMI F6, lower detectable limit of instrument).

5.2.11 *mass flow controller (MFC)* — a self-contained device, consisting of a mass flow transducer, control valve, and control and signal-processing electronics, commonly used in the semiconductor industry to measure and regulate the mass flow of gas (as defined in SEMI E29).

5.2.12 *pure gas* — an inert gas, minimum purity of 99.9995%, and less than 1 ppb of each impurity that is specified to be removed by the DUT.

5.2.13 *purifier* — generally a catalytic (getter, reactive), resinous, or diatomaceous material within a pressure vessel which removes particulate and/or trace gas impurities from a gas stream (as defined in SEMI F22).

5.2.14 *purifier capacity* — the total quantity of each trace gas impurity that may be sorbed by the purifier media. Defined as liters impurity/liter purifier media.

5.2.15 *regeneration* — the process of reactivating the purifier media.

5.2.16 *test duration* — total time required to complete the test procedure.

5.2.17 *test flow rate* — flow rate through DUT (slpm).

5.2.18 *test pressure* — pressure immediately upstream of the DUT.

5.2.19 *test temperature* — operating temperature of DUT.

5.2.20 *ultratrace analytical instrumentation* — instrumentation that has sufficient sensitivity to measure all impurities of interest at the specified level of the customer, the ppb or sub-ppb level.

5.2.21 *zero gas* — nitrogen, argon, helium or hydrogen with an estimated level an order of magnitude, or more, lower than the lowest calibration point for each impurity of interest (as defined in SEMI F33).

6 Summary of Method

6.1 This method will allow a user to quantify the impurity removal capacity of a given inert gas purifier for that impurity.

7 Safety Precautions

7.1 This test method may involve hazardous materials, operations, and equipment. The test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations before using this method.

7.2 Exhaust from the DUT should be properly vented.

7.3 Only the appropriate gas should be used for purifier testing. Use of the inappropriate gas may cause exothermic reactions and possible explosions.

7.4 Electric discharges or mechanical friction might trigger combustion within a getter. Avoid situations where there is an accumulation of electrostatic charge.

7.5 Purifiers are generally designed for use with impurity levels less than 1% and should not be used to purify air or other inappropriate gases. Contact the manufacturer if there is any question as to the suitability for a particular gas.

7.6 Care should be taken to minimize the purifier's exposure to room air (even filtered air). Room air may chemically react with some purifiers shortening the purifier lifetime. Follow manufacturer's installation procedures.

8 Test Protocol

8.1 *Test Conditions*

8.1.1 The test should be conducted following manufacturers recommended handling procedures to activate new media or regenerate existing purifier media.

8.1.2 The test is to be conducted at a room temperature maintained between 18°C (64°F) and 26°C (78°F). Environmental temperature fluctuations within this range are not expected to have any measurable effect on the instrumentation used to detect the level of impurities. Follow instrument manufacturer's operating procedures.

8.1.3 Testing performed at high impurity challenge may alter test results, and may not be appropriate to do for all types of purifiers. Any significant temperature change during the test could have adverse or false effects on the capacity results.

8.1.4 For a mixture of more than 1 impurity, competing reactions may occur between impurities, which may lead to different results.

8.2 *Apparatus*

8.2.1 *Materials*

8.2.1.1 *Test Gas* — a mixture of pure gas and challenge gas. Select the appropriate concentration level. For initial studies, a higher concentration range, e.g., 500 ppm to 1% is suggested for each given impurity. For more representative studies done over longer time periods, 1–10 ppm for each given impurity is suggested.

8.2.1.2 *Pressure Regulators* — all wetted internal surfaces, where appropriate, should be made of electropolished 316L stainless steel with an internal surface finish of 0.18 µm (7 µin) R_a and 0.25 µm (10 µin) $R_{a,max}$, to control system pressures.

8.2.1.3 *Pressure Gauge* — all wetted internal surfaces, where appropriate, should be made of electropolished 316L stainless steel with an internal surface finish of 0.18 µm (7 µin) R_a and 0.25 µm (10 µin) $R_{a,max}$, to monitor system pressures.

8.2.1.4 *Standard Test Flows* — use appropriate mass flow devices. One MFC with appropriate range of 0–50 slpm for the pure gas is suggested. Various MFCs with appropriate ranges of 0–25 sccm, 0–100 sccm and 0–1 slpm for the challenge gas is suggested.

8.2.1.5 *Tubing* — made of electropolished 316L stainless steel, with an internal surface finish of 0.18 µm (7 µin) R_a and 0.25 µm (10 µin) $R_{a,max}$, to transport gas.

8.2.1.6 *Fittings* — the appropriate size face-seal fitting is used.

8.2.1.7 *Gaskets* — use metal gaskets for all connections. New gaskets should be used for each new connection. Use of cleanroom gloves is required when handling gaskets and fittings.

8.2.2 *Instrumentation*

8.2.2.1 An APIMS or other ultratrace analytical instrumentation is used to determine the level of each gaseous impurity exiting the DUT.

8.2.2.2 An impurity analyzer is used to measure higher concentrations of impurities such as found in the test gas.

8.2.2.3 Electronically controlled mass flow controllers are used to accurately blend the impurity challenge level.

8.2.2.4 Data collection equipment is used to gather output from the ultratrace analytical instrumentation.

8.2.2.5 All instruments used should be calibrated regularly, according to manufacturer's specifications.

8.2.3 *Test Set-up and Schematic*

8.2.3.1 Assemble the test setup according to Figure 1. Do not install the DUT until a purge flow is established through MFC1.

8.2.3.2 For the test set-up, pure gas is blended with challenge gas to create a test gas mixture.

8.2.3.3 The DUT is connected, purged per the manufacturer's recommendation, positioned with the appropriate attitude (if required by the manufacturer), and heated (if required by manufacturer) under pure gas flow.

8.2.3.4 Challenge gas flow is introduced and the impurity analyzer measures the impurity levels. If appropriate, the APIMS or other ultratrace analytical instrumentation may be used to measure the test gas while the test gas bypasses the DUT. See Section 9 on Exposure Precautions.

8.2.3.5 Measure and record the test gas concentration for the desired impurity.

8.2.3.6 Following measurement of the test gas, the bypass should be purged with pure gas to ensure impurity removal from the section of the test set-up that is downstream of the DUT.

8.3 *Test Procedures* — Refer to Figure 1.

8.3.1 Use of the impurity analyzer is recommended to protect the APIMS or ultratrace analytical instrumentation from high impurity concentrations which may harm the instrument. The test may be conducted without the impurity analyzer at the risk of exposing the APIMS or ultratrace analytical instrumentation to high impurity concentrations.

8.3.2 *Analytical Instrumentation Setup*

8.3.2.1 Set up and calibrate the analytical instrumentation (APIMS or ultratrace analytical instrumentation and impurity analyzer) according to manufacturer specifications. This includes establishing the appropriate flow rate to the instrument.

8.3.2.2 Acquire zero data to establish the analytical instrumentation baseline and stability prior to starting the test.

8.3.3 Establish flow of pure gas through the manifold bypass:

8.3.3.1 Start with all valves closed except purge gas to analytical instrumentation (V11 and V13 open).

8.3.3.2 Open V1 and adjust R1 to the suggested operating pressure range of 275–415 kPa (40–60 psig).

8.3.3.3 Open V2, V8, V9 and adjust R3 to provide appropriate backpressure for operation of the APIMS or other ultratrace analytical instrumentation. R3 will vent excess gas providing the volume challenge to the DUT. Set MFC1 to the appropriate flow rate. Readjust R1 and R3 to obtain the proper operating conditions.

8.3.4 Monitor drydown of the manifold bypass:

8.3.4.1 Close V11 and Open V10.

8.3.4.2 Purge the bypass manifold until the impurity level is in the range of the APIMS or ultratrace analytical instrumentation.

8.3.4.3 Close V13 and Open V12. Close V10 and Open V11.

8.3.4.4 Purge the bypass manifold until the moisture impurity level at the APIMS or ultratrace analytical instrumentation is below 1.0 ppb.

8.3.5 Re-isolate the APIMS or ultratrace analytical instrumentation:

8.3.5.1 Close V12 and Open V13. Maintain a constant purge to the analytical instrumentation.

8.3.6 Install the DUT, Purging with Pure Gas:

8.3.6.1 Open V6. Remove the DUT inlet face-seal connection. Quickly install the DUT inlet. Remove the DUT outlet face-seal connection and install the DUT outlet. Open V7.

8.3.6.2 Isolate the manifold bypass, directing all flow through the DUT, close V8 and V9.

8.3.6.3 Adjust R1 and R3 until P1 measures the stated purifier operating pressure.

8.3.6.4 Purge the DUT per the manufacturer's recommendation. If required, heat the DUT per manufacturer's recommendation.

8.3.7 Monitor the impurity level at the outlet of the DUT until stable:

8.3.7.1 Initial impurity monitoring may be done with the impurity analyzer. Close V11, open V9 and V10.

8.3.7.2 When the impurity level is in the range of the APIMS or ultratrace analytical instrumentation, Close V13 and Open V12. Close V9 and V10, Open V11.

8.3.7.3 Monitor impurity level until stable.

8.3.8 Initiate Impurity Challenge:

8.3.8.1 Isolate the DUT and APIMS or ultratrace analytical instrumentation. Close V7 and V12, open V13.

8.3.8.2 Open V3 and adjust R2 to the suggested operating pressure range of 275–415 kPa (40–60 psig). Open V5 and set MFC2 to the desired flow. (See Appendix 1 to determine the desired flow for MFC2).

8.3.8.3 Verify test gas impurity. Open V4, V8, and V10 and then close V5 and V11, supplying test gas to the impurity analyzer. Adjust R2 as necessary to maintain appropriate pressure for supplying MFC2. Monitor test gas impurity until stable and verified to theoretical impurity value (See Appendix 1).

8.3.8.4 Initiate test. Direct input test gas through the DUT to the APIMS or ultratrace impurity analyzer, Open V6 and V7. Open V12 and close V13. Isolate impurity analyzer, Close V8 and V10. Open V11.

8.3.8.5 Zero test gas flow totalizers (Pure Gas MFC1 and challenge gas through MFC2) beginning Purifier Capacity Test.

8.3.9 Determination of purifier capacity:

8.3.9.1 The test will require several weeks or months depending on the purifier's capacity for retention of and the concentration of the impurity.

8.3.9.2 The test may be done on newly activated media or may be done using existing media that has been regenerated. The test may be destructive to the DUT.

8.3.9.3 Constant monitoring of the purifier effluent over the duration of the test is preferred. However, periodic monitoring, e.g. every few hours is sufficient.

8.3.9.4 The test gas can be periodically monitored at the impurity analyzer by closing V11 and opening V8 and V10. If significant, ensure that flow volume to impurity analyzer during this time is subtracted from total volume input through DUT. In addition, instrument calibration should be monitored as recommended by the manufacturer.

8.3.9.5 Monitor trends in outlet purity until the breakthrough point for the impurity is detected. Time, liters of gas, and outlet purity should be recorded.

8.4 Repeat test for each new impurity to be analyzed using a new or regenerated DUT.

9 Exposure Precautions

9.1 The APIMS or ultratrace analytical instrument should not be exposed to high levels of impurities. After installation of the purifier, it should be purged well, per the manufacturer's recommendation. A typical recommendation might be to purge a minimum of 150 bed volumes before directing the flow to the APIMS.

10 Calculation of Purifier Capacity

10.1 Use the following formula to calculate Purifier Capacity:

10.2 (Test Duration (min)) × (Test Flow Rate slpm) = Total Liters Test Gas (TLTG)

10.3 Impurity(liters) = (TLTG) × ppm × 10^{-6}

10.4 Purifier Capacity = (Total Impurity (liters)/(Purifier Volume(liters))

10.5 Purifier Capacity is reported as total liters of each given impurity per liter purifier, and is a dimensionless number.

11 Reporting Results

11.1 The following test conditions should be reported:

11.1.1 Date and time of test,

11.1.2 Operator,

11.1.3 Pure gas flow rate (slpm),

11.1.4 Challenge gas flow rate (sccm),

11.1.5 Test pressure kPa (psig or psia),

11.1.6 DUT operating temperature (° C),

11.1.7 Purifier manufacturer, model, and serial number, and volume,

11.1.8 Ultratrace analytical instrumentation used,

11.1.9 Test gas impurities and levels, and

11.1.10 Calibration certificates for the mass flow devices, pressure gauges and ultratrace analytical instrumentation.

Suggested Point of Use Purifier Capacity Test Setup

APPENDIX 1
MFC SIZING

NOTE: The material in this appendix is an official part of SEMI F67 and was approved by full letter ballot procedures on August 27, 2001.

A1-1 To determine purifier efficiency, the concentration of impurity entering the purifier and the quantity of impurity downstream of the purifier must be determined.

A1-2 Determine the manufacturer's recommended flow rate for the purifier. As an example, assume a flow rate of 5 slpm.

A1-3 Determine the flow rate of challenge gas required. As an example, 5 sccm of a 1% challenge gas would be blended into 4,995 sccm of pure gas to generate a 10 ppm test gas.

$$\text{TestGas} = \frac{10{,}000\ \text{PPM} \times 5\ \text{sccm}}{5\ \text{sccm} + 4{,}995\ \text{sccm}} = 10\ \text{PPM}$$

SEMI F68-1101
TEST METHOD FOR DETERMINING PURIFIER EFFICIENCY

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 The purpose of this document is to define a test method to quantify the efficiency of a purifier for removal of an active gaseous impurity from a matrix gas.

2 Scope

2.1 To determine the efficiency of a gas purifier to remove a given impurity species. Efficiency tests are performed by adding ppm levels of gaseous impurities to a pure matrix gas and monitoring the effluent of the test purifier for active impurity species. Tests are done at supplier recommended flow rate, operating temperature and pressure.

2.2 To establish a method of determining instantaneous purifier efficiency.

2.3 The test method applies to point of use (POU) and large scale purifiers.

2.4 This method is for UHP efficient removal of low level contaminants.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate and safety health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The inherent limitation to this method is the limit of detection (LOD) of the analytical instrument employed by the user.

3.2 This test method can only be used to compare purifier efficiency results if the user application for flow rate, pressure, and temperature are the same as the test conditions. Different user and/or different operating conditions may result in different purifier performance results.

3.3 In testing mixtures of impurities, some impurities may influence the efficiency results of other impurities. Discussion with the manufacturer is highly recommended prior to testing.

3.4 The test method does not apply to particulates.

3.5 This test method will provide efficiency information only for impurities that are used in the challenge gas.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *APIMS* — atmospheric pressure ionization mass spectrometer

5.1.2 *°C* — degrees Celsius

5.1.3 *DUT* — device under test

5.1.4 *°F* — degrees Fahrenheit

5.1.5 *in* — inch

5.1.6 *kPa* — kiloPascal

5.1.7 *LOD* — limit of detection

5.1.8 *m* — meter

5.1.9 *MFC* — mass flow controller

5.1.10 *NMHC* — non methane hydrocarbons

5.1.11 *POU* — point of use

5.1.12 *ppb* — parts per billion, volume basis

1 American National Standards Institute, New York Office: 11 West 42nd Street, New York, NY 10036, USA. Telephone: 212.642.4900; Fax: 212.398.0023 Website: www.ansi.org

5.1.13 *ppm* — parts per million, volume basis

5.1.14 *psi* — pounds per square inch

5.1.15 *psia* — pounds per square inch absolute

5.1.16 *psig* — pounds per square inch gauge

5.1.17 R_a — surface roughness average (as defined in ANSI B46.1)

5.1.18 $R_{a,max}$ — surface roughness maximum (as defined in ANSI B46.1)

5.1.19 *s* — second

5.1.20 *sccm* — standard cubic centimeters per minute

5.1.21 *slpm* — standard liters per minute

5.1.22 *UHP* — ultra high purity

5.2 *Definitions*

5.2.1 *activation* — the process of initially preparing the purifier media to be chemically reactive with gas impurities.

5.2.2 *activation temperature* — temperature at which DUT was initially prepared.

5.2.3 *atmospheric pressure ionization mass spectrometer (APIMS)* — an instrument consisting of an atmospheric pressure ion source where gas phase impurities are ionized via charge exchange reactions with the bulk gas. These ions are directed into a vacuum chamber where they are then separated by a mass analyzer and detected by an electron multiplier.

5.2.3.1 *ion source* — the section of a mass spectrometer used to generate sample ions by electron impact, chemical ionization, or charge exchange.

5.2.3.2 *mass analyzer* — a device that utilizes electric and/or magnetic fields to separate charged particles or ions according to their mass-to-charge (m/e) ratios. Examples of mass analyzers include quadrupole, magnetic and/or electric sector, time of flight, and ion traps.

5.2.3.3 *electron multiplier* — a device that detects and amplifies electro-magnetic phenomena such as positive/negative ions.

5.2.4 *back pressure regulator* — a self-contained device, consisting of a mechanical or electrical sensor and control device, commonly used in the semiconductor industry to maintain a constant pressure upstream of the regulator.

5.2.5 *breakthrough* — the point in time when an individual impurity level in the purifier effluent exceeds the level specified by the manufacturer. Typically in the range of 1–100 ppb.

5.2.6 *challenge gas* — a gas mixture containing high levels of gas impurities. Typically, a challenge gas has impurities of between 500 ppm to 1% which is used to shorten the test duration; however, challenges in the range of 1–10 ppm for the impurities is more representative.

5.2.7 *efficiency* — a measure of the ability of a purifier to remove active impurities from a matrix gas stream. It is calculated as the ratio of the difference between the inlet concentration and the concentration of impurity leaving the purifier to the concentration of impurity entering the purifier.

5.2.8 *gaseous impurities* — gas phase elements and compounds in the gas stream other than the process or base gas.

5.2.9 *impurity analyzer* — an appropriate analyzer to measure the concentration of desired impurities in a gas stream from the ppm to the percent (%) concentration range.

5.2.10 *inert gas* — a gas, which at ambient conditions, does not react chemically with other materials or chemicals.

5.2.11 *limit of detection (LOD)* — lowest concentration that can be detected by an instrument. LOD is typically defined as three times the standard deviation of the mean noise level (see SEMI F6, lower detectable limit of instrument).

5.2.12 *mass flow controller (MFC)* — a self-contained device, consisting of a mass flow transducer, control valve, and control and signal-processing electronics, commonly used in the semiconductor industry to measure and regulate the mass flow of gas (as defined in SEMI E29).

5.2.13 *pure gas* — an inert gas, minimum purity of 99.9995%, and less than 1 ppb of each impurity that is specified to be removed by the DUT.

5.2.14 *purifier*— generally a catalytic (getter, reactive), resinous, or diatomaceous material within a pressure vessel which removes particulate and/or trace gas impurities from a gas stream (as defined in SEMI F22).

5.2.15 *purifier capacity* — the total quantity of each trace gas impurity that may be sorbed by the purifier media. Defined as liters impurity/liter purifier media.

5.2.16 *regeneration* — the process of reactivating the purifier media.

5.2.17 *test duration* — total time required to complete the test procedure.

5.2.18 *test flow rate* — flow rate through DUT (slpm).

5.2.19 *test pressure* — pressure immediately upstream of the DUT.

5.2.20 *test temperature* — operating temperature of DUT.

5.2.21 *ultratrace analytical instrumentation* — instrumentation that has sufficient sensitivity to measure all impurities of interest at the specified level of the customer, the ppb or sub-ppb level.

5.2.22 *zero gas* — nitrogen, argon, helium or hydrogen with an estimated level an order of magnitude, or more, lower than the lowest calibration point for each impurity of interest (as defined in SEMI F33).

6 Summary of Method

6.1 This method will allow a user to quantify the impurity efficiency of a point-of-use (POU) or large scale purifier.

7 Safety Precautions

7.1 This test method may involve hazardous materials, operations, and equipment. The test method does not purport to address the safety considerations associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations before using this method.

7.2 Exhaust from the DUT should be properly vented.

7.3 Only the appropriate gas should be used for purifier testing. Use of inappropriate gases may cause exothermic reactions and possible explosions.

7.4 Electric discharges or mechanical friction might trigger combustion within a getter. Avoid situations where there is an accumulation of electrostatic charge.

7.5 Purifiers are generally designed for use with impurity levels less than 1% and should not be used to purify air or other inappropriate gases. Contact the manufacturer if there is any question as to the suitability for a particular gas.

7.6 Care should be taken to minimize the purifier's exposure to room air (even filtered air). Room air may chemically react with some purifiers shortening the purifier lifetime. Follow manufacturer's installation procedures.

8 Test Protocol

8.1 *Test Conditions*

8.1.1 The test should be conducted following manufacturer's recommended handling procedures to activate new media or regenerate existing purifier media.

8.1.2 The test is to be conducted at a room temperature maintained between 18°C (64°F) and 26°C (78°F). Environmental temperature fluctuations within this range are not expected to have any measurable effect on the instrumentation used to detect the level of impurities. Follow instrument manufacturer's operating procedures.

8.2 *Apparatus*

8.2.1 *Materials*

8.2.1.1 *Test Gas* — a mixture of pure gas and challenge gas. The mixture should contain gaseous impurities of between 1 ppm and 10 ppm.

8.2.1.2 *Pressure Regulators* — all wetted internal surfaces, where appropriate, should be made of electropolished 316L stainless steel with an internal surface finish of 0.18 µm (7 µin) R_a and 0.25 µm (10 µin) $R_{a,max}$, to control system pressures.

8.2.1.3 *Pressure Gauge* — all wetted internal surfaces, where appropriate, should be made of electropolished 316L stainless steel with an internal surface finish of 0.18 µm (7 µin) R_a and 0.25 µm (10 µin) $R_{a,max}$, to monitor system pressures.

8.2.1.4 *Standard Test Flows* — use appropriate mass flow devices. One MFC with appropriate range of 0–50 slpm for the pure gas is suggested. Various MFCs with appropriate ranges of 0–25 sccm, 0–100 sccm and 0–1 slpm for the challenge gas are suggested.

8.2.1.5 *Tubing* — made of electropolished 316L stainless steel, with an internal surface finish of 0.18 µm (7 µin) R_a and 0.25 µm (10 µin) $R_{a,max}$, to transport gas.

8.2.1.6 *Fittings* — the appropriate size face-seal fitting is used.

8.2.1.7 *Gaskets* — use metal gaskets for all connections. New gaskets should be used for each new connection. Use of cleanroom gloves is required when handling gaskets and fittings.

8.2.2 *Instrumentation*

8.2.2.1 An APIMS or other ultratrace analytical instrumentation is used to determine the level of each gaseous impurity exiting the DUT.

8.2.2.2 An impurity analyzer is used to measure higher concentrations of impurities such as found in the test gas.

8.2.2.3 Electronically controlled mass flow controllers are used to accurately blend the impurity challenge level.

8.2.2.4 Data collection equipment is used to gather output from the ultratrace analytical instrumentation.

8.2.2.5 All instruments used should be calibrated regularly, according to manufacturer specifications.

8.2.3 *Test Setup and Schematic*

8.2.3.1 Assemble the test setup according to Figure 1. For a large scale system which may include components such as flow meters, pressure regulation and indication, and bypass loops around the purifying media(s), the test setup may be modified accordingly in order to use these built in attributes while adhering to the procedural steps. Do not install the DUT until a purge flow is established through MFC1.

8.2.3.2 Pure gas is blended with challenge gas to create a test gas mixture containing approximately 1–10 ppm of gaseous impurities.

8.2.3.3 The DUT is connected, purged per the manufacturer's recommendation, positioned with the appropriate attitude (if required by the manufacturer), and heated (if required by manufacturer) under pure gas flow.

8.2.3.4 Challenge gas flow is introduced and the impurity analyzer measures the impurity levels. If appropriate, the APIMS or other ultratrace analytical instrumentation may be used to measure the test gas while the test gas bypasses the DUT. See Section 9 on Exposure Precautions.

8.2.3.5 Measure and record the test gas concentration for the desired impurity.

8.2.3.6 Instantaneous impurity efficiencies may be calculated at any point by knowing the level of each impurity entering and exiting the purifier.

8.3 *Test Procedures* — Refer to Figure 1.

8.3.1 Use of the impurity analyzer is recommended to protect the APIMS or other ultratrace analytical instrumentation from impurity spikes which may harm the instrument. The test may be conducted without the impurity analyzer at the risk of such spikes.

8.3.2 *Analytical Instrumentation Setup*

8.3.2.1 Set up and calibrate the analytical instrumentation (APIMS or ultratrace analytical instrumentation and impurity analyzer) according to manufacturer specifications. This includes but is not limited to establishing the appropriate flow rates to the instruments.

8.3.2.2 Acquire zero data to establish the instrumentation baseline and stability prior to starting the test.

8.3.3 Establish flow of pure gas through the manifold bypass:

8.3.3.1 Start with all valves closed except purge gas to analytical instrumentation (V11 and V13 open).

8.3.3.2 Open V1 and adjust R1 to the suggested operating pressure range of 275–415 kPa (40–60 psig).

8.3.3.3 Open V2, V8, V9 and adjust R3 to provide appropriate backpressure for operation of the APIMS or other ultratrace analytical instrumentation. R3 will vent excess gas providing the volume challenge to the DUT. Set MFC1 to the appropriate flow rate.

8.3.4 Monitor drydown of the manifold bypass:

8.3.4.1 Close V11 and Open V10.

8.3.4.2 Purge the bypass manifold until the impurity level is in the range of the APIMS or ultratrace analytical instrumentation.

8.3.4.3 Close V13 and Open V12.

8.3.4.4 Purge the bypass manifold until the moisture impurity level at the APIMS or ultratrace analytical instrumentation is below 1.0 ppb.

8.3.5 Re-isolate the APIMS or ultratrace analytical instrumentation:

8.3.5.1 Close V12 and Open V13. Close V10 and open V11. Maintain a constant purge to the analytical instrumentation.

8.3.6 Install the DUT, purging with Pure Gas (may not be necessary, as installed in the test set-up for large scale systems):

8.3.6.1 Open V6. Remove the DUT (purifier) inlet face-seal connection. Quickly install the DUT inlet. Remove the DUT outlet face-seal connection and install the DUT outlet. Open V7.

8.3.6.2 Isolate the manifold bypass, directing all flow through the DUT, close V8 and V9.

8.3.6.3 Adjust R1 and R3 until P1 measures the stated purifier operating pressure.

8.3.6.4 Purge the DUT (purifier) per the manufacturer's recommendation. If required, heat the DUT (purifier) per manufacturer's recommendation.

8.3.7 Monitor the impurity level at the outlet of the DUT until stable:

8.3.7.1 Initial impurity monitoring may be done with the impurity analyzer. Close V12, Open V9 and V10. Close V11.

8.3.7.2 When the impurity level is in the range of the APIMS or ultratrace analytical instrumentation, Close V13 and Open V12. Close V9 and V10, Open V11.

8.3.7.3 Monitor impurity level until stable.

8.3.8 Initiate Impurity Challenge:

8.3.8.1 Isolate the DUT and APIMS or ultratrace analytical instrumentation. Close V7 and V12, open V13.

8.3.8.2 Open V3 and adjust R2 to the suggested operating pressure range of 275–415 kPa (40–60 psig). Open V5 and set MFC2 to the desired flow. (See Appendix 1 to determine the desired flow for MFC2).

8.3.8.3 Verify test gas impurity. Close V5 and V11, Open V4, V8, and V10 supplying test gas to the impurity analyzer. Monitor test gas impurity until stable and verified to theoretical impurity value (See Appendix 1).

8.3.8.4 Initiate test. Isolate impurity analyzer, Close V8 and V10, Open V11. Input test gas through the DUT to the APIMS or ultratrace impurity analyzer, Open V6 and V7. Close V13 and Open V12.

8.3.8.5 Monitor and record the outlet impurity level until stable.

8.3.8.6 If necessary, repeat the test for a different challenge gas mixture.

8.3.9 Determination of instantaneous purifier efficiency:

8.3.9.1 The test may be done on newly activated media or may be done using existing media that has been regenerated. The test may be destructive to the DUT (purifier).

8.3.9.2 Repeat the test as necessary to provide a statistically valid number of test results. A discussion of what is statistically valid is beyond the scope of this document.

9 Exposure Precautions

9.1 The APIMS or ultratrace analytical instrument should not be exposed to high levels of impurities. After installation of the purifier, it should be purged well, per the manufacturer's recommendation. A typical recommendation might be to purge a minimum of 150 bed volumes before directing the flow to the APIMS.

9.2 Alternative instrumentation should be used to measure the challenge gas when the concentration of the challenge gas is greater than the normal calibration range of the APIMS or other ultratrace analytical instrumentation.

10 Calculation of Instantaneous Purifer Efficiency

10.1.1.1 Use the following formula to calculate the Instantaneous Purifier Efficiency:

$$\%eff = \left(1 - \frac{outlet\,impurity}{inlet\,impurity}\right) \times 100$$

Example: Let impurity outlet = 10 ppb and impurity inlet = 10 ppm,

$$\%eff = \left(1 - \frac{10}{10{,}000}\right) \times 100 = 99.9$$

11 Reporting Results

11.1 The following test conditions should be reported:

11.1.1 Date and time of test,

11.1.2 Operator,

11.1.3 Pure gas flow rate (slpm),

11.1.4 Challenge gas flow rate (sccm),

11.1.5 Test pressure kPa (psig or psia),

11.1.6 DUT operating temperature (° C),

11.1.7 Purifier manufacturer, model, and serial number, and volume,

11.1.8 Ultratrace analytical instrumentation used,

11.1.9 Test gas impurities and levels (Table 1), and

11.1.10 Calibration certificates for the mass flow devices, pressure gauges and ultratrace analytical instrumentation.

APPENDIX 1
MFC SIZING

NOTE: The material in this appendix is an official part of SEMI F68 and was approved by full letter ballot procedures on August 27, 2001.

A1-1 To determine purifier efficiency, the concentration of impurity entering the purifier and the quantity of impurity downstream of the purifier must be determined.

A1-2 Determine the manufacturer's recommended flow rate for the purifier. As an example, assume a flow rate of 5 slpm.

A1-3 Determine the flow rate challenge gas required. As an example, 5 sccm of a 1% challenge gas would be blended into 4,995 sccm of pure gas to create at 10 ppm test gas.

$$\text{Test Gas} = \frac{10{,}000 \text{ PPM} \times 5 \text{ sccm}}{5 \text{ sccm} + 4{,}995 \text{ sccm}} = 10 \text{ PPM}$$

As a large scale system, with a flow of 1,000 slpm, a flow of 1 slpm of challenge gas (1% impurity) is required to create a 10 ppm challenge.

$$\text{Test Gas} = \frac{10{,}000 \text{ PPM} \times 1 \text{ slpm}}{1 \text{ slpm} + 999 \text{ slpm}} = 10 \text{ PPM}$$

SEMI F69-0302
TEST METHODS FOR TRANSPORT AND SHOCK TESTING OF GAS DELIVERY SYSTEMS

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the North American Facilities Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org December 2001; to be published March 2002.

1 Purpose

1.1 This document provides test methods for qualifying the mechanical integrity of gas delivery systems through vibration and shock testing.

2 Scope

2.1 The test methods recommended herein provide for vibration (transport simulation) and shock testing of gas delivery systems for semiconductor processing.

2.2 The test methods recommended herein apply to gas delivery systems not crated or packaged for shipment. Specifically, the test methods are to be applied to the assembled and interconnected gas delivery components and their associated mounting panel (back plane), with or without a sheet metal enclosure.

2.3 For the purpose of this guideline, transportation vibration, and its simulation, are expectedly more severe than in-use vibrational levels. Thus the transportation simulation test is considered acceptable to assess mechanical integrity adequate for both shipment and life-cycle vibrational stress of the gas delivery systems.

2.4 The intent of the shock test is to provide further assessment of equipment malfunction that may result from shocks experienced during unpacking, installation, or use in the field.

2.5 Successful completion of the tests recommended herein is a recommended metric of mechanical integrity for gas delivery systems architecture, design, and assembly techniques.

2.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document, as a guide, does not provide detailed information sufficient for conducting the tests. It is the responsibility of the user and testing entity to procure a copy of the referenced test procedures from the issuing organization(s).

3.2 The test methods recommended herein are intended to evaluate gas delivery systems architectures, design principles, and assembly methodologies, not individual production gas delivery systems.

3.3 The functional components of gas delivery systems, for example mass flow controllers and pressure transducers, may be adversely affected by the forces seen during these tests. Such components may require recalibration after testing.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Standards*

SEMI F1 — Specification for Leak Integrity of High-Purity Gas Piping Systems and Components

4.2 *Military Standards*[1]

MIL-STD-810 — Environmental Engineering Considerations and Laboratory Tests

5 Terminology

5.1 *bag leak test* — A helium leak testing procedure in which the system undergoing leak test is placed in a helium-filled plastic bag while connected to a functional helium leak detector.

5.2 *g* — A unit of force equal to that exerted by gravity upon a mass in equilibrium on the earth's surface. Expressed in Newtons (kg-m/sec.^{2}).

5.3 *leak tight* — Having a helium leak rate no greater than that specified by the customer or end-user.

6 Vibration Testing

NOTE 2: Vibration testing should be performed in its entirety before continuing to the shock testing.

6.1 In general, conduct vibrational testing according to MIL-STD-810, Part Two, Laboratory Test Method 514.5, Procedure 1, Category 4, for 3 hours in each axis (a total of 9 hours). This will subject the gas delivery

1 DODSSP, Building 4 / Section D, 700 Robbins Avenue, Philadelphia, PA 19111-5094

systems to the equivalent physical stress of a 4828 kilometer (3000 mile) motor freight shipment over improved or paved highways. Because vibration tables are commonly single-axis devices, the gas delivery systems will be subjected to single-axis random vibrational frequencies in the range of 5—500 Hz, sequentially, in each of its three axes.

6.2 Prior to initiating the test, examine the gas delivery systems for physical defects and document the results.

6.3 Prior to initiating the test, thoroughly prepare the gas delivery systems for testing. This includes, but is not limited to, insuring all fasteners and sealing mechanisms are tightened to manufacturers' or design specifications.

6.4 The MIL-STD-810 transportation test recommended herein provides for different acceleration levels for each of the 3 axes of the device under test. Because the majority of gas delivery systems are shipped in a vertical orientation, this convention is maintained for the purpose of the transportation simulation tests. Thus the vertical orientation would have the gas delivery system mounted vertically with respect to the vibration table top (see Figure 2), the longitudinal orientation would have the gas delivery system mounted flat to the vibration table top (see Figure 1), and the transverse orientation would have the gas delivery system mounted on its side, against the vibration table top (see Figure 3). Note that the terms "vertical," "longitudinal," and "transverse," are contextual to motor freight transport, and receive different acceleration levels, within MIL-STD-810. A simplified and conservative approach to applying MIL-STD-810 involves applying the highest acceleration level, associated with the vertical axis, to all three orientations as illustrated in Figures 1–3.

6.5 Mount the gas delivery system, in any of its untested axes, securely to the vibration table. See Figures 1–3.

6.6 Prior to initiating the test at the test site, make certain that the gas delivery system is leak tight using inboard test procedures per SEMI F1. A bag leak test method is recommended in conjunction with this test.

6.7 Initiate and run for 3 hours the vibration test corresponding to the orientation of the gas delivery system.

6.8 At the conclusion of the test, examine the gas panel for physical defects and document the results

6.9 At the conclusion of the test, leak test the gas delivery system using inboard leak procedures per SEMI F1. A bag leak test method is recommended in conjunction with this test. Alternatively, by agreement with the customer, all leak testing may be withheld until completion of all shock and vibration testing. This presumes specific failure mode information is not required.

6.10 Repeat Sections 6.5 through 6.9 until all 3 axes are tested.

6.11 The post-test report should include, at minimum, the following:

(1) Pre-test examination results.

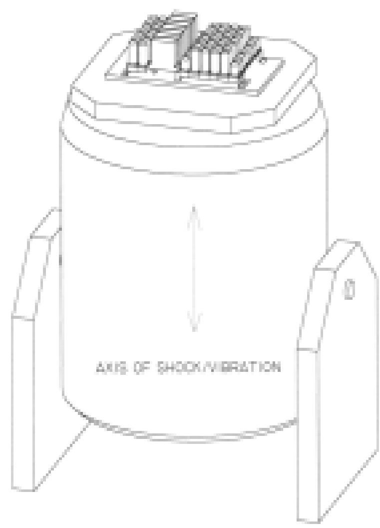
(2) Pre-test leak rates.

(3) Summary and chronology of test events, test interruptions, and test failures.

(4) All vibration measurement data.

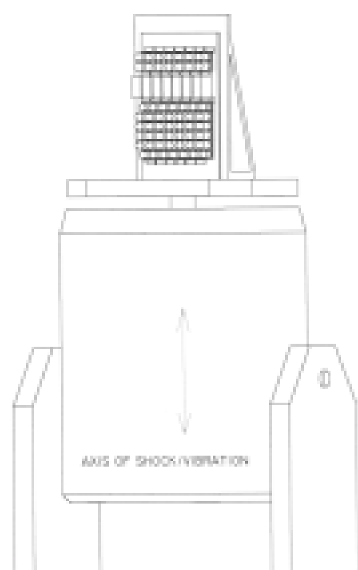
(5) Post-test examination results.

(6) Post-test leak rates.



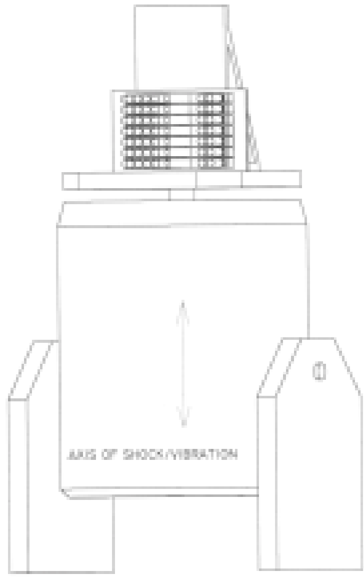
NOTE 1: Plane of gas sticks is parallel to shock/vibe table and transverse to test input.

Figure 1
Horizontal Orientation



NOTE 1: Plane and axes of gas sticks are normal to shock/vibe table and parrallel to test input.

Figure 2
Vertical Orientation



NOTE 1: Plane of gas sticks is normal to shock/vibe table and axes of sticks are transverse to test input.

Figure 3
Lateral Orientation

7 Shock Testing

7.1 In general, conduct shock testing according to MIL-STD-810, Part Two, Laboratory Test Method 516.5, Procedure 1 (Functional Shock). This test will subject the gas delivery system to a peak acceleration of 40 g's employing a terminal peak sawtooth shock pulse.

7.2 The test should be conducted in each of the gas delivery system's three axes as illustrated in Figures 1–3.

7.3 Prior to initiating the test, examine the gas delivery system for physical defects and document the results.

7.4 Prior to initiating the test, thoroughly prepare the gas delivery system for testing. This includes, but is not limited to, insuring all fasteners and sealing mechanisms are tightened to manufacturers' or design specifications.

7.5 Prior to initiating the test, make certain that the gas delivery system is leak tight using inboard test procedures per SEMI F1. A bag leak test method is recommended in conjunction with this test.

7.6 Secure the gas delivery system under test to the shock table in one of its three orientations: horizontal, vertical, or lateral. The gas delivery system should be fastened directly to the table with no cushion or other intermediary between the two. A rigid mounting is desirable, taking caution not to introduce stress to the gas delivery system.

7.7 Conduct the shock test.

7.8 At the conclusion of the test, examine the gas panel for physical defects and document the results.

7.9 If, as a result of the test, an apparent physical failure occurred that would likely prevent the safe operation of the gas panel and/or would likely compromise the leak tightness of the gas panel, the physical failure should be corrected, the gas panel retested for leak tightness, and the test repeated.

7.10 At the conclusion of the test, leak test the gas delivery system using inboard leak procedures per SEMI F1. A bag leak test method is recommended in conjunction with this test. Alternatively, by agreement with the customer, all leak testing may be withheld until completion of all shock and vibration testing. This presumes specific failure mode information is not required.

7.11 Repeat 7.6 through 7.10 for a second orientation.

7.12 Repeat 7.6 through 7.10 for the third and final orientation.

7.13 The post-test report should include, at minimum, the following:

1) Pre-test examination results.

2) Pre-test leak rate.

3) Summary and chronology of test events, test interruptions, and test failures.

4) All shock measurement data, including that of any accelerometers mounted to the gas delivery system.

5) Post-test examination results for all three axes.

6) Post-test leak rate for all three shock tests.

SEMI F70-0302
TEST METHOD FOR DETERMINATION OF PARTICLE CONTRIBUTION OF GAS DELIVERY SYSTEM

This test method was technically approved by the Global Facilities Committee and is the direct responsibility of the Japanese Facilities Committee. Current edition approved by the Japanese Regional Standards Committee on January 11, 2002. Initially available at www.semi.org January 2002; to be published March 2002.

1 Purpose

1.1 The purpose of this document is to provide a standardized methodology and procedure for measuring the particle contribution performance of a gas delivery system in terms of number of particles added to gas flowing through the system. This standardized procedure is intended to be used commonly by the component suppliers, gas suppliers, equipment suppliers, and users.

2 Scope

2.1 This test method applies to all types of surface mount and conventional gas delivery systems used in semiconductor manufacturing facilities and comparable research and development areas.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 All components must meet quality requirements as established and controlled by manufacturers prior to testing (e.g., dimensional, functional, etc.).

3.2 Care should be exercised in handling of components to maintain manufacturer's specifications.

4 Referenced Standards

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *ISO Standards*[1]

ISO 14644-1 — Cleanrooms and Associated Controlled Environments – Part 1: Classification of air cleanliness

4.2 *JIS Standards*[2]

JIS B 9921 — Light Scattering Automatic Particle Counter

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *CNC* — condensation nucleus counter

5.1.2 *LPC* — laser particle counter

5.1.3 *MFC* — mass flow controller

5.1.4 *MFM* — mass flow meter

5.1.5 *slm* — standard liters per minute, the gas volumetric flow rate measured in liters per minute at 0°C and 1 atm.

5.2 *Definitions*

5.2.1 *background counts* — particle counts contributed by the test apparatus (including false counts) with the spool piece in the place of the test object as function of particle size.

5.2.2 *counting efficiency* — the ratio of the particle concentration calculated from the particle counts to the actual particle concentration in the sampled gas for particles equal to or larger than a given particle size.

5.2.3 *design flow rate* — flow rate normally applied to the gas delivery system.

5.2.4 *false counts* — particle counts contributed by electrical noise or by other events and not particles in the sampled gas.

5.2.5 *gas delivery system* — a system installed in semiconductor manufacturing equipment to supply process and carrier gases to reactors, which typically consists of tubing, fittings, valves, filters, mass flow controllers and regulators; can be surface mount or conventional system.

5.2.6 *minimum counting particle diameter* — a predefined minimum diameter of particles to be counted in this test method.

1 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland, website: www.iso.ch

2 Japanese Standards Association, 1-24, Akasaka, 4-Chome, Minato-ku, Tokyo 107 Japan

5.2.7 *particle counts* — a counted value from a laser particle counter (LPC) or condensation nucleus counter (CNC) shown for particles or larger than or equal to the minimum counting particle diameter.

5.2.8 *sample flow rate* — the volumetric flow rate through the particle counter.

5.2.9 *spool piece* — a null component consisting of a straight piece of electropolished tubing or like object and appropriate fittings used in place of the test system to establish the background.

5.2.10 *test flow rate* — the volumetric flow rate through the test systemRequired Apparatus

6 Required Apparatus

6.1 *Filter* — Filters with the following performance specified by the manufacturer.

Characteristic	*Performance*	*Condition*
Filtration Efficiency	9 log	particle size: 0.02 μ m
Flow Rate	300 slm	inlet pressure: 0.34 MPa

6.2 *Tubing Material* — 1/4 inch or 3/8 inch SUS 316L electropolished tubing or better.

6.3 *Particle Counter* — The particle counter may be either LPC or CNC of which the minimum counting particle diameter is 0.1 μ m or smaller, and has the following performance as specified by JIS B 9921.

6.3.1 *Counting Efficiency*

Diameter of Polystyrene Latex Standard Particle	*Counting Efficiency*
Minimum countable particle diameter of the counter (See NOTE 1.)	50 ± 20 %
1.5 to 2.0 × Minimum countable particle diameter of the counter	100 ± 10 %

NOTE 1: For a CNC, the minimum countable diameter shall be defined as a diameter having counting efficiency of 50 ± 20%.

6.3.2 *False Count* — Equal to or less than 1 in 5 minutes.

6.3.3 *Acceptable Error of Flow Rate* — ± 5%

6.4 *Sampler* — A system used to perform partial sampling of the gas stream exiting the test system, that consists of a diffuser equipped with a pressure reducing device in which gradual expansion to atmospheric pressure occurs and a sample probe. It is desirable that the sampler is designed to obtain isokinetic sampling. The average velocity of gas flowing through the sample probe should approximate the average velocity in the external tubing in which the sample probe is inserted. The sample probe overlap with the external tube must be of appropriate length, and it must be confirmed before use that the surrounding atmospheric gas is not drawn in the sample.

7 Test Condition

7.1 *Test Gas* — Liquid Nitrogen (LN_2) or cleaner Nitrogen (N_2) or Argon (Ar).

7.2 *Temperature* — Room temperature (between 18 and 26° C)

7.3 *Environment* — ISO/FDIS 14644-1 class 5 or better.

8 Preparation of Apparatus

8.1 Set up apparatus and the gas supply system as shown in Figure 1.

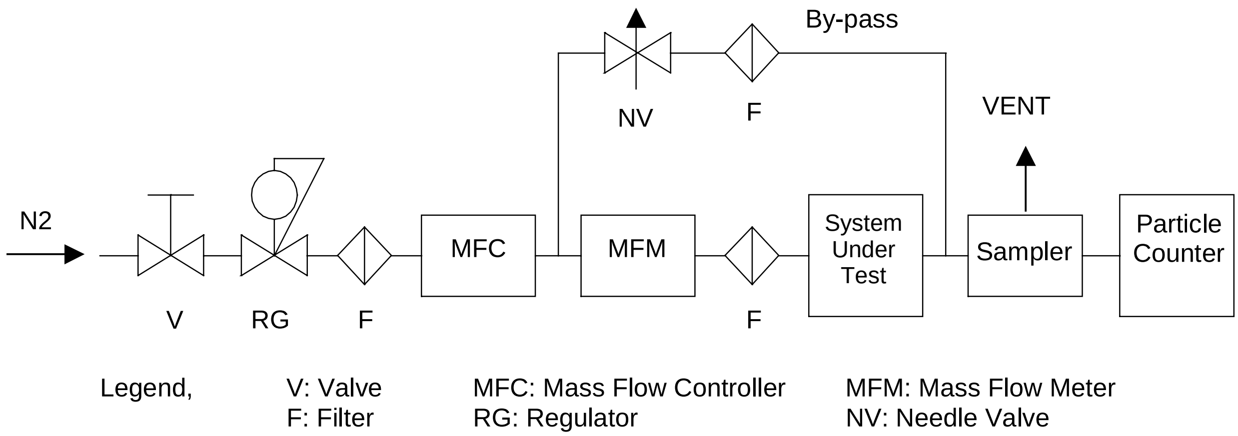


Figure 1
Test Set Up Basic Flow Diagram

8.2 If the test flow rate is equal to or less than the sample flow rate required by the particle counter, insert a filter in place of the sampler to fulfill the sample flow rate. (See Figure 2.)

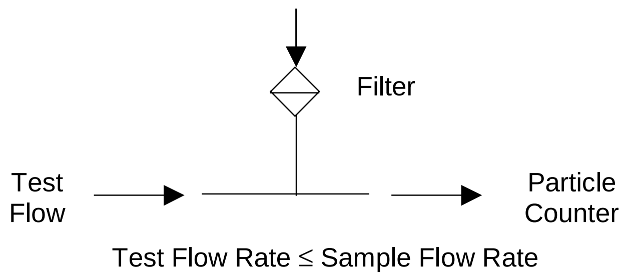

Figure 2
Full Sampling

8.3 If the test flow rate is higher than the sample flow rate required by the particle counter, use the sampler for partial sampling. (See Figure 3.) To establish the test flow rate and obtain an isokinetic condition, it is required to adjust the MFC in the test set up and the NV on the by-pass line. The by-pass line is required to have a capability to handle the maximum test flow when the valves in the system under test is closed position during the pulse test.

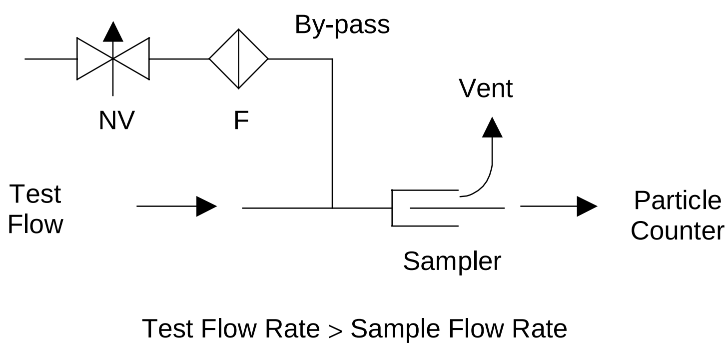

Figure 3
Partial Sampling

9 Procedure

9.1 A typical gas delivery system configuration is shown in Figure 4. The following test procedure shall be interpreted to apply to the actual test system and recorded by the operator.

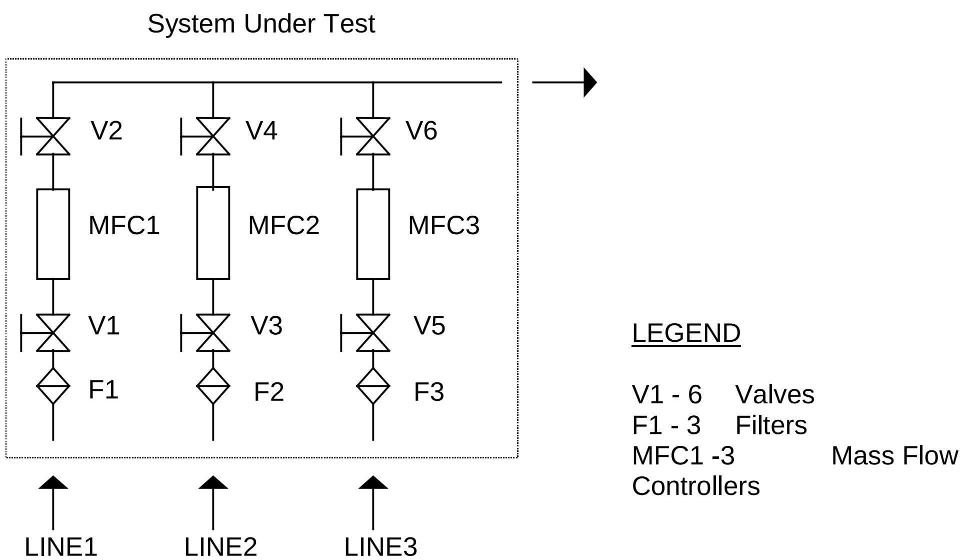

Figure 4
Typical Gas Delivery System Configuration

9.2 *Determination of Background Counts*

9.2.1 For test set up, insert a spool piece in place of the system under test (i.e. the gas delivery system) as in Figure 1.

9.2.2 Establish the test flow rate as 1.5 times of the design flow rate and supply N_2 (or Ar). In this case the design flow rate is determined as the flow rate of the line which has maximum flow rate in the system under test. Purge the test set up for more than 10 minutes.

9.2.3 Confirm the particle count is not more than 1 during 10 minutes after the purge. If the total volume of the test flow is less than 28.3 liters, extend the sampling time until it achieves more than 28.3 liters. If the particle count is more than 1, repeat Sections 9.2.2 and 9.2.3.

9.2.4 Replace the spool piece with the test system.

9.3 *Static Flow Test*

9.3.1 Close all valves in the line 2 and 3, set the MFCs as full scale or purge mode if available and fully open the valves in the line 1.

9.3.2 Supply N_2 (or Ar) to the line 1 with 1.5 times of the design flow rate of the line 1 and purge the test set up for more than 10 minutes. In many case, this will require the activation of the valve override on any MFCs on the test line. It is also required to verify that all components in the system can withstand 1.5 times the design flow rate.

9.3.3 Count particles for more than 10 minutes. If the total volume of the test flow is less than 28.3 liters, extend the sampling time until it achieves more than 28.3 liters.

9.3.4 Repeat Sections 9.3.2 and 9.3.3 per all lines.

9.4 *Pulse Flow Test*

9.4.1 Close all valves in the line 2 and 3, set the MFCs as full scale or purge mode if available and fully open the valves in the line 1.

9.4.2 Supply N_2 (or Ar) to the line 1 with 1.5 times of the design flow rate of the line 1 and purge the test set up for more than 10 minutes.

9.4.3 Actuate V1 at the rate of 30 cycles/minute for 10 minutes if V1 is pneumatically operated valve. For manually operated valve, actuate the valve at 4 cycles/minute for 10 minutes. Each cycle consists of on and off actuation of the valve. The on and off cycles should be of equal duration. If the total volume of the test flow is less than 28.3 liters, extend the sampling time until it achieves more than 28.3 liters. Count particles during the period.

9.4.4 Repeat Section 9.4.3 for V2.

9.4.5 Repeat Sections 9.4.1 to 9.4.4 per all lines.

NOTE 2: For the pulse test, the total volume of the test flow shall be half of the test flow rate multiplied by the sampling time.

10 Calculation and Report

10.1 The following test conditions are to be included in the test report:

- counter type (LPC or CNC)
- manufacturer of counter
- counter model (manufacturer's model # or part #)
- sample flow
- particle diameter
- sampler diameter
- sample probe diameter
- test gas
- background count
- valve operation interval (for the pulse flow test)
- flow diagram of the system under test

10.2 *Calculation of Data* — The test result is reported in number of particles in liters denoted by floating point representation with two significant digits (ex. 2.3×10^{-2}/L). The method of calculation is shown in Section 10.2.1.

10.2.1 The following formula is used to calculate the particles in a liter:

$$PARTICLES = \frac{N}{V}$$

where N: Total particle counts in 10 minutes or in the extended period if the total volume of the test flow is less than 28.3 liters.

V: Total sampling volume in liter in 10 minutes (mass flow meter read value) or in the extended period if the total volume of the test flow is less than 28.3 liters.

If the sample flow rate is equal to or more than the test flow rate, V is equal to the total volume of the test flow in liter in the sampling time.

If the sample flow rate is less than the test flow rate, V is equal to the total volume of the sample flow in liter in the sampling time.

10.3 *Report Format* — Sample report formats are given in Appendixes 1 and 2.

APPENDIX 1
SAMPLE REPORT FORMAT FOR STATIC FLOW PARTICLE TEST

NOTE: This appendix is being balloted as an official part of SEMI F70 by full letter ballot procedures, but the recommendation in this appendix are optional and are not required to conform to this standard.

STATIC FLOW PARTICLE TEST REPORT

Line	*Design Flow (l/min)*	Test Flow (l/min)	*Sampling Method*	Total sampling volume (l)	Total particle count	*Particle Count (particle/l)*

Sample Flow:	28.3 l/min
Particle Diameter:	≥ 0.1 μ m
Sampler Diameter:	30.0 mm
Sample Probe Diameter:	7.53 mm
Test gas:	LN_2
Background Count	0
Valve Operation Interval:	30 cycle/ minute

NOTE 1. The test period for O2 line was extended to 76 minutes in order that the total volume of the test flow achieves more than 28.3 liters.

SEMI S1-0701
SAFETY GUIDELINE FOR EQUIPMENT SAFETY LABELS

This safety guideline was technically approved by the Global Environmental Health and Safety Committee and is the direct responsibility of the North American Environmental Health and Safety Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2001. Initially available at www.semi.org May 2001; to be published July 2001. Originally published in 1986; previously published in 1990.

This document replaces S1-90 in its entirety.

1 Purpose

1.1 This guideline provides guidance for the content and format of equipment safety labels and gives examples of symbols to use.

1.2 This guideline is intended for use by equipment manufacturers to create safety labels that alert persons to hazards associated with the equipment.

1.3 This guideline is intended to provide a unified international semiconductor-industry-specific safety labeling format.

2 Scope

2.1 This guideline is intended to assist in developing safety labels for manufacturing equipment used in the semiconductor industry.

NOTE 1: This guideline may also be used for the design of safety signs for the facilities where semiconductor manufacturing equipment is installed.

NOTE 2: The guidance provided in this document may also be adapted to help communicate safety information in installation instructions, operation and maintenance manuals, and other similar written communication relating to a product.

NOTE 3: This guideline may also be adapted for the design of computerized user interfaces on equipment.

NOTE 4: In order to present a more consistent user interface, it is recommended that the use of the words DANGER, WARNING, and CAUTION, in such interfaces be limited to the meanings and uses given for them in this guideline.

2.2 This document contains the following sections:

1. Purpose
2. Scope
3. Limitations
4. Referenced Standards
5. Terminology
6. General Provisions
7. Formats
8. Signal Words
9. Symbols
10. Word Messages
11. Lettering
12. Colors
13. Placement
14. Translation
15. Related Documents

Appendix 1 — Safety Symbols

Appendix 2 — Translations of Signal Words

2.3 This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Various components or assemblies used in semiconductor manufacturing equipment may carry safety labels that are designed and affixed in accordance with other international standards. It is not the intent of this guideline to replace or supersede such labeling requirements.

3.2 Some safety label formats and content are dictated by other applicable standards and guidelines or by law (e.g., laser labeling and chemical hazard communication labeling in certain countries of use). It is not the intent of this guideline to replace or supersede such labeling requirements.

3.3 New safety labels and safety labels that are significantly redesigned should conform to the latest version of SEMI S1. This guideline is not intended to be applied retroactively.

4 Referenced Standards

NOTE 5: Unless otherwise indicated, all documents cited shall be the latest published versions.

4.1 *SEMI Standards*

SEMI S10 — Safety Guideline for Risk Assessment

4.2 *ANSI Standards*[1]

ANSI Z535.1 — Safety Color Code

ANSI Z535.3 — Criteria for Safety Symbols

ANSI Z535.4 — Product Safety Signs and Labels

4.3 *ISO Standards*[2]

ISO 3864 — Safety Colours and Safety Signs

4.4 *IEC Standards*[3]

IEC 61310-1 — Safety of Machinery - Indication, Marking and Actuation - Part 1: Requirements for Visual, Auditory and Tactile Signals

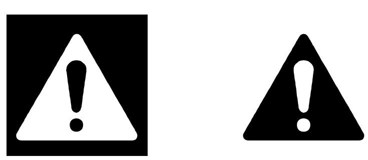
5 Terminology

5.1 *hazard* — a condition that is a prerequisite to a mishap.

5.2 *mishap* — an unplanned event or series of events that results in death, injury, occupational illness, damage to or loss of equipment or property, or environmental damage.

5.3 *panel* — area of a safety label having a distinctive background color which is different from other areas, or which is delineated by a line, border, or margin. See Figures 3 and 4 for examples of panel placement.

5.4 *safety alert symbol* — a specific symbol (see Figure 1) that indicates a potential personal injury hazard.



(Left: For DANGER, Right: For WARNING and CAUTION)

Figure 1
Safety Alert Symbols for Signal Word Panel Use

5.5 *safety label* — a sign, label, or decal that provides safety information.

5.6 *signal word* — the word that calls attention to the safety label and designates a degree or level of hazard seriousness.

5.7 *surround shape* — a geometric configuration that is placed around a symbol and which conveys additional safety information.

5.8 *symbol* — a graphical representation, either abstract or representational, of a hazard, a consequence of engaging a hazard, or a method to avoid a hazard, or some combination of these ideas.

NOTE 6: Some label design standards use the term "pictorial" in the same sense as this guideline uses the term "symbol."

5.9 *target audience* — the audience to be advised of the hazard.

6 General Provisions

6.1 Safety labels should communicate information about specific hazards. Safety labels should be simple, direct, and understandable by the target audience.

6.2 *Content* — Safety labels should communicate:

6.2.1 the seriousness of the hazard (indicated by the signal word);

6.2.2 the nature of the hazard (e.g., type of hazard) or the probable consequence of engaging the hazard; and

6.2.3 how the hazard can be avoided.

6.3 See Figure 2 for examples of how this information can be communicated on a safety label.

1 American National Standards Institute, 11 West 42nd Street, New York, New York 10036, USA, http://www.ansi.org

2 International Organization for Standardization, C.P.56, CH-1211 Geneva 20, Switzerland, http://www.iso.ch

3 International Electrotechnical Commission, 1 rue de Varembe, Geneva, Switzerland, http://www.iec.ch

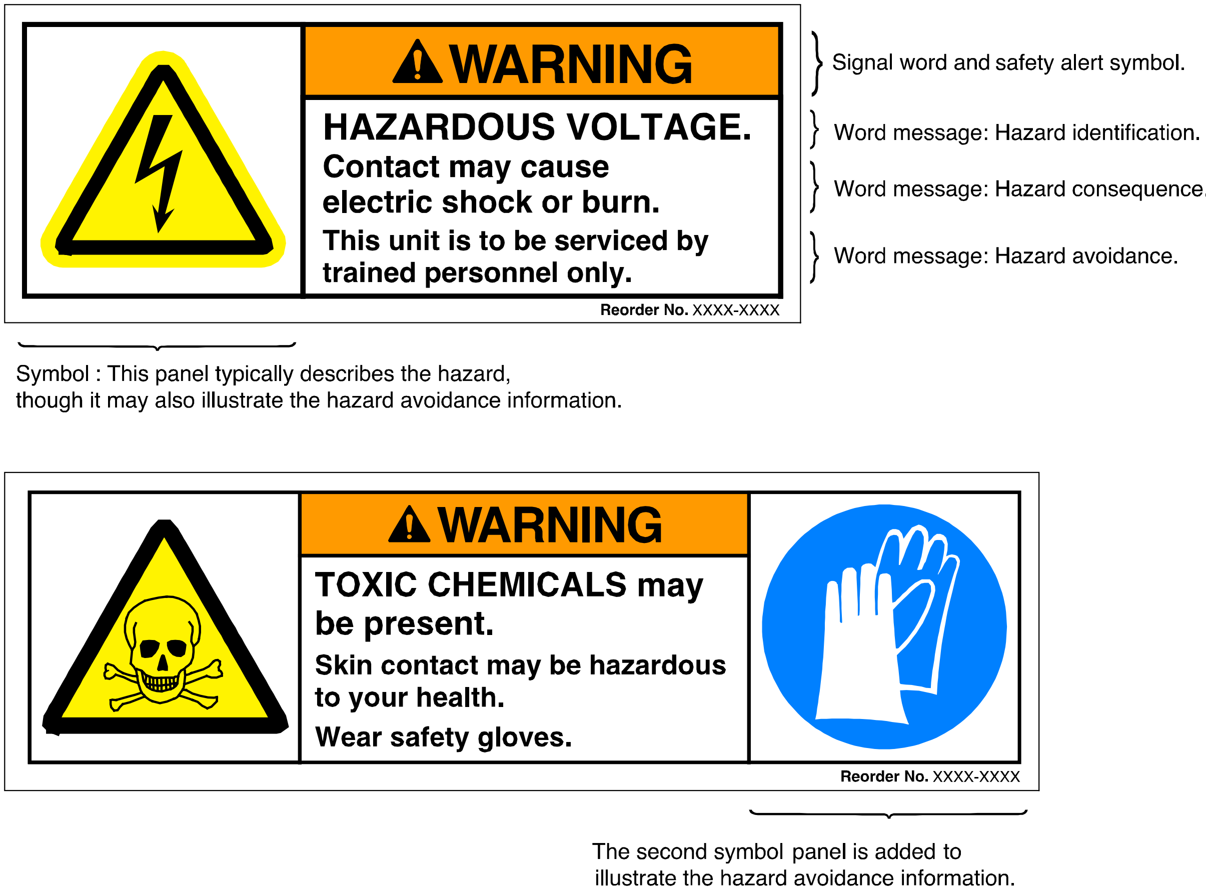


Figure 2
Examples of How Product Safety Labels Communicate Content
(Note that the order and content of the word message is flexible).

6.4 *Identifier* — Safety labels should have a unique identifier (e.g., a part number) printed on the label, to facilitate ordering replacement labels from the equipment manufacturer.

NOTE 7: If a safety label becomes illegible, the user may want to replace it.

6.5 *Durability* — Safety labels should have a reasonable useful life. Determination of reasonable useful life should take into consideration the expected life of the product and the intended environment of use.

NOTE 8: Two factors that may be used for judging useful life are color stability and legibility when viewed at a safe viewing distance. Legibility is affected by letter height.

7 Formats

7.1 Safety labels should consist of at least three panels: signal word panel, word message panel, and symbol panel. Figure 3 provides examples of some possible horizontal and vertical formats incorporating these panels.

EXCEPTION 1: A symbol panel is not necessary for labels that indicate only potential property damage hazards.

EXCEPTION 2: When space limitations exist, such as under guards or on small parts, for safety labels whose target audience is maintenance or service personnel, symbol-only formats with surround shapes (i.e., no signal word, word message, or symbol panels; see Figures 7, 8, and 9) may be used. In this case, borders around the surround shapes should be used. Alternatively, for the same situations, a safety label may be used that has a signal word panel and a word message panel but does not have a symbol panel.

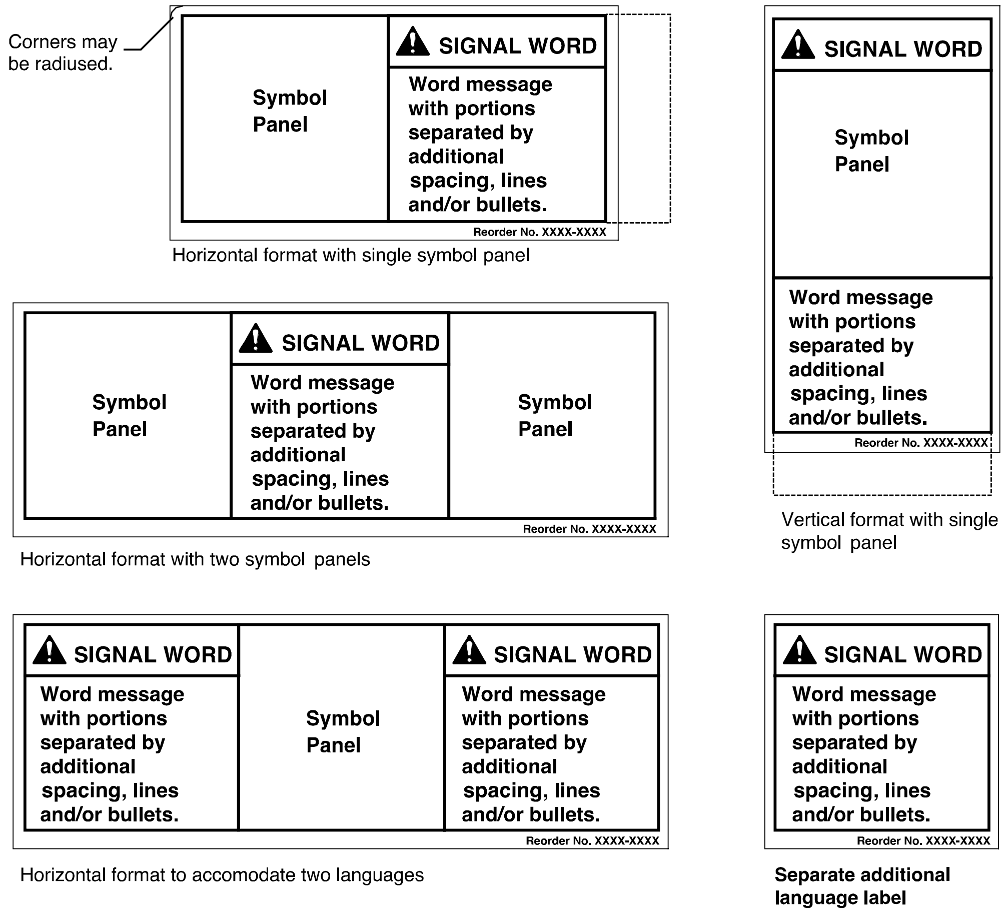

Figure 3
Examples of Format Options for Product Safety Labels

7.2 *Multiple Hazard Formats* — More than one hazard may be conveyed on a single safety label (see Figure 4 for examples).

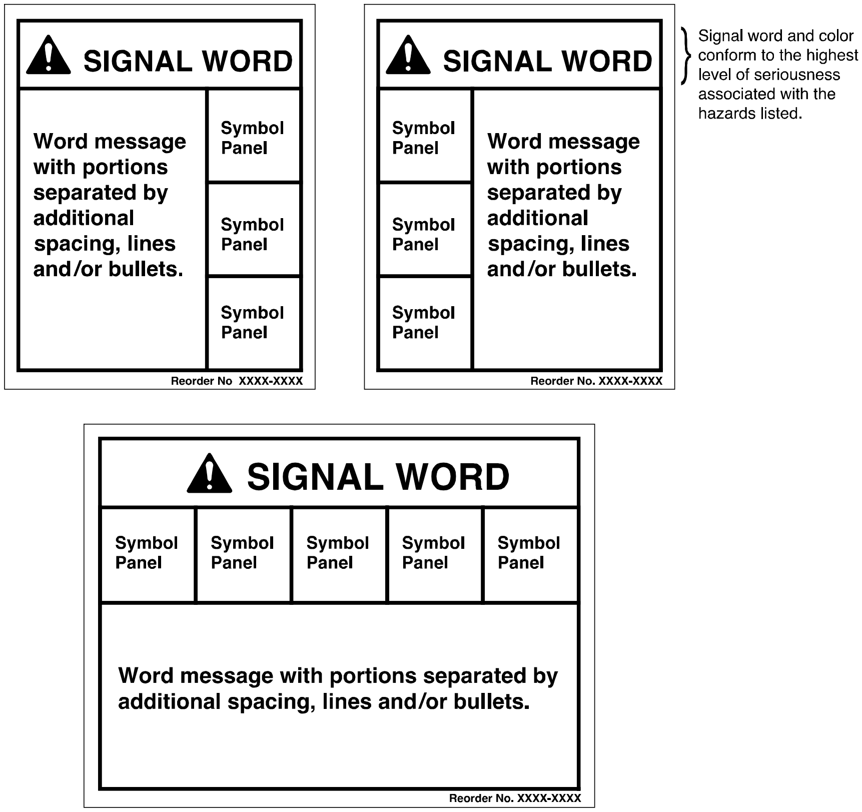

Figure 4
Examples of Multi-Hazard Safety Label Formats

8 Signal Words

8.1 The signal words for safety labels are DANGER, WARNING, and CAUTION.

8.1.1 DANGER is the signal word used to indicate an imminently hazardous situation that, if not avoided, will result in death or severe injury. This signal word is to be limited to the most extreme situations.

8.1.2 WARNING is the signal word used to indicate a potentially hazardous situation which, if not avoided, could result in death or severe injury.

8.1.3 CAUTION is the signal word used to indicate a potentially hazardous situation which, if not avoided, could result in moderate or minor injury. It may also be used to alert against unsafe practices.

NOTE 9: CAUTION without the safety alert symbol may be used as a signal word to indicate a potentially hazardous situation which, if not avoided, could result in property damage.

NOTE 10: SEMI S10 contains examples of ways to categorize severe, moderate, and minor injuries.

8.2 The signal word is placed in the signal word panel.

8.2.1 For DANGER, WARNING, and CAUTION signal words, the safety alert symbol (see Figure 1) is located immediately to the left of and on the same level as the signal word (see Figure 5).

Figure 5
Signal Word Panels

8.2.2 The safety alert symbol should not be used to alert persons to property-damage-only hazards.

8.2.3 When multiple hazard situations are addressed on one safety label, and the hazards are classified at different levels of seriousness, the signal word corresponding to the greatest hazard level should be used.

9 Symbols

9.1 Symbols are graphic representations chosen to convey specific safety messages.

9.2 The symbol panel should contain the safety label's symbol(s).

9.2.1 More than one symbol panel may be used on a safety label.

NOTE 11: See also Section 7.2.

9.2.2 More than one symbol may be used in each symbol panel.

9.3 Symbols may be used to clarify or supplement a portion of a safety label's word message.

NOTE 12: In some cases, symbols may replace the word message. See the exception to Section 10.2.

9.4 A symbol should represent the nature of the hazard, or the potential consequence of engaging the hazard, or actions to be taken to avoid the hazard.

9.5 Symbols should be compatible with the safety label's word message.

NOTE 13: It is preferable to use the symbols shown in Appendix 1.

NOTE 14: For additional information on symbol design, see Annex A of ANSI Z535.3.

9.6 Symbols should be shown in their appropriate surround shape as defined in Section 9.10.

9.7 When an effective symbol does not exist or cannot be created to illustrate the specific hazard or specific avoidance information, the ISO 3864 general warning symbol should be used with a text message that conveys specific information about the hazard (see Figure 6).

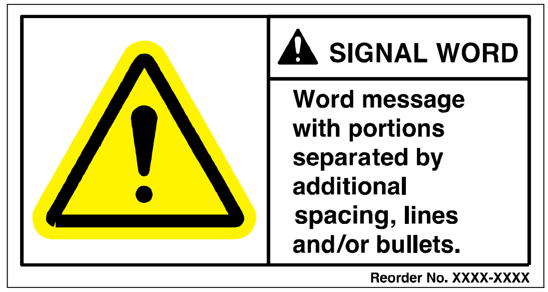

Figure 6
Safety Label with General Warning Symbol

9.8 *Location* — Symbols should be located on safety labels in the areas designated in the examples in Figures 2, 3, and 4, or located in a similar manner. If multiple symbols are used on a multi-hazard safety label, the symbols should appear in the same order as the safety information described in the word message.

EXCEPTION: Location of the safety alert symbol is governed by section 8.2.1.

9.9 *Safety Alert Symbol* — The safety alert symbol is composed of an equilateral triangle surrounding an exclamation mark.

NOTE 15: See Figures 1 and 5 and Section 12.3.4 for format and color information.

9.10 *Symbol Surround Shapes* — Safety symbols should be shown in their appropriate surround shapes (see Figures 7, 8, and 9).

NOTE 16: This is for purposes of international harmonization. The surround shapes have been taken from ISO 3864 and IEC 61310-1.

9.10.1 *Hazard Identification Surround Shape (see Figure 7)* — A symbol located inside a hazard identification surround shape should be used to indicate a personal injury hazard.

9.10.1.1 *Format and Color* — The background color should be yellow. The triangular band should be black. The symbol or pictorial representing the hazard should be black. The border should be yellow; the border is optional if the surrounding background is yellow or white. See Figure 7 for more information.

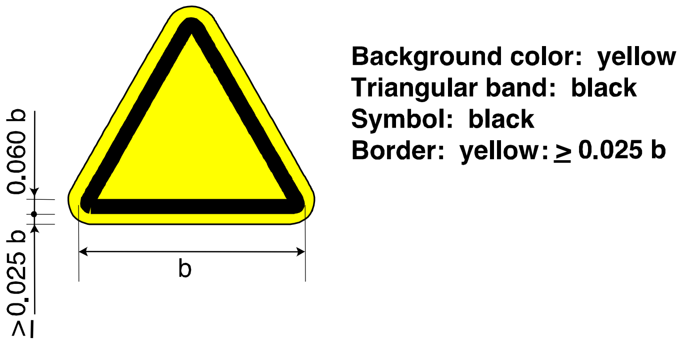

Figure 7
Hazard Identification Symbol Surround Shape

9.10.2 *Prohibition Surround Shape (see Figure 8)* — A symbol located inside a prohibition surround shape should be used to indicate that an action should not be taken or should be stopped.

9.10.2.1 *Format and Color* — The prohibition surround shape should be a circular band with a diagonal bar. The background color should be white. The circular band and diagonal bar should be red. The symbol representing the prohibited action should be black and is preferably shown behind the red slash. The border should be white; the border is optional if the surrounding background is white or yellow. See Figure 8 for more information.

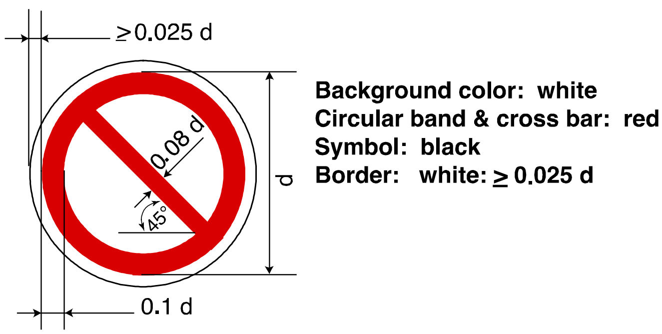

Figure 8
Prohibition Symbol Surround Shape

9.10.3 *Mandatory Action Surround Shape (see Figure 9)* — A symbol located inside a mandatory action surround shape should be used to indicate that an action should be taken to avoid a hazard.

9.10.3.1 *Format and Color* — The background color should be blue. The symbol representing the mandatory action should be white. The border should be white; the border is optional if the surrounding background is white. See Figure 9 for more information.

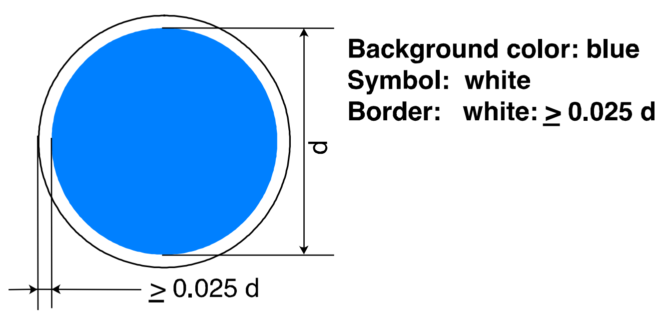

Figure 9
Mandatory Action Symbol Surround Shape

10 Word Message

10.1 The word message is placed in the word message panel.

10.2 The word message preferably contains a description of the hazard, the consequence of engaging the hazard, and how to avoid the hazard. The ordering of this content in the word message is flexible.

EXCEPTION: Parts or all of the word message may be omitted, depending on such factors as whether the message can be inferred from a symbol, other text messages, user training, or the context in which the safety label is used.

10.3 The word message on a safety label should be concise and readily understood.

10.4 Messages on the same safety label that warn of different hazards should be formatted, when feasible, to prevent them from visually blending together. Bullets, lines, and extra line spacing are examples of such formatting.

10.5 When detailed instructions, precautions, or consequences would require a lengthy message, the message may alternatively refer the reader to another source for additional safety information. Examples of such sources include safety instructions, operation and maintenance manuals, service manuals, operating procedures, and safety bulletins.

11 Lettering

11.1 Signal words should be in the lettering style shown in Appendix 2.

11.2 For languages using the "Roman" alphabet, such as the official languages used in the Americas and in much of the European Union, the lettering should be a combination of upper- and lowercase sans serif letters. Uppercase only lettering may be used for short messages or for emphasis of individual words.

NOTE 17: Preferred Roman sans serif lettering styles include those named Arial, Arial Bold, Folio Medium, Franklin Gothic, Helvetica, Helvetica Bold, and Univers.

11.3 Lettering should be of a size that enables a person with normal vision, including corrected vision, to read the safety label at a safe viewing distance from the hazard.

NOTE 18: Related Information 1 provides an example of a method of calculating minimum letter heights.

NOTE 19: The proportions and spacing of individual letters also affect readability.

12 Colors

12.1 *Color Specifications* — Colors should conform to those colors specified in ISO 3864.

NOTE 20: For purposes of reproduction, the closest PANTONE color match for opaque safety colors is:

- Red – PANTONE 485
- Orange – PANTONE 152
- Yellow – PANTONE 109
- Blue – PANTONE 2945

(PANTONE is a registered trademark of Pantone, Inc.).

NOTE 21: Perceived color will be different under colored light (e.g., "yellow room") conditions. The committee knows of no current technical solution.

12.2 *Symbol and Surround Shape Color Specifications* — See section 9.10 for symbol and surround shape color criteria.

12.3 *Signal Word Panel* — The three signal words should be colored as follows (see Figure 5):

12.3.1 The word DANGER should be in white letters on a red background.

12.3.2 The word WARNING should be in black letters on an orange background.

12.3.3 The word CAUTION should be in black letters on a yellow background.

12.3.4 *Safety Alert Symbol* — The solid triangle portion should be the same color as the signal word lettering, and the exclamation mark portion should be the same color as the signal word panel background.

12.4 *Optional Use of Red* — The color red may be used in a symbol to indicate heat or fire.

13 Placement

13.1 *Location of Safety Labels* — Safety labels should be permanently attached to the equipment and, when possible, located near the hazard.

13.2 *Safe Viewing Distance* — Safety labels should be placed to allow the viewer enough time to:

- be informed by the safety label; and
- have sufficient time to avoid the hazard or take appropriate evasive action to reduce the potential harm from the hazard.

13.3 *Placement* — Safety labels should be placed so that they are legible, non-distracting, and not hazardous in themselves.

13.4 *Inadvertent Removal, Visual Blockage* — Safety labels should not be located in areas where they may be removed by the motion of equipment or rendered ineffective by situational conditions.

13.4.1 Safety labels should not be blocked from view by moveable panels such as doors, windows, and racks where this would limit the effectiveness of the blocked label.

14 Translation

14.1 This guideline is not intended to suggest that safety labels be written in or translated into any particular language.

NOTE 22: National laws may require that safety label information be provided in one or more particular languages.

APPENDIX 1
SAFETY SYMBOLS

NOTE: The material in this appendix is an official part of SEMI S1 and was approved by full letter ballot procedures on April 30, 2001 by the North American Regional Standards Committee.

This appendix illustrates symbols used on safety labels for hazards commonly found in the semiconductor manufacturing industry. Additional symbols may need to be developed for other hazards (see *ANSI Z535.3-1998 Informative Annex A* for an example of symbol development guidelines).

To determine what symbol should be used on a safety label, it is first necessary to determine what message is to be communicated. Symbols may enhance a safety label's meaning and may be useful to communicate across many languages.

When appropriate, the following symbols should be used.

NOTE A1-1: Some symbols (e.g., laser, biohazard, and radiation) are required by law or regulation in some jurisictions.

Table A1-1 Hazard Identification Symbols

#	*Referent*	*Source*	*Symbol*	*Description*
1	**Flammable Material**	**IEC 61310**		Flames
2	**Explosive Material, Explosion Hazard**	**IEC 61310**		Object exploding
3	**Danger: Electricity, Electrical Hazard**	**IEC 61310, ISO 3864**		Lightning bolt
4	**Corrosive Material, Corrosion**	**IEC 61310**		Test tube, hand, drops
5	**Toxic Material, Poison**	**IEC 61310**		Skull and crossbones
6	**Slip Hazard**	**ANSI Z535.3**		Person falling on surface
7	**Trip Hazard**	**ANSI Z535.3**		Person tripping over object

#	*Referent*	*Source*	*Symbol*	*Description*
8	**Drop, Fall Hazard**	**IEC 61310**		Person falling
9	**Lifting Hazard, Heavy Object**			Person bent over weight, strain flare above back
10	**Tipover**			Person with object tipping over and arrow
11	**Entanglement Hazard (hand in gears)**	**ANSI Z535.3**		Hand in gears Note: other body parts or orientations may be substituted as necessary
12	**Pinch point (hand in rollers)**	**ANSI Z535.4**		Hand in rollers Note: other body parts or orientations may be substituted as necessary
13	**Cut/Sever (hand and sharp object)**	**ANSI Z535.3**		Hand and sharp object Note: other body parts or orientations may be substituted as necessary
14	**Crush Hazard**			Hand between two surfaces, arrow Note: other body parts or orientations may be substituted as necessary
15	**Heat, Hot Surface**	**ISO 3864, ISO 7000**		Heat waves
16	**Cold**			Snow flake
17	**Strong Magnetic Field**			Horseshoe magnet

#	*Referent*	*Source*	*Symbol*	*Description*
18	**Radioactive Material,** **Radiation Hazard**	**IEC 61310**		Abstract three blades
19	**Laser Beam**	**IEC 60825-1**		Radiating sunburst, line
20	**Biological Risk,** **Biohazard**	**IEC 61310**		Abstraction
21	**Non-Ionizing Radiation,** **Radio Frequency**	**IEC 61310**		Abstract radiation transmitter
22	**UV Light Hazard**			The letters "UV" inside a sunburst
23	**Inhalation Hazard (e.g., toxic gas, asphyxiation hazard)**			Human figure breathing in particles
24	**General Warning** **(should be supplemented with words)**	**ISO 3864**		Exclamation point (See Figure 6 for an example of a safety label using the General Warning symbol)

Table A1-2 Mandatory Action Symbols

#	*Referent*	*Source*	*Symbol*	*Description*
1	**Wear Eye Protection**	**IEC 61310**		Head with eyeglasses
2	**Wear Ear Protection**	**IEC 61310**		Head with ear protection

#	*Referent*	*Source*	*Symbol*	*Description*
3	**Wear Head Protection**	**IEC 61310**		Head with hard hat
4	**Wear Respiratory Protection**	**IEC 61310**		Head with respirator
5	**Wear Safety Boots**	**IEC 61310**		Shoes (one with metal plate shown)
6	**Wear Safety Gloves**	**IEC 61310**		Two gloves
7	**Lift with Mechanical Assistance**			Mechanical jack supporting object
8	**Lift with Two Persons**			Two persons grasping object
9	**Read Manual**			Person reading open book
10	**Lock Out in De-Energized State**			ON and OFF symbols next to locked clasp

Table A1-3 Prohibition Symbols

#	*Referent*	*Source*	*Symbol*	*Description*
1	**No Smoking**	**ANSI Z535.3**		Lighted cigarette
2	**No Open Flame**	**IEC 61310**		Lighted match
3	**No Access For Unauthorized Persons**	**IEC 61310**		Person shouting with outstretched hand
4	**No Portable Transmitters**			Wireless telephone
5	**No Pacemakers**			Ball and line attached to heart
6	**General Prohibited Action** **(should be supplemented with words)**	**ISO 3864**		Prohibition surround shape

APPENDIX 2
TRANSLATIONS OF SIGNAL WORDS

NOTE: The material in this appendix is an official part of SEMI S1 and was approved by full letter ballot procedures on April 30, 2001 by the North American Regional Standards Committee.

Translation of the signal words and word message are optional considerations. If the signal word of a safety label is to be translated, the following translations should be used.

Language	DANGER	WARNING	CAUTION
Chinese:	危險	警告	注意
Danish:	FARE	ADVARSEL	FORSIGTIG
Dutch:	GEVAAR	WAARSCHUWING	VOORZICHTIG
English:	DANGER	WARNING	CAUTION
Finnish	VAARA	VAROITUS	HUOMIO
French:	DANGER	AVERTISSEMENT	ATTENTION
German:	GEFAHR	WARNUNG	VORSICHT
Greek:	ΚΙΝΔΥΝΟΣ	ΠΡΟΕΙΔΟΠΟΙΗΑΣΗ	ΠΡΟΣΟΧΗ
Italian:	PERICOLO	AVVERTENZA	ATTENZIONE
Japanese:	危険	警告	注意
Korean:	위험	경고	주의
Norwegian:	FARE	ADVARSEL	FORSIKTIG
Portuguese:	PERIGRO	ATENÇÃO	CUIDADO
Russian:	ОПАСНО	ОСТОРОЖНО	ВНИМАНИЕ
Spanish:	PELIGRO	ADVERTENCIA	ATENCIÓN
Swedish:	FARA	VARNING	OBSERVER
Turkish:	TEHLİKE	UYARI	DİKKAT

NOTICE:

Paragraphs entitled "NOTE" are not an official part of this safety guideline and are not intended to modify or supersede the official safety guideline. These have been supplied by the committee to enhance the usage of the safety guideline.

SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of the guideline is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials or equipment mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this guideline may require use of copyrighted material or of an invention covered by patent rights. By publication of this guideline, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this guideline. Users of this guideline are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

RELATED INFORMATION 1
MINIMUM LETTER HEIGHT CALCULATIONS

NOTE: This related information is not an official part of SEMI S1 and is not intended to modify or supersede the official guideline. It has been derived from the informative Annex B of ANSI Z535.4-1998. Publication is authorized by vote of the responsible committee. Determination of the suitability of this material is solely the responsibility of the user.

R1-1 A common concern when designing safety labels is determining the minimum letter height of text. This Related Information describes one method that may be used to determine a minimum letter height.

Table R1-1 Examples of Word Message Uppercase Letter Heights at Various Viewing Distances

Viewing Distance	***Minimum** Letter Height for FAVORABLE Reading Conditions*	***Recommended** Letter Height for FAVORABLE Reading Conditions*	***Recommended** Letter Height for UNFAVORABLE Reading Conditions*
300 mm (12 in.) or less*	2 mm (0.08 in)	2 mm (0.08 in)	2 mm (0.08 in)
600 mm (24 in.)	2.5 mm (0.10 in)	4 mm (0.16 in)	4 mm (0.16 in)
900 mm (35 in.)	3 mm (0.12 in)	4.75 mm (0.19 in)	6 mm (0.24 in)
1.2 m (47 in.)	3.5 mm (0.14 in)	5.5 mm (0.22 in)	8 mm (0.31 in)
1.5 m (59 in.)	4 mm (0.16 in)	6.25 mm (0.25 in)	10 mm (0.39 in)
1.8 m (71 in.)	4.5 mm (0.18 in)	7 mm (0.28 in)	12 mm (0.47 in)
2.1 m (83 in.)	5 mm (0.20 in)	7.75 mm (0.31 in)	14 mm (0.55 in)
2.4 m (94 in.)	5.5 mm (0.22 in)	8.5 mm (0.33 in)	16 mm (0.63 in)

* 2 mm (0.079 in.) is the suggested minimum type size for use on safety labels.

Calculations for **Recommended** Letter Heights (in mm) for FAVORABLE Reading Conditions:

600 mm or less: (viewing distance in mm) / 150

>600 mm to 6 m: [(viewing distance in mm - 600) x .0025] + 4

Calculation for **Recommended** Letter Heights for UNFAVORABLE Reading Conditions (all distances):

(viewing distance) / 150

NOTICE:

SEMI S2-0302
ENVIRONMENTAL, HEALTH, AND SAFETY GUIDELINE FOR SEMICONDUCTOR MANUFACTURING EQUIPMENT

This safety guideline was technically approved by the Global Environmental, Health, and Safety Committee and is the direct responsibility of the North American Environmental, Health, and Safety Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available on www.semi.org December 2001; to be published March 2002. Originally published in 1991; previously published in February 2000.

1 Purpose

1.1 This safety guideline is intended as a set of performance-based environmental, health, and safety (EHS) considerations for semiconductor manufacturing equipment.

2 Scope

2.1 *Applicability* — This guideline applies to equipment used to manufacture, measure, assemble, and test semiconductor products.

2.2 *Contents* — This document contains the following sections:

1. Purpose
2. Scope
3. Limitations
4. Referenced Standards
5. Terminology
6. Safety Philosophy
7. General Provisions
8. Evaluation Process
9. Documents Provided to User
10. Hazard Warning Labels
11. Safety Interlock Systems
12. Emergency Shutdown
13. Electrical Design
14. Fire Protection
15. Heated Chemical Baths
16. Ergonomics and Human Factors
17. Hazardous Energy Isolation
18. Mechanical Design
19. Seismic Protection
20. Automated Material Handlers
21. Environmental Considerations
22. Exhaust Ventilation
23. Chemicals
24. Ionizing Radiation
25. Non-Ionizing Radiation and Fields
26. Lasers
27. Sound Pressure Level
28. Related Documents

Appendix 1 — Enclosure Openings

Appendix 2 — Design Principles and Test Methods for Evaluating Equipment Exhaust Ventilation

Appendix 3 — Design Guidelines for Equipment Using Liquid Chemicals

Appendix 4 — Ionizing Radiation Test Validation

Appendix 5 — Non-Ionizing Radiation (Other than Laser) and Fields Test Validation

Appendix 6 — Fire Protection: Flowchart for Selecting Materials of Construction

2.3 *Precedence of Sectional Requirements* — In the case of conflict between provisions in different sections of this guideline, the section or subsection specifically addressing the technical issue takes precedence over the more general section or subsection.

2.4 This safety guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guideline is intended for use by supplier and user as a reference for EHS considerations. It is not intended to be used to verify compliance with local regulatory requirements.

3.2 It is not the philosophy of this guideline to provide all of the detailed EHS design criteria that may be applied to semiconductor manufacturing equipment. This guideline provides industry-specific criteria, and refers to some of the many international codes, regulations, standards, and specifications that should be considered when designing semiconductor manufacturing equipment.

3.3 Existing models and subsystems should continue to meet the provisions of SEMI S2-93A. Models with redesigns that significantly affect the EHS aspects of the equipment should conform to the latest version of SEMI S2. This guideline is not intended to be applied retroactively.

3.4 In many cases, references to standards have been incorporated into this guideline. These references do not imply applicability of the entire standards, but only of the sections referenced.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *ACGIH®* — American Conference of Governmental Industrial Hygienists (ACGIH is a registered trademark of the American Conference of Governmental Industrial Hygienists.)

5.1.2 *ASHRAE* — American Society of Heating, Refrigeration, and Air Conditioning Engineers

5.2 *Definitions*

5.2.1 *abort switch* — a switch that, when activated, interrupts the activation sequence of a fire detection or fire suppression system.

5.2.2 *accredited testing laboratory* — an independent organization dedicated to the testing of components, devices, or systems; competent to perform evaluations based on established safety standards; and recognized by a governmental or regulatory body.

5.2.3 *baseline* — for the purposes of this document, "baseline" refers to operating conditions, including process chemistry, for which the equipment was designed and manufactured.

5.2.4 *breathing zone* — imaginary globe, of 600 mm (two foot) radius, surrounding the head.

5.2.5 *capture velocity* — the air velocity that at any point in front of the exhausted hood or at the exhausted hood opening is necessary to overcome opposing air currents and to capture the contaminated air at that point by causing it to flow into the exhausted hood.

6 ACGIH, 1330 Kemper Meadow Road, Cincinnati, Ohio 45240, USA, www.acgih.org

7 ASHRAE, 1791 Tullie Circle, NE, Atlanta, Georgia 30329, USA, www.ashrae.org

10 International Fire Code Institute, 5360 Workman Mill Road, Whittier, California 90601-2298, USA, www.ifci.org

5.2.6 *carcinogen* — confirmed or suspected human cancer-causing agent as defined by the International Agency for Research on Cancer (IARC) or other recognized entities.

5.2.7 *chemical distribution system* — the collection of subsystems and components used in a semiconductor manufacturing facility to control and deliver process chemicals from source to point of use for wafer manufacturing processes.

5.2.8 *cleanroom* — a room in which the concentration of airborne particles is controlled to specific limits.

5.2.9 *coefficient of entry (C_e)* — the ratio of actual airflow into the exhausted hood to the theoretical airflow if all hood static pressure could be converted into velocity, as would be the case if the hood entry loss factor (K or F_h) were zero. $C_e = (VP/|SP_h|)^{0.5}$ where VP = duct velocity pressure and SP_h = hood static pressure (see also Appendix 2).

5.2.10 *combustible material* — for the purpose of this guideline, a combustible material is any material that does propagate flame (beyond the ignition zone with or without the continued application of the ignition source) and does not meet the definition in this section for noncombustible material. (See also the definition for *noncombustible material*.)

5.2.11 *equipment* — a specific piece of machinery, apparatus, process module, or device used to execute an operation. The term "equipment" does not apply to any product (e.g., substrates, semiconductors) that may be damaged as a result of equipment failure.

5.2.12 *face velocity* — velocity at the cross-sectional entrance to the exhausted hood.

5.2.13 *facilitization* — the provision of facilities or services.

5.2.14 *fail-safe* — designed so that a failure does not result in an increased risk.

NOTE 2: For example, a fail-safe temperature limiting device would indicate an out-of-control temperature if it were to fail. This might interrupt a process, but would be preferable to the device indicating that the temperature is within the control limits, regardless of the actual temperature, in case of a failure.

5.2.15 *failure* — the termination of the ability of an item to perform a required function. Failure is an event, as distinguished from "fault," which is a state.

5.2.16 *fault* — the state of an item characterized by inability to perform a required function, excluding the inability during preventive maintenance or other planned actions, or due to lack of external resources.

5.2.17 *fault-tolerant* — designed so that a reasonably foreseeable single point failure does not result in an unsafe condition.

5.2.18 *flammable gas* — any gas that forms an ignitable mixture in air at 20 °C (68 °F) and 101.3 kPa (14.7 psia).

5.2.19 *flammable liquid* — a liquid having a flash point below 37.8 °C (100 °F).

5.2.20 *flash point* — the minimum temperature at which a liquid gives off sufficient vapor to form an ignitable mixture with air near the surface of the liquid, or within the test vessel used.

5.2.21 *gas cylinder cabinet* — cabinet used for housing gas cylinders, and connected to gas distribution piping or to equipment using the gas. Synonym: gas cabinet.

5.2.22 *gas panel* — an arrangement of fluid handling components (e.g., valves, filters, mass flow controllers) that regulates the flow of fluids into the process. Synonyms: gas jungle, jungle, gas control valves, valve manifold.

5.2.23 *gas panel enclosure* — an enclosure designed to contain leaks from gas panel(s) within itself. Synonyms: jungle enclosure, gas box, valve manifold box.

5.2.24 *hazard* — a condition that is a prerequisite to a mishap.

5.2.25 *hazardous production material (HPM)* — a solid, liquid, or gas that has a degree-of-hazard rating in health, flammability, or reactivity of class 3 or 4 as ranked by NFPA 704 and which is used directly in research, laboratory, or production processes that have as their end product materials that are not hazardous.

5.2.26 *hazardous voltage* — unless otherwise defined by an appropriate international standard applicable to the equipment, voltages greater than 30 volts rms, 42.4 volts peak, 60 volts dc are defined in this document as hazardous voltage.

NOTE 3: The specified levels are based on normal conditions in a dry location.

5.2.27 *hood* — in the context of Section 22 and Appendix 2 of this guideline, "hood" means a shaped inlet designed to capture contaminated air and conduct it into an exhaust duct system.

5.2.28 *hood entry loss factor (K or F_h)* — a unitless factor that quantifies hood efficiency. If the hood is 100% efficient, then K or $F_h = 0$. Related equations:

$Q = 4.043A[(SP_h/d)/(1+F_h)]^{0.5}$

where:

Q = volumetric flow rate in m^3/sec,

A = cross sectional area of the duct in m^2,

SP_h = hood static pressure in mm water gauge (w.g.),

and d = density correction factor (unitless).

(US units: $Q = 4005A[(SP_h/d)/(1+F_h)]^{0.5}$

where:

Q = volumetric flow rate in cfm.

A = cross sectional area of the duct in ft^2,

SP_h = hood static pressure in inches water gauge (w.g.),

and d = density correction factor (unitless).)

5.2.29 *incompatible* — as applied to chemicals: in the context of Section 23 of this guideline, describes chemicals that, when combined unintentionally, may react violently or in an uncontrolled manner, releasing energy that may create a hazardous condition.

5.2.30 *intended reaction product* — chemicals that are produced intentionally as a functional part of the semiconductor manufacturing process.

5.2.31 *interlock* — a mechanical, electrical or other type of device or system, the purpose of which is to prevent or interrupt the operation of specified machine elements under specified conditions.

5.2.32 *ionizing radiation* — alpha particles, beta particles, gamma rays, x-rays, neutrons, high-speed electrons, high-speed protons, and other particles capable of producing ions in human tissue.

5.2.33 *laser* — any device that can be made to produce or amplify electromagnetic radiation in the wavelength range from 180 nm to 1 mm primarily by the process of controlled stimulated emission.

5.2.34 *laser product* — any product or assembly of components that constitutes, incorporates, or is intended to incorporate a laser or laser system (including laser diode), and that is not sold to another manufacturer for use as a component (or replacement for such component) of an electronic product.

5.2.35 *laser source* — any device intended for use in conjunction with a laser to supply energy for the excitation of electrons, ions, or molecules. General energy sources, such as electrical supply mains, should not be considered to be laser energy sources.

5.2.36 *laser system* — a laser in combination with an appropriate laser energy source, with or without additional incorporated components.

5.2.37 *likelihood* — the expected frequency with which a mishap will occur. Usually expressed as a rate (e.g., events per year, per product, or per substrate processed).

5.2.38 *local exhaust ventilation* — local exhaust ventilation systems operate on the principle of capturing a contaminant at or near its source and moving the contaminant to the external environment, usually through an air cleaning or a destructive device. It is not to be confused with laminar flow ventilation. Synonyms: LEV, local exhaust, main exhaust, extraction system, module exhaust, individual exhaust.

5.2.39 *lower explosive limit* — the minimum concentration of vapor in air at which propagation of flame will occur in the presence of an ignition source. Synonyms: LEL, lower flammability limit (LFL).

5.2.40 *maintenance* — planned or unplanned activities intended to keep equipment in good working order. (See also the definition for *service.*)

5.2.41 *mass balance* — a qualitative, and where possible, quantitative, specification of mass flow of input and output streams (including chemicals, gases, water, deionized water, compressed air, nitrogen, and by-products), in sufficient detail to determine the effluent characteristics and potential treatment options.

5.2.42 *material safety data sheet (MSDS)* — written or printed material concerning chemical elements and compounds, including hazardous materials, prepared in accordance with applicable standards.

NOTE 4: Examples of such standards are USA government regulation 29 CFR 1910.1200, and Canadian WHMIS (Workplace Hazardous Material Information System).

5.2.43 *mishap* — an unplanned event or series of events that results in death, injury, occupational illness, damage to or loss of equipment or property, or environmental damage.

NOTE 5: For the purpose of this guideline, a "series of events" is limited to those events resulting from a single point failure. See also Section 6.5.

5.2.44 *noncombustible material* — a material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat. Typical noncombustible materials are metals, ceramics, and silica materials (e.g., glass and quartz). (See also the definition for *combustible material*.)

5.2.45 *non-ionizing radiation* — forms of electro-magnetic energy that do not possess sufficient energy to ionize human tissue by means of the interaction of a single photon of any given frequency with human tissue. Non-ionizing radiation is customarily identified by frequencies from zero hertz to 3×10^{15} hertz (wavelengths ranging from infinite to 100 nm). This includes: static fields (frequencies of 0 hertz and infinite wavelengths); extremely low frequency fields (ELF), which includes power frequencies; subradio-frequencies; radiofrequency/microwave energy; and infrared, visible, and ultraviolet energies.

5.2.46 *non-recycling, deadman-type abort switch* — a type of abort switch that must be constantly held closed for the abort of the fire detection or suppression system. In addition, it does not restart or interrupt any time delay sequence for the detection or suppression system when it is activated.

5.2.47 *occupational exposure limits (OELs)* — for the purpose of this document, OELs are generally established on the basis of an eight hour workday. Various terms are used to refer to OELs, such as permissible exposure levels, Threshold Limit Values®, maximum acceptable concentrations, maximum exposure limits, and occupational exposure standards. However, the criteria used in determining OELs can differ among the various countries that have established values. Refer to the national bodies responsible for the establishment of OELs. (Threshold Limit Value is a registered trademark of the American Conference of Governmental Industrial Hygienists.)

5.2.48 *operator* — a person who interacts with the equipment only to the degree necessary for the equipment to perform its intended function.

5.2.49 *parts-cleaning hood* — exhausted hood used for the purpose of cleaning parts or equipment. Synonym: equipment cleaning hood.

5.2.50 *positive-opening* — as applied to electromechanical control devices. The achievement of contact separation as a direct result of a specified movement of the switch actuator through non-resilient members (i.e., contact separation is not dependent upon springs).

5.2.51 *potentially hazardous non-ionizing radiation emissions* — for the purposes of this guideline, non-ionizing radiation emissions outside the limits shown in Appendix 5 are considered potentially hazardous.

5.2.52 *pyrophoric material* — a chemical that will spontaneously ignite in air at or below a temperature of 54.4°C (130°F).

5.2.53 *radio frequency (rf)* — electromagnetic energy with frequencies ranging from 3 kHz to 300 GHz. Microwaves are a portion of rf extending from 300 MHz to 300 GHz.

5.2.54 *readily accessible* — capable of being reached quickly for operation or inspection, without requiring climbing over or removing obstacles, or using portable ladders, chairs, etc.

5.2.55 *recognized* — as applied to standards; agreed to, accepted, and practiced by a substantial international consensus.

5.2.56 *rem* — unit of dose equivalent. Most instruments used to measure ionizing radiation read in dose equivalent (rems or sieverts). 1 rem = 0.01 sievert.

5.2.57 *reproductive toxicants* — chemicals that are confirmed or suspected to cause statistically significant increased risk for teratogenicity, developmental effects, or adverse effects on embryo viability or on male or female reproductive function at doses that are not considered otherwise maternally or paternally toxic.

5.2.58 *residual* — as applied to risks or hazards: that which remains after engineering, administrative, and work practice controls have been implemented.

5.2.59 *risk* — the expected losses from a mishap, expressed in terms of severity and likelihood.

5.2.60 *safe shutdown condition* — a condition in which all hazardous energy sources are removed or suitably contained and hazardous production materials are removed or contained, unless this results in additional hazardous conditions.

5.2.61 *safety critical part* — discrete device or component, such as used in a power or safety circuit, whose proper operation is necessary to the safe performance of the system or circuit.

5.2.62 *service* — unplanned activities intended to return equipment that has failed to good working order. (See also the definition for *maintenance*.)

5.2.63 *severity* — the extent of the worst credible loss from a mishap caused by a specific hazard.

5.2.64 *sievert (Sv)* — unit of dose equivalent. Most instruments used to measure ionizing radiation read in dose equivalent (rems or sieverts). 1 Sv = 100 rems.

5.2.65 *standard temperature and pressure* — for ventilation measurements, either dry air at 21°C (70°F) and 760 mm (29.92 inches) Hg, or air at 50% relative humidity, 20°C (68°F), and 760 mm (29.92 inches) Hg.

5.2.66 *supervisory alarm* — as applied to fire detection or suppression systems; an alarm indicating a supervisory condition.

5.2.67 *supervisory condition* — as applied to fire detection or suppression systems; condition in which action or maintenance is needed to restore or continue proper function.

5.2.68 *supplemental exhaust* — local exhaust ventilation that is used intermittently for a specific task of finite duration.

5.2.69 *supplier* — party that provides equipment to, and directly communicates with, the user. A supplier may be a manufacturer, an equipment distributor, or an equipment representative. (See also the definition for *user*.)

5.2.70 *testing* — the term "testing" is used to describe measurements or observations used to validate and document conformance to designated criteria.

5.2.71 *trouble alarm* — as applied to fire detection or suppression systems; an alarm indicating a trouble condition.

5.2.72 *trouble condition* — as applied to fire detection or suppression systems; a condition in which there is a fault in a system, subsystem, or component that may interfere with proper function.

5.2.73 *user* — party that acquires equipment for the purpose of using it to manufacture semiconductors. (See also the definition for *supplier*.)

5.2.74 *velocity pressure (VP)* — the pressure required to accelerate air from zero velocity to some velocity V. Velocity pressure is proportional to the kinetic energy of the air stream. Associated equation:

$VP = (V/4.043)^2$, where V = air velocity in m/s, and VP = velocity pressure in mm water gauge (w.g.).

[U.S. units: $VP = (V/4005)^2$, where

V = velocity in feet per second, and

VP = velocity pressure in inches water gauge (w.g.)]

5.2.75 *volumetric flow rate (Q)* — in the context of Section 22 and Appendix 2 of this guideline, Q = the volume of air exhausted per unit time. Associated equation: Q = VA, where V = air flow velocity, and A = the cross-sectional area of the duct or opening through which the air is flowing at standard conditions.

5.2.76 *wet station* — open surface tanks, enclosed in a housing, containing chemical materials used in the manufacturing of semiconductor materials. Synonyms: wet sink, wet bench, wet deck.

6 Safety Philosophy

6.1 A primary objective of the industry is to eliminate or control hazards during the equipment's life cycle (i.e., the installation, operation, maintenance, service, and disposal of equipment).

6.2 The assumption is made that operators, maintenance personnel, and service personnel are trained in the tasks that they are intended to perform.

6.3 The following should be considered in the design and construction of equipment:

- regulatory requirements;
- industry standards;
- this guideline; and
- good engineering and manufacturing practices.

6.4 This guideline should be applied during the design, construction, and evaluation of semiconductor equipment, in order to reduce the expense and disruptive effects of redesign and retrofit.

6.5 No reasonably foreseeable single-point failure condition or operational error should allow exposure of personnel, facilities, or the community to hazards that could result in death, significant injury, or significant equipment damage.

NOTE 6: The intent is to control single fault conditions that result in significant risks (i.e., Critical, High, or Medium risks based on the example risk assessment matrix in SEMI S10).

6.6 Equipment safety features should be fail-safe or of a fault-tolerant design and construction.

6.7 Components and assemblies should be used in accordance with their manufacturers' ratings and specifications, where using them outside the ratings would create a safety hazard.

6.8 A hazard analysis should be performed to identify and evaluate hazards. The hazard analysis should be initiated early in the design phase, and updated as the design matures.

6.8.1 The hazard analysis should include consideration of:

- the application or process;
- the hazards associated with each task;
- anticipated failure modes;
- the probability of occurrence and severity of a mishap;
- the level of expertise of exposed personnel and the frequency of exposure;
- the frequency and complexity of operating, servicing and maintenance tasks; and
- safety critical parts.

NOTE 7: EN 1050 contains examples of hazard analysis methods.

6.8.2 The risks associated with hazards should be characterized using SEMI S10.

6.9 The order of precedence for resolving identified hazards should be as follows:

6.9.1 *Design to Eliminate Hazards* — From the initial concept phase, the supplier should design to eliminate hazards.

NOTE 8: It is recommended that the supplier continue to work to eliminate identified hazards.

6.9.2 *Incorporate Safety Devices* — If identified hazards cannot be eliminated or their associated risk adequately controlled through design selection, then the risk should be reduced through fixed, automatic, or other protective safety design features or devices.

NOTE 9: It is recommended that provisions be made for periodic functional checks of safety devices, when applicable.

6.9.3 *Provide Warning Devices* — If design or safety devices cannot effectively eliminate identified hazards or adequately reduce associated risk, a means should be used to detect the hazardous condition and to produce a warning signal to alert personnel of the hazard.

6.9.4 *Provide Hazard Warning Labels* — Where it is impractical to eliminate hazards through design selection or adequately reduce the associated risk with safety or warning devices, hazard warning labels should be provided. See Section 10 for label information.

6.9.5 *Develop Administrative Procedures and Training* — Where hazards are not eliminated through design selection or adequately controlled with safety or warning devices or warning labels, procedures and training should be used. Procedures may include the use of personal protective equipment.

6.9.6 A combination of these approaches may be needed.

7 General Provisions

7.1 This guideline should be incorporated by reference in equipment purchase specifications. The user and supplier should agree on deviations from this guideline. The intent is for the user to purchase equipment conforming with SEMI S2, not to design the equipment.

7.2 The equipment must comply with laws and regulations that are in effect at the location of use. All equipment requiring certification or approval by government agencies must have this certification or approval as required by regulations.

NOTE 10: It is recommended that the supplier request from the user information regarding local laws and regulations.

7.3 The manufacturer should maintain an equipment/product safety program to identify and eliminate hazards or control risks in accordance with the order of precedence (see Section 6.9).

7.3.1 The supplier should provide the user's designated representative with bulletins that describe safety related upgrades or newly identified significant hazards associated with the equipment. This should be done on an ongoing basis as needed.

7.4 Model-specific tools and accessories necessary to operate, maintain, and service equipment safely should be provided with the equipment or specified by the supplier.

NOTE 11: The official values in this guideline are expressed in The International System of Units (SI). Values that:

- are expressed in Inch-Pound (also known as "US Customary" or "English") units,
- are enclosed in parentheses, and
- directly follow values expressed in SI units

are not official, are provided for reference only, and might not be exact conversions of the SI values.

8 Evaluation Process

8.1 This section describes the evaluation of equipment to this guideline, the contents of the evaluation report, and supporting information needed to perform the evaluation.

8.2 *General* — The evaluating party (see Section 8.4) should evaluate the equipment according to this guideline and create a written evaluation report.

NOTE 12: The intent is that the "should" provisions of this guideline be used as the basis for evaluating conformance. The intent is also that the "may," "suggested," "preferred," "recommended," and "NOTE" provisions of this guideline not be used for evaluating conformance.

8.2.1 Conformance to specific sections of SEMI S2 may be achieved by instructions included in the supplier's equipment installation instructions (reference SEMI E6) or other documentation.

8.3 *Evaluation Report Contents: General* — The evaluation report should include only the manuals (Section 9.6) and the design-specific sections (Sections 10 through 27). The Appendices should be used in the evaluation, and referenced in the report, only as they pertain to the specific application.

8.3.1 For each numbered section, the evaluation report should state one of the following, and provide supporting rationale:

- "Conforms" — equipment conforms to the section or to the intent of the section.
- "Does not Conform" — equipment conforms to neither the section nor to the intent of the section.
- "N/A" — section is not applicable to equipment.

8.3.1.1 The results of a risk assessment indicating no significant risk may be used in determining that the equipment conforms to the intent of a section.

8.3.1.2 The evaluation report should include a determination per SEMI S10 of the level of risk associated with nonconformance findings.

8.3.1.3 Supporting rationale may include test data or documented engineering rationale.

8.4 *Evaluation Report Contents: Other Information* — The evaluation report should also include:

- manufacturer's model number;
- serial number of unit(s) evaluated;
- the date(s) that the equipment was evaluated;
- a system/equipment description including configuration, options, and essential diagrams; and
- a statement of the qualifications of the evaluating party. An in-house body, independent laboratory, or product safety consulting firm ("third party") meeting the provisions of SEMI S7 may be used to supply testing or evaluation of conformance to this document.

8.5 *Supporting Information Provided to Evaluator* — The following documentation should be provided to, or developed by, the evaluator, as necessary to demonstrate conformance to the provisions of this guideline.

NOTE 13: It is recommended that the manufacturer's typical configuration and process be used for evaluation purposes. Alternatively, a process agreed upon between the user and the supplier may be used.

NOTE 14: Special options or configurations that may pose additional hazards and are not included in the initial evaluation may need a separate review. It is recommended that upgrades, retrofits, and other changes that affect the safety design of the equipment be evaluated for conformance.

8.5.1 *General Information*

- Written system description, including hardware configuration and function(s), power requirements, power output, and other information necessary to understand the design and operation of the equipment.
- Engineering data used to provide the rationale that the equipment and subassembly seismic anchorages are designed to satisfy the applicable design loads (see Section 19, Seismic Protection).
- Descriptions of the purpose and function of safety devices, such as: emergency off devices (EMOs), interlocks, pressure relief devices, and limit controls.

- A hazard analysis (see Section 6.8).
- Ergonomics evaluation (see Section 16).
- A list of safety critical parts and, for each one, evidence of certification, or documentation showing that the component is suitable for its application.
- A residual fire risk assessment as described in Section 14.2.
- Tests results, certifications, and design specifications that are necessary to evaluate the equipment with respect to fire safety. Descriptions of the fire detection and suppression equipment and controls should also be provided.

8.5.2 *Industrial Hygiene Information*

8.5.2.1 An industrial hygiene report, which should include, as applicable:

- ventilation assessment (see Section 22);
- chemical inventory and hazard analysis (see Section 23);
- ionizing radiation assessment (see Section 24);
- non-ionizing radiation assessment (see Section 25);
- laser assessment (see Section 26); and
- audio sound pressure level assessment (see Section 27).

8.5.3 *Environmental Information* (see Section 21) — Documentation substantiating the following:

- consideration or inclusion of features that conserve resources (e.g., energy, water, deionized water, compressed gases, chemicals, and packaging);
- consideration of features that would promote equipment and component reuse or refurbishing, or material recycling upon decommissioning;
- consideration or inclusion of features for resource recycling or reuse;
- chemical selection methods and criteria (see Section 21.2.3);
- consideration of integrating effluent and emission controls into the equipment; and
- efforts to reduce wastes, effluents, emissions, and by-products.

NOTE 15: For purposes of Section 8.5.3, documentation may include design notes, metrics (whether normalized or not), meeting minutes, pareto evaluations, or other analyses.

9 Documents Provided to User

9.1 This section describes the documents that the supplier provides to the user.

9.2 *Evaluation Report* — Upon request by the user, the supplier should provide the user with a summary of the SEMI S2 evaluation report (see Section 8) or the full report.

9.2.1 Nonconformances noted in the report should be addressed by the supplier, by providing either an action plan or a justification for acceptance. The justification should include countermeasures in place and a risk characterization per SEMI S10.

9.3 *Seismic Information* — Refer to Section 19 of this document.

9.4 *Environmental Documentation* — The manufacturer should provide the user with the following environmental documentation as applicable:

9.4.1 Energy consumption information, including idle, average, and peak operating conditions, for the manufacturer’s most representative (“baseline”) process.

9.4.2 Mass balance, including idle, average, and peak operating conditions, for the manufacturer’s most representative (“baseline”) process.

NOTE 16: The mass balance may include resource consumption rates, chemical process efficiencies, wastewater effluent and air emission characterization, solid and hazardous waste generation (quantity and quality), and by-products.

9.4.3 Information regarding routes of unintended release (of effluents, wastes, emissions, and by-products) and methods and devices to monitor and control such releases. This should include information on features to monitor, prevent, and control unintended releases (see Section 21.2.4).

9.4.4 Information regarding routes of intended release (of effluents, wastes, and emissions) and features to monitor and control such releases (see Section 21.2.5).

9.4.5 A list of items that become solid waste as a result of the operation, maintenance, and servicing of the equipment, and that are constructed of or contain substances whose disposal might be regulated (e.g., berylium-containing parts, vapor lamps, mercury switches, batteries, contaminated parts, maintenance wastes).

9.5 *Industrial Hygiene Information* — Refer to Sections 22–27 of this document.

9.6 *Manuals*

9.6.1 The supplier should provide the user with manuals based on the originally intended use of the equipment. The manuals should describe the scope and normal use of the equipment, and provide information to enable safe facilitization, operation, maintenance, and service of the equipment.

9.6.2 The manuals should conform to SEMI S13.

NOTE 17: Fire suppression agents, and chemicals used to test fire detection or suppression systems, fall under the MSDS provisions of SEMI S13 when they are provided with the equipment.

NOTE 18: Hazardous energies within fire detection or suppression systems fall under the hazardous energy control provisions of SEMI S13 when fire detection or suppression systems are provided with the equipment.

9.6.3 In addition to the provisions of SEMI S13, the manuals should include:

- specific written instructions on routine Type 4 tasks, excluding troubleshooting (refer to Section 13.3);
- instructions for energy isolation ("lockout/tagout") (refer to Section 17.2);
- descriptions of the emergency off (EMO) and interlock functions;
- a list of hazardous materials (e.g., lubricants, cleaners, coolants) required for maintenance, ancillary equipment or peripheral operations, including anticipated change-out frequency, quantity, and potential for contamination from the process;
- a list of items that become solid waste as a result of the operation, maintenance, and servicing of the equipment, and that are constructed of or contain substances whose disposal might be regulated (e.g., berylium-containing parts, vapor lamps, mercury switches, batteries, contaminated parts, maintenance wastes); and
- maintenance and troubleshooting procedures needed to maintain the effectiveness of safety design features or devices (i.e., engineering controls).

9.6.4 Information should be provided regarding potential routes of unintended releases (see Section 21.2.4).

9.6.5 Recommended decontamination and decommissioning procedures should be provided in accordance with SEMI S12, and should include the following information:

- identity of components and materials of construction, in sufficient detail to support recycling, refurbishment, and reuse decisions (see Section 8.5.3); and
- residual hazardous materials, or parts likely to become contaminated with hazardous materials, that may be in the equipment prior to decommissioning.

NOTE 19: It is recommended that the manual state that changes to the typical process chemistry or to the equipment could alter the anticipated environmental impact.

9.6.6 *Maintenance Procedures with Potential Environmental Impacts* — The supplier's recommended maintenance procedures should:

- identify procedural steps during which releases might occur, and the nature of the releases; and
- identify waste characteristics and methods to minimize the volume of effluents, wastes, or emissions generated during maintenance procedures.

9.7 *Fire Protection Documentation* — The equipment supplier should provide:

- a summary fire protection report as described in Section 14.3;
- descriptions of optional fire risk mitigation features (see Section 14.3.2);

  NOTE 20: It is recommended that this be provided prior to purchase.

- fire detection system operations, maintenance, and test manuals;
- fire suppression system operations, maintenance, and test manuals;
- acceptance documents provided by licensed designers and installers (see Sections 14.4.4.12 and 14.4.5.16); and
- a list of any special apparatus needed to test the fire detection or suppression features of the equipment. The list should note whether the apparatus is included with the equipment, or is sold separately.

10 Hazard Warning Labels

10.1 Where it is impractical to eliminate hazards through design selection or to adequately reduce the associated risk with safety or warning devices, hazard warning labels should be provided to identify and warn against hazards.

10.2 Labels should be durable and suitable for the environment of the intended use.

10.3 Labels should conform to SEMI S1.

EXCEPTION: Some hazard label formats and content are dictated by law (e.g., laser labeling and chemical hazard communication labeling in certain countries of use) and may not conform to SEMI S1.

11 Safety Interlock Systems

11.1 This section covers safety interlocks and safety interlock systems.

NOTE 21: If a fire detection or suppression system is provided with the equipment, see Section 14 for additional information.

11.2 Where appropriate, equipment should use safety interlock systems that protect personnel, facilities, and the community from hazards inherent in the operation of the equipment.

NOTE 22: Safety critical parts whose primary function is to protect the equipment (e.g., circuit breakers, fuses) are typically not considered to be safety interlocks.

11.3 Safety interlock systems should be designed such that, upon activation of the interlock, the equipment, or relevant parts of the equipment, is automatically brought to a safe condition.

11.4 Upon activation, the safety interlock should alert the operator immediately.

EXCEPTION: Alerting the operator is not expected if a safety interlock triggers the EMO circuit (see Section 12) or otherwise removes power to the user interface.

NOTE 23: An explanation of the cause is preferred upon activation of a safety interlock.

11.5 Safety interlock systems should be fault-tolerant and designed so that the functions or set points of the system components cannot be altered without disassembling, physically modifying, or damaging the device or component.

EXCEPTION: When safety interlock systems having adjustable set points or trip functions are used, access should be limited to maintenance or service personnel by requiring a deliberate action, such as using a tool or special keypad sequences, to access the adjustable devices or to adjust the devices.

NOTE 24: This section does not address the defeatability of safety interlocks. See Section 11.7 for additional information.

11.6 Electromechanical devices and components are preferred, but solid-state devices and components may be used, provided that the safety interlock system, or relevant parts of the system, are evaluated for suitability for use. The evaluation for suitability should take into consideration abnormal conditions such as overvoltage, undervoltage, power supply interruption, transient overvoltage, ramp voltage, electromagnetic susceptibility, electrostatic discharge, thermal cycling, humidity, dust, vibration, and jarring.

EXCEPTION: Where the severity of a reasonably foreseeable mishap is deemed to be Minor per SEMI S10, a software-based interlock may be considered suitable.

NOTE 25: Where a safety interlock is provided to safeguard personnel from a Severe or Catastrophic mishap as categorized by SEMI S10, consideration of positive-opening type switches is recommended.

NOTE 26: Evaluation for suitability for use may also include reliability, self-monitoring, and redundancy as addressed under standards such as NEMA ICS 1.1 and UL 991.

NOTE 27: Solid-state devices include operational amplifiers, transistors, and integrated circuits.

11.7 The safety interlock system should be designed to minimize the need to override safety interlocks during maintenance activities.

11.7.1 Safety interlocks that safeguard personnel during operator tasks should not be defeatable without the use of a tool.

11.7.2 When maintenance access is necessary to areas protected by interlocks, defeatable safety interlocks may be used, provided that they require an intentional operation to bypass.

11.7.2.1 Upon exiting or completing the maintenance mode, all safety interlocks should be automatically restored.

11.7.2.2 If a safety interlock is defeated, the maintenance manual should identify administrative controls to safeguard personnel or to minimize the hazard.

11.8 The restoration of a safety interlock should not initiate equipment operation or parts movement where this can give rise to a hazardous condition.

11.9 Switches and other control device contacts should be connected to the ungrounded side of the circuit so that a short circuit to ground does not result in the interlocks being satisfied.

11.10 Where a hazard to personnel is controlled through the use of an enclosure, the enclosure should either: require a tool to gain access and be labeled regarding the hazard against which it protects personnel; or be interlocked. In addition to enclosures, physical barriers at the point of hazard should be included where inadvertent contact is likely.

NOTE 28: Where the removal of a cover exposes a hazard, consider additional labels. See Section 10 for guidance.

12 Emergency Shutdown

12.1 The equipment should have an "emergency off" (EMO) circuit. The EMO actuator (e.g., button), when activated, should place the equipment into a safe shutdown condition, without generating any additional hazard to personnel or the facility.

EXCEPTION 1: An EMO circuit is not needed for equipment rated 2.4 kVA or less, where the hazards are only electrical in nature, provided that the main disconnect meets the accessibility provisions of Section 12.5.2 and that the effect of disconnecting the main power supply is equivalent to activating an EMO circuit.

EXCEPTION 2: Assemblies that are not intended to be used as stand-alone equipment, but rather within an overall integrated system, and that receive their power from the user's system, are not required to have an emergency off circuit. The assembly's installation manual should provide clear instructions to the equipment installer to connect the assembly to the integrated system's emergency off circuit.

NOTE 29: It is recommended that the emergency off function not reduce the effectiveness of safety devices or of devices with safety-related functions (e.g., magnetic chucks or braking devices) necessary to bring the equipment to a safe shutdown condition effectively.

NOTE 30: If a fire detection or suppression system is provided with the equipment, see Section 14 for additional information.

12.1.1 If the supplier provides an external EMO interface on the equipment, the supplier should include instructions for connecting to the interface.

12.2 Activation of the emergency off circuit should deenergize all hazardous voltage and all power greater than 240 volt-amps in the equipment beyond the main power enclosure.

EXCEPTION 1: A non-hazardous voltage EMO circuit (typically 24 volts) and its supply may remain energized.

EXCEPTION 2: Safety related devices (e.g., smoke detectors, gas/water leak detectors, pressure measurement devices, etc.) may remain energized from a non-hazardous power source.

EXCEPTION 3: A computer system performing data/alarm logging and error recovery functions may remain energized, provided that the energized breaker(s), receptacle(s), and each energized conductor termination are clearly labeled as remaining energized after EMO activation. Hazardous energized parts that remain energized after EMO activation should be insulated or guarded to prevent inadvertent contact by maintenance personnel.

EXCEPTION 4: Multiple units mounted separately with no shared hazards and without interconnecting circuits with hazardous voltages, energy levels or other potentially hazardous conditions may have:

- separate sources of power and separate supply circuit disconnect means if clearly identified, or
- separate EMO circuits, if they are clearly identified.

12.2.1 The EMO circuit should not include features that are intended to allow it to be defeated or bypassed.

12.2.2 The EMO circuit should consist of electromechanical components.

12.2.3 Resetting the EMO switch should not re-energize circuits, equipment, or subassemblies.

12.2.4 The EMO circuit should shut down the equipment by deenergizing rather than energizing control components.

12.2.5 The EMO circuit should require manual resetting so that power cannot be restored automatically.

12.3 The emergency off button should be red and mushroom shaped. A yellow background for the EMO should be provided.

NOTE 31: Non-lockable self-latching (i.e., twist- or pull-to-release) EMO buttons may be required by regulations.

12.4 All emergency off buttons should be clearly labeled as "EMO," "Emergency Off," or the equivalent and should be clearly legible from the viewing location. The label may appear on the button or on the yellow background.

12.5 Emergency off buttons should be readily accessible from operating and regularly scheduled maintenance locations and appropriately sized to enable activation by the heel of the palm.

12.5.1 Emergency off buttons should be located or guarded to minimize accidental activation.

12.5.2 No operation or regularly scheduled maintenance location should require more than 3 m (10 feet) travel to an EMO button.

12.5.3 The person actuating or inspecting the EMO button should not be exposed to serious risks of tripping or falling or of coming in contact with energized electrical parts, moving machinery, surfaces or objects operating at high temperatures, or other hazardous equipment.

12.6 See Section 13.5 for additional EMO guidelines when EMOs are used with UPSs.

13 Electrical Design

13.1 This section covers electrical and electronic equipment that use hazardous voltages.

13.2 *Types of Electrical Work* — The following are the four types of electrical work defined by this guideline:

Type 1 — Equipment is fully deenergized.

Type 2 — Equipment is energized. Energized circuits are covered or insulated.

NOTE 32: Type 2 work includes tasks where the energized circuits are or can be measured by placing probes through suitable openings in the covers or insulators.

Type 3 — Equipment is energized. Energized circuits are exposed and inadvertent contact with uninsulated energized parts is possible. Potential exposures are no greater than 30 volts rms, 42.4 volts peak, 60 volts dc or 240 volt-amps in dry locations.

Type 4 — Equipment is energized. Energized circuits are exposed and inadvertent contact with uninsulated energized parts is possible. Potential exposures are greater than 30 volts rms, 42.4 volts peak, 60 volts dc, or 240 volt-amps in dry locations. Potential exposures to radio-frequency currents, whether induced or via contact, exceed the limits in Table A5-1 of Appendix 5.

13.3 *Energized Electrical Work* — The supplier should design the equipment to minimize the need to calibrate, modify, repair, test, adjust, or maintain equipment while it is energized, and to minimize work that must be performed on components near exposed energized circuits. The supplier should move as many tasks as practical from category Type 4 to Types 1, 2, or 3. Routine Type 4 tasks, excluding troubleshooting, should have specific written instructions in the maintenance manuals.

13.4 *Electrical Design* — Equipment should conform to the appropriate international, regional, national or industry product safety requirements.

13.4.1 Nonconductive or grounded conductive physical barriers should be provided:

- Where it is necessary to reach over, under, or around, or in close proximity to hazards.
- Where dropped objects could cause shorts or arcing.
- Where failure of liquid fittings from any part of the equipment would result in the introduction of liquid into electrical parts.
- Over the line side of the main disconnect.
- Where maintenance or service tasks on equipment in dry locations are likely to allow inadvertent contact with uninsulated energized parts containing either: potentials greater than 30 volts rms, 42.4 volts peak, or 60 volts dc; or power greater than 240 volt-amps.

NOTE 33: A dry location can be considered to be one that is not normally subject to dampness or wetness.

NOTE 34: Removable nonconductive and noncombustible covers are preferred.

13.4.2 Where test probe openings are provided in barriers, the barriers should be located, and the probe openings should be sized, to prevent inadvertent contact with adjacent energized parts, including the energized parts of the test probes.

13.4.3 Where failure of components and assemblies could result in a risk of electric shock, fire, or personal injury, those components and assemblies should be certified by an accredited testing laboratory and used in accordance with the manufacturer's specifications, or otherwise evaluated to the applicable standard(s).

NOTE 35: With the exception of implementation of ground fault protection, shunt trip units that require power to trip (actuate) are not recommended to be used in a safety control circuit, because they are not fail-safe.

13.4.4 Electrical wiring for power circuits, control circuits, grounding (earthing) and grounded (neutral) conductors should be color coded according to appropriate standard(s) per Section 13.4, or labeled for easy identification at both ends of the wire. Where color is used for identification, it is acceptable to wrap conductor ends with appropriate colored tape or sleeving; the tape or sleeving should be reliably secured to the conductor.

EXCEPTION 1: Internal wiring on individual components, e.g., motors, transformers, meters, solenoid valves, power supplies.

EXCEPTION 2: Flexible cords.

EXCEPTION 3: Nonhazardous voltage multi-conductor cables (e.g., ribbon cables).

EXCEPTION 4: When proper color is not available for conductors designed for special application (e.g., high-temperature conductors used for furnaces and ovens).

13.4.5 Grounding (earthing) conductors and connectors should be sized to be compatible in current rating with their associated ungrounded conductors according to appropriate standard(s) per Section 13.4.

13.4.6 Electrical enclosures should be suitable for the environment in which they are intended to be used.

13.4.7 Enclosure openings should safeguard against personnel access to uninsulated energized parts. (Refer to Appendix 1 for examples of openings for protection against access from operators.)

13.4.8 Top covers of electrical enclosures should be designed and constructed to prevent objects from falling into the enclosures. (Refer to Appendix 1 for examples of acceptable top enclosure openings.)

13.4.9 The current interrupting capacity (also known as amperes interrupting capacity, or AIC) of the equipment main disconnect should be identified in the facility installation and maintenance manuals.

13.4.10 The equipment should be provided with main overcurrent protection devices and main disconnect devices rated for at least 10,000 rms symmetrical amperes interrupting capacity (AIC).

NOTE 36: Some facilities may require higher AIC ratings due to electrical distribution system design.

EXCEPTION: Cord- and plug-connected single phase equipment, rated no greater than 240 volts line-to-line/150 volts line-to-ground and no greater than 2.4 kVA, may have overcurrent protection devices with interrupting capacity of at least 5,000 rms symmetrical amperes interrupting capacity (AIC).

13.4.11 Equipment should be designed to receive incoming electrical power from the facility to a single feed location that terminates at the main disconnect specified in Section 13.4.9. This disconnect, when opened, should remove all incoming electrical power in the equipment from the load side of the disconnect. The disconnect should also have the energy isolation (“lockout”) capabilities specified in Section 17.

EXCEPTION 1: Equipment with more than one feed should be provided with provisions for energy isolation (lockout) for each feed and be marked with the following text or the equivalent at each disconnect: “WARNING: Risk of Electric Shock or Burn. Disconnect all [number of feed locations] sources of supply prior to servicing.” It is preferred that all of the disconnects for the equipment be grouped in one location.

EXCEPTION 2: Multiple units mounted separately with no shared hazards and without interconnecting circuits with hazardous voltages, energy levels or other potentially hazardous conditions may have:

- separate sources of power and separate supply circuit disconnect means, if they are clearly identified; or
- separate EMO circuits, if they are clearly identified.

13.4.12 A permanent nameplate listing the manufacturer’s name, machine serial number, supply voltage, phase, frequency and full-load current should be attached to the equipment where plainly visible after installation. Where more than one incoming supply circuit is to be provided, the nameplate should state the above information for each circuit.

NOTE 37: Additional nameplate information may be required depending on the location of use.

13.5 *Uninterruptable Power Supplies (UPSs)* — This section applies to UPSs with outputs greater than: 30 volts rms, 42.4 volts peak; 60 volts dc; or 240 volt-amps.

13.5.1 Whenever a UPS is provided with the equipment, its location and wiring should be clearly described within the installation and maintenance manual.

13.5.2 Power from the UPS should be interrupted when any of the following events occur:

- the emergency off actuator (button) is pushed; or
- the main equipment disconnect is opened; or
- the main circuit breaker is opened.

EXCEPTION: Upon EMO activation, the UPS may supply power to the EMO circuit, safety related devices, and data/alarm logging computer systems as described in the exception clauses of Section 12.2.

13.5.3 The UPS may be physically located within the footprint of the equipment provided that the UPS is within its own enclosure and is clearly identified.

13.5.4 The UPS should be certified by an accredited testing laboratory and be suitable for its intended environment (e.g., damp location, exposure to corrosives).

13.5.5 The UPS wiring should be identified as “UPS Supply Output” or equivalent at each termination point where the UPS wiring can be disconnected.

13.6 *Electrical Safety Tests*

13.6.1 Equipment connected to the facility branch circuit with a cord and plug should not exhibit surface leakage current greater than 3.5 milliampere (mA) measured from any point on the surface of the equipment covers and associated controls to earth ground. (Refer to SEMI S9 or other appropriate standards for recognized test methods.)

EXCEPTION: Equipment with leakage current exceeding 3.5 mA is acceptable if documentation is provided to substantiate that the equipment is fully compliant with an applicable product safety standard that explicitly permits a higher leakage current.

13.6.2 Equipment grounding circuits should have a measured resistance of one-tenth (0.1) ohm or less between the main equipment grounding conductor terminal and any accessible metal surfaces that are: accessible to operator without the use of tools; and likely to become energized in a single-point failure condition. Refer to SEMI S9 or other appropriate standards for recognized test methods.

13.7 Equipment in which flammable liquids or gases are used should be assessed to determine if additional precautions (e.g., purging) in the electrical design are necessary.

NOTE 38: NFPA 497 and EN 1127-1 provide methods for making this assessment.

14 Fire Protection

14.1 *Overview* — This section applies to fire hazards that are internal to the equipment.

14.1.1 This section provides minimum safety considerations for fire protection designs and controls on the equipment.

14.1.2 This section also provides minimum considerations for fire detection and suppression systems when provided with the equipment.

NOTE 39: Detailed guidance on fire risk assessment and mitigation for semiconductor manufacturing equipment is provided in SEMI S14.

14.2 *Risk Assessment*

14.2.1 A documented risk assessment should be performed or accepted by a party qualified to determine and evaluate fire hazards and the potential need for controls. The risk assessment should consider normal operations and reasonably foreseeable single-point failures within the equipment. It should not consider exposure to fire or external ignition sources not within the specified use environment.

NOTE 40: This risk assessment can be combined with the overall hazard analysis performed for this guideline, provided the risk assessor has the required professional expertise to perform risk assessments for fire hazards. SEMI S7 describes qualifications for such an assessor.

14.2.2 If an accurate risk assessment depends on the user's adherence to specified procedures or conditions of use, the supplier should describe such procedures or conditions and state their importance.

14.2.3 SEMI S14 should be used to assess and report risks to property and the environment.

14.3 *Reporting*

14.3.1 A summary report should be provided to the user. The summary should include the following characterizations, per SEMI S10, for each residual fire hazard identified:

- the assigned Severity;
- the assigned Likelihood; and
- the resulting Risk Category.

14.3.2 Optional fire risk reduction features should be described in the pre-purchase information provided to the user.

14.3.3 The scope and effectiveness of the means of fire risk reduction should also be identified and reported, including the expected risk reduction (as described in Section 14.3.1).

14.3.4 If, due to fire hazards within the equipment, thermal or non-thermal (e.g., smoke) damage is possible outside of the equipment, then this possibility should be reported to the user. This report should include a qualitative description of the foreseen scenario.

14.4 *Fire Risk Reduction*

14.4.1 *Materials of Construction* — Equipment should be constructed of noncombustible materials wherever reasonable. If process chemicals do not permit the use of noncombustible construction, then the equipment should be constructed of materials, suitable for the uses and compatible with the process chemicals used, that contribute least to the fire risk.

NOTE 41: Some regional codes (e.g., Uniform Fire Code) may require construction with noncombustible materials.

14.4.1.1 The flowchart in Appendix 6 may be used for the selection of materials of construction for equipment.

14.4.1.2 Any portion of equipment that falls within the scope of SEMI F14 (Guide for the Design of Gas Source Equipment Enclosures) should be designed in accordance with that guide.

14.4.2 *Elimination of Process Chemical Hazards* — The option of substituting non-flammable process chemicals for flammable process chemicals should be considered.

14.4.3 *Engineering Controls*

14.4.3.1 Fire risks resulting from process chemicals may be reduced using engineering controls (e.g., preventing improper chemical mixing, preventing temperatures from reaching the flash point).

14.4.3.2 Fire risks resulting from materials of construction may be reduced using engineering controls (e.g., non-combustible barriers that separate combustible materials of construction from ignition sources, installing a fire suppression system that extinguishes ignited materials).

14.4.3.3 Equipment power and chemical sources that present unacceptable fire risks should be interlocked with the fire detection and suppression systems to prevent start-up of the equipment or delivery of chemicals when the fire detection or suppression is inactive.

NOTE 42: Some jurisdictions require interlocking.

NOTE 43: Refer to Section 6.5 for criteria for acceptability.

14.4.3.4 Shutdown or failure of a fire detection or suppression system need not interrupt the processing of product within the equipment by immediately shutting down the equipment, but should prevent additional processing until the fire detection or suppression is restored. Software or hardware may be used for this function.

14.4.3.5 Controlling smoke by exhausting it (using the supplier-specified equipment exhaust) from the cleanroom may be used to reduce fire risks from the generation of products of combustion. When used, this reduction method should be combined with detection or suppression when flames can be propagated.

NOTE 44: Controlling smoke may be sufficient when smoke is the only consequence (e.g., smoldering components that generate smoke).

NOTE 45: For controlling smoke to be effective, the smoke must be removed not only from the equipment, but also from the cleanroom. This is typically accomplished by using ducted exhaust.

NOTE 46: The use of exhaust to remove smoke may be subject to regulations, such as building and fire codes.

NOTE 47: The use of exhaust to remove smoke may create hazards within the exhaust system. Therefore, a description of the expected discharge (i.e., anticipated air flow rate, temperature, and rate of smoke generation) into the exhaust system may be important information for installation of equipment.

14.4.4 *Fire Detection* — The following criteria apply to any fire detection system determined to be appropriate for fire protection by the fire risk assessment:

NOTE 48: Heat detectors, smoke sensing devices, and other devices used solely for monitoring equipment status may not need to meet these requirements. Some local jurisdictions, however, may require that all smoke detectors be connected to building systems and be compliant with all applicable fire alarm codes.

14.4.4.1 The fire detection system, which includes detectors, alarms and their associated controls, should be certified by an accredited testing laboratory and suitable for the application.

NOTE 49: Such certifications typically require that the components of fire detection systems are readily identifiable and distinguishable from other components in the equipment.

14.4.4.2 The fire detection, alarm and control system should be installed in accordance with the requirements of the certification in Section 14.4.4.1, and in accordance with requirements of the appropriate international or national codes or standards (e.g., NFPA 72).

14.4.4.3 The fire detection system should be capable of interfacing with the facility's alarm system. It may be preferable for the equipment supplier to specify the location and performance of detectors, but not provide them, so that the user may better integrate the detection in the equipment with that in the facility. This alternative should be negotiated explicitly with the user.

14.4.4.4 The fire detection system should activate alarms audibly and visually at the equipment.

14.4.4.5 Manual activation capability for the fire detection system should be considered, for the purpose of providing notification to a constantly attended location.

14.4.4.6 Activation of trouble or supervisory conditions should result in all of the following:

- notification of the operator;
- allowing the completion of processing of substrates in the equipment;
- prevention of processing of additional substrates until the trouble or supervisory condition is cleared; and
- providing, through an external interface, a signal to the facility monitoring system or a constantly attended location.

14.4.4.7 The fire detection system should be capable of operating at all times, including when the equipment is inoperable (e.g., equipment controller problems) or in maintenance modes (e.g., some or all of the equipment's hazardous energies are isolated ("locked out")).

EXCEPTION: Operability is not required during maintenance of the fire detection system.

NOTE 50: For the purposes of this section, "inoperable" includes the equipment state after an EMO is activated, and during maintenance of a duration less than the battery life expectancy of the fire detection system. Therefore, it is recommended that the detection system not require hazardous energies (e.g., line alternating current) to operate following an EMO activation.

14.4.4.8 A back-up power supply, capable of sustaining the detection system for 24 hours, should be provided.

NOTE 51: Back-up power must be provided in accordance with local regulations. The requirements for back-up power vary among jurisdictions.

14.4.4.9 The fire detection system should remain active following EMO activation.

14.4.4.10 There may be cases where the internal power supply for a detection system cannot supply power for the full length of extended maintenance procedures (i.e., procedures longer than the expected duration of the back-up power supply). In such cases, the supplier should provide written procedures for either removing the fire hazard or safely supplying power to the fire detection system.

14.4.4.11 Activation of the fire detection system should shut down the equipment within the shortest time period that allows for safe equipment shutdown. This includes shutdown of any fire-related hazard source that could create additional fire risks for the affected module or component.

NOTE 52: See Sections 14.4.3.3 and 14.4.3.4 for related provisions.

EXCEPTION 1: A non-recycling, deadman abort switch is acceptable on detection systems that are used for equipment shutdown, but not on those used for activation of a suppression system.

EXCEPTION 2: Activation of the fire detection system should not remove power from fire and safety systems.

14.4.4.12 The equipment design and configuration should not prevent licensed parties from certifying the design and installation of fire detection systems.

NOTE 53: This is not meant to suggest installation by licensed parties; however, some jurisdictions require fire detection and suppression system installers to be licensed as specified by the jurisdiction.

14.4.5 *Fire Suppression* — The following criteria apply to any fire suppression system determined to be appropriate by the fire risk assessment.

NOTE 54: As a fire detection system is generally required to provide the initiating sequence for the suppression system, it is the intention of this guideline that this be the same fire detection system described in Section 14.4.4.

14.4.5.1 The fire suppression system, which includes nozzles, actuators, and their associated controls, should be certified by an accredited testing laboratory and suitable for the application.

NOTE 55: Such certifications typically require that the components of fire suppression systems are readily identifiable and distinguishable from other components in the equipment. This includes adequate labeling of piping.

14.4.5.2 The fire suppression agent should be accepted for the application by an accredited testing laboratory. The suppression agent selection process should include an evaluation of potential damage to a cleanroom, and the least damaging effective agent should be selected. If more than one agent is effective, the options should be specified to the user so that the user may specify which agent should be provided with the equipment. The supplier should also specify if the user may provide the agent.

14.4.5.3 The fire suppression agent and delivery system should be designed and installed in accordance with the appropriate international or national standard (e.g., NFPA 12, NFPA 13, NFPA 2001). It may be preferable for the equipment supplier to specify the location and performance of suppression system components, but not provide them, so that the user may better integrate the suppression in the equipment with that in the facility. This alternative should be negotiated explicitly with the user.

14.4.5.4 Activation of the fire suppression system should alarm audibly and visually at the equipment. This may be done by the same system that initiates activation.

14.4.5.5 If the discharge is likely to present a risk to personnel, the alarm should provide adequate time to allow personnel to avoid the hazard of the agent discharge.

14.4.5.5.1 If there is a confined space in the equipment, the asphyxiation hazard posed by the suppression system should be assessed.

14.4.5.6 The fire suppression system should be capable of operating at all times, including when equipment is inoperable and during equipment maintenance.

NOTE 56: For the purpose of this section, “inoperable” includes the equipment state after the EMO is activated.

EXCEPTION: Most suppression systems contain sources of hazardous energy. These sources should be capable of being isolated (i.e., “locked out”) to protect personnel.

14.4.5.7 The fire suppression system should remain active following EMO activation.

14.4.5.8 There may be cases where the internal power supply for a suppression system cannot supply power for the full length of extended maintenance procedures (i.e., procedures longer than the expected duration of the back-up power supply). In such cases, the supplier should provide written procedures for either removing the fire hazard or safely supplying power to the fire suppression system.

14.4.5.9 Allowances can be made to provide for the deactivation of an automatic discharge of the suppression system when in the maintenance mode. Such deactivation switches should be supervised (i.e., if the suppression system is deactivated, there should be an indication to the user and the resumption of production in the equipment should be prevented.)

NOTE 57: Hazardous energies associated with the fire suppression system may be isolated (i.e., "locked out") using an energy isolation procedure (see Section 17) during equipment maintenance.

NOTE 58: The permissibility of deactivation of suppression systems varies among jurisdictions.

14.4.5.10 A back-up power supply, capable of sustaining the suppression system for 24 hours, should be included where the suppression system requires independent power from the detection system used to activate the suppression.

NOTE 59: The requirements for back-up power vary among jurisdictions.

14.4.5.11 The fire suppression system should be capable of interfacing with the facility's alarm system. This may be done via the fire detection system.

14.4.5.12 Activation of the fire suppression system should shut down the equipment within the shortest time period that allows for safe equipment shutdown.

NOTE 60: See Sections 14.4.3.3 and 14.4.3.4 for related provisions.

EXCEPTION: Activation of the fire suppression system should not remove power from fire and safety systems.

14.4.5.13 The fire suppression system should be capable of manual activation, which should shut down the equipment and activate an alarm signal locally and at a constantly attended location.

14.4.5.14 The fire suppression system should be tested on a representative sample of the equipment. The test procedure should include a suppression agent discharge test, unless precluded for health or environmental reasons. This test may be performed at the equipment supplier's or other similar facility, but should be performed under conditions that adequately duplicate any factors (e.g., equipment exhaust) that may reduce the effectiveness of the suppression. This representative sample need not be fully operational, but should duplicate those factors (e.g., exhaust, air flow) that could negatively affect the performance of the system.

14.4.5.15 Procedures for controlling access to the suppression agent source (e.g., protecting agent cylinders from disconnection by unauthorized personnel) should be provided.

14.4.5.16 The equipment design and configuration should not prevent licensed parties from certifying the design and installation of fire suppression systems.

NOTE 61: This is not meant to suggest installation by licensed parties; however, some jurisdictions require fire detection and suppression system installers to be licensed as specified by the jurisdiction.

14.4.5.17 *Installation of Piping for Fire Suppression Agent* — The fire suppression piping system should be:

- made from corrosion-resistant components,
- designed to minimize water accumulation around components and control other conditions that promote corrosion, and
- designed so mechanical inspections are easily performed.

14.4.5.18 Piping should be designed, installed, and tested to ensure that it is capable of containing the high pressures generated by the discharge of the suppression agent.

14.4.5.19 The supplier should provide information necessary for proper field installation of piping.

14.5 *Warnings and Safe Work Practices* — Warnings and safe work practices related to fire detection and suppression features of the equipment (e.g., restrictions on using open flames within range of active fire detection systems, hazardous stored energy in pressurized suppression systems) should be part of the documentation provided by the supplier.

14.6 *Maintenance and Testing of Fire Detection and Suppression Systems* — The equipment supplier should provide detailed maintenance and testing procedures for the fire systems provided with each piece of equipment. These procedures should include testing frequency, as well as details of special equipment required for testing.

14.6.1 Chemical generating test apparatus (e.g., canned smoke) should be avoided for cleanroom applications.

NOTE 62: Information about UV/IR generating sources used for testing fire detection systems may require consideration of Section 25 (Non-Ionizing Radiation).

14.6.2 The maintenance testing procedure should include testing of the facility interface and verifying that all the equipment fire detection and suppression systems are functional.

14.6.3 The detection and suppression systems should be designed so that preventative maintenance of components does not degrade their performance (e.g., by resulting in displacement or destruction of sensors).

14.6.4 Supplier should document the sound pressure level generated during suppression agent discharge, if the test is performed.

14.6.5 Materials or procedures used for testing and maintenance of the fire detection and suppression system should not degrade the equipment's ability to perform its intended function.

14.6.6 Suppliers should describe hazardous energies present in fire detection and suppression systems, and provide instructions for their proper isolation (see Section 17.2).

14.7 *Environmental* — Suppliers should provide guidance to users regarding the impact on emissions of any fire suppression agents used in the equipment.

15 Heated Chemical Baths

15.1 Refer to SEMI S3 for the minimum safety design considerations for heated chemical baths. Each heated chemical bath should have the following:

- grounded or GFCI-protected heater;
- power interrupt;
- manual reset;
- automatic temperature controller;
- liquid level sensor;
- fail-safe over-temperature protection;
- proper construction materials;
- exhaust failure interlock; and
- overcurrent protection.

NOTE 63: See Section 14 for fire protection risk assessment considerations for baths using combustible or flammable chemicals.

16 Ergonomics and Human Factors

16.1 *General* — Ergonomics and human factors design principles should be incorporated into the development of equipment to identify and eliminate or mitigate ergonomics- and human factors-related hazards.

16.2 *Provisions for Conformance* — Equipment should be assessed to the guidelines set forth in SEMI S8. The Supplier Ergonomic Success Criteria (SESC; see SEMI S8), or the equivalent, should be used to document the assessment.

17 Hazardous Energy Isolation

17.1 *General*

17.1.1 Lockable energy isolation capabilities should be provided for tasks that may result in contact with hazardous energy sources.

17.1.2 Where service tasks may be safely performed on subassemblies, energy isolation devices (e.g., circuit breakers, disconnect switches, manual valves) may be provided for the subassemblies for use as an alternative to shutting down the entire equipment system. The isolation devices should isolate all hazardous energy to the subassemblies and be capable of being locked in the position in which the hazardous energy is isolated.

17.1.3 The person actuating or inspecting an energy isolating device should not be exposed to serious risks of tripping or falling or of coming in contact with energized electrical parts, moving machinery, surfaces or objects operating at high temperatures, or other hazardous equipment.

NOTE 64: Hazardous energies include electrical, stored electrical (e.g., capacitors, batteries), chemical, thermal/cryogenic, stored pressure (e.g., pressurized containers), suspended weight, stored mechanical (e.g., springs), generated pressure (e.g., hydraulics and pneumatics), and other sources that may lead to the risk of injury.

NOTE 65: In order to minimize down-time and provide ease of use, it is preferred to have energy isolation devices located in the areas where maintenance or service is performed.

NOTE 66: Energy isolation devices for incompatible hazardous energy sources (e.g., electrical and water, incompatible gases) are recommended to be separated.

NOTE 67: Isolation of hazardous energy may include: deenergizing of hazardous voltage; stopping flow of hazardous production material (HPM); containing HPM reservoirs; depressurizing or containing HPM and pneumatic lines; deenergizing or totally containing hazardous radiation; discharging of residual energy in capacitors; stopping of hazardous moving parts; and shutting off hazardous temperature sources.

NOTE 68: Energy isolation devices with integral locking capabilities are preferred, but may not be feasible or commercially available, in which case detachable lockout adapters may be used.

NOTE 69: See Section 14 for information on fire protection hazardous energies.

17.2 *Installation and Maintenance Manuals*

17.2.1 Installation and maintenance manuals should identify the types of hazardous energies within the equipment.

17.2.2 Installation and maintenance manuals should provide specific instructions for the equipment on how to:

- shut down the equipment in an orderly manner;
- locate and operate all the equipment's energy isolating devices;
- affix energy isolating (“lockout/tagout”) devices;
- relieve any stored energies;
- verify that the equipment has actually been isolated and deenergized; and
- properly release the equipment from its isolated state.

17.2.3 Where the manufacturer provides written maintenance procedures for tasks within subassemblies, and intends that these tasks be performed without controlling hazardous energies at the entire equipment level, the installation and maintenance manuals should provide appropriate energy isolation procedures at the subassembly level.

17.3 *Electrical Energy Isolation*

17.3.1 The main energy isolation capabilities (equipment supply disconnect) should be in a location that is readily accessible and should be lockable only in the deenergized position.

NOTE 70: For equipment with multiple incoming supply sources, it is recommended that all of the energy isolation devices be located in one area.

17.4 *Non-Electrical Energy Isolation*

17.4.1 The equipment should include provisions and procedures so that hazardous energy sources, such as pressurized systems and stored energy, can be isolated or reduced to a zero energy state prior to maintenance or service work.

17.4.2 The hazardous energy isolation devices should be in a location that is readily accessible.

17.4.3 The hazardous energy isolation devices should be capable of being locked in the position in which the hazardous energy is isolated.

18 Mechanical Design

18.1 This section covers hazards due to the mechanical aspects of the equipment.

NOTE 71: This is similar to the essential requirements of European Union directives. The supplier has the option of demonstrating compliance by choosing standards that are appropriate to the machine and application.

NOTE 72: Pressurized vessels must meet applicable codes and regulations.

18.2 *Machine Stability* — Equipment, components, and fittings should be designed and constructed so that they are stable under reasonably foreseeable shipping, installation, and operating conditions. The need for special handling devices and anchors should be indicated in the instructions. Unanchored equipment in its installed condition should not overbalance when tilted in any direction to an angle of 10 degrees from its normal position.

NOTE 73: See IEC 61010-1 for an example of stability tests.

18.3 *Break-up During Operation* — The various parts of the equipment and its linkages should be able to withstand the stresses to which they are subjected when used as designed. Precautions should be taken to control risks from falling or flying objects.

18.3.1 The potential effects of fatigue, aging, corrosion, and abrasion for the intended operating environment should be considered as part of the mechanical hazards risk assessment.

18.3.2 Where a risk of rupture or disintegration remains despite the measures taken (e.g., a substrate chuck that loses its vacuum), the moving parts should be mounted and positioned in such a way that, in case of rupture, their fragments will be contained.

18.3.3 Both rigid and flexible pipes carrying liquids or gases should be able to withstand the foreseen internal and external stresses and should be firmly attached or protected against external stresses and strains. Based on the application, an appropriate factor of safety should be included.

18.4 *Moving Parts* — The moving parts of equipment should be designed, built, and positioned to avoid hazards. Where hazards persist, equipment should be fitted with guards or protective devices that reduce the likelihood of contact that could lead to injury.

18.4.1 Where the machine is designed to perform operations under different conditions of use (e.g., different speeds or energy supplies), it should be designed and constructed in such a way that selection and adjustment of these conditions can be performed safely.

18.4.2 *Selection of Protection Against Hazards Related to Moving Parts* — Guards or protective devices used to protect against hazards related to moving parts should be selected on the basis of a risk assessment that includes the:

- hazards that are being guarded against;
- probability of occurrence and severity of injury of each hazard scenario; and
- frequency of removal of guards.

18.4.3 Guards and protection devices. Guards should:

- reduce the risk that personnel will contact the mechanical hazard to an acceptable level; and
- not give rise to additional risk.

18.5 *Lifting Operations* — Equipment presenting hazards due to lifting operations (e.g., falling loads, collisions, tipping) should be designed and constructed to reduce the risk to an acceptable level.

18.6 *Extreme Temperatures* — Surfaces that are accessible to personnel, and that are at high (per temperature limits in Table 1) or very cold temperatures (below -10°C [14°F]), should be fitted with guards or designed out.

18.6.1 Where it is not feasible to protect or design out the exposures to extreme temperature, temperatures exceeding the limits are permitted, provided that either of the following conditions is met:

- unintentional contact with such a surface is unlikely; or
- the part has a warning indicating that the surface is at a hazardous temperature.

19 Seismic Protection

NOTE 74: Users have facilities located in areas that are susceptible to seismic activity. The end user may require more stringent design criteria because of increased site vulnerability (e.g., local soil conditions and building design may produce significantly higher accelerations) and local regulatory requirements. Certified drawings and calculations may be required in some jurisdictions.

19.1 *General* — The equipment should be designed to control the risk of injury to personnel, adverse environmental impact, equipment and facility damage due to movement, overturning, or leakage of chemicals (including liquid splashing), during a seismic event. The design should also control equipment damage due to failure of fragile parts (e.g., quartzware, ceramics) during a seismic event.

NOTE 75: These criteria are intended to accomplish two things:

(1) allow equipment suppliers to correctly design the internal frame and components to withstand seismic forces; and

(2) allow equipment designers to provide end-users with the information needed to appropriately secure the equipment within their facility.

19.1.1 Because preventing all damage to equipment may be impractical, the design should control the failure of parts that may result in increased hazard (e.g., hazardous materials release, fire, projectile).

NOTE 76: It is recommended that the hazard analysis described in Section 6.8 be used to evaluate both the risk of part failure and the effectiveness of control measures.

19.1.1.1 These parts should be accessible for evaluation of damage.

NOTE 77: SEMI S8 contains guidelines for maintainability and serviceability; these may be used to determine accessibility.

19.2 *Design Loads* — The equipment, subassemblies, and all devices used for anchoring the equipment should be designed as follows:

19.2.1 For equipment containing hazardous production materials (HPMs), the equipment should be designed to withstand a horizontal loading of 94% of the weight of the equipment, acting at the equipment's center of mass.

19.2.2 For equipment not containing hazardous production materials (HPMs), the equipment should be designed to withstand a horizontal loading of 63% of the weight of the equipment, acting at the equipment's center of mass.

NOTE 78: Subassemblies may include transformers, vessels, power supplies, vacuum pumps, monitors, fire suppression components, or other items of substantial mass that are attached to the equipment.

Table 1 Potentially Hazardous Surface Temperatures

Accessible Parts	*Maximum Surface Temperature, in °C*		
	Metal	*Glass, Porcelain, Vitreous Material*	*Plastic, Rubber*
Handles, knobs, grips, etc., held or touched for short periods (5 seconds or less) in normal use.	60	70	85
Handles, knobs, grips, etc. held continuously in normal use.	51	56	60
External surfaces of equipment, or parts inside the equipment, that may be touched.	65	80	95

19.2.3 Horizontal loads should be calculated independently on each of the X and Y axes, or on the axis that produces the largest loads on the anchorage points.

19.2.4 When calculating for overturning, a maximum value of 85% of the weight of the equipment should be used to resist the overturning moment.

NOTE 79: Because equipment may be placed into service anywhere in the world, it is recommended that the seismic protection design of the equipment be based upon requirements that allow the equipment, as designed, to be installed in most sites worldwide. The above loads are based on 1997 Uniform Building Code (UBC) requirements for rigid equipment in Seismic Zone 4, and are assumed to satisfy most design situations worldwide.

NOTE 80: If the equipment or internal component is flexible as defined by the UBC, is located above the midheight of the building, or is within 5 km of a major active fault, the horizontal design loadings in Sections 19.2.1 and 19.2.2 may not be conservative. Likewise, there are several conditions for which the horizontal design loadings are overly conservative (e.g., rigid equipment with rigid internal components located at grade, or sites with favorable soils conditions). For these conditions, designing based on the more detailed approach in the UBC may result in a more economical design. It is recommended that the user engage a professional mechanical, civil, or structural engineer to make these determinations.

19.3 The supplier should provide the following data and procedures to the user. This information should be included in the installation instructions as part of the documentation covered in Section 9.

- A drawing of the equipment, its support equipment, its connections (e.g., ventilation, water, vacuum, gases) and the anchorage locations identified in Section 19.4.
- The type of feet used and their location on a base frame plan drawing.
- The weight distribution on each foot.
- Physical dimensions, including width, length, and height of each structurally independent module.
- Weight and location of the center of mass for each structurally independent module.
- Acceptable locations on the equipment frame for anchorage.

NOTE 81: A "structurally independent module" reacts to seismic loads by transferring substantially all of the loads to its own anchorages, as opposed to transferring the loads to adjacent modules.

19.4 The locations of the tie-ins, attachments, or seismic anchorage points should be clearly identified.

NOTE 82: It is not the intent of SEMI S2 that the supplier provide the seismic attachment point hardware. Such hardware may be provided as agreed upon between supplier and user.

NOTE 83: It is the responsibility of the user to verify that the vibration isolation, leveling, seismic reinforcing, and load distribution is adequate.

20 Automated Material Handlers

20.1 This section covers automated material handlers, which include:

- substrate handlers;
- industrial robots and industrial robot systems; and
- unmanned transport vehicles (UTVs).

NOTE 84: Substrate handlers typically handle a single substrate at a time, and are distinguished from industrial robots by their small load capacity.

20.2 *General* — The means of incorporating personnel safeguarding into automated material handlers should be based on a hazard analysis. The hazard analysis should include consideration of the size, capacity, speed, and spatial operating range of the handler.

20.2.1 *Subsystem Stops* — If a separate stop button is used for the automated material handler, it should be differentiated from the EMO button.

20.3 *Substrate Handlers* — See Section 20.2, *General.*

20.4 *Industrial Robots and Industrial Robot Systems* — Industrial robots and industrial robot systems should meet the requirements of appropriate national or international standards, e.g., ANSI/RIA R15.06, ISO 10218, EN 775. If there are deviations from these standards because of semiconductor applications of the robot, these deviations may be found acceptable based on risk assessments.

20.5 *UTVs*

NOTE 85: There are two basic types of UTVs: (1) the floor-traveling (including both rail-guided and rail-independent) UTV, that automatically travels on the floor to a specified destination where it is unloaded or loaded; and (2) the space-traveling UTV, which automatically travels without resting on the floor (e.g., in the space below the ceiling) to a specified destination where it is loaded or unloaded. UTVs do not include rail-guided mechanisms that are attached to equipment (such as in wet benches).

20.5.1 *Collision Avoidance* — UTVs generally travel in wide areas and are used in a system rather than stand alone operation. UTVs should be equipped with a non-contact approach sensing device so that they do not inadvertently contact people or other objects.

20.5.2 *UTVs: Loading and Unloading Equipment*

20.5.2.1 UTVs should be interlocked with equipment such as semiconductor process equipment, automated load ports, stockers, ground-based conveyors, and automated warehouses as needed to ensure that the load remains secure and that the UTV and transfer components are not in conflict with one another.

20.5.2.2 If loading results in an unsafe condition, the equipment should detect and indicate the condition, and movement of all loading equipment should stop immediately. The system should not reset or restart automatically.

21 Environmental Considerations

21.1 This section covers environmental impacts throughout the life of the equipment.

NOTE 86: It is recommended that environmental impacts be balanced against other factors, including safety and health, legal, and regulatory requirements.

NOTE 87: It is recommended that the manufacturer maintain awareness of relevant environmental regulations, either internally or through the user.

NOTE 88: The user is responsible for providing the manufacturer with information regarding any environmental restrictions that are specific to a given site and that may impact equipment design (e.g., cumulative emissions limits, permit requirements, site-specific programs).

NOTE 89: See Section 14 for fire suppression emission issues.

NOTE 90: References to “process” in this section are meant to refer to the baseline process.

21.2 *Design*

21.2.1 The following design guidelines apply to all phases of equipment life, from concept to decommissioning and disposal.

NOTE 91: The documentation described in Sections 8.5.3 and 9.4 provide information that can be used for evaluating conformance to this section.

21.2.2 *Resource Conservation*

21.2.2.1 The manufacturer should consider resource conservation (i.e., reduction, reuse, recycling) during equipment design, for example:

- water reuse or water recycling within the equipment;
- reduced chemical consumption, energy use, and water use (e.g., reducing resource use when no process is occurring);
- reduced use of resources during maintenance procedures (e.g., parts cleaning procedures could include minimum rinse rates and rinse times);
- recycling or reusing chemicals in the equipment, rather than consuming only new materials;
- reducing volume of packaging, increasing recycled content of packaging, and/or designing reusable packaging.

21.2.3 *Chemical Selection*

21.2.3.1 Chemical selection for process, maintenance, and utility uses (e.g., gases, etchants, strippers, cleaners, lubricants, and coolants) should take into account effectiveness, environmental impacts, volume, toxicity, by-products, decommissioning, disposal, and recyclability; use of the least hazardous chemical is preferred. To the extent practicable, the utilities, maintenance, and process should be designed so that the equipment operates without the use of:

- ozone depleting substances (ODSs) as identified by the Montreal Protocol, such as chlorofluorocarbons (CFCs), methylchloroform, hydrochlorofluorocarbons (HCFCs), and carbon tetrachloride, or
- perfluorocompounds (PFCs), including CF_4, C_2F_6, NF_3, C_3F_8, and SF_6, and CHF_3 due to their global warming potential.

21.2.4 *Prevention and Control of Unintended Releases*

21.2.4.1 Equipment design, including feed, storage, and waste collection systems, should prevent potential unintended releases. At a minimum:

21.2.4.2 Secondary containment for liquids should be capable of holding at least 110% (see first row of Table A3-1 of Appendix 3) of the volume of the single largest container, or the largest expected volume for any single point failure.

NOTE 92: In some circumstances secondary containment may be specified by the equipment supplier, but provided by the user.

21.2.4.3 Chemical storage containers and secondary containment should be designed for accessibility and easy removal of collected material.

21.2.4.4 Secondary containment should have alarms and gas detection or liquid sensing, as appropriate, or have recommended sensing points identified in the equipment installation instructions.

21.2.4.5 Equipment design should allow personnel to determine all in-equipment container levels conveniently without having to open the containers, where ignorance of the level could result in an inadvertent release.

21.2.4.6 Overfill level detectors and alarms should be provided for in-equipment containers.

21.2.4.7 Secondary containment and other control systems should be designed to ensure that chemicals cannot be combined, where the combination could result in an inadvertent release.

21.2.4.8 Equipment components should be compatible with chemicals used in the manufacturing process. Chemical systems should be designed for the specified operating conditions, and have sufficient mechanical strength and corrosion resistance for the intended use.

21.2.4.9 Equipment should be able to accept a signal from a monitoring device and stop the supply of chemical, at the first non-manual valve within the affected system.

21.2.4.10 Chemical distribution systems should be capable of automatic shutoff and remote shutdown.

21.2.5 *Effluents, Wastes, and Emissions*

NOTE 93: It is recommended that the manufacturer document its efforts to minimize the equipment's generation of hazardous wastes, solid wastes, wastewater, and air emissions.

NOTE 94: It is recommended that SEMI F5 be used for guidance in gaseous effluent handling.

21.2.5.1 Equipment design that allows connection to a central waste collection system is preferred, except where collection at the equipment may facilitate recycling or reuse opportunities or otherwise reduce environmental impacts.

NOTE 95: It is recommended that individual drains and exhausts be kept separate (e.g., separate outlets for acid drain, solvent drain, deionized (DI) water drain; acid exhaust, solvent exhaust).

21.2.5.1.1 Point-of-use collection containers should be designed for accessibility as well as the possible reuse and recycling of the collected materials.

21.2.5.2 Equipment should use partitions, double-contained lines, or other similar design features to prevent the mixing of incompatible waste streams.

21.2.5.3 The manufacturer should evaluate the feasibility of including integrated controls for effluent and emission treatment.

21.2.5.4 Dilution in excess of process or safety requirements should not be used to reduce contaminant discharge concentrations.

21.2.5.5 Segregation of effluents, wastes, and emissions should be provided in the following cases:

- where chemically incompatible;
- where segregation facilitates recycling or reuse; or
- where separate abatement or treatment methods are required.

NOTE 96: It is recommended that the equipment design documentation show evidence of consideration of by-products generated during equipment operation, clean-up, maintenance, and repair. By-products can include deposits in drains or ducts, and replaceable parts (e.g., batteries, vapor lamps, contaminated parts).

21.2.6 *Decommissioning and Disposal*

21.2.6.1 Equipment design should address (see Section 8.5.3 for documentation provisions) construction material and component reuse, refurbishment, and recycling.

21.2.6.2 The equipment should be designed to facilitate equipment decontamination and disposal, e.g., by use of removable liners or replaceable modules. This includes minimizing the number of parts that become contaminated with hazardous materials.

NOTE 97: It is recommended that SEMI S12 "Guidelines for Equipment Decontamination" be used for guidance during equipment decontamination.

22 Exhaust Ventilation

22.1 Equipment exhaust ventilation should be designed to prevent potentially hazardous chemical exposures to employees as follows:

22.1.1 As primary control when normal operations present potentially hazardous chemical exposures to employees by diffusive emissions that cannot be otherwise prevented or controlled (e.g., wet decks, spin coaters).

NOTE 98: In the context of this section, "primary control" means that it is the control of first choice (e.g., rather than personal protective equipment).

22.1.2 As supplemental control when intermittent activities (e.g., chamber cleaning, implant source housing cleaning) present potentially hazardous chemical exposures to employees which cannot reasonably be controlled by other means. Supplemental exhaust hoods or enclosures may be integrated into the equipment design, or supplied completely by the equipment user.

22.1.2.1 When a procedure (e.g., cleaning) specified by the supplier requires exhaust ventilation, the supplier should include the minimum criteria for exhaust during the procedure.

22.1.3 As secondary control when a single-point failure presents the potential for employee exposures to hazardous materials, and this exposure cannot be controlled by other means (e.g., use of all welded fittings).

EXCEPTION: Secondary exhaust control enclosures for non-welded connections (e.g., valve manifold boxes that enclose piping jungles) are not included in this guideline for those hazardous gases that are transported below atmospheric pressure (e.g., via vacuum piping systems) if it can be demonstrated that equivalent leak protection is provided. Equivalent protection may include such things as equipping the vacuum delivery system with a fail-safe (e.g., to close) valve automatically activated by a loss of vacuum pressure. Loss of vacuum pressure should also activate a visual and audible alarm provided in visual or audible range of the operator.

22.2 Equipment exhaust ventilation should be designed and a ventilation assessment conducted (see Section 23.5, Appendix 2, and SEMI S6) to control, efficiently and safely, for potential worst-case, realistic employee exposures to chemicals during normal operation, maintenance, or failure of other equipment components (hardware or software). All design criteria and test protocols should be based on recognized methods. See also Section 23.3.

22.3 Documentation should be developed showing the equipment exhaust parameters and relevant test methods, and should include (see also Appendix 2):

- duct velocity (where needed to transport solid particles);
- volumetric flow rate Q;
- capture velocity (where airborne contaminants are generated outside an enclosure);
- face velocity (where applicable);
- hood entry loss factor F_h or K;
- coefficient of entry $C_{e.}$;
- hood static pressure SP_h;
- duct diameter at the point of connection to facilities; and
- location(s) on the duct or hood where all ventilation measurements were taken.

22.4 Exhaust flow interlocks should be provided by the manufacturer on all equipment that uses hazardous production materials (HPMs) where loss of exhaust may create a hazard. Flow (e.g., pitot probe) or static pressure (e.g., manometer) switches are the preferred sensing methods.

NOTE 99: Sail switches (switches that are connected to a lever that relies upon air velocity to activate) are generally not recommended.

NOTE 100: It is recommended that the pressure or flow measuring point be located upstream of the first damper.

NOTE 101: Section 11 contains provisions for safety interlocks.

22.4.1 When the exhaust falls below the prescribed set point, an alarm should be provided within audible or visible range of the operator, and the process equipment should be placed in a safe stand-by mode. A time delay and exhaust setpoint for the equipment to go into standby mode may be allowable, based on an appropriate risk assessment. The system should be capable of interfacing with the facility alarm system.

NOTE 102: It is recommended that non-HPM chemical process exhaust be equipped with audible and visible indicators only.

22.4.2 Exhaust flow interlocks and alarms should require manual resetting.

22.4.3 Exhaust flow interlocks should be fault-tolerant.

22.5 Equipment and equipment components should be designed using good ventilation principles and practices to ensure chemical capture and to optimize exhaust efficiency (see Appendix 2).

NOTE 103: It is recommended that exhaust optimization be achieved with total equipment static pressure requirements of –1 to –38 mm (–0.05 to –1.5") H_2O (see also Section A2-1 of Appendix 2, and Section 8.3.6.1 of SEMI S6-93).

23 Chemicals

23.1 The manufacturer should generate a chemical inventory identifying the chemicals anticipated to be used or generated in the equipment. At a minimum, this should include chemicals in the recipe used for equipment qualification or “baseline” recipe, as well as intended reaction products and anticipated by-products. Chemicals on this list that can be classified as hazardous production materials (HPMs), or odorous (odor threshold < 1 ppm) or irritant chemicals (according to their material safety data sheets), should also be identified.

23.2 A hazard analysis (see Section 6.8) should be used as an initial determination of chemical risk as well as to validate that the risk has been controlled to an appropriate level.

23.2.1 The hazard analysis, at a minimum, should address the following conditions:

- potential mixing of incompatible chemicals;
- potential chemical emissions during routine operation;

- potential chemical emissions during maintenance activities; and
- potential key failure points and trouble spots (e.g., fittings, pumps).

23.2.2 All routes of exposure (e.g., respiratory, dermal) should be considered in exposure assessment.

23.3 The order of preference for controls in reducing chemical-related risks is as follows:

23.3.1 substitution or elimination (see also Section 21.2.2);

23.3.2 engineering controls (e.g., enclosure, ventilation, interlocks);

23.3.3 administrative controls (e.g., written warnings, standard operating procedures);

23.3.4 personal protective equipment.

23.4 The design of engineering controls (e.g., enclosure, ventilation, interlocks) should include consideration of (see also Appendix 3):

- pressure requirements;
- materials incompatibility;
- equipment maintainability;
- chemical containment; and
- provisions for exhaust ventilation (see Section 22).

23.5 During equipment development, the supplier should conduct an assessment that documents conformance to the following airborne chemical control criteria (see also Appendix 2). All measurements should be taken using recognized methods with documented sensitivities and accuracy. A report documenting the survey methods, equipment operating parameters, instrumentation used, calibration data, results, and discussion should be available.

23.5.1 There should be no chemical emissions to the workplace environment during normal equipment operation. Conformance to this section can be shown by demonstrating ambient air concentrations to be less than 1% of the Occupational Exposure Limit (OEL) in the worst-case personnel breathing zone. Where a recognized method does not provide sufficient sensitivity to measure 1% OEL, then the lower detection limit of the method may be used to satisfy this criterion.

23.5.2 Chemical emissions during maintenance activities should be minimized. Conformance to this section can be shown by demonstrating ambient air concentrations to be less than 25% of the OEL, in the anticipated worst-case personnel breathing zone, during maintenance activities.

23.5.3 Chemical emissions during equipment failures should be minimized. Conformance to this section can be shown by demonstrating ambient air concentrations to be less than 25% of the OEL, in the anticipated worst-case personnel breathing zone, during a realistic worst-case system failure.

NOTE 104: The use of direct reading instrumentation under simulated operating, maintenance, or failure conditions is the preferred measurement method. Where used, it is recommended that the sample location(s) be representative of the worst-case, realistic exposure locations(s). It is recommended that the peak concentration be directly compared to the OEL to demonstrate conformance to Sections 23.5.1–23.5.3.

NOTE 105: It is recommended that integrated sampling methods be used when direct-reading instrumentation does not have adequate sensitivity, or when direct-reading technology is not available for the chemicals of interest. Where integrated sampling is used, it is recommended that the sample duration and locations(s) be representative of the worst-case, realistic, anticipated exposure time and locations. The resulting average concentration is directly compared to the OEL to demonstrate conformance to Sections 23.5.1–23.5.3.

NOTE 106: Tracer gas testing (see SEMI F15 for an acceptable method) may be used when direct-reading instrumentation does not have adequate sensitivity, or when direct-reading technology is not available for the chemicals of interest. Tracer gas testing should be used where testing conditions may be hazardous (e.g., system failure simulation with potential release of hazardous gas to atmosphere). It is recommended that tracer gas testing be used only when an accurate rate of chemical emission can be determined. Where used, it is recommended that the sample location(s) be representative of the worst-case, realistic exposure location(s).

23.5.4 Chemical emissions outside the enclosure during a realistic worst-case system failure should be less than the lower of the following two values: 25% of the lower explosive limit (LEL), or 25% of the OEL.

23.6 Equipment that uses hazardous gases may require continuous detection and, if so, should have sample points mounted in the equipment, or have recommended sampling points identified in the equipment installation instructions. Where the gas supply is part of or controlled by the equipment, the equipment should be able to accept a signal from an external monitoring device and shut down the supply of the gas.

23.7 Appropriate hazard warning labels should be placed at all chemical enclosure access openings.

24 Ionizing Radiation

24.1 This section covers equipment that produces ionizing radiation (e.g., X-rays, gamma rays) or uses radioactive sources.

24.2 Accessible emissions of ionizing radiation should be designed as low as reasonably achievable. This criteria can be met by demonstrating conformance to the provisions in Sections 24.2.1 and 24.2.2 and Appendix 4.

24.2.1 Accessible levels of ionizing radiation during normal operations should be less than 2 microsieverts (0.2 millirem) per hour above background. See also Table A4-1 of Appendix 4.

24.2.2 Accessible levels of ionizing radiation during maintenance and service procedures should be less than 10 microsieverts (1 millirem) per hour above background. See also Table A4-1 of Appendix 4.

24.2.3 Access to radioactive contamination or internal exposure (e.g., inhalation, ingestion) to radioactive materials should be minimized. The hazards and controls for the prevention of personnel contamination and internal exposures should be detailed in the operation and maintenance manuals.

NOTE 107: The use of radioactive material is strictly regulated around the world. Import, export, and transportation of radioactive materials is also highly regulated. Licenses may be required to possess, use, and distribute radioactive materials.

NOTE 108: Many regions require both user and import licenses, and the timely acquisition of these licenses depends on the information provided by the equipment supplier.

NOTE 109: Radiation producing machines are also regulated around the world. Regulations and licensing requirements may cover activities such as importing, exporting, installing, servicing and using radiation producing equipment.

24.2.4 The manufacturer should supply, in the user documentation, a contact phone number and address for the manufacturer's radiation safety support personnel.

24.3 Equipment should be designed to minimize access or exposure to ionizing radiation during normal operation, maintenance, and service. Potential exposures should be controlled in the following order of preference:

24.3.1 *Engineering Controls* — Engineering controls (e.g. shielding, interlocks) should be the primary mechanism to minimize emission of ionizing radiation or access to ionizing radiation.

24.3.1.1 Radiation shielding for the equipment facilities connections (e.g., gas and exhaust lines) should be designed such that removal and replacement of the shielding during installation is minimized.

24.3.2 Non-defeatable safety interlocks should be provided on barriers preventing maintenance access to radiation fields in excess of 10 microsieverts (μSv) or 1 millirem per hour.

24.3.3 *Administrative Controls* — When administrative controls (e.g., distance, time, standard operating procedures, labeling) are to be used, the equipment supplier should provide detailed documentation explaining the use of the administrative controls.

24.4 Equipment utilizing or producing ionizing radiation should be labeled appropriately.

NOTE 110: Label contents are typically controlled by regulation in the country in which the equipment is to be used.

24.5 The manufacturer should conduct an assessment to document conformance to the criteria specified in Sections 24.2.1 through 24.2.2 during normal equipment operation, maintenance, and service.

24.5.1 A radiation survey should be used to confirm design compliance and serve as a baseline survey (see also Table A4-1 of Appendix 4).

24.5.2 Measurements should be taken using recognized methods with documented sensitivities and accuracy. A report documenting the survey methods, equipment operating parameters, instrumentation used, calibration data, source locations, results, and discussion should be made available.

24.5.3 If supplemental administrative controls are recommended based on survey results or calculations, a discussion should be provided in the operations and maintenance manuals describing the source locations, radiation levels, and recommended control measures.

NOTE 111: Ionizing radiation sources must be registered or licensed according to the regulations of the country of destination. These radiation sources must conform to the regulations of central or local government agencies, whichever is stricter.

NOTE 112: It is recommended that equipment containing radioactive materials should demonstrate conformance to licensing with local regulatory agencies prior to shipment.

NOTE 113: Equipment that uses particle acceleration in its process has the potential for generating ionizing radiation as a result of nuclear interactions between the accelerated particles and various materials. These materials can include materials of construction of the equipment, accumulated residual process materials in the equipment, and the target materials.

25 Non-Ionizing Radiation and Fields

25.1 This section covers equipment that produces non-ionizing radiation, except laser sources, in the following categories:

- static electric and magnetic (0 Hz),
- sub-radio frequency electric and magnetic fields (< 3 kHz),
- radio frequency (3 kHz–300 GHz),
- infrared radiation (700 nm–1 mm),
- visible Light (400 nm–700 nm), and
- ultraviolet Light (180–400 nm).

25.2 Potentially hazardous non-ionizing radiation emissions that are accessible to any personnel should be limited to the lowest practical level. This criterion can be met by demonstrating conformance to the following provisions:

EXCEPTION: Emissions of non-ionizing radiation exceeding the cardiac pacemaker limits in Appendix 5 but less than the levels in Sections 25.2.1 and 25.2.2 should be identified with appropriate labeling. See also Section 25.5.1.

25.2.1 Accessible levels of non-ionizing radiation during normal operations are less than the Operator-Accessible Limit (see Appendix 5);

25.2.2 Accessible levels of non-ionizing radiation during maintenance and service procedures are less than the Maintenance- and Service-Accessible Limit (see Appendix 5).

25.3 Sources of potentially hazardous non-ionizing radiation should be identified in the operation and maintenance manuals, and appropriate parameters listed. Parameters include frequency, wavelength, power levels, continuous wave or pulsed (see also Appendix 5). If pulsed, parameters also include the pulse repetition rate, pulse duration, and description of the pulse waveform.

EXCEPTION: Visible sources which are intended to be viewed or which provide illumination (e.g., display panels, visible alarm indicators), and are not lasers, do not need to be identified.

NOTE 114: It is recommended that UV/IR generators that are part of fire protection test apparatus, and are provided with the equipment, be considered as possible sources of potentially hazardous non-ionizing radiation.

25.4 Equipment should be designed to minimize access or exposure to non-ionizing radiation during normal operation, maintenance, and service. Potential exposures should be controlled in the following order of preference:

25.4.1 engineering controls (e.g., enclosure, shielding, guarding, grounding, interlocks);

25.4.2 administrative controls (e.g., written warnings, standard operating procedures, labeling); and

25.4.3 personal protective equipment.

25.5 Equipment utilizing or producing potentially hazardous non-ionizing radiation should be labeled.

25.5.1 Hazard warning labels should be provided by the manufacturer when emission levels are measured that may impact cardiac pacemakers or magnetizable prostheses. These warning labels should be located where the emissions exceed the pacemaker limit. (See Appendix 5 for pacemaker labeling levels and references.)

25.6 The manufacturer should conduct an assessment to document conformance to the criteria specified in Sections 25.2.1 and 25.2.2. Engineering calculations may be used as part of this assessment. All measurements should be taken using recognized methods with documented sensitivities and accuracy. A report documenting the survey methods, equipment operating parameters, instrumentation used, calibration data, source location(s), and discussion should be provided. See Appendix 5.

25.6.1 If supplemental administrative controls are recommended based on survey results or calculations, a discussion should be provided in the operations and maintenance manuals describing the source location(s), radiation levels, and recommended control measures.

25.6.2 Administrative control procedures recommended for operation, maintenance, or service activities should be documented in the operations and maintenance manuals.

26 Lasers

26.1 Equipment should be identified with a laser product classification based on the laser energy accessible during operation, per the applicable standard.

NOTE 115: A Class 1 label may be required in some jurisdictions, but is not currently required in the United States.

26.1.1 The laser energy (or power), wavelength, and temporal mode (continuous wave or pulsed) should be identified in the documentation provided to the user.

NOTE 116: The laser product classification for some equipment will be Class 1 or 2, even though an embedded laser is of a higher hazard classification.

26.1.1.1 If pulsed, the pulse repetition rate, pulse duration and description of the pulse waveform should be identified in the documentation provided to the user.

26.1.1.2 For Class 3b or 4 embedded laser systems, the above information and the physical location of the laser sources within the laser product should be identified in the documentation provided to the user and in the maintenance manual.

26.1.2 Equipment should not exceed the laser product classification of Class 2; however, individual lasers may exceed this classification prior to integration into the final equipment assembly.

26.2 Equipment, including beam diagnostic or alignment tools, should be designed to prevent injury from all lasers during normal operation, and should minimize risk of injury during maintenance or service. Potential exposures should be controlled in the following order of preference:

26.2.1 Engineering controls (e.g., enclosures, shielding, filters, use of fiber optics to transmit energy, interlocks).

26.2.2 Temporary enclosures or control measures for maintenance, service, and non-routine tasks.

26.2.3 Administrative controls (e.g., written warnings, standard operating procedures, labeling).

26.2.4 Personal protective equipment.

NOTE 117: Temporary enclosures and personal protective equipment are considered to be administrative controls, because they require human action to implement.

NOTE 118: Certain classes of laser products are regulated around the world. Regulations and licensing requirements may cover activities such as importing, exporting, distributing, demonstrating, installing, servicing, and using these laser products.

26.3 The equipment supplier should provide the following in the operation and maintenance manuals:

- a description of laser-related hazards present during operation, maintenance, or service, and methods to minimize the hazard;
- justification for any procedures that require a laser controlled area and the dimensions of this hazard zone;
- administrative controls used in maintenance and service activities; and
- a description of necessary personal protective equipment.

26.4 The following detailed information should be available for the evaluator:

- justification for when engineering controls are not feasible to limit exposure during operation or maintenance tasks, and how administrative controls provide equivalent protection (see Section 26.2); and
- documentation showing compliance with an appropriate international laser product safety or industry standard, or the national standard for country of use.

27 Sound Pressure Level

27.1 Equipment should be designed to control exposures to sound pressure levels equal to or greater than 80 dBA continuous or intermittent sound pressure level, and 120 dB instantaneous (impulse) sound pressure level.

NOTE 119: It is recommended that efforts be made to decrease sound pressure levels as they approach 80 dBA (i.e., 77 to 80 dBA), due to the additive sound pressure level effects of multiple pieces of equipment in the same vicinity.

27.2 The order of preference for controlling exposures is as follows:

27.2.1 *Engineering Controls* (e.g., source sound pressure level reduction, absorption, enclosures, barriers, acoustic dampening) — At a minimum, the design of the engineering controls should consider the sound pressure levels and type, the frequency, and the appropriate control technologies.

27.2.2 *Administrative Controls* — Acceptable administrative controls should be limited to supplemental hazard warning labels and operating procedures.

NOTE 120: Noise labeling is typically implemented as signs located in the users facility.

27.3 Sound level surveys should be conducted by the manufacturer during equipment development for equipment that may emit hazardous sound pressure levels.

27.3.1 The survey should be conducted in accordance with a recognized standard. In addition, the following test criteria should be applied:

27.3.1.1 The equipment mode of operation during the sound pressure level tests should simulate as closely as possible the actual modes and operating positions that may be experienced by the equipment user.

27.3.1.2 Measurements should be taken in locations that best simulate actual positions of operators relative to the equipment. As a general guideline, the microphone should be traversed 1 meter from the equipment, 1.2 meters above the ground to simulate seated operators, 1.5 meters above the ground to simulate standing operators, and 3.5 meters (or as far as possible) away from the nearest walls or sound-reflecting objects. Measurements are taken 360 degrees around the equipment wherever possible.

Table 2 Sound Pressure Level Test Criteria

NOTE 121: Background level may be subtracted using an accepted method. If the sound pressure level difference is less than 3 dBA, the contribution of the source from the background cannot be adequately distinguished and the survey results would not be valid for values over 80 dBA.

Difference between sound pressure level measured with noise source operating and background sound pressure level (dBA)	*Correction to be subtracted from the sound pressure level measured with the noise source operating to obtain the sound pressure level due to noise source alone (dBA)*
3	3
4	2.5
5	1.7
6	1.3
7	1
8	0.8
9	0.6
10	0.4

27.3.2 If the measured sound pressure level is less than 70 dBA, the manufacturer should provide to the evaluator test data documenting sound pressure levels, survey equipment, equipment calibration, test conditions and results.

27.3.3 If the measured sound pressure level is greater than 70 dBA, the test data should include all of the information in Section 27.3.2, and should also include the expected duration of personnel exposure.

27.3.4 If measured sound pressure level is greater than 75 dBA, information should be provided in the equipment maintenance manual describing the sound pressure level(s) and location(s).

APPENDIX 1
ENCLOSURE OPENINGS

NOTE: The material in this appendix is an official part of SEMI S2 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A1-1 This appendix provides guidance on sizes of openings in enclosures.

Table A1-1 Examples of Openings for Protection Against Access from Operators

Distance Between Opening and Danger Point		*Maximum Opening*	
mm	*inches*	*mm*	*inches*
13–38	0.5–1.5	6	0.250
38–64	1.5–2.5	10	0.375
64–89	2.5–3.5	11.9	0.470
89–140	3.5–5.5	16	0.625
140–165	5.5–6.5	19	0.750
165–191	6.5–7.5	22	0.875

A1-1.1 Alternatively, an IEC accessibility probe, as specified in SEMI S9, may be used to determine suitability of mesh openings.

A1-2 *Top Openings in Electrical Enclosures* — The top openings in electrical enclosures should meet one of the following:

- not exceed 5 mm in any dimension, or
- not exceed 1 mm in width regardless of length, or
- be so constructed that direct, vertical entry of a falling object is prevented from reaching uninsulated live parts within the enclosure by means of trap or restriction (see Figure A1-1 below for examples of top cover designs that prevent such direct entry), or
- meet the intent through other equivalent means.

Figure A1-1

APPENDIX 2
DESIGN PRINCIPLES AND TEST METHODS FOR EVALUATING EQUIPMENT EXHAUST VENTILATION — Design and Test Method Supplement Intended for Internal and Third Party Evaluation Use

NOTE: The material in this appendix is an official part of SEMI S2 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A2-1 Introduction

A2-1.1 This appendix provides specific technical information relating to Section 22. In general, it provides guidelines for:

- ventilation design for semiconductor manufacturing equipment, and
- test validation criteria.

A2-1.2 This appendix is intended to be used as a starting point for reference during equipment design.

A2-1.3 This appendix is not intended to limit hazard or test evaluation methods or control strategies (e.g. design principles) employed by manufacturers or users. Many different methods may be employed if they provide a sufficient level of protection.

A2-1.4 This appendix is not intended to provide exhaustive methods for determining final ventilation specifications. Other methods may be used where they provide at least equivalent sensitivity and accuracy.

A2-1.5 The exhaust velocities, volume flow rates and pressures listed are derived from a mixture of successful empirical testing and regulatory requirements.

A2-1.6 Test validation criteria are generally referenced from the applicable internationally recognized standard. It is the user's responsibility to ensure that the most current revision of the standard is used.

Table A2-1 Ventilation

Hood Type	*Recommended Test Methods*	*Typical Design and Test Exhaust Parameters (See NOTE 1.)*	*References*
Wet Station	Primary: vapor visualization, air sampling Supplemental: Capture velocity, slot velocity, tracer gas, air sampling	0.28–0.50 m/s (55–100 fpm) capture velocity for non-heated 0.36–0.76 m/s (70–150 fpm) capture velocity for heated 110–125% of the laminar flow volume flow rate across the top of the deck	ACGIH Industrial Ventilation Manual SEMI F15
Gas Cylinder Cabinets	Primary: face velocity, tracer gas Supplemental: vapor visualization	1.0–1.3 m/s (200–250 fpm) face velocity	ACGIH Industrial Ventilation Manual SEMI F15
Equipment Gas Panel Enclosure	Primary: tracer gas, static pressure Supplemental: vapor visualization	4–5 air changes per minute –1.3 to –2.5 mm (–0.05 to –0.1 in.) H_2O static pressure	ACGIH Industrial Ventilation Manual SEMI F15
Diffusion Furnace Scavenger	Primary: face velocity, vapor visualization Supplemental: tracer gas, air sampling	0.50–0.76 m/s (100–150) fpm face velocity NOTE: Do not use hot wire anemometer.	ACGIH Industrial Ventilation Manual SEMI F15
Chemical Dispensing Cabinets	Primary: static pressure Supplemental: vapor visualization, air sampling where safe, tracer gas where emission rates can be accurately calculated	–1.3 to –2.5 mm (–0.05 to –0.1 in.) H_2O static pressure 2–3 air changes per minute	ACGIH Industrial Ventilation Manual SEMI F15

Hood Type	*Recommended Test Methods*	*Typical Design and Test Exhaust Parameters (See NOTE 1.)*	*References*
Parts-Cleaning Hoods	Primary: face velocity, vapor visualization Supplemental: tracer gas, air sampling	0.40–0.64 m/s (80–125 fpm) face velocity	ASHRAE Standard 110 SEMI F15 ACGIH Industrial Ventilation Manual
Pump and Equipment Exhaust Lines	Primary: static pressure Supplemental: tracer gas	–6 to –25 mm (–0.25 to –1.0 in.) H_2O static pressure 125% maximum volume flow rate from pump	ACGIH Industrial Ventilation Manual SEMI F15
Glove Boxes	Primary: static pressure, tracer gas Supplemental: vapor visualization, air monitoring	No consensus for a reference at the time of publication of this guideline.	ACGIH Industrial Ventilation Manual SEMI F15
Drying/ Bake/ Test Chamber Ovens	Primary: static pressure, tracer gas Supplemental: vapor visualization, air monitoring	–1.3 to –2.5 mm (–0.05 to –0.1 in.) H_2O static pressure	SEMI F15 ACGIH Industrial Ventilation Manual
Spin-Coater (cup only)	Primary: vapor visualization, velometry Supplemental: air sampling	(see SEMI S2 Sections 23.5.1–3)	ACGIH Industrial Ventilation Manual
Supplemental Exhaust	Primary: capture velocity, vapor visualization, air sampling	0.50–0.76 m/s (100–150 fpm) capture velocity	ACGIH Industrial Ventilation Manual

NOTE 1: All measurements should be within ± 20% of average for face velocity, ± 10% of average along the length of each slot for slot velocity, and ± 10% of average between slots for slot velocity.

A2-2 Exhaust Optimization

A2-2.1 Exhaust optimization is the use of good ventilation design to create efficient equipment exhaust. The design and measurement methods discussed below confirm that equipment exhaust is acting as the manufacturer intended. This information is not meant to prohibit alternate methods of achieving or verifying good ventilation design. References for ventilation design are included at the end of this Appendix.

A2-2.2 *Design Recommendations*

A2-2.2.1 Equipment exhaust design can attempt to reduce inefficient static pressure losses caused by: friction losses from materials; openings, and duct geometries (elbows, duct expansions or contractions); turbulent air flow; fans; internal fittings such as blast gates and dampers; directional changes in airflow.

A2-2.2.2 Other good design principles can include minimizing distance between the source and hood, and reducing enclosure volumes.

A2-2.2.3 For non-chemical issues such as heat from electrical equipment, heat recapture rather than exhaust may be appropriate.

A2-2.2.4 The possible impact of highly directional laminar airflow found in most fabs should be considered when designing equipment exhaust.

A2-2.3 *Recommended Equipment Controls* — The location of internal blast gates or dampers inside equipment, and their appropriate settings, should be clearly identified. The number of equipment dampers and blast gates should be minimized. Gates/dampers should be lockable or otherwise securable. Static pressure or flow sensors installed on equipment by the manufacturer should have sufficient sensitivity and accuracy to measure exhaust flowrate fluctuations that place the equipment out of prescribed ranges.

A2-2.4 *Recommended Measurement/Validation Method* — Measurements should be made to identify optimal exhaust levels and confirm that safety and process requirements are being addressed. The manufacturer should be able to identify any critical equipment locations for chemical capture, and quantify appropriate exhaust values. Multiple validation/ measurement methods may be needed.

A2-2.4.1 Measurements should be done after equipment components are assembled.

A2-2.4.2 Computer modeling can be done to predict exhaust flow and hazardous material transport in equipment by solving fluid mechanics conservation of energy and mass equations. Modeling can be used in the equipment design stage or to improve existing equipment. Computer models should be verified experimentally, using one or more of the methods discussed below.

A2-2.4.3 Tracer gas testing provides a method to test the integrity of hoods by simulating gas emission and measuring the effectiveness of controls. Testing until there is a failure, and then slightly increasing the flow rate until the test is successful, can be used to help minimize air flow specifications.

A2-2.4.4 Chemical air or wipe monitoring can be used to confirm that chemical transport is not occurring into unintended areas of the equipment.

A2-2.4.5 Velocity profiling will confirm expected airflows, the direction of flow, and the effect of distance.

A2-2.4.6 Vapor visualization will confirm expected airflows, the direction of flow, and the effect of distance. Vapor visualization is the observation of aerosols (e.g., aerosols generated by using water, liquid nitrogen, or dry ice) so that exhaust flow patterns can be observed. Smoke tubes or aerosols may also be used, however they can produce contamination.

A2-3 Chemical Laboratory Fume Hoods, Parts Cleaning Hoods

Lab fume hoods and part cleaning hoods are designed to control emission by enclosing a process on five sides and containing the emission within the hood.

A2-3.1 *Design Recommendations*

A2-3.1.1 Fully enclosed on five sides, open on one side for employee access and process/parts placement and removals.

A2-3.1.2 Front (employee access side) should be provided with sliding door and/or sash.

A2-3.1.3 Minimize size of the hood based on process size.

A2-3.1.4 Minimize front opening size based on size of process and employee access needs.

A2-3.1.5 Ensure hood construction materials are compatible with chemicals used.

A2-3.2 *Control Specifications* — Face velocity is the specification generally used with hoods open on only one side.

A2-3.2.1 Generally acceptable laboratory fume hood face velocities range from 0.40 to 0.60 m/s (80–120 fpm) with no single measurement ± 20 % of average. 0.64 to 0.76 m/s (125–150 fpm) is recommended for hoods in which carcinogens or reproductive toxicants may be used.

A2-3.2.2 Velocities as low as 0.30 to 0.40 m/s (60–80 fpm) can be effective but require no cross drafts or competing air movement in the work area.

A2-3.2.3 An average face velocity of 0.50 m/s (100 fpm) is generally found to be acceptable in most applications.

A2-3.2.4 Face velocities of 0.64 to 0.76 m/s (125 to 150 fpm) may be required when a lab hood is installed in an area with laminar air flow.

A2-3.2.5 Face velocity above 0.76 m/s (150 fpm) should be avoided to prevent eddying caused by a lower pressure area in front of an employee standing at the hood.

A2-3.3 *Recommended Measurement/Validation Method*

A2-3.3.1 The preferred method is measurement of average face velocity and hood static pressure. Measurements are taken with a velometer or anemometer. Multiple measurements are taken in a grid, at least 10 to 40 per square meter (1–4 per square foot) of open area, in the plane opening of the hood. This allows representative, evenly spaced measurements to be taken (see also open-surface tanks).

A2-3.3.2 Additional confirmation by visualization check of containment using smoke or vapor testing.

A2-3.3.3 ASHRAE Method 110, or equivalent (use appropriate sections), for tracer gas testing of lab hoods may be used as a supplemental verification provided that an accurate emission rate can be defined. (ASHRAE 110 lists 3 tests: “as manufactured,” “as used,” and “as installed.” The “as manufactured” test is the test that is used most frequently.)

A2-4 Wet Stations

Wet stations are slotted hoods designed to capture laminar air flow while also capturing wet process emissions from the work area. Wet stations can be open on the front, top and both sides (it is usually preferable to enclose as much as possible).

A2-4.1 *Design Recommendations*

A2-4.1.1 Slots should be provided uniformly along the length of the hood for even distribution of airflow.

A2-4.1.2 Additional lip exhaust slots should be provided around tanks or sinks to control emissions.

A2-4.1.3 The plenum behind the slots should be sized to ensure even distribution of static pressure. These slots should be designed to ensure adequate airflow is provided by the side slots, and to minimize turbulence that could reduce exhaust performance.

A2-4.1.4 Velocity along length of slot should not vary by more than 10% of the average slot velocity.

A2-4.1.5 Additional use of end or side panels/baffles can reduce negative impact of side drafts.

A2-4.1.6 Exhaust volume settings should consider laminar air flow volumes and be balanced to minimize turbulence and to ensure capture.

A2-4.1.7 The station design should consider airflow patterns in the operating zone to minimize turbulent horizontal airflow patterns into and across the work deck.

A2-4.1.8 Additional considerations to reduce exhaust demand include providing covered tanks, and recessing tanks below deck level.

A2-4.2 *Control Specifications*

A2-4.2.1 Wet station specifications are complicated by the fact that wet stations generally do not have an easily definable face velocity to measure. A number of methods have been used and are all acceptable if used consistently and provided documentation indicates chemical containment meets the 1% of the OEL at distances beyond the plane of penetration at the exterior of the wet station.

A2-4.2.2 Maintain an average capture velocity of 0.33 to 0.50 m/s (65–100 fpm) immediately above a bath.

A2-4.2.3 Calculate the total exhaust volume requirement by determining the total volumetric flow of laminar air hitting the deck and increasing this value by 20 to 25%.

A2-4.2.4 For some wet stations that are partially enclosed from the top, an artificial plane opening ("face") can be defined where the downward laminar air flow penetrates the capture zone (at "face velocity") of the wet station. Depending on the hood design and laminar air flow provided, average face velocities can range from 0.20 to 0.50 m/s (40 to 100 fpm). The measurement location can greatly influence the measured face velocity; therefore, this method should be supplemented with at least one of the preceding methods for greater accuracy and reproducibility at the user's facility.

A2-4.3 *Recommended Measurement/Validation Method*

A2-4.3.1 Confirmation of capture using vapor visualization.

A2-4.3.2 Confirmation of laminar flow of make up air into the station using vapor visualization.

A2-4.3.3 Tracer gas testing may be used as supplemental verification, provided an emission rate can be accurately defined.

A2-5 Supplemental Exhaust

Supplemental exhaust, if not designed into the equipment, can be provided by a flexible duct with a tapered hood. This can be placed in the work area to remove potential contaminants before they enter the breathing zone. Supplemental exhaust is frequently used during maintenance or service.

A2-5.1 *Design Recommendations*

A2-5.1.1 Retractable or movable non-combustible flex ducting for easy reach and placement within 150 to 300 mm (6 to 12 inches) of potential emissions to be controlled.

A2-5.1.2 Manual damper at hood to allow for local control, i.e., shut off when not required.

A2-5.1.3 Tapered hood with a plane opening as a minimum. The additional use of flanges or canopies to enclose the process will result in improved efficiency.

A2-5.2 *Control Specifications*

NOTE A2-1: This is one equation that is most commonly used. Other equations may be appropriate; see also ACGIH Industrial Ventilation Manual, and Semiconductor Exhaust Ventilation Guidebook.

A2-5.2.1 A minimum capture velocity of 0.50 m/s (100 fpm) is required at the contaminant generation point for releases of vapor via evaporation or passive diffusion. Ventilation should not be relied upon to prevent exposures to hazardous substances with release velocities (e.g., pressurized gases). For a plane open ended duct without a flange, the air flow required at a given capture velocity can be calculated by:

$Q = V(10X^2 + A)$

Where: Q = required exhaust air flow in m^3/s (cfm)

V = capture velocity in m/s (fpm) at distance X from hood

A = hood face area in square meters (square feet)

X = distance from hood face to farthest point of contaminant release in meters (feet). NOTE: This is only accurate when X is within 1.5 diameters of a round opening, or within 0.25 circumference of a square opening.

A2-5.3 *Recommended Measurement/Validation Method*

A2-5.3.1 Measurement of capture velocity at farthest point of contaminant release. Measurements taken with a velometer or anemometer.

A2-5.3.2 Confirmation by visualization check of capture using vapor capture testing.

A2-6 Equipment Gas Panel Enclosures

Equipment gas panel enclosures, also known as gas boxes, jungle enclosures, gas jungle enclosures, valve manifold boxes, and secondary gas panel enclosures, are typically six-sided fully enclosed enclosures with access panels/doors on at least one side. These ventilated enclosures are designed to contain and remove hazardous gases from the work area in the event of a gas piping failure or leak. Gas panel enclosures are typically of two types, those requiring no access while gas systems are charged, and those that must be opened during processing while gas systems are charged. There is also a distinct difference in control specifications for those with pyrophorics or other flammables vs. other HPMs, specifically in the control of pocketing.

A2-6.1 *Design Recommendations*

A2-6.1.1 Compartmentalize potential leak points.

A2-6.1.2 Minimize the total size of the panel and its enclosure.

A2-6.1.3 Minimize size and number of openings.

A2-6.1.4 Minimize static pressure requirements of the enclosure; control has been shown to be achievable with –1.3 to –2.5 mm (–0.05 to –0.1 in.) w.g.

A2-6.1.5 Design for sweep. Minimize the number and size of openings. Seal unnecessary openings (e.g., seams, utility holes).

A2-6.1.6 Where routinely used access doors are required:

- Make the access door as small as practical.
- Place the openings to the enclosure in the access door to minimize air flow requirements.
- Provide baffles behind the door to direct leaks away from the door and openings.
- Compartmentalize the enclosure so that access to one area does not affect air flow control in other areas.

A2-6.2 *Control Specifications*

A2-6.2.1 Exhaust volumes as low as 4–5 air changes per minute or less can be specified and meet the S2 criteria in Section 23.5 if the design principles listed above are considered when designing equipment and enclosures.

A2-6.2.2 Where there is potential for chemical exposure during access which can be controlled by face velocity, the enclosure should also provide a minimum face velocity of 0.36 to 0.76 m/s (70 to 150 fpm) when open. Face velocity should not be relied upon to control emissions from a pressurized fitting.

A2-6.2.3 Enclosures for pyrophoric or flammable gases should be designed to ensure adequately uniform dilution (i.e., prevent “pocketing”) and to prevent accumulation of pyrophoric and flammable gases above their lower explosive limit. Uniform dilution can generally be verified through exhaust vapor visualization techniques. Ventilation flow rate should be adequate to maintain concentrations below 25% of the lower explosive limit for the gas with the lowest LEL that is used in the enclosure. This can generally be verified using engineering calculations to verify dilution, and vapor visualization to verify mixing.

A2-6.3 *Recommended Measurement/Validation Method*

A2-6.3.1 Preferred validation by tracer gas testing per SEMI F15.

A2-6.3.2 Additional confirmation by visualization check of air flow, mixing and sweep using smoke or vapor testing.

A2-6.3.3 Measurement of average face velocity at inlet(s), opening(s), or routinely used access doors. Measurements should be taken with a velometer or anemometer. For larger openings, multiple measurements are taken in a grid, at least 10 to 40 per square meter (1–4 per square foot) of open area. Useful equation: $V = 4.043\ (VP/d)^{0.5}$, where V = velocity in m/s, VP = velocity pressure in mm H_2O, and d = density correction factor (unitless).

A2-7 Equipment Exhaust Ventilation Specifications and Measurements

A2-7.1 Specifications for equipment exhaust should be provided by the supplier and define:

A2-7.1.1 The control specification or standard for the hood or enclosure, i.e., face velocity or capture velocity if applicable.

A2-7.1.2 The airflow in the duct required to maintain the control volume or flow required. Measurements should be made using the ACGIH pitot traverse method described below.

A2-7.1.3 The location where the Pitot traverse measurement in the duct was made.

A2-7.1.4 Static pressure requirements.

A2-7.1.5 Coefficient of Entry (C_e) (see definitions and Section 22.3).

A2-7.1.6 Hood Loss Factor (K or F_h) (see definitions and Section 22.3).

A2-8 Duct Traverse Method

A2-8.1 Because the air flow in the cross-section of a duct is not uniform, it is necessary to obtain an average by measuring velocity pressure (VP) at points in a number of equal areas in the cross-section. The usual method is to make two traverses across the diameter of the duct at right angles to each other. Reading are taken at the center of annular rings of equal area. Whenever possible, the traverse should be made 7.5 duct diameters downstream and 3 diameters upstream from obstructions or directional changes such as an elbow, hood, branch entry, etc. Where measurements are made closer to disturbances, the results should be considered subject to some doubt and checked against a second location. If agreement within 10% of the two traverses is obtained, reasonable accuracy can be assumed and the average of the two readings used. Where the variation exceeds 10%, a third location should be selected and the two air flows in the best agreement averaged and used. The use of a single centerline reading for obtaining average velocity is a very coarse approximation and is *not* recommended. If a traverse cannot be done, then the centerline duct velocity should be multiplied by 0.9 for a coarse estimate of actual average duct velocity. Center line duct velocity should not be used less than 5 duct diameters from an elbow, junction, hood opening, or other source of turbulence.

A2-8.2 For ducts 150 mm (6 in.) and smaller, at least 6 traverse points should be used. For round ducts larger than 150 mm (6 in.) diameter, at least 10 traverse points should be employed. For very large ducts with wide variation in velocity, 20 traverse points will increase the precision of the air flow measurement.

A2-8.3 For square or rectangular ducts, the procedure is to divide the cross-section into a number of equal rectangular areas and measure the velocity pressure at the center of each. The number of readings should not be less than 16. Enough readings should be made so the greatest distance between centers is less than 150 mm (6 in.).

A2-8.4 The following data are required:

A2-8.4.1 The area of the duct at the traverse location.

A2-8.4.2 Velocity pressure at each point in the traverse and/or average velocity and number of points measured.

A2-8.4.3 Temperature of the air stream at the time and location of the traverse.

A2-8.4.4 The velocity pressure readings obtained are converted to velocities, and the velocities (not the velocity pressures) are averaged. Useful equation: $V = 4.043\ (VP/d)^{0.5}$, where V = velocity in m/s, VP = velocity pressure in mm H_2O, and d = density correction factor (unitless). Some monitoring instruments conduct this averaging internal to the instrument.

A2-8.5 Flow measurement taken at other than standard air temperatures should be corrected to standard conditions (i.e., 21°C [70°F], 760 mm [29.92 in.] Hg).

APPENDIX 3
DESIGN GUIDELINES FOR EQUIPMENT USING LIQUID CHEMICALS — Design and Test Method Supplement Intended for Internal and Third Party Evaluation Use

NOTE: The material in this appendix is an official part of SEMI S2 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A3-1 Introduction

A3-1.1 This appendix provides specific technical information relating to Section 23. In general, it provides information on potential hazards, recommended control methods, and design considerations.

A3-1.2 This appendix is not intended to limit hazard evaluation methods or control strategies (e.g., design principles) employed by manufacturers. Alternative methods are acceptable if they provide an equivalent level of hazard control.

A3-1.3 This appendix is intended to be used as a starting point for reference during equipment design. An example would be during a formal hazard analysis in a brainstorming session.

Table A3-1 Liquid Chemicals

<table>
<tr><th>Potential Hazard</th><th>Recommended Control Method</th><th>Design Considerations</th></tr>
<tr><td rowspan="3">Exposure to operators</td><td>Containment, control, and alarm notification for spills, leaks or vapors.</td><td>Appropriately sized secondary containment (minimum 110% volume of entire contents)
Equipment exhaust
Leak sensors to initiate auto shutdown.</td></tr>
<tr><td>Controlled access to chemical containment areas.</td><td>Door/access cover interlocks that automatically depressurize the area of the system being accessed.</td></tr>
<tr><td>Control of access to point-of-operation hazards.</td><td>Physical guarding/presence-sensing devices</td></tr>
<tr><td rowspan="2">Exposure to maintenance personnel</td><td>Control of chemical delivery pressure; control of residual chemicals.</td><td>Depressurization upon system failure, interlock activation, or normal shutdown
Transparent doors/covers allow visual inspection.</td></tr>
<tr><td>Serviceability</td><td>Built-in system purge and flush capabilities
System components accessible and easy to service.</td></tr>
<tr><td rowspan="2">General equipment and component failure</td><td>Chemical resistance/compatibility</td><td>Appropriate materials used for equipment construction and components.</td></tr>
<tr><td>Pressure rating</td><td>Pressurized systems designed to withstand 150% of maximum foreseeable pressure, or provide a suitable relief valve.</td></tr>
<tr><td rowspan="4">Chemical delivery system leak</td><td>Durable bulk chemical containers</td><td>Use of approved (e.g., DOT, UN Dangerous Goods) containers in bulk distribution systems.</td></tr>
<tr><td>Control of pressurized vessels and piping.</td><td>Provide visual pressure indicators with or without alarms.
Pressurized vessels and piping are designed and built to recognized standards.</td></tr>
<tr><td>Spill control</td><td>Automatic system pressure check prior to allowing dispense.
Use of normally closed valves on distribution lines.</td></tr>
<tr><td>Drum change-out controls</td><td>Over-fill sensors on chemical baths
Monitoring for excess flow.
Keyed and color-coded quick-connects</td></tr>
</table>

Potential Hazard	*Recommended Control Method*	*Design Considerations*
Fire	Control of ignition sources.	NFPA 70 (NEC) Class I, Div. 2 wiring methods, intrinsically safe components, or nitrogen-purged enclosures Physical separation of ignition sources and/or potentially flammable atmospheres. Use of low voltage to reduce the risk for ignition.
	Control of static electricity (i.e., one type of ignition source).	Maintain ground continuity
	Heat/fire/chemical detection Limiting concentrations of fuels and oxidizers.	(No consensus for a specific recommendation at the time of publication of this guideline.)

APPENDIX 4
IONIZING RADIATION TEST VALIDATION — Design and Test Method Supplement Intended for Internal and Third Party Evaluation Use

NOTE: The material in this appendix is an official part of SEMI S2 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A4-1 Introduction

A4-1.1 This appendix provides specific technical information relating to Section 24. In general, it provides information on hazard evaluation methods, examples of control strategies, and test validation criteria.

A4-1.2 This appendix is not intended to limit hazard evaluation methods or control strategies (e.g. design principles) employed by the manufacturers. Alternative methods are acceptable if they provide an equivalent level of hazard control.

A4-1.3 Test validation criteria are generally referenced from the applicable internationally recognized standard. It is the users responsibility to ensure that the most current revision of the standard (or its national equivalent) is used.

Table A4-1 Ionizing Radiation

Ionizing Radiation Type	*Emission Limit microsievert/hr (millirem/hr)*	*Test Method*
X or Gamma	Operator 2 µSv/hr (0.2 mrem/hr)	Direct doserate measurement with an Ion Chamber (or equivalent) calibrated to ± 10% of true doserate at the surface of the equipment (or at the closest approach) in all areas where the operator may have access with the ionizing radiation source active.
X or Gamma	Maintenance and Service 10 µSv/hr (1 mrem/hr)	Direct doserate measurement with an Ion Chamber (or equivalent) calibrated to ± 10% of true doserate during simulated maintenance and service procedures. Measurements should be made at the surface emitting the ionizing radiation or the closest approach to the emitting surface with the ionizing radiation source active. NOTE: For these measurements, panels and/or shields should be removed only if removal is required for maintenance or service activities.

A4-2 Basic Radiation Control Methods

Time — If the radiation field exists and it must be entered, then minimize the time spent in the field to minimize the exposure to the individual. This gives a linear dose reduction.

Distance — If the radiation field is present, stay as far away form the source as possible to perform the required tasks. Dose is reduced by the square of the distance from the source.

Shielding — If the radiation field is intense and the source is small, shielding the source is generally the most practical.

Quantity — If there exists an opportunity to minimize the amount of radiation or radioactive material that is required for the task, then the exposure can be minimized also.

APPENDIX 5
NON-IONIZING RADIATION (OTHER THAN LASER) AND FIELDS TEST VALIDATION — Design and Test Method Supplement Intended for Internal and Third Party Evaluation Use, But Not for Field Survey of Installed Equipment

NOTE: The material in this appendix is an official part of SEMI S2 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A5-1 Introduction

A5-1.1 This appendix provides specific technical information relating to Section 25. In general, it provides information on hazard evaluation methods and test validation criteria.

A5-1.2 This appendix is not intended to limit hazard evaluation methods or control strategies (e.g., design principles) employed by manufacturers. Alternative methods are acceptable if they provide an equivalent level of hazard control.

A5-1.3 Test validation criteria are generally referenced from the applicable internationally recognized standards. It is the user's responsibility to ensure that the most current revision of the standard is used.

A5-2 Non-Ionizing Radiation Surveys should be conducted at the maximum operational power level and, when applicable, at the most limiting frequency.

A5-3 Measurements should be taken at the exterior surfaces of the equipment and at surfaces that maintenance and repair personnel could encounter, whenever practical (electric field measurements with paddle-shaped sensors may not be possible in some places due to the size and shape of the sensor). Measurements for the purpose of evaluating emissions accessible to operators should be taken at the operators console and material loading station.

A5-4 Measurements to assess electromagnetic emissions from equipment for safety purposes should be taken in an area that is reasonably free of energy of the wavelengths/frequencies of interest, especially if the strength of the energy fluctuates in a manner that is unpredictable. Instruments used for safety-related measurements should be calibrated at a facility capable of calibrating such instruments using standards traceable to the National Institute of Standards and Technology in the USA or an equivalent standards service elsewhere, per the guidance of the instrument manufacturer. This should be determined by conducting surveys in the test area before the equipment is set up for the measurements. Measurements taken for safety purposes can also be combined with measurements taken to address electromagnetic interference concerns. The specific measurement locations may vary between electromagnetic interference and safety-related measurements.

NOTE A5-1: The values in the table below are shown as 20% of the limit stated in the applicable standard (referenced).

Table A5-1 Non-Ionizing Radiation

Energy Category	*Physical Quantity Measured (units)*	*Operator-Accessible Limit*	*Maintenance- and Service-Accessible Limit*	*Pacemaker Labeling Level*	*Testing Methods*
Static[4] 0 Hz. (e.g., static magnets in etch/implant equipment)	Magnetic Field Strength (A/m or Gauss) (See NOTES 1 and 2.)	8 mT (80 G)	40 mT (400 G)	0.5 mT (5 G)	Use a Hall effect probe at each location (use three axis probe or make three mutually orthogonal measurements at each location). Measure field at exterior surfaces of equipment (2 to 3 cm from the surface). Locate 5 gauss (G) line to post pacemaker warnings and 30 G to identify where flying tools, etc. and dislocations of magnetizable prostheses could become a hazard.

Energy Category	*Physical Quantity Measured (units)*	*Operator-Accessible Limit*	*Maintenance- and Service-Accessible Limit*	*Pacemaker Labeling Level*	*Testing Methods*
Sub Radio-frequency[1] 1 Hz to 3 kHz (e.g., electromagnets in etch equipment) *See exception below for 50 and 60 Hz power frequencies.	Electric Field Strength (V/m) (See NOTE 1.)	1–100 Hz 5 kV/m* 100 Hz to 3 kHz 500,000/f (Hz) in V/m	1–100 Hz 5 kV/m* 100 Hz to 3 kHz 500,000/f (Hz) in V/m	1 kV/m	Use a displacement sensor. Determine the maximum field strength and orientation at the surface of the equipment (2–3 cm). Remove field perturbations by using a long non-conductive handle extension or remote fiber optic readout. Locate 1 kV/m line to post pacemaker warnings.
Sub Radio-frequency[1] 1 Hz to 3 kHz (e.g., electromagnets in etch equipment) *See exception below for 50 and 60 Hz power frequencies.	Magnetic Field Strength (A/m or G) (See NOTES 1 and 2.)	1–300 Hz 12/f (Hz) in mT 300 Hz to 3 kHz 0.04 mT (400 mG)*	1–300 Hz 12/f (Hz) in mT 300 Hz to 3 kHz 0.04 mT (400 mG)*	0.1 mT (1 G)	Use a loop sensor at each location (use three axis probe or make three mutually orthogonal measurements at each location). The sensor should be almost contacting the equipment surface (2 cm from surface). Identify 1 G line to post pacemaker warnings.
Power Frequency (50 or 60 Hz) [1,5] (e.g., electromagnets in etch equipment)	Electric Field Strength (V/m) (See NOTE 1.)	1 kV/m	2 kV/m	1 kV/m	See Sub radiofrequency Electric Field Testing Method, but probe is positioned as needed to determine distance to 1 kV/m.
Power Frequency (50 or 60 Hz) [1,5] (e.g., electromagnets in etch equipment)	Magnetic Field Strength (A/m or G) (See NOTES 1 and 2.)	0.02 mT (200 mG)	0.1 mT (1 G)	0.1 mT (1 G)	See Sub radiofrequency Magnetic Field Testing Method, but probe is positioned as needed to determine distance to 1 G pacemaker criterion.
Radio-frequency Field [2] 3 kHz to 100 kHz (e.g., RF used to generate plasma)	Induced current and contact current (mA)	Frequency-dependent: 180f (kHz) in mA through both feet 90f through each foot 90f for contact. where f is in MHz	Frequency-dependent: 400f (kHz) in mA through both feet, 200f through each foot 200f for contact. where f is in MHz	NA	Contact instrument vendor for suitable instrument based on frequency and emission characteristics. Measurement of induced and contact currents for freq. < 100 MHz should be made when approaching 20% of the applicable electric field emission limit.

Energy Category	*Physical Quantity Measured (units)*	*Operator-Accessible Limit*	*Maintenance- and Service-Accessible Limit*	*Pacemaker Labeling Level*	*Testing Methods*
Radio-frequency Field [2] 100 kHz to 100 MHz (e.g., RF used to generate plasma)	Induced current and contact current (mA)	18 mA through both feet 9 mA through each foot 9 mA contact	40 mA through both feet 20 mA through each foot 20 mA contact	NA	Contact instrument vendor for suitable instrument based on frequency and emission characteristics. Measurement of induced and contact currents for freq. < 100 MHz should be made when approaching 20% of the applicable electric field emission limit.
Radio-frequency Field [2] 3 kHz to 300 MHz (e.g., RF used to generate plasma)	Electric Field Strength (V/m) (See NOTE 1.)	Frequency dependent (see ANSI/IEEE C95.1). 20% of Uncontrolled limit in Table 2 of C95.1	Frequency dependent (see ANSI/IEEE C95.1). 20% of Controlled limit in Table 1 of C95.1	NA	Use a diode rectifier or displacement sensor at each location (use three axis probe or make three mutually orthogonal measurements at each location). Measurements should be made at 20 cm from the surface.
Radio-frequency Field [2] 3 kHz to 300 MHz (e.g., RF used to generate plasma)	Magnetic Field Strength (A/m) (See NOTES 1 and 2.)	Frequency dependent (see ANSI/IEEE C95.1). 20% of Uncontrolled limit in Table 2 of C95.1	Frequency dependent (see ANSI/IEEE C95.1). 20% of Controlled limit in Table 1 of C95.1	NA	Use a coil sensor at each location (use three axis probe or make three mutually orthogonal measurements at each location) Measurements should be made at 20 cm of the surface.
Radio-frequency Fields [2] 300 MHz to 300 GHz (e.g., RF used to generate plasma)	Power Density (mW/cm^2) (See NOTE 1.)	Frequency dependent (see ANSI/IEEE C95.1). 20% of Uncontrolled limit in Table 2 of C95.1	Frequency dependent (see ANSI/IEEE C95.1). 20% of Controlled limit in Table 1 of C95.1	NA	Use a diode rectifier or thermocouple at each location (use three axis probe or make three mutually orthogonal measurements at each location). Measurements should be made at 20 cm of the surface.

NOTE 1: It is assumed that electric and magnetic fields exist separately at frequencies below 300 MHz. It is assumed that electric and magnetic fields exist as a combined entity (electromagnetic radiation) at higher frequencies. Two evaluations are needed at frequencies <300 MHz and only one (usually made by measuring the electric field) at higher frequencies.

NOTE 2: 1 gauss (G) ≈ 79.55 amperes per meter (A/m). 1 tesla (T) = 10,000 G, 1 millitesla (mT) = 10 G.

Table A5-2 Optical Energy

Optical Energy	*Physical Quantity Measured (units)*	*Access Limit*	*Testing Methods*
Infrared Energy[1] 700 nm to 1 mm (e.g., heating lamps)	Irradiance W/m^2 (See NOTES 1, 2, and 3.) Radiance W/m^2 - sr	Wavelength dependent 20% of the applicable exposure limits. (See Reference 1.)	Thermocouple, thermopile, pyroelectric, photoelectric Direct measurements locating the maximum irradiance and orientation of the energy at the closest approach to the view port(s) or accessible leakage point(s).

Optical Energy	*Physical Quantity Measured (units)*	*Access Limit*	*Testing Methods*
Visible Light[1] 400 nm to 700 nm (e.g., heating lamps)	Irradiance $\mu W/cm^2$ (See NOTES 1, 2, and 3.) Radiance W/m^2 - sr	Wavelength dependent 20% of the applicable exposure limits. (See Reference 1.)	Thermocouple, thermopile, pyroelectric, photoelectric Direct measurement locating the maximum irradiance and orientation of the light energy at the closest approach to view port(s) or accessible leakage point(s).
Ultraviolet Energy[1] 315 nm to 400 nm (e.g., plasma, stepper)	Irradiance mW/cm^2 (See NOTES 1 and 2.)	0.2 mW/cm^2	Photoelectric detectors with filters and or controlled phosphors Direct measurements locating the maximum irradiance and orientation of the energy at the closest approach to the view port(s) or accessible leakage point(s).
Ultraviolet Light[1] 180 nm to 315 nm (e.g., plasma, stepper)	Effective Irradiance $\mu W/cm^2$ (See NOTE 4.)	0.02 $\mu W/ cm^2$	Photoelectric detectors with filters and/or controlled phosphors (See NOTE 5.) Direct measurements locating the maximum irradiance and orientation of the energy at the closest approach to the view port(s) or accessible leakage point(s).

NOTE 1: "Irradiance" is essentially the same as "power density."

NOTE 2: Lamp manufacturer data can sometimes be used to estimate and evaluate exposures using a spreadsheet.

NOTE 3: These guidelines cover visible, IR-A, and IR-B, and are frequency dependent. Separate evaluations may be needed for thermal or photochemical retinal hazards and infrared eye hazards.

NOTE 4: "Effective irradiance" is irradiance adjusted to account for the wavelength-dependent biological hazard. Permissible exposure time = 0.003 J/cm2 divided by the effective irradiance.

NOTE 5: Instrumentation is commercially available that accounts for the wavelength dependence of the standard and gives results in effective irradiance.

CONTENTS

RELATED INFORMATION 1
EQUIPMENT/PRODUCT SAFETY PROGRAM

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R1-1 Preface

R1-1.1 Compliance with design-based safety standards does not necessarily ensure adequate safety in complex or state-of-the-art systems. It is often necessary to perform hazard analyses to identify hazards that are specific to the system, and develop hazard control measures that adequately control the associated risk beyond those that are covered in existing design-based standards. This document provides guidelines for developing a deliberate, planned equipment/product safety (EPS) program integrating the compliance assessment activities with hazard analyses and other activities needed to provide a safe system throughout the life of equipment or products.

R1-1.2 An effective EPS program reduces the cost, schedule slips, and liability associated with the late identification and correction of hazards. To be most effective, an EPS program should be begun by the manufacturer early during the design phase. Starting early allows safety to be designed into the system and its subsystems, equipment, facilities, processes, procedures, and their interfaces and operations. These guidelines are designed to assist the manufacturer in planning and implementation of an effective EPS program.

R1-1.3 The lowest costs for implementing safety can be achieved when hazards are identified and resolved before hardware is built and firmware or software is coded. This guide is intended to provide the basis for a methodology for implementing a safety program for early and continued hazard identification and the elimination or reduction of associated risks.

R1-1.4 EPS program success depends directly upon management emphasis and support applied during the system design and development process and throughout the life cycle of the product. This emphasis should include the following management controls:

R1-1.4.1 Agreement from management that the EPS program will be maintained and supported throughout the product or facility life cycle;

R1-1.4.2 Clear and early statements of agreement with EPS objectives and requirements;

R1-1.4.3 Understanding of, and participation in, the risk acceptance process; and

R1-1.4.4 Continuing consideration of risk reduction during the management review process.

R1-2 Purpose

R1-2.1 This guide describes an approach for developing and implementing an EPS program of sufficient comprehensiveness to identify the hazards of a product and to develop design and administrative controls to prevent incidents. The EPS program addresses hazards from many sources to include system design, hazardous materials, advancing technologies, and new techniques. The goal is to eliminate hazards or reduce the associated risk to an acceptable level.

R1-3 Scope

R1-3.1 This guide applies to every activity of the product life cycle (e.g., research, technology development, design, test and evaluation, production, construction, checkout/calibration, operation, maintenance and support, modification and disposal).

R1-4 General Guidelines

R1-4.1 *EPS Program* — The supplier should establish and maintain an EPS program to support efficient and effective achievement of overall EPS objectives. Depending upon the needs of the company, the EPS Program may be a company wide program covering all projects, separate programs for each project, or some combination of the two.

R1-4.1.1 *Management System* — The supplier should establish an EPS management system to implement provisions of this guide commensurate with the needs of the program. The program manager should be responsible for the establishment, control, incorporation, direction and implementation of the EPS program policies and should assure that risk is identified and eliminated or controlled. The supplier should establish internal reporting systems and procedures for investigation and disposition of product related incidents and safety incidents, including potentially hazardous conditions not yet involved in an incident.

R1-4.2 *EPS Design Guidelines*

R1-4.2.1 EPS design requirements should be specified after review of pertinent standards, specifications, regulations, design handbooks, safety design checklists, and other sources of design guidance for applicability to the design of the system. The supplier should establish EPS design criteria derived from applicable data including the preliminary hazard analyses. These criteria should be the basis for developing system specification EPS requirements. The supplier should continue to expand the criteria and requirements for inclusion in development specification during the subsequent program phases.

R1-5 Detailed Guidelines

R1-5.1 The purpose of the EPS program is to ensure that the equipment or product is designed and documented in a manner that reduces the safety risk associated with that equipment or product to a level that is acceptable to the customer. This consideration applies to all life cycle phases of the equipment or product. The following sections include detailed elements of a formal EPS program. Management should select or tailor the elements appropriate to their needs.

R1-5.2 *EPS Program Plan (EPSPP*) — The purpose of a EPS Program Plan (EPSPP) is to describe the tasks and activities of EPS management and engineering required to identify, evaluate, and eliminate/control hazards, or reduce the associated risk to an acceptable level throughout the system life cycle. The plan provides a basis of understanding of how to organize and execute an effective EPS program.

R1-5.2.1 *EPS Program Scope and Objectives* — Each EPSPP should describe, as a minimum, the following four elements of an effective EPS program:

- a planned approach for task accomplishment,
- qualified people to accomplish tasks,
- authority to implement tasks through all levels of management, and
- appropriate commitment of resources (both staffing and funding) to assure tasks are completed.

The scope and objectives should:

- Describe the scope of the overall program and the related EPS program.
- Identify the tasks and activities of EPS management and engineering functions. Describe the interrelationships between EPS and other functional elements of the program. Identify the other program requirements and tasks applicable to EPS.
- Account for major required EPS tasks and responsibilities.

R1-5.2.2 *EPS Function* — The EPSPP should describe:

R1-5.2.2.1 The EPS function within the organization of the total program, including organizational and functional relationships, and lines of communication. Other functional elements that are responsible for tasks that impact the EPS program should be included. This description should include the integration/management of associate suppliers, subcontractors and engineering firms. Review and approval authority of applicable tasks by EPS should be described.

R1-5.2.2.2 The responsibility and authority of EPS personnel, other supplier organizational elements involved in the EPS effort, subcontractors, and EPS groups. Identify the organizational unit responsible for executing each task and the authority in regard to resolution of identified hazards.

R1-5.2.2.2.1 One highly effective organizational approach to hazard resolution authority is through the use of a EPS Working Group (EPSWG). The activities of the EPSWG could include:

- Identifying safety deficiencies of the program and providing recommendations for corrective actions or prevention of reoccurrence.
- Reviewing and evaluating the hazard analyses to develop agreement that the hazards have been properly identified and controlled.
- Provide recommendations to the proper level of management concerning the need for additional hazard controls and the acceptability of residual risks.
- The staffing of the EPS function.
- The procedures by which the supplier will integrate and coordinate the EPS efforts.
- The process through which supplier management decisions will be made.
- Details of how resolution and action relative to EPS will be effected at the program management level possessing resolution and acceptance authority.

R1-5.2.3 *EPS Program Milestones* — The EPSPP should include:

- Identification of the major EPS program milestones. These should be related to major program milestones, program element responsibility, and required inputs and outputs.
- A program schedule of EPS tasks, including start and completion dates, reports, and reviews.
- Identification of subsystem, component, software safety activities as well as integrated system level activities (i.e., design analyses, tests, and demonstrations) applicable to the EPS program but specified in other engineering studies and development efforts to preclude duplication.

R1-5.2.4 *General EPS Guidelines and Criteria* — The EPSPP should:

- Describe general engineering requirements and design criteria for safety.
- Describe the risk assessment procedures (see SEMI S10). The hazard severity categories, hazard likelihood categories, and the EPS precedence that should be followed to satisfy the safety requirements of the program.
- Describe closed-loop procedures for taking action to resolve identified unacceptable risks including those involving non-developmental items.

R1-5.2.5 *Hazard Analysis* — The EPSPP should describe:

- The analysis techniques and formats to be used to identify hazards, their causes and effects, hazard elimination, or risk reduction requirements and how those requirements are met.
- Recommended techniques for identification of hazards and hazard scenarios include Preliminary Hazard Lists, Preliminary Hazard Analysis, HAZOPs, FMEA, FTA, "what if?" and process control analyses. Other types of hazard analysis techniques are discussed in a variety of sources, such as EN 1050, Annex B. No single method is the best for all types of systems, subsystems, subsystem interaction or facilities. A combination of techniques may be most appropriate.
- The integration of subcontractor or supplier hazard analyses and safety data with overall system hazard analyses.
- Efforts to identify and control hazards associated with materials used during the system's life cycle.

R1-5.2.6 *System Safety Data* — The EPSPP should describe the approach for collecting and processing pertinent historical hazard, incident, and safety lessons learned, data.

R1-5.2.7 *Safety Verification* — The EPSPP should describe:

- The verification (test, analysis, inspection, etc.) methods to be used for making sure that safety is adequately demonstrated. Identify any requirements for safety certification, safety devices or other special safety verification or documentation requirements.
- Procedures for transmitting safety-related verification information to the customer or others for review and analysis.

R1-5.2.8 *Audit Program* — The EPSPP should describe the techniques and procedures to be employed to make sure the objectives and requirements of the EPS program are being accomplished.

R1-5.2.9 *Incident Reporting* — The supplier should describe in the EPSPP the incident alerting/notification, investigation and reporting process including notification of the customer.

R1-5.2.10 *EPS Interfaces* — The EPSPP should identify:

- The interface between EPS and all other applicable safety disciplines.
- The interface between EPS, systems engineering, and all other support disciplines such as: maintainability, quality control, reliability, software development, human factors engineering, and others as appropriate.
- The interface between EPS and product design, integration and test disciplines.

R1-5.3 *Hazard Analysis Documentation*

The hazard analysis process is used to identify hazards and their controls. This information should be documented in a closed loop tracking system to track the implementation of the controls and may also be required for presentation to management, the customer and others. The safety documentation could include a system description, the identification of hazards and their residual risks, as well as special procedures and precautions necessary for safety.

The documentation should include the following:

R1-5.3.1 *System Description* — This should consist of summary descriptions of the physical and functional characteristics of the system and its components. Reference to more detailed system and component descriptions, including specifications and detailed review documentation should be supplied when such documentation is available. The capabilities, limitations and interdependence of these components should be expressed in terms relevant to safety. The system and components should be addressed in relation to its function and its operational environment. System block diagrams or functional flow diagrams may be used to clarify system descriptions. Software and its role(s) should be included in this description.

R1-5.3.2 *Data* — This should consist of summaries of data used to determine the safety aspects of design features.

R1-5.3.3 *Hazard Analysis Results* — This should consist of a summary or a total listing of the results of the hazard analysis. Contents and formats may vary according to the individual requirements of the program. The following data elements may be used for documenting the results of hazard analyses:

R1-5.3.3.1 *System/Subsystem/Unit* — The particular part of the system that is the concern in this part of the analysis. This is generally a description of the location of the component being considered.

R1-5.3.3.2 *Component/Phase* — The particular phase/component with which the analysis is concerned. This could be a system, subsystem, component, software, operating/maintenance procedure or environmental condition.

R1-5.3.3.3 *Hazard Scenario Description* — A description of the potential/actual hazards inherent in the item being analyzed, or resulting from normal actions or equipment failure, or handling of hazardous materials.

R1-5.3.3.4 *Effect of Hazard* — The detrimental effects that could be inflicted on the subsystem, system, other equipment, facilities or personnel, resulting from this hazard. Possible upstream and downstream effects can also be described.

R1-5.3.3.5 *Recommended Action(s*) — The recommended action(s) that are necessary and sufficient to eliminate or control the hazard. Sufficient technical detail is required in order to permit the design engineers and the customer to adequately develop and assess design criteria resulting from the analysis. Include alternative designs and life cycle cost impact where appropriate.

R1-5.3.3.6 *Risk Assessment* — A risk assessment for each hazard (classification of severity and likelihood). This may include an assessment of the risk prior to taking any action(s) to eliminate or control the hazard and a separate assessment of the risk following implementation of the Recommended Action(s). (See SEMI S10.)

R1-5.3.3.7 *Remarks* — Any information relating to the hazard not covered in other blocks; for example, applicable documents, previous failure data on similar systems, or administrative directions.

R1-5.3.3.8 *Status* — The status of actions to implement the recommended control, or other, hazard controls. The status should include not only an indication of “open” or “closed,” but also reference to the drawing(s), specification(s), procedure(s), etc., that support closure of the particular hazard. The person(s) or organization(s) responsible for implementation of the control should also be recorded.

RELATED INFORMATION 3
HAZARD LABELS

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R3-1 INTRODUCTION: The system shown below is a single label design that combines requirements from ANSI Z535, used in the USA, and ISO 3864 and IEC 1310-1, used elsewhere in the world. *The suitability of this design for any specific jurisdiction must be determined by the equipment manufacturer.*

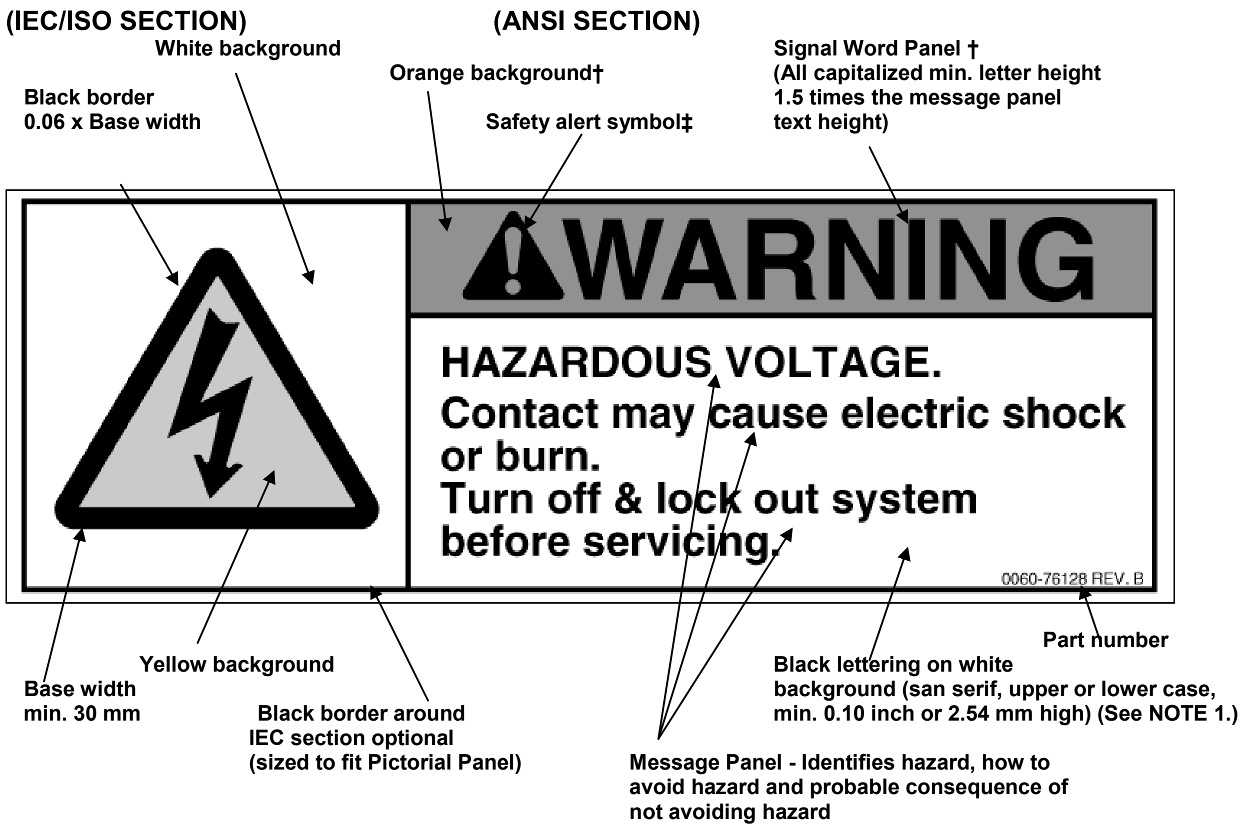

Figure R3-1
Example of a Combination ANSI/IEC Hazard Label Format

†SIGNAL WORD (san serif font)	‡SAFETY ALERT SYMBOL
DANGER - White Lettering / Red Background (Safety Red: per ANSI Z535.4 - 15 parts Warm Red, 1 part Rubine Red, 1/4 part Black)	**White Triangle / Red Exclamation Point**
WARNING - Black Lettering / Orange Background (Safety Orange: per ANSI Z535.4 - 13 parts Yellow, 3 parts Warm Red, 1/4 part Black)	**Black Triangle / Orange Exclamation Point**
CAUTION - Black Lettering / Yellow Background (Safety Yellow: per ANSI Z535.4 - Pantone 108C)	**Black Triangle / Yellow Exclamation Point**

NOTE 1: Message Panel Letter height (min. 0.10 inch or 2.54 mm high) for FAVORABLE reading conditions may, in some instances be reduced further for application to small products or products having limited surface area on which to apply the message. However, it should not be less than 0.05 in. (1.27 mm) for lower case letter height.

NOTE 2: Upon request from end-user(s), translation(s) to other languages may also be deemed appropriate.

Suggested IEC/ISO Symbols for Various Hazards

RELATED INFORMATION 4
EMO REACH CONSIDERATIONS

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R4-1 INTRODUCTION: Although SEMI S8 limits EMO button heights to 164 cm, it does not explicitly address the situation where a person must reach over, say, a work surface to reach the EMO button. The calculations shown below show one method of addressing this situation. *Other issues, besides those shown below, must also be taken into account when locating EMO buttons; see SEMI S2 and SEMI S8.*

The maximum height allowed for an EMO is determined by the following equation: (design for 5% female)

Max height = Shoulder Height + B

Max height should never exceed:

164 cm for standing station

100 cm for sitting station

Where:

A = Length of horizontal barrier to EMO

B = Distance above shoulder

C = Upper limb length for 5% female (always 51.5 cm)

And for 5% female:

Standing shoulder height = 114.0 cm

Sitting shoulder height = 46.5 cm

Ex. Standing:

$B^2 = C^2 - A^2$

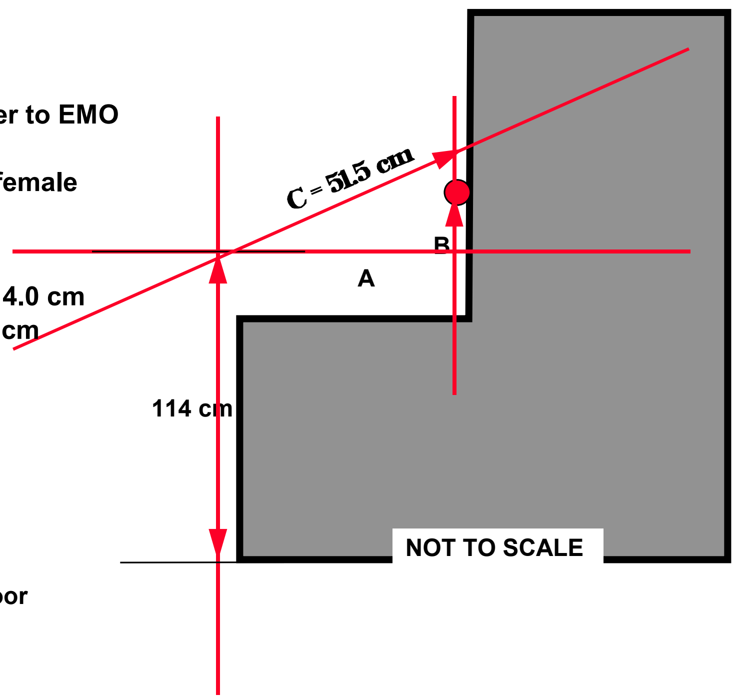
If A = 30 cm then

$B^2 = 51.5^2 - 30^2$

B = 41.8 cm

The button could be located at a maximum of:

114 + 41.8 = 155.8 cm from the floor



RELATED INFORMATION 5
SEISMIC PROTECTION

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R5-1 Seismic Protection Checklist

Supporting Review Criteria for Seismic Protection of Related Components

If the answer to Questions A.1 or A.2 is "No," or the answer to any other of these questions in the checklist is "Yes," then a detailed analysis may need to be performed by a structural or mechanical engineer.

A. Equipment Anchorage

1. Have lateral force and overturning calculations been performed (see example)?
   ❑ Yes ❑ No Comments:

2. Are all modules fastened at a minimum of four points and can the fasteners support the forces identified in question 1 above?
   ❑ Yes ❑ No Comments:

3. Is it possible that there could be excessive seismic anchor movements that could result in relative displacements between points of support or attachment of the components (e.g., between vessels, pipe supports, main headers, etc.)?
   ❑ Yes ❑ No Comments:

4. Is there inadequate horizontal support?
   ❑ Yes ❑ No Comments:

5. Is there inadequate vertical supports and/or insufficient lateral restraints?
   ❑ Yes ❑ No Comments:

6. Are support fasteners inappropriately secured?
   ❑ Yes ❑ No Comments:

7. Is there inadequate anchorage of attached equipment?
   ❑ Yes ❑ No Comments:

NOTE R5-1: One way of judging whether supports, fasteners, or anchorages are "inadequate" or inappropriately secured" is to determine whether their stress levels under seismic loading stay below the allowable stress levels set by building code. Such allowable stress levels are typically a fraction < 1 of the yield strength.

B. Equipment Assembly, Installation and Operation

1. Are the materials of construction of the components susceptible to seismic damage?
   ❑ Yes ❑ No Comments:

2. Are there significant cyclic operational loading conditions that may substantially reduce system fatigue life?
   ❑ Yes ❑ No Comments:

3. Are there any threaded connections, flange joints, or special fittings?
   ❑ Yes ❑ No Comments:

4. If answer to Question 4 is "Yes," are these connections, joints, or special fittings in high stress locations?
   ❑ Yes ❑ No Comments:

5. Are there short or rigid spans that cannot accommodate the relative displacement of the supports (e.g., piping spanning between two structural systems)? Is hazardous gas piping provided with a "pigtail" (i.e., spiral) or bent 3 times (z, y, and z direction) to absorb 3-dimensional displacements?
   ❑ Yes ❑ No Comments:

6. Are there large, unsupported masses (e.g., valves) attached to components?
   ❑ Yes ❑ No Comments:

7. Are there any welded attachments to thin wall components?
   ❑ Yes ❑ No Comments:

8. Could any sensitive equipment (e.g., control valves) be affected ?
   ❑ Yes ❑ No Comments:

C. Seismic Interactions

1. Are there any points where seismically induced interaction with other elements, structures, systems, or components could damage the components (e.g., impact, falling objects, etc.)?
   ❑ Yes ❑ No Comments:

2. Could there be displacements from inertial effects?
   ❑ Yes ❑ No Comments:

R5-2 Derivation of Section 19, Seismic Load Guidelines

R5-2.1 The horizontal loadings of 94% and 63%, found in Sections 19.2.1 and 19.2.2, were based on following assumptions for factors in formula 32-2 in Section 1632.2 of the 1997 Uniform Building Code (UBC):

- a_p = 1.0 (i.e., treat the equipment as a rigid structure)
- C_a = 0.44(1.2) (i.e., seismic zone 4, soil profile type S_D, and site 5 km from a seismic source type A)
- I_p = 1.0 and 1.5 for non-HPM and HPM equipment, respectively
- h_x/h_r = 0.5 (i.e., equipment attached at point halfway between grade elevation and roof elevation)
- R_p = 1.5 (i.e., shallow anchor bolts).

Starting with equation 32-2, letting $I_p = 1.5$, and substituting the above values:

- $F_{p\ (ultimate)}$ $= [(1.0 * 0.44(1.2) * 1.5)/ 1.5]\ [1 + 3(0.5)]\ W_p$
  $= [0.44(1.2)]\ [1 + 1.5]\ W_p$
  $= [0.528]\ [2.5]\ W_p$
  $= [1.32]\ W_p$

NOTE R5-2: This number is now adjusted from ultimate strength loading to yield strength loading by dividing by 1.4:

- $F_{p\ (yield)}$ $= F_{p\ (ultimate)} / 1.4$
  $= [1.32] / 1.4\ W_p$
  $= [0.94]\ W_p$

And for $I_p = 1.0$,

- $F_{p\ (yield)}$ $= [.94]\ [1.0/1.5]\ W_p$
  $= [.63]\ W_p$

Notes re selection of a_p value of 1.0:

- Table 16-O of 1997 UBC, line 3.C., was interpreted to read: "Any *flexible* equipment..."
- in structural terms, the structure of typical semiconductor equipment is considered "rigid."

R5-2.2 *Assumptions Used for Above Derivation*

R5-2.2.1 Because typical semiconductor equipment is considered rigid, a frequency response analysis was not considered to be necessary.

R5-2.2.2 Seismic waves typically have vertical as well as horizontal components associated with them; however, these components typically arrive out of phase (i.e., they do not reach maximum values simultaneously). The vertical component serves to, in effect, reduce the amount of equipment mass that is available to resist overturning or toppling. The task force chose to take this into account by limiting the calculated weight available to resist overturning to 85% of the weight of the equipment. An alternate method, not chosen by the task force, could have been to simultaneously apply a vertical (Z) force.

R5-3 Source for Examples of Seismic Anchorage Details

R5-3.1 Detailed illustrations of examples of seismic anchorage details were developed by Working Group #9 of the Japan 300 mm ("J300") effort, and were printed in their Report No. 9 in the *2nd Lecture, ICs Factory Design for 300 mm Wafer Line Standardizing Study, December, 1996.*

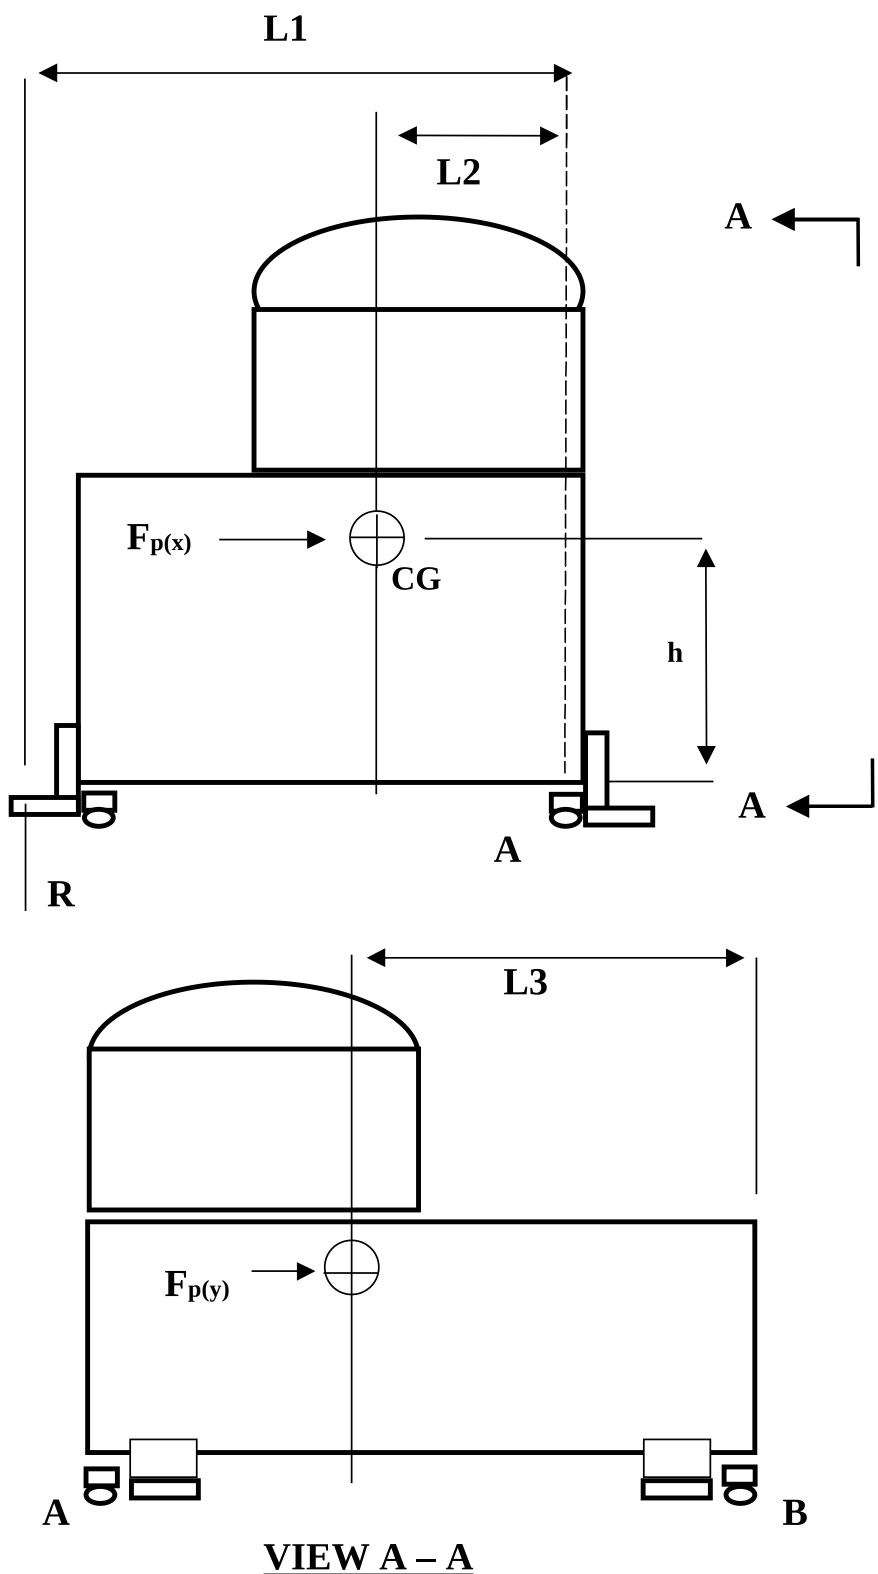


Figure R5-1
Design Example

DESIGN EXAMPLE (continued; refer to Figure R5-1 for illustration of example)

Disclaimer: the calculations below are not a complete seismic analysis. A complete analysis might also include such things as: stress distribution through a multiple-fastener connection; prying action; bearing stress; simultaneous combined stresses on the fasteners; and a review of weld geometry. A complete seismic analysis should be done by a qualified engineer.

R5-4 Calculation of Lateral Force

R5-4.1 Lateral force on each leg is equal to F_P/# of legs = $F_P/4$

R5-4.2 The lateral force acts as shear on the floor anchor fasteners and shear or tensile loading on the equipment anchor fasteners depending upon orientation. The actual reactions of the fasteners should be calculated by a qualified engineer.

R5-5 Calculation of Overturning Force

R5-5.1 Sum the moments of the reactions on the system about line through the legs A and B:

$$(CW =+)\ \sum M_{AB} = 0 = F_P(h) - 0.85W_P(L_2) - 2R(L_1) = 0$$

$$R = \frac{F_P(h) - 0.85W_P(L_2)}{2L_1}$$

$$F_P = 0.94W_P$$

$$R = \frac{W_P(0.94h - 0.85L_2)}{2L_1}$$

If 0.94h ≥ $0.85L_2$, then there is a tension reaction, R, at the two anchors, to resist overturning of system.

Example:
L1 = 50 inch
L2 = 20 inch
h= 36
W = 5000 lbs

Lateral force = Fp/4 = 0.94(5000)/4 = 1175

Overturning force = $R = \frac{W_P(0.94h - 0.85L_2)}{2L_1}$

$$= \frac{5000\,(0.94(36) - 0.85(20))}{2(50)}$$

R = 842 lbs

RELATED INFORMATION 6
CONTINUOUS HAZARDOUS GAS DETECTION

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R6-1 *Scope* — This related information provides a list of gases for which continuous monitoring is recommended, and another list of gases for which continuous monitoring may be recommended depending on variables listed below. The list is not intended to be exhaustive (gases that do not appear on the list may need to be continuously monitored).

R6-2 *Intent* — The purpose of this Related Information is to provide equipment manufacturers with an indication as to what gases are currently continuously monitored by device manufacturers, as guidance for when it may be appropriate to provide an interface (see also Section 23).

R6-3 The following variables should be taken into consideration when determining the necessity for continuous monitoring:

- Chemical toxicity,
- Warning property/OEL ratio,
- Delivery pressure,
- LEL,
- Flow rate of potential leak,
- Engineering controls in place, and
- Concentration.

Monitoring Recommended	*Monitoring May Be Recommended*
	ammonia
arsine	
boron trifluoride	
	bromine
	carbon dioxide
carbon monoxide	
	carbon tetrabromide
chlorine	
diborane	
dichlorosilane

RELATED INFORMATION 7
DOCUMENTATION OF IONIZING RADIATION (SECTION 24 AND APPENDIX 4) INCLUDING RATIONALE FOR CHANGES

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R7-1 International Background Information

R7-1.1 *The International Atomic Energy Agency (IAEA)*

Mailing address:

P.O. Box 100
Wagramerstrasse 5
A-1400, Vienna, Austria

Telephone: (+43-1) 2060-0; Facsimile: (+43-1) 20607:
E-mail: Official.Mail@iaea.org

R7-1.2 Basic approaches to radiation protection are consistent all over the world. The International Commission on Radiation Protection (ICRP) recommends that any exposure above the natural background radiation should be kept as low as reasonably achievable, but below the individual dose limits. The total individual dose limit for radiation workers over 5 years is 100 mSv, and for members of the general public, is 1 mSv per year. These dose limits have been established based on a prudent approach by assuming that there is no threshold dose below which there would be no effect. This hypothesis proposes that any additional dose will cause a proportional increase in the chance of a health effect. This relationship has not yet been established in the low dose range where the dose limits have been set.

R7-1.3 The ICRP and the IAEA recommend the individual dose must be kept as low as reasonably achievable and consideration must be given to the presence of other sources that may cause simultaneous radiation exposure to the same group of the public. Also, allowance for future sources or practices must be kept in mind so that the total dose received by an individual member of the public does not exceed the dose limit.

R7-2 How Does This Apply to the Semiconductor Industry?

R7-2.1 A person who can potentially be exposed to ionizing radiation during the normal course of business in excess of the annual limit for the general public should be considered a radiation worker. A radiation worker is trained to recognize and protect him or herself from the hazards of ionizing radiation. They may require exposure monitoring to determine compliance with local radiation regulations. Radiation workers are covered by a radiation safety program. A radiation safety program is an administrative control. Engineering controls minimize the need for spending resources in a large scale radiation program.

R7-2.2 The exposure limit for the radiation worker is 20 millisievert (2000 millirem) per year. Based on a 40 hour/week, 50 week/working year basis, the allowable ionizing radiation emissions are 10 microsieverts/hr (1.0 millirem/hr). This exposure rate should be evaluated as an emission rate from any accessible surface of the equipment (the closest approach to the surface that the radiation is penetrating).

R7-2.3 Maintenance technicians for radiation machines should be participants in the radiation safety program as radiation workers. The equipment should be designed to allow maintenance technicians access to areas that do not exceed 10 microsieverts/hr.

R7-2.4 Service technicians for radiation machines should be participants in their employer's radiation safety program as radiation workers. The equipment should be designed to allow service technicians access to areas that exceed the 10 microsievert per hour level when operating, but not while the radiation is present.

R7-2.5 The person operating radiation producing equipment (Operator) should not be considered a radiation worker. The emission limit for the operator accessible areas is recommended to be 20% of the occupational limit. The maximum allowable ionizing radiation emissions for operator accessible areas is recommended to be 2 microsieverts/hr (0.2 millirem/hr). This exposure rate should be evaluated as an emission rate from any surface foreseeably accessible by an operator of the equipment, and should be measured as an instantaneous rate.

R7-3 Definitions

R7-3.1 *accessible* — a significant part of the whole body, head, or eyes.

R7-3.2 *bremsstrahlung* — is radiation produced by slowing of charged particles. The term means "braking radiation."

NOTE R7-1: During design of shielding, the properties of the radiation should be considered as well as the properties of the shielding materials. Bremsstrahlung production should be minimized. Some shielding materials are considered hazardous materials. These hazardous properties should be considered and identified.

R7-3.3 *radiation machine* — means any device capable of producing ionizing radiation except those devices with radioactive material as the only source of radiation.

R7-3.4 *radiation producing machine* — is a radiation machine that produces ionizing radiation as a by-product of the process it uses, e.g., ion implanter or scanning electron microscope.

R7-3.5 *radiation worker* — "worker" means an individual engaged in radiation related work under a license or certificate of registration issued by the Agency and controlled by a licensee or registrant, but does not include the licensee or registrant.

R7-3.6 *radioactive material* – means any material (solid, liquid, or gas) that emits ionizing radiation spontaneously.

R7-3.7 *X-ray machine* — is a radiation machine that generates X-rays as a primary function of the equipment. This category of radiation machine has a specific limit due to the existence of performance standards against which the equipment is evaluated. The equipment must be below this limit to be sold in some parts of the world.

R7-3.8 *X-rays* — are produced with electricity and therefore can be turned off. X-rays seem to be the most prevalent radiation type in semiconductor manufacturing equipment. They are produced when charged particles are slowed or stopped. This slowing results in "bremsstrahlung." The majority of the equipment does not intentionally produce X-rays. This energy is a by-product of the process.

R7-4 Radioactive Materials

R7-4.1 Gamma radiation is a by-product of atomic transformations (decay) and is a release of energy from the nucleus. This radiation energy must be shielded since there is no off switch.

R7-4.2 Radioactive Materials are controlled by licensing. There are quantities of certain radioactive materials that are exempt from regulation. These sources should be identified.

R7-4.3 External radiation hazards from radioactive materials include gamma rays. These are controlled and evaluated much like the X-rays.

R7-4.4 Internal radiation hazards from radioactive materials include Alpha and Beta particles. Radioactive materials ingested or inhaled can be metabolized or damage surrounding tissue. Allowable levels of airborne radioactivity and radionuclide intakes are specified in regulations. The objective is still to maintain all exposure to ionizing radiation (internal and external) as low as reasonably achievable, but always less than the allowable regulatory limits.

RELATED INFORMATION 8
DOCUMENTATION OF NON-IONIZING RADIATION (SECTION 25 AND APPENDIX 5) INCLUDING RATIONALE FOR CHANGES

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R8-1 The user of this table is responsible for obtaining the current revision of the standards cited for Occupational Exposure Limits (OEL).

R8-2 The emission values in Appendix 5 that are not to be exceeded were chosen based on a review of all known international standards as well as a consideration for best available control technology (i.e., lowest values currently achievable for each radiation type). Where a general public limit existed, 20% of this value was selected. Where there was no public limit, the value selected is generally 20% of the OEL value (instantaneous field strength measurement peak). The latter case would have the occupational and general public levels the same. Where there was an occupational exposure limit specified in a standard, the maintenance emission limit was set at 20% of this level.

R8-3 Most health standards differentiate between “occupational” and “general public” exposure criteria. IEEE C95.1 differentiates between “controlled access” and “uncontrolled access” exposures. According to C95.1 “controlled access” environments are those where “locations where there is exposure that may be incurred by persons who are aware of the potential for exposure as a concomitant of employment, by other cognizant persons, or as the incidental result of transient passage through areas where analysis shows the exposure levels may be above those shown in Table 2 but do not exceed those of Table 1, and where the induced currents may exceed the values in Table 2, Part B, but do not exceed the values of Table 1, Part B.” According to C95.1, “uncontrolled access” environments are “locations where there is the exposure of individuals who have no knowledge or control of their exposure. The exposure may occur in living quarters or workplaces where there are no expectations that the exposure levels may exceed those shown in Table 2 and where induced currents do not exceed those in Table 2, Part B.” Task force members advise that C95.1 “controlled access” and other “occupational exposure” standards should be applied to personnel performing maintenance and service of equipment and that “uncontrolled access” or other “general public” standards should be applied to equipment operators during routine work and to other locations. These IEEE definitions are particularly relevant to broadcast facilities as well as normal industrial environments such as fabs. Task force members recommend that uncontrolled access limits be applied to fetal exposure.

R8-4 As with the rationale in the Ionizing section, the operator is considered a member of the general public or to be in an uncontrolled area. Maintenance or service technicians should be trained to know how to control the hazardous energy and protect themselves from the hazard and its adverse effects.

LASER CERTIFICATION REQUIREMENTS BY REGION OF USE

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

Table R10-1 Regional Laser Standards

	USA	*Europe*	*Japan*	*Pacific Rim*
Classification Standards	21 CFR 1040.10	EN 60825-1	JIS C 6802	IEC 60825-1
Certification Standards	21 CFR 1000-1010	TBD	TBD	TBD

R10-1 USA

Food and Drug Administration (FDA)
Center for Devices and Radiological Health (CDRH)

R10-1.1 Laser products must comply with the performance requirements of Title 21 of the Code of Federal Regulations Part 1040.10 (21 CFR 1040.10). Manufacturers (including modifiers) of laser products must certify to the FDA/CDRH in writing that the product complies with the requirements of 21 CFR SubChapter J.

R10-1.2 The reporting requirements are detailed in 21 CFR 1000–1010. Product report forms and the guidance document are available from the CDRH. These documents should soon be available from the CDRH Web server at:

http://www.fda.gov/cdrh

R10-1.3 The CDRH Office of Compliance can be reached by telephone at (301) 594-4654

R10-1.4 The CFR references may be obtained by searching the website at:

http://www.access.gpo.gov/nara/cfr/cfr-table-search.html

but these documents do not include figures or tables.

R10-1.5. When a laser product is imported, the importing company is considered the laser manufacturer and must certify the laser product.

R10-2 Europe

International Electrotechnical Commission (IEC)

R10-2.1. European governments have adopted IEC 60825-1 as the laser product safety standard. Manufacturers of laser products should comply with Section 2 of the IEC 60825-1 document. An IEC committee is currently working on a checklist for laser product manufacturers to follow to assess compliance with the IEC document. Other IEC 60825 series documents may apply to the product either now or in the future.

R10-2.2. EN 60825-1 is the normative standard, which has been adopted by the European Union and EFTA countries.

R10-2.2.1 The EN 60825-1 should be available through the various European government agencies or government printing offices.

R10-2.3. The laser product manufacturer should review ISO 11553 for requirements that apply to laser equipment that processes materials.

R10-2.4. The IEC document can be obtained from:

International Electrotechnical Commission

R10-3 Japan

R10-3.1. The Japanese Safety Association published an English version of the Japanese laser safety standard based on the IEC 60825 series document. This standard is Japanese Industrial Standard (JIS) C 6802. The Japanese version is still the official standard, but the English version has the warning hazards described with the Japanese symbols in the images.

R10-3.2. As in the IEC document the manufacturing requirements are specified in Section 2. There is a companion document JIS C 6801 that provides the Glossary of terms and their translations into English.

R10-3.3. The JIS documents can be obtained through the Japanese Safety Association.

R10-3.4. Japanese Standards Association

(In English) http://www.hike.te.chiba-u.ac.jp/ikeda/JIS/index.html
(In Japanese) http://www.jsa.or.jp

R10-4 Other (e.g., Pacific Rim)

R10-4.1 The manufacturer is responsible to determine the appropriate standard to use in other countries.

R10-4.2 In the absence of any specific standard for a country, the IEC 60825-1 document should be used as the guide for compliance

R10-4.3 In many countries, prefectures, states, or provinces, local laser safety regulations exist. Much of this regulation is aimed at the user, but may include product performance requirements. The manufacturer has the responsibility to identify these requirements.

R10-4.4 Addresses of many national standards organizations are found at:

http://www.iec.ch/cs1sot-e.htm

RELATED INFORMATION 11
OTHER REQUIREMENTS BY REGION OF USE

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R11-1 *Japan* — Earth Leakage Breaker/Ground Fault Circuit Interrupter/Ground Fault Equipment Protection Circuit Interrupter/ Residual Current Devices

R11-1.1 Japanese regulations may require the use of Ground Fault Circuit Interrupter (GFCI), Ground Fault Equipment Protection Circuit Interrupter (GFEPCI), Residual Current Devices (RCD), or Earth Leakage Breaker (ELB) with the equipment.

EXCEPTION 1: The rating of the equipment is less than 20 amperes and less than 150 volts rms.

EXCEPTION 2: The equipment is supplied from the ungrounded secondary of an AC mains isolation transformer.

R11-1.2 The GFCI, GFEPCI, RCD or ELB, when required to satisfy Japanese requirements, should have trip ratings of not greater than 30 mA and 0.1 second.

EXCEPTION 1: If there is no accessible live circuit during maintenance tasks, trip ratings of up to 300 mA are acceptable.

EXCEPTION 2: If the equipment satisfies Exception 1 and the earth impedance is less than 50 ohms, a GFCI, GFEPCI, RCD or ELB of 500 mA maximum is acceptable.

EXCEPTION 3: If the equipment is connected to a source of supply that is provided with a GFCI, GFEPCI, RCD or ELB, an additional GFCI, GFEPCI, RCD or ELB is not required for the equipment.

R11-2 *USA*

R11-2.1 *Nameplates* — In addition to the nameplate requirement noted in the Electrical section of S2, equipment evaluated as "Industrial Machinery" per NFPA 79 and intended for use in the United States may be required to display additional nameplate information, such as ampere rating of the largest motor or load, short circuit interrupting capacity of the machine overcurrent protective device where furnished as part of the equipment, and the electrical diagram number(s) or the number of the index to the electrical diagrams. Furthermore, where overcurrent protection is provided, the equipment must be marked "overcurrent protection provided at machine supply terminals."

R11-2.1 *Hazard Communication* — Federal government OSHA regulations, found in 29 CFR 1910.1200, establish various requirements for labeling of containers of hazardous chemicals and providing Material Safety Data Sheets.

R11-3 *Europe*

R11-3.1 *Nameplates* — In addition to the nameplate requirement noted in the Electrical section of S2, equipment evaluated as "Industrial Machinery" per IEC 60204-1 (EN 60204-1) and intended for use in Europe may be required to display additional nameplate information, such as: certification mark, where required; current rating of the largest motor or load; short-circuit interrupting capacity of the machine overcurrent protective device, where furnished as part of the equipment; and the electrical diagram number(s) or the number of the index to the electrical drawings.

R11-3.1.1 Where only a single motor controller is used, this information may instead be provided on the machine nameplate where it is plainly visible.

R11-3.1.2 The full-load current shown on the nameplate shall be not less than the combined full-load currents for all motors and other equipment that can be in operation at the same time under normal conditions of use. Where unusual loads or duty cycles require oversized conductors, the required capacity shall be included in the full-load current specified on the nameplate.

R11-3.2 European Union requires compliance to CE marking.

R11-4 *Worldwide* — Hazard Alert Labels

R11-4.1 *USA* — Labels intended for use in the USA should conform to ANSI Z535.4.

R11-4.2 *Other Countries* — Labels intended for use in countries other than the USA should conform to ISO 3864.

RELATED INFORMATION 12
LIGHT TOWER COLOR AND AUDIBLE ALERT CODES

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

R12-1 Colors for Light Towers

R12-1.1 Where used for safety, a light tower should have the following characteristics:

Table R12-1 Light Tower Color Code

Color	*Explanation*	*Examples*
Red	Hazardous, dangerous or abnormal condition requiring immediate attention	Pressure/temperature out of safe limits; Voltage drop; Breakdown Overtravel of a stop position Indication that a protective device has stopped the machine, e.g., overload
Yellow	Abnormal, caution/marginal condition; Change or impending change of critical condition requiring monitoring and/or intervention (e.g., by re-establishing the intended function)	Pressure/temperature exceeding normal limits Tripping of protective device Automatic cycle or motors running; some value (pressure, temperature) is approaching its permissible limit. Ground fault indication. Overload that is permitted for a limited time.
Green	Normal condition; machine ready	Pressure/temperature within normal limits Indication of safe condition or authorization to proceed. Machine ready for operation with all conditions normal or cycle complete and machine ready to be restarted.

R12-2 Audible Alert (Buzzer) Code

R12-2.1 Where used for safety, audible alert (buzzer) for the light tower should have the following characteristics:

Table R12-2 Light Tower Buzzer Code

Color	*Audible Alert (Buzzer)*
Red	Continuous
Yellow	Intermittent
Green	Intermittent/no sound (selectable)

RELATED INFORMATION 13
SURFACE TEMPERATURE DOCUMENTATION

NOTE: This related information is not an official part of SEMI S2 and was derived from practical application by task force members. This related information was approved for publication by vote of the responsible committee on October 21, 1999.

The following is some of the research leading to the values in Table 1 in Section 18 of this guideline.

R13-1 The proposed Hazardous Temperature Limits were derived from UL1950[11] and IEC950[12] by adding ambient temperature (25°C) to the maximum temperature rise allowed for external parts of information technology equipment. Because several SEMI members have questioned whether these limits might subject operators and maintenance personnel to contact with potentially hazardous temperatures, a review has been done of several other sources of suggested temperature limits.

R13-2 The proposed hazardous surface temperatures for handling and touching of metal handles, knobs, etc., for brief periods in normal use is 60°C. Assuming a brief handling time to be 5 seconds or less, this limit is supported in MIL-STD-1472[13], MIL-HDBK-759A[14] and EN563[15] (which are the same or more conservative by 2°C), and is equal to the pain and tissue damage threshold listed in the Human Factors Design Handbook[16]. Thus, this temperature limit seems appropriate for momentary (five seconds or less) contact with uncoated metal handles, knobs, etc., and other material with high thermal conductivity.

R13-3 The proposed hazardous surface temperatures for handling and touching of glass/porcelain handles, knobs, etc., for brief periods in normal use is 70°C. This temperature limit is supported by MIL-STD-1472 and EN563. MIL-HDBK-759 is not applicable because it must be assumed that it applies only to material with high thermal conductivity.

R13-4 The proposed hazardous surface temperatures for handling and touching of plastic/rubber handles, knobs, etc., for brief periods in normal use is 85°C. This temperature limit is similarly supported by MIL-STD-1472 and EN563. MIL-HDBK-759 is not applicable.

R13-5 The proposed hazardous surface temperatures for continuous handling and touching of metal handles, knobs, etc., during normal usage is 55°C. It is suggested, based on observations of semiconductor equipment in use, that a continuous handling time of one minute be used. With this duration, the limit of the MIL-STD and the MIL-HDBK ranges from 49 to 52°C. The EN563 burn threshold limit for contact with metal for one minute is 51°C. The burning heat pain level listed in the Human Factors Design Handbook is 49°C (no time frame given; assume high thermal conductivity material). Thus, the proposed temperature limit appears to be somewhat high for reasonably foreseeable extended handling contact with uncoated metal handles, knobs, etc., and other material with high thermal conductivity. The Section 18 Table 1 limit is 51°C, which might be somewhat painful to more sensitive personnel, but should not result in tissue damage.

R13-6 The proposed hazardous surface temperatures for extended handling and touching of glass/porcelain handles, knobs, etc., during normal usage (again assuming 1 minute) is 65°C. The limit of MIL-STD-1472D is 59°C for "prolonged contact" with glass. The EN563 burn threshold limit at 1 minute is 56°C. Thus, the proposed temperature limit appears to be slightly high for reasonably foreseeable extended handling contact with glass/porcelain surfaces of moderate thermal conductivity. The Section 18 Table 1 limit is 56°C, which is the more conservative of the recommendations. This limit could be raised based upon the results of the risk assessment for actual and foreseeable normal usage.

R13-7 Similarly, the proposed hazardous surface temperatures for extended handling and touching of plastic/rubber handles, knobs, etc., during normal usage (again assuming 1 minute) is 75°C. The limit of MIL-STD-1472D is 69°C for "prolonged contact" with plastic. The EN563 burn threshold limit at 1 minute is 60°C. Thus, the proposed temperature limit again appears to be slightly high for reasonably foreseeable extended handling contact with plastic/rubber surfaces of low thermal conductivity. The Section 18 Table 1 limit is 60°C, which is the more conservative of the recommendations. This limit could be raised based upon the results of the risk assessment for actual and foreseeable normal usage.

R13-8 The proposed hazardous surface temperatures for external surfaces and internal parts which may be

11 UL 1950, Safety of Information Technology Equipment, 1989 (Underwriters Laboratory Standard).

12 IEC 950, Safety of Information Technology Equipment, 1986 (International Electrotechnical Commission Standard).

13 MIL-STD-1472D, Human Engineering Design Criteria for Military Systems, Equipment & Facilities (Military Standard).

14 MIL-HDBK-759A, Handbook for Human Engineering Design Guidelines, 1981 (Military Handbook).

15 EN 563, Safety of Machinery – Temperatures of Touchable Surfaces, 1994 (European Normative Standard).

16 Human Factors Design Handbook, Second Edition, Woodson, Tillman & Tillman, 1992 (Reference).

touched are 70°C for metal, 80°C for glass/porcelain, and 95°C for plastic/rubber. It is assumed that this limit applies to inadvertent touching by the operator/maintenance person, resulting in the person instantly breaking contact with the hot surface. There are no analogs in either the MIL-STD or the MIL-HDBK for these temperature limits. The EN563 burn threshold range for one-second contact with uncoated metal is 65 to 70°C, while the range for one-second contact with glass is 80 to 86°C. The proposed temperature limit appears to be slightly high for reasonably foreseeable inadvertent contact with external metal surfaces. The Section 18 Table 1 limit for contact with external metal surfaces is 65°C, which is the conservative end of the EN563 range.

R13-9 No information was available to support or refute the temperature limits for contact with external plastic/rubber surfaces. With regard to internal parts, the proposed temperature limits may be adequate given the foreseeable cooling which would likely occur prior to handling of internal parts. The actual thermal lag of components likely to be handled could be verified by thermocouple readings on specific equipment during a risk assessment.

SEMI

SEMI S3-91
SAFETY GUIDELINES FOR HEATED CHEMICAL BATHS

NOTICE: These guidelines do not purport to address all of the safety issues associated with their use. It is the responsibility of the users of these guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

1 Purpose/Scope

This safety guideline pertains to open top heated chemical baths, or “wet stations”, used in the manufacturing of semiconductors. The purpose of this guideline is to provide general safety information for the construction, operation, and maintenance of chemical baths heated by electric immersion, externally bonded or heat exchange type heating devices. This guideline is not intended to provided detailed design information for the individual components of the heating systems, but rather to supply the safety criteria for the design of these systems. (See Figure 1.)

2 Introduction

2.1 Failure to follow the manufacturer’s instructions as to the application or installation of heating systems used for chemical baths can result in accidents and fires in which such systems may be implicated.

2.2 The human element plays a major role in how well the hardware is used. The user of heated chemical bath systems needs to understand the available technology to minimize the risk involved.

2.3 The issue of bath operation and maintenance has been included in this guideline to support the safe use and maintenance of heated baths over their normal service life.

3 Heated Bath Methodology

3.1 *Electric Immersion Heaters* — Electric immersion bath heaters are resistive element heaters. The element itself is typically protected by an outer sheathing which acts as a corrosion and electrical barrier. The element is mounted to the inside of the bath.

3.2 *External Tank Heaters* — External type heaters are normally bonded by a mastic to the outside of a chemical bath. The most common types are manufactured from a thin metal foil material that results in a very low profile configuration.

3.3 *Heat Exchangers* — The most common type of heat exchanger employs a separate heating source that may be remote from the station. This heating source can be electrically powered to generate steam or some other heat transfer fluid. The heat transfer fluid is then delivered by chemically compatible plumbing to the bath and recirculated to the heater.

4 Minimum Heated Bath Safety Requirements

To ensure the safe operation and maintenance of heating systems, the following features are required.

- overcurrent protection
- power interrupt
- manual reset
- automatic temperature controller
- liquid level sensor
- overtemperature protection
- proper grounding and ground fault protection
- compatible construction materials

NOTE: Interlocks should operate as outlined in SEMI S2. These features should be totally compatible with each other.

4.1 *Overcurrent Protection* — A fused disconnect switch or circuit breaker sized for the amperage of the heater.

4.2 *Power Interrupt* — In the event of an overtemperature, low liquid level, or ground fault condition, power to the heater(s) is interrupted upon receiving the respective signal. The interrupt should be separate from any relay incorporated into the automatic temperature controller. The interrupt should be wired in such a manner that any signal from the liquid level sensor, overtemperature sensor, or ground fault condition should shut off power to the heaters and place the system in a “fail safe” condition.

4.3 *Manual Reset* — This reset should be incorporated into the power interrupt device so that when the system shuts off power to the heating element, a manual reset is required to re-energize the system.

4.4 *Automatic Temperature Controller* — An automatic temperature controller maintains the liquid at a set temperature by turning the heating element on and off. The controller is activated by signals from a sensor that is located at the bath. To preserve the integrity of this system, quarterly service/testing and calibration in accordance with the manufacturer's recommendations should be performed.

4.5 *Liquid Level Sensor* — This sensor will act to shut down the heating element if the liquid level falls below a safe operating level. When employing either an immersion or externally mounted type heater, it is recommended that this level be no less than five centimeters (two inches) above the heating element's "hot zone" as established by the manufacturer. This should prevent the element from losing the heat sink created by the liquid.

4.5.1 The selection of a suitable sensor should take into account:

4.5.1.1 The physical properties of the liquids being heated and the environmental conditions to which the sensor(s) will be subjected.

4.5.1.2 The mode of failure, if the sensor fails.

4.5.2 To preserve the integrity of these components, they should be tested on a quarterly basis and serviced following the manufacturer's recommendations.

4.6 *Overtemperature Protection*

4.6.1 *Liquid Overtemperature* — A dedicated liquid overtemperature sensor should typically be set to trip at a temperature below the autoignition temperature of the chemical being used in the bath, and in no case higher than 10°C (18°F) above the normal operating temperature.

4.6.1.1 This temperature setting should compensate for the initial over-shoot often encountered when bringing the liquid from ambient to operating temperature.

4.6.1.2 The sensor should be located in the liquid at an elevation approximating the top of the heating elements "hot zone" and no more than seven centimeters (three inches) away from the heater.

4.6.2 *Heating Element Overtemperature* — When using an electrical immersion type heater, a sensor should be used to shut down the heating element if the surface temperature of the element exceeds a preset value. The sensor is typically placed between the resistance coil and the protective sheath covering.

4.7 *Proper Grounding & Ground Fault Protection* — The amount of insulation surrounding a heater element depends upon the type of heater. This insulation not only provides protection from the corrosive properties of the solution, but also acts as an electrical barrier. If the barrier breaks down, it is possible for the solution to become energized.

4.7.1 The electric heater elements should be equipped with a ground, the construction of which should be approved by a nationally recognized testing laboratory (NRTL).

4.7.2 A ground fault circuit interrupter (GFCI) should be used to preclude worker exposures to potential electrical shock.

4.7.3 The station or equipment in which the heated bath will be used needs to be reviewed to ensure that all National Electrical Code requirements have been addressed.

4.8 *Compatible Construction Materials* — All portions of the station that could come in contact with process chemicals should be constructed from materials compatible with these chemicals. It is recommended that metal materials be used in the station's construction when using combustible or flammable solutions.

5 Operation and Maintenance

5.1 Before heated baths are put into service, a detailed review of the wet station operation and maintenance should be conducted for all employees operating or servicing the station. New employees should receive the same information prior to work assignment.

5.1.1 All safety features included with the station's heating system should be user tested, and the frequency of testing should be noted in the user's periodic maintenance procedures.

NOTE: Recommended minimum frequency of testing is quarterly and after any station maintenance.

5.1.2 Vendor-supplied information on the bath operation and limitations that may apply should be reviewed and appropriate employee training conducted.

5.1.3 When the user plans to install the baths and to perform maintenance, the suppliers should provide guidance to ensure that all aspects of the system, such as the controller and the heated bath safety systems, are integrated properly.

5.1.4 Review the process requirements to ensure that operating temperatures are within the range and capability of the safety controls. For flammable and combustible liquids, operating temperatures should be below the ignition temperature.

5.1.5 Limit the interchanging of parts that were not included in the original design unless so advised by the supplier. Alternate parts can lead to failures resulting in a fire or physical injury.

NOTICE: These guidelines do not purport to address all of the safety issues associated with their use. It is the responsibility of the users of these guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of these guidelines is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI S4-92
SAFETY GUIDELINE FOR THE SEGREGATION/SEPARATION OF GAS CYLINDERS CONTAINED IN CABINETS

NOTICE: This guideline does not purport to address all of the safety issues associated with its use. It is the responsibility of the user of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

NOTE: The configuration generally considered to be the best is **one cylinder of process gas per gas cabinet.** An inert gas may be in the same cabinet with a process gas.

1 Purpose

This safety guideline provides the method for determining which types of gas (in cylinders) should be maintained in separate gas cabinets and which types may be combined with other types. The guideline is designed to be used by those working or doing research in semiconductor-related technology, but the application is not limited to this field. The guideline also recommends a classification scheme which is consistent with that given by Federal OSHA in 29 CFR 1910.1200.

2 Scope

This guideline refers to gases; however, it also includes those materials stored in cylinders as liquids and used in gaseous form because of their vapor pressure, or because they may be transported as a vapor by a carrier gas. It also includes all sizes and types of cylinders. It does not include those special cases where cylinder gases are incorporated within a specific piece of process equipment as a part of the equipment, such as lecture bottles. The primary intent of the guideline is directed to a cylinder gas in use in, or being dispensed in, the manufacturing process. Mixtures of two or more gases should be considered to have the hazardous properties of their individual components. If the dilution of the hazardous component removes the hazard, the mixture may then be classified according to its actual characteristics.

5 Terminology

5.1 *cylinder* — Pressure vessel designed for containing chemicals at a pressure higher than 276 kPa (40 psia) and having a circular cross section. It does not include a portable tank, multiunit tank car tank, cargo tank, or tank car.

5.2 *acid* — A corrosive material whose chemical reaction characteristic is that of an electron acceptor.

5.3 *base* — A corrosive material whose chemical reaction characteristic is that of an electron donor.

5.4 *corrosive* — A chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the site of contact. A chemical is considered to be corrosive if, when tested on the intact skin of albino rabbits by the method described in the U. S. Department of Transportation in Appendix A to 49 CFR 173, it destroys or changes irreversibly the structure of the tissue at the site of contact following an exposure period of four hours. This term shall not refer to action on inanimate surfaces.

5.5 *flammable gas* — A gas which is flammable in a mixture of 13% or less (by volume) with air, or the flammable range with air is wider than 12% regardless of the lower limits.

NOTE: Certain gases which meet the above criteria may be labeled as nonflammable by the Department of Transportation in 49 CFR 172.101. Ammonia, for example, is not flammable at less than 13%; however, the *Matheson Gas Data Book*, 6th Edition and the Union Carbide catalog, *Gases for the Electronics Industry*, 1988 Edition lists its flammable range as 15-28%, giving it a 13% range (wider than 12%).

5.6 *gas cabinet* — A metal enclosure which is intended to provide local exhaust ventilation, protection for the gas cylinder from fire from without the cabinet, and protection for the surroundings from fire from within.

5.7 *gas* — Materials [which] are shipped in compressed gas cylinders, or act as a gas upon release at normal temperatures and pressure, or are used or handled as a gas, whether or not in strict accordance with the definition of a compressed gas as set forth in Article 9 of the Uniform Fire Code.

5.8 *hazardous production materials (HPM)* — A solid, liquid, or gas that has a degree of hazard rating in health, flammability, or reactivity of Class 3 or 4 as ranked by NFPA 704 and which is used directly in research, laboratory, or production processes which have as their end product materials which are not hazardous. (Uniform Fire Code, Section 51.102)

5.9 *inert gas* — A gas which at ambient conditions does not react chemically with other materials.

5.10 *oxidizer gas* — A gas which will support combustion or increase the burning rate of a combustible material with which it may come in contact.

5.11 *pyrophoric gas* — A gas which upon contact with air will ignite spontaneously at or below a temperature of 54°C (130°F).

5.12 *separation of gases* — The National Fire Codes use the terms, "separated," "segregated," and "isolated" when referring to storage of hazardous materials. Separation as defined by NFPA 49 is "storage within the same fire area, but separated by as much space as practical, or by intervening storage from incompatible materials." Segregated storage is generally defined by NFPA Standards as "storage in the same room, but physically separated by space or barrier from incompatible materials." Isolation is defined by NFPA 49 as "storage away from incompatible materials in a different storage room or in a separate and detached building located at a safe distance."

NOTE: For the purposes of this document, the terms "separation" and "segregation" will both be understood to have the meaning "being kept in different gas cabinets."

5.13 *toxic gas* — A chemical that has a median lethal concentration (LC_{50}) in air of more than 200 parts per million but not more than 2,000 parts per million by volume of gas or vapor, or more than 20 milligrams per liter of mist, fume, or dust, when administered by continuous inhalation for one hour (or less if death occurs within one hour) to albino rats weighing between 200 and 300 grams each.

5.14 *highly toxic gas* — A chemical that has a median lethal concentration (LC_{50}) in air of 200 parts per million by volume or less of gas or vapor, or 2 milligrams per liter or less of mist, fume, or dust, when administered by continuous inhalation for one hour (or less if death occurs within one hour) to albino rats weighing between 200 and 300 grams each.

5.15 *irritant* — A chemical, which is not corrosive, but which causes a reversible inflammatory effect on living tissue by chemical action at the site of the contact. A chemical skin irritant if, when tested on the intact skin of albino rabbits by the method of 16 CFR 1500.41 for four hours exposure or by other appropriate techniques, it results in an empirical score of five or more. A chemical is an eye irritant, if so determined under the procedure listed in 16 CFR 1500.42 or other appropriate techniques.

5.16 *water reactive* — A chemical that reacts with water to release a gas that is either flammable or presents a health hazard.

5.17 *unstable (reactive)* — A chemical which in the pure state, or as produced or transported, will vigorously polymerize, decompose, condense, or will become self-reactive under conditions of shocks, pressure, or temperature.

5.18 *other health hazard* — (Those items in this section that are not listed elsewhere are included here.) A chemical for which there is statistically significant evidence based on at least one study conducted in accordance with established scientific principles that acute or chronic health effects may occur in exposed employees. The term "health hazard" includes chemicals which are carcinogens, toxic or highly toxic agents, reproductive toxins, irritants, corrosives, sensitizers, hepatotoxins, nephrotoxins, neurotoxins, agents which act on the hematopoietic system, and agents which damage the lungs, skin, eyes, or mucous membranes.

5.19 *carcinogen* — A chemical is considered to be a carcinogen if:

(a) it has been evaluated by the International Agency for Research on Cancer (IARC), and found to be a carcinogen or potential carcinogen; or

(b) it is listed as a carcinogen or potential carcinogen in the Annual Report on Carcinogens published by the National Toxicology Program (NTP) (latest edition); or

(c) it is regulated by OSHA as a carcinogen.

6 Requirements

6.1 The requirements for the segregation/separation of gases are found in the Uniform Fire Code, BOCA National Fire Prevention Code, and SBCCI Standard Fire Prevention Code. The thrust of these requirements is summed up in the following excerpts from the Uniform Fire Code:

“Separate cabinets shall be provided for each class of hazardous materials. Flammables, acids, bases, oxidizers, toxics, and other incompatible materials shall not be stored within the same cabinet. Inert materials may be intermingled with other materials.”

“Separation requirements within storage rooms. Flammables, corrosives, oxidizers, water-reactive solids, and liquids within a storage room shall be separated from each other in accordance with Table No. 51-110-A of the Uniform Fire Code. Table No. 51-110-A provides the requirements if distance is to be the method of segregation/separation.”

The code further states “HPM gas shall be separated from HPM liquids and solids by at least a one-hour fire-resistive occupancy separation.”

It should be noted that the code recognizes gas cabinets as the first method of segregation/separation.

6.2 Gases should be classified according to the following categories and assigned a symbol as shown:

Classification	*Symbol*
Flammable	F
Pyrophoric	P
Corrosive Acid	CA
Corrosive Base	CB
Toxic or Highly Toxic	T or HT
Oxidizer	O
Inert	I
Irritant	IRR
Water Reactive	WR
Unstable (Reactive)	UR
Other Health Hazard (Target Organic Toxics)	OHH
Carcinogen	CAR

A material may be assigned more than one category if it possesses more than one of these characteristics.

Gases should be separated from one another if they do not possess the same classification symbols in all categories. The exception to this rule is the classification (I) designating an inert gas. An inert gas does not have to be separated from any other gas.

A list of gases and their classification symbols appears in Appendix 1.

Appendix 2 is a matrix of 52 of the materials generally used in gaseous or vapor form. The black dot in the matrix system indicates those gases at the dot intersection may be placed in the same cabinet. (Local Code may permit some other combinations.) This represents the minimum level for gas separation. The best system is one gas per cabinet (an inert gas may also be in the same cabinet).

APPENDIX 1

Gas	*Classification*
Ammonia	F-CB-IRR
Argon	I
Arsenic Pentafluoride	HT-CA-CAR-OHH-WR
Arsine	HT-F
Boron Trichloride	CA
Boron Trifluoride	T-CA
Carbon Dioxide	I
Carbon Tetrachloride	CAR-OHH
Chlorine	T-CA-O
Diborane	T-P-IRR-WR
Dichlorosilane	T-F-CA-WR
Diethyl Telluride	F-IRR
Diethyl Zinc	P-UR-WR-CA
Dimethyl Zinc	P-UR-WR-CA
Halocarbon 11 (trichlorofluoromethane)	I*
Halocarbon 12 (dichlorodifluoromethane)	I*
Halocarbon 13 (chlorotrifluoromethane)	I*
Halocarbon 13B1 (bromotrifluoromethane)	I*
Halocarbon 14 (tetrafluoromethane)	I
Halocarbon 23 (fluoroform)	I*
Halocarbon 115 (chloropentafluoroethane)	I*
Halocarbon 116 (hexafluoroethane)	I
Germane	HT-F-IRR-UR
Helium	I
Hydrogen	F
Hydrogen Chloride	CA
Hydrogen Fluoride	T-CA
Hydrogen Sulfide	T-F-IRR
Methyl Chloride	F-IRR
Methyl Fluoride	F-IRR
Nitric Oxide	HT-O-IRR
Nitrogen	I
Nitrogen Trifluoride	O-IRR
Nitrous Oxide	O
Oxygen	O
Perfluoropropane	I*
Phosphine	HT-P
Phosphorous Pentafluoride	T-CA-WR
Silane	P
Silicon Tetrachloride	CA-WR
Silicon Tetrafluoride	T
Sulfur Hexafluoride	I*
Trichlorosilane	F-CA-UR
Triethyl Aluminum	P
Trimethyl Aluminum	P
Trimethyl Antimony	T-F
Trimethyl Arsine	T-F
Trimethyl Gallium	P
Trimethyl Indium	P
Trimethyl Phosphine	T-F
Tungsten Hexafluoride	T-CA

* Generally considered as inert; however, may react in a hazardous way under special conditions.

Additional materials may be used at the present time or may be suggested in the future. Any new material should be categorized in a way that material of similar chemical characteristics are treated. If detailed chemical data is not available, the material should be considered in the worst case and should only be stored with inert materials.

APPENDIX 2

× Indicates Compatible Materials
